Chester was the last English city to yield to William the Conqueror (1070) who in 1071 set up a palatine earldom there. From 1071 until 1237 Chester castle was the seat of government of a line of seven powerful earls. In the second half of the 12th century Ranulf de Blundeville, earl of Chester, met Henry II's policy of extending the control of the central government over the great feudal franchises by applying to himself new principles of sovereignty, so that what was later called the county palatine of Chester came into being. Henry III annexed the earldom to the crown in 1241, and in 1254 conferred it on his son Edward. (See CHESTER, EARLS OF.) The establishment of royal control at Chester made possible Edward I's conquest of north Wales. Chester played a vital part as Edward's supply base during the Welsh wars (1275–84); and, because of this function, the separate organization of the county palatine was preserved. It was to continue until Henry VIII's reign. Chester was royalist in the Civil Wars, and was intermittently besieged for over two years, finally surrendering on Feb. 3, 1646, after the battle of Rowton Moor fought about 3 mi. S.E.

The earliest extant charter, granted by Henry II in 1176, empowered the burgesses to trade with Ireland as freely as they had done in the reign of Henry I. By a charter of about 1200–02 Earl Ranulf de Blundeville granted the citizens recognition of their guild merchant. Chester had its own purely urban sheriffs before 1150 and by 1238 had a mayor. In 1300 Edward I granted the citizens the fee farm of the city at a yearly rent of £100. By "the Great Charter" of 1506 Henry VII constituted Chester a county, incorporated the governing body and granted the city its own quarter sessions. This charter, confirmed by later sovereigns, permitted the citizens annually to elect the governing body, a privilege seldom exercised before 1835.

The port of Chester reached the height of its importance in the second half of the 13th and the first half of the 14th century. Its trade was always largely with Ireland. Grain, hides and fish were imported from Ireland, and large quantities of wine from Gascony. From the mid-14th century the gradual silting up of the Dee caused trade to decline. Consequently, in 1486 the fee-farm rent was reduced to F20.

In the 16th century there was some revival and trade with Spain, primarily with Basque ports. The principal imports were iron, wine, oil and fruit. From Portugal came wine, cork, sugar and spices. In 1553 a company of merchant venturers for trading to Spain and Portugal received a royal charter of incorporation. Imports of raw hides from Ireland account for the importance of the tanners, glovers and other leather crafts in Chester. In the 18th century there were considerable imports of Irish linen. Apparently Chester's chief exports were cloth, lead and tanned hides. The failure of schemes for improving the navigation of the Dee and the rise of Liverpool caused Chester finally to lose its position as a port in the 18th and early 19th century.

The Cathedral.— The bishops of Mercia apparently had a seat at Chester, but the city ceased to be episcopal until 1075 when Peter. bishop of Lichfield. removed his seat to Chester, making the collegiate church of St. John his cathedral. His successor removed the see to Coventry in 1102, and Chester remained part of the diocese of Coventry and Lichfield until 1541. The present church of St. John, with massive Norman arcades, transitional triforium and Early English clerestory, represents the crossing and nave of the collegiate church.

The present cathedral buildings, though restored in the 19th century under the supervision of Sir G. G. Scott and Sir A. Blomfield, are those of the medieval abbey of St. Werburgh. Hugh Lupus, first Norman earl, found there a Saxon monastery of secular canons, and in its place, with the help of St. Anselm of Bec, he founded a great Benedictine abbey. By his charter of 1093, Hugh richly endowed it and granted it the right to hold an annual fair for three days at the feast of St. Werburgh. Although there was often friction between the abbey and the city, tradition asserts that the Chester mystery plays, which were performed by the city guilds, were translated from the French in 1327–28 by Ranulf Higdon (or Higden), a monk of St. Werburgh's. The abbey was dissolved in 1540, and in 1541 Henry VIII made Chester a bishopric and founded the cathedral church of Christ and the Virgin Mary. The present diocese covers only Cheshire.

The cathedral church, built of red sandstone, is cruciform, with a central tower and nave (145 ft.) of six bays. The peculiar plan, with a short nave, very small north transept and large south transept with aisles, is the outcome of its position, as the conventual buildings to the north and the city to the west prevented expansion in these directions. The north transept and northwest tower remain from the Norman church, and on the west of the cloisters is a Norman undercroft.

A great rebuilding of the monastery was begun in Edward I's reign, and the refectory, parlour, chapter house and Lady chapel are mainly Early English. The choir, a fine example of Early English and Decorated work, is enhanced by magnificent carved

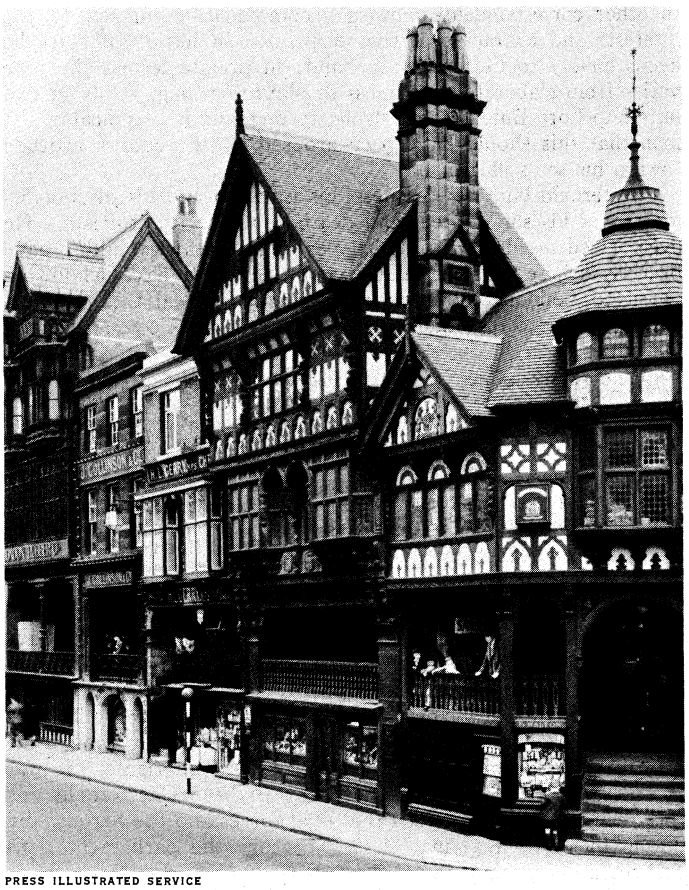
wooden stalls of the late 14th century. The south transept and nave are mainly Decorated, with later additions. The 14th-century abbey gateway remains.

The Town.—St. Peter's, founded in 907, which occupies part of the site of the Roman principia or headquarters building, St. Mary's, built in the Perpendicular style, whose foundation dates back at least to the early 12th century, and St. John's (see above), are noteworthy churches.

The four main streets, following the line of the Roman streets, radiate at right angles from the Cross and terminate in the four gates. A unique feature of these streets are "the Rows," consisting of a double tier of shops, one at ground level and the other at first-floor level, each provided with a footpath, the upper one being set over the ground-level shops and covered by projection of the second stories of the buildings. The Rows and the ancient timber-framed houses give the city a picturesque and individual character. Examples of fine timbered houses of the 16th and 17th centuries are Stanley palace, Bishop Lloyd's house and Leche house in Watergate street and the Bear and Billet in Lower Bridge street. Medieval crypts exist under several shops.

Chester is the only city in England that still possesses its walls intact (12–40 ft. high) in their entire circuit of 2 mi. The gates have been rebuilt at various dates since 1768: the north and east gates on the sites of the Roman gates. The castle was mainly rebuilt between 1789 and 1813, but the square, early 13th-century Agricola tower remains. The 13th-century Old Dee bridge was Chester's only bridge until the Grosvenor bridge was built in 1832. The latter carries the main route to north Wales across the Dee and has a single stone span of 200 ft. Farther up the river the suspension bridge connects with the suburb of Queen's Park. The causeway which crosses the river diagonally from the Old Dee bridge is said to have once provided power for the famous Mills of Dee, demolished in 1909. The Roodee, a level tract by the river, has been used as a racecourse since the 16th century. An annual race meeting is held there in May:

The Grosvenor museum contains the finest collection of Roman inscribed stones in England, and also other local antiquities and a natural history section. The King's school, founded by Henry VIII in 1544. was reorganized in 1873.



PRESS ILLUSTRATED SERVICE

"THE ROWS," 16TH- AND 17TH-CENTURY DOUBLE TIER SHOPS, CHESTER, ENG.

Development has been mainly in light industry. Manufactures include paint, electrical switchgear, metal window frames and lead. There is a considerable tourist industry. Chester is also a military centre, being the headquarters of western command.

Chester was not represented in parliament until 1547. It returned two members from 1547 until 1885, when its representation was reduced to one. The city of Chester parliamentary division includes the rural district of Chester.

Burne, *Chester Cathedral from Its Founding by Henry VIII to the Accession of Queen Victoria (1958)*. (M. E. FH.)

CHESTER, an industrial city of Delaware county in southeastern Pennsylvania, U.S., is located on the Delaware river 15 mi. S.W. of Philadelphia and is a part of the Philadelphia metropolitan area. Pop. (1960) 63,658. One of the oldest communities in the state, it was a thriving settlement long before William Penn established Philadelphia. The Swedish crown granted the Chester area to a bodyguard of the governor of New Sweden in 1644, and after 1655 Dutch settlers joined the Swedes to establish the town of Upland. William Markham, Penn's deputy governor, located his seat of government there when he arrived on the Delaware in 1681 to establish the colony of Pennsylvania and when Penn arrived he convened there the first general assembly of the province. Meanwhile Penn renamed the community Chester, reputedly in honour of his friend Lord Chester. From this era dates the Caleb Pusey house, built in 1683 and the oldest English-built house in Pennsylvania remaining intact. Chester was incorporated as a borough in 1701 and chartered as a city in 1866.

After Penn moved his government upriver to Philadelphia, Chester fell quickly into eclipse. It was only after 1,850, when the city became an adjunct of rapidly industrializing Philadelphia, that rapid growth began. Shipbuilding, steel, chemicals and paper products are among the principal industries. The John Roach Co. founded at Chester in 1872 was one of the first iron or steel shipbuilding enterprises in the United States. Foreign immigration and later a large influx of Negroes swelled the Chester population, which remains largely crowded into narrow streets near the river front. Farther north and west are the better residential sections of the city, as well as the campus of the Pennsylvania Military college, a private college founded in 1821. On the edge of the city is the Crozer Theological seminary (Baptist) founded in 1867. (R. F. WE.)

CHESTERFIELD, PHILIP DORMER STANHOPE, 4TH EARL OF (1694–1773), English statesman, diplomat and wit, now chiefly remembered as the author of the famous Letters to His Son. He was born in London on Sept. 22, 1694, the son of Philip Stanhope, 3rd earl (1673–1726) and Elizabeth Savile, daughter of the sagacious "trimmer," George Savile, marquess of Halifax. The strongest early influences were those of his grandmother, the marchioness of Halifax, and of his tutor, the Huguenot Jouneau: the former taught him manners; the latter gave him a lifelong interest in classical and French civilization. He matriculated at Trinity hall, Cambridge, on Aug. 8, 1712, and for about 18 months enjoyed the usual roistering life of the young gallant. He left without taking a degree and went abroad. At Antwerp he met the duke and duchess of Marlborough. She praised his good sense and wit; the young man admired the duke's dignity and desire to please. At Paris, under Louis XIV, he perceived his own lack of finish as a man of the world. The art of capturing the admiration of men and women became all-important to him, and he linked it with powers of persuasion and with grace in speech and writing.

He returned to London in Dec. 1714 to be presented by his influential kinsman, Gen. James Stanhope, to George I. He became member of parliament for St. Germans, Cornwall, but had

to go abroad in Xug. 171 j to avoid the consequences of having spoken in the house of commons when under age. In Paris he attached himself to the English ambassador, Lord Stair, and learned the rudiments of diplomacy. He came back to England in 1716, was elected member for Lostwithiel in 1722 and, on the death of his father in 1726, became 4th earl of Chesterfield.

His 12 years' service as gentleman (afterward, lord) of the bedchamber to the prince who had become George II resulted in his appointment in April 1728 as English ambassador to The Hague. Through his close friendship with the grand pensionary, Simon van Slingelandt, he managed in 1728 to obtain Dutch support for the treaty of Seville. He also initiated discussions for the marriage of the prince of Orange to George II's eldest daughter, Anne. For these services he received the Garter (1730) and became lord steward. (1730). In the following year he negotiated the second treaty of Vienna, but shortly afterward resigned his embassy to return home to regain his health and recoup his finances. His stay in Holland was memorable not only for the great impression made by his winning manners and skillful diplomacy, but for a more personal reason. As a result of an affair with a governess, Elizabeth du Bouchet, the child who was to be the recipient of Chesterfield's famous *Letters to His Son* was born in 1732. He was illegitimate but was given the name of Philip Stanhope.

In England, Chesterfield took up his parliamentary career again, and so strongly opposed Sir Robert Walpole's Excise bill that he sacrificed (1733) his office of lord steward in defeating the measure. In spite of marriage to the king's half sister, Melusina von der Schulenburg, countess of Walsingham, in Sept. 1733, Chesterfield lost favour at court. For the next ten years he was one of the most effective leaders of the opposition. His acid contributions to *Fog's Journal* (1736), *Common Sense* (1737) and *Old England* (1743) all served to intensify the king's dislike. Even when Walpole and Lord John Carteret had fallen and the Pelhams had come into office, they had to overcome strong objections from George II before they could offer Chesterfield "honourable Irish exile"—the viceroyalty of Ireland.

Before he took up the post, Chesterfield was sent (Jan. 1745) to The Hague to obtain Dutch support for the part England played in the War of the Austrian Succession. In Ireland his work was an unqualified success. He held office there (Aug. 1745–April 1746) only for the length of the young pretender's stay in Scotland and England, but managed to maintain George's authority by a policy of toleration toward Roman Catholics and by recruiting four extra regiments of Protestants from northern Ireland. Poverty seemed to him the worst of Irish ills, and he won general support for his vigorous economic measures, encouraging agricultural improvement and the linen, glass and paper industries. Chesterfield found the task of ruling congenial and enjoyed acting as a benevolent despot.

He was far less happy when he became secretary of state in Oct. 1746. With Henry Pelham, he pressed for immediate peace with France but could not overcome the opposition of the king and the duke of Newcastle. A competent administrator, he was subjected to the fussy meddling of Newcastle; he resigned in Feb. 1748 and refused a dukedom, but pressed for and obtained royal favours for two relatives.

He had begun building Chesterfield house, London, in 1747, as a centre of polite life and as a symbol of good taste, but, ironically, he was overcome by deafness and found himself isolated in the society he loved. He gradually retired from public life, and his last great service to the nation took place in 1751 when he helped to bring about a reform of the calendar by a brilliant speech introducing the Calendar (New Style) bill, which came into force in 1752.

Chesterfield's relations with the leading literary figures of the day were cordial. He won their praise for his wit and urbanity, and was on familiar terms with Pope, Swift, Lord Bolingbroke, Voltaire and Montesquieu. He was also the patron of many struggling authors. One of them, Samuel Johnson, planned to produce an English dictionary, and Chesterfield gave him an interview and £10. Seven years passed before the project came to Chesterfield's notice again; then he wrote two articles in the *World* recommending the dictionary. Johnson found out their author's name and composed (Feb. 1755) his famous letter attacking patrons. Opinions differas to the merits of his case, but it is certain that he was unfair to Chesterfield

Johnson did Chesterfield's reputation another disservice when he described the *Letters to His Son* as teaching "the morals of a whore, and the manners of a dancing master." The phrase neatly summarizes something less than a half-truth, and Chesterfield's outlook is better understood from his own Letter XCI, in which he advises his son. ". . . first, to do your duty towards God and man, without which, everything else signifies nothing; secondly, to acquire great knowledge, without which you will be a very contemptible man, though you may be a very honest one; and lastly to be very well bred, without which you will be a very disagreeable, unpleasing man, though you should be an honest and a learned one." Chesterfield intended his son for the diplomatic service and drew on his own experience for methods of fashioning a boy who had scholarly tastes but was naturally gauche. The emphasis on deportment is better known than any other side of his teaching, though his advice to his son to enjoy a liaison with a woman of refinement (instead of promiscuous relationships) has been frequently noted and condemned. To understand his point of view, it is necessary to recall the prevailing code of the Restoration and Augustan periods. Chesterfield can then be appreciated as a man of discrimination, one who admired the French attitude to sexual relationships as much as he respected French achievements in literature and social life. The strongest charge against his philosophy of life is that it leads to a concentration on place and power, on worldly aims. At the same time, this may well have led to the instant and perennial success of the *Letters to His Son* Here is a rational view of life, coolly, elegantly and wittily presented; it wins acceptance, whether grudging or whole-hearted, by its directness, its shrewd assessments and its pleasing style based on the conventions of well-bred conversation.

Chesterfield took delight in forming the character of the young, and he wrote further letters in the same vein to his godson and to Lord Huntingdon. He also composed many hundreds of letters to other correspondents, always accommodating himself to the interests and character of the recipient. In letters of state he keeps lucidly to the matter in hand; in private letters the tone varies from elaborate courtliness to playful trifling. Only in two letters to Lord Bute is there strong feeling, and it is typical of the man that this should have been aroused by the court's attitude toward his son's illegitimacy.

Chesterfield bore his deafness, his isolation and his disappointment over his son's career and death (1768) with stoicism. He even jested at his own physical decline: "Tyrawley and I have been dead these two years, but we don't choose to have it known." Dying in London on March 24, 1773, he showed to the end a courteous regard for others and a cool acceptance of man's many infirmities.

CHESTERFIELD, a market town and municipal borough of Derbyshire, Eng., 12 mi. S.S.E. of Sheffield by road, lies at the junction of the Rother and Hipper rivers. Pop. (1961) 67,833. Area 13.2 sq.mi. Roman lead mines were found there. In 1204 King John granted it the privileges of a free borough, although the town probably already had prescriptive borough rights. It was incorporated by Elizabeth I in 1598. In 1266 Chesterfield was the scene of a battle between the royal forces and the barons, and during the Civil War in the 17th century the parliamentarians suffered a defeat there.

The 14th-century parish church of St. Mary and All Saints

(chiefly Decorated) has a lead-covered wooden spire 228 ft. high, which because of timber warping is twisted nearly 8 ft. out of the perpendicular. The Stephenson Memorial hall (1870), used as a civic theatre, commemorates George Stephenson (*q.v.*), the engineer, who lived at Tapton house (now a secondary school) and is buried in Holy Trinity church. The grammar school, now the Chesterfield school, was founded in 1594. The Revolution house at Old Whittington, formerly the Cock and Pynot inn and restored in 17th-century style in 1938, when it was acquired by the corporation, was the place where the earl of Devonshire and other conspirators met in 1688 to plan the overthrow of James II.

Chesterfield's industries include mining and agricultural and mechanical engineering; iron, steel and brass founding; tanning; the manufacture of cardboard boxes, steel tubes, railway freight cars, surgical dressings, electric lamps, gas governors, pottery and decorated glassware, furniture and confectionery. In the neighbourhood are ironstone and sandstone quarries; chemicals, nonbituminous fuels and refractories are also manufactured.

CHESTER-LE-STREET, an urban district of County Durham, Eng., near the Wear river, 7 mi. N. of Durham by road. Pop. (1961) 18,948. Area 4.2 sq.mi. Chester-le-Street (Conangium) was a Roman station, where many Roman and pre-Roman relics were excavated, including the probable headquarters of the camp commandant or governor. As Cunecastre it became the seat of the bishop of Bernicia in 883 and the body of St. Cuthbert, brought by monks from Holy Island, reposed there until the see and shrine were removed to Durham in 995. The church of SS. Mary and Cuthbert contains the 14 Lumley funerary monuments, most of them Elizabethan forgeries.

The Durham coal field employs a large section of the population. In the town there are two factories manufacturing confectionery and dresses, and a large transport undertaking.

CHESTERTON, GILBERT KEITH (1874–1936), English journalist and author, who was outstanding as critic, polemicist and rhetorical poet, and who was known for his exuberant personality and rotund figure, was born in London, May 29, 1854. He was educated at St. Paul's school, where, at an unusually early age, he gained the Milton prize for English verse. On leaving school, from 1892 to 1895 he studied art at the Slade school and English literature at University college, London; though he had a talent for draftsmanship, his natural bent was literary, and he went through the usual apprenticeship of free-lance journalism, occasional reviewing and work in a publisher's office. In 1900, after having produced a volume of poems, *The Wild Knight* (1900), which led to some critical expectation for the future, he became a regular contributor of signed articles to the *Speaker* and the *Daily News*. In 1901 he married Frances Blogg.

One of the last of his school reports (July 1892) at St. Paul's reads: "Not a quick brain, but possessed by a slowly moving tortuous imagination. Conduct always admirable." This was singularly unprophetic, for in debating and brilliant public lecturing, in journalism and fantastic fiction, his agile mind was perhaps the most prolific of his generation. He early developed the weapon of paradox to turn conventional platitudes on their heads and he was exasperatingly successful in "debunking" late Victorian decadence. But the paradox assumed its most significant role when, like the witty conceit of the metaphysical poets in the 17th century, it probed for his own day the profound ambiguities of Christian theology.

His earlier writings, to 1910, were concerned with three main areas of interest. First, his social criticism, largely scattered in his voluminous journalism, was gathered in *The Defendant* (1901), *Twelve Types* (1902) and *Heretics* (1905). This writing had been given intensity by his strong views on the South African War (though deeply patriotic, he was pro-Boer); and, in 1912, his social writing had an even darker intensity from his part in attacking political corruption in the "Marconi affair" *(see* LLOYD GEORGE OF DWYFOR, DAVID LLOYD GEORGE). The chapter in his *Autobiography* (1936), "The Case Against Corruption," is his most lucid expression of political integrity; he had begun his political thinking as a Liberal, but after a brief radical period became, with Hilaire Belloc, a "Distributist," phases in his thinking which were reflected in *What's Wrong With the World* (1910). "Distributism" he described as "a simple idea . . . to restore possession" of land, quoting with approval Francis Bacon's aphorism, "Money is like muck, not good except it be spread."

His second preoccupation in writing was with literary criticism. *Robert Browning* (1903) in the "English Men of Letters" series provided him with a congenially complex and paradoxical subject. *Charles Dickens* (1906) was a profounder work and was followed by a brilliant series of prefaces to the individual novels, *Appreciations and Criticisms of the Works of Charles Dickens* (1911); his sensitive exploration of "dignity and pathos" in *Pickwick Papers*, of the discordant ugliness of *Oliver Twist* and of the "serene irony" of *Great Expectations* remain his finest contributions to criticism, though his *George Bernard Shaw* (1909), the handbook, *The Victorian Age in Literature* (1913), together with the studies of *William Blake* (1910) and the later monographs on *William Cobbett* (1925) and *Robert Louis Stevenson* (1927) have a spontaneity which place them above the works of many academic critics. He was frequently cavalier in his treatment of facts and sources; yet his *St. Thomas Aquinas* (1933) was highly praised by the great French medievalist Étienne Gilson.

This work was in fact the crowning product of his third major field of writing, theology and religious argument. He became a Roman Catholic in 1922 and though he had long argued the relation between theology and society (having already had the stimulus for some years of the brilliant group of Anglican sociologists of the Christian Social union, Bishop Charles Gore, Conrad Noel, Percy Dearmer and Canon Henry Scott Holland, wittily and affectionately described in the *Autobiography),* his conversion added edge to his controversial writing, notably *The Catholic Church and Conversion* (1926), his writings in *G. K.'s Weekly* and the late *Avowals and Denials* (1934). The most immediate (as it remained the most engaging) work which came from his conversion was *St. Francis of Assisi* (1923), a serene biography, followed by the essay in "historical theology," *The Everlasting Man* (1925).

Chesterton was equally prolific in three fields of creative writing, in verse, essays and short stories, to which must be added two plays. Under pressure from Bernard Shaw, Chesterton wrote his first play, *Magic,* for production at the Little theatre in 1913; it was not a success, nor was the later play *The Judgment of Dr. Johnson* (1927).

His verse is more successful. He was a master of ballad forms, whether in the grave and stirring "Lepanto" (1911), in the drinking songs of *The Flying Inn* (1914), in the tiny suggestion of a ballad off stage in "The Donkey," written in strict "fourteeners," or in the savage turn of "Elegy in a Country Churchyard," written at the height of his bitter attack on Rufus Isaacs and Lloyd George over the "Marconi affair." Indeed, when it was not uproariously comic, his verse was frankly partisan and didactic.

His essays developed his pawky, paradoxical irreverence to its ultimate point of real seriousness. At times the quirk is desired for its own odd sake; too frequently the self-evident is turned upside down for the mere fun of it. But at its best his style illuminates a truism and makes a commonplace mint-new. "A Defence of Nonsense" (1901; in *Stories, Essays and Poems,* "Everyman" series, 1935) shows him at his happiest: "Nonsense and faith (strange as the conjunction may seem) are the two supreme symbolic assertions of the truth that to draw out the soul of things with a syllogism is as impossible as to draw out Leviathan with a hook."

Most readers probably value his fictional writing most highly, and especially the Father Brown stories of detection. He had early produced *The Napoleon of Notting Hill* (1904), a romance of civil war in suburban London. nhich was followed by the loosely knit collection of short stories, *The Club of Queer Trades* (1905), *The Man Who Was Thursday* (1908) and *The Ball and the Cross* (1910). But the most successful association of fiction with his characteristic social judgments is to be found in the Father Brown series *(The Innocence of Father Brown* in 1911, followed by *The Wisdom . . .* , 1914, *The Incredulity . . .* , 1926, *The Secret . . .* , 1927, and *The Scandal of Father Brown* in 1935). Though physically a child of Chesterton's own fancy, Father Brown was based

on the mental characteristics of his friend, the Rev. (later Monsignor) John O'Connor, the "detection" turning upon the unique union of direct simplicity, innocence and priestly insight in Father Brown.

In any final assessment of Chesterton, however, it is likely to be not the writer, nor even the brilliant controversialist in print or in public debate, that will be ultimately memorable, but rather the man who was the focus of so many friendships with men as diverse and of such contradictory intellectual qualities as H. G. Wells, Shaw and Belloc. He had worked happily with Gore, Charles Masterman and Scott Holland; had earned the profound affection of Maurice Baring, Edmund Bentley and Max Beerbohm. There was indeed no effervescent group, few creative personalities, scarcely an important movement of the intellect, with which he was not closely associated, either in active collaboration or in vigorous opposition, for nearly half a century. He had written and spoken with unpopular force on the South African War: he was to live to pass brooding judgment on fascism in the 1930s. To read the *Autobiography* is to be most impressed not by the intellect. the proliferating ideas, but by the largeness of a personality whose laugh could be heard "many doors away" and which could direct its ridicule most successfully on itself. Chesterton died at Beaconsfield, Buckinghamshire, on June 14, 1936.

CHESTNUT. This name is usually restricted to four species of the genus *Castanea* (family Fagaceae) whose burlike fruits contain two or three nuts. Other members of the genus. featuring small single-fruited burs borne in racemose clusters, are called chinquapins. Golden chinquapins with similar fruits, but with persistent foliage the undersurfaces of which are a golden yellow, belong to the genus *Castanopsis,* also of the Fagaceae. The horse chestnut (*q.v.*), a totally unrelated tree, is included in the genus *Aesculus* of the family Hippocastanaceae.

Chestnuts are moderately large to large trees characterized by alternate, simple, deciduous leaves with bristle-tipped margins. Their small, inconspicuous, unisexual flowers are borne in catkins. Many of the inflorescences are wholly staminate; others are bisexual with the pistillate flowers inserted only at the base of the rachis. The fruit, a nut, borne in clusters of two or three, is enclosed in a leathery husk clothed with multibranched spines.

Chestnuts are prolific seeders but during periods of prolonged drought seedlings often die out in large numbers. On the other hand, once young trees have become established they develop deep root systems, and older trees are capable of withstanding drought much better than most other species with which they are associated. Best development occurs on loose, porous, moderately dry soils which are either acid or neutral rather than alkaline. All species exhibit a remarkable capacity for vegetative reproductivity through the development of vigorous coppice sprouts arising from the root collar following the removal of the bole in harvesting operations.

Chestnuts play an important role in the forest economy of the regions in which they are endemic. Both wood and bark are richly endowed with tannin, a chemical complex which is extracted in commercial quantities and used in converting raw hides into leather. The fruits are an article of diet for both man and animal. The soft, firm. durable wood has many uses. Roundwood is especially suited for poles, posts, piling, crossties and mine props, while large logs are sawed into lumber for further remanufacturing into furniture, dimension timbers, planing-mill products and paneling.

European Chestnut. — The European chestnut, C. *sativa* (also termed Spanish chestnut), is probably the most important species. Seldom found over 4,000 ft. of elevation, it ranges through much of southern Europe, northern Africa and southern Asia east to the Caucasus. It has been successfully propagated in England. Scotland, India and Australia. During the 19th century it became widely established in eastern United States as well as on the Pacific coast. While most of the eastern trees have been destroyed, it is still frequently encountered in California and in the Pacific northwest. Trees of the European chestnut often attain massive proportions, and what was probably the largest of all was a tree at the foot of Mt. Etna in Sicily, that in 1850 was reputed to have had a girth of 204 ft. and to exceed an age of 2,000 years. It was later destroyed by volcanic action. This species is the principal source of the chestnuts consumed in Europe and the United States. The largest nuts, called marrons, are eaten ram, or they may be boiled or roasted. Those of lesser size are commonly allowed to dry and harden, after which they are milled into flour that is substituted for cereals in making soups, bread and other foodstuffs. The small nuts, when gathered, are fed to livestock.

J. HORACE MCFARLAND CO.

CHINESE CHESTNUT (CASTANEA MOLLISSIMA); (RIGHT) SPINY HUSK OPEN, EXPOSING NUTS

Japanese Chestnut. — The Japanese chestnut, *C. crenata,* is a tree of modest proportions found in the mountains of Japan, usually below an altitude of 3,000 ft. Trees in excess of 60 ft. in height or 36 in. in diameter are only rarely encountered. This species is an abundant fruiter, and, although the nuts are smaller and of poorer texture and flavour than those of the European chestnut, they are a common article of the Japanese diet. Their flavour, however, is decidedly improved by boiling or roasting. The Japanese chestnut was introduced into the United States in 1876, and became naturalized in some areas.

Chinese Chestnut. — The Chinese chestnut, *C. mollissima,* attains about the same stature as the Japanese species, and is often found in highlands up to elevations of 8,000 ft. The tree was initially introduced into the United States in 1853, but only after the U.S. department of agriculture became interested in its horticultural possibilities in 1906 were seeds imported and distributed in large quantities. The trees varied greatly in form and stature, but those of squat habit with large spreading crowns were preferred by pomologists.

The nuts, although not as large as the European marrons, are well formed and exceedingly tasty, and a number of varieties have been developed. Among the most popular of these are the Bartlett, Carr, Hobson, Milford, Reliance, Stokes, Yankee and Zimmerman.

American Chestnut. — The American chestnut, C. *dentata,* was once one of the nation's most valued timber trees. Its range extended from southern Maine west to southeastern Michigan, thence south and west to southwestern Florida and eastern Arkansas. It was particularly abundant in the Appalachian mountains below elevations of 3,000 ft. and was to be found over much of eastern United States except on the coastal plains. Growth was rapid on good sites and mature trees commonly attained a height of 100 ft. and a diameter of more than 42 in. (maximum 120 ft. × 10 ft.). Few American timbers enjoyed more diverse uses. As a core material in furniture panels it had no peer.

Chestnut Blight. — At the turn of the 20th century, however, the American chestnut became infected with a fungus disease, chestnut blight *(Endothia parasitica),* which was inadvertently introduced into the United States on planting stock brought in from the orient. Only a mild-mannered organism in its native realm, it proved to be a lethal parasite on not only the American chestnut, but upon the European chestnut which was being propagated in orchards as well. From the initial point of infection on Long Island. N.Y., the disease spread rapidly. In the short space of 35 years this species became the victim of one of the world's greatest forest tragedies. Early efforts to control the spread of the organism failed completely, and thousands upon thousands of dead trees and snags remained in silent testimony to the ravages of the disease. Occasional healthy trees. which are obviously blight resistant. are encountered at wide intervals. but little attempt has been made to propagate their progeny. Experiments reveal that hybrids of the American and Jrpanese chestnuts also exhibit considerable disease resistance, but little use has been

made of them in forest plantings (*see* also PLANT DISEASES: *Fungi*).

See also *NUT*. (E. S. HR.)

CHETTLE, HENRY (*c.* 1560–*c.* 1607), English dramatist in many respects typical of the versatile, popular writer of the Elizabethan age. He began his career as a printer and associated with literary men like Robert Greene and Thomas Nashe. He prepared for publication Greene's posthumous *Groatsworth of Wit* (1592), with its attack on Shakespeare as an "upstart crow," but offered Shakespeare compliments and an olive branch in his own *Kind-Heart's Dream* (entered in the Stationers' Register. 1592), a topical satire framed in a dream fable. His *Piers Plainness' Seven Years' Prenticeship*, a narrative blending pastoral and picaresque. appeared in 1593, and *England's Mourning Garment*, a lament for Queen Elizabeth I. in 1603. By 1598 he had written enough plays for Francis Meres in *Palladis Tamia* to commend him as one of our "best for comedy." and between 1598 and 1603 he is known to have had a hand in 49 plays. Of these only five were published: *The Downfall of Robert, Earl of Huntington* (1601), a play mainly by Anthony Munday revised by Chettle; *The Death of Robert, Earl of Huntington* (1601), written with Munday; *The Pleasant Conzedy of Patient Grissill* (1603'1. with Thomas Dekker and William Haughton: *The Blind Beggar of Bednal-Green* (1659), with John Day; and *The Tragedy of Hoffman*, the only play extant which can be attributed to Chettle alone. A play of the popular revenge type, it enjoyed a revival shortly before its publication in 1631. Chettle also helped to revise the play of *Sir Thomas More*, the manuscript of which has one passage in his handwriting. He died not later than 1607, when Dekker's *A Knight's Conjuring* described his arrival in the Elysian fields.

See H. Jenkins, *The Life and Work* of *Henry Chettle* (1934). (HD. J.)

CHEVAL-DE-FRISE, a military obstacle apparently originating in the Dutch War of Independence. was often used in field operations as a defense against cavalry. hence the name (French for "Friesland horse"), as the Dutch were weak in the mounted arm and had to check the enemy's cavalry by artificial obstacles. A single cheval-de-frise consisted of a long wooden beam or barrel with holes drilled through it at intervals for insertion of spears or other pointed weapons. Standing three or four feet above the ground, something like a huge carpenter's sanhorse, it presented a hedge of spears to the enemy. A line of chevaux-de-frise chained together could be used to close the breach of a fortress or to entangle the attackers of a fortified position. Felled trees were commonly used for this purpose in the 18th century, their branches pointing outward to make a seemingly impenetrable thicket. Chevaux-de-frise are the tactical ancestors of the barbed-wire entanglements of the 20th century.

CHEVALIER, MICHEL (1806–1879), French economist, an early convert to the theories of the duc de Saint-Simon (q *v.*). He became a member of the Institut de France in 1850 and in 1851 published his *Examination of the Commercial System Known by the Name* of *Protective System*. He was influential in the discussion of the Cobden treaty between France and Great Britain in 1860. In that year he became a member of the French senate.

Among his other works are *Course [of Lectures] in Political Economy* (1842–50); *Essays in Industrial Politics* (1843); and *Concerning the Probable Decline [in Value] of Gold* (1859). translated into English by Cobden. (FK. L. K.)

CHEVALIER, ULYSSE (1841–1923), French priest and scholar and the author of important bibliographies on medieval history, was born at Rambouillet on Feb. 24, 1841. He published a great number of documents relating to the history of Dauphiné and a *Bibliothèque liturgique* in six volumes (1893–97), the third and fourth volumes of which constitute the *Repertorium hymnologicum*, containing more than 20,000 articles. His principal nork was the *Répertoire des sources historiques du moyen âge*. Of this, the first part, *Bio-bibliographie* (1877–78; 2nd ed, 1905), contained the names of all the historical personages alive between the years 1 and 1500 who are mentioned in printed books, together with the precise indication of all the places where they are mentioned. The second part, *Topo-bibliographie* (1894–1903), contained not only the names of places mentioned in books on the history of the middle ages, but, in a general way, everything not included in the *Bio-bibliographie*. The *Répertoire* remains one of the most important bibliographical monuments ever devoted to the study of medieval history. Chevalier was professor of ecclesiastical history at Lyons from 1887. He died at Romans in Dauphiné in 1923.

CHEVALIER (literally "horseman"; *see* CAVALIER), a French title originally equivalent to the English knight. For its connotation in medieval times *see* KNIGHTHOOD AND CHIVALRY. Later the title chevalier came to be used in a variety of senses. It by no means always denoted membership of any order of chivalry, being very often used by men of noble birth or noble pretensions who could not claim any of the standard territorial titles (countships: marquisates, etc.). An ordinance of 1629 tried to forbid its being assumed except by virtue of royal letters patent or "eminent personal quality" (*éminence de qualité personnelle*). On the other hand a younger son of a great family X, who could neither take any title from any of its great estates nor get himself a suitably high position in the church, might be admitted to the Order of the Hospital of St. John of Jerusalem (knights of Malta) and so be styled the chevalier de X. Chevaliers of the French royal orders usually had some territorial title by which they remained designated (as an English duke is not designated as Sir . . . . though he be a knight of the Garter). There was some controversy as to whether the nobility attached to the title was hereditary.

Napoleon laid down certain conditions for the assumption of the title by members of the Legion of Honour. He also reserved the right of appointing chevaliers of the empire as he might see fit.

CHEVERUS, JEAN LOUIS LEFEBVRE DE (1768–1836), French prelate, was born on Jan. 28, 1768, in Mayenne. He was made assistant. then pastor. of Notre Dame of Mayenne, but because of the Revolution he fled in 1792 to England where he founded Tottenham chapel. Arriving in Boston. Mass., in 1796, he assisted at Holy Cross church and served the Indian missions in Maine. His courage and charity during the yellow fever epidemic of 1798, together with his eloquent preaching. attracted many Protestants. In 1808 the diocese of Boston was created with Cheverus its bishop; he was consecrated Nov. 1, 1810. At the insistence of Louis XVIII he returned to France in 1823 to become bishop of Montauban. In 1826 he was made archbishop of Bordeaux and peer of France, serving in the upper chamber of the legislature until 1830. Nominated by Louis Philippe to the college of cardinals, he was invested in Feb. 1836. Founder of a retirement system for the clergy of Bordeaux, and author of *Statuts du Diockse de Bordeaux*, he died in that city on July 19, 1836.

BIBLIOGRAPHY.—André Hamon, *Life* of *Cardinal Cheverus* (1839); Robert H. Lord, "Jean Lefebvre de Cheverus, First Catholic Bishop of Boston," *Proceedings* of *the Mass. Hist. Soc.*, vol. 65, pp. 64–78; Annabelle M. Melville, *Jean Lefebvre* de *Cheverus* (1958), with bibliography. (A. M. M.)

CHEVET, in architecture, the entire eastern termination of a church choir (*q.v.*), a term used especially for churches with apses (*q.v.*); also an ambulatory from nhich a series of radiating chapels-open. It was a distinctly French development, appearing in a highly organized form in many 12th-century Romanesque churches; *e.g.*, Notre Dame du Port. Clermont-Ferrand and St. Paul. Issoire. It resulted from attempts to place as many subsidiary altars in chapels as possible in close association with the high altar and the procession path around it. The development of the chevet produced many spaces of unusual shape whose vaulting was one of the great incentives toward the evolution of the ribbed and pointed vault: the chevet, therefore. played an important part in the transition from Romanesque to Gothic architecture.

The radiating chapels were usually uneven in number, and the central one, frequently much larger than the others, was dedicated to the Virgin Mary and known as the Lady chapel (*q.v.*).

CHEVIOT CLOTH, a woolen fabric made originally from the wool of Cheviot sheep, and now also made from other types

of wool or from blends of wool and man-made fibres. Cheviot wool possesses good spinning qualities. since the fibre is fine, soft and pliable. The true cheviot type of fabric has a crispness of texture similar to serge cloth except that it is slightly rougher and heavier.

Cheviot fabric may be produced either from woolen or worsted yarns according to the character and texture or feel desired in the finished fabric. Some qualities are produced from crossbred worsted yarns that are adapted for furnishing crispness of texture. Cheviot suitings for sportswear are made from the harder-spun worsted yarns, while some qualities are also made from botany worsted. So-called cheviot suitings of inferior quality contain an admixture of cotton, while other low-grade cheviots are weighted with flocks.

Cheviot shirting is a stout, twilled, cotton fabric woven with small geometrical patterns or with warp stripes and bleached weft. (H. N.)

CHEVIOT HILLS, a tract of highland followed for about 35 mi. by the boundary between England and Scotland. The most important route across is the main road over Carter Bar (1,370 ft.). a pass from the head of Redesdale in Northumberland to the valley of the Jed. The hills east of Carter Bar were carved from a great pile of volcanic rocks of Devonian age. In the heart of a mass of andesitic lavas, granite was later intruded, and forms the twin summits of The Cheviot (2,676 ft.) and Hedgehope hill (2.348 ft.). The hills are steep, but smoothly rounded, and are dissected by deep glens almost deserted save for a few shepherds' cottages, though evidences of prehistoric occupation are numerous. Rest of Carter Bar the Border hills nowhere reach 2 000 ft.. and the rocks are of Lower Carboniferous age, mainly shales and sandstones; but, heavily coated with glacial drift, they form undulating, peaty moorlands. Apart from tongues of farmland, the area forms an extensive tract of grass and heather moorland, used as grazing for hardy sheep of the local Cheviot or Blackface breeds. Since World War II, homever, the Border fells in the upper basins of the North Tyne and Rede have been the scene of major afforestation.

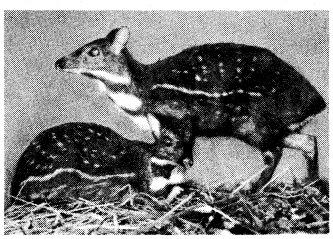
As well as being the scene of much Border warfare, the area was for centuries the fastness of cattle thieves who raided the neighbouring lowlands where fortified farmsteads, known as pele castles, are a characteristic feature. The land controlled by the forestry commission became a National Forest park in 1955, and an even larger adjacent area was designated as the Northumberland National park. (AR. E. S.)

CHEVREUSE, MARIE DE ROHAN-MONTBAZON, DCCHESSE DE (1600–1679), French princess whose attractive person and bold diplomacy made her a power in politics for nearly 30 years. was born in Dec. 1600, the daughter of Hercule de Rohan, duc de Montbazon. Married in 1617 to Charles d'Albert, later duc de Luynes (*q.v.*), she was appointed superintendent of the queen's household and soon captivated the queen, Anne (*q.v.*) of Austria. Widowed in Dec. 1621, she was in March 1622 dismissed from court by Louis XIII for having accidentally caused Anne's miscarriage (Anne fell while running with her), but secured her readmission by hastily marrying, in April, the influential Claude de Lorraine, duc de Chevreuse. In 1625, when the earl of Holland nas in Paris for Henrietta Maria's marriage to Charles I of England, the duchesse became his mistress. Their efforts to promote a liaison between Anne and the duke of Buckingham led to the latter's scandalous behaviour when they were all escorting the bride on her may to England. In England the duchesse won Charles I's favour but discredited her husband's embassy by her conduct with Buckingham and Holland. Back in France, she organized the widespread opposition to the king's plan for the marriage of Gaston, later duc d'Orléans (*q.v.*). This grew into a dangerous conspiracy (1626). When its nominal leader. J. B. d'Ornano. was arrested, the duchesse seduced the young marquis de Chalais (Henri de Talleyrand) into carrying it on. He was beheaded. Exiled from court, she fled to Lorraine. where in 1627 she easily persuaded the duke, Charles IV, to join Buckingham's anti-French coalition.

Late in 1628 the cardinal de Richelieu, judging her too dangerous as an enemy, allowed her return to France. She then collaborated with him for a time, but in 1633 was exiled to Touraine for having betrayed to foreign powers state secrets extracted from the infatuated keeper of the seals, Charles de l'Aubespine, marquis de Châteauneuf. In 1637, after the Val-de-Grâce affair, she fled in disguise to Spain. Going thence to England, she spent two years in prevaricating correspondence about returning to France, then went to join the French malcontents in the Spanish Netherlands (1640). Louis XIII's will forbade her ever returning to France, but on his death (1643) she returned—to find Anne, now regent. under Cardinal Mazarin's influence. Having inspired the conspiracy of "les Importants" (see BEAUFORT, FRANÇOIS DE VENDÔME, DUC DE), she was again exiled from Paris. She fled again to the Netherlands via England in 1645. Returning to Paris in April 1649 (see FRONDE), she negotiated first the agreement between the Frondeurs and Mazarin for the arrest of the Condé princes (1650), then the reconciliation of the Frondeurs and the Condés (1651). When Condé broke the bargain that his brother Conti should marry her daughter Charlotte (Mlle de Chevreuse), she made her final peace with Mazarin and, after Charlotte's sudden death (1652). retired to Dampierre to live quietly. A widow again in 1657, she may have secretly married her last lover, Geoffroy de Laigue. She died at Gagny on Aug. 12, 1679. (J. G. R.-S.)

CHEVRON, an ornament formed of two slanting lines meeting at an angle. In heraldry (*q.v.*) it is a bent bar. It is also one of the most common distinguishing marks for military and naval uniforms, where it is placed on the sleeves and serves either as a mark of honour or to indicate a special function (see INSIGNIA, MILITARY). In architecture, the term is sometimes applied to the angle formed by the meeting rafters of a roof, but it is more commonly used for the purely decorative form. Chevrons joined together zigzag were one of the commonest of Romanesque geometric ornaments, especially in areas under Norman influence. It was a frequent decoration for arch moldings and column shafts. The chevron appeared early in primitive work and is found on pottery all over the world. It also occurred frequently in textiles, on Egyptian walls and ceilings and in Aegean art as a column decoration; *e.g.*, Tholos of Atreus at Mycenae, *c.* 1200 B.C.

CMEVROTAIN (MOUSE DEER), any member of the infraorder Tragulina; the most primitive of the living Ruminantia, found in the warmer parts of Asia and in parts of Africa. They are delicately built with very slender legs, are about the size of a large rabbit and despite their popular name have no close affinity with deer or mice. The fur is reddish-brown with spots and irregular stripes of paler colour or white; the underside is pale. They have no horns, but the males have small, curved tusks protruding from the mouth in the upper jaw. Several species (*Tragulus*) are known from the forests of India, Malaya and the East Indies. where they inhabit dense jungle. They are crepuscular and usually solitary; two young are generally born at the end of the rainy season. The slightly larger water chevrotain (*Hyemoschus*) of western Africa inhabits the thick cover on the banks of rivers. Chevrotains are timid and become very tame in captivity. Their method of tripping daintily on their hoof tips is characteristic. See also references under "Chevrotain" in the Index volume. (L. H. M.)



ERNEST P. WALKER

WATER CHEVROTAIN (HYEMOSCHUS AQUATICUS)

CHEWING GUM. Chewing gum is a confection product prepared from chicle and similar resilient substances, combined with sweetening and flavouring. For many centuries past the Mayans and other Central Americans chewed chicle, the coagulated milky juice (latex) of the sapodilla tree, just as people in many lands chewed various resins, leaves and grasses for relaxation and enjoyment. From the Indians of New England, the American colonists learned to chew spruce tree resins, and spruce gum was marketed in the United States in the early 1800s as the

first commercial chewing gum. Later, chewing gum made of paraffin wax was introduced.

In the 1860s the use of chicle as a chewing-gum base was developed. Its resilient chewing quality and ability to carry flavours won preference for this type of gum and pdved the way for the major rise in the popularity of chewing gum which began in the early 1900s with the advent of modern processing, packaging and promotional methods.

Modern cheuing gum consists, by weight, of approximately 20% gum base, 19% corn sirup, 60% sugar and 1% flavouring. To ensure uniform chewing texture, gum base may be blended of as many as 25 latex products and like materials. The latex products are obtained from trees growing wild in tropical forests. The trees are tapped with grooved cuts from which the latex flows into containers The latex is then collected, boiled down and molded into blocks. Chicle from Central America, leche caspi and sorva from the Amazon valley and jelutong from British Borneo and Indonesia are the principal types of latex products used.

Synthesized preparations having similar properties, such as vinyl resins and microcrystalline waxes, have been developed for use in combination with the tropical latex products. In the manufacturing process, the gum-base ingredients are washed, ground, sterilized and blended. In mixing kettles, the melted base is combined with corn sirup, sugar and flavouring. The doughlike mixture is then rolled into sheets, and divided into sticks or pellets. Essential oils from mint plants — peppermint and spearmint — provide the two leading flavours. In food content, one stick of gum contains nine calories.

The use of chewing gum rises in periods of social tension, and it increased rapidly during and after World Wars I and II. In the United States annual per capita consumption, for example, went from 39 sticks in 1914 to 89 in 1924; from 98 in 1939 to 16j in 19j3. The English-speaking and Latin-American countries are the largest chewing-gum consumers. Second to the United States in per capita consumption is Canada. (P. H. E.)

CHEYENNE, an Algonkian-speaking Indian tribe inhabiting the western Great Plains of the United States in the 19th century. As late as the 17th century the homeland of the Cheyenne was located in central Minnesota. They were thus originally a hunting and wild rice gathering people. In the general westward displacement of eastern woodland tribes by European settlers the Cheyenne. in the 18th century, migrated into the plains. In close contact with the sedentary Mandan and Hidatsa villages of the upper Missouri river, the Cheyenne adopted horticulture and the earth lodge. At the close of the 18th century, smallpox and the aggression of the Dakota decimated the village tribes at the same time that the horse and gun were becoming generally available in the northeastern plains. The Cheyenne quickly abandoned the village way of life. moving west of the Missouri to establish their range in the vicinity of the Black hills. Here, between 1780 and 1830. they developed their unique version of the nomadic Plains Indian culture.

The Cheyenne had no clans. They were bilaterally organized in ten major bands. In the spring of each year, the bands gathered for the performance of one of three great tribal ceremonies, the Sun Dance (*q.v.*), the Sacred Arrows and the Buffalo Hat ceremony. A communal buffalo hunt followed. The tribal government, consisting of a sacred council of 44 chiefs plus the seven military societies, was then dominant. Tribal mythology derives Cheyenne customs and institutions from the teachings of two culture heros, Erect Horns and Sweet Medicine, who were instructed by Maiyun (the Great Supernatural) within a cave in Bear butte, located near Sturgis, S.D.

From 1857 to 1879 the Cheyenne were embroiled in wars with the United States. In 1950 there were 1,900 northern Cheyenne on the Tongue River Indian reservation in southeastern Montana and 3,100 intermingled southern Cheyenne and Arapaho on allotted lands in the vicinity of Anadarko, Okla. See also ALGONKIAN TRIBES; PLAINS INDIANS.

BIBLIOGRAPHY.—G. B. Grinnell, *The Cheyenne Indians,* 2 vol. (1923), *The Fighting Cheyennes (1915)*; E. A. Hoebel, *The Cheyennes* (1960); K. N. Llewellyn and E. A. Hoebel. *The Chevenne Way (1941).*

(E. A. HL.)

CHEYENNE, capital city of Wyoming, U.S., and the seat of Laramie county, is located near the southeast corner of the state on Crow creek just east of the point nhere the Great Plains meet the Laramie mountains, front range of the southern Wyoming Rockies. It is the state's oldest city. Squatters arriving in the summer of 1867 came just ahead of the Union Pacific railroad: by Nov. 1867 the population was 4.000. Officials of the railroad claimed the townsite under its land grant but had to get army assistance before some of the squatters mould recognize the company's rights. During the few months in 1867–68 when the city was the end of the tracks vigilante action was necessary to maintain order. When the unruly element moved westward with the construction gangs only 1,000 people remained to build for the future. In 1869 Cheyenne was designated capital of the new Wyoming territory. a position it retained after statehood in 1890. The city is named after the Indian tribe.

The Union Pacific railroad has always been important in the city's economy. In the 1870s Cheyenne became a major shipping point for cattle from Texas. Surrounded by grazing lands, it has never lost its cow town atmosphere although sheep now share the range with cattle. Frontier days, a six-day celebration each July, recalls cattle kingdom days of yesteryear, with rodeo events and parades in period costumes.

Cheyenne has always had a military installation. At the outset it was Ft. D. A. Russell. In 1930 the name was changed to Ft. Francis E. Warren in honour of the city's most famous citizen. In 1957 the fort became the headquarters for the nation's first Atlas intercontinental ballistic missile base and launching pads soon surrounded the city.

Cheyenne's economy is well diversified with employment provided by railroads, airlines, trucking companies. state government, the fort, an oil refinery, cattle and sheep ranches, dry-farming enterprises, a veterans' hospital; several small manufacturing industries and tourism. For comparative population figures *see* table in WYOMING: *Population.* (T. A. LN.)

CHEZY, ANTOINE LÉONARD DE (1773–1832), French orientalist. the first occupant of the chair of Sanskrit in the Collège de France. Born at Neuilly on Jan. 15, 1773, he was attracted to the study of oriental languages by the post he held from 1799 in the manuscripts section of the Bibliothèque Nationale. He held his chair at the Collège de France from 1814 and translated various works from Persian and Sanskrit of which the most notable were *Les Amours de Medjnoun et Leila* (1807) and *La Reconnaissance* de *Sacountala* (1830). He died of cholera at Paris on Aug. 31, 1832.

CHHATARPUR, a town and district of Madhya Pradesh, India. The town (pop. [1961] 22,142) is 140 mi. S.E. of Jhansi by road. The nearest railway station is Harpalpur (32 mi. N.) on the Jhansi-Manakpur line. The town was named after Chhatarsal, an 18th-century Bundela chief who successfully resisted the authority of the Mogul emperor Aurangzeb (*q.v.*). The town has a college affiliated to Saugar university, a museum, and a modern officers' colony.

CHHATARPUR DISTRICT (area 3,380 sq.mi.; pop. [1961] 587,-611) absorbed on Jan. 1, 1950, the former princely states of Chhatarpur, Bijawar and parts of Charkhari and Panna, and formed part of Vindhya Pradesh which was merged in Madhya Pradesh on Nov. 1, 1956. It is a fertile plain lying between the Dhasan and Ken rivers and is dotted with wooded hills rising to 1,500 ft. It contains many ancient monuments including the Khajuraho (*q.v.*) (29 mi. E.); and Rajgarh fort and palace (28 mi. S.E.).

(S. M. A.)

CHHINDWARA, a town and district in Madhya Pradesh, India. The town (pop., 1951, 27,652), 64 mi. N.N.W. of Nagpur, is the district headquarters and a market town with small local industries; situated on the Satpura plateau about 2,000 ft. above sea level, it is a pleasant place with a fairly temperate climate. It is connected by Southeastern railway metre-gauge lines with Nagpur and Jabalpur on the Central railway.

CHHINDWARA DTSTRICT (area 4,565 sq.mi.) had a Population in

1961 of 786.596; about 75% were Hindus and most of the rest Gonds and other aboriginal tribes. In the north of the district, bordering the Mahadeo range and Hoshangabad district, are hills rising to about 3,000 ft. and containing some sal forest. The rugged country immediately south of the hills were the jagirs or feudal estates of the Gond chiefs, who once preyed upon travelers and raided the open country on their borders. South of this is the more level Satpura plateau, extending from Betul in the west to Seoni in the east and drained by the Pench and Kanhan rivers. The southern and eastern parts of the plateau include the fertile wheat plain of Chaurai. On the south again the country drops into the Nagpur plain, to which it geographically belongs. This is a rich cotton and jowar (big millet) area and is the richest and most populous part of the district; the language of the area is Marathi. On the southeast the plateau, there called the Lahmarpani, projects into the plain, and this part is noted for its breed of cattle. The lowlands of the district are hot and the uplands have a temperate climate. There are fairly extensive coal fields to the north of Chhindwara, connected by narrow-gauge railway with that town and by a broad-gauge line with Betul. In the south. near the Nagpur district border, are valuable deposits of manganese.

(D. G. NA.)

CHIABRERA, GABRIELLO (1552–1638), Italian poet who introduced new lyric metres and a Hellenic style into Italian poetry. He was born at Savona on June 18. 1552, and, after studying philosophy at the Jesuits' college in Rome. entered the household of a cardinal. He mixed in the literary society of his day but presently mas drawn into a quarrel which compelled him to leave Rome. He retired to Savona, where he read Pindar and Anacreon and Pierre de Ronsard. He determined to enrich Italian poetry with new forms, and his imitations from the classics include some successful innovations in Italian verse, which were adopted by the lyrists of the next century. Chiabrera's output is great and varied: epics, pastorals, odes, lyrics, satires, dramas and religious and didactic poems. His best poetry, however, is to be found in his gracefully musical *canzonette,* described as *anacreontiche*. His autobiographical sketch is also interesting. With his adoration of Greek (when a thing pleased him greatly he was wont to talk of it as "Greek poetry"), his delight in journeys and sight-seeing, his dislike for literary talk save with intimates and equals, his vanities and vengeances, his pride in the memory of favours bestowed by popes and princes and his quiet Christianity, as a personality he deserved more study than his literary importance would suggest. He died at Savona. Oct. 14, 1638.

BIBLIOGRAPHY.—A selection of Chiabrera's works was edited by L. Negri, *Canzonette, rime varie, dialoghi* (1952). *See* also F. Neri, *Il Chiabrera e la Pléiade française* (1920); *G*. CHIA-I or KAGI, a city in one of Formosa's major south central agricultural basins, about 135 mi. S.S.W. of T'ai-pei and 35 mi. N.W. of T'ai-nan. Pop. (1956) 153,032. It is connected by railway with A-li Shan, a forested mountain several miles away. Industrial plants include sawmills, paper mills and plywood factories. Chia-i also is an important marketing centre for rice, mangoes, betel nuts and longans (dragon's eyes). Near Chia-i are extensive areas of sugar cane from which yeast, alcohol and solvents and butanol are manufactured. Chia-i is a typical medium-sized Formosan marketing-manufacturing centre. It is the seat of the Chia-i *hsien* government. (N. S. G.)

CHIANA (anc. CLANIS), a river of central Italy which has its source near Arezzo, runs through a wide valley toward Chiusi (anc. Clusium), passes through Lake Chiusi and, after receiving the Paglia near Orvieto, flows into the Tiber 3 mi. S. of Orvieto. In ancient times all of the wide middle valley of the river drained to the Tiber, but a natural dam at Chiusi formed by alluvial material prevented proper drainage throughout the middle ages. As a result the wide Val di Chiana became marshy and malarial from Arezzo to Chiusi. In 1788 detailed engineering plans made by Vittorio Fossombroni were begun and the work was completed between 1826 and 1838 by Lucignano and A. Manetti. The watershed was moved southward and as a result the Val di Chiana drains partly to the Arno, partly to the Tiber, and has been almost entirely reclaimed for cultivation. (G. KH.)

CHIANG KAI-SHEK (1887–), Chinese soldier and statesman, ruler of China from 1928 to 1949 and subsequently head of a Chinese government in exile on Formosa, was born on Oct. 31, 1887, into a moderately prosperous merchant and farmer family in the coastal province of Chekiang. He prepared for a military career, first (1906) at the Paoting Military academy in north China and subsequently (1907–11) in Japan. For two years (1909–11) he served in the Japanese army, whose spartan ideals he admired and adopted. More decisive an infiuence was that of youthful compatriots whom he met in Tokyo; plotting to rid the motherland of its alien Manchu dynasty, they converted Chiang to republicanism and made him a revolutionary.

In 1911, upon hearing of revolutionary outbreaks in China, Chiang returned home and helped in the sporadic fighting that led to the overthrow of the Manchus. But the revolutionists soon lost control of the new republic by handing its presidency to Yuan Shih-k'ai (*q.v.*). Yiian, aiming at personal rule, used his office to crush the party that had put him into it. The revolutionists, Chiang among them, struck back; but their "second revolution" soon collapsed, and Chiang had to flee the country (1913). He returned to Japan, where he remained with one interruption to the end of 1915. Meanwhile, Yuan discredited himself, especially by an attempt to restore the monarchy with himself as emperor. Chiang returned home to participate in the "third revolution," which by dashing Yuan's hopes of founding another dynasty saved the life of the republic.

After these sallies into public life, Chiang relapsed into obscurity. For two years (1916–17) he lived in Shanghai, where he apparently belonged to the Green gang, a secret society involved in financial manipulations. In 1918 he re-entered public life by going south to join Sun Yat-sen, the leader of the Nationalist party or Kuomintang (*see* KUOMINTANG). Now began the close association with Sun on which Chiang was to build his fame. Sun's chief concern at the time was to reunify China, which the downfall of Yiian had left divided among warring military satraps. Having wrested power from China's alien dynasty, the revolutionists had lost it to indigenous warlords; unless they could defeat these, they would thus have struggled for nothing.

Chiang joined the southern armies as a major general but could not gain control of them; for they were actually warlord troops that supported the Kuomintang only because Sun had struck bargains with their commanders. Each side intended to outwit the other, so that treachery followed treachery. Often outmaneuvered by their confederates. the revolutionists found their southern base insecure; twice they had to abandon it and return to the north. They needed an army of their own, and to build up an army they needed foreign help. Presently they turned to Russia, the only foreign power to have shown their cause any sympathy. Chiang visited Russia in 1923 to study Soviet institutions, especially the Red army. Back in China after four months, he became commandant of a military academy established on the Soviet model at Whampoa near Canton. Russian advisers poured into Canton, and the Chinese Communists were admitted into the Kuomintang. Chiang read Marx and Lenin and, like many Asian patriots of the time. seized on Lenin's doctrine of imperialism as the clue to his country's weakness and poverty. Henceforward Leninism coloured his outlook, but it did not make him tolerant of any efforts to sovietize his own country. The Chinese Communists made such efforts as they gained strength, especially after Sun's death in 1925. Chiang. with the Whampoa army behind him the strongest of Sun's heirs, met this threat with consummate shrewdness. By alternate shows of force and of leniency, he prevented a communist coup without losing Soviet support. Moscow supported him until 1927, when, in a bloody coup of his own, he finally broke with the Communists.

Meanwhile, Chiang had gone far toward reunifying the country. Commander in chief of the revolutionary army since 1925. he had launched a massive campaign against the warlords in the following year. It ended in 1928 when he entered Peking, the capital. A new central government with Chiang at its head was established at

Nanking, farther south. In the same year Chiang became Christian. apparently at the instance of the westernized Soong family, whose youngest daughter, Mei-ling, had recently become his wife. But compared with the Japanese and the Leninist influence on his thinking, that of Christianity remained minor. Chiang stood committed to a program of social reform, but most of it remained on paper, partly because his control of the country always remained precarious. In the first place, the warlords, whom he had neutralized rather than crushed, still disputed his authority. The Communists posed another continuing threat, having withdrawn to rural strongholds and formed their own army and government. In addition, Chiang faced certain war with Japan, which, after seizing Manchuria in 1931, showed designs upon China proper. Chiang decided not to resist the Japanese until after he had crushed the Communists—a decision that aroused many protests, especially since the Communists continued to elude him. To give the nation more moral cohesion, Chiang revived the state cult of Confucius and launched a campaign, the so-called New Life movement, to inculcate Confucian morals (1934). Simultaneously he pushed western notions of hygiene and urged conscious emulation of the Japanese as models of spartan discipline.

War with Japan broke out in 1937 and for over four years China fought alone. The effort nearly broke her endurance, and Chiang repeatedly received advice to negotiate a separate peace. But he stood firm, and China stayed in the war. Her reward was an honoured place among the victors as one of the Big Five. But internally Chiang's government showed signs of decay. which multiplied as it resumed the struggle against the Communists. Civil war recommenced in 1946; by 1949 Chiang had lost continental China. He moved his government to the island of Formosa, and, vowing to recover the mainland, continued to fight the Communists in the Formosa straits.

Among the reasons for Chiang's defeat, one frequently cited is the corruption that he countenanced in his government. But corruption is not a mortal disease, or few governments would live long. Nor can Chiang's downfall be ascribed to personal failings alone. Insofar as these contributed. however, none proved more fatal than his loss of flexibility in dealing with changing conditions. Growing more rigid, he became less responsive to popular sentiment and less tolerant of subordinates venturing novel ideas. He came to prize loyalty more than competence and to rely more on personal ties than on ties of organization. His growing dependence on a trusted clique also showed in his army, in which he favoured narrow traditionalists over many an abler officer. But to list Chiang's failings is not to deny his historical significance, which emerges from the contradictions that he combined in himself. Soldier and politician, revolutionary and traditionalist. Christian and Confucian. anti-Communist with a Leninist bias, Chiang embodies the crosscurrents and confusion of a transitional period in Chinese history.

(C. BT.)

CHIANGMAI (CHIENGMAI; KIANGMAI), a province (changwat) of northern Thailand with an area of 8.878 sq.mi. and population (1960) of 787,038. The capital and largest city in the *changwat* is also called Chiangmai, and is the terminus of the 467-mi. railway from Bangkok. For centuries this city was the capital of the Thai kingdom, Thai Yuan. The city of Chiangmai with a population (1960) of 63,464 is the fourth largest city in Thailand and serves as the regional geographic capital of the nine *changwats* comprising North Thailand. It is a religious, medical, economic. cultural, historical, educational and transportation centre for both North Thailand and some of the Shan provinces of Burma. Chiangmai is on the Ping river, the largest tributary of the Chao Phraya river, and is near the centre of a fertile intermontane basin about 80 mi. long and 20 mi. wide. The basin is covered with Chiangmai loams, the second most productive type of soil in Thailand. Where water is available for irrigation, two crops per year can be grown. Rice. the principal crop grown in the wet monsoon season (May through November) may be followed with a crop of soybeans, peanuts, corn or tobacco during the dry season (December through April). Mountain peaks that surround the basin range in height from 6,000 to 7,000 ft., but the city is at about 1,000 ft. above sea level. The mixed deciduous forests that cover the *changwat* outside the basin contain valuable stands of teak. Although teak exploitation has been curtailed and only half of the teak cut in Thailand is exported, Chiangmai is still the centre of the teak industry, as it has been for decades.

The American Presbyterian mission was opened in 1867 and its chief local institutions still are McCormick hospital and the Chiangmai Leper asylum. A Roman Catholic mission also established schools there. Chiangmai has a two-year teachers college, a junior college agricultural school and a technical institute.

Chiangmai, 453 mi. N.N.W. of Bangkok, is a tourist centre for both the Thai and for foreigners. Travelers may use an all-weather road, Thai Airways or the Northern Railway. (T. F. B.)

CHIANGRAI, the northernmost province of Thailand, bordered by Burma on the northwest and Laos on the northeast. Area, 7,260 sq.mi. (18.803 sq.km.); pop. (1960) 800,026. The capital, Chiangrai (pop. [1957 est.] 11,998), and Phayao (16,555) are the commercial centres of the north and south, respectively. Both towns, as well as Chiangsaen, were formerly walled seats of independent principalities. Natural topography orients the province northward toward the Maekhong river, but a highway built in the 1920s connects the chief towns with Lampang to the south. Major crops are tobacco and rice paddy, and there are over 25 commercial rice mills. (G. W. SK.)

CHIAPAS, a Pacific coast state of southern Mexico on the Guatemalan frontier, bounded by the states of Tabasco on the north and Veracruz and Oaxaca on the west. Pop. (1960) 1,215,475, largely Indians; area 28,732 sq.mi., mainly forested. The Sierra Madre crosses the southern part of the state parallel with the coast. The mountain region includes a fertile temperate plateau which contains the larger part of the state's population, but isolation and lack of transportation facilities have retarded its development.

The extension across the state to the Guatemalan frontier of the Pan-American railway (from Ixtepec, on the Tehuantepec national line) and the Inter-American highway improved the industrial and social conditions of the people. The main occupations are agriculture, which is very backward, stock raising, timber cutting, fruit farming and saltmaking. Coffee is cultivated on the Pacific slope of the Sierra Madre at elevation of 2,000 to 4,000 ft. Rubber plantations have also been laid out, principally by U.S. companies. The exports include mahogany, dyewoods, cattle, hides, coffee, rubber, fruit and salt. The mineral resources include gold, silver, copper and petroleum. The capital. Tuxtla (pop. [1960] 42,433), is on the plateau. San Cristobal (pop. [1950] 17,448), about 40 mi. east of Tuxtla, is an interesting old town and the seat of the bishopric of Chiapas, founded in 1525 and made famous through its associations with Bartolomé de Las Casas (*q.v.*).

Linked with Guatemala in colonial days, Chiapas became a Mexican state in 1824; its boundaries were fixed in 1882. The early Maya ruins of Palenque, now accessible to tourists, are in the northeast jungle. Maya Bonampak, with its famous murals, may be reached with difficulty from Tuxtla. (J. 4. CW.)

CHIAROSCURO, the disposition of light and shade in a painting (Ital. chiaro, "light"; oscuro, "shade"); the term is applied to an early method of printing woodcuts in various tones from several blocks, and also to a picture in black and white or brown and white only. It has also come to mean the atmospheric effect produced by the handling of highlights and shadows.

CHIATURA, a town of the Georgian Soviet Socialist Republic in the U.S.S.R., stands on the Kvirila river in a deep trench in the southern foothills of the main Caucasus range 28 mi. E.N.E. of Kutaisi. Pop. (1956 est.) 19,200. It is the centre of one of the largest manganese mining areas of the world. First discovered in 1849. the ore has been exploited since 1879. The mines encircle the town and the ore is sent by cable railway and transporter to

enriching plants in the town, whence the bulk is sent by railway to the ports of Poti and Batumi on the Black sea coast. Some of the ore is utilized in the nearby Zestafoni iron foundry.

(R. A. F.)

CHIAVARI, a town of northwest Italy in the Liguria region, Genoa province, is situated on the coast of the Riviera di Levante at the mouth of the Entella, 44 km. (27 mi.) E. of Genoa by road. Pop. (1957 est.) 22,161 (commune). It is on the main line from Genoa to La Spezia and Rome. which there follows the coast. threading a series of tunnels. Chiavari is in a fertile plain surrounded by hills with the sea to the south-southwest. The old part of the town is full of arcades. The 15th-century cathedral was rebuilt in 1823. Other buildings of interest, all 13th century, are the castle, the church of S. Giovanni Battista and the mansions of the Via Rivarola and Portici Neri. Tourism, chair making, lace and silk manufacture and the marketing of agricultural produce are carried on. The town grew up on the traces of a Roman camp on the Via Aurelia. In World War II it was captured by the Allies in April 1945. (Eu. P.)

CHIBA (CHIBA-KEN), Japanese prefecture, located on the Pacific coast of the Kanto plain, central Honshu. It is formed by the Boso peninsula, which lies east of Tokyo bay and south of the Tone river. Area: 1,944 sq.mi. Pop. (1960) 2,306,010. Agricultural Chiba produces surpluses of rice, vegetables and eggs for Tokyo, and its offshore fisheries flourish. The Tokyo industrial belt has expanded eastward into Chiba; otherwise, there is little industry except the making of rice wine (sake) and the processing of raw materials. Large natural-gas deposits have been tapped. Important centres of population are Choshi. Tateyama, Ichikawa and Funabashi.

CHIBA is the capital and largest (241,615 in 1960) city of Chiba-Ken, located on the northeastern coast of Tokyo bay. It is the prefectural administrative, commercial and cultural centre. A large steel mill was erected in 1952. (J. D. EE.)

CHIBCHA, the South American Indians who at the time of the Spanish conquest occupied the high valleys surrounding the modern cities of Bogotá and Tunja in Colombia. With a population of over 500,000, the Chibcha are notable for having been more centralized politically than any other South American people outside the Inca empire. Numerous small districts, each with its own chief, had been consolidated through conquest and alliance into two major states and several lesser ones, each headed by a hereditary ruler. Although these states were not very stable, it seems clear that the arrival of the Spanish cut short the development of even larger political units.

The political complexity of Chibcha society was based on an economy featuring intensive agriculture, a variety of crafts and considerable trade. Weekly markets in the larger villages facilitated the exchange of farm produce, pottery and cotton cloth; and trade with neighbouring tribes provided the gold which was used extensively for ornaments and offerings. The use of gold was a prerogative of the members of the upper class, who were also carried in litters and shown great deference. Since descent was matrilineal, chiefs and religious leaders were succeeded by their sisters' sons, although land was inherited patrilineally. Heirs to important offices underwent long periods (6 to 12 years) of fasting and seclusion in preparation for their future duties.

The religion was dominated by a hereditary but unorganized priesthood which maintained numerous temples and shrines and held elaborate but infrequent public ceremonies. Offerings, especially of gold and cloth, were a prominent part of all religious observances, and on special occasions human sacrifices were made to the sun.

See A. *L.* Kroeber, "The Chibcha" in Handbook of South American Indians, ed. by Julian H. Steward, Bureau of American Ethnology, Bulletin 143, vol. 2, pp. 887–909 (1946); José Pérez de Barradas, *Los muiscas antes de la conquista,* 2 vol. (1950–51). (SE. L.)

CHIBCHAN, a linguistic stock consisting of languages spoken or once spoken in Central America and northwestern South America. The name is from "Chibcha" (*q.v.*), the people who formed the nucleus of the Chibchan empire and who are also called "Muisca," based on the word for "man" in their language.

In 1960 scholars had not yet reached agreement about the languages to be included in this stock. One classification recognizes at least eight divisions, each with one or more languages, and given in approximate north to south order, as follows: Paya; Watuso; Talamancan: Bribi, Cabecar, Boruca; Guaymian: Guaymi. Terraba; Dorasque; Cuna; Muiscan: Rama, Chimila, Cagaba. Bintucua, Muisca, Tunebo, Dobocubi; Timotean: Cuica, Mocochi. With respect to more remote relationships, it has been suggested that the least distant ties of Chibchan are with Tanoan, Uto-Aztecan, Cuitlatec, Misuluan and Tucanoan. Earlier classifications grouped Chibchan with Barbacoan languages, but these are perhaps best classified apart, even while admitting distant kinship.

The phonetics of Chibchan languages tend to be simple, but comparative evidence suggests greater complexity in earlier times. The structure is mildly inflectional, with person, tense-mode, voice and derivative notions expressed by affixes.

CHICAGO, a city, a port of entry and seat of Cook county, Ill., the second city in the United States in population, commerce and manufacturing in the 1960s and the sixth largest city in the world. Strategically located at the mouth of the Chicago river at the southwest corner of Lake Michigan, the natural transshipment centre for the grain, lumber and livestock of the growing middle west in the 19th century, Chicago in the 20th century became the transportation, commercial and industrial centre of the north central United States. By air it is about 713 mi. from New York city, 1,858 mi. from San Francisco and 833 mi. from New Orleans. The climate is very changeable and is much affected by the lake; changes of more than 30° F. in temperature in 24 hours are not rare, and changes of 20° are common.

The land area of Chicago is 224.5 sq.mi., one-third less than that of New York city and not quite half that of Los Angeles. Chicago spreads loosely and irregularly backward from the lake over a shallow alluvial basin, which is bordered on the west by a low moraine watershed divide that separates the drainage of the lake from that of the Mississippi valley. The site has been built up out of the Lake Chicago of glacial times, which exceeded Lake Michigan in size. Lake Calumet, almost 5 sq mi., and part of Wolf lake, with a water surface of about 63 sq.mi., lie within the municipal limits. Chicago (41° 51' N. lat., 87° 38' W. long.) is 656 ft. above sea level. The original elevation of what is now the business heart of the city was only about seven feet above Lake Michigan, but between 1855 and 1860 the level was greatly raised—in some places more than ten feet—over a large area. The west side. especially the northwest near Humboldt park. is much higher (highest point, 75 ft. above Lake Michigan). The Chicago river. a narrow inlet from the lake, runs west from its shore for about a mile, dividing into a north and south branch, which run respectively to the northwest and southwest, thus cutting the city into the three divisions known as the north, the west and the south sides.

HISTORY

Early History.— Chicago (the name is derived from an Indian word of doubtful origin, meaning, according to some, "skunk" or "wild onion," but more likely "powerful") was first known as a place of portage in the 17th and 18th centuries. In 1673 Louis Jolliet and Jacques Marquette used it on their way to the Illinois country. René Robert Cavelier, sieur de la Salle, and other French explorers also came, as did traders and other adventurous spirits. During the first half of the 18th century Chicago was heard of occasionally as military base, Indian village, council point and trade centre. Following the defeat of the Indians by Anthony Wayne in the battle of Fallen Timbers in 1794, the United States gained control of six square miles of land at the mouth of

the Chicago river and in 1803 Ft. Dearborn was located there. In 1812 the garrison and settlers, who had abandoned the fort under Indian attack and were retreating toward safety. were massacred by the Indians about 1½ mi. S. of the fort. Rebuilt in 1816 the fort was occasionally occupied until it was finally evacuated in 1836.

Settlement. — On Aug. 4. 1830, James Thompson, a civil engineer, filed a survey and plat of the tonn, and Chicago received its first legal geographic location. Life remained uncertain because of the threat of Indian attacks until the defeat of Black Hawk (q v.) in 1832, when the Indians relinquished title to the region from the southern half of Lake Michigan to the Mississippi. Soon came a rush of immigrants. and a settled community life began. In 1833 a town government was set up; a semipublic school was opened and three places of worship nere built; the first newspaper, the Chicago *Democrat*, appeared on Nov. 26; and on Jan. 1, 1834, a mail route to Ottawa, 84 mi. S.W., was opened. In 1837 Chicago adopted a city form of government and soon became the trading point of the nearby countryside.

Arrival of the Railroads. — In 1848 the Illinois and Michigan canal connecting the Chicago river with the Illinois nas completed, bringing the promise of a rich and vast tonnage in foodstuffs from the farming region to the southwest. In the same year the Chicago and Galena Union, the city's first railroad, completed its first experimental trip of five miles and foreshadowed the day, not far distant, when Chicago broke the control of other cities over the trade of the northwest and other sections By 1870 rails reached north, south, east and nest. In 1854 the Chicago, Rock Island and Pacific set up communications with Rock Island, Ill, and Chicago and Alton, Ill., were linked by the Chicago, Alton and St Louis. The Illinois Central established direct traffic between Chicago and Cairo, Ill., in 1856. The Chicago, Burlington and Quincy strengthened its previous connections with Chicago (by short lines) with a direct run to Aurora, Ill., in 1865, and in the next decade this railroad covered the rich grain-producing areas directly to the south and nest of Chicago, and with a connection at Burlington, Ia., opened up a route to Omaha, Nebr. In 1864 the Chicago and North Western Railway company absorbed the Chicago and Galena Union and became a significant agent in the transportation of grain and other produce from the land lying northwest and west of Chicago. With the completion of the Union Pacific railway in 1869, which for a time marked the last major extension of the transportation system leading west, Chicago was within about 106 hours of traveltime from San Francisco. Calif.

With the extension of railroads eastward through the Michigan Central and Michigan Southern (after 1852). the Pittsburgh. Fort Wayne and Chicago (1856), the Pennsylvania (1858) and eventually other connections, the lake lost its priority both in shipments and in passenger traffic east.

Civil War. — During the American Civil War the city, despite the earlier strength of the Democratic party, remained loyal to the North. The war brought a tremendous increase in the grain trade; production and sales of reapers and other farm implements rose as farm workers entered the armies; and Chicago became the leading pork producer in the nation. surpassing Cincinnati. O , and one of the leading markets for tents and uniforms, saddles and harnesses. salt, beef, bread and lumber. By 1870 the city had almost 300.000 inhabitants and was a commercial centre of immense importance.

The Great Fire. — On Oct. 8, 1871. a fire began, its origin undetermined, and continued until the night of Oct. 9. Two-thirds of the city's buildings were wood, and the summer and autumn had been excessively dry; to make conditions worse, a high and veering wind fanned the flames. The conflagration crossed the river, burned over an area of approximately 2,000 ac . destroyed about 18,000 buildings and property valued at $196,000.000 and left about 90.000 people homeless; at least 300 persons lost their lives. The flames traveled 2¼ mi, in an air line within 6½ hours. Thousands of persons, fleeing before the flames and firebrands, sought refuge on the shore and even in the naters of the lake. On the south side the fire was checked on Oct. 9 by the use of gunponder; in the north (where the waterworks were early destroyed) it had extepded almost to the prairie nhen rainfall finally brought it to an end after about 27 hours of destruction

The common council acted with expedition to provide for the destitute and to safeguard the general interests of the community. By ordinance it fixed the price of bread at eight cents for a 12-oz. loaf; Mayor Roswell B. Mason pledged the credit of the city to pay for necessities; by other proclamations he regulated charges for hacks and similar carriers, opened public buildings as places of refuge and as distribution centres, closed saloons for one week at 9 P.M . invited volunteers to serve as emergency police, and entrusted the preservation of order largely to Lieut. Gen. Philip H. Sheridan, U S. army, commanding the military division of the Missouri. Aid came from many places, organizations and individuals throughout the country. Though the fire was calamitous, it left unharmed the sources of Chicago's commercial prowess. The city had not lost its strategic location with reference to river, lake and canal and could, therefore, preserve a leadership in water-borne traffic. The railroads still provided contact with the main sources of the city's commerce and trade. Some grain elevators were unharmed; there was at hand a supply of lumber; and the Union stockyard and some manufacturing establishments were outside the line of the fire. In about a year the business district nas largely rebuilt. The retail district moved south on Wabash and Michigan avenues and west to State street where in the 1860s Potter Palmer and Marshall Field had established their dry goods business. Manufacturing plants shifted from the north bank of the river to the neighbourhood of the south branch at 22nd street and Western avenue, and wholesale houses were located chiefly along West Monroe, West Madison and Wells streets. Banking interests took over Washington and LaSalle streets. From a large area use of wood was prohibited in the construction of new buildings, which were designed to be fire resistant. Business. in general, recovered rapidly. By 1873. when a serious panic struck the country, Chicago had already begun a climb touard prosperity and was affected by the depression less quickly than nere many other places.

Labour Movement. — The growth of industry after the great fire was accompanied by intensified efforts to organize labour. Labour troubles increased, and Chicago was known as a centre of discontent and even of radical or anarchistic movements. In 1877 railuay strikes in the east spread to the city and inaugurated a series of spectacular disturbances. Signs of discontent increased in 1884, 1885 and 1886, and several industries were the scenes of strikes On May 3, 1886. a clash took place between strikers and scab labourers brought in to break a strike at the McCormick Harvesting Machine company works The police were summoned and in the confusion six men were killed. A protest meeting was called by anarchists for the next evening at the Haymarket square on Randolph street between Desplaines and Halsted streets. Mayor Carter Harrison attended for a while and found the meeting peaceable except for the impassioned addresses of some anarchist leaders. He ordered the police reserves home and left the scene. Sometime later, however, a subordinate police officer, angered by the speeches, marched upon the meeting with a large force and ordered it to disperse. Thereupon a bomb was thrown, killing seven policemen and injuring many others. Under an excited public opinion the anarchist leaders were indicted, tried and found guilty, although the actual bomb thrower was never brought forward. The death penalty was imposed on seven and life imprisonment on an eighth, a verdict later upheld by the United States supreme court. Eventually four were hanged, one committed suicide, two had their death sentences commuted to life imprisonment. and an eighth was sentenced to prison for 15 years. In 1893 Gov. John Peter Altgeld (*q.v.*) pardoned the surviving three on the ground that the jury was packed and that the defendants were not proved guilty of the crimes charged in the indictment, and that there was no case at all against one of them. In liberal circles Governor Altgeld's actidn received commendation, but to others the pardons appeared a shocking miscarriage of justice. For the legitimate labour movement the Haymarket affair proved to be a setback. although these labour organizations were not led

by persons committed to the philosophy of anarchism.

In 1894 a strike at the Pullman Car company works again attracted national attention. The cause of the workers was taken up by the powerful American Railway union, led by Eugene V. Debs. Transportation throughout the north came to a standstill. On the ground of protecting the transmission of mail, Pres. Grover Cleveland ordered 2.000 federal troops to Chicago despite the objection of Governor Altgeld that such aid was not requested and that the situation could be handled locally. The strike collapsed, and Debs and three other union officers were indicted for conspiracy (see DEBS, EUGENE VICTOR). Eventually Debs appealed to the U.S. supreme court the sentence he had received; the court, by upholding the decision of the lower court, announced significantly that the federal government had an implied right to protect interstate commerce even when there was no explicit law.

By 1890 about 65,000 norkers in Chicago were reported to be organized, over a third of them in the American Federation of Labor. Chicago continued to be essentially a union town. The radical Industrial Workers of the World was founded there in 1905, but it represented a minority of the labour force. After the 1930s unskilled labourers, small shopowners and merchants, some white-collar workers and similar groups were organized by the American Federation of Labor and the Congress of Industrial Organizations (A F.L. and C I.O.).

Civic Life.—In World War I, despite its large German population and the openly expressed pro-German attitude of Mayor William Hale Thompson, Chicago supported the government with large Liberty Loan bond drives ($3,292,183,450) It contributed $12,000,000 to the activities of the Young Men's Christian association and $15,000,000 to the Red Cross. During World War II Chicago again gave generously to the war effort. Four service centres entertained 17,500,000 service personnel. In seven war bond drives Cook county residents bought bonds valued at $6,667,-867,447, and they participated actively in the thrift drives for steel, fat and paper. The people of Chicago contributed 642,392 pints of blood.

Equally responsive to public needs have been humanitarian enterprises throughout the city's history. Often promoted by private benefactions, they represent both individual and collective sensitivity to the needs of the unfortunate. Chicagoans have contributed generously to hospitals, infirmaries and homes for dependent children and adults. The Community Fund (1934), United Charities (1909), Jewish Federation of Metropolitan Chicago (1958; precursor founded 1857) and Catholic and Protestant church welfare organizations represent unified action. Well-known settlement houses, particularly Hull house, established by Jane Addams and Ellen Gates Starr (1889), have been copied throughout the United States. Large congregations reflected steady growth in organized religion. In the second half of the 20th century, over 1,900,000 in Chicago were Roman Catholics and the Chicago archdiocese is the largest see in the United States. About 709,000 Protestants worshiped in 1,600 churches, and there were about 100 Jewish congregations.

The 400th anniversary of the discovery of America was commemorated by the World's Columbian exposition held at Chicago (1893) in Jackson park and the adjoining Midway. The grounds comprised 686 ac., of which 188 ac. were covered by buildings, planned by a commission of architects; John W. Root and Daniel H. Burnham were responsible for the general scheme. Forty years later (1933) Chicago threw open the gates of its second international exposition, A Century of Progress, celebrating the centennial of the first incorporation of the municipality.

Because of its central location, Chicago has been the United States' most famous convention city and the scene of the nominations of presidents Lincoln (1860), U. S. Grant (1868), James A. Garfield (1880), Grover Cleveland (1884 and 1892), Benjamin Harrison (1888), Theodore Roosevelt (1904), William Howard Taft (1908), Warren G. Harding (1920), F. D. Roosevelt (1932, 1940 and 1944); and Dwight D. Eisenhower (1952).

Politics and Civic Awakening.—From its early days Chicago, in common with other frontier towns, had a reputation for rawness, lawlessness and crime. Over the years gambling establishments, houses of prostitution, saloons and dram shops flourished. By 1849, according to one Chicago newspaper, there were more gambling establishments in the city than in Philadelphia; by 1858 there were said to be more than 100 houses of prostitution. Although much of the liquor trade was carried on illicitly, in 1859 the city collected $44,548 in licence fees and ten years later collected $110,136. Charges of open and flagrant violations of city ordinances became common, as did reports that justices and constables pocketed fines and that the police engaged in blackmail and were given to accepting gifts and bribes. Churches, temperance organizations and reform groups in general attempted to eliminate the causes of these conditions.

In the late 1890s the city experienced a great civic awakening. A civil service system was inaugurated in 1895. Numerous reform associations attempted to rouse public opinion, such as the Citizens' Association of Chicago which had been organized in 1874, the Civic federation (1894), the Municipal Voters' league (1896), the Legislative Voters' league (1901), the Referendum League of Illinois (1901), the Municipal Lectures association (1902), the Civil Service Reform Association of Chicago, the Civil Service Reform Association of Illinois (1902), the Merchants' club, the City club (1903), Law and Order league (1904) and Society of Social Hygiene (1906); and many women's clubs took an active part. These organizations stood for effective enforcement of the laws, sanitation, pure food, public health, the improvement of the schools and the widening of their social influence and (especially the women's clubs) aesthetic, social and moral progress. The Merchants' club reformed the city's bookkeeping and secured the establishment (1899) of the first state pawnbrokers' society. The Civic federation demonstrated (1896) that it could clean the central streets for little more than half the sum the city was paying (the city later saved the difference); it originated the movement for vacation schools and other educational advances, and started the Committee of One Hundred (1897), from which sprang various other reform clubs. The Municipal Voters' league investigated and published the records of candidates for the city council, and recommended their election or defeat. The reform movement, in its various phases, came to its full tide under the administration of Carter H. Harrison, Jr., who was elected to his fifth term as mayor in 1911.

Unfortunately the reform spirit failed to carry over into the years immediately following the adoption of the prohibition amendment (18th) to the federal constitution in Jan. 1919. A building boom and postwar prosperity attracted many lawbreakers to the city. The huge profits of the illicit liquor trade led to the organization of powerful criminal gangs, and competition between these organizations resulted at times in murder and banditry. It was during this period that the notorious gang leader Al ("Scarface") Capone came into power. The growth of the gang system subjected Chicago to wide criticism. William Hale Thompson, Republican, was mayor from 1915 to 1923. The term of William E. Dever, Democrat (1923–27), elected as a reform candidate, did not appreciably stem the tide of lawlessness. Thompson returned to the City hall in 1927 and served as mayor until 1931 when Anton J. Cermak, Democrat, took over and inaugurated a cleanup campaign.

Under the centralized regime adopted by Cermak, Chicago politics, long dominated by ward and district leaders, developed along the lines of Tammany in New York. The organization brooked no rebellion in its ranks. Although bloc voting had been promoted as early as the 1870s by the Irish boss Daniel O'Hara and by the German Anton C. Hesing, and by others later, it grew somewhat haphazardly. With Cermak came sophistication of management, and Chicago abandoned the frontier town characteristics it had long possessed. Cermak died on March 6, 1933, at Miami, Fla., the victim of an assassin's bullet intended for President-elect Franklin D. Roosevelt. His organization, however, remained firmly entrenched under Mayor Edward J. Kelly, Democrat (1933–47), who made the machine one of the most powerful vote-getting organizations in the country. The election of Martin H. Kennelly, Democrat (1947–55), a prominent businessman, inaugurated a mild reform. Under his successor, Mayor Richard J. Daley, also

a Democrat, the machine continued its local domination and its prominent role in state and national politics.

20th-Century Progress. — During the 20th century Chicago pioneered in the production of drugs; recognition of the city's leadership in medicine is world-wide. After Enrico Fermi achieved the first self-sustaining nuclear chain reaction at The University of Chicago in 1942, work continued at the Argonne Cancer Research hospital and the Enrico Fermi Institute for Nuclear Studies. The Armour Research foundation of the Illinois Institute of Technology began operation of the first research reactor to be used only for private industrial research in 1956.

Construction of skyscrapers, a contribution of late 19th-century Chicago architects, brought to the city rare distinction in building design. The Wrigley building, *Tribune* tower and the Board of Trade building, among others, gave Chicago a uniquely beautiful skyline. In the second half of the 20th century the Prudential Insurance, *Chicago Sun-Times–Daily News,* Inland Steel, Borg-Warner and Marina City buildings added to the architectural distinction of the city.

POPULATION

City. — In 1833, the year in which Chicago was incorporated as a town, only about 350 people lived there; by 1837, when it was incorporated as a city, there were approximately 4,000. The number increased to 29,963 by 1850, less than one half of whom were born in the United States. The population was 1,099,850 by 1890; it was 2,185,283 in 1910; 2,701,705 in 1920; 3,376,438 in 1930; 3,396,808 in 1940; 3,620,962 in 1950; and 3,550,404 in 1960. The increase from 1920 to 1930, partly as a result of annexations, was 674,733, largest gross gain in the history of the city.

Almost from the beginning Chicago was a cosmopolitan city; its social fabric included people from all parts of the world. The large number of European immigrants Chicago attracted in the 19th and early 20th centuries was added to the earlier population of American settlers, many of whom came from the eastern part of the United States, particularly from New England and New York. At first these persons of eastern origin made up the leaders of the city's political and economic life, but as the immigrants became assimiiated they too began to play their part in civic life. Shortly after the Civil War this assimilation had been accomplished for many of the early immigrants, but Chicago continued to have many roots in the soil of other countries. As late as 1960 approximately one out of five white Chicagoans was foreign born. In 1850 the largest part of Chicago's foreign-born population was Irish; the second largest group was of German origin. Although Poles comprised less than 1% of the population in 1850, a century later they made up the largest number of foreign born (94,009); Germans (56,635) ranked second, followed by Italians (54,954), Russians (52,879), Swedes (31,104) and Irish (29,804 from the Republic of Ireland, 751 from Northern Ireland).

The tendency of newcomers to congregate in neighbourhoods where their conationals predominated gave rise to distinct islands of settlement where foreign languages were often heard. Local ethnic associations reflected their members' attachment and ties to the old country. At the same time these organizations often helped immigrants to adjust to their new homes and provided work through their employment agencies, as well as insurance and other benefits. Besides such ethnic organizations, other welfare agencies developed to perform similar services not only for the foreign born but for all minority groups.

After World Wars I and II the Negro population increased considerably: from 109,458 in 1920 to 277,731 in 1940; to 812,637 in 1960. The increase in the proportion of Negroes in the city proper has been due largely to the continued migration of Negroes into the city while the white population was moving to the suburbs. In 1960 Japanese comprised the largest oriental group in the city (11,375), the second largest being Chinese (5,082). American Indians numbered 3,394.

Metropolitan Area. — In the 1960 census the vast urban complex centring on Chicago was designated by the census bureau as the Chicago standard consolidated area. This consolidated area consisted of the Chicago standard metropolitan statistical area, comprising Cook, Du Page, Kane, Lake, McHenry and Will counties in Illinois, and the Gary-Hammond-East Chicago standard metropolitan statistical area, comprising Lake and Porter counties in Indiana (see GARY). The census bureau definition did not include adjacent communities in Wisconsin, with most of which Chicago has long enjoyed economic ties. In 1960 the population of the Chicago standard consolidated area was 6,794,461; that of the standard metropolitan statistical area was 6,220,913. Although the city occupied about 5½% of the metropolitan area it contained 57.1% of the population in 1960. Between 1950 and 1960 the population of the city dropped 1.9% but in the metropolitan area increased 20.1% and in the consolidated area 24.9%. The rate of regional growth outside the city was stimulated not only by the extension of motor traffic and hard-surfaced highways but also by the desire of many to live in less crowded areas. Part of the population growth in the second half of the 20th century is attributable to an increase in births over deaths; in the 1950s only about 30% was due to the excess of in-migrants over out-migrants. Population experts foresaw a continuing rise in population because persons of ages 15 to 44 (the reproductive years) had reached a low point by the mid-1950s, and this segment of the population would increase in numbers as "war babies" came of age. Projected industrial expansion was also regarded as a probable incentive for population increases.

Within the standard metropolitan statistical area of Chicago are many incorporated cities and towns. Thirty-four of these towns have populations exceeding 20,000. (For comparative population figures *see* table in ILLINOIS: *Population.)*

GOVERNMENT

The City. — The basic framework of Chicago's government had been established even before the city's adoption in 1875 of the Illinois general city charter law of 1872. Although minor amendments have somewhat altered the original charter the government operated even after mid-20th century under prescriptions designed for a rural rather than an urban age.

A mayor, elected for a term of four years, is the executive of the city government. His salary was raised in 1959 from $25,000 to $30,000. At one time only the presiding officer of the common council, the mayor has come to occupy a position of considerable influence. He has power of appointment to many positions, including heads of administrative departments who make up a so-called cabinet. As the demands of governing a growing city have increased, commissions to care for various urban problems have been created under these appointive powers. The mayor selects the perspnnel of special advisory agencies such as the commission on human relations; he chooses the members of commissions in charge of city functions, such as the school board, the public library board, the commission in charge of elections and that in charge of the Municipal Tuberculosis sanitarium. His appointive powers, however, do not extend to most city employees, who are under a civil service law.

A unicameral city council is composed of one alderman elected quadrennially from each of the city's 50 wards. It controls the budget, police, excise, city contracts and franchises (the latter, however, subject to popular referendum). The council confirms appointments by the mayor and may pass legislation by a two-thirds vote over his veto.

In the 20th century services performed by the city multiplied even within departments the charter had set up. In the police department, for example, special units were created in the 1950s to deal with pressing problems: a task force that moved from neighbourhood to neighbourhood as conditions required; a youth bureau, supplanting a unit in the crime prevention division and co-operating with the mayor's advisory committee on juvenile welfare, to combat juvenile delinquency.

Cook County. — Like most U.S. cities Chicago has a dual city and county government. Cook county, of which Chicago is the seat, retains practically all of the extensive government functions of rural counties of the type that arose in the southern colonies, in which the county was the real unit of local government. This complication of dual government in Cook county ex-

tends to Chicago's suburbs which have separate municipal organizations. The county was laid out after 1848 in townships, and these too had some governmental functions; it was not until 1900 that the town organizations within the territory, gradually annexed to the original village of Chicago, were deprived of their political structure and divested of governmental functions within the city. As late as 1903 ten townships exercised taxing powers within the municipal area. In addition to the original duplications of government, new quasi-governmental bodies were set up for special purposes and in some cases were granted police and taxing powers. The sanitary district, practically an independent government in itself, with powers of tax levy and debt making, has jurisdiction within the territory of Chicago and Cook county. The forest preserves, too, represent another quasi-governmental body with some sovereign powers. In all, there are more than 400 distinct political units in Cook county, empowered to levy 600 different sorts of taxes.

The grant of independent taxing power to so many governmental bodies is a result of state constitutional limitations upon the public debt. Chicago, as a municipal corporation, cannot incur debt exceeding 5% of the value of city property. Therefore many independent agencies have been created to meet current needs.

The Chicago Sanitary district, established by the state legislature in 1889, is such an agency, designed to provide for the disposal of sewage. A drainage canal, constructed between 1892 and 1900, joined the south branch of the Chicago river with the Des Plaines, and so with the Illinois and Mississippi. The canal, or sewer, is flushed with water from Lake Michigan (the amount of water so diverted being a source of prolonged dispute between Chicago and the states bordering the Great Lakes and Canada).

Water for the use of Chicagoans is pumped from Lake Michigan through several tunnels connecting cribs located two to five miles from shore. The first tunnel was completed in 1867. Chicago must supply more than 50 suburbs (in the Sanitary district) as well as the city proper.

In 1906 the archaic system of administering petty justice through justices of the peace was abolished and a co-ordinated municipal court with numerous judges and a chief justice was established. The juridical system is complicated by the fact that the circuit court is a constitutionally established court of the state. The superior, municipal and other special courts are created by statute. The first juvenile court in the United States was established by Cook county in 1899, becoming known in 1949 as the Family court; it is a branch of the circuit court.

City Planning.— Advisory committees have come to play an increasingly important part in the city's management. One of the most important is the Chicago Plan commission, an outgrowth of the brilliant plans of Daniel H. Burnham (1846–1912), architect and city planner, and of the Commercial club. Since 1909 under the commission's influence, improvements of the lake front and park systems have been undertaken, Wacker drive along the river was built and slums and other depressed areas have been improved. On Jan. 1, 1957, the commission was made a department of the city with enlarged powers. The Northeastern Metropolitan Local Services commission (Randolph commission) was established in 1955 to furnish services needed for co-operative activity in the metropolitan area. Public housing projects and slum clearance had advanced considerably by the 1930s. The Chicago Land commission, serving without salary, developed from the Illinois Blighted Areas act of 1947 and had important powers of demolition, relocation of families and condemnation and acquisition of property. In various projects financing is a combination of municipal, state and federal grants. The Hyde Park project near The University of Chicago demonstrated the effectiveness of co-operative endeavours by municipal, state and federal governments.

Finance and Taxation.— The budget for the city of Chicago called for the expenditure of more than $500,000.000 annually in the second half of the 20th century for operating expenses, the public library, the Municipal Tuberculosis sanitarium and civil defense. In addition other local governmental agencies affecting Chicago in whole or in part appropriated money. The board of education alone appropriated about $250,000.000 annually.

The largest source of the city's tax dollar was the general property taxes. which provide more than 40% of the city's revenues. Other sources included aid from other governments, sales and receipts, licences and permits and charges and miscellaneous sources.

ECONOMY

Chicago's location at the head of the most southwestern of the Great Lakes gave the city, from its earliest days, considerable importance in trade and industry. The largest railway centre in the United States, Chicago became the commercial outlet and centre of trade of the northern Mississippi valley. The most important economic undertaking during the city's early years was the grain trade. In 1851 Chicago became the largest corn market in the United States, and in 1854 the largest wheat trade centre. The power of grains over the city's destiny persisted, and was responsible, at first, for making Chicago the exchange point of the middle west. Lumber, too, was of early importance to Chicago's economy; in 1856 the city became the country's foremost lumber market. and by the 1870s and 1880s it was described as the greatest distributing centre in the world.

Even before the Civil War, Chicago showed promise of a later position of primacy in livestock trade and meat packing. By 1862 the city had surpassed Cincinnati as a pork-packing centre. In these undertakings Chicago's early economy found a secure foundation. The city's paramount position as a great market during the 19th century was associated with the extractive industry of the U.S. economy of that period, and its trade consisted principally in the acquisition and distribution of the raw crops and resources of fields and forests; its industries were mainly processing raw products, such as meat packing, woodworking, flour milling, tanning etc. With the rest of the United States the city underwent an industrial and commercial transformation following the Civil War By 1890 Chicago ranked second in the country in manufacturing, surpassed only by New York. During the 20th century the city's economic endeavours were to be characterized more and more by great variety and enormous size.

Manufacturing and Industry.— No other manufacturing centre in the country except New York is as important as Chicago in so many industries. Among its chief manufactures are food products, primary metals, nonelectrical machinery and electrical machinery.

In terms of value the manufacture of primary metals, including steel-mill operations, foundry and forge shop operations and the smelting and refining of nonferrous metals, had, by the second half of the 20th century, assumed first place. Until 1953 the Pittsburgh area led in production, but in that year Chicago outdistanced its long-time rival. The largest proportion of steel comes from mills in the Calumet region south of the city and from mills just over the Illinois line in Indiana. This district was important as early as the 1880s when promoters recognized the desirability of a site where artificial harbours could easily be constructed and where there was vacant, level and low-cost land near a large volume of clean water required by the industry. Other advantages were the district's location on the shore of Lake Michigan, its railway facilities, accessibility to the source of supplies and a rich consuming market nearby. With the opening of the rich iron deposits in the upper peninsula of Michigan in the 1850s, nearness by water to the Lake Superior ranges proved a prime factor in the evolution of Chicago as an iron and steel centre. By the late 1890s two-thirds of all the ores used in the United States came from the south shore of Lake Superior.

The gigantic United States Steel Corp. mills in Gary (*q.v.*), Ind., the company's south works and the Inland Steel Co. plant —all in the Chicago metropolitan area—are the three largest steel mills in the United States. Others of great productive capacity in the area include the mills of the Republic Steel Corp., the Wisconsin Steel Works of the International Harvester Co., and the Youngstown Sheet & Tube Co. These companies enjoyed their greatest expansion after mid-20th century, their mills in the Chicago metropolitan area supplying more than 14,000 manufacturing plants.

Rails and railroad equipment factories have long been heavy consumers of steel; the first steel rail in the United States was rolled in Chicago in 1865. Pullman-Standard car manufacturing company, a direct descendant of George M. Pullman's Palace Car company established in 1867, the Electro-Motive Division of General Motors Corp. and the General American Transportation Corp. (GXTX) manufacture freight and passenger cars. locomotives and specialized rolling stock, and scores of additional concerns fabricate numberless other metal products.

The making of agricultural implements and other farm equipment has a long and enviable history in Chicago. Cyrus H. McCormick (*q.v.*) set up his factory in Chicago in 1848 at the threshold of the rising wheat empire of the great middle valley. By the 1850s sales had multiplied, and the shortage of man power during the Civil War led to more widespread use. Soon Chicago-made reapers were found throughout the country, and their exhibition in London in 1851 and in Paris in 1855 demonstrated their superiority over others. By 1880 McCormick had conquered the world market. Ten years later agricultural implements manufactured by Chicago firms stood fifth among the city's leading products in terms of value added by manufacture. The International Harvester Co., a consolidation in 1902–03 of the McCormick Harvesting Machine company and other companies, became one of the giant industrial organizations of Chicago and the largest manufacturer of agricultural machinery in the world.

The manufacture of electrical machinery is one of the city's seven leading industries, followed by the manufacture of fabricated metal products. After the 1940s the metalworking field in general had a tremendous expansion. After the Civil War printing and publishing assumed an important position. rising from third in the city's economy in 1880 to first by 1910, by the second half of the 20th century the annual value added by manufacture exceeded $1,000,000,000. A few chemical plants manufacturing paint, varnish and glycerine had been established by the 1850s. A century later about 700 such plants manufactured a wide variety of products. The manufacture of petroleum and coal products was a major industry after mid-20th century.

Meat Packing and Food Products.——Yo economic enterprise has played a more significant role in Chicago history than has meat packing and its affiliated trade in livestock. The plants of Armour & Co. and Swift & Co. were founded by Philip D. Armour and Gustavus F. Suift after their arrival in the city in 1875. In a few years Chicago was the meat capital of the world. Within two years after he started in Chicago, Swift began shipping dressed beef to Boston, and in 1882 Armour sent refrigerated beef east. Chirago meat packers shipped to European as well as American markets. By the late 1870s Libby, McNeill & Libby, among others. shipped canned meat overseas. and in 1885 Armour and company alone filled an order from the British government for 2,500,000 lb. of compressed beef for the Nile expedition of the Egypt and Sudan campaign. By the beginning of the 20th century wholesale slaughtering and meat packing ranked first among Chicago's industries in terms of value added by manufacture.

As animal-raising areas were developed farther west in the late 19th century, packing establishments were set up nearer to the source of supplies. Many of the new plants nere owned and managed by Chicago packers who thereby ensured the city's continued dominance in the industry. After mid-20th century the Union stockyard (opened in 1865) became more and more a place of sales and trade. Although Armour continued to pack hogs. Swift ceased slaughtering, dressing and packing them in 1952, processing only pork slaughtered elsewhere; even this activity in pork was abandoned in April 1957. On Jan. 25, 1958, Swift discontinued also the processing of lamb and veal, and in April stopped making so-called domestic meats (sausages, bologna and frankfurters). Libby, McNeill & Libby, engaged since 1868 principally in canning, continued to purchase already slaughtered animals.

Associated with the packing industry from an early day were the processing and marketing of by-products, including hides and skins, edible and inedible fats and the livers. hearts and other products not sold with the carcass. In the second half of the 20th century the value of by-products tended downward relative to the value of the live animal because of the development of competing products frdm nonanimal sources.

Although meat products topped the list. a variety of other food products was turned out in large quantities. Chicago became the largest producer of candy and related products in the country. Other important food products included bakery goods, dairy products, canned and frozen foods and grain mill products.

Even as early as the late 1860s, Chicago showed signs of losing its pre-eminence as a grain market to cities nearer the shifting grain-producing areas. By 1870 both Milwaukee and St. Louis had moved ahead, and soon Minneapolis, too, had surpassed Chicago. Furthermore, the struggle of the north and south railway lines in the Mississippi valley to divert grain and other freight to ports on the Gulf of Mexico brought about loss to Chicago. A considerable increase in the cereal trade of Philadelphia, Baltimore and Newport News and Norfolk, Va., was partly caused by the traffic eastuard over lines south of Chicago. Altogether, the competition of the Gulf roads and lines running southwest from Duluth had done much to exclude Chicago by 1899 from the grain trade west of the Missouri river. Nonetheless its facilities for receiving and distributing remained unequaled, and it continued to monopolize the traffic between the northern Atlantic seaboard and the central west. Since the mid-1850s large elevators have provided storage for the huge volume of grain passing through the city.

The Board of Trade, the greatest speculative grain and provisions market in the world, was organized in 1848, and no other agency has continuously played a more important role in the city's economic development. Its future prices are the basis of cash prices wherever farmers sell.

Wholesale and Retail Trade.—Chicago's wholesale trade accounted for more than 8% of the wholesale trade of the nation in the late 1950s. The major products handled by more than 12,000 wholesalers in the city are groceries, confections, meats, machinery, industrial equipment and supplies, produce, electrical goods and equipment, drugs and chemicals, dry goods and apparel, lumber and construction materials and paper and paper products. Throughout the 20th century wholesalers organized trade shows, or fairs, in Chicago. By the second half of the century a yearly average of more than 500 such shows attracted about 500,000 buyers to the city each year.

The Loop is the largest single centre of Chicago's retail trade, the seven blocks along State street drawing an average of almost 500.000 people each day. Following World War II, competitors—off-street shopping centres, usually built in new neighbourhoods or in suburbs and made up of a variety of stores—arose to challenge both State street and the neighbourhood stores. Many of the State street stores met this competition by opening branch stores in the nen centres. In addition. a modernization program was instituted on State street; and new parking facilities for Loop shoppers were built.

Chicago's foreign trade is mostly by rail through other ports, although after the opening of the St. Lawrence seaway in 1959 ocean-going vessels from the Atlantic reached the city.

Employment and Income.—Chicago, in general, enjoyed a higher level of employment in the second half of the 20th century than did the country as a whole. A higher proportion of those in the active age group was part of the labour force, and women were actively engaged as wage earners to a greater degree in Chicago than in the country at large. Per capita income also was above the national average. The cost of living in Chicago reflects local as well as national economic factors and usually has been among the higher index figures in the nation.

Public Utilities.—Much of Chicago's factory industry is due to an abundance of electric power, supplied by a system of interconnected generating stations. The electrical output. 5,574,961,000 kw.hr. in 1929, increased to more than 20,000,000,000 kw.hr. yearly in the second half of the 20th century. The first electric power generated by atomic energy entered the system in the spring of 1960.

Chicago's gas supply is interconnected by pipelines with the natural gas fields of Texas and with producing plants and consumers within a wide radius of the city. Use is also made

of surplus by-product gases generated in the steel and iron industry.

Banking. — Although Chicago is one of the most important banking centres of the nation. it has not attained national leadership or the international standing New York enjoys. The large banks are located in the Loop. Since branch banking was prohibited by state law in 1923, neighbourhood banks serve the small businessmen of the community and individual depositors and borrowers. Savings and loan organizations experienced tremendous growth after World War II and by 1960 outnumbered banks by two to one; currency exchanges are even more numerous. In 1914 one of the 12 regional banks of the Federal Reserve system was established in Chicago. With its member banks (in Illinois, Iowa, Michigan and Wisconsin) it became the Seventh (Chicago) Reserve district.

The Midwest Stock exchange plays an important role in financing industrial and general business activities. The exchange was established in 1949 by a merger of the old Chicago Stock exchange (organized in 1882) and the exchanges of Cleveland, O.; St. Louis, Mo.; and Minneapolis-St. Paul, Minn.

TRANSPORTATION

Chicago is the world's largest railroad and air traffic centre. The highway network makes possible vast movements of people and of raw and manufactured products by truck, bus and automobile. Waterways throughout the city's history have served as a means of transport.

Railroads. — The combined mileage of the city's 19 trunk lines is about half that of all the railroad systems in the Cnited States. Trunk lines reach east to Montreal, Que., Boston, Mass.. New York, Philadelphia, Pa., and Baltimore, Md. (the nearest point on the Atlantic coast, 854 mi.); south to Charleston, S C., Savannah, Ga., Mobile, Ala., New Orleans, La., Port Arthur and Galveston, Tex.; west to Los Angeles and San Francisco, Calif., and Seattle and Vancouver, Wash. Chicago is also the greatest Canadian railway centre from the standpoint of traffic. The Canadian National and Canadian Pacific enter the city through subsidiaries.

The so-called terminal district from which the trunk lines operate reaches in the form of a crescent from Muskegon (Mich.) on the north to Joliet on the southwest and Gary on the southeast. Through this district stretch 7,800 mi. of track, seven belt lines, switching facilities and three electric line railroads. More than 200 freight terminals, industrial yards having a capacity of approximately 200.000 freight cars, some 250 freight houses and almost 400 team yards and specially constructed coal yards are within the terminal district. In the second half of the 20th century over 35,000 freight cars were handled each week-day. 5.000 through. 10.000 intraterminal and 20.000 inbound and outbound. About 43.000 firms in the district owned their own sidings. The Elgin, Joliet & Eastern railway, also called the Chicago Belt. runs from the steel mills at Gary at the south to Waukegan on the north. Because it crosses every railroad coming into Chicago and maintains facilities for interchange the Chicago Belt line carries more tonnage per mile than any other Class I railroad.

Railroad passenger service likewise is extensive. Each day about 550 trains pass through Chicago and 1,225 carry the city's commuters. On a normal business day about 280,000 commuters and 47,000 passengers use the trains.

The passenger terminal situation for the greatest railroad centre of the country has not measured up to the performance of the railroads, and there is no central station. The passenger station of the Chicago and North Western railway was opened for service in 1911. The Union station, directly to the south of this terminal and used by the Pennsylvania, the Burlington, the Gulf Mobile and Ohio and the Milwaukee railways, was finished in 1925.

The far more numerous railways entering the city on the south side spent years working on plans for the consolidation and rearrangement of their terminal facilities, but decline of railway passenger traffic and weakened railway finances during the depression of the 1930s diminished interest in the projects. The increased patronage enjoyed by air lines and the greater use of automobiles and trucks even in prosperous days further decreased the revenue not only of railroad passenger service but of freight traffic, and the railways continued to use four separate passenger terminals.

Of many physical improvements undertaken by various railroads, the use of diesel engines had particular significance. In 1934 the Burlington road inaugurated such a run between Chicago and Denver. In 1936 the Santa Fe railway introduced passenger streamliners for a trip of 39¾ hours between Chicago and Los Angeles. The North Western's "400" had already covered the distance between Chicago and Minneapolis-St. Paul in a mile-a-minute, the first to make this speed for this distance. Sixteen-hour passenger service between Chicago and New York started in 1938.

Air Traffic. — The first municipal airport in Chicago was established in 1927. By 1960 over 20 airports served the area and the three city-owned airports handled millions of passengers annually. Midway airport, so-called for the United States victory at Midway Island in 1942 and because it was situated midway between the majority of national airways. became the busiest airport in the world. O'Hare International airport, named for World War II hero Lieut. Comdr Edward ("Butch") O'Hare. was opened in 1956. Through O'Hare field the city has direct airplane connection with London, Paris. Bombay and other cities throughout the world. Meigs field, a downtown airport located on Northerly Island. has held a passenger station since 1947. It was designed primarily to accommodate private planes and helicopters.

Airfreight and airmail lines expanded in numbers and services, particularly during the 1950s. Through its air division the American Railway express increased the speed of its service. Before the mid-1950s helicopters carried air mail to numerous towns near Chicago, and after 1956 the use of helicopters expanded considerably; they provided service to the three municipal airports and increasingly served private interests.

Trucking. — The growth of transportation by truck is one of the best illustrations of the changing pattern of the United States economy in which Chicago participates. The transition from horse-drawn wagons, found even as late as the 1920s. to motorized, heavy vehicles capable of carrying an average of 20 tons of freight. occurred in less than three decades. The process was gradual until the 1940s. when the needs created by World War II stimulated the trucking business. By this development in the transport of freight the railroads suffered greatly, as they had by the transport of passengers by motorbus.

Chicago became the chief centre of trucking in the United States, with more than 2.000 cartage companies in the city and its suburbs. The majority were organized after World War II, although a few prominent cartage companies were teamsters before then. By the mid-1950s about 10 000 trucks entered and departed from Chicago in an average day. bearing all kinds of cargo, from canned foods to steel. About 85% of the livestock entering the Union stockyard was transported by truck. Refrigerated trucks transported fresh and frozen foods. and armoured trucks, the property of Brink's Inc , founded in Chicago in 1859, carried money to approximately 2,000 cities and towns in the United States and Canada.

Water Traffic. — Ship traffic on Lake Michigan, important since the city's earliest days, became principally a matter of transporting bulk cargoes of iron ore, coal, coke and limestone directly from mine rail terminals to the great iron, steel and cement plants with their own docks on the south shore of the lake. Throughout the 20th century traffic shifted to the ports on the southern extremities of Chicago — Calumet harbour, Indiana harbour, etc — and steamers that formerly docked in the river called, after 1915, at Navy pier. which projects 3,000 ft. into Lake Michigan north of the Chicago river. Some lake cargo destined for Chicago is landed at Milwaukee, Wis., and proceeds by rail.

Upon completion of the Illinois waterway in 1933 (connecting Chicago through the Illinois and Mississippi rivers with New Orleans by a barge route of nine-foot draft) the Chicago river became an important link for through-water traffic. With the completion of the St. Lawrence seaway in 1959, Chicago was connected with the Atlantic ocean, making the city a world port.

Improvement of the Chicago outer harbour by the federal government began in 1833. Great breakwaters protect the river

mouth from the silting shore currents of the lake, and an outer roadstead affords secure shelter from storms. The river itself has about 15 mi. of navigable channel, in part lined with docks. The channel has been deepened several times and, from 1896, widened and straightened after overhanging building constructions along the river banks were removed. In 1890 the federal government assumed control of the river as a navigable stream. In the days when it served Chicago as an important highway of commerce, the shores of the river were lined with grain elevators, lumberyards, coalyards and warehouses.

With the opening of Wacker drive at the northern boundary of the Loop business section in 1927, abutting buildings disappeared from the south bank of the river to Lake street. This construction, which connects with the Michigan avenue bridge and the two-level boulevards approaching it, was the beginning of a plan to make the south and east banks of the river into broad traffic arteries. Farther south, the south branch of the river, which curves west for about a mile, was moved westward a quarter of a mile to permit the building of wide streets from the south into the Loop.

The port of Chicago includes Chicago harbour and Calumet harbour on the lake front, Lake Calumet, the Chicago and Calumet rivers, the Chicago Sanitary and Ship canal and the Calumet-Sag channel.

Local Transportation. — The first city ordinance providing for streetcar service was passed in 1855, but the initial trip was not made until 1859. By 1890 electrification began to supersede the cable system, and two years later the electric trolley car was introduced. The last years of the 1880s saw the beginning of an elevated railway system. Under a state referendum act the city voted for municipal ownership and operation in 1902; and the next year the state legislature (in the Mueller law) granted the city the requisite powers. In 1906 acquisition of all roads by the city seemed assured, but the necessary bond issue was declared unconstitutional (1907). The electorate reversed its stand in 1907, voting for private ownership but greater municipal control. In 1927 the franchise arrangement terminated and the lines operated under temporary agreements.

With increasing congestion of the streets by motor traffic and the growth of the city. surface electric lines failed to meet the demands made upon them. Elevated railway lines also were inadequate to serve potential passengers. In 1938 the construction of a subway to connect with the elevated was started, but the first unit did not begin running until 1943. A second unit was opened in 1951. This transportation, city owned, is operated by the Chicago Transit authority (C.T.A.), a semipublic body, publicly owned but privately financed. The C.T.A. lines comprise one of the largest local transportation systems in the world, operating gasoline, diesel and electric buses and elevated and subway trains in Chicago and other Cook county municipalities.

EDUCATION AND CULTURE

Education. — The general control of the public schools is the responsibility of the board of education, a policy-making agency, appointed by the mayor. The board serves without pay. At the head of the administrative staff is a general superintendent. The cost of operating the public schools is met largely from local taxes, some state aid, and income from school lands. Some aid comes from federal grants such as the Smith-Hughes act for vocational training. Special schools provide instruction for the physically handicapped, for the socially maladjusted, for those wishing vocational training and for the exceptionally gifted. Educational facilities are made available for children in hospitals; teachers visit homes where children are bedridden; and some instruction is carried on by television. The city system also includes the Chicago Teachers college, with its three branches, and six junior colleges.

Besides elementary and high schools supported by public funds there are many private and parochial schools, of which Roman Catholic (approximately 400 elementary schools and 90 high schools) and Lutheran (approximately 120 elementary schools and 3 high schools) are the most numerous.

The University of Chicago is described in a separate article (see CHICAGO, THE UNIVERSITY OF). Northwestern university, established in 1851 under the auspices of the Methodist Episcopal Church, maintains a campus on the shore of Lake Michigan in Evanston, north of Chicago, and professional and evening schools in Chicago. De Paul university (chartered in 1907), Loyola university (1909) and Mundelein college for women (1929) are the principal Catholic institutions of higher education in the city. Roosevelt university was founded in 1945 and in less than a decade had an enrollment of more than 4,000 students. In 1940 the Lewis institute and the Armour Institute of Technology were consolidated as the Illinois Institute of Technology (I.I.T.). The Institute of Design, founded as the New Bauhaus by Laszlo Moholy-Nagy in 1937, became a part of the design division of I.I.T. in 1956. The University of Illinois *(see* ILLINOIS: *Education)* has professional schools in Chicago and an undergraduate branch. George Williams college (founded 1890) and North Park college (1891) also offer college courses. Theological schools include the Presbyterian Theological seminary, the Chicago seminary (Congregational, opened in 1858, and including German, Danish-Norwegian and Swedish institutes); the Seabury-Western Theological seminary and Garrett Biblical Institute, both in Evanston; a German Lutheran Theological seminary and an Evangelical Lutheran Theological seminary.

Chicago's medical centres offer outstanding educational as well as research and treatment facilities. On the south side are Michael Reese and Mercy hospitals, The University of Chicago medical group and the Argonne Cancer Research hospital. On the near north side are the Northwestern university medical school and, nearby, Passavant and Wesley Memorial hospitals and a Veterans administration research hospital. The West Side Medical centre was first proposed in 1917; in 1941 the state legislature set up the Medical Centre district. Associated in this major concentration of medical resources are Cook County hospital, the largest in the world and internationally known for medical training; the University of Illinois-Chicago Research and Educational hospitals; Presbyterian-St. Luke's hospital; and other institutions.

Libraries and Museums. — When the great fire occurred in 1871 Chicago had no free tax-supported library, although several private libraries were semipublic in practice. The nucleus of the Chicago public library, established the year after the fire, was a collection of books from England, Ireland, Germany, France and other countries to which many contemporary literary and other celebrities made contributions; the library was opened in 1874. There are more than 2,000,000 volumes in the main library. There are about 40 independent branch libraries throughout the city. The John Crerar library, endowed in 1889 by John Crerar, manufacturer of railway supplies, has more than 700,000 volumes on physical, natural and medical sciences and other applications. The Newberry library, endowed in 1885 by a bequest of Walter L. Nenberry and opened in 1887, contains more than 650,000 volumes, chiefly in literature, history, music and genealogy. The Burnham Library of Architecture and the Ryerson library devoted to the fine arts are located in the Art Institute of Chicago. The Municipal library in the city hall has gathered data on city government; the Chicago Law institute is a law library located in the County building. The Chicago Historical Society library, established in 1856, houses a rich collection of Chicago history. In 1949 the Midwest Inter-Library centre was organized to provide participating midwestern universities with research materials. Other libraries include those of the universities and various trade and professional organizations with headquarters in Chicago, as well as libraries connected with several museums.

Among important museums are the Museum of Science and Industry, opened in 1933; the John G. Shedd aquarium, opened in 1929; the Chicago Natural History museum, founded in 1893 as the Columbian museum; and the Adler Planetarium and Astronomical museum, with a collection of antique astronomical instruments.

Newspapers.—About 600 periodicals and newspapers are published in Chicago. The Chicago *Tribune,* established in 1847, is the city's oldest English-language newspaper. The *Sun,* founded in 1941, merged with the *Times* in 1947 as the *Sun-Times*. The

afternoon papers are the *Daily News* and *Chicago's American* (formerly the *Herald-American*). In 1956 the Tribune company bought the *Herald-American,* formerly a Hearst newspaper, and in Jan. 1959 Field Enterprises, Inc., publisher of the *Sun-Times,* purchased the *Daily News,* which began continuous publication the first of the year 1876. The *Defender,* founded in 1905, is one of the country's largest Negro newspapers. A large number of foreign-language dailies serve many readers.

Art and Music.—The first important organization to study art history and methods in Chicago was the Chicago Academy of Design (1867). In 1882 the Chicago Academy of Fine Arts (established in 1879) became the Art Institute of Chicago. Under the administration of its first president, Charles L. Hutchinson (1882–1924), the Art institute built its museum and school on the lake front and assembled under its roof outstanding collections, including those of private citizens. Widely acclaimed are the institute's collections of 19th-century French paintings, Chinese bronzes and Japanese prints. The institute's art school offers training in painting, drawing, sculpture, commercial illustrating, decorative design and architecture. The Arts club of Chicago, which opened Nov. 11, 1918, was for a time a rival, bringing to Chicago the art of 20th-century European moderns But the Art institute gradually accepted the innovators and finally absorbed the functions of the Arts club.

As early as 1833 monthly concerts were given in Chicago, and in 1835 a Chicago Harmonic society was organized. In 1857 George P. Upton started the Mendelssohn society, which later became the Apollo club, still in existence.

On Oct. 16, 1891, after several visits to the city with touring orchestras, Theodore Thomas (*q.v.*) raised his baton over a newly created and permanent Chicago Symphony orchestra and inaugurated a golden age of symphonic music in the city. Upon Thomas' death in 1905. Frederick Stock (*q.v.*) succeeded to the position of conductor. holding it. except briefly during World War I, until his death in 1942. Stock in turn was succeeded by Désiré Defauw (1943–47), Artur Rodzinski (1947–48) and Rafael Kubelik (1950–53). Fritz Reiner became conductor in 1953.

Until 1910 the city relied on touring companies to provide opera, but in that year Chicano and New York businessmen organized the Chicago Grand Opera company and eventually brought in Mary Garden (*q.v.*) as not only its prima donna but its artistic manager as well. Upon withdrawal of the New York supporters. the company was reorganized as the Chicago Opera association. In 1921 a reorganization again occurred and the name was changed to the Civic Opera company. The Lyric Opera company was organized in 1954. Althcugh Chicago enjoyed its first season of opera as early as 1858–59, opera companies have failed to sustain a continuous existence comparable with that of the Chicago Symphony orchestra.

There are many minor orchestras and opera companies and scores of singing societies. Open-air concerts are offered in Grant park throughout the summer in a program that is a successor of similar events scheduled in the 1930s under the auspices of the Works Progress administration. Both opera and symphony organizations appear in concerts during the summer at Ravinia park, 25 mi. N. of Chicago. Many schools of music, including the American Conservatory of Music, the Cosmopolitan School of Music and the Chicago musical college are 'located in the city.

PARKS

The city's park system covers an area of approximately 7.550 ac. Popular agitation for a park system began in 1835, two years after Chicago was incorporated as a town, when an unsuccessful effort was made to gain possession of the Ft. Dearborn reservation for a public square. In the 1840s only small plots adorned with shrubs and grass fringed the scrubby and unkempt streets. Concern over the abrasion of the shores along Lake Michigan came to a climax in 1851 when the state legislature forbade the sale of block 39 of the original town, reserved it for a public square and invested the city's council with the right to grade and improve it. Various attempts to establish parks in the different divisions of the city failed. In 1861, 80 ac. in the north division of the city were laid out and called La Frambois park, later becoming a part of Lincoln park. Lake park (later named Grant park) along the lake shore was acquired in 1864, and five years later the state legislature enacted legislation which led to the establishment of a true system of parks. In 1870 about 1.887 ac. were devoted to parks. Chicago then acquired the name of the Garden city, still emblazoned on the municipal coat of arms.

Lincoln park (1.119 ac.), near the lake shore on the north side, was much enlarged by an addition reclaimed from the lake. It has fine monuments, a conservatory. a zoological garden and the collections of the Academy of Sciences. Jackson and Washington parks are the most important parks on the south side. Jackson park (543 ac), the main site of the World's Columbian exposition of 1893, lying along the shores of Lake Michigan, is joined to Washington park (371 ac.) by a mile-long boulevard known since the Columbian exposition as the Midway Plaisance. Along the Midway are the buildings of The University of Chicago. Grant park occupies 303 ac. of land along the lake near the downtown district; in it are located the Art institute, the Adler planetarium, the Shedd aquarium, the Chicago Natural History museum. Soldier field, with a capacity of more than 100,000, and McCormick Place, an exposition centre. South of Grant park is Burnham park (598 ac.). Northerly Island, in the lake off Grant park, has an area of 91 ac. On the west side of the city are three large parks—Douglas (182 ac.), Garfield (187 ac.) and Humboldt (206 ac.). which has a remarkable rose garden—and on the extreme south side several others, including Calumet. by the lakeside, and Marquette.

In 1933 the state legislature passed an act consolidating the 22 park systems. Under the act, approved by popular referendum, the Chicago Park district became operative in April 1934. A board of five commissioners is appointed by the mayor and confirmed by the city council but not subject to council control. A functional merger of the city of Chicago and the Chicago Park district occurred in 1957; control of all parks and playgrounds was placed under the park district commissioners. the city assuming the obligation of maintenance and policing of all boulevards.

In addition to the city park system, the Cook county forest preserves, a broad belt of wooded lands (38,000 ac.) acquired over many years, extend north, south and west of the city.

CHICAGO, THE UNIVERSITY OF, an institution of higher learning in Chicago, Ill., was founded in 1891 and opened on Oct. 1, 1892. It is privately supported and coeducational. Though originally established as a Baptist university, requirements for Baptist membership on the board of trustees were progressively relaxed by the Northern Baptist convention, and the university became nondenominational.

The university is approximately 8 mi. S. of the downtown section of Chicago. with frontage for three-fourths of a mile on both sides of the Midway Plaisance, uhich links Jackson and Washington parks. The campus of more than 100 ac. has over 100 buildings, most of which are collegiate Gothic in architectural style and grouped in quadrangles. Newer buildings, however, departed from the Gothic style, though general uniformity was maintained with limestone exteriors. Growth of the university in facilities, program and influence was rapid, largely because of the combination of John D. Rockefeller, its founder, who provided liberal and consistent financial support, and William Rainey Harper. who served as the first president until Jan. 10, 1906.

Harper had original educational ideas and enthusiasm, and he gathered a distinguished faculty, including nine presidents of colleges and universities. From the start, therefore, the university was eminent in research and advanced study.

Although the university gained an international reputation as a centre of research, it also was continuously concerned with the development of undergraduate education. Harper established junior and senior college divisions, of two years each, which prevailed until 1931, when the Chicago plan was instituted. This program was extended in 1941 to provide a four-year liberal education curriculum, beginning at the end of the sophomore year of high school. Under that plan, yearlong integrated courses covering the broad fields of knowledge were developed. Students met the requirements for the bachelor's degree by passing, either through comprehensive examinations or placement tests taken at the beginning of their residence, 14 required courses. At the beginning of the academic year 1954 the plan was modified to relocate undergraduate education primarily at the end of high school, and to provide approximately half of the requirements in specialized fields. Early admission was continued, as was the four-year program entirely in liberal arts for students so electing, but the large majority of entering students were high-school graduates. Many of the innovations of the Chicago plan, including the integrated courses, early admission of qualified students and renewed attention to liberal education, had a wide influence on collegiate programs of the country.

An administrative reorganization also was made in 1930, establishing largely the present university organization: the College; four divisions—the physical. biological and social sciences and the humanities; the professional schools—business, divinity. education, law, library science, medicine and social service administration; the library; the press; extension (University college for adult education; and home study, for correspondence work). This grouping includes the Oriental institute, engaged in research on earlier civilizations; Yerkes observatory, Williams Bay, Wis. (whose astronomers and those of the University of Texas have joint faculty appointments and staff Texas' McDonald observatory, Mt. Locke. Tex.); the laboratory schools (nursery, elementary and high school); an orthogenic school; the University clinics; and two basic research organizations, established in 1945, the Institute for Study of Metals and the Enrico Fermi Institute for Nuclear Studies (named in honour of Fermi in 1955). Much of the research and advanced study is conducted through interdivisional and interdepartmental committees. The University of Chicago Press, established in 1892, publishes many learned journals and an average of 80 books a year.

In addition to the building during Harper's administration, there was extensive construction during the period 1924–32, which trebled floor space. Principal units built after World War II were new hospitals, the administration building, the accelerator building (housing a 450,000,000-ev synchrocyclotron) and laboratories for the new institutes in nuclear energy and metals. Another period of extensive construction began in the mid-1950s.

Harper, a professor of biblical literature at Yale university before he became the university's first president, was succeeded in 1907 by Harry Pratt Judson. Judson had served as dean of the faculty under Harper and was the first head of the political science department. He consolidated and co-ordinated the university, following its rapid development and expansion under Harper. Judson retired in 1923 and was succeeded by Ernest DeWitt Burton, a New Testament scholar who was also a member of the original faculty. In his two-year administration, terminated by his death, Burton displayed remarkable qualities of enthusiasm and leadership, initiating a program of expansion and implementing it with the university's first public campaign for funds, an effort that produced $9,500,000 in gifts. Max Mason, a mathematical physicist, succeeded Burton in 1925, and on July 1, 1929, Robert M. Hutchins (*q.v.*), dean of the law school of Yale university, became the fifth president at the age of 30. Under Hutchins the Chicago plan for undergraduate education, mentioned previously, was introduced and the faculties were reorganized. Hutchins' title was changed by trustee action to that of chancellor in 1945. He resigned on Dec. 19. 1950 (effective June 30, 1951).

Lawrence A. Kimpton, professor of philosophy and vice-president in charge of development of the university, was elected chancellor April 12, 1951. He announced his resignation hfarch 30, 1960, after reorienting the college, raising about $100,000.000 in new funds, initiating a construction program which added 15 major new buildings, and leading successful efforts to protect the environment of the university from deterioration with programs of clearance and rehabilitation. After Kimpton's resignation became effective Sept. 8, 1960, R. Wendell Harrison, vice-president of the university. dean of faculties and professor of microbiology. served as chancellor. In Jan. 1961 George W. Beadle (*q.v.*), 1958 Nobel prize winner in medicine and physiology and former professor and chairman of the division of biology at the California Institute of Technology, became chancellor. Later that same year a reorganization of the university administration eliminated the office of chancellor and Beadle was named president of the university.

For the university's association with *Encyclopædia Britannica*, *see* ENCYCLOPAEDIA; *see* also references under "Chicago, The University of," in the Index volume. (W. V. M.)

CHICAGO HEIGHTS, an industrial city of Cook county, Ill., U.S., 27 mi. S. of the Chicago loop. The elevation averages 95 ft. above the surrounding area, hence the name. The site was the intersection of the Hubbard trail, from Vincennes to Fort Dearborn, and the Sauk trail, used by Indians going from their hunting grounds to the fur post and garrison at Detroit; the Sauk trail later became an important route to the west. The settlement was known as Thorn Grove in the 1830s; in 1849 it was renamed Bloom by German settlers in honour of Robert Bluehm, a German patriot executed at Vienna in 1848. In 1890 the Chicago Heights Land association induced manufacturers to establish plants there, and in 1901 the city of Chicago Heights was incorporated It was the earliest and for a time the most important of the steel-making communities in the Chicago district. Other industrial plants manufacture chemicals, glass specialties, roofing, textiles, school supplies, fertilizers and paints. For comparative population figures *see* table in ILLINOIS: *Population.* (D. A. PR)

CHICAGO SANITARY AND SHIP CANAL, in the Cnited States. an engineering development of special importance to the city of Chicago and surrounding districts, was first opened in 1900. Before the construction of the canal Chicago discharged sewerage through the Chicago river into Lake Michigan, which was also the source of the water supply. A canal channel was dug by which the Chicago was connected with the Des Plaines river (which flows southwest to the Illinois river and thence to the Mississippi river) and at the same time the Row in the Chicago river was reversed from east to west. The canal is 34 mi. long, 160 ft. wide and 24 ft. in depth. Another phase of the project, completed in 1933, mas the creation of an all-water route with a minimum depth of 9 ft. between the Great Lakes and the Gulf of Mexico.

CHICHA, a freshly fermented, unfiltered liquor brewed from maize (Indian corn) by many Indian groups of Latin America. It also has been known as *cangüi* among the Avas and Chiriguanos of Bolivia, *asua* among the Quechua-speaking groups of Ecuador and *tesvino* or *texguino* among Nahuatl-speaking tribes of Mexico.

Chicha has a cloudy appearance and an aroma and taste resembling beer, but lacks the bitter undertone and character of the missing hops. One of a number of fermented drinks known to Latin-American Indians, it is not made commercially, but is a popular home brew made and consumed in modern times much as in pre-Columbian days, particularly along the altiplano or high levels of the Andean range from Colombia to southern Chile, as well as in Mexico and Central America. Used by the Indians as both a social and ceremonial beverage, it is ritually dedicated to the earth to promote an abundant maize crop and is drunk at celebrations of births, marriages and other important occasions.

Two basic methods of production are known. In the first, the corn is allowed to sprout, becoming a corn malt containing the enzyme diastase. After it is ground into meal, water is added and the mixture cooked; then the pot is covered and set aside for a

few days to permit fermentation. When bubbling subsides, fermentation is completed and the liquor is potable. In the more remote areas, unmalted corn is chewed and spit into a pot, the salivary enzyme ptyalin performing the starch-to-sugar conversion function of the diastase of malt. The remainder of the process is the same. *Chicha* keeps for some time in the cold climate of the high Andes, but at warmer temperatures spoils in a few days.

See W. La Barre, "Native American Beers," *Amer. Anthrop.*, 40:224–234 (1938); J. M. Cooper, "Stimulants and Narcotics," in Julian H. Steward (ed), *Handbook of South American Indians,* 5:525–558 (1949), with bibliography. (H. J. GN.)

CHICHELE (CHICHELEY), **HENRY** (1364–1443), archbishop of Canterbury, cofounder with Henry VI of All Souls college, Oxford, was born at Higham Ferrers, Northamptonshire, and educated at Winchester and Oxford. He served as advocate in the court of arches and was ordained in 1396. Chichele was the English envoy to Innocent VII in 1405 and to Gregory X in 1407 concerning the great papal schism. He negotiated peace with France in 1406. In 1409 he represented the English bishops at the council of Pisa, which elected a third papal claimant. In 1410, in an important test case before king's bench, papal decrees were declared not to supersede English law and Chichele had to resign his numerous minor benefices. In the second phase of the Hundred Years' War, he fought against the Armagnacs at Paris and helped to negotiate the peace of 1413. In 1414 he was consecrated archbishop of Canterbury. The charges in Hall's *Chronicle* and in Shakespeare's *Henry* V that Chichele agitated for war nith France in 1414 to avert attention from the disendowment of the church are ill-founded. He suppressed the Lollards but upheld the independence of the national church against papal claims. In 1419 he assisted in the capture of Rouen and negotiated the marriage of Henry V to Katherine of France. A patron of education, he established a burse for poor students and two colleges at Oxford (in addition to All Souls, another, the ancestor of St. John's college) and a college at Higham Ferrers. Chichele died on April 12, 1443, and was buried at Canterbury.

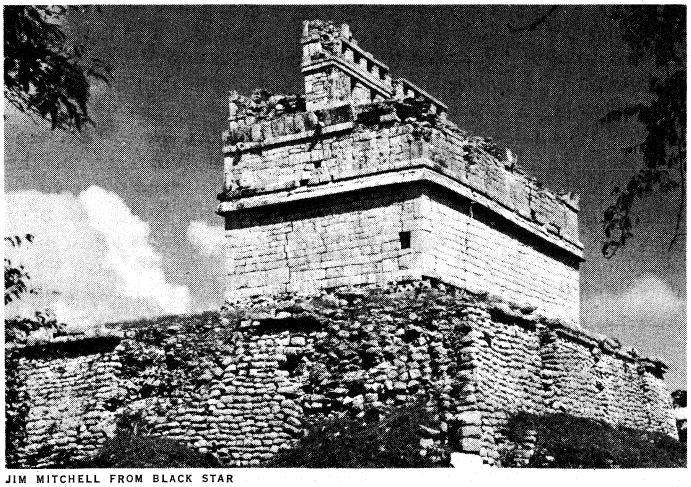
CHICHÉN-ITZÁ, the ruins of an ancient Mayan city of that name, in the south-central part of the state of Yucatbn, Mex, near the boundary of Quintana Roo, about 20° 30' N. lat. and 88° 30' W long. The dry, waterless region around Chichén-Itzá is of limestone formation, with only an underground water supply, available in but a few places called *cenotes* by the Mayans, where the limestone cap has fallen into the caves through which the water flows. Two large *cenotes* determined the location of the city and gave it its distinctive name, ***Chi,*** which in Mayan means "mouths," *chen,* "wells," and *Itzá,* the name of the particular Mayan tribe or group that first settled there, the whole meaning the "Mouths of the Wells of the Itzá."

Founded not later than A.D. 530, the settlement for about the first century constituted but a frontier post of a Mayan civilization, the Old Empire, which at that time was flourishing in the much greater centres to the southnard — Copin, Tikal, Quiriguá, Palenque (*q.v.*) and a dozen other equally important cities. When about a century later these great flourishing southern cities were finally abandoned, Chichén-Itzá was also temporarily abandoned, AD. 668, and the Itzá trekked westward across Yucatán to a new capital, Chakanputun, south of the modern Campeche. Chakanputun was burned in A D 944 and the "Holy Men of the Itzá" led their people back to Chichén-Itzá, where in A D 964 they re-established their household gods and rebuilt their shrines and altars. It was the period of the founding of the New Empire, with Uxmal (q v), Mayapán and a group of satellite cities sharing with Chichén-Itzá a superb renaissance of Mayan culture and power. In AD. 1004 the three greater cities formed an alliance, the League of Mayapán, and the calm and order and prosperity that followed gave rise to a golden age of Mayan religion, science and art, with majestic temples and superb sculptures scattered about the land. At Chichén most of the middle section of the city lying south and west of the Thousand Columns was built at this time, graced by the Akab'tzib (House of the Dark Writing). the Chichanchob (Red House), the House of the Deer, and parts of the Monjas (Monastery).

In 1201 the League of Mayapán was disrupted by an attack of the Mayapán people upon Chichén-Itzá because of conspiracies against the league by Chac Xib Chac (The Very Red Man), the Itzan ruler With the aid of Toltec and Aztec allies from Central Mexico the Mayapán people conquered the Itzans. Henceforth the city was held in thrall by the Toltec-Aztec allies of the Mayapin group These Toltec-Aztec conquerors brought with them the worship of the fair, golden-haired god, Quetzalcóatl, the "Feathered Serpent." who became "Kukulcán," the Itzan equivalent. During this period Chichén-Itzá rose to heights of prosperity, prominence and architectural development surpassing anything in its earlier history, and highly adorned temples, sanctuaries and shrines rose. the principal temple, the so-called Castillo, covering an acre of ground and rising 100 ft above the plain, the Thousand Columns enclosing a central plaza of more than five acres with pyramid temples. colonnaded halls, sunken courts, terraces and theatres; the Tlachtli-ground or Ball Court; the Temple of the Jaguars; the Temple of the Tables; the Astronomical observatory; the High Priest's grave; and a host of others.

The two *cenotes* upon which the city depended for its very life constituted the religious as well as the economic centre of the city and its culture. Young Itzan maidens were sacrificed to the gods of the wells, as were all kinds of valuables, in gruesome spectacles that drew thousands to share in the ceremonies and the rites and gave to the city its holy character. The natural setting of the wells, the grandeur of the temples built beside them, the austerity and dignity of the rites. all contributed to the lure and made Chichén-Itzi the Mecca of the Mayan world for almost two and one-half centuries until about the middle of the 15th century when it was rather suddenly and finally abandoned, only a few stragglers making their homes there and doing homage to the old gods. *See* also MAYA INDIANS.

See S. G. Morley, "Chichén-Itzá, an Ancient American Mecca," *Natl. Geog. Mag.,* vol. xlvii, no. 1, pp. 63–95 (Jan. 1925). (W. E. E.)



JIM MITCHELL FROM BLACK STAR

CHICHANCHOB (RED HOUSE), CHICHÉN-ITZÁ, MEX.; ABOUT A.D. 1004

CHICHERIN, GEORGI VASILIEVICH (1872–1936), Soviet statesman who conducted the foreign policy of the Russian Soviet Federated Socialist Republic from 1918 and of the U.S.S.R. from 1922 to 1928, the son of an official in the Russian ministry for foreign affairs. was born in Tambov *oblast.* He was educated at a Russian higher school and at St. Petersburg university and entered the diplomatic service in the archives department of the foreign ministry. Having been drawn into the revolutionary movement, he resigned from the diplomatic service in 1904, renouncing his estates. and went to Berlin, where he followed closely the German Social Democratic movement. He was at first attached to the Russian Socialist Revolutionary party, but later joined the Social Democratic party and until 1918 remained a member of its Menshevik wing. He was prevented by illness from taking part in the revolution of 1905. He spent 12 years in revolutionary activities

in London, Paris and Berlin, being elected secretary of the central bureau of the Russian Social Democratic party organizations abroad in 1907. In the same year he was arrested in Berlin for the possession of a false passport and banished from Prussia.

During World War I he assisted the pacifist Labour elements in Great Britain and organized relief for Russian political refugees —philanthropic work which had a revolutionary aspect in maintaining contact with Russian revolutionaries. After the Bolshevik revolution in Nov. 1917, when Russia, having opened peace negotiations with the Central Powers, was no longer considered an ally, Chicherin was imprisoned in Brixton jail on the ground of "enemy associations." On Jan. 3, 1918, he was exchanged for Sir George Buchanan by the Soviet government, returned to Russia and joined the Bolsheviks. Trotski having resigned the post of people's commissar for foreign affairs in March 1918, Chicherin was appointed to it in May. In 1922 he headed the Soviet delegation to the conference of Genoa (*q.v.*) of which the unexpected result mas the treaty of Rapallo (*q.v.*) between Soviet Russia and Germany. He thereafter conducted Soviet foreign policy till late in 1928, when illness began to prevent him from carrying on his duties. Chicherin finally retired in July 1930 and died in Moscow on July 7, 1936.

CHICHESTER, a city and municipal borough in the Chichester parliamentary division of Sussex, Eng., and county town of the administrative county of West Sussex, is 62 mi. S.W. of London by road. Pop. (1961) 20,118. It lies in the coastal plain at the foot of a spur of the South Downs, a mile from the head of Chichester harbour, an inlet of the English channel and a noted yachting centre. Chichester is probably on the site of Noviomagus or Regnum, the capital of the realm of Cogidumnus, native ruling prince of the Regnenses, who enjoyed legatine authority from imperial Rome.

On Roman roads to London and Winchester, Chichester (Cisseceastre of the Saxons in 895, Cicestre in Domesday Book) remained of considerable importance under the South Saxon kings and it had a mint in about 928. A charter of Henry I mentions the borough, but the earliest extant charter is that of Stephen, about 1135, confirming the rights of the borough and guild merchant as held in the time of William I. This grant shows the Chichester guild merchant to be possibly the oldest in England. This was confirmed by Henry II in 1155. By Edward II's charter, the customs of wool, hides and skins were reserved to the king. Edward III directed that the Sussex county court should be held at Chichester. James II in 1685 granted the charter now in force. Chichester returned two members to parliament from 1295 to 1867, and one from then until 1886. Throughout the middle ages the town was commercially important, and a wool staple was probably established as early as 1314. Chichester had five fairs in 1889; all but Sloe fair (granted by Henry I, about 1107–08) were abolished. Thomas Fuller mentions the Wednesday market as being famous for corn (grain), while William Camden speaks of the Saturday market as the greatest for fish in the county.

The cathedral church of the Holy Trinity was founded toward the close of the 11th century, after the see was transferred to Chichester from Selsey in 1075. It was dedicated in 1108; Bishop Ralph Luffa (1091–1123) was the first great builder, followed by Seffrid II (1180–1204), but disastrous fires led to further building throughout the 13th century. Norman work appears in the nave (arcade and triforium), choir (arcade) and elsewhere; but there is much beautiful Early English work. as in the ambulatory. The nave is remarkable in having continuous chapels parallel with the north and south aisles, thus giving the effect of double aisles. The church is unique among English cathedrals for its detached campanile, a massive Perpendicular structure with an octagonal top story. The original 14th-century central tower and spire fell in 1861, but were skilfully rebuilt in their former style; the spire is 277 ft. high. The Lady chapel, the cloisters of irregular plan, the library and the 12th-century stone carvings are among the many features of interest. The cathedral is 393 ft. long within, 131 ft. across the transepts and 90 ft. across the nave with its aisles and chapels. The bishop's palace nearby retains its Early English chapel. The diocese includes all Sussex except for a few parishes, with small portions of Kent and Surrey.

At the junction of the four main streets of the city, which preserves its Roman plan, stands an octagonal market cross built and given by Bishop Edward Story in 1501, one of the finest of its kind in the country. St. Mary's hospital was founded in the 12th century, but the existing buildings are of late 13th- and early 14th-century date; its use as an almshouse is maintained. Other ancient buildings are St. Olave's church; the 13th-century guildhall, formerly the choir of the Gray Friars' church; the Canon gate leading into the cathedral close; and the Vicars' hall. The city retains a great part of its ancient walls, which have a circuit of about 1½ mi. and were built about A.D. 200. There is a theological college and a women teachers' training college. The county hall was built in 1936. The city has a large cattle market and a considerable agricultural trade. but no outstanding industry. It is celebrated for its wealth of Georgian architecture. A canal connects with Chichester harbour. Goodwood Park. 3 mi. N.E. is the scene of the fashionable race meet held each July.

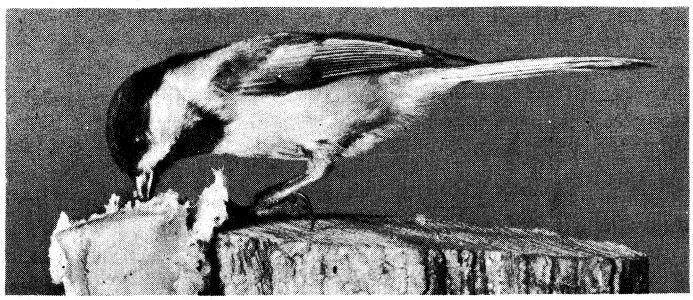
CHICHESTER OF BELFAST, ARTHUR CHICHESTER, BARON (1563–1625), English lord deputy of Ireland who decisively influenced English policy there, in particular in planning the colonization of Ulster, was born in May 1563 at Raleigh, Devonshire. Like many younger sons of Devonshire gentry he sought his fortune overseas, serving in the armed forces at Cádiz (1596), uhere he was knighted, and in the Netherlands. He went to Ireland in 1599, and took a leading role in the successful campaigns in Ulster against Hugh O'Neill. When the war ended (1603) he was granted large estates in Belfast and Carrickfergus.

His appointment as lord deputy in 1604 was unexpected, and his two chief incursions into general politics suggest that he brought to the problems of government more the direct approach of the soldier than the political awareness of the statesman. In 1605 his attempt to reverse the earlier policy of religious toleration by banishing priests and imprisoning recusants brought him into difficulties uith the Roman Catholic gentry, and the English privy council was forced to intervene in 1606. Chichester again followed an uncompromising policy when he tried to crush all opposition in the forthcoming parliament of 1613 by creating 40 government boroughs whose members would outnumber those of the 39 Catholic boroughs.

But Chichester is chiefly remembered for his role in the plantation of Ulster (see IRELAND: History). His religious policy and the declaration of 1605 against the quasi-feudal authority of the Gaelic lords over their tenants were partly responsible for the flight of the Ulster earls of Tyrone and Tyrconnell (1607). This, together with Sir Cahir O'Dogherty's rebellion of 1608, led to Chichester's plans for confiscating the land of the six Ulster counties. His scheme was more moderate than the government's final plan, but like other aspects of his policy it yielded to immediate temptation without due consideration of the ultimate consequences. Chichester himself acquired a vast estate in Inishowen, and, in his own words. he preferred "to labour with his hands in the plantation of Ulster than to dance or play in that of Virginia." He was raised to the peerage in 1613, and retired in 1615 with the honorary post of lord high treasurer. He was sent on an embassy to the Palatinate by James I in 1622, and died in London on Feb. 19, 1625.

See T. W. Moody, *The Londonderry Plantation, 1609-41* (1939); R. D. Edwards (ed.), "Letter-Book of Sir Arthur Chichester," *Analecta Hibernica,* no. viii (1938). (H. F. KE.)

CHICKADEE, common American name (derived from the call note) for a plump, black-throated, black-capped bird (*Parus atricapillus*) of the northern states and Canada; in England it is called the willow tit. The brown-capped chickadee (P. hudsonicus) is resident in Canada and northern New England. The smaller Carolina chickadee (P. carolinensis) breeds in the southeastern states. The mountain chickadee (P. gambeli) is resident in the Rocky mountains and westward; it has a white stripe



JOHN H. GERARD

BLACK-CAPPED CHICKADEE. THE ENGLISH WILLOW TIT (PARUS ATRICAPILLUS)

over the eye. The Alaska chickadee (P. *cinctus alascensis*) is also found in eastern Siberia. The chestnut-backed chickadee (P. rufescens) lives on mountains from Alaska to Montana and California. Others are found in Mexico. All are closely allied with the old world titmice. See TITMOUSE. (G. F. Ss.)

CHICKAMAUGA, BATTLE OF, Sept. 19–20, 1863, during the American Civil War, was a vital part of the maneuvering and fighting to control the important railroad centre at nearby Chattanooga. As Gen. William S. Rosecrans (*q.v.*), commanding the Army of the Cumberland moved against Chattanooga, Gen. *Braxton Bragg* (*q.v.*), to avoid being surrounded in the city, withdrew his Army of Tennessee to La Fayette about 20 mi. S E. in Georgia. There he could await reinforcements and possibly, if Rosecrans chose to follow him, defeat the Union army in detail as it was widely dispersed among the several routes through the intervening hills and low mountains. Rosecrans, however, succeeded in moving his army without serious interference and established headquarters at Chickamauga about 12 mi. S.E. of Chattanooga. Meanwhile Bragg was collecting reinforcements and was preparing to give battle. The Confederate high command recognized the importance of stopping this Federal advance and sent Gen. *James Longstreet* (*q.v.*) from Lee's Army of Northern Virginia to *Bragg's* assistance. On Sept. 9 the first of *Longstreet's* men left by a roundabout route through the Carolinas to Atlanta, and thence up the Western Atlantic railroad to the scene of the impending battle. The first of them arrived barely in time to play what may well have been the decisive role in the battle.

The conflict raged for two days along Chickamauga creek over a very small area, not quite five miles from east to west and even less from north to south. Most of the area was in virgin forest badly tangled with undergrowth that made it difficult to distinguish between friend and foe. Both commanders soon lost anything like general direction of the fighting. On the second day, Longstreet, who had arrived the night before, was placed in command of the Confederate right wing. He found a hole in the extended Federal line, poured his men through quickly and moved to crush the flanks on either side. Rosecrans, assuming that his left ming had also fallen, retreated pell-mell to Rossville and on to Chattanooga. But Gen. George H. Thomas (*q.v.*), the "Rock of Chickamauga," soon to supersede Rosecrans in command. skillfully organized the defenses and withstood the attack until the reserve corps came to his assistance and made possible an orderly withdrawal to Chattanooga. Some 120,000 men about equally divided between the Blue and the Gray participated. Casualties totaled 34.000, about 18,000 of them Confederate, making Chickamauga one of the bloodiest battles of the war. Bragg did not choose to follow up this decisive victory, and two months later in the fighting around Chattanooga (see CHATTANOOGA, BATTLE OF) it mas completely nullified. An Act of Congress in 1890 created the Chickamauga and Chattanooga National Military park. comprising 10 sq.mi. of the Chickamauga battlefield and some detached areas important in the succeeding Chattanooga campaign. See also AMERICAN CIVIL WAR.

For an extended nontechnical account *see* Gilbert E. Govan and J. W. Livingood, *The Chattanooga Country, 1540–1951 (1952).* (C. W. TE.)

CHICKASAW, an American Indian tribe of Muskogean linguistic stock residing originally in northern Mississippi and Alabama, and later forming one of the "five civilized tribes" (*q.v.*) after removal to Oklahoma. The Chickasaw were an offshoot of the Choctaw (*q.v.*) and closely related in language and culture. First seen by De Soto in 1540–41, they became involved in the power struggles between the British and French in the 18th century and suffered considerable losses. At the time of removal to Oklahoma between 1822 and 1838 they numbered about 5,000; at mid-20th century the population was about 9,000, including many persons of mixed blood. The Chickasaw were an agricultural and hunting people living in scattered "towns" built around a ceremonial square. They were organized in a dual division, with matrilineal exogamous clans and a Crow-type kinship system (see KINSHIP TERMINOLOGY), the dual divisions being associated with war and peace. respectively, and forming opposing sides in games and ceremonies. The supreme deity was associated with the sky, sun and fire; and a harvest ceremony, similar to the Creek busk, was performed annually. *See* also MUSKOGEAN INDIANS.

See J. R. Swanton, "Indians of the Southeastern United States," Bureau of American Ethnology, Bull. 137 (1946). (R. R. B.)

CHICKEN, a name generally applied to the most widely domesticated barnyard fowl and its many varieties, originally descended from the wild red jungle fowl, *Gallus gallus*, of southeastern Asia (*see* FOWL). The females — mature hens and younger pullets—are raised for their edible eggs and meat; the males—variously called cocks, stags, roosters or chanticleers — are also raised for meat. *See* POULTRY AND POULTRY FARMING.

CHICKEN POX or varicella, a contagious disease characterized by an eruption of vesicles in the skin. The disease usually occurs in epidemics, and the patients are generally between two and six years old. The incubation period is at least two weeks; there are practically no premonitory symptoms, though slight fever for about 24 hours may precede the eruption. A number of raised red papules appear on the back or chest; in from 12 to 24 hours these develop into tense vesicles filled with a clear fluid, which in another 36 hours or so becomes opalescent. During the fourth day these vesicles shrivel up and the scabs fall off, leaving, as a rule, no scar. Fresh spots appear during the first three days, so that at the end of that time they can be seen in all stages of growth and decay. The eruption is most marked on areas covered by clothing, but it also occurs on the face and limbs and on the mucous membrane of the mouth and palate. The temperature rarely rises above 102° F. The disease runs a favourable course in most cases and aftereffects are rare. The patient should be isolated. The diet should be light, and the patient should be prevented from scratching the spots, which would lead to ulceration and scarring. After the first few days there is no necessity to confine the patient to bed. In the large majority of cases it is easy to distinguish the disease from smallpox but sometimes it is difficult. The chief points in the differential diagnosis are as follows: (1) In chicken pox the rash is chiefly on the trunk, and less on the limbs and face; (2) some of the vesicles are oval, whereas in smallpox they are always hemispherical. They have not at the outset the hard shotty feeling of the more virulent disease; (3) the vesicles attain their full growth within 12 to 24 hours; (4) the rash appears "in crops"; (5) there is no premonitory period. The disease is caused by a virus.

A curious and imperfectly understood relationship exists between chicken pox and herpes zoster (shingles). Contact with chicken pox gives rise in some individuals to herpes zoster, while the reverse may also occur though to a lesser extent. There also appears to be a certain degree of cross-immunity between the two diseases.

CHICK-PEA is a plant belonging to the family Leguminosae. It is cultivated as a porridge food in southern Europe, in Egypt and western Asia. *See* GRAM.

CHICKWEED, any low annual or perennial herb of the genus Stellaria (family Caryophyllaceae, *q.v.*), called also starwort, tongue grass and winter weed. All are Eurasian but naturalized throughout North America and other regions. They have weak, reclining, much-branched stems, oval or ovate leaves and small white flouers. In mild climates they are found blooming

throughout the year; in colder regions, as in the northeastern U.S., they withstand severe frosts and may be discovered blossoming under light snow in midwinter. Various species of Arenaria, *Paronychia* and *Cerastium* are known as chickweeds but the latter is better known as the mouse-ear chickweed. Some of them are cosmopolitan. Most plants called chickweed, though abundant as weeds, are not readily eradicated by cultivation, especially the perennials, which are sometimes persistent in lawns. Annual species are controlled by cultivation; for winter annuals and perennials spraying with 2,4-D is fatal if done in bright sun. (N. TR.)

CHICLAYO, a city of northern Peru, capital of Lambayeque department; pop. (1958 est.) 54,390. It is located on the Inter-American highway about 400 mi. N.W. of Lima, in the midst of an irrigated area producing sugar cane, cotton and rice. The city is the leading commercial centre of the department, with industries dependent on its regional produce, among which are cattle from the highlands. Chiclayo has an airport and is connected by rail with two ports. Puerto Eten and Pimentel. (P. E. J.)

CHICLE (CHICLE GUM), the coagulated milky juice (latex) of the sapodilla (*q.v.*) or naseberry (*Achras zapota*), a tropical American tree of the family Sapotaceae, the fruit of which is used in tropical and subtropical regions. Chicle was first introduced to the U.S. as a substitute for rubber, but by about 1890, it was imported in increasing quantities as the basic ingredient of commercial chewing gum.

The latex is collected by making deep intersecting zigzag cuts in the bark to a height of 30 ft. or more up the trunk, the same tapping method used in gathering balata and gutta-percha. The viscous "milk" oozes from the cuts and runs down slowly to a receptacle at the base of the tree. The flow lasts for several hours and may amount to several quarts. The native collector (chiclero) collects this latex from his "walk" of trees once a day, gathering about a ton per season from 200 to 300 or more trees. which are rested from 6 to 10 years between tappings (about 15% of the trees die by this method of bleeding). The raw latex is boiled in kettles until about 67% of the water is lost; the semisolid mass is then molded into *marquetas* or blocks of about 25 lb. weight, which are packed in groups of four for transportation.

For manufacture into chewing gum, the grayish-brown chicle is remelted and cleared of foreign matter; other gums, sugar and flavouring extracts are added; and the finished product is molded and wrapped into packages.

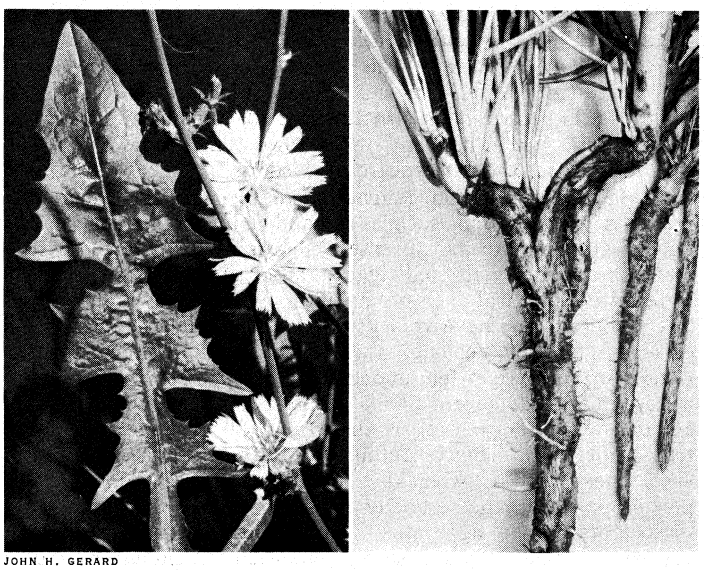
Most chicle comes from wild trees in Yucatan and Guatemala; attempts to grow it profitably on plantations have failed. Insufficiency of chicle after 1924 led to the importation of jelutong and sorva from the East Indies and South America, gums from *Dyera* costulata and Couma macrocarpa (family Apocynaceae; *q.v.*) which are mixed with chicle to make chewing gum. Since 1948, chicle has been largely supplanted by synthetic products as the basis for chewing gum.

See also CHEWIKG GUM. (J. S. KG.)

CHICOPEE, a city of Hampden county, Mass., U.S.. located just north of Springfield on rolling hills. Bounded on the east by the Connecticut river and bisected by the Chicopee river, the city is divided into a number of identifiable communities which take on different character from the ethnic groups, especially Polish, French and Irish, which predominate in each. Pop. (1960) 61,553; Springfield-Chicopee-Holyoke standard metropolitan statistical area (see SPRIKGFIELD) 478,592.

Originally part of Springfield, portions of the city were settled in 1652. Industrialization began early in the 19th century when the Chicopee river was first dammed. Separated from Springfield in 1848, it became a city in 1890. The name is an Indian word meaning "cedar tree." Chicopee has had a steady growth in population; for comparative population figures see table in MASSACHUSETTS: Population. It has a wide variety of industry, with the manufacturing of machinery and rubber and sporting goods predominating. (GE. G.)

CHICORY, *Cichorium intybus* (family Compositae), is a plant native to Europe and introduced to the United States late in the 19th century. It has a long fleshy taproot, a rigid branching



JOHN H. GERARD

CHICORY (CICHORIUM INTYBUS): (LEFT) FLOWERS WITH A BASAL LEAF; (RIGHT) ROOTS

hairy stem rising to a height of 3 to 5 ft., the leaves around the base being lobed and toothed, not unlike those of the dandelion. The flower heads are of a bright blue colour, few in number, and measure nearly an inch and a half across. Common chicory is cultivated extensively on the continent of Europe—the Netherlands, Belgium, France, Germany. In North America chicory is an introduced weed which has become widely distributed. It is abundant in pastures and along roadsides in the eastern United States and Canada, and is usually considered a pest. As a cultivated crop common chicory is gronn to some extent for its root.

Its roots, roasted and ground, are used as a substitute for, an adulterant of, or an addition to coffee; both roots and leaves are employed as salads; and the plant is grown as a fodder or herbage crop for cattle. In Great Britain it is chiefly in connection with coffee that chicory is employed. A large proportion of the chicory root used for this purpose is obtained from neighbouring continental countries but a considerable quantity is cultivated in England, chiefly in Yorkshire. It gives the coffee additional colour, bitterness and body.

The loose. blanched leaves are much esteemed by the French as a winter salad, *barbe de capucin.* In Belgium and elsewhere tighter heads or crowns called *Witloef* (or witloof) are preferred. There, also, the fresh roots are boiled and eaten with butter, and throughout Europe the roots are stored to supply leaves for use as salads during minter.

The roots are grown in the open during the summer and are taken up in the fall to be forced during the winter. One method of forcing produces *barbe* de *capucin* and another produces witloof. If the seed is sonn early in the spring in temperate regions having a growing season of five and a half to six months, the plants may go to seed instead of forming large storage roots suitable for forcing. In such regions seed should be sown in June. The roots may be forced under greenhouse benches, in cellars or out of doors. See also ENDIVE.

CHICOUTIMI, an industrial town of the Lake St. John and Saguenay region, Quebec, Can., is situated on low terraces overlooking the canyon of the Saguenay river (*q.v.*), 70 mi. W.N W. of its junction with the St. Lanrence. Chicoutimi is an Indian word meaning "limit of deep water" Lying on the main highway from Quebec. Chicoutimi is a commercial, manufacturing and administrative centre closely associated with the extensive Saguenay hydroelectric development. which provides power for aluminum production at nearby Arvida. Established in 1676 as a Jesuit mission and trading post. it grew rapidly after 1850 with the development of lumbering. Pulp, paper, furniture and textile plants were established later. Pop. (1961) 30.549. (J. D. I.)

CHIDAMBARAM, a town in South Arcot district, Madras state, India is 122 mi. (by rail 153 mi.) S.S.W. of Madras city

on the Southern railway. Pop. (1961) 40,740. It is noted for its great Hindu Siva temple, dedicated to Nataraja, or Siva in his aspect of "cosmic dancer." The temple is entered by lofty towergates and its *mandapam* or hall is supported by more than 1,000 pillars. Chidambaram is also the seat of Annamalai university, founded in 1929. The name of the town comes from Tamil chit plus *ambalam,* "the atmosphere of wisdom." (G. KN.)

CHIEF, the common designation of the political leader of a primitive social group, such as a band, tribe or confederacy of tribes. In a more technical sense a chief is any person who participates, by publicly accepted right, in an organization of specialists in primitive political decision-making. Among the simpler primitive peoples chiefs have very little coercive authority and depend on community consensus for the implementation of recommendations; furthermore, often among these simpler peoples a number of recognized chiefs form a tribal chiefs' council. Among the more advanced preliterate peoples there may be a single paramount tribal chief with coercive authority. Such a paramount chief is sometimes called a divine king because of the sacredness of his person, paraphernalia and utterances and because the accompanying elaborate social apparatus of noble courtiers, army, lesser village chiefs. peasantry and slaves somewhat resembles the feudal society of medieval Europe and Asia.

Popular literature has introduced a number of mistaken notions about the identity and role of the chief in primitive society. In loose usage, the word has been used to denote any famous war leader or orator aho frequently appears in negotiations with whites. Such a man may well be a leader in his community but not be recognized as a chief. An example is the Sauk Indian Black Hawk. who led a band of Sauk and Fox in the so-called Black Hawk War (1832). Black Hawk was not a member of the Sauk chiefs' council and was never recognized as a chief by the Sauk tribe, despite his prominence as a warrior and as a spokesman for those who opposed abandonment of the native settlements in Illinois. Similarly, Europeans have often sought to confer upon prominent and co-operative natives the title of chief, although the political role expected of these persons had no place in the aboriginal political system.

Primitive societies may be broadly classified into three groups to which correspond three different types of political organization. hunters; mixed hunters and gardeners; and primarily agricultural or herding societies with relatively dense populations In simple hunting societies, such as those of the Eskimo and the Ona of Tierra del Fuego, there are often no real chiefs; the adult community achieves decision by consensus influenced by such leaders as successful hunters and shamans. Among the mixed hunters and gardeners, represented by such North American Indian tribal groups as the Iroquois and Sauk, there is characteristically a chiefs' council of half a dozen to several dozen men representing kin and community or tribal units, with nonchiefly specialists responsible for such technical tasks as war leadership, record-keeping and the proper oratorical presentation of council policy. Sometimes two classes of chiefs are recognized, war chiefs and civil chiefs, the civil chiefs (sometimes called sachems) usually holding higher status except during war emergencies. In densely populated agricultural or herding societies, such as those of the Aztec and Inca, the west African kingdoms and Polynesian island societies, the divine king type of chieftainship, with its associated elaborate political and religious bureaucracy, is characteristic.

The qualifications of a chief generally include both a particular kinship status and recognized competence in policy formulation, the precise nature and combination of these criteria depending on local circumstances. In the mixed hunting and gardening groups, the chief may represent his own kin group in council deliberations; in the more complex societies, competence for tribal-wide decisions may be conceived to be hereditary in a particular kin line. But competence, demonstrated both before and during chieftainship, is generally requisite. The particular functions of chieftainship are highly varied, depending both on the political structure of the group and on its economic, religious and military problems. Chiefs may recommend or decide policy on hunting, planting. war, migration and intergroup relations; they may serve as ritual leaders; and, particularly in the agricultural populations, they may function as economic intermediaries, receiving economic produce and distributing it according to tribal custom.

CHIEF JUSTICE. The chief justice of the United States is the highest judicial officer of the country. He is appointed by the president with the advice and consent of the senate and has life tenure. His primary functions are to preside over the supreme court of the United States (q v) in its public sessions when the court is hearing arguments and during its private conferences when it is discussing and deciding cases. In the court he serves as chairman and has authority to assign the writing of opinions where he is a member of the majority; otherwise his powers are the same as those of any other supreme court justice. When the office is occupied by a person of extraordinary intellectual capacity and dynamic personality, as was the case with Charles Evans Hughes (*q.v.*), the administrative powers may be utilized to exert a great influence on the court's work. When the occupant of the centre chair is a lesser figure, as has often been the case, he is likely to be overshadoued by other members of the court.

The chief justice of the Cnited States is also the presiding officer of the Judicial Conference of the United States, which is made up of the chief judges of the United States courts of appeals, the chief judge of the court of claims, and 11 senior district court judges. The conference has four major duties. First, it investigates problems relating to the administration of justice in the federal courts and recommends legislation pertaining thereto. Second, it provides for an interchange of information among the lower court judges concerning common problems. Third, it studies the effectuation of the rules of procedure governing practice in the lower federal courts and initiates suggested changes in those rules for promulgation by the supreme court. Fourth, the conference supervises and directs, through the administrative office of the U.S. courts, matters pertaining to budget, travel, the interchange of judges among courts and other matters of judicial administration. The chief justice is responsible for utilizing the judicial power of the federal courts to best advantage by assigning judges from one federal court to another as occasion demands.

The chief justice customarily administers the oath of office to the president and vice-president at the time of their inauguration.

The title of chief justice is usually accorded the presiding judicial officer within any multi-judge court as well as to the highest judicial officer within a state of the United States. But the title varies from jurisdiction to jurisdiction: in New York and Maryland, for example, the judge presiding over the high court is designated as chief judge; in West Virginia, as president; and in South Dakota, as presiding judge. Equally variant are the methods of selection. the terms of office and the administrative functions to be performed.

Since 1860, the title of lord chief justice of England (*q.v.*) has been given to the officer presiding over the queen's bench division of the high court of justice. The title had been assumed by Sir Edward Coke and his successors before 1860, but until the abolition of the chief justiceship of the court of common pleas it was not strictly appropriate. See also COURT; JUDICIARY-AND COURT OFFICERS. (P. B. K.)

CHIEMSEE (BAYRISCHES MEER), the largest lake in Bavaria, Ger., lies 1.699 ft. above the sea between the Inn (to which it drains through the Alz) and Salzach rivers. With a length of 5 and a breadth of 9 mi., it has an area of 31 sq.mi. and contains three islands, Herreninsel, Fraueninsel and Krautinsel. The wooded Herreninsel was the seat of a bishop from 1215 to 1805 and until 1803 contained a Benedictine monastery; it is the site of an interesting castle which is an imitation of the palace at Versailles. The shores of the lake are flat on the north and south sides, but its other banks are flanked by undulating hills. The waters are clear and well stocked with trout and carp; however, the fishing is strictly preserved. The lake has steamer service.

(R. E. DI.)

CH'IEN-LUNG (given name HUNG-LI; temple name KAO-TSUNG) (1711–1799), fourth emperor of the Manchu (Ch'ing) dynasty in China, was born on Sept. 25, 1711. He became emperor in 1736, inheriting a soundly governed empire extending beyond China to Manchuria, Mongolia, Kokonor and Tibet. He himself directed from 1755 to 1759 the expeditions for the conquest of Sinkiang and in 1790–92 the successful expedition across the Himalayas against Nepal. The latter campaign marked the zenith of Manchu military power.

Internally the first four decades of Ch'ien-lung's reign gave evidence of vigour, integrity and wisdom in the use of power—an autocratic power under less restraint than ever before in Chinese history. The prestige of China under his rule was reflected in the increase in population, improvement in arts and crafts, expanding favourable foreign trade at Canton, admiration expressed by the Europeans serving at his court in Peking, and the vogue of Chinese styles in Europe, from landscaping to the wearing of pigtails. Public works were built on a large scale. and enormous literary projects were undertaken, culminating in the production of the seven manuscript sets of the Imperial library, the Ssu-k'u *ch'üan-shu,* each set comprising more than 3,450 titles in nearly 36.000 volumes. Yet the revenue was abundant and the treasury full. The long period of success and prosperity contributed to the vanity of the emperor, which increased with age. After 1780 he placed his trust in the unscrupulous minister Ho-shen, who knew how to satisfy that vanity. Corruption in government became rampant, and morale deteriorated. Thereafter the power of the dynasty was on the decline.

Ch'ien-lung himself enjoyed good health until his death. A strict disciplinarian, he conducted an exemplary life as a Manchu horseman and archer, was well versed in Chinese scholarship and could speak Manchu and Mongolian fluently and even some Turkish. He was always conscious of his duties and attended to state affairs with regularity. In his leisure he painted, practised calligraphy, wrote essays or composed poems, of which he left more than 40,000. George Staunton, who was on the Macartney mission in 1793 and saw the emperor, then 82 years old, said that he "walked firm and erect." In 1796 he abdicated in favour of his 15th son, but in name only, for he continued to rule. with the help of Ho-shen. until his death on Feb. 7, 1799, concluding a reign of more than 63 years, one of the longest in recorded history.

See A. W. Hummel (ed.), *Eminent Chinese of the Ch'ing Period,* 2 vol. (1943–44). (C. FA)

CHIETI, a town in the Abruzzi e Molise region of Italy, the chief town of Chieti province and a metropolitan episcopal see, lies 225 km. (140 mi.) E.N.E. of Rome. Pop. (1957 est.) 43 841 (commune). It is 1.085 ft. above sea level. From its position the town dominates the Pescara valley. It consists of an upper residential area on the side of a hill and a rapidly developing industrial and commercial area (Chieti-Scalo) in the valley where there are branches of several national industries including cellulose, sugar, wire and tobacco.

The most notable Roman and medieval monuments are the ruins of the Roman theatre (1st century A.D.), the baths, the temple of the Dioscuri and the octagonal church of Sta. Maria del Tricalle, built in 1317 on the pagan temple of Diana Trivia. The cathedral is a very old building with 15th-century frescoes and a great Gothic tower at its side (1335–1498). Chieti has a considerable academic reputation and contains a large provincial library, the National Museum of Archaeology, the Institute of Art, a theological university and a provincial picture gallery.

Chieti is the ancient Teate, capital of the Marrucini. It later became a Roman municipium, and was sacked and destroyed by the barbarians. Rebuilt by Theodoric the Ostrogoth, it was successively a Lombard stronghold, a Norman county and the possession of the Hohenstaufens, the Angevins, the house of Aragon and the Caracciolo. It gives its name to the religious order of the Theatines, founded in 1524. (G. LA.)

CHIFFON is a French word used in English with a considerable change in meaning. In French it means "a rag." In English it is used to mean a delicate, lightweight, sheer fabric of a plain weave, usually of silk or one of the man-made fibres, although it is not limited by fibre content. It is a relatively strong, balanced fabric although delicate in appearance. The term chiffon is also used as a modifier to mean a lightweight or softly draping condition, *e.g.,* chiffon velvet, chiffon taffeta, chiffon stockings, chiffon net and so forth. In Rumania chiffon means a bleached cotton shirting; in Germany and Austria it means a stout, fine, plain-noven linen fabric of smooth finish that is used for making shirts and underwear. (G. R. Co.)

CHIFLEY, JOSEPH BENEDICT (1885–1951), Australian statesman and an outstanding leader of the Australian Labor movement, was born at Bathurst. New South Wales, on Sept. 22, 1885. He became a locomotive driver and, interested in politics like many Irish-Australians, was an active member of his trade union. He was elected to the federal parliament in 1928 and became minister of defense in the 1929 Labor government. In 1931 he was defeated partly because of J. T. Lang, premier of New South Wales and leader of a rebel Labor group. Chifley spent the 1930s mainly in a fierce and successful struggle with Lang, although he also sat on a royal commission on banking and monetary reform in 1935–36. In 1939, on the outbreak of mar. he became adviser on labour in R. G. Menzies' government, returning to parliament in 1940 with high prestige. He was treasurer in John Curtin's Labor government (1941–45) and then succeeded to the premiership (1945–49). Throughout these years he played a tremendous part in maximizing Australia's war effort and shaping the policies that dramatically hastened the country's economic and social development: extensive government interference in the economy, full employment, the development of power, large-scale immigration, extension of social services and the encouragement of education. Chifley, serene and idealistic, came to have heroic stature in the eyes of Labor sympathizers.

Chifley's leadership was decisively rejected in the 1949 election, largely because of his abortive legislation to nationalize all trading banks. This radical proposal illustrated his socialist belief and also how his stubbornness and contempt for advantage seeking verged on disregard for democratic processes and reactions. The problem of Communism also accelerated his downfall, caught as he was between his deep feeling for political liberty and the extremist behaviour of the Australian Communists. Chifley remained leader of the opposition until his death in Canberra on June 13, 1951. He was buried from the Roman Catholic cathedral at Bathurst, having retained a rather equivocal attachment to that faith.

See L. F. Crisp, *Ben Chifley* (1961). (O. M. R.)

CHIGGER, the common name given to the larval stage of certain mites of the family Trombiculidae. The larvae are parasitic on vertebrates including man. Many of them are uniformly coloured or spotted with red.

Chiggers, variously known as scrub mites, harvest mites, bête rouge or chigger mites, are not insects but arachnids, relatives of the spider (see ARACHNIDA). However, the name "chigger" is also sometimes used (erroneously) for another skin-burrowing pest, an insect better known as the chigoe, jigger or jigger flea (*q.v.*).

The attacks of the chigger larvae on man often result in a dermatitis accompanied by intense itching. At times the scratching of infested areas may result in sores and secondary infections. While a few persons may not be greatly affected by chigger "bites," most human victims have a marked reaction and may develop large blisters.

The common chigger or "red bug" that attacks man in North America is *Trombicula (Eutrombicula) alfreddugesi.* This species occurs from New York to Minnesota and South to the Gulf and into Mexico. In the summer months it is especially abundant in the southern states, where it is a notorious pest. The larvae are very tiny and easily penetrate clothing. Once on the skin surface they attach by their barbed appendages, the palpi, and pincerlike hooked chelicerae. The chelicerae are usually inserted near a hair follicle or in the region of the body where clothing is tightest. The mite larva injects into the tissue a fluid that digests the tissue with which it comes in contact; the surrounding tissue becomes hardened and forms a tube. As it ingests the liquified tissue the mite continues to feed, thus lengthening the tube. The digestive juices

of the mite are the cause of the severe itching suffered by the host.

Having fed well, the larval mites drop to the ground and molt first into a nymphal stage and then into the adult. These stages are not parasitic on vertebrates but feed on plant materials and perhaps other arthropods.

The eggs are laid by the adult singly on the ground or on the leaves or stems of low-growing plants.

Other species of chiggers including Trombicula *splendens* and T. *batatus* are found in the United States. In Europe Trombicula *autumnalis* attacks not only man but cattle, dogs, horses and cats. Many other species of mite pests occur in various parts of the world.

In the orient certain species of Trombicula are the vectors of a disease known as tsutsugamushi (Japanese for "dangerous bug") fever or scrub typhus. The causative organism of this disease is a microscopic rickettsia carried by the chigger. The reservoir of this disease is in mice, rats and other rodents. Larval mites become infected while feeding on infected rodents. The rickettsiae are then passed through the nymphal stages to the adults and then into the eggs. Larvae hatched from these infected eggs then pass the disease on to man. (*See* TYPHUS FEVER: *Scrub* Typhus.) Because of the importance of chiggers as disease carriers, much research has been done on developing effective mite repellents or acaricides, some of which, in solutions, are used to impregnate clothing.

See also MITE. (C. J. GO.; M. L. G.)

CHIGI-ALBANI, the Roman branch of the Chigi, a noble Italian family of Sienese origin with branches still surviving also in Siena. They began as bankers in the 13th century. The first member of the family to win more than local eminence was Agostino "il Magnifico" (c. 1465–1520), a merchant prince who, as a banker in Rome, developed one of the richest business houses in Europe, lending money to popes, administering church revenue and spending lavishly on display and the patronage of artists and writers. It was he who built the palace and gardens later known as the Farnesina, decorated by Raphael. The Roman branch, however, descends not from him but from another Agostino, the nephew of Fabio Chigi, who was elected pope as Alexander VII in 1655 and who created his nephew successively prince of Farnese (1658), prince of Campagnano (1661) and duke of Ariccia (1662); the Holy Roman emperor Leopold I also made Agostino a prince of the empire (1659). After Alexander's death the Roman Chigi continued to prosper in the service of the papacy. In 1852, on the extinction of the Albani family, with whom they had intermarried in 1735, they added that name to their own.

As cardinal and then as pope, Fabio Chigi was mainly responsible for gathering the Biblioteca Chigiana, a rich collection of manuscripts and books, now incorporated in the Vatican library.

See G. Cugnoni, *Agostino Chigi il Magnifico* (1883); L. Pastor, *History of the Popes,* vol. viii (1908) and vol. xxxi (1940).

(P. J. J.)

CHIGWELL, an urban district (1933) in the Chigwell parliamentary division of Essex, Eng., 11 mi. N.E. of London by road. Pop. (1961) 61,001. The village, which is mentioned in Domesday Book, lies in a branch of the Roding valley with fragments of Hainault forest on its south and east. The district includes Buckhurst Hill and Loughton. The scenery of the neighbourhood is described in Charles Dickens' Barnaby Rudge; and the King's Head inn (Dickens' "Maypole") still stands. The old grammar school was founded by Samuel Harsnett, archbishop of York (d. 1631), whose fine memorial brass is in St. Mary's church, a Perpendicular structure with a Norman south door.

CHIHUAHUA, the largest state of Mexico, bounded north and northeast by the United States (New Mexico and Texas), east by Coahuila, south by Durango, and west by Sinaloa and Sonora. The population in 1960 was 1,235,891, and the area, 94,831 sq.mi. Indian influence is slight. The once fierce Apache tribes are almost extinct. The surface of the state is in great part an elevated plain, sloping gently toward the Rio Bravo del Norte (Rio Grande). The western side, however, is much broken by the Sierra Madre Occidental and its spurs. which form elevated valleys of great fertility. The more elevated plateaus and valleys have heavy rainfall. but over most of the state it is less than 20 in.; an impermeable clay substratum prevents its absorption by the soil, and the bare surface carries it off in torrents. The state's Copper canyons dwarf the Grand canyon but are still inaccessible. The Bolsón de Mapimí, an enclosed depression, in the southeastern part of the state, was once considered to be an unreclaimable desert, but experiments with irrigation have shown its soil to be highly fertile. The only river of consequence is the Conchos, which flows north and northeast into the Rio Bravo del Norte across the whole length of the state.

Agriculture has made progress in Chihuahua, but the scarcity of water has been a serious obstacle to its development outside the districts where irrigation is practicable. Stock-raising is an important industry in the mountainous districts of the west, where there is excellent pasturage for the greater part of the year. Cotton farming and meat packing were important developments of the area in the 1950s. The principal industry of the state, however, is mining of iron, antimony, gold, silver, copper, mercury, lead, zinc and coal. The silver mines of Chihuahua are among the richest in Mexico and include the famous mining districts of Batopilas. Chihuahuilla. Cosihuiriachic, Jesús Maria, Parral and Santa Eulalia or Chihuahua el Viejo. There are more than 100 of these mines. The state is well served by air lines, highways, mainline railways and by several short branches to the mining districts. The Mexican hairless or Chihuahua dog is also from this region.

In colonial times Chihuahua with Durango formed part of the province of Nueva Viscaya. An effort was made to overthrow Spanish authority in 1810, but its leader Miguel Hidalgo y Costilla and two of his lieutenants were captured and executed, after which the province remained passive. Chihuahua was not separated from Durango until after independence in 1823. The people of the state have been active partisans in most of the revolutionary outbreaks in Mexico, and in the war of 1862–66 Chihuahua was loyal to Benito Juárez. Porfirio Diaz at the end of the 19th century doled out several million acres in the state to seven families. The Terrazas ranch alone contained 15,000,000 ac.

Principal towns are the capital Chihuahua, Hidalgo del Parral, 120 mi. S.S.E. of the state capital, in a mining district, pop. (1950) 32,061; and Ciudad Juárez (*q.v.*) across the Rio Bravo del Norte from El Paso, Tex. (1958 est.) 220,000. (J. A. CW.)

CHIHUAHUA, capital of Chihuahua state, Mex., about 1,000 mi. N.W of Mexico city and 225 mi. S. by E. of El Paso, Tex. Pop. (1950) 86,961; (1960) 144,653. The city stands in a beautiful valley opening northward and hemmed in on all other sides by spurs of the Sierra Madre Occidental. It is 4,635 ft. above sea level. and its climate is mild and healthful.

The city is laid out regularly. with broad streets, and a handsome plaza with a monument to Miguel Hidalgo y Costilla and his companions of the revolution of 1810, who were executed there. The most noteworthy of its public buildings is the fine old parish church of San Francisco, one of the best specimens of 18th-century architecture in Mexico reputedly to have been built with the proceeds of a small tax on the output of the famous Santa Eulalia mine Other prominent buildings are the government palace, the Porfirio Diaz hospital, the old Jesuit college (now occupied by a modern institution of the same character), the mint and an aqueduct built in the 18th century.

Chihuahua has excellent air, rail and highway connections. Cattle raising, cotton farming, and mining are the main occupations of the surrounding area.

Chihuahua was officially founded in 1709, but was originally settled in the 16th century. Because of the rich mines in its vicinity it became one of the most prosperous towns in northern Mexico, although the state was constantly raided by hostile Indians. In 1763 it had a population of nearly 5,000. In the war between Mexico and the United States, Chihuahua was captured on March 1, 1847, by Col. A. W. Doniphan, and again on March 7, by Gen. S. Price. In 1864 Pres. Benito Juárez made the city his provisional capital for a short time. In the revolution of 1910 Pancho Villa captured the town by smuggling in his men disguised as peones. Modern Chihuahua is a thriving, energetic city,

with strong American influences. It has modern textile mills, meat canning plants and good hotels. (J. A. Cw)

CHIKAMATSU MONZAEMON (pseudonym of SUGIMORI NOBUMORI) (1653–1725), widely regarded as the greatest Japanese dramatist. credited by some scholars with as many as 160 plays, most of which were written for the puppet theatre. Before Chikamatsu, plays for the puppet theatre and kabuki had been turned out by hack writers whose chief concern was to provide ample opportunities for the actors (or puppet operators) to display their virtuosity, but Chikamatsu attempted from early in his career to write dramas of artistic merit. His dissatisfaction nith the liberties taken aith his texts by actors may have been responsible for his decision to write mainly for puppets.

Chikamatsu's works fall into two main categories: historical romances and domestic tragedies Modern critics generally prefer the latter plays because they are more realistic and closer to western conceptions of drama The historical plays suffer in comparison because of their heavy reliance on the exaggerated actions and declamations that Chikamatsu felt were necessary if wooden puppets were to seem alive Some of Chikamatsu's views on the art of the puppet theatre have been preserved in *Naniwa Miyage,* a work written by a friend in 1738 Chikamatsu declared. "Art is something which lies in the slender margin between the real and the unreal," and he endeavoured accordingly in his own norks to steer between the fantastic nonsense that had been the rule in the puppet theatre and the facile realism that was coming into vogue. Chikamatsu's domestic tragedies seem closer to reality, if only because they deal not with generals and princesses but with merchants housewives, thieves and prostitutes and all the great variety of people who made up the Osaka of his day. Most of the domestic tragedies were based on actual incidents (though modified in the direction of a more artistic "unreal"). such as the frequent double suicides of lovers. *Sonezaki Shinju* ("The Love Suicides at Sonezaki." 1703), for example. was written by Chikamatsu within a fortnight of the actual suicides he dramatized The haste of composition is not at all apparent in this first of his double suicide plays, the archetype of his other domestic tragedies

Chikamatsu's most popular work was *Kokusenya Kassen* ("The Battles of Coxinga." 1715), a historical melodrama based loosely on events in the life of the Chinese-Japanese adventurer who attempted to restore the Ming dynasty in China. Another famous work is *Shinju Ten no Amijima* ("The Love Suicide at Amijima." 1720), still frequently performed. Despite Chikamatsu's eminence, however, the fact that he arote for the puppet theatre with its special requirements has meant that with the decline in the fortunes of that theatre most of his plays have become unfamiliar to the public, except in the abridgements and considerably revised versions used in the *kabuki* and elsewhere. *See* also DRAMA.

Works available in English include *The Love Suicides at Sonezaki,* in Donald Keene, *Anthology of Japanese Literature* (1955), and *The Battles of Coxinga* (1951), both translated by Keene; and *The Love Suicide at Amijima,* tr. by Donald Shively (1953). (DD. K.)

CHIKMAGALUR, a town and district of Mysore state, India. The town, about 90 mi. N.W. of Mysore city, had a population of 21,744 in 1951. It is a coffee trading centre.

CHIKMAGALUR (formerly KADUR) DISTRICT has an area of 2.787 sq.mi. Pop. (1961) 595,849. The larger part consists of the Malnad or hill country, which contains some of the wildest mountain scenery in southern India. The western border is formed by the Ghats, of which the highest peaks are the Kudremukh (6,207 ft.) and the Meruti Gudda (5,444 ft.). The centre is occupied by the horseshoe range of the Baba Budans, containing the highest mountain in Mysore, Mulainagiri (6,317 ft.), and enclosing the Maidan or plain country, a fertile, well-watered region, with the famous "black cotton" soil. The principal rivers are the Tunga and Bhadra, which rise near each other in the Ghats and unite to form the Tungabhadra, a tributary of the Kistna. The eastern region is watered by the Vedavati (Hagari). From all the rivers water is drawn off into irrigation channels by means of anicuts or weirs. The chief natural wealth of Chikmagalur is in its forests, which contain large supplies of the finest timber, especially teak, and provide shelter for the coffee plantations. Iron is found and smelted, and there is corundum in some places. Coffee is groan on the hill slopes of the west, and rice in the valleys and in the Maidan, where cotton, tobacco and millet are also grown. The district is served by the Southern railway, on which, 23 mi. N.E. of Chikmagalur, is Kadur, from which the district formerly took its name.

CHILAS, a subagency, part of the Gilgit agency of West Pakistan, is administered as an unsettled area by an assistant political agent. Pop. (1951) 16,060; area 1,635 sq.mi. Chilas village is an important settlement (4,010 ft.) far up the Indus, about 100 mi. N.N.E. of Abbottabad. It holds an important position on the Muzaffarabad-Gilgit route, via Kaghan valley (Hazara district') and Babusar pass. It is connected with Gilgit (about 80 mi.) via Bunji by a road suitable only for jeeps.

The village has a small fort, hospital and bazaar, providing the essential needs of the population. There is a middle school, and a small airstrip for light aircraft.

The Chilas valley is rich and green, in part covered with forests. Maize (corn) is the chief crop, though some black wheat, potatoes and caraway (*Carum carvi*) are also grown. Sheep are the main domestic animals. (K. S. AD.)

CHILBLAIN (PERNIO) is an injury of the skin caused by damp cold. It occurs most frequently in hands, feet and legs of children and young women. Chilblain differs from frostbite (q *v.)* in that freezing of tissue never occurs; it closely resembles erythrocyanosis of the leg and trench foot. In acute chilblain there is intense itching and burning of the red or reddish-purple skin. Ulceration may occur in severe and chronic chilblain. Persons prone to develop chilblain should avoid damp cold and protect susceptible parts with dry, warm clothing. (F. A. FN.)

CHILD, CHARLES MANNING (1869–1954), U.S. zoologist and experimentalist who attacked the central problem of biology, that of organization, by experiments on regeneration and the alteration of development. He was born at Ypsilanti, Mich., on Feb. 2, 1869. He was educated in Connecticut and at the University of Leipzig, and spent his academic life in the zoology department of The University of Chicago (1895–1934). Child died on Dec. 19, 1954.

From his experiments, Child developed the theory of the axial gradient, a gradation in the rate of physiological processes along the axis of organisms. He believed this gradient, produced by the action of external factors on protoplasm, to be the mechanism of correlation by which the multitudinous cells of which an animal is composed are maintained as a unified whole. The chief factor in correlation is antero-posterior dominance, *i.e.,* each level dominates the region behind and is dominated by that in front *(see* REGENERATION : *Polarity; Gradient Theory;* DEVELOPMENT, ANIMAL). Of several books published on his ideas and researches the most important are: *Individuality in Organisms* (1915) and *Patterns and Problems of Development* (1941). *A* biography and complete bibliography appear in *Biographical Memoirs* of the National Academy of Sciences, vol. 30, 1957. (L. H. H.)

CHILD, SIR FRANCIS (1642–1713), English banker who was the first to give up goldsmithing and confine his operations to banking and consequently has been called the "father of the profession of banking." He was born in Wiltshire and, after an eight-year apprenticeship in London, became a goldsmith in 1664. About 1690 the firm began to deal exclusively in banking transactions. Child was appointed jeweler to the king and lent considerable sums of money to the government. Being a freeman of the City of London. he was selected a member of the court of common council in 1681; in 1689 he became an alderman, and in the same year a knight. In 1699 he served as lord mayor of London. He was a director of the East India company and was four times elected to parliament. Sir Francis died Oct. 4, 1713. The bank remained in the Child family until 1924. (J. R. LT.)

CHILD, FRANCIS JAMES (1825–1896), U.S. scholar and educator, was born in Boston, Mass.. Feb. 1, 1825. He graduated at Harvard in 1846, taking the highest rank in his class, and remained as a tutor in various subjects. After two years of study

in Europe he succeeded Edward T. Channing in 1851 as Boylston professor of rhetoric, oratory and elocution and in 1876 became professor of English at the same institution. Child studied the English drama and Germanic philology, the latter at Berlin and Gottingen during a leave of absence, 1849–53; and he took general editorial supervision of a large collection of the British poets. He edited Edmund Spenser (5 vol., 1855) and published an important treatise in the *Memoirs of the American Academy of Arts and Sciences* for 1863, entitled "Observations on the Language of Chaucer." His largest undertaking, however, grew out of an original collection of *English and Scottish Ballads* (8 vol., 1857–58). He accumulated, in the university library, one of the largest folklore collections in existence, studied manuscript rather than printed sources and carried his investigations into the ballads of all other tongues, meanwhile giving a sedulous but conservative hearing to popular versions still surviving His final collection was published as *The English and Scottish Popular Ballads*, first in ten parts (1882–98) and then in five quarto volumes, which remain the authoritative treasury of their subject. Child died in Boston Sept. 11, 1896, having completed his task save for a general introduction and bibliography.

CHILD, SIR JOHN (d. 1690), English deputy governor of Bombay from 1679 to 1681 and president of Surat from 1682 to 1690, was the first person to be placed in control of all the East India company's factories in India. While still a youth he was apparently sent to India to live with relatives who were associated with the company. In 1672 he married Susannah, daughter of Capt. John Shaxton, commander of the Bombay garrison. He was implicated in the mutiny of Shaxton's troops two years later but was restored to favour through the influence of his namesake, Sir Josiah Child, the powerful governor of the company in London. Like his patron he was utterly unscrupulous and had a passion for intrigue. His tyrannical behaviour as president led to Capt. Richard Keigwin's rebellion at Bombay in 1683. Acting under instructions from London, Child became involved in war with the Mogul emperor Aurangzeb, but the seizure of Surat by Mogul troops forced him to sue for peace. One of the conditions was that Child should be removed from India, but while the matter was still pending he died in Bombay on Feb. 4, 1690.

See R. and *O.* Strachey, *Keigwin's Rebellion* (1916). (C. C. D.)

CHILD, SIR JOSIAH (1630–1699), English merchant. economist and governor of the East India company. was born in London in 1630, the son of a London merchant He amassed a comfortable fortune as victualler to the navy under the Commonwealth. and became a considerable stockholder in the East India company. His advocacy, both by speech and by pen, under the pseudonym of Philopatris, of the East India company's claims to political power, as well as to the right of restricting competition with its trade, brought him to the notice of the shareholders, and he became a director in 1677, and, subsequently, deputy governor and governor. He was for a time virtually the sole ruler of the company and directed its policy as if it were his own private business. He died on June 22, 1699.

Child made some important contributions to the literature of economics, especially *Brief Observations Concerning Trade and the Interest of Money* (1668) and *A New Discourse of Trade* (1668 and 1690). He viewed Dutch prosperity as deriving in part from a low-interest policy, in part from a relatively liberal trade policy, and Child advocated similar policies for the British. He had the mercantilist partiality for a numerous population and propounded a new scheme for the relief and employment of the poor; he advocated the reservation by the mother country of the sole right of trade with its colonies. (D. F. DD.)

CHILD, LYDIA MARIA (née FRANCIS) (1802–1880), U.S. author and reformer, was born at Medford. Mass., Feb. 11, 1802, and died at Wayland, Mass., Oct. 20, 1880. One of the most prominent women of her day, Mrs. Child's present claims to remembrance are the contemporaneous popularity of her stories *Hobomok* (1824), *The Rebels* (1825) and *Philothea* (1836); her editorship of the *Juvenile Miscellany*, the first children's monthly periodical in the United States; and her efforts in behalf of the slaves, freedmen and Indians, including her stirring *Appeal for That Class of Americans Called Africans* (1833) and her editing of the *Anti-Slavery Standard* (1840–44) in association with her husband.

In spite of the 35 editions of her *Frugal Housewife* (1829) and the German. the eight American and the 12 English editions of her *Mother's Book* (1831), these and her many other stories and books on feminism, religion, biography and history have been superseded by later works.

BIBLIOGRAPHY.—*Letters of Lydia* Maria *Child* (1882); T. W. Higginson, Contemporaries (1899).

CHILD, WILLIAM (1606–1697), English organist and composer of church music. Born at Bristol, he was a chorister at Bristol cathedral and became a lay clerk at St. George's chapel, Windsor, in 1630. In 1632 he was appointed organist there and at the Chapel Royal. Expelled with the other royal musicians in 1643, he became a gentleman of the Chapel Royal at the Restoration and a private musician to the king. In 1663 he received a doctorate at Oxford and about this time became a friend of Pepys. He died at Windsor, March 23, 1697.

Child was influenced by the polyphonic idiom of the early 17th century. His conservative tendencies are also seen in the fact that his anthems do not use string *ritornelli*. He published his *First Set of Psalms* for three voices in 1639. Other compositions appeared in his *Divine Anthems*, in John Hilton's *Catch That Catch Can* and in John Playford's *Musical Companion* and *Court Ayres*. (A. *D. F.*)

CHILDBIRTH, the act of bringing forth a child. Because this process requires considerable physical effort on the part of the mother it has been termed and is usually known as "labour." The term "parturition" (a bringing forth) is also applied to the process of childbirth.

At the termination of pregnancy (*q.v.*) in the human female, the irregular intermittent contractions of the uterus (womb) that began in the early months of pregnancy become more regular and increase in frequency and intensity. This assumption of a rhythmic character by the uterine contractions marks the beginning of the process by which the maternal organism separates and expels the mature products of conception.

For descriptive purposes labour is divided into three stages: (1) the first stage (dilatation), which has to do with the opening up of the neck of the womb; it begins with the onset of labour and ends when the cervix or neck of the womb is dilated sufficiently to permit the passage of the child's head (*i.e.*, nine to ten centimetres, or about four inches, in diameter); (2) the second stage (expulsion), which is concerned with the passage of the child through the maternal birth canal; it begins when the cervix is sufficiently dilated to permit the passage of the child's head and terminates with the expulsion of the child; (3) the third or placental stage, that part of labour which is related to the separation and extrusion of the placenta (afterbirth); it begins with the birth of the child and ends when the placenta is expelled and bleeding from the vessels in the uterus is arrested.

STAGES OF LABOUR

First **Stage** (Dilatation). — Early in labour the uterine contractions come on at intervals of 20 to 30 minutes and last about 40 seconds. They are then accompanied by slight pain, which usually is felt in the small of the back. The term "labour pains" often is used as a synonym for uterine contractions. As labour progresses these uterine contractions become more intense and progressively increase in frequency until at the end of the first stage, when dilatation is complete, they recur about every three minutes and are quite severe. With each contraction a twofold effect is produced to facilitate the opening up of the cervix. Since the uterus or womb is a muscular sac containing a bag of waters that more or less surrounds the child, contraction of the musculature of its walls should diminish its cavity and compress its contents. Because its contents are quite incompressible, however, they are forced in the direction of least resistance, which is in the direction of the internal *os* or upper opening of the neck of the womb, where they act like a wedge and are driven farther and farther into this opening. In addition to forcing the uterine

contents in the direction of the cervix, shortening of the muscle fibres which are attached to the neck of the womb tends to pull these tissues upward and away from the opening and thus add to its enlargement. By this combined action, each contraction of the uterus not only forces the bag of waters and fetus downward against the dilating neck of the womb but also pulls the resisting walls of the latter upward over the advancing bag of waters and presenting part of the child.

In spite of this seemingly efficacious mechanism, the duration of the first stage of labour is rather prolonged, especially in women who are in labour for the first time. In them, the average time required for the completion of the stage of dilatation is between 13 and 14 hours, while in women who have previously given birth to children the average is 8 to 9 hours. Not only does a previous labour tend to shorten this stage but the tendency often increases with succeeding pregnancies, with the result that a woman who has given birth to three or four children may have a first stage of one hour or less in her next labour. Since the cervix of a young woman dilates more readily than does that of a woman who has her first child late in the fourth decade of life, the duration of the first stage of labour often is somewhat prolonged in women who become pregnant for the first time after they have passed the age of 35. A similar delay is to be anticipated if the cervix is extensively scarred as a result of previous labours or an amputation, deep cauterization or other operation on the cervix. Even a woman who has borne several children and whose cervix accordingly should dilate readily may have a prolonged first stage if the uterine contractions are weak and infrequent or if the child lies in a faulty position and as a result cannot be forced into the mother's pelvis. In this connection it may be noted that early rupture of the bag of waters often increases the strength and frequency of the labour pains and thereby shortens the stage of dilatation. On the other hand, premature loss of the naters occasionally leads to molding of the uterus about the child and thereby delays dilatation by preventing its normal descent into the pelvis. Just as an abnormal position of the child and molding of the uterus may prevent the normal descent of the child, an abnormally large child or an abnormally small pelvis may interfere with the descent of the child and prolong the first stage of labour.

Second Stage (Expulsion).—About the time that the cervix becomes fully dilated, the bag of waters breaks and the force of the involuntary uterine contractions is augmented by voluntary bearing-down efforts of the mother. With each labour pain she takes a deep breath and then contracts her abdominal muscles. The increased intra-abdominal pressure thus produced may equal or exceed the force of the uterine contractions. When properly used, accordingly, these bearing-down efforts may double the effectiveness of the labour pains. As the child descends into and passes through the birth passages the sensation of pain often is increased. This is especially true of the terminal phase of the stage of expulsion when the child's head distends and dilates the maternal soft parts as it is being born.

Anterior Position of the Occiput.—The manner in which the child passes through the birth canal in the second stage of labour depends upon the position in which it is lying and the type of the mother's pelvis. In this discussion, the mechanism presently to be described is that which is frequently followed when the mother's pelvis is of the usual or gynecoid type and the child is lying with the occiput (the back of its head) lowermost and directed toward the fore part of the mother's left side (figure. A). The back of the child's head accordingly is the leading pole and is in the left anterior quadrant of the mother's pelvis, while the long diameter of the head circumference which is to pass through the pelvis lies obliquely. This is one of the commonest mechanisms and is chiefly concerned with the various movements of the head. These usually are grouped under the following heads: (1) flexion, (2) internal rotation. (3) extension, (4) restitution and (5) external rotation.

1. The force derived from the uterine contractions and the bearing-down efforts exerts pressure on the child's buttocks and is trdnsmitted along the vertebral column to drive the head into and through the pelvis. Because of the eccentric attachment of the spine to the base of the skull, the back of the head is made to advance more rapidly than the brow, with the result that the head becomes flexed until the chin comes to lie against the breast bone (figure, B). As a consequence of this flexion mechanism, the ovoid head circumference which entered the birth canal is replaced by a smaller, almost circular circumference, the long diameter of which is about two centimetres or almost one inch shorter than that of the replaced circumference. The advantage of flexion, therefore, is equivalent to a reduction of almost one inch in the long diameter of the head as it passes through the pelvis.

2. As the head descends more deeply into the birth canal it meets the resistance of the bony pelvis and of the slinglike pelvic floor or diaphragm, which slopes downward, forward and inward. When the back of the head, the leading pole of the child, is forced against this sloping wall on the left side, it naturally is shunted forward and to the right as it advances, just as a ferryboat is shunted into its wharf by meeting the sloping resistance of its ways (figure, C). This internal rotation of the head brings its longest

diameter into relation with the longest diameter of the pelvis and thus greatly assists in the adaptation of the advancing head to the configuration of the cavity through which it is to pass.

3. Further descent of the head directly downward in the direction in which it has been traveling is opposed by the lower portion of the mother's bony pelvis behind and the resisting soft parts which are interposed between it and the vaginal orifice (figure. C). Less resistance, on the other hand, is offered by the soft and dilatable walls of the lower birth canal, which is directed forward and upward. The occiput (back of the child's head) accordingly ad-

vances along the lower birth canal, distending its walls and dilating its cavity as it progresses. Soon the back of the child's neck becomes impinged against the bones of the pelvis in front and the chin is forced farther and farther away from the breast bone. Thus, as extension takes the place of flexion, the occiput, brow, orbits, nose, mouth and chin pass successively through the vulvovaginal orifice (external opening of the lower birth canal) and are born (figure, D).

4. The neck, which was twisted during internal rotation of the head, untwists as soon as the latter is freed from the grasp of the vulvovaginal ring. Almost immediately after its birth, therefore, the occiput is turned toward the left and backward to assume the same relative position which it occupied at the onset of labour (figure. E).

5. As it advances, the child's lower shoulder meets the sloping resistance of the pelvic floor on the right side and is shunted forward and to the left toward the middle of the pelvis in front. This brings the long diameter of the shoulder circumference into relation uith the anteroposterior or long diameter of the pelvic cavity. As the shoulders rotate internally, the occiput is turned farther backward and to the left so that the child's face comes to look directly at the inner aspect of the mother's right thigh (figure, F).

Birth of the *Shoulders.*—Soon after the shoulders rotate, the one in front appears in the vulvovaginal orifice and remains in this position while the other shoulder is swept forward by a lateral bending of the trunk, through the same upward and forward curve which was followed by the head as it was being born. After this shoulder is delivered the shoulder in front and the remainder of the child's body are expelled almost immediately and without any special mechanism.

An average of about one hour and 45 minutes is required for the completion of the second stage of labour in women who give birth for the first time. In subsequent labours the average duration of the stage of expulsion is somewhat shorter.

Posterior Position of the Occiput.—The child may lie so that the back of its head (occiput) is directed backward and toward either the right or left side. The leading pole is then in the right or left posterior quadrant of the mother's pelvis, and the condition is referred to as a posterior position of the occiput. In such cases. the back of the child's head usually rotates to the front of the pelvis and labour proceeds as in anterior positions. Because of the longer rotation required and the difficulty sometimes encountered in securing flexion, labour may be somewhat more prolonged than in anterior positions.

Face *Presentation.*—When the child's head becomes extended so that it enters and passes through the pelvis face first, the condition is know11 as a face presentation. The chin is then the leading pole and follows the same course that is followed by the back of the head in occipital presentations. If the chin lies to the front as it enters the pelvis, labour often is easy and of short duration. Should it be directed backward, on the other hand, considerable difficulty map be encountered, and the head may have to be flexed or rotated artificially or a complete turning of the child may be necessary.

Breech Presentation.—The condition in which the lower extremities or buttocks pass through the pelvis first is encountered about once in every 30 labours. Because the head in such cases is the last part of the child to be delivered and because this part of the delivery is the most difficult, the umbilical cord (navel string) may be compressed while the aftercoming head is being born, with the result that the child may be asphyxiated. Asphyxia or injuries to the child which result from the attendant's effort to hasten the delivery and prevent its asphyxiation are responsible for the loss of three times as many breech babies as head-on babies. The infant mortality varies from 2% to 10% according to the size of .the child and the skill of the attendant. Because very small premature infants are particularly susceptible to the dangers of breech delivery, the mortality among them is very high when they are born breech first.

Transverse Presentation or Cross Birth.—This is relatively rare, being encountered only once in several hundred labours. In this situation the long axis of the child tends to lie across or transverse to the long axis of the mother. Unless the child is very small or has been dead for some time and has become greatly softened. delivery through the natural passages is impossible in such cases For this reason the child must be turned by the attendant or delivered by Caesarean section if it is alive.

That the latter complications are infrequent and can be cared for easily is shown by the excellent statistics of many maternity services In them the maternal death rate is less than 1 per 1,000 and nould be still lower if the deaths caused by general systemic diseases rather than pregnancy and labour were excluded. The infant mortality usually is also low, ranging between 2% and 3%. It likeaise would be much lower if the premature and poorly developed infants were excluded. In other words, the risk to a healthy mother who carries her child to maturity is less than 1 per 1,000, and the risk to her mature child is about 1%.

Third Stage (Placental).—With the expulsion of the child, the cavity of the uterus is greatly diminished. As a consequence the site of placental attachment becomes markedly reduced in size. with the result that the placenta (afterbirth) is separated in many places. Within a few minutes subsequent uterine contractions complete the separation and force the afterbirth into the vagina, from which it is expelled by a bearing-down effort. The third stage of labour accordingly is of short duration, seldom lasting longer than 1 j minutes. Occasionally, however, the separation may be delayed and accompanied by profuse bleeding, in nhich circumstance its artificial removal is necessary. Because of the ever-present danger of hemorrhage as long as the afterbirth is retained, the attendant always remains with the mother until the third stage is completed and the possibility of post *partum* hemorrhage is eliminated by firm contraction and retraction of the uterus.

RELIEF OF PAIN IN LABOUR

Not much was done to relieve the suffering of childbirth before chloroform was first used for this purpose in the mid-19th century. Because of its toxicity, even this drug was employed sparingly and ultimately came to be used only during the second or expulsive stage of labour. Early in the 20th century, morphine and scopolamine were given according to the "twilight sleep" technique to lessen the pain that accompanies the stage of cervical dilatation. While this technique was found to be less safe than had been hoped, it gave a new and strong impetus to the search for a satisfactory method of pain relief, with the result that the old methods nere improved and many new ones were suggested. Among these were the use of chloroform, ether, nitrous oxide, ethylene, cyclopropane, trichloroethylene, morphine and scopolamine. the barbiturates and scopolamine, demerol and scopolamine, paraldehyde and local, paravertebral. presacral, caudal and spinal anesthesia. While this long list of agents indicates the praiseworthy efforts that were made to find a satisfactory method of pain relief suitable for use during childbirth. it also indicates that no such method was found. It remained impossible to secure 100% relief from pain in all women without adding to the maternal and fetal risk. On the other hand, the judicious employment of one or more of these drugs eliminates much of the pain of childbirth with safety. (See also ANESTHESIA AND ANESTHETICS.)

Morphine and Scopolamine (Twilight Sleep).—By the use of hypodermic injections of morphine and scopolamine a condition of seminarcosis, "twilight sleep," is induced. When it is successful, the mother awakens after her child is born and has no recollection of having felt any pain during her labour. Such a result is attributable either to the actual relief of pain or to her inability to remember such pain as did occur because of the scopolamine-induced amnesia. If given too soon, these drugs may stop the labour completely. If given too late, their effect on the child's respiratory centre may cause its death from asphyxia. This lack of safety has led to more or less abandonment of the twilight sleep routine. Morphine and scopolamine, on the other hand, can be given within the limit of safety and still relieve much of the pain of childbirth. They accordingly are used extensively for this purpose.

Barbiturates.—These drugs, usually combined with scopola-

mine. are frequently employed for the relief of pain during labour. As in the case of twilight sleep, their successful use is followed by a loss of memory, and the mother either has no pain or forgets it completely. To obtain a satisfactory result, unpleasant side effects sometimes are encountered. The commonest of these is excitement of varying degrees. Restraint accordingly may be necessary, and the constant presence of a nurse or other attendant is required. Restlessness or the patient's inability to use her bearing-down efforts properly often makes it necessary to deliver the child with instruments under nitrous oxide–ether anesthesia. Although some infants delivered in this way do not breathe so readily as do those born to mothers who have had no medication for the relief of pain, the effect of the barbiturates on the child is much less marked than that produced by the twilight sleep routine.

Demerol.—Demerol, combined with scopolamine. has been employed to produce analgesia and amnesia during labour. Accumulating evidence after mid-20th century seemed to indicate that this combination would ultimately prove to be the safest and best method of pain relief during the first stage. Because of the antispasmodic action of demerol, the dilatation of the cervix apparently is hastened by its use. If the combination of demerol and scopolamine is supplemented by local anesthesia during the stage of expulsion, the greater part of the pain of childbirth may be eliminated without risk to mother or child.

Nitrous **Oxide.**—Nitrous oxide, or "laughing gas," is one of the most popular of the analgesic agents. It is given during the latter part of the first and throughout the second stage of labour and is administered only for the duration of the uterine contractions. While the child is being delivered the addition of ether usually is necessary. Unless adequate amounts of oxygen are added to the nitrous oxide mixture which the mother breathes, the child may suffer from anoxia or die from asphyxia

Chloroform, Ether, Ethylene and **Cyclopropane.**—These are often given while the child is being delivered. Because of its toxicity. chloroform lost much of its popularity, with the result that its use became restricted largely to those cases in which the duration of the anesthesia is to be short. Ether is much safer than chloroform but is not so pleasant to take and is irritating to the respiratory passages. Ethylene and cyclopropane are excellent gaseous anesthetic agents and are well suited to the needs of obstetric practice. Because of their highly explosive nature a special and elaborate apparatus for their administration is required and adequate measures to prevent the occurrence of static sparks must be employed. Trichloroethylene. a volatile anesthetic agent. has been found to be suitable for self-administration during the latter part of labour. The patient inhales this gas through a special inhaler which she places over her nose and mouth at the onset of each uterine contraction. Loss of consciousness occurs before the contraction ends; the inhaler thus drops away from her nose and the administration of the gas is discontinued Trichloroethylene anesthesia is used extensively in Great Britain.

Continuous Caudal Anesthesia. — This map be produced by surrounding the terminal portion of the spinal cord with an anesthetic agent. For this purpose a special flexible needle is passed into the canal at the base of the spine which contains this portion of the spinal cord and is left in place. Through it from time to time a solution of the anesthetic agent, metycaine, is injected. Perfect anesthesia for a prolonged period without loss of consciousness accordingly is made possible by this method. Unfortunately the technique is difficult to master and requires the constant attendance of one who is capable of recognizing and treating the accidents that may arise from its administration. These accidents. unlike those that may accompany the use of other methods of anesthesia, may cause death because of their sudden occurrence and because of the difficulties surrounding their treatment. This narrow margin of safety together with the fact that only 60% of the women who have children are suitable subjects for continuous caudal anesthesia militates against the universal application of this method.

Spinal Anesthesia. — Spinal anesthesia has been used late in labour. It is obtained by passing a needle betneen two of the lower vertebrae into the spinal canal and injecting a solution of procaine (novocaine). Folloning the injection, relief of pain is prompt and lasts for one to two hours. Unfortunately this form of anesthesia often destroys the reflex responsible for the bearing-down efforts and thus greatly increases the need for instrumental delivery of the child. Like caudal anesthesia it has no effect on the child and most infants born under its influence breathe and cry immediately after birth. Accidents occasionally occur and may cause the sudden death of the mother. For this reason, spinal as well as caudal anesthesia should be administered only by trained anesthetists who are careful to follow the meticulous technique required by both methods and who are capable of immediately recognizing and treating untoward reactions.

Local Anesthesia. — Local anesthesia of the lower birth tract may be secured by infiltrating these structures with an anesthetic agent or by surrounding the trunk of the nerves that supply this region with the same. A solution of procaine (novocaine) is most frequently used for this purpose. It is easily injected by means of a hypodermic syringe. Because the technique of its administration may be easily learned and because it can be given without risk to the mother or child. local anesthesia is one of the best means of relieving the pain that accompanies the actual delivery of the child. Demerol and scopolamine in the first stage, supplemented by local anesthesia in the latter part of the stage of expulsion. provide probably the safest and best means of relieving most of the pain of childbirth in most women.

PUERPERIUM OR PERIOD OF INVOLUTION

Within six to eight weeks after childbirth most of the structures of the maternal organism that underwent change during pregnancy return more or less to their prepregnancy state. The enlarged uterus, which at the end of gestation weighed about 1,000 g. (33 oz.), shrinks to a weight of about 60 g.(2 oz.). Accompanying this process of uterine involution, its lining membrane is almost completely shed and replaced by a new lining, which is then (six to eight weeks after delivery) ready for the reception of another fertilized ovum (egg). The greatly dilated neck of the womb and lower birth passage likewise undergo marked and rapid involution, but they seldom return exactly to their prepregnancy condition. 4s a rule, examination of a woman who has given birth accordingly reveals evidence of this. The markedly stretched abdominal wall also undergoes considerable involution. particularly if abdominal exercises are carried out. Although the zigzag intradermal tears (striae *gravidarum*) become smaller and silvery white, they do not completely disappear but remain as evidence of the marked and rapid stretching of the skin that took place during pregnancy. The breasts, unlike most of the other organs. continue to increase in size. By the second or third day following childbirth they become so distended that they are painful. After the milk comes in on the third day this distension recedes somewhat. but the breast enlargement persists as long as lactation continues. If the child is not allowed to nurse on its mother's breasts, lactation ceases within a short time and mammary involution follows.

CHILDE, V(ERE) GORDON (1892–1957), Australian prehistorian who made a systematic study of European prehistory in the third and second millennia B.C., seeking to evaluate the relationships between Europe and the orient and to examine the structure and character of the barbarian cultures of the western world in antiquity. Born at Sydney, New South Wales, on April 14, 1892, he began his research at Oxford under Arthur Evans and John Linton Myres on problems of archaeology as affecting the Indo-European languages, publishing The *Aryans* in 1926. In the following year he mas appointed the first Xbercromby professor of prehistoric archaeology in the University of Edinburgh, remaining there until 1946, when he became director of the Institute of Archaeology in the University of London. In many publications

he presented a synthesis of knowledge covering a vast and complex field in a manner unique and authoritative, and made himself easily the greatest prehistorian in Britain of his generation, and probably in the world. *The Dawn of European Civilization* (1925) appeared in six successive editions up to 1957; *The Danube in Prehistory* (1929) is a classic of European prehistory. His insistence on an international approach founded a tradition of prehistoric studies, while his more popular works interpreted prehistory in terms of social and technological development. He died on Mount Victoria. New South Wales, on Oct. 19, 1957. *See* also CIVILIZATION AND CULTURE: *Concepts of Civilization and Culture.*

See the obituary by S. Piggott in *Proceedings of the British Academy,* vol. *44,* pp. *305–312 (1959).* (S. PT.)

CHILDEBERT, the name of three Frankish kings, of the Merovingian dynasty.

CHILDEBERT I (c. 495–558) was a son of Clovis and Clotilda. In the division of territory that followed the death of Clovis in 511, he received Paris as the capital of a kingdom which stretched from the Somme valley to Brittany and included the Seine valley and the cities of Nantes, Angers and Bourges. He annexed Chartres and Orleans after murdering the heirs of his brother Clodomir (d. 524). Childebert took part in campaigns against the Burgundians (523–534) thereby acquiring Mâcon, Geneva and Lyons; he forced the Visigothic king Amalaric to retreat toward the Spanish border (531); and, when Provence was ceded to the Franks by the Ostrogoths, received Arles and Marseilles (537). Having already tried unsuccessfully to despoil his nephew Theudibert I of Austrasia in 534, he attacked his brother Clotaire I in 540, and peace was restored only when the queen mother Clotilda intervened. Then, with Clotaire. he invaded Visigothic Spain (541–542). In this campaign, his greatest military exploit, he captured Pampeluna (Pamplona) but was forced to abandon the siege of Saragossa. He brought back the tunic of St. Vincent as a trophy; in its honour he built the monastery of St. Vincent (now St. Germain-des-Prés), where he was afterward buried. He died on Dec. 23, 558.

CHILDEBERT II (c. 570–595) was proclaimed king of Austrasia after the murder of his father Sigebert in Dec. 575. During his minority his mother Brunhilda (*q.v.*) struggled with the aristocracy for power in Austrasia; while his uncles, Chilperic I, king of Tournai, and Guntram, king of Burgundy, contended to enforce on him their protection. Childebert was adopted by Guntram in 577 and by Chilperic in 581, but when Chilperic tried to embroil him in an attack on Guntram in 583, the *minor populus* of Austrasia rebelled. After Chilperic's death in 584, Childebert and Guntram united against the claims of a pretender, Gundobald. They made a treaty at Andelot on Nov. 28, 587, arranging a new partition of Charibert's patrimony. Guntram received Sigebert's original share: Childebert took the city of Meaux, two-thirds of Senlis, and the cities and territories of Tours, Poitiers, Avranches, St. Lizier, Bayonne, Aire and Albi. When Guntram died in 592, Childebert annexed his lands. Hoping to become master of the whole Frankish kingdom, he then tried unsuccessfully to seize the small remaining territory of Clotaire II, Chilperic's son. Childebert had made several expeditions into Italy between 584 and 589, finally treating with the Lombards. He had also made contacts and sought an alliance with the Byzantine empire: 24 letters exchanged between his chancellery and that of the emperor Maurice are extant. He died in Dec. 595.

CHILDEBERT III (c. 683–711), a son of Theuderic (Thierry) III, was placed on the throne of Neustria by Pepin of Herstal in 695, but had no effective power. He died early in 711.

CHILDERIC, the name of three Frankish kings, of the Merovingian dynasty.

CHILDERIC I (d. 481 or 482) was king of the Salian Franks, who, in treaty with the Roman empire, had been settled since 428 in Belgica Secunda, between the Somme and the Meuse, making their capital at Tournai. The account given by Gregory of Tours of the first part of his reign is largely legendary: according to Gregory, Childeric, son of Merovech, was expelled by his subjects and took refuge in Thuringia with a certain king Basin, whom he repaid by seducing his wife, Basine. When Childeric was recalled by the Franks eight years later, Basine followed him. Their child was Clovis (*q.v.*). Childeric's role as a barbarian ally of the Romans was important. He helped their *magister militum* Aegidius to repel the Visigoths near Orleans in 463 and, at the request of Count Paulus, Aegidius' successor, he attacked the Visigoths again in 469. Soon afterward he cleared the district around Angers of Anglo-Saxon pirates. Childeric died in 481 or 482 and was buried at Tournai. His tomb, discovered in 1653, was found to contain a stone slab engraved with his name and some rich cloisonne ornaments.

CHILDERIC II (649–675), the second son of Clovis II and of Bathilda, was proclaimed king of Austrasia in 662, in place of the rightful heir Dagobert, son of Sigebert III. He reigned under the joint tutelage of his aunt Himnechildis (Dagobert's mother) and of Wulfoald, the mayor of the palace. When his elder brother Clotaire III, king of Neustria and Burgundy, died in 673, Ebroïn, the Neustrian mayor of the palace, tried to introduce Clotaire's and Childeric's youngest brother, Theuderic (Thierry) III as his successor. But the Neustrian magnates, whom Ebroi'n had not consulted, appealed to Wulfoald and Childeric II and swiftly deposed Theuderic. Childeric thus became master of the kingdoms of Neustria and Burgundy as well as Austrasia. He quickly forgot his promises to respect the customs of each kingdom and he sent into exile in the monastery of Luxeuil, Leger, bishop of Autun, who had severely censured his conduct. Childeric II was the last Merovingian to attempt the exercise of genuine authority, but he lacked political ability. A party hostile to Austrasian rule grew up in Neustria and Childeric was assassinated, while hunting near Chelles, between Sept. 10 and Nov. 15, 675.

CHILDERIC III (d. 755) was the last Merovingian king. Effective power in France had long been wielded by the Carolingian mayors of the palace, but the revolt which followed the death of Charles Martel in 741 made it wise for his sons Carloman and Pepin the Short, in 743, to place Childeric III, a Merovingian of questionable legitimacy, on the Frankish throne, so that they could dissemble their authority behind his name. Carloman entered a monastery in 747 and when Pepin felt sufficiently secure to have himself elected king of the Franks (751), Childeric was deposed and confined in the monastery of Sithiu, near Saint Omer. He died in 755.

CHILDERMAS: *see* INNOCENTS' DAY.

CHILDERS, HUGH CULLING EARDLEY (1827–1896). English statesman who was a fervent supporter of William Gladstone and served the Liberal party ably in several departments, was born in London on June 25, 1827, and educated at Wadham college, Oxford, and Trinity college, Cambridge. Emigrating to Australia in 1850, Childers rose rapidly in the civil service before becoming a member of the cabinet in the newly created parliament of Victoria in 1856. He was also a founder of the University of Melbourne and its first vice-chancellor. Returning to London in 1857 as agent-general for Victoria, Childers soon entered British politics and business in the City. Elected Liberal member of parliament for Pontefract in 1860, he became financial secretary to the treasury (1865–66), where his ability impressed Gladstone. In 1868 Gladstone appointed Childers first lord of the admiralty—an office he managed successfully until his retirement through ill-health in 1871. He was chancellor of the duchy of Lancaster in 1872 but resigned to make way for John Bright a year later. Childers returned to active politics in 1880 as Gladstone's secretary for war, succeeding the prime minister as chancellor of the exchequer in 1882. His orthodox budgets were well received until 1885, when proposals for increased taxation contributed to the fall of a divided government. Defeated for the first time at Pontefract as an advocate of Home Rule, Childers was returned for

South Edinburgh in 1886 and became home secretary in Gladstone's brief third ministry. He retired from parliament in 1892 and died in London on Jan. 29, 1896.

See Lieut. Col. *E.* S. Childers, *The Life and Correspondence of Hugh C. E. Childers,* 2 vol. *(1901).* **(A. F. T.)**

CHILDERS, ROBERT ERSKINE (1870–1922), Irish writer and political agitator, whose support for the republican cause in the civil war which followed the establishment of the Irish Free State led to his execution for treason, was born in London on June 25, 1870. He was a first cousin of Gladstone's colleague Hugh Childers. Educated at Haileybury and Cambridge university, he was from 1895 to 1910, apart from service in the South African War, a clerk in the house of commons. After 1910 he devoted himself to propaganda for the cause of Home Rule and in July 1914 he landed a cargo of rifles for the Irish volunteers at Howth, near Dublin, in his own yacht. During World War I, however, he served with distinction in the British forces before joining (1917) the convention set up to evolve some form of Irish settlement by consent. His advocacy of Home Rule grew quickly into full support for an Irish republic: in 1921 he was elected a Sinn Fein deputy for Wicklow. That year he was secretary to the Irish delegation for the talks preceding the Anglo-Irish treaty, but, dissenting from this agreement, sided with the republican opposition which resorted to civil war. He was taken prisoner at his home in County Wicklow on Nov. 10, 1922, court-martialed on a charge of unauthorized possession of a revolver and executed on Nov. 24.

As a writer, Childers is best remembered for *The Riddle of the Sands* (1903), a brilliant spy story which was the fruit of his enthusiasm for yachting and for the secret service. He also wrote vol. v of *"The Times" History of the War in South Africa* (1907). (D. G.)

CHILD LABOUR. In Europe, North America and Australia and New Zealand, children under 15 rarely work except in commercial agriculture, thanks to the effective enforcement of laws passed in the first half of the 20th century. But miilions of children (some as young as seven) still toil in the quarries, mines, factories, fields and service enterprises of less industrially developed countries. They make up more than 10% of the labour force in some countries in the middle east and from 2% to 10% in much of Latin America and some parts of Asia. Few, if any, laws govern their employment or the conditions under which work is performed. Restrictive legislation is barred largely by family poverty and lack of schools.

The movement to regulate child labour began in Great Britain at the close of the 18th century, when rapid development of large scale manufacturing had resulted in the exploitation of very young children in mining and industrial work *(see* COAL AND COAL MINING: *Mining and Miners).* The first law, aimed at controlling the practice of apprenticing pauper children to cotton mill owners in 1802, was ineffective because it did not provide for enforcement. In 1833 the Factory act did provide a system of factory inspection. Organized international efforts began with the first International Labour conference in Berlin in 1890. Although agreement on standards was not reached at that time, similar conferences and other international moves followed. In 1900, the International Association for Labour Legislation was established at Basel, Switz., with branches in at least 16 countries, to promote child labour provisions as part of other international labour legislation. In 1919, the treaty of Versailles contained provision for an International Labour organization (ILO) to be affiliated with the League of Nations and to include all its members.

A few years earlier, just at the turn of the 20th century, aggressive campaigns were under way in the United States to combat widespread child labour. In 1832, two-fifths of the factory workers in New England had been children; and by 1870 the census had reported that 750,000 children between ten and fifteen years of age were working throughout the country. Their number increased steadily from 1870 to 1910.

Agitation for compulsory school attendance legislation had begun in the 1820s. In the 1840s, Connecticut, Massachusetts and Pennsylvania had passed laws limiting the hours of employment of minors in textile factories. By the 1870s, the Knights of Labor had started the campaign for state laws prohibiting the labour of children. By the turn of the century, conditions in canneries, the glass industry, anthracite mining, etc., had begun to attract considerable attention. The number of child labourers in the south had tripled in the decade ending in 1900. In 1904 the National Child Labor committee was organized, and it was chartered by congress in 1907. The committee investigated conditions in various states and industries and led the successful push for state legislation to regulate child labour. By 1920 census reports began to reflect a decline in child labour that continued in the 1930s. The slowness of certain states to adopt legislation, however, and the lack of uniformity of state legislation led to demands for federal regulation. Attempts to secure congressional regulations were set aside by the supreme court in 1918 and 1922 *(Hammer* v. *Dagenhart; Bailey* v. *Drexel Furniture Co.).* In 1924 a child labour amendment was submitted to the states but was never completely ratified. Nevertheless, minimum age standards were incorporated in 500 separate industrial codes adopted under the National Industrial Recovery act (1933–35). In 1936 the Walsh-Healey act was passed with minimum age standards imposed on suppliers of goods produced for the federal government and in 1937 the Sugar act was passed with a minimum age for employment in cultivating and harvesting sugar beets and cane.

But it was the enactment of the Fair Labor Standards act in 1938 that signified the beginning of the end of child labour in the United States. This federal law set the minimum age at 14 for employment outside of school hours in nonmanufacturing, at 16 for employment during school hours in interstate commerce, and at 18 for occupations called hazardous by the secretary of labor. Other state and federal laws, the increasing mechanization of industry, the growth of labour unions and the enlightenment of progressive business and industrial leaders all contributed to the elimination of child labour (except in commercial agriculture, especially the employment of migrant labour, in which area the National Child Labor committee was still working in the second half of the 20th century).

In Europe and Asia, progress was reversed during and after World War II. Children were required to do the work of adults, some even as soldiers. In the most devastated countries, they sank to levels unprecedented in the 20th century, engaging in hazardous and sometimes illicit work.

In 1944, the International Labour conference adopted a declaration that redefined the aims and purposes of the ILO. Further action in 1945 and 1946 provided that any member of the United Nations might become a member by declaring its formal acceptance of membership obligations. Other countries could be enrolled upon the vote of the conference. Much of the ILO's work was devoted to setting standards. The report it published in 1960 on law and practice among more than 70 member-nations showed serious gaps in protection afforded young workers in non-industrial employments, including agriculture and handicrafts. Governments that needed help in formulating and enforcing standards received technical assistance from the ILO. Its experts helped in drafting labour codes and laws containing basic provisions, in setting up labour inspection services and in training staffs. Regional conferences in the 1950s gave special attention to the problems of young workers in agriculture, coal mines, inland waterways and the construction industries and to elementary protective measures needed in the middle east, Asia and Latin America.

The newly emergent countries of Africa sought membership of the ILO soon after attaining independence and by the 1960s were gradually ratifying where possible international labour conventions and modeling their labour legislation on the provisions of the international labour code. Most states inherited from the former colonial administrations laws restricting the employment of children. Legislation in Ghana, for example. dating from 1948 prohibits the employment of persons "under the apparent age of fifteen years" except where such employment is with the child's own family and involves light work of an agricultural or domestic character only. The difficulty has been in providing regular in-

spection to see that the laws are observed. Workers' and employers' organizations co-operate with labour and factory inspectorates in enforcing the law in shops, offices and factories. Other more indirect social pressures have to be brought to bear against child labour on farms and in rural village craft workshops.

With the provision of more schools and teachers for primary education and the rapid expansion of educational programs as undertaken in Ghana and Nigeria, for example, pressures have been exerted on parents and relatives to release their children for schooling. In areas of scattered population boarding schools at the post-primary grade help to keep the elder children at school. If emergent states could continue to support expanding school systems and aim to introduce compulsory free primary education, as did Ghana in Sept. 1961, school attendance inspection would check further child labour offenses.

Resistance to releasing children for school has been found to decline in areas where adults participate in mass literacy campaigns and can see for themselves the positive economic benefits associated with literacy and the acquisition of new knowledge and skills brought by the extension services of health, agriculture and community development departments of government.

The development of patriotic youth movements associated with political parties and, in independent states, with the school system, and the formation of young farmers' clubs are agencies reaching out to the remote country districts and precipitating change. These in turn may bring a new form of exploitation of children and young people in hard physical work, as has been observed in Guinea and the People's Republic of China, through the ambitious construction tasks and projects set by over-zealous party officials.

Information on child labour throughout the world is published regularly in ILO periodicals (the *International Labor Review* and *Industry and Labor).* Information on child labour in agriculture and youth employment in the United States is published by the National Committee on Employment of Youth, a division of the National Child Labor committee, in its pamphlets and periodicals (the *American Child* and *Youth and Work).*

CHILD PSYCHOLOGY AND DEVELOPMENT. Child psychology seeks to give a systematic account of the ways in which the mental processes of children differ from those of adults, of the manner in which they develop from birth to the end of adolescence, and of the mental differences observable between one child and another. Pronouncements on these topics, sometimes based on shrewd observation, sometimes purely fanciful, are to be found in the writings of the early educationists, such as J. A. Comenius, R. Ascham, J. J. Rousseau and J. H. Pestalozzi. But, as a branch of scientific inquiry seeking to establish its conclusions on a firm empirical basis rather than on casual experience or unverified speculation child study is of comparatively recent growth. F. Froebel and J. F. Herbart both insisted that the training of the child, whether at home, in the kindergarten or at school, should be founded on psychological principles; yet for the most part their views on mental development were purely deductive. derived as corollaries to their philosophy of society and mind.

The first attempts at methodical observation were those of Charles Darwin. In 1875 he began to keep a day-to-day record of the progress of one of his own children, collecting and recording the data after the manner in which, as a naturalist, he would have observed some strange animal. A few years later a more elaborate study along similar lines was published by the German physiologist W. T. Preyer (*The Mind* of *the Child,* 1881). This set the fashion for a series of such studies. In 1891 G. Stanley Hall decided that the time had come to establish an American periodical, the *Pedagogical Seminary,* devoted entirely to child psychology and pedagogy. Shortly afterward James Sully founded an Association for Child Study in Britain. During the first half of the 20th century many important researches were initiated in various countries by highly original investigators—A. Binet in France, E. Meumann in Germany, E. L. Thorndike and A. Gesell in the United States and J. Piaget in Switzerland. Nearly every contemporary university has a department devoted to the subject.

METHODS AND TECHNIQUES

As in other branches of modern science, two main types of procedure are used in child psychology: experiment, wherever the essential variables can be deliberately produced or controlled, and observation where experiment is impossible. In both cases every effort is made to secure information in quantitative form. This implies not merely measuring the variables (the chief causes and effects) but also measuring the frequencies with which different values are encountered and the intensity of the relation between two or more variables. As a result, child psychology has come to be largely a statistical study.

Methods.—The techniques employed depend partly on the nature of the problem to be investigated and partly on the available sources of data. The chief methods of obtaining information are the following:

1. Observations by parents, relatives, teachers or social workers, recorded in the form of diaries, school record cards, personal files, official reports or the like.

2. Data elicited by direct questioning of parents, teachers or others concerned, either at interviews or through questionnaires. Whenever possible, the questions are framed so that a quantitative assessment or rating is secured (stating, for example, the frequency with which a certain type of behaviour is noted), or the presumed strengths of particular traits are assessed on a comparable scale (*i.e.,* one that may be compared with assessments obtained in the same way for other children).

3. The past productions of the child himself, surviving in the form of paper records, such as letters, stories, essays, poems, drawings and musical compositions.

4. Memories of childhood set down in an autobiographical document, or given in reply to questions addressed by mail or personally, or compiled from material collected by psychiatrists in the form of case histories.

5. Direct answers by the child when interviewed by a professional psychologist together with incidental notes on his demeanour, and systematic observations on the behaviour of the child at play as recorded by a trained observer; for the latter purpose a special playroom equipped with a one-way window or screen is often used so that the children are unaware that they are being watched.

6. The performances of the child when tested in the classroom or the psychological laboratory; the tests may be either verbal or nonverbal, given in group form to a number of children at once (as in school examinations), or to each individually and alone (as with tests involving elaborate apparatus).

7. The introspective reports of the child explaining (or professing to explain) how certain test problems were attacked and solved, what kind of imagery was used, what difficulties were involved, or again what were the reasons or motives for certain actions; here should be included direct studies of the child's unconscious processes by psychoanalytic procedures, *e.g.,* the familiar techniques of dream analysis or free association.

Problems.—The questions studied by child psychologists fall into three main groups.

1. Attempts, based on actual observation and experiment, are made to describe the course of mental development either of the child as a whole or of some particular function, trait or type of

behaviour. Here two modes of approach are possible: the so-called "normative" approach which takes, as it were, cross sections of the developmental process by examining different individuals, or more often a number of typical individuals, selected to represent successive ages; and the "genetic" or longitudinal approach, which follows up the same child, or the same sample of children, year after year. In both cases quantitative assessments are indispensable for purposes of comparison. Hence the commonest but by no means the only procedure consists in the application of standardized tests.

2. Intensive studies may be made of certain basic mental processes regardless of their history or mode of development. Here, for example, belong the detailed studies of the process of learning and its various conditions and results. A wide variety of methods may be used according to the nature of the process studied.

3. The problems that have been most fully studied are those of individual differences and, in particular, the relative influence of heredity and environment on their nature and degree. Here, in addition to measuring the processes or performances of the child, it is also necessary to measure those of his parents, brothers and sisters and, if possible, other relatives, and also to study and assess the conditions in his material and social environment. Since the basic problem is a comparison of two or more variables, special statistical techniques based on the analysis of variance or the calculation of correlations are needed to secure exact results.

Classification of Mental Characteristics. — If the mental differences between children at different ages, or between one individual child and another, are to be described, it is necessary to adopt some kind of classificatory scheme for distinguishing the essential characteristics, and to use an agreed vocabulary of descriptive terms, each carefully defined. **A** good deal of psychological research carried out on children has been directed toward this end. the main procedure being the statistical technique known as factor analysis. (See PSYCHOLOGICAL TESTS AND MEASUREMENTS: Factor Analysis.) Ancient writers, in particular Plato and Aristotle, and later the scholastics, gradually worked out a simplified scheme based mainly on observation and introspection and expressed in a Greco-Latin nomenclature. This is the basis of the popular psychological vocabulary now used by teachers and indeed by most people. The underlying theory has been progressively modified in the light of later biological, physiological and experimental work, but in the main, with these and other minor rectifications, this traditional scheme has been confirmed by modern statistical research.

Broadly speaking, it appears that we can distinguish between (1) cognitive (*i.e.*, intellectual and practical) characteristics on the one hand and (2) affective and conative (*i.e.*, motivational) characteristics on the other. Further, under each main heading a distinction can be drawn between (a) relatively specific components entering into certain limited groups of characteristics and (b) a more general component underlying the whole set. Thus among the cognitive traits must be considered (1a) a number of special abilities not unlike the old-fashioned faculties, consisting partly of formal abilities such as observation, memory and imagination and partly of capacities for dealing with different kinds of material (verbal, numeral, spatial, visual, auditory and the like). According to the views of British psychologists, we must also consider (*1b*) a general all-round ability called intelligence. Similarly, on the motivational side (*2*), there appear (*2a*) a miscellaneous set of personality traits or tendencies (the simpler corresponding roughly to the old-fashioned instincts or emotions, the more complex to what are variously called interests, sentiments or complexes) and various underlying temperamental characteristics, and (*2b*) a general factor, usually termed general emotionality.

MENTAL DEVELOPMENT

Stages of Mental Growth. — Generally speaking the time required for an animal to become full grown varies with its size: a mouse matures in three months, an elephant in 20 years. If differences in size are allowed for, it will then be found that the period varies with the degree of intelligence attained by the creature when adult. No other creature has so long a period of childhood as the human being. The guinea pig, the lamb and the colt can walk, run and fend for themselves almost from birth; the newborn human baby is helpless. Cats and dogs reach full size and are able to mate when between 12 and 18 months old, gorillas and chimpanzees when they are ten years old; but with man sexual maturity is postponed until about the 13th year and full size and strength until about the 20th. Thus of all living creatures man is allowed the longest time to mature and to learn.

Most of the traditional descriptions of the child's development divide the entire period from birth to maturity into a series of well-marked stages. The limits and the designations of each vary from one writer to another. In general, however, an arbitrary but convenient method which divides childhood into three phases of equal duration is preferred. Indeed it is often maintained that a critical change overtakes the child every seven years, the close of the first being marked by the beginning of the second dentition, that of the second by the onset of puberty, and the last by the legal coming of age. Each of the broader divisions is then commonly subdivided into two successive sections. This yields six stages in all: (1) infancy: (a) babyhood, 0–3 years, (b) early school period, 4–7 years; (2) childhood: (c) junior stage, 7–10 years, (d) senior or prepubertal stage, 11–14 years; (3) adolescence: ***(e)*** puberty, 14–17 years, (f) late adolescence, 18–21 years.

In point of fact, mental development shows no sharp or sudden breaks. It resembles a steady advance up an inclined plane, smoothed by a gentle curve at the beginning and end, not a jerky ascent from one level to another by a succession of clearly defined steps. Nevertheless, for purposes of exposition it will be convenient to keep more or less to the traditional scheme.

General Theories. — Several notable attempts have been made to bring the whole course of mental development under the terms of some general scheme or formula.

Stratification Theory. — One of the most popular theories in the past has been what is sometimes called the stratification theory. The adult mind is depicted as built up of superposed layers or strata, laid down during the successive stages of childhood. This view. it will be noted, treats the distinctions between the several stages as much more than mere conveniences of exposition or administration; it supposes them to be based on certain natural or intrinsic changes. According to an ancient view, the child's sensory capacities are developed first; then his motor capacities (walking, speech, simple manual skills); then memory; and last of all imagination and reasoning. Among modern writers, Jean Piaget has been the most vigorous supporter of the view that development proceeds by a succession of stages. each qualitatively different from the last. He, too. recognizes four main stages with age limits much the same as those indicated above.

Recapitulation Theory. — A somewhat similar theory explains the distinctive features of the various stages, and the regular order in which they unfold, by assuming that they recapitulate the successive phases through which the animal kingdom has evolved in progress from the one-celled organism to man. "Each individual," it is said, "climbs up his own ancestral tree." This recapitulation theory yields subdivisions slightly different from that of the stratification theory and was suggested by the way in which certain features of the human embryo (gill slits, tail, hairy coat) seem to repeat similar features exhibited by its adult ancestors, in much the same order. Obviously the principle cannot be accepted as universally true, since sexual reproduction would then start during infancy and a maternal interest in dolls only toward puberty.

Growth Curves. — Later investigations of the actual course of mental development by means of standardized tests have shown that the essential changes consist mainly in a quantitative increase in the complexity, efficiency and organization of processes which are present in an elementary form at or soon after birth, rather than in a succession of qualitatively different stages with fresh capacities or instincts maturing at the beginning of each. Graphs of physical development (*e.g.*, for height and weight) reveal a slight acceleration in longitudinal growth about the time of the

1st. 7th and 15th years (rather earlier with girls) followed in each case by a longer phase of accelerated increase in breadth and weight, showing a series of "springing up" periods followed by "filling out." There are analogous fluctuations in mental growth, roughly parallel in time to the physical fluctuations, new advances being folloned by periods of consolidation. But, except at the very beginning and end of childhood, the variations in rate of growth are decidedly small, particularly if average data instead of those for single individuals are taken. Indeed in most measurable characteristics, notably memory, reasoning and general intelligence. the annual increments, at least from about age 4 or 5 to 13, are almost equal. so that the curve is virtually a straight line. During the first year or so after birth there is a marked acceleration, and with the onset of puberty a marked retardation; and from age 15 onward the annual increments are almost negligible. Hence the whole curve is S-shaped and can be neatly expressed by the equation for what is called a "logistic" curve — the curve commonly used to describe the growth of both human population and populations of microscopic organisms. Moreover, with this formula the slight rhythmic fluctuations can be included by inserting extra terms. It applies, however. only to those functions in which the changes are quantitative rather than qualitative, and to curves based on averages; curves for individual children are far more irregular.

Each of the foregoing theories contains a minor element of truth, but each would be misleading if treated as covering all the known facts.

Prenatal Development. — Mental development begins well before the child is born. Knowledge of the development of the human fetus is derived from three main sources: (1) reports by the mother of her own experience of the movements of the unborn child; (2) observation of the fetus by stethoscopic, electrical, X-ray and other modes of examination; (3) the study of living fetuses removed by operation where termination of pregnancy has been necessary on medical grounds. In the living fetus the earliest movement of importance is the heart beat, which can be demonstrated during the third week of pregnancy. At the end of eight weeks stimulation of the skin will provoke perceptible movement, vague at first but definitely localized later on. By the fourth month respiratory movements may be detected, though of course the liquid environment precludes true lung breathing At this age the cortex of the brain consists only of a single layer of cells; but it now differentiates rapidly into five main layers, developing from within outward. At birth, the outermost layer, which subserves the highest functions, is still only about half the proportionate depth it attains in the adult. The differentiation starts first in the motor area, then appears in the visual area and finally spreads to the frontal lobes. During the last two or three months of pregnancy it is possible to secure electroencephalograms from the fetus by placing electrodes on the mother's abdomen. Finally, during the last three or four weeks, movement can be provoked by loud sounds, and experiments based on auditory stimulation indicate that something very like learning may occur even before the child is born.

From early times it has been widely believed that the mother's thoughts or experiences may directly influence the unborn child. No doubt if they are serious enough to impair the mother's physical health, the child's general development may suffer as a result. But, except for the chemical interchange between the two blood streams and the transmission of infections or their products, there is no way in which the mother's condition can affect the child.

Newborn Child. — Postnatal development, like prenatal, proceeds partly by differentiation, partly by integration. As a result of the growth that has already taken place before birth, the newborn infant is no mere automaton. He comes into the world as a fairly well organized creature with an extensive repertory of responses, chiefly those needed for the preservation of life (such as breathing, feeding and avoiding painful stimulation>. During the first week or so he is asleep for 60% to 80% of the day, usually in spells of three or four hours. An increasing amount of his waking time. however, is spent in movements which are at first more or less random and spontaneous. In the main, behaviour proceeds from a generalized total pattern of movement to a specialization of partial or localized movements within it. Contractions of the larger muscles, of the muscles nearer the trunk and particularly of muscles nearer the head end are mastered first; control of the finer muscles, of the more distal parts and the lower extremities, much later.

From the outset, however, certain definite reactions are carried out in response to specific stimuli. The earliest are those excited by hunger. At birth the mouth is a far more efficient organ than the hand, both for touch and for prehension. The reflexes for lip searching. sucking and swallowing are all fully effective. As Samuel Pepys noted in his diary (1667), if an infant's cheek is touched the head turns and the lips open to grasp the finger. Visual reflexes also can be aroused, but reactions to auditory stimuli are more difficult to elicit. The birth cry is only a respiratory response; but subsequent cries, evoked by pain, discomfort or any violent stimulation, form a regular part of the innate equipment of the newly born.

The later development of sensory consciousness is similar to the development of movement. The older view, that the child at first experiences separate sensations within himself, then "projects" them into outer space and later still combines them into objects, is decidedly misleading. To begin with (as William James puts it), "the baby, assailed by ears, nose, skin, and entrails at once, feels it all as one great blooming buzzing confusion." Against this general background certain intrusive sensations stand out and seem to attract discriminative notice, and appropriate muscular reaction follows.

After birth there is no further multiplication of the cells in the brain; but their fibres continue to proliferate and branch for some months and, according to some physiologists, for a good many years to come. The motor area is well advanced at 10 or 11 months. The speech area lags behind by several weeks. Of the rest of the brain cortex, the areas for the sense of movement and for vision and then the other projection areas are the earliest to mature. The regions around them develop next. and the so-called association areas last of all. The frontal region is not fully developed until about the fourth year. (See also BRAIN.)

First Year. — For the first few years of life the typical achievements of the average child have been tabulated month by month on the basis of numerous tests and observations, and the results provide a standardized scale for assessing the progress of any given individual. The range of individual differences, however, is considerable. The order in which various capacities or reactions develop is by no means the same for every child; a child may be precocious in one respect and slow in another.

Before the end of the first month the average infant can hold up his head, grasp one's finger and make several sounds besides crying. He follows a moving light with his eyes and is startled by unexpected noises. During the next month or so he shows adaptive changes in behaviour — for example, with regard to feeding habits—which indicate simple learning. On the other hand, some of the earlier reflexes, such as the "suspension grasp" and "startled clasp" (reflexes which some regard as legacies from our arboreal ancestors) soon begin to fade. By the age of six months he has started to crawl, can hold a spoon and will clutch at a ring. Manual exploration now becomes one of his main occupations: he has an urge to touch, finger and grab at all he can reach. By ten months he can stand up when held. By the end of the year he can point with his finger, walk if led, obey simple requests and even articulate two or three duplicated sounds, though rather by way of expressing his feelings in the presence of an audience than with any clear notion that they are associated with definite persons or objects.

During the first few weeks there is little differentiation between the emotions. Soon it becomes possible to distinguish reactions of three types — distress, delight and simple excitement. At one month there is a difference between the cries of pain, of hunger and of mere discomfort; by three months, pleasure is expressed by smiling and vocal gurgling; and a couple of months later it is easy to distinguish between the expression of fear, anger. grief and even disgust (*e.g.,* at an unpleasant taste).

By the end of the first year the child already has a personality of his own. His social consciousness is displayed by sensitivity to approval and disapproval. He can inhibit actions when forbidden, and he becomes shy or coy in the presence of strangers.

Second Year.—By the age of 13 months the average child is able to stand alone and. a week or two later, to walk alone. By the middle of his second year he can pull a toy on a string and climb upstairs, and by the end of the year he can jump, run and kick a ball along the floor. His skill with his hands will have increased: at the beginning of the year he can unwrap a sweet and shortly afterward scribble clumsily with a pencil on paper; at about 18 months he can build a tower of three or four blocks and, by the end of the year, turn a screw, make perpendicular and horizontal strokes and throw a ball into a basket.

The child has now entered the stage of symbolic vocalization. By 14 months the average child is able to use two or three words with an appropriate meaning, and as soon as he discovers that things have names he displays great interest in the process of naming. Wide individual differences are discernible. The gifted child learns to walk a month earlier than the average, and to talk about three months earlier. Girls are slightly more precocious than boys. At 18 months the child should be able to use half a dozen words intelligently and combine them in pairs (*e.g.*, "Bow-wow gone"). By the end of the year he should have a spontaneous vocabulary of 20 words or more and know the meaning of 300 or 400. He can name half a dozen familiar objects and use sentences of four or five syllables.

Fairly dependable bowel control is commonly acquired by about 19 months and bladder control during daytime a month or so later (though delay in achieving such control should cause no concern). At the end of the year the child can give help in dressing or undressing himself. He is now awake for about ten hours each day, and is thus free to get better acquainted with the world around him. Since he can run about by himself, he is becoming more independent of his parents. The natural result is an occasional clash of wills, and, as the psychoanalysts have amply demonstrated, the way the child is treated in these situations during the first two or three years of life may affect his whole character for the future. If another child is born or brought into the house. he may display marked jealousy; and he is still oriented more strongly toward adults than toward those of his own size. At a party or a nursery school he shows far more interest in the things around him than in the persons, and in his play is more likely to ignore other children than to join in their games.

End of **Babyhood.**—During his third and fourth years the child makes rapid intellectual progress. This is shown most clearly in his use and understanding of language, the most intellectual acquirement at this age. Here, however, much depends on his family. Tests of fairly large samples show that by the age of three the average child already uses pronouns. plurals, past tenses and two or three spatial prepositions (for instance "in," "under" or "behind"). At three he can repeat two numbers, at four years three numbers and at five four numbers. At the age of four he can count four pennies, and at five he can copy a square. His talk is no longer concerned only with his immediate wants or feelings but expresses ideas and communicates them to others: in a word, it has become socialized rather than egocentric.

During the second and third years there is, as a rule, a manifest increase in imaginative activity. A large element of make-believe enters into the child's play and gives it a purpose and meaning. When resting, he begins to amuse himself with daydreams. The commonest subjects are the child's own self-glorification, the possession of coveted toys, the presence of an imaginary playmate and fanciful reconstructions of the personalities of those with whom the child is in closest contact. Cinderella's grieving over the death of the kindly mother and the cruelty of the unkind stepmother and her older sisters, and her dreams of a fairy godmother coming to her rescue and gratifying all her wishes, are typical of the fantasies in which many children now begin to indulge. Like other forms of play, these imaginative exercises serve a useful function. The child can consider how he may interpret the world in a more reasonable way, he can think out his wishes and fears without immediately facing the problems of reality, and he can rehearse his own behaviour, and so adapt it a little better to the actual situation when the time arrives.

Throughout this period the child should be gaining increased control over his emotions. Crying that results from distress usually declines, though crying from anger will probably increase. During the third year of life fear is evoked by such stimuli as loud noises, strange persons and being left alone. By the age of five such reactions are quite exceptional. What he now fears are anticipated or imagined misfortunes—accidents, bodily injuries, the dark and being punished or scolded. Anxiety arising from emotional conflict or guilt is increasingly common. Individual emotional differences become more and more conspicuous, varying according to each child's personal experiences and social environment.

Five to Seven Years.—This stage corresponds with the first years of school attendance. The child is now rapidly acquiring a basic notion of the world of reality in which he lives. He has already discovered that objects have a permanent identity. unchanged by motion or temporary concealment; that there is a space surrounding him, in which he and other things can move; and that causal effects can be produced by other agencies besides himself. His knowledge of the life of human beings has hitherto been gained largely by imitating their actions in his play, but now, if he is not unwisely repressed, he will increase his fund of information by badgering his parents with unending questions.

By the age of six he should be able to take fairly good care of himself and to act in a group. He can probably hop, skip and jump, dress and undress, tie a bow and use scissors. He no longer grasps his pencil with a fist-hold but with a finger-hold, and his drawings of men, houses, trains and the like are readily recognizable. His memory is good enough to be of practical service. He can repeat sentences of about 10 or 12 syllables, and execute an order involving three distinct instructions. His retentiveness is rapidly improving, but he learns best by doing, not by sitting down and listening or repeating things mechanically.

Entry into school confronts the child with new social situations. and this results almost at once in new social problems and a rapid social development. Instead of just crying or whining he now expresses his wants and complaints in words; instead of merely displaying temper or force he seeks to work his way through his difficulties by the aid of language. He is able to join in small co-operative enterprises, playing with one or two others at keeping house or shop, or with a larger group in games organized by the teacher. He associates with both sexes quite easily, but on the whole spends more time with his own. Quite frequently he has to defend himself and his possessions, and so becomes conscious of himself as a person with a status. He has developed a conscience and finds it difficult to conceal or to bear any sense of guilt. But as yet he has acquired no broad ethical principles, except the simple maxims of his parents or teachers.

Junior Stage.—During the earlier years of school life the child's performances in various directions are closely correlated. If he is bright, he is usually bright all round; if dull, dull all round. About the age of seven, however, special abilities and disabilities begin to be increasingly noticeable. It will therefore be instructive to consider the various mental processes that are important for school work, beginning with the most elementary—that is, sensory capacity.

At seven the eye of the child is still underfocused and ill adapted for close work. Books for the teaching of reading should therefore be printed in fairly large letters, diminishing year by year to about 11 or 12 point at the age of 11 or 12. At every age girls have on an average a somewhat poorer visual acuity than boys, but their colour discrimination is superior.

By the age of seven, auditory acuity is as good as it ever will be, but the discrimination of pitch continues to improve for three or four years. Throughout the junior period, however, harmony arouses very little interest, and even melody, as a rule, has less appeal than rhythm. The boys' favourite rhythm is the march rather than the waltz. Girls seem to take quite as readily

to triple time as to double, and by age eight or nine, if not before, have already picked up the more popular dance measures.

The kinesthetic sense (the muscle-and-joint sense), through which we feel the position of our limbs and hands and fingers, is of special importance for practical work in school. It increases remarkably throughout the school period and is partly responsible for the rapid improvement in manual dexterity.

The ability to control movement develops later than the ability to interpret simple sensation. During infancy the child learns how to use the larger muscles of the trunk and limbs, and during the junior period he learns the finer control of the more delicate muscles, those of the eye. the tongue and especially the fingers. Throughout these years he is pre-eminently active. The average boy already shows greater muscular strength than the average girl. The difference is as yet comparatively small, but it reveals itself in the differences between the games and the physical exploits of the two sexes. In finer finger work. however. girls are somewhat superior to boys. though in drawing, at least up to puberty, boys are slightly better.

The mental imagery of the child during these earlier years is extremely concrete. The adult. particularly the educated adult, thinks in terms of unspoken words; the child thinks in terms of actual sensations — recalling or imagining the object or situation as it would be presented to the eye, the ear, the sense of touch or movement. During infancy, it would seem, his imagery is largely tactile and kinesthetic. During the junior period, however, the majority of children develop into visualizers, a few into audiles. The particular store of images with which the child's mind gets stocked, the working content of his thoughts, depends chiefly on his immediate environment. Motion pictures. television and, to an increasing extent, books and magazines appreciably enlarge its range; but, except among those who are exceptionally bright, observant or imaginative, it still remains far more limited than teachers generally assume.

It used to be a commonplace of educational textbooks that the period from age 7 to 14 is the best period for memorizing and the period from 14 to 21 the best period for reasoning. Both generalizations are somewhat misleading. Standardized tests reveal nothing like the sudden growth in memory or, later on, in reasoning that is popularly assumed. From the earliest years up to maturity the power to memorize improves at a fairly uniform pace. It appears stronger only because at this stage it is easier for the inexperienced youngster to learn things by rote than to understand their reasons.

Both memory and reasoning work through association; but in mechanical memory the associations between one idea and another are not made conscious or explicit, whereas in reasoning the child not only associates the two things but also perceives how they are related. The commoner and simpler relations such as those of space. time, number, similarity, difference and contrast can all be grasped by the average child before the age of seven, provided the material is sufficiently elementary. Reasoning, however, depends not simply on the direct perception of relations such as these, but on the perception of relations between these relations. At the age of five a child can discover which is the bigger of two boxes or the heavier of two weights. Not until nearly seven can he solve such problems as "Tom is bigger than Jim: Jim is bigger than George. Which is the biggest of the three?" By seven or eight years of age most children can manage the elementary forms of deductive reasoning. Their improvement. as the years go by, consists chiefly in the number and variety of relations they can organize into coherent logical arguments of increasing length and complexity. The systematic study of children's attempts at inductive reasoning is comparatively recent. Much has been done in this direction by J. Piaget and his co-workers. The main conclusion to be drawn from their work is that inductive thinking usually depends, far more than deductive thinking, on a specialized knowledge of the particular subject or field to which the thinker's problem belongs.

During the junior period the child's emotional interests become more objective and more clearly defined. Owing to his growing strength, size and independence he seeks a wider radius of movement. He spends more of his time outdoors, playing in the street if he lives in town. roaming the fields and woods if he lives in the country. The upholders of the recapitulation theory maintain that within the remaining period of childhood (from the age of seven up to puberty) it is possible to distinguish four successive phases, each lasting about two years and corresponding to the hunting, pastoral, agricultural and commercial stages of primitive man. Although children's spontaneous play exhibits much that seems to support this parallel, the exceptions in regard to ages and order are too numerous to justify any assumption of direct biological transmission. At the beginning of the junior period the child's play is still for the most part individualistic. Even when two or three children are playing together, each child still tends to play against the others rather than with them. Among the youngest, simple games of chase are extremely popular, and much time also is spent in hurling things, aiming at targets with sticks or stones, and hunting birds or stray cats, often regardless of cruelty. This is followed by games of competition — fighting, wrestling and mimic combats with toy pistols or imaginary machine guns. Indoors, boys become increasingly attracted by tales of battles by sea or land, films of heroic adventure and television thrillers. With girls these self-assertive impulses come to the fore in a different way; they love to dress up. dance, recite and pose in front of an audience, and before the junior period is over some will be secretly trying the effects of cosmetics. After World War II, however, a liking for boyish activities and for stories or programs intended for boys became increasingly common among girls.

Puberty and Adolescence — According to the recapitulation theory, the stage of adolescence represents in the individual the final phase of the evolution of the race — that which marked the transition from the primitive to the civilized era. At this stage, it is supposed, a new group of innate faculties and impulses emerges and matures. The doctrine is still widely accepted by teachers, educationists and those who write about teen-agers, but the element of truth it contains is rather slender, and the majority of psychologists incline toward a simpler theory. All the apparent modifications that take place at this stage, they hold, are really secondary effects of one fundamental change — the maturing of the sex glands. Yet even this theory demands some qualification. First, the psychological changes do not show anything like a constant relation to the physiological changes; they arise sometimes earlier, sometimes later, and are spread out more widely. Puberty in fact is not a sudden crisis but rather the culmination of a long process of growth which has been proceeding steadily from birth, though at varying rates in different individuals. Secondly, as later research has shown, many of the psychological characteristics that once were commonly supposed to result from internal physicochemical changes are to a large extent determined by external alterations in the scholastic, domestic and financial circumstances of the individual; for example, in those social classes in which children leave school or college comparatively late, appearance of these characteristics is appreciably delayed.

On the intellectual side, the most noticeable feature of the whole pubertal period is the way in which mental growth, like physical, gradually slows down and comes eventually to a halt. This is most clearly seen in the average measurements of general intelligence at successive ages. There is first, at an age that seems to vary with the age at which the pubertal period begins, a slight quickening of the pace, and then toward 13 the annual increments get smaller and smaller, until after about 16 it is hard to detect any further increase. Again there are wide individual differences. The brighter children continue developing till a later age than the others; the dull and defective come earlier to an arrest. Changes in special abilities are somewhat more irregular. During early adolescence nearly all boys and many girls become for a time more clumsy and amknard in their movements and untidy in their general behaviour, as may be seen, for instance, in the deterioration in handnriting that is so often noted. The growing reliance on speech, reading and bookwork tends to make mental imagery increasingly verbal, particularly among the brighter boys. Just after puberty, particularly among girls, there is often an outbreak

of creative imagination. Daydreaming, sometimes morbid, sometimes helpful (as in thinking over possible careers), becomes for a while much commoner and at times concentration on work is apt to suffer.

Reasoning now undergoes a change of type. Up to the age of about 10 or 11 it proceeds roughly in conformity with the traditional subject-and-predicate logic, but thereafter the child tends increasingly to argue in terms of propositions. This becomes obvious if what is implicit in his thinking is written out in a formal notation: with the younger child little more than the calculus of classes is required to express his arguments; with the older, inferences belonging to the calculus of relations and propositions become increasingly frequent. The tendency to reason in propositions results largely from the growing habit of discussing things self-consciously with other people, particularly other children ("Jim said it's a bird; but everybody knows birds have feathers; if you ask me, I'd say it was a bat"). Children, of course. are as unfamiliar with the laws of logical syntax as they are with those of grammatical syntax. They pick up both by incidental learning in the form of implicitly apprehended schemata, blank frames that are filled in by the concrete data suggested. Just as the rules of grammar can be taught, so (as a few enterprising schools have shown) logical techniques may also be taught with appreciable benefit to the child's way of thinking and behaving.

It is. however, changes in emotional, social and moral attitudes that distinguish the period of adolescence most conspicuously. To begin with, the final maturing of the reproductive system strengthens the sex instinct, and a marked interest in the opposite sex now manifests itself in the majority of youths and girls. As with many animals toward the mating season, there is an increasing fondness for personal adornment and self-display. Gregarious tendencies are shown by the growing frequency of team .games and informal clubs or cliques. During the preadolescent stages boys in particular begin to cling more closely together in little bands or social groups. When they leave school, they are apt, in the absence of other facilities, to form organized gangs of their own. They invent codes, passwords and perhaps a secret language. They engage in spirited enterprises and predatory ventures which may end in downright delinquency. Play becomes increasingly rough; and humour takes the form of slapstick comedy and practical jokes. at times amounting to thoughtless cruelty. Power is sought and enjoyed for its own sake, regardless of consequences. Thus nearly all the primary emotions are for a time intensified, and as a result the teen-ager appears a bundle of contradictions, now shy, now aggressive, at one moment yearning for solitude and the next for company. Hysterical laughter or giggling is followed by a spell of dejection or weeping and even thoughts of suicide, violence to persons or property by moods of heartbroken penitence. He may, in short, exhibit an emotional instability which at any other stage would be regarded as a definite neurotic disorder. With British children these tendencies reach their height at about 15 or 16; with American children, it would seem, a year or two earlier.

On the social side there is at first an increasing impatience of authority and at times an obstinate independence of parental control. The adolescent, whether boy or girl, tends more and more to adopt the code and the attitude of others of his own age rather than those of the adults around him. This may even bring with it a stubborn resistance to traditional conventions. Yet all the time the consolidation of these different emotional tendencies is going on apace. Codes of behaviour, guiding interests. sentiments for various persons, repressed emotional complexes, ideals, good or bad, moral or nonmoral. are being shaped and finally fixed. Adolescence is thus a crucial period in the formation of character. It includes the peak ages for juvenile delinquency and the periods during which religious problems and religious experiences are most profoundly felt. (See also ADOLESCENCE).

INDIVIDUAL DIFFERENCES

The picture of mental development outlined above is that of the average child brought up in an average civilized environment. Each child is a unique individual, however, and few are average in all forms of behaviour. Since most people (including teachers, educationists and many psychologists) are familiar only with one narrow section of their own community, they seldom realize the vast range of individual variation. The investigation of such differences has been carried out chiefly during the school period as it is then easier to obtain representative samples of complete populations or age groups. Detailed information about the child's personal and family history can be more readily procured, and the children themselves have more time to spare for interviews and tests and are well accustomed to being questioned and examined.

The main problems of such research are to determine first the nature and extent of the differences among individuals and secondly the causes or conditions which tend to produce them. so that they can, if necessary, be forestalled or remedied. The causes themselves fall under two main headings: (1) genetic (or, as they are popularly termed, inborn or hereditary) factors and (2) postnatal or environmental factors. All observable characteristics are the product of both, each set interacting with the other.

The characteristics most strongly influenced by genetic constitution are those that are most immediately dependent on anatomical structures (*i.e.*, on the sense organs and various parts of the central nervous system) or on biochemical influences (*e.g.*, the hormones secreted by the endocrine glands). The laws governing the hereditary transmission of such characteristics are the same as the laws that govern the transmission of bodily characteristics; viz., the so-called Mendelian principles. Most mental differences are quantitative rather than qualitative. a matter of tendency rather than type, and so far as they are innate, they must therefore be the result of multifactorial inheritance; *i.e.*, of genes whose effects are small, similar and cumulative. The distribution of such differences conforms with the so-called "normal" curve: average or intermediate grades are the commonest, and the larger the deviation from the mean, the rarer it is. Moreover. contrary to popular opinion, inheritance, as thus determined, is responsible not only for resemblances but also for dissimilarities. Hence occasionally quite bright children may be born to parents who are extremely dull.

So far as intellectual differences are concerned, the characteristic most fully studied is innate general cognitive ability or what older psychologists called "intelligence." As we have seen, during the early years the child's mental development is largely dependent on this initial capacity, since environmental influences have not yet modified the effects of heredity. and more specialized abilities or disabilities do not, as a rule, manifest themselves until later. Differences in intelligence can be roughly assessed by intelligence tests; but such tests need to be constructed, applied and interpreted by trained psychologists. About 75% of the differences so revealed are attributable to genetic constitution. (See also PSYCHOLOGICAL TESTS AND MEASUREMENTS.)

The range of the differences is unexpectedly wide. Among 1,000 children aged 10 by the calendar, the dullest may have a mental age of only 4 or 5 and the brightest one of 15 (that is, in terms of the intelligence quotient a range of 50 to 150); in larger groups these limits will be exceeded. The amount of deviation increases with age: a child who is retarded by 1 year at the age of 5 will be retarded by 2 years at the age of 10 and by 3 at the age of 15. This is one of the reasons commonly urged for classifying pupils of 11 and upward in different "streams" or different schools. To some extent the differences are related to differences in social class, but within each social class the individual differences range over 80 or 90 points and the absolute number of gifted children in the lower social classes, owing to the greater size of the group, greatly exceeds the number in the professional classes. (*See* RETARDED CHILDREN.)

In order to give each child the type of education his particular allowance of ability deserves, it would be desirable to assess his innate potentiality at the earliest possible age. Longitudinal studies, In which children have been followed up during the whole school period and often to the time when they have settled down to their adult occupations, show that such attempts are only

partly successful. Except in cases of gross mental deficiency, estimates of ability made before the age of six are highly unreliable. Even after that age, scores obtained at a single sitting are still not accurate enough for scientific research. In studies where the assessments have been based on at least two examinations at the beginning and end of the follow-up period, there is a fairly high agreement; with intervals of 10 or 15 years, correlations between 0.65 and 0.75 have been reported.

By "special abilities" the psychologist understands those hypothetical capacities which make for efficiency in particular fields of work, over and above that conferred by general intelligence. Here the differences are far more difficult to assess and far less is known about their inheritability. According to the rather meagre evidence, it seems that special abilities (and disabilities) for verbal, numerical and manual work, for mechanical memory and for certain types of imagery often run in families. The occurrence of infant prodigies in mathematics and music suggests that such gifts rest in part on a genetic basis. But the widespread notion that every child can be classified into one of three types—intellectual, practical and technical—at the age of just over 11 is grossly mistaken. During adolescence specialization becomes much more clearly marked, though it is always difficult to say how far it is due to late-maturing genetic differences and how far to emotional or environmental factors—to new interests, for example, resulting from personal motivation and external influences rather than from a specific intellectual endowment.

The motivational factors themselves are far more susceptible to social than to intellectual influences. As we have seen, the chief genetic bases appear to be inheritable differences in what older writers termed instincts, with their associated emotions. And there is some slender evidence that an excessive strength of such primitive impulses as anger, fear, sex and possibly migration tends to run in families. General emotional stability is almost certainly determined to a large extent by the individual's innate constitution, and the differences which suggested the ancient doctrine of temperaments must also rest in part on genetic variations (see TEMPERAMENT). According to this doctrine (modified by factorial research and formulated in modern terminology) it is pbssible to classify most individuals according to four main tendencies arranged in antithetical pairs, extrovertive and introvertive, euphoric (optimistic) and dysphoric (pessimistic). The differences are largely a difference of degree; and here, too, the mixed or mediocre types are as usual the commonest.

In the main, however, the development of character consists in the progressive organization of the child's emotions about certain key ideas to form what are variously called sentiments, interests, attitudes or complexes. The earliest relate to persons—mother. father, sisters and brothers—and the later to teachers, playfellows and friends. Impersonal sentiments relate to possessions, hobbies, games and later on to various intellectual pursuits. Many of them, as the psychoanalysts have shown, may be more or less unconscious. Here lie the most important clues to differences in individual personality. The sentiment which exerts the widest influence on behaviour is the child's "self-regarding complex" or "ego-ideal" as it is sometimes termed. How far these various character qualities can be assessed by projection tests, clinical interviews and the like is discussed elsewhere. (See also EGO; ATTITUDE; SENTIMENT; PSYCHOLOGICAL TESTS AND MEASUREMENTS: Tests of Personality and Temperament.)

Within a free society the status eventually attained by a particular child when he reaches the end of the developmental period depends on three main factors. Their mode of operation has been admirably elucidated by studies of social mobility carried out in the United States, Great Britain, France, Sweden, Denmark and Belgium, in all of which the main conclusions are virtually the same. First, the child's innate general capacity sets an upper limit to what he can ultimately achieve but is seldom the deciding factor. In an industrial community with a modern educational system, it will (with a few notable exceptions) be the child's educational attainments rather than sheer intelligence that determines his eventual vocation; and the education he receives may still depend partly on the financial resources of the family or the opportunities available in his district. Secondly, within the limits which intelligence has set, motivational factors are of prime importance, and these depend not merely on the strength and stability of the child's innate temperament but also on the interests and aspirations that he has acquired during his earlier years. Thirdly, and perhaps most influential of all, there is the continued pressure of the child's social environment. The aims, the ideals, the daily urging of his parents will affect him chiefly during the more plastic stages of his mental life, though their effects will not always take the direction intended. The parents' influence on the child's development, intellectual as well as motivational, is strongest in the smaller family. But the parents' attitudes will in turn be largely the product of the system of customs and values that prevails in the social groups to which they belong. As the child grows older, these various social influences will tend to affect him more directly, notably through his companions. The school itself has to take all this into account, and its guiding purpose therefore should be to determine, at the earliest possible age, the child's intellectual and temperamental potentialities; then to direct and develop them so far as may be practicable; and, finally, to equip him for that type of career for which nature seems to have marked him out. See PERSONALITY; PSYCHOLOGY; CONCEPT FORMATION, PSYCHOLOGY OF; EDUCATIONAL PSYCHOLOGY; see also references under "Child Psychology and Development" in the Index volume.

CHILDREN (ARTICLES ON). The principles of child care from birth until the walking-alone stage are outlined in INFANCY. The physical and mental progress of the typical child from infancy through the various preadolescent stages and adolescence, and the signs of adjustment that may be observed in each phase of growth, are described in CHILD PSYCHOLOGY AND DEVELOPMENT.

CHILDREN, DISEASES OF discusses the major hazards to child health, and the advances of modern pediatrics in overcoming them. Nutritional problems are described, in conjunction with those of adults, in DIET AND DIETETICS; NUTRITION; and VITAMINS.

Among the articles and sections of articles in which psychological questions are treated are PSYCHOLOGY, ABNORMAL; DEFENSE MECHANISMS; PERSONALITY: Social *Influences* on Personality; and PSYCHIATRY: Child Psychiatry. PSYCHOLOGICAL TESTS AND MEASUREMENTS discusses various types of aptitude, intelligence and personality tests. RETARDED CHILDREN deals with the problems of physically and mentally handicapped children; exceptionally gifted children are discussed in GIFTED CHILDREN. The problem of the left-handed child is treated in HANDEDNESS.

Articles concerned with the legal status of children include CHILDREN, LAWS COXCERNING; and CHILD LABOUR. Delinquency is treated in BORSTAL SYSTEM; CHILDREN'S COURT; and JUVENILE DELINQUENCY.

DAY NURSERY discusses facilities for the care of young children of working mothers. Provision for orphaned and abandoned children is described in ADOPTION and CHILD WELFARE.

Articles devoted to children's organizations include BOY SCOUTS; BOYS' BRIGADE, THE; CAMP FIRE GIRLS; GIRL GUIDES; GIRL SCOUTS; FOUR-H CLUBS; and FUTURE FARMERS OF AMERICA. The origins of familiar games are discussed in CHILDREX'S GAMES AND SPORTS. The history of juvenile literature is summarized, and the best-loved works of various eras and styles are cited, in CHILDREN'S LITERATURE.

SCHOOL AND CURRICULUM gives a survey of educational principles and methods, and the evolution of these is summarized in EDUCATION, HISTORY OF. PRE-ELEMENTARY EDUCATION is devoted to the education of children of the youngest age group. Among many articles dealing with the older groups are ELEMENTARY EDUCATION and SECONDARY EDUCATION. Educational topics of a general nature are treated in such articles as COEDUCATION; PARENT EDUCATION; and the articles listed in EDUCATION (ARTICLES ON). The child is discussed in the context of society in CIVILIZATION AND CULTURE: Role of Childhood, and in FAMILY: *Influence of the* Family on Individual Personality.

CHILDREN, DISEASES OF. The major developments in pediatrics, the special branch of medical science that deals with the prevention and treatment of diseases of children, took place after the turn of the 20th century. Prior to that time there existed but little exact knowledge of, or great interest in, the special problems of child health. Infants and young children were regarded merely as miniature adults whose physical, mental and emotional disorders required no special consideration beyond that afforded mature persons. As a result of this attitude and the undeveloped state of medical science and practice, the incidence of disease and the mortality rates among children were appalling; 20% to 40% of all infants born alive died during the first year of life. Of the total deaths in the entire population, three out of four occurred in children under 12 years. However, as a result of revolutionary advances in the field of pediatrics and intensive application of sound public health principles, death rates among children in the more advanced parts of the world had been reduced by the early 1960s to one-tenth of those figures.

Differences in Children. — One of the most important steps in the progress of modern pediatrics was the recognition by both medical practitioners and laymen of certain fundamental differences between the child and the adult. Because of his state of immaturity, the infant or young child differs from the mature person physiologically, psychologically, immunologically and anatomically. The constant changes in functional patterns incident to growth and development impose different standards for health appraisal and for nutritional, medicinal and other health requirements in the very young.

Throughout the wide range of diseases affecting infants and children, the concept of prevention predominates that of treatment in the mind of the properly oriented physician. Fortunately, advances in the sciences of genetics, nutrition, microbiology, immunology, epidemiology, hygiene and sanitation made it possible for medical practitioners and public health officers to exercise a large measure of control over many of the most devastating physical diseases. Improvements in diagnostic laboratory techniques together with revolutionary developments in pediatric surgery and treatment with drugs and immune blood serums reduced the dire effects of certain nonpreventable diseases to a minimum as well.

Classification of Diseases. — The diseases that affect infants and children may be classified according to the nature of their causes, the particular organ systems primarily involved or a combination of these methods. Since pediatrics is based upon the concepts of growth and development of the individual. the pediatric physician must take into account, so far as is feasible, all factors known to influence the orderly course of these normal processes from the moment of conception throughout the periods of infancy, childhood and adolescence. For example, such determining factors as heredity, prenatal influences (including maternal illness) and injuries incident to the process of birth explain most cases referred to as diseases of the newborn.

Hereditary and Congenital Disease. — Examples of the hereditary diseases are hemophilia, erythroblastosis fetalis, familial periodic paralysis, certain nervous and mental diseases, many cases of inborn errors of metabolism and a tendency to allergic disorders. such as infantile eczema and bronchial asthma. Of the congenital diseases known to be acquired by the infant before birth as a result of maternal disease, syphilis, toxoplasmosis and certain anatomical anomalies, *e.g.,* congenital cataracts and possibly malformations of the heart, are best known. Prematurity of birth, the leading cause of mortality among infants, is caused in the main by fetal anomalies or by impaired health of the mother during the period of gestation. Accidents incident to the birth process, such as asphyxia (suffocation), brain hemorrhage, fractures and muscular paralyses, may result in immediate death or may be followed by such consequences as retarded mental development, epilepsy and cerebral palsy.

Nutrition Disorders. — Disorders of nutrition, together with the alimentary or enteric diseases, presented the most serious of all problems involved in the care of infants and young children prior to the time when their specific causes were discovered. Thereafter, however, it became possible to prevent the major number of these entirely, or to effect a cure in most instances, once the disease had developed. The nutritional requirements of children for normal growth and development and for normal functioning of the organ systems of the body are greater, in relation to the individual's size, than those of mature men and women. The essential food substances required are water, protein (essential amino acids), energy foods (carbohydrates and essential fatty acids), vitamins and minerals (calcium, iron, iodine, magnesium, potassium, sodium, phosphorus, chloride, sulfur and the so-called trace elements).

Prolonged deficiency of any one or any combination of these essential nutritional factors causes more or less specific symptom complexes. (*See* MALNUTRITION.) For example, unless water is furnished for young children and infants in required amounts, a state of underhydration ensues. This is manifested by dryness of the skin and mucous membranes, fever, interference with normal circulatory and secretory functions, and obvious discomfort from intense thirst. Severe protein privation in the young interferes with building new and maintaining pre-existing protoplasm in the living cells of the body and interferes with blood protein formation. Insufficient intake of fats and carbohydrates to satisfy the energy needs of the body likewise limits growth. Of the minerals, calcium and phosphorus are required for bone formation and for certain other vital cellular functions. Magnesium plays a role in cellular function somewhat similar to that of calcium. Sulfur derived from certain essential amino acids of the diet (methionine and cystine) plays a specific role in the formation of certain all-important substances, such as enzymes, insulin and glutathione. Iodine is essential for synthesis of thyroxin, the hormone secreted by the thyroid gland that is essential for normal growth and development. Iron is an essential constituent of the red blood cell pigment, hemoglobin, which carries oxygen from the lungs to all parts of the body. A deficient intake of this element results in the development of a common form of anemia. The monovalent elements (*e.g.,* sodium and potassium), which together with the chloride, phosphate and bicarbonate ions constitute the chief electrolytes in the body fluids, serve essential roles in maintaining the normal chemical environment of all living cells, as well as the normal acid-base balance. Alterations in their concentrations in the body fluids, whether caused by certain endocrine disorders, kidney disease, diarrhea, vomiting or profuse sweating, produce serious illness.

Vitamin Deficiencies. — Specific diseases develop from vitamin deficiencies in the diet. Deprivation of vitamin A manifests itself as xerophthalmia (conjunctivitis) and also as night blindness arising from disturbed function of the retinal enzymes and pigments. A variety of disease states occur in infants and growing children deprived of different members of the vitamin B complex. The best known of these are beriberi (caused by lack of thiamine); pellagra (deficiency of niacin); ariboffavinosis (lack of riboflavin) and megaloblastic anemia of infants (lack of folic, or folinic, acid and vitamin B_{12}). Dietary deficiency in vitamin B_6 or pyridoxine is one known cause of convulsions in infants. Scurvy is caused by inadequate amounts of ascorbic acid (vitamin C) in the diet. Rickets is caused by a deficiency of vitamin D in the diet, unless the skin is exposed directly to ultraviolet light waves. Hemorrhagic disease of the newborn infant is caused by a relative deficiency of vitamin K in the mother's diet during her period of pregnancy. These deficiency diseases rarely occur, however. if the diet contains sufficient amounts of natural foods. including milk, meats, egg yolk, fish liver oils, fresh citrus fruits,

green vegetables, salt and water. Cure of existing vitamin deficiency diseases is accomplished most promptly by administration of the missing vitamin in concentrated or synthetic forms. Many genetically conditioned diseases are known to be due to absence or dysfunction of essential enzyme systems. Some of the latter are related to hormonal and vitamin actions.

Diseases Caused by *Organisms.*—Many serious diseases of childhood are caused by pathogenic or parasitic living organisms. Such diseases are classified into general categories according to the type of pathogen responsible for the particular disease state. For example, there are (1) the bacterial diseases, caused by microscopically visible germs; (2) the viral diseases, caused by specific viruses too small to be seen with ordinary optical microscopes; (3) the rickettsia1 diseases, caused by an intermediate type of microorganism; (4) the mycotic diseases, caused by invasion of the tissues by certain plant molds or moldlike organisms; (5) the animal parasitic diseases, caused by unicellular animal parasites (protozoa); and (6) the diseases caused by infestation with comparatively large and complex animal parasites, such as worms.

Most of the communicable diseases customarily referred to as childhood diseases are caused by pathogenic organisms. For information about these diseases, such as mumps, measles and whooping cough, see articles under the disease name and BACTERIAL AND INFECTIOUS DISEASES.

Respiratory Diseases.—The common respiratory diseases of infancy and childhood, such as the common cold, infantile pneumonitis, influenza, atypical pneumonia (all caused by specific viruses) and the bacterial pneumonias (caused by various types of bacteria) are more serious infections in infants than in older children. While attempts to prevent them by vaccination had met with no success by the early 1960s (except for short periods in the case of influenza), sulfonamide and antibiotic drug therapy had proved to be amazingly effective in the treatment of infections caused by bacteria. Unfortunately, such therapeutic agents are far less, if at all, effective in the treatment of respiratory diseases caused by viruses.

Tuberculosis.—The treatment of tuberculosis is greatly improved if the combined use of three antituberculous drugs—streptomycin, isoniazid, para-aminosalicylic acid—is begun early in the course of the disease. The value of immunization with attenuated tubercle bacilli (BCG [Bacillus-Calmette Guérin]) remains controversial. Among populations where the disease incidence is comparatively low and where it is feasible to discover and isolate active cases through community-wide programs of tuberculin testing and chest X-ray surveys, attempts to immunize would appear to be unnecessary.

Congenital Syphilis.—Congenital syphilis can be prevented by treating the mother with antibiotics or arsenical drugs before the infant is born, or it may be cured in the infected baby or older child by use of these drugs.

Cystic Fibrosis.—This childhood illness was first recognized as a separate disease entity in 1938. Its cause is unknown although apparently linked to inherited metabolic defects. The disease is expressed by two main sets of symptoms: a voracious appetite without gain in weight and a persistent cough that fails to clear the respiratory tract of the thick, sticky mucus that accumulates there and interferes with breathing or leads to secondary infections such as pneumonia or bronchitis. It is believed that about one child in 600 live births is affected. The symptoms may appear immediately after or several years after birth. The disease has a high (80%) mortality, although mild cases may survive to adulthood. By the early 1960s no cure for the disease had been established, although patients were helped by a diet high in protein and calories but low in fat, supplementary feedings of vitamins A and C and the administration of antibiotics and extracts of pancreatic juices from animals.

Other Organic Diseases.—Meningitis, lymphadenitis (inflammation of the lymph glands) and bacteremia (bacteria in the blood), caused by meningococci, streptococci, pneumococci, staphylococci, *Hemophilus influenzae* and certain other bacteria, can usually be treated successfully with sulfonamide and antibiotic drugs. Infections caused by the gonococcus yield readily to modern chemotherapy also, as do typhoid, typhus and malarial fever.

Many of the congenital malformations of the heart and blood vessels. the gastrointestinal tract, the nervous system and the extremities are amenable to surgical treatment.

The underlying cause of acute rheumatic fever is repeated streptococci-infections. Chronic rheumatic heart disease may be a serious complication. Reappearance of streptoccal infections can be prevented by serial treatments with penicillin in small doses.

Advances in endocrinology made possible the successful hormone treatment of such disorders as diabetes mellitus, spontaneous hypoglycemia, diabetes insipidus, parathyroid tetany, adrenal insufficiency, adrenal hyperactivity, pituitary insufficiency, hypothyroidism and certain diseases of the sex glands.

Mental Disease.—Mental, emotional and social maladjustments in children have tardily gained recognition as having health significance quite comparable with that of the common physical or organic diseases. The functional and organic components of a child's illness may at times be so thoroughly fused as to require use of the special techniques of the psychiatrist for its successful diagnosis and treatment. Appreciation of this fact gave origin to the branch of child psychiatry designated as psychosomatic pediatrics. Prevention of such disorders by consistent application of proper mental hygiene is obviously of paramount importance.

CHILDREN, LAWS CONCERNING. Since the middle of the 19th century there has been a steady increase in legislation designed to protect children from ill treatment and to offer them the advantages of secure and healthy childhoods. The present article is primarily concerned with the deveiopment and content of such legislation in England and the United States; certain aspects of the law relating to children in other countries are discussed in the articles devoted to particular legal systems, such as FRENCH LAW AND INSTITUTIONS; GERMAN LAW; ROMAN LAW. Additional material on law, as well as related services and institutions, is contained in CHILD LABOUR; CHILD WELFARE; SOCIAL SERVICE. Special topics are treated in ADOPTION; BASTARD; LEGITIMACY. For the legal responsibility of children, see CHILDREN'S COURT; CONTRACT; CRIMINAL LAW.

ENGLAND

Legislative Development.—The tendency to intervene in family care of children where it falls short of standards set by the state is of recent origin. Under the *patria potestas* of Roman law, wide powers of life and death were allotted to the head of the family. These powers were not carried over to the European feudal systems of law, although these systems reflected Roman civil law in stressing the family's importance and in maintaining strict controls by means of the family council and curatorship over children. In England, however, there was no general legal principle that all children must have guardians. As a result, child protection doctrines evolved slowly. Under the common law, guardianship, an outgrowth of feudal land law, conferred a right that was profitable to the guardian. Only gradually did guardianship become a trust for the benefit of the ward. By the 13th century, rights of wardship were recognized which enabled a feudal lord, upon the death of a tenant leaving an infant heir, to administer the tenant's estate as guardian during the heir's minority. English law, by the Statute of Marlborough in 1267, penalized the guardian for waste but did not require that he be called to account for any other type of abuse.

Over several centuries, guardianship, whether of the natural parent'or other guardian, has slowly been recognized as including the right of custody of the child, control over his education and religious training, consent to his marriage, right of chastisement,

right of enjoyment of his services, and control of his estate subject to the use of a sufficient portion for his education and maintenance. By an act of 1660 the father was given power to appoint by will or deed a guardian for his children to act after his death. Between this date and the Guardianship of Infants act, 1886, the mother was helpless to interfere with the father's appointment. Under provisions of this act, however, she could be designated as guardian if the father had made no appointment, or as joint guardian if he had, and she was also permitted to appoint a guardian to act after her death. In 1925 legislation placed the parents on an equal footing regarding the guardianship of their children. Similar progress has occurred with respect to rights of custody. In the course of a century the mother's position improved from one of utter subjection to the father's will to an equal or perhaps even superior claim to custody.

In England, the court of chancery, in the delegated exercise of the authority of the sovereign as *parens patriae*, assumed wardship if rights of guardianship were abused, and applied the property as far as necessary for the maintenance of the child. The courts gradually acquired control over abuse of the power of chastisement and heard actions for assault against the person concerned, whether parent, guardian, teacher or employer. If punishment resulted in the death of the child, the charge was for murder or manslaughter.

Guardianship law, as it evolved, concerned children who were heirs to land. If a child had no property of his own, legal provision for his care and supervision was sadly lacking. Although provision by way of grant of relief mas made for destitute children as early as the 1601 poor law, not until 1889 were poor law officials authorized to assume parental rights of control over deserted children. The authority of the poor law officials was further extended in 1899 to include orphans and children of parents who were disabled, imprisoned or unfit to care for them. In the same period the position of private "rescue" societies devoted to the care of children of neglectful parents was strengthened by passage of the Custody of Children act, 1891. It authorized the courts to refuse to enforce a parent's right to the custody of his child if the parent had abandoned or deserted him or was unfit to provide for his care. Similar powers were developed in continental countries, particularly in France and later in Belgium and Denmark.

In Great Britain and on the continent of Europe the growth of children's laws extended to the protection of life, the prevention of ill treatment or cruelty, the regulation of dangerous occupations, the imposition of employment restrictions and the compilation of a great children's charter. In England ill-treatment proscribed by law originally consisted of blows. or threats and was gradually broadened to include neglect to supply necessaries. The Offenses Against the Person act. 1861, imposed punishment for the exposure of infants and for neglect or ill-treatment of apprentices or servants. The Poor Law Amendment act, 1868, made it an offense for parents to neglect to supply necessaries (*e.g.,* food, lodging, medical aid and clothing) for their children. At the instigation of the National Society for the Prevention of Cruelty to Children, a series of statutes aimed at preventing cruelty to children in their own homes was passed in 1889 and progressively extended between 1894 and 1933.

Measures to protect life included the Infant Life Protection act of 1872, passed one year after a parliamentary investigation of baby farming (the boarding of infants for pay), and a similar act of 1897. as well as an act of 1908 protecting infants maintained for pay by foster parents. Infant life protection laws were buttressed, commencing in 1874, by statutes providing for compulsory registration of births and deaths.

The 19th century was punctuated by struggles over the regulation of child employment in England, the United States and continental Europe. In all countries the initial stage of the child labour movement was marked by an appeal for shorter hours of work. Legislation in England initially concerned the labour conditions of apprentices and of chimney sweeps, on whose behalf efforts were made for a century before effective regulation of chimney sweeping was secured. The Health and Morals of Apprentices act, 1802, limited the child's workday in cotton mills to 12 hours, prohibited night work, and required instruction in elementary subjects. The Factory act of 1833, which further limited the hours of work to nine per day, extended regulation to all textile industries and introduced a scheme of national inspection to secure enforcement of the restrictions on employment. The history of child labour legislation in England may be traced through various industries as one type of employment after another came within state regulation. By the late 19th century more adequate machinery for the enforcement of regulatory standards had been created and certain occupations of a particularly hazardous nature had been altogether barred to children. Restrictions on the employment of children in casual occupations and amusements were finally imposed in 1903 and extended by the Education acts of 1918 and 1921 and the Children act of 1932. The employment of children in injurious work, in street trading, or at night was prohibited.

Paralleling the enactment of child labour laws was a series of education acts passed in the late 19th and early 20th centuries. The parent's obligation to educate his child, like the obligation of support, was one of the common law's "imperfect," or unenforceable, duties. Because the obligation existed, however, the earliest education laws dealt only with the instruction of destitute children. Beginning with an act of 1834, poor law officials had a responsibility for the elementary education of all children under their care. The education of children who were employed in mills and factories was provided for in the factory acts, which required instruction periods as one aspect of the regulation of child labour. The pattern of half-work, half-school which became popular in England can be traced to these beginnings. The year 1870 marked the passage of the first piece of comprehensive education legislation, the Elementary Education act, which permitted every school board to compel parents to send their children to school. Six years later the law asserted it to be a parental duty to cause every child to receive efficient elementary instruction and provided penalties for failure to discharge this duty.

By the beginning of the 20th century a belief in the obligation of the state to provide general protection for children was gaining acceptance in countries of the western world. England's Children act of 1908 was looked upon as signifying the new point of view. This act. a consolidating measure which drew together for the first time the amending laws and piecemeal legislation accumulated over several decades, publicly emphasized the social rights of children. It embodied the earlier laws for infant life protection and prevention of cruelty to children. Protective measures for child health and morals controlled the sale of tobacco and prohibited the presence of children in brothels, in bars and on street corners for the purpose of begging. Progressive changes were made with respect to the hearing of charges in juvenile courts, and a large number of statutes relating to probation and the reformatory and industrial schools were consolidated. The act also contained a provision for visiting and inspecting the voluntary homes widely used by the poor law officials in an effort, which proved to be largely ineffective, to establish a minimum level of child care.

In the Children and Young Persons act of 1933, heightened interest in the treatment of juvenile offenders was reflected in changes respecting the constitution and procedure of the juvenile courts and the forging of a much closer link between the work being carried on for delinquent and neglected children and the work of the local education authorities. The act extended state responsibility for child welfare to that group of children in need of care and protection and conferred increased powers on local authorities to enable them to carry out their duties for this group, as well as for the delinquent and neglected. The prevailing emphasis in the 1933 act was upon rehabilitation of the child by means of removal from his inadequate home and by provision of a substitute family. The child's welfare. thus regarded, entailed lodging greater power in the court and local authority and led to closer supervision of voluntary homes and agencies, under whose auspices much of the substitute family care was made available.

Following investigation by the Curtis committee of 1946, the Children act, 1948, embodied the committee's far-reaching recommendations. Responsibility for the care of children who have been deprived of normal home life was placed on the local authorities. The act enlarged the authority's power of assumption

of parental rights over children under their care and widened their duty to act as fit persons at the behest of the courts; at the same time it directed the authorities to undertake rehabilitation of the child in his home and to aim at all times, in those cases where substitute family care was required, for the restoration of the child to his own family. Administrative powers were centralized in the home office and a stricter control of voluntary organizations was imposed.

Modern English Law.—At the outset it is necessary to attempt some definition of terms. Those who have not attained the age of 21 are known as "infants," and the status of infancy has certain disabilities attached to it: an infant does not enjoy the franchise, either in parliamentary or municipal elections; he may not marry without the consent of his parent or that of a court of competent jurisdiction; his capacity to enter into contracts is limited. In addition there are a certain number of by no means uniform statutory definitions of "children" and "young persons." In connection with either of these terms it would be useless to look for, or to try to formulate, any single comprehensive definition; the right approach, in relation to any statute dealing with either, is to ask what, for the purposes of this act of parliament, do the words "children" or "young person" mean?

The words "child" and "children" have, obviously, meanings which are important in law as expressing a relationship. In statutes, deeds and wills alike, a "child" is generally a legitimate child unless the context indicates otherwise, although there are exceptions to this rule, particularly in connection with national insurance and family allowances. For the purposes of the Fatal Accident acts, by which the personal representatives of a person killed by a wrongful act have a right of action for the benefit of the deceased's relatives, dependence rather than a particular legitimate blood relationship is the criterion, and grandchildren, stepchildren, legitimated, illegitimate and adopted children are all included. The only rule is to look at the context and then to judge what the word means.

Modern English law prescribes care for children falling into five special categories: those deprived of normal home life, in need of care and protection. beyond parental control, handicapped in mind or body, or suffering from mental illness. The care of these children is shared by local authorities, voluntary organizations and state institutions. Voluntary homes are subject to control by the secretary of state.

Children deprived of normal home life, whether orphaned. abandoned or neglected, are committed to the care of local authorities who may, in suitable cases, assume parental rights. Care may last until age 18 and may be extended to 21 if necessary. Maintenance contributions are recoverable from the parents. Children in need of care and protection, if under 17, may be brought before the juvenile courts. As defined, these children include those who have fallen into bad associations through lack of parental care, who fail to attend school and who are the victims of violence or immorality. Any such child may be sent to an approved school or committed to the care of a probation officer or other fit person. Special medical or other treatment may be recommended. Children beyond the control of their parents or guardians, if under 17, may be brought before the juvenile courts and dealt with as children in need of protection. If they are already in the care of a local authority, they may be sent to approved schools on order of the court.

Handicapped children suffering from disability of mind or body may, under the Education act, 1944, be provided by the local authorities with treatment in special schools. Medical examination may be ordered, as well as attendance at the special school selected until age 16. Further assistance between the ages of 16 and 21 is given by the local authority under the National Assistance act, 1948, in the form of rehabilitation services and provision of work at home or elsewhere. Children who are mentally ill receive treatment under a variety of acts relating to mental treatment; facilities include outpatient child guidance clinics and centres provided by local education authorities as well as hospitals.

Paid foster care of children living apart from their parents is now regulated by provisions of the Children act, 1958. The statutory protection exists until age 15 but may be extended to 18. Local-authority visitors may inspect the homes and give directions as to the care of children living there. The number of children kept in the homes is subject to regulation, and local authorities may apply to a court for an order of removal of children from unsatisfactory premises to places of safety. Similar regulations apply, under the Nurseries and Child-Minders Regulation act. 1948, to places providing day care for children.

The employment of children is regulated by the Children and Young Persons act, 1933, the Education act, 1944, and various acts relating to factories, shops and mines. The restrictions relate to hours of employment, employment while of school age and intervals for meals, rest and holidays.

Various rules protect children in criminal proceedings. Provisions include separating children from adults; granting bail; notification of proceedings to the parents, guardians and local authorities; and the presence of children during court trials. Corporal punishment was abolished by the Criminal Justice act, 1948. Charges against children are usually heard in juvenile courts and detention is prescribed in institutions other than prisons.

(C. WTR.; M. K. R.)

UNITED STATES

The tendency of United States law has been to enlarge the rights of the child and the measure of protection afforded him against ill-usage, exploitation, and hazards to health, morals and well-being. The common-law rule, by which the age of legal majority for both sexes is 21 years, has been generally adopted in the United States, except in a small group of states which has fixed the age of majority for females at 18 years. While the protective laws of the states differ considerably, certain general principles are widely accepted.

The first duty of the parents of children is to support them. This obligation rests principally upon the father, but. increasingly, state laws require the mother to share in its fulfillment. She is fully responsible for support after the father's death. Where the child would otherwise be likely to become a public charge, a variety of relatives may be held responsible for his support. The precise extent of the duty of support is determined by the law of each jurisdiction. Generally, it includes food, shelter, clothing, medical care and education. (As regards the support of illegitimate children, see BASTARD.) The Social Security act of 1935 recognized the difficulty that a widow might have in supporting her child and, by means of a grant-in-aid program to the states, provided aid to dependent children (ADC) grants for the maintenance of the child and the relative who is his caretaker.

In addition to the duty of support, a parent is required to shield his child from evil surroundings or influences. He may not injure or be cruel to the child; the parent may, however. use physical force to protect his child from danger and may, under proper circumstances, impose reasonable correction. The conduct of any adult which tends to deprave the morals of a child or to endanger his health or well-being is punishable as a criminal offense.

Parents also have an obligation to secure their children's education. The development of compulsory school-attendance laws and of accompanying child labour legislation proceeded differently in the United States from that in England. The slow industry-wide extension of labour regulation and the pattern of half-time school that characterized the British development gave way in the United States to more comprehensive efforts to compel school attendance and prohibit employment. The necessity of education in a democracy was argued in support of requiring full-time education and prohibiting the employment of children under a specified age. Because of the difficulties inherent in the enforcement of both types of laws, great effort was exerted in the United States to bring the child labour and compulsory school attendance laws into harmony so that one would reinforce the other. Modern education laws require school attendance of children in the age range of 6 to 18 years, the upper limit most commonly set by statute being age 16, and penalize the parent or guardian for failure to comply. Paralleling these requirements are provisions of state and federal child labour laws which bar the employment of children in dangerous occupations or during periods of required school attendance and

which regulate the conditions of work. Sixteen is a common minimum age for full-time employment.

It has often been said that the father has control and custody of the child and may determine where he shall live. Nevertheless, the modern tendency is to recognize an equal or larger right of the mother in these matters. In any case. the court's basis for award of custody is the welfare of the child, and either or both parents may be deprived of custody because of conduct which harms him. If one of the parents dies during the child's minority, the surviving parent assumes full control. If a child becomes an orphan or if his parents prove unfit to have his care, he may be committed in a judicial proceeding to the guardianship of a suitable person or social welfare agency. In some instances guardians of the estate will be required to deal with his property.

A guardian who is not the child's father or mother does not assume the full status of a parent. The precise nature of the rights and duties he does assume appears, in some states. to turn on whether the guardian has been nominated by the parent as a testamentary guardian or whether the guardian's appointment has been made under child welfare statutes authorizing state intervention for the removal of children from families in which inadequate child care prevails. In cases of the latter kind the guardian's role is often construed more narrowly, the courts apparently having in mind the existence of residual parental rights and the possibility of the child's return to his own family. In many of these cases, the demonstrated capacity of the parents to care for the child is too limited to support a reascnable prospect of rehabilitation of the family. To meet the contingency of long-evidenced parental neglect or inadequacy, some states provide for complete severance of the parental relationship through a termination of parental rights, thereby freeing the child for adoption or foster placement under a guardian's supervision.

By a decree of adoption (*q.v.*) the child becomes the lawful child of his adoptive parents. Legislation in mid-20th century sought to safeguard adoption proceedings by requiring an investigation of the prospective adoptive home and supervision of the child, once placed there, for a trial period before the final decree of adoption is granted. Because of abuses arising out of the casual transfer of children from their natural parents to irresponsible people, a number of states control the proper methods for transfer of parental responsibilities. The methods include guardianship or adoption proceedings and commitment orders of a juvenile court. In many jurisdictions the law also prohibits the bringing of children into one state from another for purposes of permanent care without the prior investigation and approval of the receiving state. Support for these laws stems from increased public awareness of the dangers of "black market" adoptions and the existence of other opportunities for exploitation or abuse of children resulting from ill-considered or harmful parental action.

Remarkable progress in the development of protective legislation has occurred since the beginning of the 20th century. Among the factors accounting for its growth are the decennial White House conferences on children and youth. the work of state commissions for the study and revision of child welfare laws, and the program of the United States Children's bureau. The White House conferences, first held in 1909 and followed thereafter by conferences in 1919, 1930, 1940, 1950 and 1960, have provided an important means of focusing national attention on the needs of children and the services they require. The conferences provide a forum for the interchange of professional opinion and encourage the participation of lay leaders drawn from youth groups and child-serving agencies of all kinds. The conferences have significantly advanced the cause of progressive child care in the nation.

One recommendation of the 1909 conference, whose participants were mindful of the major advances represented by the English Children act of 1908, was that each state periodically review and revise its laws pertaining to children. Beginning in 1911. when the first state commission was appointed for this purpose, the growth and consolidation of child welfare laws was markedly accelerated by the work of such commissions. In the years elapsing since World War II the work of state commissions or councils accounted for many of the significant changes which have been made in child welfare legislation. Most of the changes relate to adoption or to delinquency control and prevention.

The importance of state legislative changes can plainly be seen in the fact that most of the laws pertaining to children are found in state, rather than federal, statutes. At the beginning of the 1960s there was great variation in state laws relating to the proper care of dependent, neglected and delinquent children and in the administrative structures within which these laws were to be enforced. The 1909 conference on the care of dependent children, and all succeeding conferences, emphasized the need for each state to develop a strong department of public welfare whose functions would include the licensing of voluntary child-care agencies and institutions and the supervision of all public child welfare services, whether operated by cities, counties or the state. Licensing, or inspection and supervision, laws are designed to afford the child who must be cared for out of his home a measure of protection by establishing certain minimal standards for the operation of child care facilities. The licensing responsibility is usually discharged by the children's division of the state department of public welfare and customarily extends to children's institutions, child-placement agencies and day-care centres. The level of licensing standards and the extent to which they are enforced differ considerably from one state to another. The extent to which licensing reflects an insistence upon professional standards of child care also varies. Some jurisdictions appear to license primarily on the basis of fire and health inspections, without sufficient regard to the content of the program or to the qualifications of the staff in child-care facilities.

Despite the diversity of state child welfare legislation, the existence of reciprocal laws relating to the support of dependents and of an interstate compact on juveniles. to which a majority of states are signatories, provides a unifying influence on selected child-care programs. Certain federal statutes also establish national standards. The provisions of the Social Security act of 1935 and succeeding amendments have reduced areas of child dependency which had previously been the sole concern of the states and have created new federal grant-in-aid programs based on fulfillment of certain criteria. This act authorized three types of grants for maternal and child welfare services, as well as the aid to dependent children program, one of the categories of public assistance. The grants are for maternal and child health services, services for crippled children, and child welfare services. Of the three, child welfare service has been most intimately associated in each state with the administration of other laws pertaining to children in that jurisdiction. The 1930 White House conference on child health and protection had strongly emphasized the need for services to socially handicapped children and had pointed out the lack of existing county organization for child welfare work under state leadership. Under provisions of the Social Security act, child welfare services sought to assist state public welfare agencies in developing programs, in predominantly rural areas or areas of special need, for the protection and care of children. Child welfare, as defined in the act, includes work with delinquent, emotionally disturbed and mentally handicapped children, as well as dependent children, in their homes or in placement. Program plans must be worked out jointly by the state agency and the Children's bureau, the administering agency of the federal government. An important aspect of state plans has been their wide use of federal funds to provide professional education for child welfare workers. By an amendment of 1958 the emphasis on development of rural services was eliminated from the act; states may now allocate funds to areas of need, whether rural or urban.

The creation of a federal Children's bureau is another significant legacy of the 1909 conference on the care of dependent children. The bureau was established in 1912 to draw attention, at the national level of government, to the needs of children. Its functions include investigation and publication, and much of the nation's child welfare legislation is a reflection of the bureau's research and publicity. The bureau tends to concentrate on areas of child welfare which fall beyond the immediate concern of one state. In the 1950s, for example, it conducted numerous projects and conferences in the field of juvenile delinquency, drawing upon leaders

throughout the nation; it has also been concerned with the plight of children of migratory workers, who are too seldom regarded as the responsibility of the individual states through which a season's travels may take them.

CHILDREN'S COURT is a tribunal for juvenile offenders usually characterized by distinctive procedures and distinctive methods of treatment of children found to be delinquent. In many jurisdictions the court performs additional functions. particularly with reference to neglected and destitute children. It is generally conceded that the first juvenile court, in the modern sense of the term, was that established in Chicago (Cook county) by an Illinois statute effective July 1, 1899. Since that time juvenile courts have been established throughout the Lnited States and in many other nations.

The juvenile court may be regarded as the culmination of certain tendencies of thought originating at least as early as the 18th-century enlightenment. In the common law of England and the United States a child below the age of seven was regarded as incapable of crime, but a child over the age of 14 was fully accountable. In the intervening years the child was presumed incapable of crime, but the presumption was rebuttable upon a showing that the offender understood the nature and consequences of his conduct. There are well-authenticated instances, both in England and America, of execution of the death penalty on boys twelve years of age and even younger. In many jurisdictions well into the 19th century no special provisions were made for the arrest, detention, trial or punishment of children of tender years. Thus, it is said that in 1853 there were more than 11,000 children from 5 to 17 years of age in prisons in England and Wales. The alleviation of these conditions became one of the primary objectives of humanitarian reform.

The first efforts at reform in the United States were concerned, not with the courts, but with the detention and confinement of juvenile offenders. The first of the juvenile reformatories was established in New York in 1825. Shortly thereafter similar institutions were opened in Boston (1826) and Pennsylvania (1828) and. ultimately, throughout the United States (see REFORMATORY). The movement to supply foster homes for neglected and destitute children also originated in New York with the establishment by Charles Loring Brace (*q.v.*) and others of the Children's Aid society in 1853. As early as 1861 Chicago provided a commissioner to hear cases of petty offenses by boys from 6 to 17. Separate trials for children were instituted in Boston in 1870; and New York, in 1892, created separate dockets and records, as well as special hearings, for juveniles below the age of 16. The system of probation (*q.v.*), which is an integral feature of the modern L.S. juvenile court, had its origins in practices developed in the Massachusetts courts. A Massachusetts statute of 1869 provided that an agent of the state board of charities should attend trials of children to protect their interests and to make recommendations for disposition of the cases. Between 1878 and 1898 Massachusetts established a state-wide system of probation, and the movement thereby initiated spread throughout the United States and to many other countries. These reforms were part of a broader effort in the 19th century to advance the welfare of children. which also included the expansion of public education, agitation against the abuses of child labour and the development of services for handicapped and dependent and neglected children. Similar movements for amelioration and reform attained prominence in many nations of western Europe.

After the creation of the first juvenile courts in the United States the movement spread rapidly throughout the world. Within ten years of passage of the Illinois act in 1899, twenty states and the District of Columbia adopted juvenile court laws. By 1945 legislation had been enacted in all of the United States. In England the basis of the modern system for trial and treatment of child offenders may be said to rest on the Children act, 1908, which required that trial of juveniles be conducted in separate courts and provided for various methods of treatment intended as instruments of rehabilitation rather than of punishment. The system created by the 1908 act has been frequently modified by subsequent legislation. including provision for improvement of services such as probation (see also BORSTAL SYSTEM). Most advanced nations have adopted juvenile court legislation of some type, including France (1912), Germany (1923), Spain, Holland, Belgium, Austria, Hungary and the Scandinavian countries and Switzerland. Nations of the British commonwealth, such as Australia, Canada, South Africa and New Zealand, have well-developed systems. Juvenile courts may also be found in Israel. Iraq. Japan. various Latin American nations, and in many other countries. As might be expected, there are great variations in the theory and provisions of these statutes. The extremes are illustrated by the laws of England and Sweden. The former provide for tribunals with procedures very much like those of the ordinary criminal courts. Sweden, on the other hand, has established administrative boards, known as child welfare councils, which are not bound by the procedures or rules of evidence associated with the judicial process.

The movement leading to the establishment of the juvenile courts was founded on articulate and well-grounded dissatisfaction with the methods then generally employed in dealing with juvenile offenders. It is clear that the reforms were intended to be radical and far-reaching. A new tribunal of nonpunitive orientation was to be established. The juvenile court was described by a distinguished U.S. judge, Edward F. Waite, as one concerned with "doing something lor a child because of what he is and needs." The concept of crime was deemed inapplicable to juvenile misconduct; instead, a new label, delinquency, was devised. The treatment afforded the child, as stated by the Illinois act, should "approximate as nearly as may be that which should be given by its parents." To achieve the ends of guidance and rehabilitation, substantial contributions were anticipated from such emerging behavioural disciplines as psychology, psychiatry and social work. In legal contemplation the child was conceived as a ward of the court and subject to the authority of the state in its role of *parens patriae.* Procedures were to be modeled upon those employed in courts of chancery. They were to be informal and adapted to the rehabilitative objectives of the court.

Juvenile court legislation in the United States varies considerably in its terms and in the degree to which the underlying philosophy of the juvenile court movement is given statutory expression. In most laws the definition of the basic term "delinquency" is broad and. in some respects, vague. Typically the concept includes not only acts that are otherwise defined as criminal but many that do not result in sanctions if committed by adults, such as associating with immoral persons or incorrigibility. The upper age limits of children subject to the jurisdiction of the court vary between 16 and 21, but the usual provision includes those below the age of 18. In some states the juvenile court has original jurisdiction over all cases of juvenile misconduct, but in many of these its jurisdiction may be waived. Others limit the court's jurisdiction by excluding cases of offenses punishable by death or life imprisonment. A few states grant no exclusive jurisdiction to the juvenile court except in cases of children below the age of criminal capacity. In such states children may be tried either before the juvenile court or the ordinary courts of criminal jurisdiction. Many juvenile courts have been given responsibility for the protection and care of neglected and destitute children as well as delinquents. Frequently adults may be tried before the court for contributing to the neglect or delin-

quency of children. Legislation typically contains provisions for the initiation of proceedings. detention of children whose cases are awaiting disposition, procedures to be employed in the hearings and the modes of treatment that may be applied. Some states have created family courts with jurisdiction over a wide range of issues involving domestic relations as well as those ordinarily within the competence of the juvenile court. An increasing number of courts have been created with procedures in some respects similar to those of the juvenile court but with jurisdiction over youthful offenders above juvenile court age.

Despite the rapid acceptance of the juvenile court in the United States and throughout the world, serious problems have attended its operations. It is clear that many of the hopes and expectations of those who were part of the juvenile court movement in its early stages have not been fully realized. The reasons are many and complex. In some jurisdictions the juvenile court has not received appropriate financial and public support. One result has been that the personnel of the court is not always sufficient in numbers or of adequate quality. In many urban communities the social workers staff, which is relied on to secure needed information for sound disposition of the cases and to provide probation supervision of many of those adjudged to be delinquent, is required to assume case loads so burdensome as to preclude proper performance of its functions. Salaries are often too low to recruit and retain persons of proper training and experience. Frequently, adequate medical, psychiatric and counseling services are not available to the court. Public and private institutions for the commitment of children requiring confinement are often limited in number and restricted as to type. In some jurisdictions the methods of selecting the judge are inadequate to insure leadership by competent persons sympathetic with the objectives of the court. Certain fundamental and elementary objectives, such as separating adult from juvenile offenders during periods of detention, are not always fully attained.

The juvenile court has also been criticized on other grounds. One of the most important questions which has been raised with increasing frequency in the United States since World War II relates to the procedures employed by some juvenile courts in delinquency hearings. One fundamental objective of the founders of the juvenile court was to create a tribunal with procedures substantially different from the formal adversary processes of the criminal courts. Many critics have asserted that the tendency toward informality sometimes leads to carelessness in determining whether the child has committed acts that constitute delinquency. The problem may be aggravated by the vagueness of statutory definitions of delinquency, lack of precision in the language of petitions charging juveniles with delinquent conduct and absence of provisions for the appointment of counsel to represent the interests of indigent persons before the court. Some observers have pointed out. that despite the theory of the legislation, a finding of delinquency stigmatizes the child and that treatment ordered by the court contains an inescapable punitive element even though motivated by a desire to help and guide the child. These considerations have led many to the conclusion that the procedures of the juvenile court, however they may diverge from those of the criminal courts, should be characterized by sufficient care and formality to insure the essentials of due process of law.

Despite criticisms of the juvenile court and difficulties limiting the effectiveness of its operations, few thoughtful persons would advocate its abolition or welcome a return to the practices that generally prevailed at the time of its establishment. In many enlightened jurisdictions genuine progress has been made in improving the functioning of the court and integrating its operations with other essential programs relating to juvenile delinquency. The juvenile court remains one of the most important social inventions of the modern period.

CHILDREN'S GAMES AND SPORTS. As a child grows up and learns to play the traditional children's games and sports, he is in a sense often re-enacting the childhood of the human race, for children's games have preserved a glimpse into the prehistoric customs of the past. The "work" of adults in one age becomes the "play" of children in another, through children's imitation of the magical rites and marriage and burial customs of their elders. The study of the origins of children's games is a fascinating and distinct branch of anthropology. ethnology and folklore. For example. Oats, Peas, Beans and Barley Grow is a singing and acting game that had its origins in prehistoric fertility rites at the time of spring planting; the jump step of the game derives from the magical belief that the crops would grow as high as the dancer could jump. The French game of *L'Avoine* carries out all the motions of sowing, reaping, binding and threshing the crop. The Mulberry Bush, beloved by every kindergartner. is a survival of ancient spring festival dances in which the Maypole, or a sacred bush, is encircled by the dancers.

Other children's games, especially such team pursuit games as Prisoner's Base or We Are the Romans, derive from children's imitation of the skirmishes and warfare of adults. The game of tag (Tig, Tigge) may have had its origin in adult flight from an evil spirit, witch or devil, from whom one was safe if one touched wood or iron; this belief is preserved in such popular names for tag as Touch Wood, Horney and *Die Hexe Kornrnt* ("the witch comes"). The preservative magic of touching wood may have come from a pagan belief in the magic power of sacred trees. Iron is "safe" because, according to folklore, fairies and sprites are said to fear iron "more than any earthly thing."

Games are a distinct species or form of play, varying from the simplest pastimes to the most complex, organized and ritualistic team games and sports. There are informal play activities that seem to develop spontaneously in every country, the most notable being that of ball-playing. No doubt the first balls were stones, given magical significance by primitive peoples. It is said an ancient Gaelic game of lobbing stones gave rise to cricket. The early American Indians made balls of yucca leaves. the Eskimos used animal skin stuffed with reindeer moss. Balls of stitched skin filled with bran have been found in Egyptian tombs. The loveliest classical allusion to the game is found in book vi of the *Odyssey,* where "white-armed Nausicaä" plays ball with her maidens. Two ball games in progress are shown in relief on a relic of 5th-century B.C. Athens. Both are team games, played with curved, hockey-type sticks.

Leapfrog seems to be as old as it is universal. The *Satyricon,* a 1st-century A.D. work ascribed to Petronius. describes how a boy climbed the back of Trimalchio and cried out, "Bucca. bucca, quot sunt hit?"--the very game that English boys play, crying, "Buck. buck. how many horns [fingers] do I hold up?" The same refrain is used in an old parlor game of Forfeits.

Very few children's games can be said to be "invented"; they evolve spontaneously from generation to generation, in response to children's innate urge for playful activity. There are regional as well as national differences in games, but it is very common to find the same form of play, although often under different names, in different countries. Blindman's Buff, for example, is universal, and as late as the 17th century was played by adults. In Shakespeare's day it was called Hoodman-Blind, as the Elizabethans reversed their hoods to play. The *Menagier de Paris,* a 14th-century treatise for the instruction of a young wife, describes ladies playing tiers. or Blindman's Buff, and it is mentioned by Rabelais as one of the games that Gargantua played as a child. The early Egyptians played it, as did the ancient Greeks, who called it the Brazen Fly. The Romans called it *migare dicitis,* the

modern Italians, *Mosca cieca.* The German version is Blind Cow; the Spanish, Blind Hen.

Tops, hoops and kites are ancient and universal playthings. Virgil in the *Aeneid* speaks of whirling tops lashed around empty courts. and American Indian children and Eskimos were expert at spinning their tops on ice. Chip Stones and Peg in the Ring were English top games, and in Japan top spinning or *koma asobi* continues to be an art. In spring, the exiled Ovid recalled. "Nunc pila, nunc celeri volviture orbe trochus" ("Now flies the ball, now rolls the whirling hoop"), and Roman girls skipped ropes made of vine leaves. *(See* also GAMES, CLASSICAL: *Private Games.)*

The continuity of culture is reflected especially in the dramatic and singing games and pastimes, some of which originate in antiquity. One of the most famous is the Swallow Song of Rhodes. In ancient Greece bands of boys went from house to house in early spring, singing the song for reward. Greek boys still follow this custom each March 1, carrying a wooden swallow on a pole. Hunting the Wren. when boys come round with a live wren and sing for goodies, is still observed at the winter solstice by boys in the west of Ireland. A feather from the wren is kept as a charm, especially against shipwreck.

Many games still played by children once had magical significance. Draw a Bucket of Water hints of old well-worship rites. One of the many "arch" games played by children, London Bridge *(Bro Bro Brille* in Scandinavia, *Pont-Levis* in France) refers to the ancient custom of offering a human sacrifice at the foundations of bridges and buildings. The burning of a dummy on Guy Fawkes' day in England goes back beyond its obvious political reference—the Gunpowder plot (*q.v.*) of 1605—to pagan fire festivals at the winter solstice, when a propitiatory human sacrifice was offered. The popular nursery singing action game of Looby Loo, beginning "I put my right hand in," probably refers to an ancient rite with religious significance.

Other songs and ceremonials once part of adult life have also been spontaneously imitated and preserved by children through their innate love of dramatic play-acting. The ubiquitous ring games *(rondes* in French, rounds in the Middle English period) often lead back to primitive fertility rites and marriage customs. Go In and Out the Window, Poor Mary Sits A-Weeping and Sally Waters are singing marriage games. Drop the Handkerchief and Nuts in May represent the prehistoric custom of marriage by capture. The "nuts" of Nuts in May is a corruption of knots, or bunches of May flowers. Bunches of hawthorn were picked on May day to decorate the Maypole, the doors of houses and the "kissing bush," a relic of pagan worship of sacred trees and groves. A singing game called Posies is mentioned by Athenaeus, the Greek rhetorician (2nd century A.D.), and clearly resembles Nuts in May. Another curious survival of ancient spring festivals is the American folk game of Green!, derived from the old English game in which the person must be wearing something green or pay a forfeit.

One of the best-known funeral games is Jennie Jones, or, more properly, Jennie Jo (from the Scots *jo,* "sweetheart"). A long and complicated dramatic song carries the heroine through various domestic tasks to her death, then discards one colour after another until black is chosen for her funeral.

Thus, behind a popular kindergarten game or a casual game of tag may lie thousands of years of human custom. But the child absorbed in play is oblivious to all except the fun and joy of taking part in the game. Games are the child's first joining in group activity—one can almost say, in the human race. In the effortless, exhilarating act of playing with other children, he learns social interaction with his fellow beings and begins the first steps toward civilization and self-control. Games provide a natural outlet not only for his excess energy but also for his tensions, aggressions and emotions. As he grows older and takes part in more organized games and sports, he learns the principles of fair play and courtesy, of abiding by pre-arranged rules, and he learns to accept defeat as well as success with some degree of equanimity. Motivated by the sheer love of sport, he all unconsciously learns to join others in moving toward a common goal; his childhood ability to play with others will become his adult ability to work with others. It has been truly said that a child is not "playing" but "working"—toward becoming an adult. That is why children take their "games" so seriously, in a way adults often fail to grasp. *(See* also KINDERGARTEN.)

Games Around the World.—For centuries box kites and bird and butterfly kites have been flown by boys in China. who glue ground glass to their kite string and try to cut down their opponents' kites, exactly as do boys in India. In Japan on the Boys' Festival on May 5, boys fly their kites, fence with curved wooden swords, wrestle, and race sailboats. In Europe and the United States, building and flying model planes is popular with boys in spring, and Mumblety Peg, played with a pocketknife, makes its annual appearance then.

Marbles, another traditional spring game, was played by the Romans, and was probably brought to Britain by the Roman legions. The first marbles were undoubtedly round pebbles with distinctive markings; now they are made of baked clay, glass, steel, marble and agate ("aggies"). There are many variant games, the "champ" game, often called Ringtaw, being played in a circle ten feet in diameter, with 13 marbles forming a cross in the centre. Each player "knuckles down" or touches one knuckle to the ground and, using his special "shooter." tries to strike the marbles out of the ring. Play is often "for keeps." each boy winning the marbles he knocks out. Variant games are Kine Holes and Hit and Span. Local children make up their own games and rules, passing them to the next generation. Marbles are a favourite sport with boys the world over—in India, when the rains begin and the dust settles; in Brazil, where they play *Gude;* in Africa, where they play *Jorrah.* In Iran, Turkey and Syria the game is played with knucklebones of sheep or balls of baked clay. Chinese boys play "kicking the marbles."

In Africa children play their version of London Bridge as a hunting game, the last one caught being "the only child." Greek boys play a game mentioned by Plato—Black and White, a tug of war derived from ancient political parties—and they also play exactly the same Duck on a Rock beloved by generations of Irish and English boys. In India boys enjoy *Guli Danda,* played with a ball and a bat; *Gul Tara,* "throwing to the stars," and Seven Tiles or *Atya-Patya,* both active team games. Japanese girls are fond of *Otedama,* juggling little bags of rice.

The Hawaiians at the Makahiki, or festival of games. bowl the *maika* stone. In the Philippines youngsters play *Bagal* by kicking a coconut shell. In Mexico one of the children's favourite games is Angel and the Devil, or the courting game, *Las Calabazas* ("the gourds"). Russian children enjoy Ting-A-Ling, derived from a legend of Moscow, the city of bells.

Children in every land play tag, with its countless variations. In India a player cannot be caught if his forehead touches the ground. In Japan—and Scotland, too—he must hold onto the spot where "It" tagged him. In the U.S., he is safe if he stoops, in stoop tag. In Russia he can join in *Gorelki.* In Israel children play a tag game called *Deeb* or Wolf, with the wolf chasing sheep. Italian children play Wolf and Lamb; Chinese children love to play Cat and Mouse.

Hide and Seek is another universal game, and one that readily lends itself to many variations. In Japan it is called *Kalurembo;* in Korea, *Syomu Pak Kakomu Tjil Hat Ki!* Counting out to decide who is "It" is a part of many games, and nonsense rhymes such as "Eeny, meeny, miney, mo" and "1–2–3 alaree [O'Leary]" are widespread. In Japan the boys and girls count out by the same finger game used in Europe, Paper-Scissors-Rock. or *Jankenpon.* Skipping rhymes are handed down from generation to generation, with new variants in every locality. (For an interesting modern study of the transmission of such material, see Iona and Peter Opie, *The Lore and Language of Children* [1959], based on observation of a selected group of British children aged 6–13.)

Finger games are popular around the world. Chinese children play a game with loops of grass blade, Borneo children play the fibre game. Japanese children love to fold paper figures, a craft called *origami.* Cat's cradles have reached a peak of artistry among primitive peoples, such as the American Navahos, the Eskimos and the natives of the Guianas, Cape York and Ghana. Among the Eskimos, the game is thought to have magical power.

(UPPER LEFT AND RIGHT) FROM "YOUTHFUL SPORTS" (1801); (LOWER LEFT AND RIGHT) FROM W. CLARKE, "THE BOY'S OWN BOOK" (1838). ALL BY COURTESY OF THE OPIE COLLECTION

CHILDREN'S GAMES AS PLAYED IN THE EARLY 19TH CENTURY: (UPPER LEFT) HOOPS; (UPPER RIGHT) SHUTTLECOCK; (LOWER LEFT) MARBLES: (LOWER RIGHT) TOPS

They play it at certain seasons of the year, making string figures such as "Seal Holes," "Two Polar Bears" and "Caribou in the Willows," and they believe in a "Spirit of String Figures" who can be driven away by making the figure "Opening A." Making string figures during the hunting or fishing season is taboo, however. for fear that the boys and men will become entangled in their harpoon lines.

Shuttlecock is found in different versions in different lands. The American Indians played *Onumba* with paddles and a twig tied with feathers. In China children kick a shuttlecock made with feathers and a piece of cash (a coin with a square hole in the middle). The game of Jackstones is also played all over the world, with any suitable object—pebbles, nuts. beans or metal jacks. In the very old game of Fives or Knucklebones. from which Jackstones descends, five pebbles or bones were tossed up in the air and caught in different ways.

Wherever there is snow and ice, winter sports are enjoyed by children. Skiing and skating are as popular with them as with adults; sledding is another lively winter sport. Many group games can be adapted to snow-covered ground—Fox and Geese, for example, with safety zones tramped out in the snow. Snow-Snake, a game of throwing sticks on snow, and Saddle Bags or Sky Shinny, a game somewhat like lacrosse (which comes from the American Indians), were favourites with American Indian children. The Eskimos played shinny on the ice with a ball of walrus tusk and sticks of walrus bone.

Holidays that are celebrated in different countries frequently have similar customs associated with them. See, for example, HALLOWEEN and CHRISTMAS.

Playing the games of other children in the world, if not with them, helps a child to build a foundation of understanding and acceptance. There are many collections of games from different countries, including Frances W. Keene's *Fun* Around the *World* (1955); Children's Games *From Many Lands,* edited by Nina Millen (1951); and Sarah Ethridge Hunt and Ethel Cain, Games the World Around (1941).

Outdoor Games.—Outdoors is the natural playground of the child. Especially popular games are simplified and informal versions of such games as softball, football and cricket (*qq.v.*), other ball games such as dodge ball, and team games such as Red Rover and Pom Pom Pullaway, which can accommodate almost any number of players on the two sides. Games that involve a great deal of running, such as various forms of tag, are good outdoor games; two favourite hide-and-seek games are Kick the Can and Sardines, where the players pile up in the secret hiding place. Many of the games played outdoors can be adapted to indoor rainy-day play in a gymnasium or recreation hall.

Water Games and Sports.—Many favourite sports, such as ball, tag and ring toss, can be played in the water and they encourage a child to develop his aquatic skills. Organized water sports are popular at camps and beach outings. A candle relay is played with lighted candles on blocks of wood, and in a water-treasure hunt the different treasures are placed at various water levels, encouraging a youngster to use his skills in diving and swimming. Water potato race, umbrella race, inner-tube race, balloon relay and break the balloon are aquatic adaptations of picnic games. . Various tag games can also be played in the water. Simpler lake and seashore pastimes are skipping stones, playing Waves and Gatherers tag with shell collections, and racing toy sailboats.

Nature Games.—On picnics, hikes and at camp, children's games take on a new colouring from the world of nature. I Spy and See What I See are hiking games. Bird alphabet and nature lotto can be played at rest or while walking. Hare and hounds, treasure hunt and tree tag, where certain kinds of trees are "safe," are camp favourites. Many woodcraft contests are possible and are especially popular on camp field days. Traditional around the campfire are songs, skits, charades, group storytelling (begun by one person and continued by each participant in turn), riddles, 20 Questions and similar games.

Picnic Games.—Organized games and skill contests add to the fun of picnics and family outings. This is the time for team or relay races such as the sack race, in which each player stands in a burlap bag and hops to and from the goal, or the egg and spoon relay, in which the object is to get to and from the goal in the shortest possible time without dropping an egg carried in a spoon. Pitching horseshoes is a tradition at American picnics, as are singing and guessing games around the picnic fire.

Indoor and Parlor Games.—Parlor games are as old as the habitations of men. Sitting around the fire telling stories and playings games, singing and dancing are still favourite pastimes. Many of the old favourites of Victorian days, such as Charades (or "the Game"), 20 Questions, Concentration, Who Am I?, Scrambled Proverbs and Mind-Reading Magic, are still enjoyed. Word games, such as Ghost, Anagrams, Limerick Contest, Advertising (in which players recognize current slogans) and I Love My Love With an A, interest children of seven years and up. Favourite paper games are Dots, Hangman, Consequences, Ticktacktoe, Categories. Hidden Words and Salvo (Battleships). Games played round the table by generations of funlovers are Up Jenkins, Simon Says, All The Birds Fly (versions are found round the world), Do As I Do and Gossip. Another favourite parlor game is stunts, in which each player or couple must perform a stunt, usually within a time limit set by the master of ceremonies. The games of Forfeits and of Hot Cockles, in which the player tries to guess who

slapped his outstretched palms, are centuries-old; the Egyptians are said to have played the latter. Lively group games are broom hockey, balloon volley ball, musical chairs and Going to Jerusalem. A traditional ice-breaker is "Who Am I"?—each guest wearing a card on his back with the name of another guest, which he must discover through conversation.

Leading Children's Games.—Directed play broadens a child's interests, both by teaching him new games and by teaching him how to play, and because it aims at involving all those present, it is particularly valuable in building group feeling. Resource books in this area are abundant and can be helpful for the parent planning a party as well as for the professional or volunteer recreation leader. Most such books include suggestions on how to lead as well as directions for particular activities suitable for various age levels.

Situations in which children cannot be active—such as traveling for an extended time or being confined to bed by illness—require special planning. Resource books helpful for such situations are included in the Bibliography.

See also PLAY, ANIMAL; articles on sports, such as BASKETBALL, SWIMMING and WINTER SPORTS; articles on games, such as CHECKERS, CHESS, HOPSCOTCH and JACKSTONES; and related activities such as ARCHERY, CHARADE, KITES and ROLLER SKATING.

CHILDREN'S LITERATURE may be said to include all books mritten especially for children, other than textbooks (*q.v.*), and also the many books written for adults which have been widely read by children. The fascination of a story is as old as the human race itself, but the production of literature especially for young readers is modern, coming after the development of printing and book production, which in itself is a modern development (see BOOK). The following account of children's literature is mainly historical, tracing its development in Great Britain and the United States from Elizabethan times onward.

The Beginnings.—One of the first books intended for children was produced by William Caxton (*q.v.*), England's first printer. This volume. called A Book of *Courtesy* (1477), is now a scholarly curiosity, but Caxton's books intended for adults, including *Reyn*ard the Fox (1481), Aesop's Fables (1484) and his edition of Sir Thomas Malory's *Morte d'Arthur* (1485), are still read by children in modernized versions. Aesop's Fables, gathered from Egyptian and oriental sources, went through many hands before being collected by a 15th-century German. Stainhowel, translated into French by a monk of Lyons, Jules Machault, and at last put into English by Caxton. The tales of King Arthur came from the Welsh hero tales The *Mabinogion* (*q.v.*), and were paraphrased by Geoffrey of Monmouth and others (see ARTHURIAN LEGEND). Malory's version mas written during his 20-year imprisonment in London, where he had access to the Greyfriars library, founded by Richard Whittington (*q.v.*), better known to children as "Dick Whittington, thrice Lord Mayor of London." Caxton altered Malory's text to suit his own needs, and for centuries the original manuscript was lost. It was not until 1934 in Malory's "Camelot," the city of Winchester. that the original manuscript was found in the library of Winchester college.

During the first century after the invention of printing, reading and writing were arts still largely confined to the clergy and to clergy-trained clerics who kept records and accounts. With the wider production of books. literacy increased and more children, particularly boys, were taught to read, not for pleasure but to help teach them morals and religion.

Of the few surviving 16th- and 17th-century books then read by children. Aesop's Fables was easily the most often translated and the most popular. The Gesta *Romanorum* (*q.v.*), a scrap bag of tales and fables, although not now considered a children's book, was read by them until the 18th century. As the limits of the known world expanded through the voyages of explorers, books of travel and adventure such as the Voyages of Richard Hakluyt (*q.v.*) appealed to children as well as to their elders. They also enjoyed Plutarch's Lives, which appeared in the well-known English translation by Sir Thomas North in 1579.

One of the earliest examples of the attitude that recreational reading was morally dangerous and might lead to idleness and "false beliefs" is found in Hugh Rhodes's Book of *Nurture* (c. 1545). He warns parents especially to keep their children from reading "feigned fables, vain fantasies, and wanton stories, and songs of love, which bring much mischief to youth" (F. J. Harvey Darton, *Children's* Books *in* England, Cambridge University Press, 1958, p. 45). A century later the Puritans held the same views, and the followers of Locke and Rousseau saw no good in such frivolities as fairy tales. Nevertheless, pedagogues believed in sugar-coating learning, and as early as the 18th century a rhymed alphabet "A was an Archer" appeared in A Little Book for Little Children by "T. W." The only copy extant, although undated, is believed to have been printed about 1712.

In spite of opposition among schoolmasters and clergy, exciting tales were available to children through the chapbooks (*q.v.*)—ill-written, badly printed, poorly illustrated booklets containing versions of such popular stories as "Robin Hood." "Jack the Giant-Killer" and "Tom Thumb." The earliest chapbooks probably came into existence in the 17th century, and by the middle of the 18th century they were being published all over the British Isles. Chapbooks even found their may to America. and some were reprinted there. One of the richest sources for chapbook stories was the work popularly known as the "Arabian Nights" (see THOUSAND AND ONE NIGHTS), brought to Europe in a French edition by Antoine Galland in 1704–12. Many of the stories, including those of "Ali Baba and the Forty Thieves," "Aladdin and His Lamp" and "Sinbad the Sailor," were soon translated into English and used in the chapbooks.

The paper in these booklets, though inexpensive by the standards of their times, has survived better than pulp paper of the 20th century, despite the fact that the books were almost literally read to pieces. Although many of them were unsuitable for children from a modern point of view—for the chapbooks mere often coarse and outspoken, as well as brutal—these booklets furnished the most accessible reading for children for many years.

At the same time children's morals were not neglected. The so-called "Puritan" books, written to instruct, to save and to counteract those dangers of romance, adventure and other "nonsensical writings," were common at the same time as the later chapbooks. Many of the religious writings for children were didactic and oppressively narrow in their attitudes. Since from the Puritan point of view children were "not too little to go to hell." it is not surprising that parents should try to save them from damnation by exposing them to such books as James Janeway's popular A Token *for* Children: Being an Exact *Account* of the *Conversion, Holy* and *Exemplary* Lives, and Joyful *Deaths* of Several *Young* Children, and John Foxe's Book of Martyrs. Children apparently read many of these religious, moral tales, and some may even have enjoyed them. They at least satisfied a taste for the morbid, quite common among children, that is met in the 20th century by the horror "comic" books.

Out of Puritanism came the great writer John Bunyan (*q.v.*), whose *Pilgrim's* Progress was at once adopted by children. Although Bunyan deplored his own youthful reading of "vain" literature such as chapbooks, he nonetheless wrote a "thriller," the stirring adventures of Christian in his search for the Celestial City —a religious allegory full of pious discussions but also full of excitement and suspense. The modern child would find the original, with its long moralizing passages, too slow to hold his attention, but the abridged version by Mary Godolphin with bold, dramatic, black-and-white illustrations by Robert Lawson (1939) is still

being read. Bunyan's attempts to write especially for children were less successful, though his verses originally entitled *A Book for Boys and Girls* (1686), later published as *Divine Emblems,* were certainly given to children for many years.

Divine and Moral Songs for Children (1715) by Isaac Watts (*q.v.*), the great hymn writer, was far more successful with children. and indeed became one of the most popular books of its period. running through a hundred editions before the middle of the century. It was also very popular in the American colonies and was reprinted there many times. It is now virtually forgotten; in fact, two of his moral songs are more famous in their parodied form in *Alice's Adventures in Wonderland* — "How doth the little crocodile" for Watts's "How doth the Little Busy Bee" and "'tis the voice of the Lobster" for Watts's "'tis the voice of the sluggard" — than in their original form.

Despite the popularity of importations, probably the most widely printed book of the American colonies mas a school book, the *New England Primer* (*q.v.*). Ascribed to Benjamin Harris, a London bookseller who came to Boston, Mass., in 1686, the book went through numerous editions. It has been estimated that the number of copies printed between about 1690 and 1830 must have been over 6.000.000.

18th-Century Classics. — Some of the most enduring favourites among children's books date from the early 18th century. One, Daniel Defoe's *Robinson Crusoe* (1719–20), took an early lead in popularity and continued to be in demand. The first part was pirated and made into an abridged edition within four months of publication. Another abridged edition, published in 1722 by Edward Midwinter, became so popular that Defoe eventually bought a share in the abridgment. Most 20th-century editions for children are also abridged, some badly, others more acceptably.

The popularity of *Robinson Crusoe* was so great and the book had so many imitations that they were called *Robinsonnades* by French bibliographers. One of the best was *Adventures of Philip Quarll* (1727) by "Mr. Dorrington" (a pseudonym for Peter Longueville). There was also the still-popular *Swiss Family Robinson,* published at Ziirich in two parts in 1812–13 by Johann David Wyss; an English translation by William Godwin, Shelley's father-in-law, appeared in 1814, and it has been suggested that Shelley helped in the translation. Later a French version was made by Mme de Montolieu, who added several incidents with Wyss's condescending consent, and the story was again added to by W. H. Kingston, in the version generally published now. In spite of its wordiness, unscientific "science" and prayerful interruptions, it is still popular.

Jonathan Swift's *Gulliver's Travels* (1726), like *Pilgrim's Progress,* was intended as an allegory for adults, but was also read by children for its breathless excitement, its daring voyages and its strange lands and people. Most versions for children include only the voyage to Lilliput and delete the savagely satirical material on Brobdingnag, the island of Laputa and the land of the Houyhnhnms and the Yahoos.

Philosophy and Plum Cake: John **Newbery.**—John Locke's *Some Thoughts Concerning Education* (1693) is among the first books on educational theory to consider the child as something more than a miniature adult. Locke's observations, made during his experiences as a tutor of several children, had great impact both in England and on the continent, and had a direct effect on children's books through John Newbery (1713–67), for whom the Newbery medal is named. The son of a Berkshire farmer. Newbery moved to London in 1744, finally settling at St. Paul's Churchyard in his shop "Bible & Sun," in 1745. His friend Oliver Goldsmith describes him in *The Vicar of Wakefield* as a philanthropic bookseller who wrote many books for children and was always rushing from one thing to another — for he also sold "fever powders" and other items. Though he was not the first bookseller to specialize in books for children, Newbery is perhaps the best known; his special gift was publicity and he was one of the first successful book advertisers.

In 1744 Neabery brought out *A Little Pretty Pocket Book* designed especially for children: small enough for childish hands to hold, and probably bound in the Dutch gold floral boards used so often on his later books. No copy of the original edition exists, but the first American edition, published in 1784 by Isaiah Thomas in Boston, has been made available to the public in facsimile.

Although Newbery liked to please children, he always considered the parent or nurse who held the purse strings. In *A Little Pretty Pocket Book* he addressed instructions to the nurse on the care of children, and he did not neglect to insert moral admonitions, of a gentler kind, however, than the fearsome precepts of the Puritans. Good merchant that he was, he encouraged the idea of material reward for virtue, and his slogan "Trade and Plumb Cake forever. Huzza" might well apply to Newbery himself.

h'ewbery was also credited with the publication of *Mother Goose's Melody; or Sonnets for the Cradle* (*c.* 1765). which was reprinted in America about 1785, and at least twice has been reprinted in facsimile from that edition. The date of the original edition remains conjectural, as the earliest surviving copy is dated 1791. It was not the first book of nursery rhymes published but was apparently the first to use the term "Mother Goose" for rhymes instead of tales.

Several other books of nursery rhymes appeared during these years: *The Famous Tommy Thumb's Little Story-Book* (*c.* 1754), reaching America in 1758; a collection entitled *The Top Book of All* (*c.* 1760); and *Gammer Gurton's Garland* (1784).

The authorship of one of John h'ewbery's most important publications, *The History of Little Goody Two Shoes* (1766), is often attributed to Goldsmith. Newbery also published the *Lilliputian Magazine,* significant as a forerunner of later children's magazines although it lasted only a year (1751).

Books of all kinds mere also being published for children in Europe, according to an amusing footnote in Percy Muir's *English Children's Books, 1600–1900* (1954), which quotes a German schoolmaster who visited the Leipzig Book fair in 1787: "No other form of literary Manufactury is so active for young people of all grades and classes . . . Almanacks . . . newspapers . . . journals . . . collections . . . stories . . . comedies . . . dramas . . . geography . . . history . . . physics . . . logic . . . for children, and unlimited variations on the same theme, so that the literary doll shops are crammed all the year round . . . but especially . . . when loving parents and aunts and uncles may be attracted by the appositeness of the notice 'Christmas Gifts for good children!' " (used by permission of the publisher. Frederick A. Praeger, Inc., 1954). He lists nearly as many categories as one would find in the 20th century, with the exception of space travel.

Rousseau and Didacticism. — The great social changes of the latter half of the 18th century had their effect on writers of children's books. Particularly influential were the ideas of Jean Jacques Rousseau (*q.v.*), whose *Émile* (1762) fascinated a generation of educators. Locke believed that children should be invited, not beaten, into learning, using their natural curiosity as a stimulant. Rousseau believed that children should be accompanied into learning, with a wise teacher always at hand to answer questions and to clarify the situation when the self-taught child becomes confused. Other writers, taking up Rousseau's device of a fictional guide, created a multitude of parents, relatives and teachers who knew all and told all. As a result books became more didactic than ever. Even now the curse of the conversational uncle explaining the universe to the inquisitive child occasionally mars an otherwise good factual book.

During this time a group of female educators laid a heavy didactic hand on writing for children, not yet entirely lifted. The group included Sarah Fielding (1710–68), who wrote *The Governess: or, tlze Little Female Academy;* Anna Laetitia Barbauld (*q.v.*), who wrote *Hymns in Prose for Children* (1781) and had a masterly command of English; and Mrs. Sarah Trimmer (1741–1810), whose educational magazine for adults, *The Guardian of Education,* reviened children's books. condemned all fairy tales and had considerable effect upon English education of the day. Another successful woman of the moral school of literature for children was Mary Martha Sherwood (1775–1851), whose *The History of tlze Fairchild Family* (1818–47) was still in print in the United States as late as 1931. A lighter touch was furnished by Catherine Sinclair, who infused a spirit of laughter and natural-

ness into her *Holiday House* (1839).

Maria Edgeworth (*q.v.*), another author for children much influenced by Rousseau, wrote stories that, although didactic, were skilfully plotted and show a genuine understanding of children. "Rosamond and the Purple Jar," one of her best-known tales, is contained in her first collection, *The Parent's Assistant* (1796).

Among the men affected by Rousseau's educational ideas were Arnaud Berquin (1749?–91) in France and in England Thomas Day (*q.v.*), nhose *Sandford and Merton* (1783–89) was widely read for over a generation.

Charles Lamb wrote contemptuously of these writers to Coleridge in 1802. Yet he, with his sister Mary, was persuaded by his publisher. W. Godwin, to "rewrite" Shakespeare's plays for children and produced *Tales From Shakespeare* (1807), a book still available in numerous editions. Another book he and Mary Lamb wrote, *Mrs. Leicester's School,* more about than for children, was in print as late as 1949.

Verse and Poetry.— After Isaac Watts, verse for children seems sparse until the early years of the 19th century. The one brilliant exception, William Blake's *Songs of Innocence* (1789). was largely ignored at the time; not until the 20th century has it been considered an indispensable part of children's poetry. In the 18th century there was considerable question as to the value of poetry or verse for children; both Watts and Mrs. Barbauld doubted whether children had the ability to understand its artifices. The prejudice against it was finally broken down by the publication in England of *Original Poems for Infant Minds* (1804–05) by "Several Young Persons" including Ann and Jane Taylor (*qq.v.*). These gay, moral, "cautionary" rhymes for the nursery became vastly popular. Kate Greenaway illustrated the Taylors' poems in 1883, and Edith Sitwell wrote the introduction for a selection of their verses published in 1925 called *,Meddlesome Mattie, and Other Poenzs for Infant Minds.* "Twinkle, twinkle, little star," the most famous poem either wrote, was included in their *Rhymes for the Nursery* (1806).

The first two popular books of "frivolous" verses, William Roscoe's *The Butterfly's Ball and the Grasshopper's Feast* with six coloured engravings after William Mulready, and Mrs. Catherine Dorset's *The Peacock "at Home,"* were both published in 1807. Their combined sale of 40,000 copies in their first year is a respectable one even in 20th-century terms. Cheerful, imaginative, good fun and charmingly illustrated, they inspired a number of imitators, but still remain somewhat outside the main stream of children's books of their time. Some of their popularity must have been due to their format: about four inches square, with large type and plenty of pictures. Although lithography was coming into use in children's books. these illustrations were done on copperplate, the colour being applied by hand.

The United States at this time seems to have been content for the most part to accept imported poetry, but two original American contributions to verse still popular are Sarah Josepha Hale's "Mary Had a Little Lamb" (1830), and Clement Moore's *A Visit From St. Nicholas* (1822), better known as *The Night Before Christmas.*

Fairy Tales and Fantasy.— In France, at the close of the 17th century, fairy tales became the rage at court. The most notable collection was Perrault's version of eight fairy tales, published in 1697 as *Histoires ou contes du temps passé, avec des moralités,* subtitled *Contes de ma mère l·oye.* The tales were "The Sleeping Beauty," "Little Red Riding Hood," "Bluebeard," "Diamonds and Toads," "Cinderella, or the Little Glass Slipper," "Hop o' My Thumb." "Puss in Boots" and "Riquet With the Tuft." They were ascribed to Charles Perrault (*q.v.*), a member of the Académie Française. Perhaps because Perrault felt it undignified to admit to their authorship. the tales were published as by his son Pierre Perrault d'Armancour, and their authorship has been much discussed; Percy Muir (see *Bibliography)* believes that the son was in reality the author, as the title page indicates. In any event, the tales were certainly traditional.

By 1729 Perrault was translated into English by R. Samber, although no actual copy earlier than 1741 has yet been discovered. In consequence some of the earlier English fairy tales, such as "Jack the Giant-Killer" and "Tom Thumb," took on lustre and were again permitted a hearing in polite circles.

Perrault's tales were but a sampling of the flood of folklore published in France. Two authors whose work is still read are Mme d'Aulnoy (*q.v.*) arid Mme de Beaumont, whose stories include "Beauty and the Beast."

In spite of the influence of Perrault and the success of *The Butterfly's Ball* and imitations of it, English children's books in the late 18th and early 19th centuries became more and more moral and informational. Only a few collections of the older. 17-ell-known tales, such as *Popular Fairy Tales* (1818) edited by Benjamin Tabart, were still available.

Then the work of two German philologists, Jacob and Wilhelm Grimm (*qq.v.*), created a new vogue for fairy tales. Their *Kinder- und Hausmärchen,* published in Germany in 1812–15, mas translated into English by Edgar Taylor, illustrated by George Cruikshank and published in England as *German Popular Stories* (1823–26). Grimms' fairy tales have remained in print and have been translated into various languages.

"Goldilocks and the Three Bears" is often attributed to Robert Southey because it appeared in his *The Doctor* (1834–37). but an original manuscript of "The Three Bears" written and illustrated by one Elizabeth Mure. dated Sept. 1831 and now in the Osborne collection of the Toronto public library, Toronto, Ont. (see *Bibliography*), claims the story to be an old folk tale.

Hans Christian Andersen (*q.v.*), the Danish genius whose impact on children's literature is still felt, appeared in English first in Mary Howitt's translation of *Wonderful Stories for Children* (1846). Translations soon appeared in America, and the stories have been available for over a hundred years, in many languages, English translations and editions. The M. R. James translation (1930) gives the sources of some of Andersen's tales. Seven were genuine Danish folk tales, such as "The Wild Swans." Most of the rest, such as "The Tinder Box," Andersen claimed to have heard as a child, but "The Emperor's New Clothes" is from a Spanish source, and several, such as "The Steadfast Tin Soldier," are original.

With increasing interest in this kind of story, fairy tales began to be gathered from many sources. Anthony Montalba's collection of *Fairy Tales of All Nations* (1849) was illustrated by Richard Doyle. Annie and Eliza Keary's translations from the Norse, *The Heroes of Asgard* (1857), and Sir George Dasent's translation (1859) of the Norwegian folk tales collected by Peter Asbjørnsen (*q.v.*) and Jørgen Moe appeared first in England, then America. Mary Frere collected Hindu tales in *Old Deccan Days* (1868). It appeared in the United States in 1869. A selection of 12 stories edited and illustrated by Katharine Pyle. entitled *Fairy Tales From India,* was published in the U.S. in 1926.

Probably the most comprehensive collections of folk and fairy tales and original fantasy mere gathered by Andrew Lang (*q.v.*) in numerous volumes named for various colours beginning with *The Blue Fairy Book* (1889). Lang also wrote some original tales. Joseph Jacobs (1854–1916) not only collected stories for his volumes of *English Fairy Tales* (1890), *Celtic Fairy Tales* (1891), their sequels and others but, like Lang, adapted and retold them as he felt necessary—especially those told in dialect or found in chapbooks, ill-written in the first place. Both Lang and Jacobs were scholars, and they based their changes on a sound knowledge of variants found in all folklore. Early editions contained notes regarding changes.

U.S. writers also contributed to the rising interest in folk literature, especially in myths and legends. Washington Irving gave children his original stories, "The Legend of Sleepy Hollow" and "Rip Van Winkle"; Nathaniel Hawthorne's *A Wonder-Book* (1852) and *Tanglewood Tales* (1853) contained stories from Greek mythology considered suitable for children. Shortly thereafter appeared Thomas Bulfinch's famous *The Age of Fable* (1855), which in revised and enlarged form is still found in many libraries. In *Uncle Remus: His Songs and Sayings* (1880) Joel Chandler Harris (*q.v.*) brought American versions of Negro folklore to children.

Original fairy tales sprang up everywhere. *Le Avventure di Pinocchio* (1882), by Carlo Collodi (pseudonym of Carlo Lo-

renzini), the story of a puppet who comes to life, mas first translated into English in 1892 and has appeared in many editions. Among the distinguished English authors who wrote for children were Charles Dickens; John Ruskin, whose *King of the Golden River* (1851) is a spirited fairy tale with a sombre fascination; and William Makepeace Thackeray, whose *The Rose and the Ring* (1855) is a gay nonsense tale. Charles Kingsley (*q.v.*) retold Greek myths in *The Heroes* (1856), but is even more famous for his original story *Water-Babies* (1863).

Of all the writers of original fantasy, Lewis Carroll (pseudonym of Charles Lutwidge Dodgson; *q.v.*) is probably the most acclaimed. *Alice's Adventures in Wonderland* (1865) and *Through the Looking-Glass* (1872) are known not only in English but in many other languages. despite the difficulty of translation. Both were brilliantly illustrated by John (later Sir John) Tenniel after Carroll's own illustrations for his original manuscript *Alice's Adventures Under Ground,* first published in facsimile in 1886. None of Carroll's other books equaled these first two in fame. although *The Hunting of the Snark* (1876) is well known, and *Sylvie and Bruno* (1889–93), *Phanfasmagoria and Other Poems* (1869) and *A Tangled Tale* (1885) have their devotees.

Nonsensical writing for children had not been unknown before Lewis Carroll's work. *Old Mother Hubbard* and *Dame Wiggins of Lee* and other nonsense nursery rhymes had appeared earlier. Edward Lear (*q.v.*) had written the *Book of Nonsense* (1846) and introduced children to such gloriously silly verses as "The Owl and the Pussy-Cat." He, like Lewis Carroll, invented nonsense words now a part of the language. Lear also illustrated his nonsense and gave the limerick (*q.v.*) its world-wide fame.

Earlier the tall tales of Baron Munchausen (*q.v.*) by Rudolf Erich Raspe had been translated from the German. as had Heinrich Hoffman's *Struvelpeter* or *Slovenly Peter* (1848), with its wildly coloured pictures and verses of "Awful Warning." Written by a German physician for the entertainment of his own children, it was subsequently translated into several languages.

George Macdonald, a friend of Lewis Carroll, wrote fairy tales of a different kind. *At the Back of the North Wind* (1871), *The Princess and the Goblin* (1872), *The Princess and Curdie* (1883) and the short tale, *Light Princess,* all have a serious undercurrent and an eerie sense of other-world happenings. Children of the 20th century still respond to the feelings of adventure, suspense and basic moral security of these stories.

There were also others in England writing original fantasy, such as Jean Ingelow, Dinah Maria Craik (née Mulock) and Oscar Wilde, whose *The Happy Prince and Other Tales* (1888) was outstanding for older children.

Among U.S. authors. Frank R. Stockton, Christopher Pearse Cranch, and most important Howard Pyle (*q.v.*) were writing original fairy tales and retelling old ones. Pyle not only brilliantly retold *The Merry Adventures of Robin Hood* (1883) and a four-volume version of the "King Arthur" stories, but also wrote his own folk tales in *Pepper and Salt* (1886), *TIze Wonder Clock* (1888) and *The Garden Behind the Moon* (1895). In 1919 *The Wonder Clock* sold six times as many copies as were sold the first year after publication. Fairy tales had come into their own.

Children's Magazines. — Although scores of children's magazines have been started, few have had a long or successful existence. Yet even among the short-lived ones, a considerable body of work by some of the more famous children's authors has appeared. Very few periodicals for children appeared in either the U.S. or Great Britain during the 18th century. In England, John Marshall seems to have made two attempts in his short-lived *Juvenile Magazine* (1788) and *The Children's Magazine,* begun in 1799. The first juvenile magazine in the U.S., also called *The Children's Magazine,* lasted only from Jan. to April 1789.

Near the beginning of the 19th century, *TIze Minor's Pocket-Book* managed to last about a dozen years in England. Jane and Ann Taylor were among its contributors. *The Child's Companion* began in 1824, lasting into the 20th century, and *The Children's Friend,* begun in 1825, was flourishing in the 1860s. These are probably the first long-lived, successful English magazines for children. Other early English children's periodicals included *The Infant's Magazine, The Youth's Monthly Visitor* and *The Youth's Miscellany of Knowledge and Entertainment.*

Among the earlier U.S. juvenile periodicals to have had some influence was *The Juvenile Miscellany* (1826–34), edited by Lydia Child.

In 1827 *The Youth's Companion,* a U.S. weekly. began its long and honourable career; it continued under its original name until 1929. when it merged with *The American Boy,* which continued until 1941. *Peter Parley's Magazine,* begun in 1832, was owned and edited by the original Peter Parley (pseudonym of Samuel Goodrich; *q.v.*), who also managed *Merry's Museum,* edited for a time by Louisa May Alcott. Goodrich's success both in the U.S. and England was extraordinary. He not only owned and edited magazines but was the author of at least 120 volumes of factual material for children, of which over 7,000,000 copies were sold during a 30-year period. He was widely pirated, and there were at least seven Peter Parleys in England, all adding to the flock of hack writing purporting to be his.

In contrast to Peter Parley with his emphasis on facts, Felix Summerly, (pseudonym of Sir Henry Cole) produced a set of books of fantasy in his *Home Treasury,* beginning in 1841, designed to bring back to English children their heritage of nursery rhymes and tales of folk and fancy. The battle between fact and fancy continues into the 20th century, although most persons concerned with children's literature believe there is a place for both kinds of writing, provided they are skilfully done.

By the middle of the 19th century, children's magazines became firmly established. In England the short-lived but excellent *The Charm* (1852–54) appeared, followed by the *Boy's Own Magazine* (1855–74) with well-known contributors and prizes. Thus began a spate of periodicals for children that lasted half a century. They included family magazines such as *Aunt Judy's Magazine* (1866–85) named by its founder, Margaret Gatty for her daughter, Juliana Horatia Ewing (*q.v.*), who was later its editor. Mrs. Ewing wrote as well as edited, and her first story appeared in Charlotte Yonge's children's magazine *The Monthly Packet* in 1861. In 1866 also appeared the first of the "penny dreadfuls," *The Boys of England,* edited by Charles Stevens.

The United States produced numerous children's periodicals, with contributions from many of the distinguished authors on both sides of the Atlantic. Lucy Larcom edited *Our Young Folks* (1865–73), in which appeared Thomas Bailey Aldrich's *The Story of a Bad Boy* (1870) and some of the humorous *Peterkin Papers* by Lucretia P. Hale. Other contributors included Louisa May Alcott. Theodore Roosevelt, Celia Thaxter, Mayne Reid and poets such as Longfellow, Whittier and Lowell. Later the magazine was sold to Scribners to become part of the even more famous *St. Nicholas Magazine* (1873–1939), which under the editorship of Mary Mapes Dodge, author of *Hans Brinker: or, the Silver Skates* (1865), gained world-wide fame. Established authors such as Kipling, Frances Hodgson Burnett. Howard Pyle, Sarah Orne Jewett, Mark Twain and Jack London wrote for *St. Nicholas.* In 1898 there was added to the magazine the St. Nicholas league, a section publishing original writings by young readers; among the many well-known authors of the 20th century who first appeared there were Edna St. Vincent Millay, Ring Lardner, Elinor Wylie, Bennett Cerf and Edmund Wilson.

The Riverside Magazine for Young People (1867–70), planned and edited by Horace Scudder in Boston, published 17 of Hans Christian Andersen's tales, some for the first time. Scudder learned Danish to be certain the translations were adequate. Scudder's anthology, *The Children's Book* (1881), was long the outstanding one in the United States, and his influence on children's literature was both worthwhile and lasting.

Harper's Young People, like *The Youth's Companion* a U.S. weekly, began in 1879 and continued for 20 years. Its editor, Kirk Munroe, also wrote many popular tales, including *The Flamingo Feather* (1887). *Wide Awake* (1875–93). another U.S. periodical, published well-known authors, both British and American.

The famous English boys' magazine, *The Boy's Own Paper* (1879–1912), had a long career under the editorship of George Andrew Hutchinson. World-wide in scope, it was read not only

by adventurous boys but by their equally adventurous sisters. Romance, adventure, school stories, all appeared there, including much of the work of Jules Verne (*q.v.*), the first of the science fiction writers.

Children's magazines of the 19th century reflect the change of emphasis in children's literature from the pious, didactic tales appearing in the first part of the century, through the factual, fantastic and realistic tales appearing in the second half. By the end of the century middle-class children throughout the English-speaking world had access to a great body of well-written, well-produced reading material. No longer were books and magazines accessible only to the few.

Picture Books of the 19th Century. — Although a few picture books mere published before the 19th century, it was not until then that the needs of the younger children were recognized Improved printing techniques also made picture books commercially attractive.

The first picture book is usually considered to be *Orbis sensualium pictus* (Eng. trans., *Tlze Visible World in Pictures* [1659]), published in Nurnberg in 1658 and attributed to a Moravian bishop, John Amos Comenius. The *Orbis pictus* was a combination of picture book, Latin text and natural history. The text. nith the Latin and the corresponding German in parallel columns, nas accompanied by copperplate illustrations of "the norld of sensible things." Soon after its publication the German portion was translated into English by Charles Hoole; this edition remained in print in England until 1777 and was widely used as a textbook.

Although there must have been other picture books. long since lost, there is little record of them. and it was the end of the 18th century before Thomas Bewick (*q.v*), an outstanding wood engraver, illustrated several books for children.

The Butterfly's Ball was one of the first of the 19th-century picture books. Although several important illustrators of children's books. such as George Cruikshank, Richard Doyle and John Leech produced good work. the reproductions were not generally good. A colour process invented in 1835 by George Baxter pointed the way to a method of producing coloured illustrations from wood blocks developed by the skilled craftsman, Edmund Evans. A whole new field developed and the work of three great illustrators was made available to children.

Walter Crane brought a missionary's zeal for graphic art and a classical taste to his work for children. More decorative than illustrative. his work is somewhat dated, but *The Baby's Opera* (1876) and *The Baby's Bouquet* (1878). with tunes arranged by his sister Lucy, are still available. Besides numerous picture books of nursery tales. he illustrated hlrs. Mary Louisa Molesworth's *Carrots, The Cuckoo Clock,* Judge Parry's retelling of *Don Quixote* and Grimm's *Household Stories.*

Kate Greenanay (*q.v.*), encouraged by Ruskin, developed her own world of children in *Under the Window* (1879) and *Marigold Garden* (1885), illustrating her own verses. *A Apple Pie, Mother Goose,* Robert Bronning's *Tlze Pied Piper of Hamelin,* and surprisingly, Bret Harte's *The Queen of the Pirate Isle* are among the well-known books for children that she illustrated.

Randolph Caldecott (*q.v.*), for whom the Caldecott medal was named, is perhaps the one of these three illustrators whose work is most enduring. His gaiety, sly humour, liveliness and story-telling qualities are implicit in all his nork, and in his illustrations for William Cowper's *John Gilpin* (1878) for example, his loving re-creation of the English countryside of his childhood makes it now come alive for children.

At the turn of the century Beatrix Potter (1866–1943) published at her onn expense a tiny book most persons consider a folk tale — *The Tale of Peter Rabbit,* later (in 1902) published by Frederick Warne nith coloured illustrations. This classic of the nursery has become increasingly popular, and in 1959 alone sold 24,000 copies. She urote several other miniature classics, most of which are masterpieces of structure and suspense.

Shortly after the appearance of *Peter Rabbit* the work of L Leslie Brooke (1862–1940) made its appearance in England and America. His nonsense picture book *Johnny Crow's Garden* (1903) achieved a sale of 3,600 copies in 1959. Besides the sequels *Johnny Crow's Party* (1907) and *Johnny Crow's New Garden* (1934). Brooke illustrated a few nursery rhymes in *Ring o' Roses* and four nursery tales in *Tlze Golden Goose Book,* including a "Three Bears" and "Three Little Pigs" whose illustrations are masterpieces of storytelling, humour and the detail so loved by children. He also illustrated some of Lear's longer poems.

School, Home and "The Wide, Wide World." — The second half of the 19th century saw the development of a variety of different kinds of stories for children, particularly those centred around school, home and world-wide adventure.

Thomas Hughes's *Tom Brown's Sclzool Days* (1857) is usually conceded to be the first school tale, and nas followed by many others, including such sentimental ones as Frederic Farrar's *Eric, or Little by Little* (1858) and such vigorous, humorous tales as Kipling's *Stalky and Co.* (1899). From the United States came Edward Eggleston's *The Hoosier School-Boy* (1883) and Ralph Henry Barhour's *The Half Back* (1899). School stories soon became sport stories. a type very successful in the 20th century.

Stories for girls in England tended to be domestic in tone, or romantic novels such as Charlotte Yonge's *The Heir of Redclyffe* (1853), R. D. Blackmore's *Lorna Doone* (1869) or Charlotte Bronte's *Jane Eyre* (1847). American girls seemed to be drawn to sentimental, lachrymose tales such as *The Wide, Wide World* (1850) by Elizabeth Wetherell (pseudonym of Susan Warner) or to such series as Martha Finley's interminable "Elsie" books beginning with *Elsie Dinsmore* (1867) and remaining with her through her grandmotherhood. The English novelist G. B. Stern in her autobiography, *Monogram* (1936), made an interesting analysis of Elsie. Of the numerous other series, some of the more durable ones include Susan Coolidge's "Katy-Did" series, beginning with *What Katy Did* (1873), and Margaret Sidney's *Five Little Peppers and How They Grew* (1881) and its sequels, dealing with the everyday life of a large family of limited means; both series have appealed to a wide audience for many years, the Sidney books perhaps being better known.

The outstanding children's author of this time in the United States was Louisa May Alcott (*q.v*). daughter of the Transcendentalist Bronson Alcott. Her *Little Women* (1868–69), based on her own family life, has delighted generations, as have other of her warmhearted, sensible family tales, such as *An Old Fashioned Girl* 11870) and *Eight Cousins* (1875). Most of her stories are still in print.

Widely read both in England and in America, Frances Eliza Burnett (*q.v ;* née Hodgson) wrote romantic, sentimental tales thrilling to girls of the 1880s and 1890s. Many a boy, however, had cause to hate *Little Lord Fauntleroy* (1886), uhose influence on Victorian mothers put the unnilling young males in velvet and lace. *Sara Crewe* (1888), enlarged to become *The Little Princess* (1905). and *The Secret Garden* (1909) both were popular when published and are still read.

During the early 19th century English adventure tales still emphasized religious fervour and moral tone, although narrative became increasingly important, as in Capt. Frederick Marryat's tales, *Mr. Midshipman Easy* (1836), *Masterman Ready* (1841–42) and *Children of the New Forest* (1847). Read with judicious skipping. these stories are entertaining even now. Other English writers popular with boys were W. H. Kingston, founder of *Kingston's Magazine for Boys* (1859), R. *M.* Ballantyne, author of *The Young Fur-Traders* (1856), *Tlze Coral Island* (1857) and others; G. A. Hentp, who covered the world in numerous historical tales such as *Under Drake's Flag* (1883); and Thomas Mayne Reid, writer of highly romantic tales. These adventure writers were similar in that they addressed their tales to a youthful audience. not to the adult as had Sir Walter Scott, whose romances *Ivanhoe* (1820), *The Talisman* (1825), *Quentin Durward* (1823) and others were adopted by young people.

It was not until 1881–82 that the adventure story appeared with no purpose but to entertain. Originally entitled *The Sea-Cook,* Robert Louis Stevenson's *Treasure Island* has become the prototype of the well-written adventure and, curiously, was first published serially in a "penny dreadful" called *Young Folks.*

After James Fenimore Cooper's *The Last of the Mohicans*

(1826), *The Deerslayer* (1841) and others, primarily written for adults, adventure tales in the United States were largely in the hands of the "hack writers" of numerous series: Oliver Optic (pseudonym of William Taylor Adams; *q.v.*), whose output included 116 full-length books and who was also editor of a children's magazine; Harry Castlemon (pseudonym of Charles Austin Fosdick [1842–1915]), who produced 58 titles; and Horatio Alger (*q.v.*), nhose *Ragged Dick* (1867) mas the first of many "rags to riches" stories so popular in their day.

Among the many authors of adventure tales for boys a few names stood out. among them Charles C. Coffin, Noah Brooks, James Otis Kaler, and Howard Pyle. The great name of the period, of course, was Mark Twain (*q.v.*), whose *The Prince and the Pauper* (1882). *The Adventures of Tom Sawyer* (1876) and *The Adventures of Huckleberry Finn* (1885) are still enjoyed by children.

Although U.S. and English writers ranged the world and time for material, children also welcomed stories by writers from other lands in English translation. Many came from France, including Paul du Chaillu, Alphonse Daudet, Verne, Ferdinand Fabre and Mme de Segur.

Perhaps no other book of its time with a foreign background has been more beloved by girls than *Heidi* by the Swiss author Johanna Spyri (1827–1901); the first English translation appeared in 1884, and there have been many later editions. Other books by Miss Spyri were translated into English but none reached the popularity of *Heidi*. From Sweden came another great book, *The Wonderful Adventures of Nils* (Eng. trans., 1907), by the Nobel prize winner Selma Lagerlof.

In the latter part of the 19th century poetry for children mas enhanced by the publication of Robert Louis Stevenson's *A Child's Garden of Verses* (1885; published originally as *Penny Whistles,* 1883). a collection whose high quality justified its wide and lasting popularity. In the U.S. Laura Richards, Eugene Field (*q.v.*) and James Whitcomb Riley were popular. In England, Walter de la Mare's first collection, *Songs for Childhood* (1902), appeared, to be followed by others up to and including his comprehensive anthology *Come Hither* (1923), whose only fault was omission of the editor's own poetry. The poetry of Rose Fyleman and Eleanor Farjeon is better known through selections in anthologies. A. A. Milne's *When We Were Very Young* (1924) and *Now We Are Six* (1927) are still popular, as are his two prose works, *Winnie-the-Pooh* (1926) and *The House at Pooh Corner* (1928). In 1960 *Winnie Ille Pu,* a Latin translation of *Winnie-the-Pooh,* became a surprise best seller in the U.S.

U S. poets appreciated by children include Dorothy Aldis. Harry Behn, Elizabeth Coatsworth, Rosemary and Stephen Vincent Benét, Vachel Lindsay and Carl Sandburg.

Developments in **the** 20th Century. — Great Britain and the United States both have their share of writers of fantasy in the 20th century, among whom are Kipling; James M. Barrie; Edith Nesbit; Kenneth Grahame. whose *The Wind in the Willows* (1908) is one of the great children's books; W. H. Hudson: Pamela L. Travers; Hugh Lofting; Anne Parrish; C. S. Lewis; Rumer Godden; J. R. R. Tolkien; E. B. White; Carolyn Sherwin Bailey; hlary Norton; and James Thurber.

Animal stories have become increasingly popular with children since the days of Anna Sewell's *Black Beauty* (1877), nith many kinds available. Horse stories seem to appeal to girls and dog stories to boys. Other animals from mice to panthers are subjects for many popular books.

By the beginning of the 20th century the public-library movement nas well established in America, but it was not until after World War I that children's librarians began to exert a considerable influence on the production of children's books. Although during the period of the war comparatively little of note was published. afterward both Great Britain and the U.S. benefited by new talent and by an influx of refugee artists and writers who brought new ideas to both writing and illustration. The work of such well-known illustrators as Arthur Rackham, Edmund Dulac, N. C. Wyeth and Louis Boutet de Monvel was augmented by that of Willy Pogany, the Petershams, the d'Aulaires, Ludwig Bemelmans, Boris Artzybasheff, Feodor Rojankovsky, Jean de Brunhoff and many others.

The first children's bookshop in the United States, managed by Bertha Mahony, opened in Boston in 1916. In 1924, under her editorship, *The Horn Rook Magazine* began publication It was the first magazine to be devoted entirely to books and reading for children and young people and is now a standard reference in its field. Anne Carroll Moore, superintendent of work nith children in the New York public library, began the first serious reviews of books for children in *The Bookman* in 1918, and in 1924 her column "The Three Owls" began to appear weekly in the *New York Herald-Tribune.* (A selection of these columns in book form, also entitled *The Three Owls,* nas published in 1925.)

The first children's book neek in America was sponsored by the Boy Scouts of America in 1919 Now called Book Week, it is usually observed early in November each year.

The increase in interest among librarians and others concerned with children's welfare led to greater sales of children's books, which in turn encouraged publishers to add a separate department concerned exclusively with the selection and production of children's books Louise Seaman headed the first such department at the Macmillan Company from 1919 to 1933. Her good taste and understanding of children's needs were of incalculable value in establishing rapport between publishers and librarians. teachers and parents. May Massee, another distinguished pioneer in children's hooks. became children's editor at Doubleday Page & Co., and later established the same department for Viking Press

The high standards shown by these two editors set the pattern for the whole industry and developed many new approaches. making an artistic as well as a commercial success of their work By the late 1920s most major publishers in the United States had children's editors, and later several publishers devoted their efforts to children's books exclusively. Most children's book editors have been women, as fen men in the first half of the 20th century concerned themselves nith books for the young. This has created an imbalance (now being remedied) that has not always worked to the advantage of the child reader.

Although the publishing of books for children increased after World War I, it was not until the publication of William Nicholson's *Clever Bill* (1927) and Wanda Gág's *Millions of Cats* (1928) that new picture books became important. A whole group of artists began turning their talents in this direction. and new processes of photolithography made larger editions possible.

By the 1930s mass-produced. inexpensive picture books were available, including the series entitled "Happy Hour Books." published by Macmillan. later supplanted by the publication of the still more inexpensive "Little Golden Books" The depression of the 1930s reduced the number of children's books published, but the lower costs made possible editions of a richness and beauty impossible to duplicate later.

Children's magazines in the United States. in the meantime, were losing ground After the demise of *St Nicholas Magazine* in 1939 — another casualty of the depression — there were none in the United States to equal it. *Boys' Life,* the official Boy Scout magazine, and *American Girl,* the official Girl Scout magazine, are still available as are *Jack and Jill, Child Life* and numerous magazines sponsored by various religious groups, the quality of nhich in many instances was improved greatly in the period after World War II. *The Young Elizabethan,* formerly *Collins Magazine,* is an English periodical that has made a place for itself in the United States as well. But the whole magazine field, particularly in the United States, has felt the competition of paperback editions of books, school activities, movies and television.

During World War II the terrible destruction of book stocks in the air raids on London. the paper shortage both in England and the United States and the shortage of steel that caused the melting of plates of many important but slow-moving titles, eliminated a great many excellent books. Prohibitive costs prevent their being reprinted.

At the same time, the increase in the number of school libraries, especially in elementary schools, increased the demand for all kinds of children's books, and by the early 1960s the number available

was enormous. In 1919 about 430 new titles were published in the United States; in the 1960s the number of new titles had more than tripled and there were also many new editions of older titles reprinted. The variety is staggering. Animal stories, biography, history, science, fiction. poetry and picture books are but a few of the categories of children's books for all ages. Outstanding in the field of realistic fiction are Laura Ingalls Wilder's "Little House" stories, based on her childhood in the pioneer sections of the midwest. They are lasting contributions to children's reading.

An interesting development after 1950 was the emphasis put upon easy-reading books planned for the beginning reader. Prior to the 1940s no major publisher realized the need, but by 1945 a few firms, such as Holiday House, produced attractive ones. A very successful easy-reading book of the 20th century was *The Cat in tlze Hat* (1957), a nonsense story in verse written and illustrated by Dr. Seuss (pseudonym of Theodore Geisel). The vocabulary was limited to 250 words and the book could be read by some first- and most second-grade children. As a change from dull, humourless primers, it caught popular attention and in 1959 sold over 100,000 copies.

Children's Book Awards. — Frederic G. Melcher, editor of *Publishers' Weekly*, established the John Newbery medal award given annually since 1922 "for the most distinguished contribution to American literature for children"; later he added the Caldecott medal awarded since 1938 "to the artist of the most distinguished American picture book for children" published in the United States during the previous year. The first Newbery medal was given to Hendrik van Loon's *The Story of Mankind.* Robert Lawson has won both: the Caldecott medal for *They Were Strong and Good* (1940) and the Newbery medal for *Rabbit Hill* (1944). Joseph Krumgold won the Newbery medal twice, for . . . *and Now Miguel* (1953) and *Onion John* (1959), as did Elizabeth Speare, for *Tlze Witch of Blackbird Pond* (1958) and *The Bronze Bow* (1961). The Caldecott medal was won twice by Robert McCloskey, for *Make Way for Ducklings* (1941) and *Time of Wonder* (1957), and by Marcia Brown, for *Cinderella* (1954) and *Once a Mouse* (1961).

Great Britain's award for outstanding books for children: the Carnegie medal, named for Andrew Carnegie, was established in 1937; the first award went to Arthur Ransome's *Pigeon Post.* These and other prizes have stimulated librarians, for the choice is theirs, and focused their attention on the new as well as the old.

For children's encyclopaedias *see* ENCYCLOPAEDIA: *20th Century: Encyclopaedias for the Yoztng.*

(Q. H.)

CHILD WELFARE embraces those services and institutions concerned with the physical, social and psychological well-being of children, and it is particularly concerned with children lacking normal parental care and supervision. Although some stirrings of interest in the welfare of children may be discovered in the deep shadows of both religious and secular history, it was not until the beginning of the 17th century with the enactment of the poor law (*q.v.*) of 1601 in England that any sustained and organized efforts were made. This law was to determine in a large measure what was done for dependent children both in England and the United States for the next three centuries. As to orphan and destitute children, this law and its successors provided that local governments might (1) set them to work along with adult paupers if they were old enough; (2) apprentice them to learn a trade; (3) auction them off, if they were very young, to the lowest bidder who would agree to care for them in his own home; or (4) send them to the poorhouse. The provision of food and clothing in the child's own home, if he had parents, was another possibility.

All of these methods of child care were brought to America by the colonists and later became the basis of a system of local care in the United States that was not finally abandoned by some states until the passage of the Social Security act in 1935. Children placed in work and free homes often were exploited and neglected, and those consigned to the local poorhouses were demoralized by exposure to the decrepit, insane and handicapped adults who also lived in these institutions.

The earliest attempts to rescue children from the harshness of the poor law were made by voluntary organizations, often religious, and took the form of separate institutions for children. Prior to 1800, there were seven orphan asylums established in the United States, and in England foundling homes and other children's institutions under private auspices were in existence as early as 1552. In European countries the church. through a variety of institutions, provided most of the care for dependent children until well into the 20th century.

There has been wide variation from nation to nation and from time to time in what constitutes child welfare services. In underdeveloped countries and in the aftermath of war and disaster these may be just the essential measures to keep children alive, such as emergency feeding, shelter and simple public health precautions. In the western world and particularly in the larger cities, child welfare includes a range of highly specialized services that go far beyond physical survival and deal with such problems as personality development, vocational guidance and use of leisure time. The general standard of living, the level of education and the financial resources of the country are among the factors which determine what the child welfare standards will be.

The following presentation is organized on the basis of various forms which child welfare may take rather than on descriptions of systems in effect in individual countries. They may be divided into services to children living in their own homes and those for children who must live away from their homes.

CHILDREN IN THEIR OWN HOMES

The most widely accepted principle of modern child welfare is that every child needs a home and family of his own. A ringing statement of this principle, which has been repeated around the world, was adopted at the first White House Conference on the Care of Dependent Children in 1909: "Home life is the highest and finest product of civilization. It is the great molding force of mind and of character. Children should not be deprived of it . . . for reasons of poverty." The abiding importance to children of a secure home life and affectional ties with parents has been urged so persuasively by child welfare experts and psychiatrists that the cornerstones of most child welfare programs are the services aimed at preserving and strengthening the child's own family.

Income Maintenance.—Supplying or supplementing family income so that parents can maintain a home for their children is

usually the first such service to be provided. Assistance may range from the distribution of food. medicine and clothing to complex systems of social insurance. In addition to programs of general family relief. special assistance to broken families is widespread. Originally limited to widows with young children and known as mothers' pensions in the United States, the never laws tend to provide wider coverage and extend to deserted and unmarried mothers and to families where the father is incapacitated.

A number of countries followed New Zealand's lead in the passage of so-called family allowance laws. Unlike public assistance, these allowances are not based on a means test hut on the number of children in the family. These small weekly amounts serve as companion measures to other income maintenance programs which frequently make no provision for dependent children of the recipients. Among the countries which provide family allowances are Canada, France. Great Britain, Italy, the Scandinavian countries, Spain and Switzerland.

Social insurance schemes offer the broadest protection against the risk of children's being removed from their homes for economic reasons. Starting in Germany in 1883, the idea of social insurance spread slowly at first but received wide acceptance after World War II. Among the common hazards to home life which social insurance systems attempt to provide against are death, unemployment, sickness, industrial injuries and temporary disability of parents. (*See* SOCIAL SECURITY.) With increased acceptance of income maintenance as a basic governmental responsibility, the efforts of voluntary and religious agencies concerned with family life shifted from relief-giving to other ways of assisting parents such as family counseling and other services described below.

Maternity and Child Welfare.—Although child welfare increasingly stresses social services, public health and medical services usually are the first to be organized in new and underdeveloped nations. This recognizes the fact that the infant and maternal death rates are the primary indices of a nation's progress in child welfare.

Infant welfare clinics mere established in some colonial territories after World War I by determined and energetic government officials supporting the pioneer work of missionary doctors. In the Gold Coast (now Ghana) women doctors of the Scottish mission inaugurated infant welfare services in 1924 and, associated with these, a voluntary agency to undertake home visits. The clinics were retrenched during the 1930s and only in a few centres were services kept going by the Red Cross. Protein malnutrition was first described clinically as a result of infant welfare studies in the Gold Coast by Cicely Williams, who gave it the name of kwashiorkor which had been used by the people themselves to describe the condition it produced in children without knowing its cause.

In many countries, particularly in Africa and Asia the first steps were public health attacks on such diseases as yaws, tuberculosis. malaria and leprosy, and efforts to improve child nutrition. This was often followed by instruction of native midwives in the simple principles of hygiene. The assistance of the United Nations Children's fund (UNICEF) and the World Health organization (WHO) was particularly significant in inaugurating these basic programs of infant and maternal welfare. The industrialized countries have gone far beyond this with the provision of professional prenatal, delivery and postnatal care for mothers without reference to their ability to pay. Infant welfare clinics where expert advice may be obtained on getting children off to a good physical as well as emotional start are widely available in Great Britain and the United States. (See MATERNAL AND CHILD HEALTH.)

Birth control as a measure to strengthen the family was recognized officially by such countries as Denmark with the authorization of Maternity Aid institutes nhere contraceptive information was given; by Poland, where abortion was legalized in 1956 and a Planned Motherhood association founded in 1957. Even more pronounced was the trend toward promoting methods of family planning in Asia and the far east with India, Pakistan and Japan the most active.

Day Care.—Nurseries and nursery schools provide a special service that frequently is necessary for successful care of children by their own families. The need for this service most frequently arises when the mother is either forced or chooses to leave the home during the day to work. One of the legacies of World War II was a tremendous increase in the number of working mothers. Facilities for the care of their children are provided under a variety of auspices—governmental agencies. voluntary agencies, commercial proprietors or, in some instances, industry itself. The nursery provides supervised indoor and outdoor play, a midday meal and naps, as a minimum. In addition, there may be instructions in arts and crafts, reading, music and elementary hygiene.

Although originally thought of solely as institutions where children of working mothers could be assured of safe custodial care—and this remains their primary purpose—nurseries have come to serve other childhood needs. They are used where the physical or emotional capacity of the parents, poor housing or other unfavourable situations make it advisable for the child to be out of the home part of the day. They are also used for children who need the socializing influence of living with other children. Some nurseries are specially staffed with or have access to psychiatrists, pediatricians and social workers, and are used for the diagnosis and treatment of emotional problems of children and their parents. A separate form of care is foster day care. This is provided in foster homes which are selected and supervised by a social agency. These are usually to be preferred to the nursery for very young children who have to be apart from their mothers during the day.

Homemaker Service.—Recognition of the harmful effects on young children of even temporary removal from their homes led to the development in the 1920s of what is known as "homemaker" or "housekeeper" service. Homemakers. selected for their skills and personalities and supervised by family welfare or children's agencies, are placed in homes where the mother is temporarily unable to care for the family. Such services have become increasingly important as the number of families without relatives or obliging neighbours attempt to survive in the impersonal atmosphere of large cities. By 1959 "home-help" agencies were reported in more than 20 countries including Israel, Italy and Turkey, where the service had just been launched. In the Netherlands and Norway government funds were used to help cover the cost of home-help service.

Services for School Children.—The school is in a particularly favourable position to detect early physical and emotional problems of children and to provide services to prevent later and more serious developments. A comprehensive school program includes both medical and social services. Routine physical examinations to discover defective vision and hearing are most common because these directly affect the child's ability to learn. Psychological testing to discover children who need special education by reason either of limited or superior mental endowment is also widespread. Other items in a complete service include dental examination and treatment, vaccinations and immunizations, and the provision of supplemental foods and vitamins for children requiring them.

School meals for needy school children were first provided in Great Britain by voluntary agencies, such as the London School Dinners association, 1889. Investigation revealed the need to systematize the haphazard activities of voluntary bodies in this field. In 1906 the Provision of Meals act established the principle that arrangements for the provision of school meals were an integral part of the education system. By the outbreak of World War II free meals, other than milk, were being provided by only about half the local education authorities in Britain. but a great expansion of the service took place during the war and actual provision was put on a sound nutritional basis. The Education act of 1944 made it a duty of local education authorities to provide school meals and milk.

For city school children provision is made by some education authorities and voluntary agencies for holidays and teaching terms at camp schools situated on the coasts or in beautiful rural locations where healthy recreation and development is facilitated in open-air living.

Social services under school auspices were first directed toward

enforcement of attendance laws; however, experience showed that mere legal enforcement did not successfully cope mith the problem of truancy. The place of the old truant officer has been taken by the school social worker who works in a constructive rather than a punitive may with parents and is concerned with the infinite range of home conditions and emotional and psychological problems which may impede a child's educational program. Early detection by the school social worker of symptoms of behaviour disorders and the securing of prompt treatment constitute an important attack on the prevention of delinquency.

In nest African territories of the British commonwealth, for example the expansion of the primary school system served to focus attention on truancy, ill-health. neglect and irregular attendance because of arrears of fees, lack of books and old and dirty uniforms. Expansion also presented these countries nith an increasing army of school-leavers looking for employment in the towns or anxious to secure further education at secondary school level. Social welfare and labour departments co-ordinated efforts to provide school welfare services, careers advisory panels and the encouragement of the formation of parent-teacher associations.

Help to children in choosing vocations and in planning advanced education is available in many secondary schools. By means of tests and counseling. both in groups and individually, vocational guidance counselors are able to help young people avoid entering blind alley occupations or embarking upon careers for nhich they are not fitted. *(See* PSYCHOLOGY, APPLIED: *Vocational Guidance.)*

Protective Services.—Not all parents love their children and some are grossly incompetent and neglectful. Children of such parents require special protective services. Societies for the prevention of cruelty to children, organized under voluntary auspices, date from the middle of the 19th century and still exist under various names in some cities. although the trend has been to place responsibility for such services in the public child welfare agencies. In some jurísdictions probation officers of the family court or children's court carry on the work. Protective services are usually invoked on the complaint of neighbours or others aware of cases of parental abuse or neglect. The fact that the services are not sought by and may be resisted by the parents requires that the protective officers have special skills and that there be some adaptation in usual casework practices. Because removal of a child from his own home. even if it is not a very good one, is such a serious matter. all reasonable efforts are made to avoid this drastic step. Some situations are so brutal and menacing to the safety of the child that prompt intervention of the police and action by the courts is necessary.

Children with welts and bruises and those whose emaciated bodies give evidence of neglect are not the only ones needing rescuing, although they are the ones most likely to be found in the case loads of protective agencies. Equally serious but less conspicuous are the emotional scars which many children bear. The subtler forms of emotional damage which parents can inflict on their children are only beginning to be recognized and the courts are still cautious in intervening. *See* also CHILD LABOUR; CHILDREN, LAWS CONCERNING; CHILDREN'S COURT; JUVENILE DELINQUENCY.

CHILDREN AWAY FROM HOME

Although modern child welfare places major emphasis on keeping children in their own homes, the unfortunate group of children who have to be removed from them absorbs more than half the time of all child welfare personnel, at least in the United States.

There have been marked changes over the years in the reasons children have lost their homes, and corresponding changes in the kinds of care provided for them. Whereas death of parents and destitution used to lead the list, in the second half of the 20th century this was no longer the case. Most so-called orphan asylums have almost no orphans and many of them have acknowledged this fact by dropping the word orphan from their institutional names. The income maintenance measures described earlier have helped to reduce economic dependency, and medical science and public health measures have succeeded in various ways in reducing the number of children who lose their parents by death. The steady decline in the number of mothers dying in childbirth, leaving young children behind, is but one example. The most frequent causes for removal of a child from his home are marital discord, parental irresponsibility and neglect. separation and illegitimacy. Temporary placement may sometimes be necessary because of behaviour problems of the child or family emergencies.

The changes which have taken place in the kinds of care provided are largely attributable to additions to knonledge from the fields of social nork, psychiatry and child development. Many of the kinds of care described below are not new, but in their modern expression give much more emphasis to the emotional needs of children.

Adoption.—Adoption is an ancient institution that was recognized in the Babylonian codes of Hammurabi and legally regulated in Greece, Egypt and Rome. In these early civilizations as well as in the orient of modern times, the purpose was primarily to secure an heir. Adoption as a child welfare measure is almost exclusively a 20th-century innovation. Although de *facto* adoption of children had existed in England for years, it was not legally provided for until 1926. Modern adoption laws and practices have as their aim the safeguarding of three sets of interests: those of the child, the natural parents and the adoptive parents. The essential features of a good law are (1) consent provisions which assure that parental ties are not severed improperly or under duress; (2) requirements for thorough social study of the adoptive home in all cases before a decree is issued; (3) a trial period in the adoptive home mith appropriate supervision before the decree becomes final; and (4) clear delineation of the legal consequences to all three parties at interest when the adoption is consummated. Because of the critical and delicate nature of the decisions involved in adoption, the importance of the social study cannot be overemphasized. Whenever possible this should be made by a social agency and placements by physicians and lawyers should be discouraged. Since a large proportion of adopted children are illegitimate, social and medical services should be available to the unmarried mother.

At one time adoption was thought of only for the perfect or near-perfect baby. This led to prolonged study and observation nith the result that many children were not placed until they were a year old or even older. The change in practice to early placement, usually under three months. and the placement of children with physical and psychological defects, reflects a basic change in philosophy among adoptive agencies. Instead of emphasizing the requirements of the adopting family, the focus is on the needs of the individual child. The trend to early placement was encouraged by psychiatrists who warned against the dangers of emotional damage to infants kept in hospitals or nurseries for extended periods of time. In the United States many older children in institutions and foster homes are denied the benefits of a permanent home because of the refusal of natural parents to consent to adoption. The rights of even very neglectful parents may sometimes be too well protected.

The existence after World War II of large numbers of orphan and refugee children led to a sharp increase in inter-country adoptions. Because of the dangers inherent in hasty and impulsive decisions to place children in homes in another land and culture, the Child Welfare League of America formulated standards to guide such adoptions. The following precautions are recommended:

> Adoption outside a child's own country should be considered only when less suitable plans can be made for him in his own country. It is usually better for any child beyond the age of infancy to be adopted within his own country, and not to be transplanted to another culture. Inter-country adoption considerations should include placements for children with certain mental defects, and for children whose family or racial background presents a handicap to their acceptance and development in their own country. Extremely careful consideration should be given before a child is removed from his own relatives for adoption. Before deciding to relinquish a child for adoption, parents should be helped to weigh the consequences—emotional, psychological and legal—against apparent economic or social advantages. Unless the parents or relatives understand and accept the meaning of adoption in the culture of the child's new country, adoption should not be considered for the child. *(Standards for Adoption Service,* Child Welfare League of America, Inc., New York, 1958.)

(See also ADOPTION.)

Foster Care.—The two basic forms of foster care are placement with families or in institutions. At one time enthusiasm for foster family care ran so high as to threaten the future of institutional care. This was during the period 1920–1940. when children's institutions usually were of the large congregate type nith regimented programs which permitted little recognition of the needs of individual children. It is now accepted that a children's agency should be able to make available both types of care since experience has shown that not all children can benefit from foster family care. For example, children whose experiences with their own parents have been emotionally devastating may not be able to fit into the intimacy of a foster family and may do better in the more impersonal life of an institution. ,The same is frequently true of emotionally disturbed adolescents.

Foster family care of children has its roots in the apprenticeship provisions of the early English and American poor laws. Gnder these lans, dependent children were placed with families to be supported and taught a trade. Typically, the period of apprenticeship was to age 18 for girls and 21 for boys. In exchange for his maintenance and trade training, the child was expected to nork for the master or mistress. With the decline of apprenticeship after the middle of the 19th century, children continued to be placed in foster homes, without formal indenture—but still with the expectation that they would earn their keep. In the United States through organizations such as the Children's Aid Society of New York thousands of children from the crowded city slums of the east coast were transported during the last decade of the 19th century to free homes in small tonns and on farms in the middle west. The objection to these earlier forms of foster care was that, once placed, there was often no supervision by the placing agency. and many children were exploited and overworked.

Modern standards for foster care emphasize careful selection of homes, close supervision of the children placed in them, and payment of board. Clothing, medical and dental care and allowances for the children are usually provided by the placing agency. Particularly important are the counseling services provided by the agency's casenorkers to foster parents In the absence of such services children may be needlessly uprooted and shifted from one home to another with damaging results These standards reflect a change in emphasis from the former concern nith the foster family's employment requirements to a concern for the child's welfare.

Fostering children, with its emphasis on the importance of the substitute family and the child s relationship nith the mother-substitute. has greatly increased the demand for foster parents and the exacting work placed upon child-care officers. In Great Britain since the Curtis report, 1947, and the Children act. 1938, shortages of both foster parents and children's officers have created public concern. It is open to doubt whether remuneration can be an important factor in deciding people to take a foster child. The most successful foster parents do it because they like to have children around them. and in Great Britain it was found that women who had had more than one foster child also had more children of their own.

The changes in institutional care of children have been of tno kinds. Instead of the former monumental buildings with rows of beds in dormitories and children sitting silently at long tables in the dining rooms. the modern institution is more likely to be of the so-called cottage type. Under the cottage system these are small homelike units with living rooms and single and double bedrooms having from five to ten children along with a housemother or couple. Meals may be served in a common dining room although many cottages have their onn dining rooms and have food delivered from a central kitchen. The purpose is to create a family rather than an institutional atmosphere. It should be noted that the shift from the congregate to the cottage type institution has been sloner in Europe and in other parts of the norld where the institutions are under religious auspices. A survey by the bureau of social affairs.United Nations secretariat. reported that by 1960 institutions with 50 or more children had practically disappeared in the United Kingdom and that progress had been made in underdeveloped countries such as Thailand in substituting cottage type for congregate institutions.

Less visible than the architectural changes, but more important, are the efforts made to understand and to meet the needs of the individual child. This individualization has come about largely through the introduction of casework services into institutional programs. The casenork process is essentially a matter of study, diagnosis and treatment of social and emotional problems characterized by a concern for individual differences. In a children's institution the process begins before the child is admitted with a careful study of all the circumstances in his case. Within the institution the caseworker is concerned nith the child's relationships with his onn family, with efforts to rehabilitate the family looking to the child's eventual return and, where this is not possible. in making other plans for the child upon his discharge.

For children with severe behaviour and emotional problems, there are specialized institutions where psychiatric treatment is provided. Austria. Germany, England and the United States are among the countries which have pioneered in developing such residential centres. It should be emphasized that the treatment institutions are not for children suffering from brain damage or the mentally retarded, but for the emotionally disturbed and neurotic child. In some of these centres the children are under the direct care of a psychiatrist; more often, however, a psychiatrist serves in a consulting capacity. Because of the quality of the staff required and the ratio of staff to children, per capita costs in such institutions are very high.

HANDICAPPED CHILDREN

Broadly viewed, progress with the problems of the physically handicapped child has taken two forms: first and most important have been the efforts to prevent crippling conditions; and, second, a change in the philosophy of care for afflicted children. Efforts to prevent orthopedic disabilities have been notably successful with such diseases as bone and joint tuberculosis, poliomyelitis and osteomyelitis. These have been due to such public health measures as required tuberculin testing of cattle and to advances in medical science. The introduction of the Salk vaccine and the development of antibiotics have led to dramatic decreases in the number of children crippled by poliomyelitis and osteomyelitis. Attacks on the problem of congenital malformation have taken the form of research into hereditary factors, nutritional deficiencies and the toxemias of pregnancy.

Measurement of progress in the prevention of blindness among children (as with other handicapping conditions) cannot be reliably made because of the inadequacy of the statistics. In some parts of the world trachoma is still a common cause of blindness because of local health and sanitary conditions. In those countries where high standards of public health prevail. prevention of blindness has taken the form of safety regulation and legislation requiring prophylactic treatment of the eyes of newborn babies. A baffling ailment, retrolental fibroplasia, nhich produced complete or partial blindness in premature babies and mas in some countries the largest single cause of congenital blindness. was brought under control after the discovery in 1954 that the disease is associated nith the amount of oxygen used in incubators.

Progress has been made in estimating the extent of blindness and surveying its causes in nide areas of east and nest Africa. Malaya and the middle east. Through the decade 1950–60 the Commonwealth Society for the Blind advanced the mork for preventing blindness in west Africa from the formerly little known disease of onchocerciasis nhich frequently led to "river blindness." Diet deficiencies in west Africa have also been studied as a probable cause. The growth of territorial organizations for the blind, schools, norkshops and training centres has progressed. Priority is to be given in the newly independent British Commonwealth countries to sending more blind children to school. In the early 1960s it nas estimated that less than 1% of blind children were at school in most African territories, whereas probably more than 50% were at school in Trinidad. Jamaica, Cyprus and Singapore. Nigeria. nith at least 20,000 blind children. had in 193'9 only two schools for the blind, accommodating 37 children. A large-scale

experiment was undertaken in Katsina province, northern Nigeria. to send blind children to normal day schools to be given special instruction by trained itinerant teachers in order to speed up the process of offering blind children some education.

The first attacks on the problem of mental retardation came with the enactment of sterilization lams. There were high hopes that by sterilizing feeble-minded persons who might become parents the problem would eventually be solved. This proved not to be the case since only a small proportion of mentally retarded children are born of feeble-minded parents. Prevention takes the form of research in the fields of biochemistry and genetics, and in improved methods of obstetrics including surgical intervention in cases of damaging conditions during pregnancy.

A summary of the changes in philosophy of care for physically handicapped children is found in the following statement:

> The physically handicapped have been handicapped in the past as much by the attitude of society as by their physical limitations. A changing attitude, placing emphasis upon abilities rather than disabilities, has accompanied the rapid growth in knowledge of the problem related to (a) recognition that the physical, mental, social, and emotional needs oi the handicapped person are not different from those of the non-handicapped; (b) realization of the importance of capitalizing upon the potential contribution of the handicapped to social and economic welfare; (c) significant advances in medical care, therapy, educational methods, psychological evaluation, vocational evaluation and training, and prostheses, aids, and appliances; and (d) growth of integrated medical, social, educational, and vocational services in rehabilitation oi the physically handicapped. (Social *Work* Year Book, *1957,* New York, National Association of Social Workers, 1957.)

While custodial institutions for crippled and blind children had practically disappeared in England and the United States by 1960, institutions and special schools for feeble-minded and seriously retarded children mere still common.

INTERNATIONAL CHILD WELFARE

The first international child welfare congress was held in Paris, France, in 1883 with delegates from Europe and America, including the United States. Ten such congresses were held in London and European cities, the last in 1933. In 1928 the first International Conference of Social Work was held. bringing together the same professions and organizations which had organized the international child welfare congresses.

In 1916 the first Pan-American Child congress was held in Buenos Aires, Arg., and brought together delegates from the Latin American republics and the United States. Resolutions passed by the congress led to organization of the International American Institute for the Protection of Childhood, in Montevideo in 1927. The work of this organization was continued by the Inter-American Children's institute after its creation in 1948 as a specialized agency of the Organization of American States.

The International Union for Child Welfare, a voluntary federation of 69 national and international organizations, with headquarters in Geneva, Switz., which was created in 1920, had as its general objective the raising of standards of child welfare through consultative services and the stimulation of demonstration projects.

World Wars I and II were followed bv emergency relief measures for children in devastated countries. Jewish, Protestant and Roman Catholic agencies from the more favoured parts of Europe and overseas, the Red Cross and other nonsectarian groups supplemented the work of governmental organizations. After World War II many children were privately aided through the Cooperative for American Remittances to Everywhere (CARE). (See also DISASTER RELIEF.)

United Nations Agencies.— Far more significant than the emergency wartime and postwar efforts to relieve misery was the development of international planning in behalf of the children of the world. A better world for children was envisaged in the Universal Declaration of Human Rights, approved Dec. 10, 1948. by the general assembly of the United Nations. Their interests were especially stressed in: "The family is the natural and fundamental group unit of society and is entitled to protection by society and the State," (art. 16, sec. 3), and "Motherhood and childhood are entitled to special care and assistance. All children, whether born in or out of wedlock shall enjoy the same social protection." (art. 25, sect. 2).

The United Nations created or encouraged the organization of services entirely or partly concerned with the welfare of children, and co-ordinated the work of these and other international agencies serving children, some of which were in existence before the UN was organized in 1945. Co-ordination of the work of the various specialized agencies and the UN became a principal responsibility of the Economic and Social Council and the administrative committee on co-ordination consisting of the secretary-general of the UN and the executive officers of the specialized agencies. The unprecedented organization and expansion of relief and child welfare services during the decade prior to mid-20th-century made their co-ordination a tremendous and urgent task.

The United Nations International Children's Emergency fund, after 1953 called the United Nations Children's fund (CNICEF), was established in December 1946 by the general assembly of the UN for the relief and rehabilitation of children in war-torn countries and for child health throughout the world. Though not a direct descendant. UNICEF inherited much of the responsibility for feeding children and providing other child welfare services nhich had been a part of the load carried by the United Nations Relief and Rehabilitation administration. Though USICEF received much less financial support than UNRRA, it was less restricted in the number of countries it could enter and less subject to military and political controls. UNICEF mas supported by voluntary contributions from governments and individuals; by 1960 an annual budget in excess of $20,000,000 was being contributed by 86 countries to support projects in 105 countries and territories. Approximately half the total amount was contributed by the United States. Prior to 1950 the fund provided a daily supplementary meal for 4,000,000 to 6,000,000 children and nursing and pregnant women. The program in the east, including the East Indies, consisted mostly of supplying medicines and equipment and training local personnel in techniques for the control of specific child welfare problems. In Europe and north Africa much progress was made in the world-wide campaign to test 100,-000.000 children for tuberculosis. A resolution adopted by the general assembly of the UN, Dec. 1, 1950, revised the policy of USICEF. Relief programs mere replaced by emergency and long-range projects whereby supplies, training and advice nere provided in underdeveloped countries with a view, wherever appropriate, to strengthening the permanent child health and child welfare programs of the countries assisted. By 1954 most of these countries had realized the advantages of UNICEF services and instead of matching UNICEF funds, as in previous years, they provided several times as much as the UN appropriations for advancing the welfare of their own children. Thus facilities for manufacturing powdered milk had been developed in the near east, Asia and Latin America where formerly milk and other relief supplies had been imported.

The World Health organization (WHO), created July 22, 1946, from its beginning gave priority to children in much of its work. In addition to the joint programs in which it promoted the mass feeding of children, improved nutrition and more effective methods of food production, the representatives of WHO surveyed the tuberculosis problem in many countries and set up laboratories for the manufacture of Bacillus-Calmette Guérin (BCG) vaccine. Outstanding among its achievements was its campaign against malaria. WHO also issued daily radio warnings of epidemics of smallpox, cholera and other pestilential diseases. Venereal diseases, in some areas affecting nearly half the population. were combated; prenatal and infantile syphilis were treated with penicillin in mass campaigns in several countries. The sanitation program of WHO led to improvement of water supply and sewage disposal systems and destruction of disease-carrying insects. With such improvements the death rate among infants in some areas was cut from 30 to 3 per 100 births in a comparatively short time. WHO and the Food and Agriculture organization (FAO)

jointly promoted a "food for health" program, stressing health education of the public.

CHILE, a republic on the Pacific coast of South America that occupies the western slope of the continent south of Peru and west of Bolivia and Argentina. In the south, Chile borders the Strait of Magellan all the way to the Atlantic ocean. It is a narrow, ribbonlike country, averaging only 110 mi. in width, but extending about 2,650 mi. in length, from 17° 30′ S. to 55° 59′ S. In the northern hemisphere this distance would be equivalent to the stretch from southern Mexico to southern Alaska. Although Chile has a greater inhabited latitudinal range than any other country in the world, about 90% of the people live in middle Chile. from 30° S. to 42° S. In this section is the capital city, Santiago (*q.v.*). The total area of the country is 286,396 sq.mi., slightly larger than the state of Texas. Its population (1960) was 7,339,546. In addition to its main area Chile owns the Juan Fernández Islands, Easter Island, and a number of other islands in the South Pacific ocean, and lays claim to a sector of Antarctica from 53° W. to 90° W. In northern and middle Chile the country is composed of three parallel strips: the Andes on the east, the coast range on the west and a series of lowlands between. South of 42° S. there is no central lowland but only a discontinuous island chain standing guard before a fiorded, mountainous coast. Northern Chile is a desert, notable for the production of copper and nitrates; southern Chile is a cold, wet region of little attractiveness and limited economic potential; but middle Chile is climatically most agreeable, and is the centre of agriculture, livestock ranching and industry.

This entry is organized according to the following outline:

I. PHYSICAL GEOGRAPHY

The northern coast of Chile conveys the impression of a great land barrier with a remarkably even sky line. This barrier consists of a mountain range with gently rounded upper surfaces that descend only slightly to the floors of the interior basins, or pampas, whereas the seaward face is generally a steep escarpment that drops from an elevation of 2,000 or 3.000 ft. directly into the sea. This coastal bluff is a serious obstacle to transportation and settlement. Only in isolated spots is there a sufficiently wide bench or alluvial fan for a townsite. South of Valparaiso the coastal escarpment is more broken and the elevations assume the characteristics of a mountain chain. From Chiloé south, subsidence has taken place, and only the higher parts of the coastal range reach above sea level as a series of islands.

The great barrier ranges of the Andes, which make up fully a third of the country, may be divided about 27° S. into a shorter northern and a longer, southern section. The southern part is composed of a single rather narrow range, whereas the northern is made up of two or more roughly parallel ranges enclosing a series of plateau surfaces whose major development, because of the narrow shape of Chile, is to be found in Bolivia and Argentina. The Andes increase progressively in height from an elevation of 6,000 or 7,000 ft. at the southern end until they culminate at 32° 39′ S. in Aconcagua (elevation 22.831 ft.), which is the highest peak in the western hemisphere. The peak is located just across the border in Argentina. Bermejo (Uspallata) pass (elevation 12,917 ft.) lies immediately south of Aconcagua, and is the most important international pass in South America. Below it at 10,469 ft. is the tunnel of the transcontinental railway that connects Valparaiso with Buenos Aires. Farther south the lower average elevation of the mountain ranges results also in lower passes. In the lake district south of 39° S. most of the passes are under 5,000 ft., a circumstance that greatly facilitates trans-Andean communication in that area. The Strait of Magellan in the extreme south is a sea level pass through the Andes. The southern Andes are intensively glaciated, U-shaped valleys and glacially-sculptured peaks being the rule. Large glaciers are still to be found in many places, and extensive moraines are in evidence, many of them acting as dams for lakes. A series of young volcanic cones are superimposed on the Andes bet een 34° and 43° S., some of them of striking beauty and symmetry.

North of 27° S. the Andes are divided into several chains of which the western forms the major eastern boundary of northern Chile. Two railroads lead across it into Bolivia, the one from Arica at 13,956 ft. and the other from Antofagasta at 12,972 ft. In 1948 the Trans-Andean railroad of the north was opened through Socompa pass (elevation 12.657 ft.), connecting Antofagasta with Salta, Arg. The extreme ruggedness, the aridity and the cold of this section limit crop raising and grazing, but it is a rich storehouse of minerals. One of the largest copper deposits known is located at Chuquicamata (latitude 22° 19′ S.) at an elevation of 9,300 ft. It has been worked since 1915 by U.S. interests. This enterprise is by far the most important economic activity in northern Chile.

Between the coast range and the Andes lies the so-called longitudinal valley. This is not a true valley but an irregular depression, in places 25 to 50 mi. wide and at times reaching an altitude of 3,000 to 4,000 ft. In some sections it is broken by isolated groups of mountains or by spurs from the main range, which divide the longitudinal valley into a series of basins, locally

known as pampas. The most northern of these is the Tamarugal, extending north from the Loa river. This differs from the others in that the ground water in places lies within four or five feet of the surface. Although on the whole this pampa is barren of vegetation there are remnants of what once must have been extensive thorn wood areas. The desert of Tarapacb lies in the western part of the Tamarugal pampa and furnishes a portion of Chile's nitrate. South of Coquimbo the desert pampas end and spurs of the Andes extend westward to the coastal ranges. Only inland from Valparaiso does the longitudinal valley again appear. The central valley extends, with interruptions, as far as Puerto Montt.

1. Geology. — Along the coast of Chile lies a belt of rocks formed mainly of old granite and schist and overlying Cretaceous and Tertiary deposits; farther inland is the western cordillera of the Andes, which is composed chiefly of intrusive masses, volcanic rocks and folded Mesozoic beds. The deposit in the great longitudinal valley of Chile, which lies between these two zones, is formed of debris that is in places more than 300 ft. thick. In northern Chile the rocks of the coastal zone, which disappear northward beneath the Pacific, consist mainly of isolated masses that stand close to the shore or that project into the sea. South of Antofagasta these old rocks, which there begin to rise to higher levels, form a nearly continuous belt along the coast, extending southward to Cape Horn and occupying the greater part of the islands of southern Chile. They are greatly folded and are doubtless Paleozoic. In northern Chile the Cretaceous and Tertiary beds of the coastal zone are of small extent, but in southern Chile the Mesozoic beds, which are at least in part Cretaceous, form a rather wide band. The Tertiary coastal beds include both marine and terrestrial deposits, and most of them appear to be of Miocene or Pliocene Age. The whole of the northern part of Tierra del Fuego consists of plateaus formed of horizontal Tertiary beds. The northern part of the Chilean Andes, which is the western cordillera of Bolivia, consists almost entirely of Jurassic and Cretaceous sediments and Tertiary eruptive rocks. The Mesozoic beds are thrown into a series of parallel folds, which run in the direction of the mountain chain. Into these folded beds are intruded granitic and other igneous rocks of Tertiary age, and upon this foundation rise the cones of Tertiary and later volcanoes. Triassic rocks are found in northern Chile near Copiapó, where coal seams containing Upper Triassic (Rhaetic) plants have been found but the entire Mesozoic series appear to be represented at different places. The Mesozoic rocks are chiefly marine sandstone and limestone, but they include also tuff and conglomerate of porphyry and porphyrite. These porphyritic rocks, which form a characteristic element of the southern Andes, are volcanic, and as they contain marine fossils they must have been laid down beneath the sea. They are not confined to any one geologic horizon but occur at different levels in the Jurassic beds and at some places in the Cretaceous. Here and there they may be traced laterally into the more normal marine deposits of the same age. A large part of the Andes is covered by the products of the great volcanoes that still form the highest summits. The volcanic rocks are liparite, dacite, hornblende andesite and pyroxene andesite. The recent lavas of the volcanoes in southern Chile are olivine-bearing hypersthene andesite and basalt.

Chile has suffered over the centuries from earthquakes as well as from volcanic eruptions. It is located on the boundary between the great heights of the Andes mountains and the equally great depths of the sea, an environment often associated with seismic activity. Over 100 serious earthquakes have been recorded in Chile since 1575. In the 20th century destructive earthquakes occurred in 1906, 1928, 1939 and 1960.

(W. H. Hs.; G. McL. Wo.; H. J. Bn.; P.E. J.)

2. Relief and Drainage. — Because of the surface configuration of the country, the rivers are short and unimportant except for the life-giving waters they bring, and have little or no significance in directing the settlement or trade of the country. In the north they are few, and for a distance of approximately 600 mi. the waters of only one, the Loa, reach the sea throughout the year. This stream is the longest in Chile (273 mi.). The Copiapó, 112 mi. long, once discharged its waters into the sea, but rarely does so now, as the needs for irrigation are greater than the supply. The rivers to the south are better fed at their heads and flow through much less arid regions. Some of them become raging torrents at certain times of the year, and a number have been harnessed for the production of electricity. The electrification of the railroad in the Chilean section of the transcontinental line is complete, together with the main line from Valparaiso to the capital. With the increased demand for electric current has come also the storage of water for irrigation.

The lakes of Chile are among the most beautiful in the world. In southern Chile, south of the Bio-Bio river, there is a series of glacial lakes in the provinces of Cautin and Llanquihue. The largest of these lakes are Ranco and Llanquihue, the former with an area of 157 sq.mi., the latter 329 sq.mi. Because of its natural beauty, this lake region has become a resort place for Chileans and tourists at all seasons of the year.

3. Climate. — Not many countries have as great climatic extremes as Chile. The north is an absolute desert, but there is a gradual increase in precipitation through middle Chile until it reaches a total in south Chile not surpassed by any extratropical region. The strong, permanent high-pressure area formed over the Pacific at about 30° dominates the climatic conditions of northern Chile, accounting for its northward flowing winds and consequently for the great aridity of the region. South of this high-pressure area is a region of variable winds that accompany the passage of cyclones moving from west to east across the South Pacific ocean. The cyclonic belt moves north in the winter and south in summer, at times causing violent winds to s eep the Andean passes between Chile and Argentina. In middle Chile it makes its influence felt as far north as the region of Coquimbo, where it produces winter rains. In certain years or series of years this migration does not take place or goes on beyond the normal and the result is either great droughts or heavy rains.

South of the southern tip of Chile is a belt made up of numerous low-pressure areas, with unusually high barometric gradients, which produce very strong winds averaging over 30 m.p.h. and reaching peak velocities three or even four times that high. These moving low-pressure areas give a constant succession of storms for which the passage around the Horn has been renowned ever since its discovery, and farther northward give the southern part of Chile its westerly winds and heavy rainfall.

North Chile is the driest region of which there is any record. During a 21-year period Iquique had an average rainfall of 1.5 mm. (0.06 in.) and Arica for a 19-year period had less than one-half as much. On the Andean slopes of this region, periodic summer rains fall as low as 8,000 ft. with occasional heavy snows. Such precipitation may produce floods that spread mud and gravel over the valley and give rise to temporary salt lakes. Needless to say, such floods are calamitous; nitrates are destroyed, the nitrate works paralyzed, and the homes of the people, because of the poor mud roofs, practically ruined. Desert conditions extend southward to the latitude (27° S.) of Caldera or Copiapó, where a mean rainfall of about 15 mm. (0.6 in.) prevails.

The rainfall increases rapidly to the south, being 141 mm. (5.6 in.) at La Serena (30° S.) and 500 mm. (19.7 in.) at Valparaiso (33° S.). The increase southward is still fairly regular, reaching 2,707 mm. (107 in.) at Valdivia (39° 50′ S.). From there south, the rainfall is more or less uniform except for local modifications with the striking maximum of 5,379 mm. (216 in.) for south Chile at Bahia Félix (53° S.).

The rain-bearing winds come from the S.W. The western Andean slopes are wetter than the valley areas in all latitudes, and this is very noticeable even on the Andean slope of the northern desert region. This dry area thrusts a finger southward through the central valley nearly as far south as Santiago. The 10 to 20 in. rainfall area, whose southern coastal limit is at Valparaiso, extends southward through the valley nearly as far as Concepción, with a rain belt on either side of 20–40 in. and with a belt along the western slope of the Andes, overlooking the beautiful agricultural valley, of 40 to 80 in. This belted arrange-

ment is still more marked in the southern rainy section. The various islands and embayments show a rainfall of 80–200 in.; the mountainous area directly to the east has a precipitation of over 200 in.; in Argentina the rainfall gradually decreases again to less than 20 in.

Irrigation is needed throughout the central valley, not only because of the low rainfall but more especially because the greater part occurs in the winter. This discrepancy becomes less marked from north to south. At La Serena over 98% of the rain comes in the six winter months and 82% in the three colder months. The percentages at Santiago for the same periods are respectively 90 and 73; for Concepción 83 and 61. Even at Punta Arenas 61% of the precipitation occurs during the six winter months, but south of the Bio-Bio the summers are not dry. The true Mediterranean climate is found from a little north of Valparaiso to just south of the Bio-Bio.

In general, for its latitude, the temperature is low. The cold Peru current, which strikes Chile in the vicinity of 40" S.. flows northward along the entire coast. and keeps the temperatures low and uniform. The average summer temperature, even at Arica, does not rise above 75" F. Similarly the mean at Iquique is only 66° F., and at Antofagasta 65° F., although southward the temperature is somewhat lower as at Valparaiso, where it is only 58° F. At the latter place, the mean monthly temperature varies from 63.5" F. in summer to 52° F. in winter, and the thermometer seldom rises to 85° or falls below 38°. Santiago, at an altitude of 1,740 ft., has recorded extremes of 96° F. and 25" F., and on rare occasions snow falls in the citv. At Valdivia. in the southern part of the central valley, January is the warmest month with 61.5" F. and July the coldest with 45° F. Because of the winter rainfall and the attendant cloudiness, the sensible winter temperatures are somewhat lower than the records indicate. But there is no doubt that the main inhabited parts of Chile enjoy some of the most pleasant climates of South America.

(H. J. Bn.; W. H. Hs.; P. E. J.)

4. Vegetation. — With more than 70% of Chile mountainous. with altitudes from sea level to more than 20,000 ft.. with rainfall from practically nothing to more than 200 in. annually. and temperatures from warm to cold, it is readily understandable that the flora is remarkably diverse. Three main plant zones, correlated chiefly with changes of altitude and climate, are evident.

An almost rainless, desertlike area, between 19° and 30° 50'. The Chilean coast from the Peruvian border to latitude 20° S. is nearly barren, more nearly approaching an absolute desert than any other part of the world. South of 20° the heavy winter fogs of the coastal hills account for a seasonal flora, prominent in Antofagasta and Atacama provinces. Between 24° and 26" 50' there are four main types of vegetation in the coast range, varying from drought-resisting desert shrubs, above and below the fog belt, to a more varied plant formation within the fog belt, containing among other species various cacti.

Mediterranean zone, between 20° 50' and 37°, having dry, cool summers and mild, rainy winters. This zone is diversified, and the flora varies with the altitude. Near sea level *Solanum maritimum* is common. Up to 2,500 ft., characteristic plants are *Crinodendron patagua* and *Bellota miersii.* Over large areas in these lower altitudes species of *Adesmia* and *Acacia* are common. On certain favoured slopes quillai *(Quillaja saponaria), Cryptocarya,* and *Lithraea,* among others, are found. Up to 4,500 ft. *Valenzuelia* and other shrubs grow. Below the snow line (about 14,000 ft. in central Chile) are developed the conspicuous cushion or mound plants, chiefly *Azorella* and *Laretia acaulis.* Many spring-flowering (October and November) plants, belonging to such genera as *Valeriana, Anemone, Cardamine, Libertia,* and *Oxalis,* are found in this zone.

A humid area from 37° to 56°, between Concepción and Tierra del Fuego, with rain the year round in some places exceeding 200 in. There is developed a dense, mid-latitude rain iorest slightly south of Valdivia to the Strait of Magellan. Several species of false beech (*Nothofagus*) and nine kinds of conifers constitute some of the principal trees in these forests. A motley variety of vines, shrubs, ferns and mosses abound, while in more open parts of the rain forest are found solid thickets of the wild bamboo, *Chusquea.*

Many distinct genera and species of plants are found only in Chile. Many of the Chilean plants are Andean in origin and relationship, others are subantarctic. Examples of relict and isolated assemblages of plants occur in the flora, suggesting correlation with past climatic and geological changes and events. (J. A. Sk.)

5. Animal Life. — Except at the extreme south, where low passes lead to Patagonia, and at the north, where the deserts of both coast and highland merge with those of Peru and Bolivia, Chile is cut off from the rich life of South America by the barrier of the Andes, which extends north and south for hundreds of miles with scarcely a pass below the snow line. The Iarger Chilean mammals are the puma and guanaco, the Andean wolf and the huemul (a large deer), the foxlike chilla. and two kinds of wild cats. The mountain rodents include the almost extinct wild chinchilla. The south Chilean forest has distinct types of marsupials (especially *Rhyncholestes*), Darwin's fox, and the little spike-horned pudu, smallest of deer. Though rich in small birds, Chile does not have many of the more conspicuous South American bird types.

The Chilean bullfrog, *Calyptocephalella,* with a bony casque, is regularly eaten. The tiny Darwin's frog, *Rhinoderma,* is remarkable in that the male takes the developing eggs into his enlarged vocal pouch, where they transform into tiny froglets. The native fresh-water fishes are extremely few. The successful introduction of North American trout into the lakes of southern Chile has made them attractive resorts for fishermen.

(K. P. S.)

II. GEOGRAPHICAL REGIONS

It is customary to divide Chile into three major geographical regions. Middle Chile (or central Chile) extends roughly from near Coquimbo to the Bio-Bio river at the latitude of Concepción. Southern Chile, south of the Bio-Bio, is divided into a densely populated northern section and a southern section (south of Puerto Montt) that is very thinly populated. Northern Chile extends northward from Coquimbo to the Peruvian border.

1. Middle Chile. — The Chilean nation is formed around a single nucleus of concentrated settlement. About 73% of the total population lives in middle Chile; and if to this area is added the population of the northern part of southern Chile (between the Bio-Bio and Puerto Montt) the area would include 90% of the Chilean people. All the activities of Chilean life are concentrated in middle Chile, where the city of Santiago is the political, economic, social and artistic centre of the nation. The division of the country into provinces is for administrative purposes only. To a much greater extent than in other countries of Latin America, Chilean institutions are organized around a single geographic area.

As noted above, this middle part of Chile is the section that enjoys a Mediterranean type of climate. It has cool, dry summers and mild, rainy winters, similar to the conditions on the west coasts of all the continents between 30° and 40" of latitude. In many ways the landscape of this part of Chile reminds one of the central valley of California.

Soon after the Spanish conquest the land in middle Chile was marked off into private estates of vast size, known in Chile as haciendas or *fundos.* The system of large private estates owned by a small minority of the people and operated by tenant workers persisted almost unchanged and unchallenged until the 1920s. The census of 1925 showed that in that year middle Chile was divided into 82,084 rural properties. Of these properties, 76.588 were less than 200 hectares (ha.; about 500 ac.) in size. Only 5,396 properties, or about 7% of the total, were classified as haciendas because they were larger than 200 ha. But this small proportion of the properties included almost 90% of all the land in farms in middle Chile. In the valley of the Aconcagua river, which lies just inland from Valparaiso, 98% of all the land in farms was included in 3% of all the properties. Some of the haciendas were huge, covering more than 5,000 ha. (12,350 ac.) each. More than half of all the farmland in middle Chile was included in these large

haciendas. The largest single property was the Hacienda Rio Colorado. near Santiago, which had an area of 160,000 ha., or about 618 sq.mi.

Most of these huge properties, however, were not arable. On the Hacienda Rio Colorado, for example, only 250 ha. were capable of being irrigated: the rest of the property was too steep or too dry for the cultivation of crops. In the part of middle Chile that lies between Santiago and Concepcibn, only about 10% of the area can be cultivated; the remainder is useful only for pasture, or is not useful at all.

After 1925, and especially after 1945, some of the large private properties were broken up. The large haciendas have by no means disappeared, but large properties are intermingled with small farms. This process of change has not been brought about by revolution, as in Mexico, nor by government decree, as in some other countries, but by economic pressure. It has proved to be so profitable for the large landowners to subdivide their lands and sell them to small buyers that many of the hacienda owners have disposed of their lands and have retained only small farms for their own use. This process is possible only because the landowning class in Chile has been willing to convert land into cash and then to invest cash in manufacturing or commercial establishments. This willingness to engage in business pursuits distinguishes the Chilean landowners from their counterparts in most other countries of Spanish America.

As long as the large landowners maintained their rural estates, they chose to use them chiefly for grazing high-grade cattle and horses. Traditionally the hacienda owner was interested in stock-raising, not in farming. The tenants who lived on the haciendas *(inquilinos)* and worked for the owners were, of course, permitted to use some parts of the hacienda to raise their own food crops, chiefly wheat, potatoes, beans, peas, lentils, onions, artichokes and peppers. Unlike most other parts of Latin America, wheat occupies more land in Chile than does maize. Yet most of the land, and almost all the better land, has traditionally been used for irrigated alfalfa and other feed crops for the animals. Chile, as a result, does not raise enough wheat and other foods for its own people, but must import these supplies. The herds of fine cattle in middle Chile are driven up into the Andes to feed on the rich high-altitude meadows in the summer and are driven back to the central valley in the winter and fed on alfalfa.

The development of a typical Mediterranean agriculture in middle Chile has been retarded by this interest of the large owners in pastoral activities. Nevertheless, some of the hacienda owners had turned their attention, even before 1925, to the production of characteristic Mediterranean crops. This is the kind of climate that is especially well suited for the production of grapes and wines. Chilean wines are generally acknowledged to be the best produced in Latin America, and of a quality that permits them to compete with wines from the Mediterranean countries of the old world. There are also small areas devoted to the growing of olives and other fruits. The total area used for these characteristically Mediterranean crops, however, is not nearly so large as the area that is physically suitable for this more intensive kind of agriculture.

The breakup of the large properties has increased the area used for Mediterranean crops, including the food crops for domestic consumption. The small property of less than 200 ha, in size is not large enough to use for pasture. Former hacienda lands, subdivided and sold in small units, are now used for orchards, vineyards and wheat. These changes in landholdings and in land use are transforming the character of middle Chile.

Along with the transformation of the rural areas of middle Chile there has been a great increase in the size of the cities and in the variety of urban manufacturing. Three of Chile's four major industrial cities are in middle Chile: Santiago, Valparaiso and Concepcibn. The fourth, Valdivia, is in the northern part of southern Chile. The first three have all grown rapidly since the 1920s: Valparaiso and Concepción have populations well over 100,000, and Santiago over 600,000 people. The original rectangular city of Santiago has been surrounded by industrial suburbs and slums.

2. Southern Chile. — For a long time after the first Spanish colonization of middle Chile. the Bio-Bio river remained a frontier. South of this river the open landscape of middle Chile originally gave way to the dense forests of the rainy south. Until 1850 the southern forests were left to the Indians, except for a few coastal towns. But in 1850 the first pioneer settlements of Germans entered this region and began to demonstrate how the forested lands could be successfully occupied. After the War of the Pacific (1879–84; *q.v.*) a flood of new pioneer settlers moved southward into the forests south of the Bio-Bio. The province of Valdivia, for example. had only 8.860 inhabitants in 1835, but by 1907 it had 133,443. The original German colonies had been north of Puerto Montt near Lake Llanquihue. But when the Chilean pioneers entered the region the forest was rapidly cleared and the whole area was settled wherever the land was level enough and dry enough to make settlement possible.

In contrast to the form of settlement in middle Chile, this southern frontier was occupied by small farmers, each doing the work on his own property. There were few large estates and no class of large hacienda owners. On the new clearings in the forest the settlers raised wheat and pastured cattle. Of the total area of southern Chile only about 20% is used for food crops; yet on this area is produced the greater part of Chile's wheat. Because of the wet climate only a kind of soft wheat is grown. The production of wheat is concentrated in the territory immediately to the north of Temuco. In addition to wheat the farmers of this region grow potatoes, oats, apples and hay, and use their fields in rotation for the grazing of beef and dairy cattle. However, because of the lack of a market for dairy products, this ideal dairy country is by no means used to capacity. Most of the cattle, here as in middle Chile, are raised for beef.

There is a considerable industrial development in the northern part of southern Chile. On the peninsula of Lebu there are coal mines, some of which extend out under the ocean. The coal is of poor quality, but after processing it can be used in the steel plant near Concepcibn. Lumber is used for the manufacture of furniture in Valdivia, and there is a boatbuilding industry on the island of Chiloé.

The northern part of southern Chile is famous for its scenery and opportunities for recreation. The lake district, with its magnificent lakes held behind glacial moraines, its background of rugged mountains and its spectacular cone-shaped volcanoes, reminds one strongly of the western borders of the Cascade mountains in Oregon and Washington. The lakes, stocked with North American trout, attract many fishermen in the summer season; in the winter this part of Chile has become one of the world's major ski centres.

All these activities, however, are concentrated in the northern part of southern Chile, between the Bio-Bio and Puerto Montt. The latter town, like Tacoma, Wash., faces the beginning of the embayed section stretching on toward the poles. The similarity of the island of Chiloé to Vancouver Island is striking. To the south, steep rocky islands rise abruptly from the water's edge. Exposed to the open ocean. the cliffed shores are pounded by terrific surf, and only in the sheltered bays and fiords can landings be made. Immediately above the rocky cliffs at the shore the wet tangle of forest covers the land—as far up as the lower limit of permanent snow, which, in Tierra del Fuego, is only 2,500 ft. above sea level. The far south of Chile has one of the world's most unpleasant climates: never very cold, never warm, always cloudy, blustery and wet with sleet or cold rain. The southern coasts are sparsely inhabited by some of the world's most primitive tribes.

Settlement by Chileans in the south is limited to a few areas. Puerto Aysén, at the head of a deep fiord, gives access to sheep pastures in Patagonia across the mountains. On the Strait of Magellan, Punta Arenas is a very old settlement that also serves a sheep-raising area in Chilean territory on the eastern side of the Andes where the climate is relatively dry. In late 1945 oil was discovered in Tierra del Fuego. Since then oil and gas have been produced in these fields, and settlements appeared where only a short time before the land had been entirely unoccupied.

3. Northern Chile. — Northern Chile lies to the north of

Coquimbo at about 30° S. and includes the Atacama desert (*q.v.*). In contrast to the rest of Chile this area is very dry and offers few spots suitable for agricultural settlement. Along the western piedmont of the Andes small Indian settlements were established long before the arrival of the Spaniards. With water taken from wells, small areas could be irrigated and used for the growth of maize. But for both Indians and Spaniards the Atacama remained for a long time only a region to be crossed as quickly as possible. When the Spaniards found silver in the mountains of what is now Bolivia, some of it mas brought to ports along the harbourless coast — such as Antofagasta. There were only a few oases where rivers from the mountains provided reasonably certain supplies of water. In the north there was the oasis of Tacna (in Peru) and its port Arica (in Chile). Far to the south, where the Loa river emerges from the Andes, there was the oasis of Calama, served by the port of Antofagasta. And far to the south, again, the oasis of Copiapó was served by the port of Caldera.

In the colonial period Tacna mas recognized as a part of Peru, Calama belonged to Bolivia, and Copiapó was in Chile. But the boundary between these territories remained undefined. During the 19th century methods were invented for making use of nitrate, the unique natural resource of the Atacama. It was first used for fertilizer early in the century and by the middle of the century its use for the manufacture of gunpowder had been started. By 1860 a thriving mining industry had been established, and for the first time the location of the boundaries became important. After many difficulties, Chile declared war on Peru and Bolivia and by 1883 had occupied and established ownership of all the desert country as far north as Arica. Several new nitrate shipping ports were established, such as Iquique, connected with the mining communities to the east by steep railroads over the coastal scarp. As long as nitrate provides economic support, mining towns can be supported in places where even water must be shipped in from outside. The part of Chile north of Copiapó has proved to contain a wealth of resources on which the Chilean economy is all too dependent.

In the 20th century copper has become even more important than nitrate. The copper comes from three large mining areas: Chuquicamata, near Calama in the Andes; Potrerillos, in the Andes a little to the north of Copiapó; and El Teniente, in the Andes east of Santiago. Northern Chile has proved to be a most valuable national asset, even though only a small proportion of the Chilean people live there. (P. E. J.)

III. THE PEOPLE

1. Racial Types. — The population of Chile is predominantly white, although intermarriage with the Araucanian and other Indian groups has taken place over the centuries and continues at a slow pace. By this process the Indians have been gradually assimilated into the white group. According to estimates made by the Chilean census bureau there are fewer than 150,000 persons, or about 2% of the total population, who could be considered predominantly Indian (largely Araucanian).

A strict and relatively efficient program for controlling immigration from Europe and from the other American republics has obviously influenced the physical structure of the population. The policy was established during the colonial period when only Spanish citizens could enter the colony. Colonists during this period came largely from the regions of the Basque provinces, Castile and Andalusia. About the middle of the 19th century a movement to bring in German immigrants was initiated and continued until the end of the century. The influence of this movement is evident throughout Chile, especially in the south around Valdivia, Llanquihue and Osorno, where many of the people still retain German customs.

Other European countries that have made important contributions to Chilean immigration include Italy, the British Isles, France, Switzerland and Yugoslavia. Small contingents of refugees from northern and central Europe were admitted after World War II. As a result of these movements family names such as O'Higgins, O'Brien, Ramsey, Edwards, Walker, Eastman, Ward and Sauer are common.

2. Languages. — Spanish is the dominant language of the country, although several Indian dialects are still spoken in relatively isolated areas. Many of the people of southern Chile still speak German but Spanish is slowly replacing it.

3. Religion. — As in all Latin-American countries, Roman Catholicism is the predominant religion. Chile, however, traditionally has maintained a policy of religious tolerance that has resulted in the development of major groups of Protestants throughout the country, especially in the cities of Santiago, Concepción, Valdivia and Antofagasta. Many of these religious groups sponsor and operate extensive programs for community development and rural welfare with emphasis upon health and education. The Roman Catholic religion was maintained by the state until 1925, when the church mas disestablished.

4. Customs and Culture. — The Chilean people are generally characterized in South America as friendly, jovial and democratic. Their belief in the democratic process of government is evident in a wide variety of forms in village and community life, including freedom of speech and of the press. Chilean women, who obtained the ballot for local elections in 1934, were among the first in the western hemisphere to assert social and political independence by participating in public affairs and by directing their own personal lives with a minimum of interference from parents and other relatives.

Chilean family life is woven tightly into a pattern of social and economic interdependence strongly fortified by a deep sense of loyalty and mutual responsibility. So complete may be the pattern that many members limit their personal contacts outside their homes almost exclusively to relatives and a few close friends. Although there has been some loosening of family ties. particularly in cities, most social life goes on within the boundaries of kinship, in Iarge part controlled by the much respected elders of the group.

Chile has been a pioneer among American nations in many fields of social welfare, labour laws, low-cost housing and accident insurance. Broad social legislation in these fields has relieved the family of some of its economic and social responsibilities, although most members still recognize obligations for family and individual misfortune when the state fails to do so.

For upper- and middle-class families meals are often social affairs of some importance, where many formalities are observed and where time is not a factor of major importance. A light breakfast and heavy lunch and dinner are supplemented by snacks *(nzeriendas)* of sandwiches and sweets at midmorning and mid-afternoon. Excellent wines are produced in quantity and liberal use is made of both red and white varieties at mealtime. Chilean cuisine is considered among the best of the Americas. Beef and fowl are prepared in a multitude of ways, as are the fish and shellfish that abound along the entire coast. Seafood specialties include *Cochayuyo,* or seaweed; *Erizos,* or sea urchins; and *Locos,* a type of scallop. Some of the more common native dishes are *empanadas,* meat-filled cakes; *pastel de choclo,* a combination of corn, meat, chicken and vegetable; *cazuela,* a stew containing chicken, corn, vegetables and rice; and *humitas,* a mass of ground sweet corn wrapped in the corn husk and boiled.

In addition to the cosmopolitan activities characteristic of the large cities, there are many dances, fiestas and other social activities throughout the nation. The folk and popular music is largely Spanish in origin, with the exception of that of the Araucanian Indians, who have preserved some of their ancient songs and instruments. Some of the native dances are strikingly gay and colourful. The *cueca* is perhaps the most uidely popular at all occasions. It has been called the dance of love or of conquest. The music for the *cueca* is rapid and rhythmic with the guitar the dominating instrument. Male and female partners dance with handkerchiefs twirling about their heads and shoulders while the audience applauds the more dextrous couples. Men frequently dance in high, hard-heeled boots with which they beat out staccato notes with considerable skill. Other popular dances include the *zapateo,* a tap dance common in South America, the Spanish fandango and the *cuando.* Semiprofessional bands may be found in most rural villages and towns.

A popular form of amusement is the rodeo, where Chilean cow-

boys or *huasos* compete in horsemanship and in the ability to turn a steer or other animal at full gallop in a round corral. So difficult is the feat that specially-bred horses are trained for the task from the day they are broken to the saddle. The costume of the Chilean *huaso* is elegant and picturesque, consisting of a broad-brimmed black hat. short and colourful poncho. short-cut jacket adorned with many buttons, and tight-fitting, high-waisted trousers pulled over low-cut boots from which hang spurs that often are of delicately-worked silver. A good rodeo with *huasos* of recognized skill will draw audiences from miles around.

5. Class Structure. — A very definite division of the population into two social and economic classes, generally referred to as upper and lower, and the influence of this division in every phase of life has been noted by many students of Chilean life. Prior to 1890 hardly any individual fell outside the limits of these two classes: the upper class, largely a landholding aristocracy, wealthy, well-traveled and cultured; and the numerous lower class group referred to popularly as the *rotos* or "broken ones." The historical basis of this classification is rural, growing out of the tremendous importance attached, during both colonial and early republican periods. to the possession of land. From the rural scene its influence spread out to affect national life at every turn. One's class conferred a practically indelible life stamp that could be erased only by special circumstance. The accumulation of wealth by one from the lower class was by no means a guarantee of admission into the upper stratum of society. Even in the case of a decline of wealth, some respectable form of government employment usually could be found for the less fortunate of the elite, sufficiently remunerative to enable them to maintain appearances. Members of the upper class dominated politics as well as professions such as law and medicine. They were in general control of banks and other financial institutions. The lower class was composed mostly of city labourers and rural tenants and wage labourers. Limited educational facilities for children of the lower classes effectively blocked their entering the professions.

By mid-20th century there was considerable evidence of change in the traditional two-class system. A large group of families and individuals exhibited many middle-class characteristics, including both an improved economic status and a set of values based upon a relatively advanced program of human rights. This was the result, in large part, of the groning strength of labour (trade) unions in the cities and mining areas, where they were obtaining higher wages and better working conditions for skilled and unskilled workers. Another important factor in this development was the improvement of a school system that formerly not only barred many poor children from participation but also offered those nho attended only the fundamentals of the three R's. Upper-class Chileans were quick to note that the new group no longer identified itself with the lower-class working group, over which it felt it had achieved something, and made no effort to identify with the aristocratic upper class, from which it had to establish its independence.

Additional material on the archaeology, settlement and ethnology of Chile will be found under INDIAN, LATIN-AMERICAN; and SOUTH AMERICA. See also ALACALUF; ARAUCANIAN; ONA; TEHUELCHE; YAHGAN. (O. E. L.)

IV. HISTORY

At the time of the Spanish conquest of Chile in the mid-16th century the region was inhabited by about 500,000 Indians. Nearly all the natives were closely related in race and language, but the culture of those tribes north of the Maule river was more advanced than that of the others, for they had been influenced first by the Chinchas of Peru and second by the Quechuas, who formed part of the extensive empire of the Incas.

The conquest of Chile began in 1536–37, when forces under Diego de Almagro (*q.v.*), associate and subsequent rival of Francisco Pizarro (*q.v.*), invaded the region as far south as the Maule river in search of an "Otro Peru" (another Peru). The discouraging reports brought back by Almagro's men forestalled further attempts at conquest until 1540–41 when Pizarro, after the death of Almagro, granted Pedro de Valdivia license to conquer and colonize the area. Valdivia, with about 150 companions, including his mistress, Inés Suárez, the only Spanish woman in the company. entered Chile in late 1540 and founded Santiago (Feb. 12, 1541). For the next two decades the settlers lived a precarious existence and were constantly threatened by the Indians, who resisted enslavement. Before the safety of the colony was guaranteed. land was apportioned to the conquerors, and thus was begun the system of large estates mentioned above. The estates were later institutionalized through the *mayorazgo,* a practice of transmitting estates by entail.

Valdivia did not undertake the conquest of the region south of the Bio-Bio river until 1550. In that year Concepción was founded and preparations were made to move southward. During the next two years settlements and forts were established in La Frontera, but the Indians rose in a revolt that led to the capture and death of Valdivia and to the beginning of a costly struggle. The Araucanians, often referred to as the Apaches of South America, kept the struggle alive until the 1880s by successfully adapting their way of life and military tactics to changing conditions. Although Concepción was destroyed on several occasions it remained as the Spanish outpost in the south as did La Serena, founded in 1544, in the north. The province of Cuyo held the same position east of the Andes until 17'76 when it was made a part of the newly created viceroyalty of La Plata. Before the end of the 16th century English pirates and freebooters, including Sir Francis Drake and Thomas Cavendish, and later Dutch adventurers harassed the coast in search of sudden wealth and as part of a prolonged effort to force Spain to permit trade with its new world colonies.

1. Colonial Period. — As little precious metal was found in Chile the settlers early turned their attention to agriculture. They grew a wide variety of cereals, vegetables, and fruits. raised livestock, and consumed nearly all of their production locally. Largely because of the poverty of the colony, there were never more than a few thousand Negro slaves, and since the Indians proved to be an unreliable source of labour the settlers often had to work the fields themselves. The lack of mineral wealth made the area unattractive to Spaniards, and at the end of the 16th century there were no more than 5,000 Spanish settlers in the entire colony. In this regard it should be pointed out that, beginning in 1600 and continuing until trade restrictions were relaxed in the late colonial period, Chile was a "deficit area" in the empire, and the Spanish crown had to provide an annual subsidy to meet the expense of maintaining officials in Santiago and an army on the Araucanian frontier.

Chile lived under the same administrative and religious systems as its neighbours, but because the colony was poor there was, until the 18th century, a tendency to send mediocre officials to preside over its destinies. The Spanish crown and the Roman Catholic Church combined to deprive the colonists of any democratic experience. The influence of the Catholic Church in secular affairs was always significant and frequently decisive.

The most apparent social development after 1600 was the rapid growth of a mestizo (mixed Indian and European) group. By the end of the colonial period, when the population of the colony reached an estimated 500,000 (not including unsubjugated Indians), approximately 300,000 were mestizos and about 150,000 were Creoles (native-born persons of European descent). About 20,000 mere peninsulars (recently arrived Spaniards), perhaps 10,000 were Negroes and a handful were recently emancipated Indians. At the end of the colonial period, the vast majority of the population nas concentrated in the Aconcagua valley and the central valley (extending from Santiago to Concepción) which together form "the cradle of Chilean nationality."

Education in colonial Chile was almost a complete monopoly of the Catholic clergy. However, in 1758, courses were opened in the Royal University of San Felipe at Santiago and attracted students from the Spanish colonies across the Andes. Nonetheless, Chile was an intellectually backward area at the beginning of the 19th century. The colony did not have a printing press until shortly before it won independence from Spain in 1818, and the paucity of contacts with the outside world prevented even the elite

group from having informed opinions on developments in Europe and the United States.

2. Struggle for Independence.— Despite the colony's isolation, its inhabitants at the start of the 19th century were feeling the effects of developments elsewhere. The most significant of those developments were the winning of independence by the 13 Anglo-American colonies and by Haiti, the French Revolution, and the inability of Spain to defend its system in America, as indicated by the British invasion of the La Plata region and increased contraband trade on the part of British and U.S. citizens. Finally and decisively came the intervention of Napoleon in Spain, an act that in 1808 threw Chile and the other colonies on their own resources and led them to take the first steps toward greater autonomy and self-government. In Chile the initial step toward independence was taken on Sept. 18, 1810, when a *cabildo abierto* (open town meeting) in Santiago, attended by representatives of privileged groups whose vaguely defined objectives included a change in administration, accepted the resignation of the president-governor and in his place elected a junta.

From 1810 to 1813 the course of the patriots was relatively peaceful. Trade restrictions were relaxed; steps were taken toward the eventual abolition of slavery; a newspaper was established to publicize the beliefs of the patriots; and education was promoted, including the founding of the Instituto Nacional. However, the embers of civil strife were also fanned. The Creoles were divided over how far the colony should go toward self-government. José Miguel Carrera (*q.v.*) and his brothers, whose desire for complete independence was equalled if not surpassed by their personal ambition, inflamed the issues. Meanwhile, Spain had taken steps to reassert its control over the colony. At the battle of Rancagua on Oct. 1 and 2, 1814, it re-established its military supremacy and ended what has been called la *patria vieja* (the old fatherland).

Following the defeat at Rancagua, patriot leaders, among them the Carrera brothers and Bernardo O'Higgins (*q.v.*), future director-dictator of Chile, migrated to Argentina. There O'Higgins won the support of José de San Martin (*q.v.*), who was raising an army to free the southern portion of the continent by first liberating Chile and then attacking Peru from the sea. The Carreras continued their spirited agitation for independence in Buenos Aires and the United States. Meanwhile, many of those who remained in Chile suffered from the harsh rule of Spain's inept representatives and became convinced that absolute independence was necessary. In Jan. 1817, San Martin's well-drilled army, with O'Higgins as one of its commanders, began its march across the Andes; and on Feb. 12, 1817, the patriot forces defeated the royalists on the hill of Chacabuco, which opened the way to Santiago. O'Higgins was proclaimed supreme director of Chile, although the act of declaring Chile's independence was not taken until a year later (Feb. 12, 1818), on the first anniversary of Chacabuco; and the decisive defeat of Spain on the Chilean mainland (Spain held the island of Chiloé until 1826) did not come until the battle of Maipo, April 5, 1818. Before emancipation was assured, O'Higgins began the creation of a Chilean navy, which by late 1818 was in the process of clearing the Chilean coast of Spanish vessels.

Chile was free, but its inherent weaknesses were everywhere manifest. The Creoles remained bitterly divided between O'Higgins and the Carreras. Two of the Carrera brothers had been executed in Mendoza, Arg., in 1818 and José Miguel Carrera suffered the same fate in the same city in 1821. The elite groups were dedicated to the retention of those institutions on which such things as law, property, family and religion were founded. The masses, who had been little more than spectators in the conflicts between 1810 and 1818, were not invited to participate in government. In any event they had few permanent values or interests to defend. As the war of independence had gone on year after year the financial hardships of the new state had increased alarmingly, force had been increasingly substituted for reason, and personalism had been raised to the level of a political ideology.

3. Dictatorship and Anarchy, 1817–30.—Personalism and force predominated between 1817 and 1830 as Chile passed through an era of political turbulence and dictatorship. O'Higgins controlled the new republic until 1823 when widespread discontent brought about his resignation and exile to Peru. He tempered the radicalism born of the independence movement with a conservatism that guaranteed the gains achieved in the struggle against Spain and made possible the utilization of basic institutions inherited from Chile's colonial past. Many of the failures attributed to O'Higgins were beyond his control to prevent, for the republic was impoverished and its leadership had a minimum of experience in self-government. O'Higgins was not a politician. He alienated the Catholic Church by his insistence upon the nation's right of patronage over ecclesiastical appointments and his opening of a cemetery for non-Catholics. His decision to abolish titles of nobility and his approval of a move to suppress the mayorazgos cost him support among the landed elite. He permitted the salaries of soldiers to remain in arrears.

Ramón Freire, militarist, anticlericalist, and sectionalist (he represented the forces of the south that resented the monopoly over the government enjoyed by Santiago), seized the power surrendered by O'Higgins. Freire continued the attacks upon the church initiated by O'Higgins and brought about the abolition of Negro slavery. An ill-advised attempt at federalism made in the constitution of 1826 was a major factor in Freire's temporary eclipse in 1827; but an election brought to power a congress and president friendly to him.

In 1828 an unworkable liberal constitution was promulgated. This constitution had the effect of sharply dividing the responsible elements of society into two parties — pelucones ("bigwigs") who were conservative and Catholic; and the *pipiolos* ("novices") who were liberal and anticlerical. Matters reached a crisis in 1829 with the outbreak of civil strife between Freire, spokesman for the liberals. and Joaquin Prieto, a military chief acceptable to the conservative elements. The issue was decided by force of arms at Lircay. April 17, 1830, with the utter defeat of the liberal forces.

4. Autocratic Republic, 1831–61.—The victory of Lircay ushered in an era of political stability and peace under conservative domination that lasted until 1861. The period has been commonly referred to as the "autocratic republic." Joaquin Prieto was president during the 1830s, but the strong man of the regime was the haughty and overbearing Diego Portales. Either as cabinet member or private citizen he ruled as a virtual dictator until he was assassinated in 1837. Before becoming the guiding genius of the nation's destiny, Portales had been a businessman and had developed an abiding contempt for the popular masses who, he asserted, "must be given both bread and blows." and for "the shibboleths of democracy, republicanism, and freedom."

As leader of the nation, Portales, the Alexander Hamilton of Chile, spoke for the rich landowners and traders. In their interests he imposed order and unity upon a previously anarchic people. The opposition press was ruthlessly silenced. The army was cleared of dissenters and made responsible to the presidential will. The privileges of the church were restored and attempts to end the entailed estates were dropped. As part of a determined effort to promote trade, the port of Valparaiso was developed, foreign businessmen and capital were invited in, and the public debt was refunded. Mineral production rose sharply as the decade drew to a close.

Rule by the class and under the system that Portales represented was legalized by the constitution of 1833, which, with a few amendments, remained the national charter until 1925. It combined aristocratic supervision with autocratic administration. The president was given almost unlimited power over a highly centralized government. Property qualifications for suffrage left control of the nation in the hands of no more than 10% of the population. The Catholic Church was given full partnership with the state.

Although Portales was indifferent to popular education, he stimulated intellectual activity by providing a favourable working climate for emigrants to Chile and by inviting scholars from abroad. The Venezuelan-born man of letters, Andrés Bello (*q.v.*) and the French naturalist, Claudio Gay, headed a distinguished list of learned men who made Chile the intellectual centre of Latin America before 1850.

Economic competition between Chile and Peru and a move on the part of Bolivian dictator Andrés Santa Cruz (*q.v.*) to federate his nation with Peru, a measure interpreted by Portales as a threat to Chile, brought a three-year war with the confederation (1836–39). Portales mercilessly crushed those who opposed the war. His assassination by mutinous soldiers in June 1837 helped to unite the nation and to popularize the war, which was carried to a successful conclusion. The victory assured the predominance of Chile on the west coast.

After the death of Portales, Chile began to enjoy its material prosperity and cultural activities, both of which had made rapid progress following the return to political stability in 1830. Chile was an enclave that was, figuratively speaking, surrounded by republics in various stages of political anarchy, economic deterioration and cultural darkness. It was in this atmosphere that Manuel Bulnes (*q.v.*) assumed the presidency. which he held from 1841–51.

Bulnes' term of office was marked by rising nationalism, material and technological advances, and cultural progress. Under the impulse of a new-found nationalism, the country began to expand its settled area and to strengthen its claims to unmarked frontiers. German immigrants were brought in and settled in the Araucanian stronghold below the Bio-Bio. Chile pushed its claims to territories around the Strait of Magellan, in Tierra del Fuego and in Patagonia. When Argentina challenged Chile's actions. diplomatic controversies were opened that were not resolved until the 20th century. The public debt was liquidated and the customs were better regulated. Steamship lines mere established, flour mills were constructed, coal mines were opened, and the output of precious and semiprecious metals was increased. A flourishing but short-lived trade with California, after gold was discovered there in 1849, added to the nation's prosperity.

Peace and progress made Chile a mecca for intellectuals—among them Domingo Faustino Sarmiento. Bartolomé Mitre. Vicente Fidel López, exiles from the Rosas tyranny in Argentina, and Juan Garcia del Rio of Colombia, who added their talents to those of intellectuals who had arrived earlier. A normal school was founded in 1842. The University of Chile with Andrés Bello as its rector opened in 1843. Within the decade, a school of agriculture. a technical school, a conservatory of music, and a school of architecture and painting were founded. Newspapers and literary journals provided forums from which Chilean intellectuals such as José Lastarria and Francisco Bilbao launched attacks upon the established order. The achievements of Manuel Montt (*q.v.*) as minister of education did much to promote his claims to the presidency of the nation, a post he held for ten years beginning in 1851.

An armed uprising aimed at preventing Montt from assuming the presidency was ruthlessly suppressed by the Conservatives. The new president displayed a keen appreciation of the need to develop the nation's natural resources, a growing conservatism. and a pedantic devotion to law. The basis of a sounder agricultural economy was laid by the suppression of the *mayorazgo*. Railroads, telegraph lines and water systems were built, and schools charged with providing skilled craftsmen and trained technicians were publicly financed. At the same time, Montt as president denied intellectuals the freedom he had guaranteed them as minister of education. With encouragement from the president, Andrés Bello completed the codification of Chilean laws, a project he had begun many years earlier.

Emerging elements in society who economically favoured industrial capitalism over agrarian feudalism and who politically insisted on greater congressional power at the expense of the executive branch were becoming increasingly vocal at a time when Montt split his own party by provoking a controversy with the church over the right of patronage. The division within conservative ranks enabled the rising elements to force personnel changes in Montt's administration. Montt later suppressed an armed revolt but realized he could not impose his own choice of a successor, so he agreed to a candidate acceptable to the new groups—José Joaquin Pérez. That acceptance ended the 30 years of absolute rule by the *pelucones*.

5. Liberal Republic, 1861–91.—Supported by a fusion of Liberals and Conservatives, the presidency of José Joaquin Pérez, from 1861 to 1871, initiated a 30-year-long era known as the "liberal republic." During these three decades conservative aristocratic governments were succeeded by liberal administrations; the political elite. however, still came from the traditional families. Politics became confused to the point where labels meant little as new parties emerged and old ones splintered. Anticlericals consistently won victories over the Catholic Church. Largely as a result of a military victory over Peru and Bolivia that gave Chile control of the rich nitrate zone of the Atacama desert. the nonagricultural sectors of the national economy spurted. New entrepreneurs stood on common ground with the old political liberals against the remnants of feudal control. The Liberal doctrine was made the philosophic justification for a new capitalism. Economic diversification, an enlarged bureaucracy. the expansion of public education, the professionalization of the army—all these contributed to a notable expansion of the middle classes. The ability of the Liberals to win the approval of the middle groups, and those members of the emerging industrial proletariat who could qualify for the vote under relaxed suffrage requirements, encouraged the Conservatives to support measures designed to weaken presidential authority.

The forces that in 1860–61 broke the political monopoly of the Conservative party almost immediately set out to exploit their newly won advantage. Before the Pérez regime ended they had given added impetus to technological development and reformed the secondary curriculum. They had amended the constitution (1865) to guarantee non-Catholics the right to educate their children in their own faith and to worship within buildings belonging to private individuals or associations. They had also weakened the executive branch of the government in 1868 by an amendment to the constitution that prohibited the chief executive from succeeding himself. An unwarranted bombardment of Valparaiso by Spain in 1866 was one of the chief episodes in a brief mar that only momentarily halted the march of progress in Chile.

Under Pres. Federico Errázuriz Zañartu (1871–76) the reform movement was accelerated. The power of the president was further restricted and a measure was adopted providing for minority representation in the house of deputies. The power of the church was further reduced when a law was passed stipulating that decent burials should be provided for Protestants in sections set apart in public cemeteries, and the Catholic clergy were made accountable to the lay courts for all civil and criminal offenses. Security and \yell-being encouraged learning. Benjamin Vicuña Mackenna and Diego Barros Arana (*q.v.*), responding to the vigour of the period and to the still rising sense of nationalism, lifted the historian's craft in Chile to unprecedented levels. The University of Chile was expanded and Santiago was modernized and beautified.

Errázuriz was succeeded in the presidency by Anibal Pinto, who was confronted with a world-wide economic depression. aggravated in Chile by crop failures and a serious decline in the price of copper. In the face of a treasury deficit the government began to issue inconvertible paper money, with the result that the cost of living rose rapidly. Before Chile was able to recover from the economic crisis, disputes with Bolivia and Peru over the nitrate area led to war. The conflict, known as the War of the Pacific, ended victoriously for Chile in 1884; the nitrate area passed to Chilean control, thereby greatly increasing the national territory and providing the government with an easy source of revenue. Chile acquired temporary control of the Peruvian provinces of Tacna and Arica with the understanding that their final disposition would be determined by a plebiscite. The final decision was postponed repeatedly and the issue became known as the Tacna-Arica dispute (*q.v.*).

In 1881, before the War of the Pacific ended. Domingo Santa Maria, an extreme Liberal, became president. Under him troops raised to fight Peru and Bolivia were sent to the south and finally subdued the Araucanian Indians. The peso depreciated to about half its former value, and prices rose accordingly. Santa María gave fervent support to liberal measures. Congress assumed the power to override the president's veto by a two-thirds vote, curtailed the powers of local officials (ordinarily tools of the presi-

dent), and relaxed the suffrage requirements by abolishing economic qualifications. Cemeteries were secularized and civil marriage was recognized.

The liberal reformer José Manuel Balmaceda (*q.v.*) was inducted as president in 1886 under seemingly auspicious circumstances. The Chilean people were confident of their destiny. They had just won a major war and had expanded their national boundaries. Revenues from nitrates made it possible to keep to a minimum the tax burden on the wealthy class and at the same time to institute a large public works program and to promote education. In 1888 Chile formally annexed Easter Island (*q.v.*) in the Pacific ocean about 2,300 mi. W. of the port of Caldera. But there were countervailing influences. The government made no attempt to abandon the system of paper money that had brought misery to the popular groups. The Liberals were split into a number of factions. The Conservatives fought the president because of his anticlericalism and indicated their objection to the increasing influence of the new professional and economic elements in education by founding Catholic University of Chile (Santiago) in 1888. Finally, the president failed to rally congress behind him. By 1890 his congressional support had melted away to the point where he could not gain approval of his budget. He countered by announcing that he would proceed without congressional sanction. thereby assuming dictatorial powers. A week later congress, supported by the navy and with widespread popular approval. voted to remove him from office, and the country was plunged into civil war. The navy promptly seized the nitrate ports, thus assuring the congressional forces a ready source of revenue. Eight months later and at the cost of thousands of lives and many millions of pesos the congressional forces were victorious. After they entered Santiago, Balmaceda took his own life.

6. Harvest of **Parliamentarism.**—The triumph of the congressional elements marked the beginning of a period during which Chile continued to cut the ties that bound it to its feudal agricultural past and associated itself more closely with industrial capitalism. But before the republic had time to examine its fortunes following the civil war it was confronted with a series of international problems that claimed much of its attention during the next two decades. Chile's success in resolving a number of thorny issues without resort to force reflected credit upon the republic.

Resentment was aroused against the United States over its sympathy for Balmaceda as indicated in 1891 by U.S. seizure (and later release) of the "Itata," a vessel sent by the Chilean rebels to obtain arms at San Diego, Calif. Still more serious was the "Baltimore" incident the same year. U.S. sailors on shore leave at Valparaiso from the "Baltimore" were attacked by a mob. and two sailors were killed. The incident was settled by Chile's offer of compensation, but only after the United States had sent an ultimatum demanding an apology and Chile had left no doubt that it considered the warlike attitude of the United States a national affront.

The "Baltimore" incident had hardly been resolved when serious friction developed with Argentina over portions of the boundaries separating the two nations. The issue involving the Puna de Atacama, in the north, was settled in 1899 by arbitration of the U.S minister in Buenos Aires. In May 1902, the two countries signed treaties providing for the arbitration of the disputed southeastern boundary (Patagonia), which had been in contention since the 1840's. The dispute was arbitrated by King Edward VII of England, who recommended division of the contested territory. In commemoration of the settlement the two nations joined in erecting on their common boundary the famous statue known as the "Christ of the Andes." In 1904 Chile signed with Bolivia the pact of Santiago by which Chile gained full sovereignty in the Atacama region but under terms which left in doubt many issues that were not resolved until the 1920s. Through Chile's understanding with Brazil and Argentina and through the participation of the three in controversies between the United States and Mexico. the country gained prestige in the hemisphere. The republic remained officially neutral during World War I, but favoured the Allied powers.

Politically the period from 1891–1918 was characterized by parliamentary rule. The omnipotence of executive rule that had produced 60 years of "praetorian peace" before 1891 gave way to the omnipotence of the legislative branch, which did hardly more than spawn national confusion. There was little room for strong presidents during the era and none appeared. On the contrary, weak executives—Jorge Montt, 1891–96; Federico Errázuriz Echaurren, 1896–1901; Germán Riesco, 1901–06; Pedro Montt, 1906–10; Ramón Barros Luco, 1910–15; and Juan Luis Sanfuentes Adonaegui, 1915–20—followed one another in a monotonous procession of mediocrities. Meanwhile, the rise and fall of cabinets became chronic—there were approximately 120 major shifts between 1891 and 1924.

The transfer of power from the executive to the legislative branch did not result, however, in a change in the locus power, as the landholding and financial elements that since the Montt regime of the 1850s had disputed political predominance finally found a basis for alliance in their mutual desire to prevent emerging social and economic groups from asserting themselves. The religious issue subsided once the landholding and financial elements united, so that no real differences separated the contending forces.

The lack of issues had a profound influence on political values. Moral discipline and public responsibility degenerated as parties and politicians, becoming more money-conscious, resorted freely to fraud and bribery to win power, which was then used for the advantage of the victors. While the political leaders interpreted electoral liberty as freedom to indulge in fraud and bribery, the working classes viewed being paid for one's vote as a right of citizenship. The middle classes, in order to share more fully in the spoils of office, made politics their chief pursuit. But there was at least one favourable aspect to this otherwise sordid political climate. Chile, in sharp contrast with a vast majority of its Latin-American neighbours, gave every evidence of having matured to the point where personalism was on its way out and parties could look forward to deriving their force from the doctrines they propounded rather than from the candidates they offered the electorate.

In the economic sphere a growing dependence on mining, exaggerated individualism, and unbridled capitalism characterized the transformation era. Mining rapidly supplanted agriculture as the first factor of progress. Nitrate production, which in 1892 was slightly over 300,000 tons, reached 1,000.000 tons in 1896, averaged 1,720,000 tons annually between 1901 and 1910, and 2,500,000 tons annually between 1911 to 1920. Meanwhile the price of nitrates in world markets increased about 75% between 1910 and 1918. Copper mining, important in the economy since the 1830s, attained an average annual production of 33,000 tons between 1901 and 1910; it increased to 68,000 tons annually between 1911 and 1920. Mining prosperity caused commerce and industry to expand. Foreign trade, which amounted to 140.000,-000 pesos in 1896, rose to approximately 580,000,000 pesos in 1906. Revenues from mines were used to beautify cities, to which the rural population flocked in search of a better life. In 1907, 43.2% of the population lived in urban centres; by 1920 the figure had risen to 46.4%. Santiago, the national capital, in 1920 contained 14% of the total population of the nation.

Expanded activity in mining, commerce and industry, each of which received added impulse from World War I, gave rise to a new and aggressive capitalist element that fought for economic privileges. A demand that economic life be free from state intervention became a fundamental postulate of this new bourgeoisie that invited foreign capital to develop the nation's resources. It was during this era that foreign capital strengthened its control in Chilean mining. Politically aligned with the old landed aristocracy, the new urban capitalists supported systematic depreciation of the currency, a measure that weakened the position of wage earners and those with fixed incomes.

An abrupt decline in the world demand for Chilean nitrates and copper follo ing the armistice of 1918 served to emphasize the fact that the social problems arising from the economic transformation had been left to multiply. Chile's infant mortality rate had become the highest among the nations of the western world. Alcoholism had become a widespread social illness. The con-

ventillos or slums of Santiago, where workers lived in cramped and unsanitary quarters, had become a symbol of national failure but had not aroused the indignation of those who controlled the government. Real wages declined by 10% between 1913 and 1923 as the industrial labourer and white collar worker were caught in a spiraling inflation.

In 1912 the Socialist Labor party was formed in a bid for labour support. But the new party was no more effective in alleviating the plight of the worker than had been the mutual aid societies and anarchist-dominated syndicates that the working man turned to increasingly after 1900. The strike was the only means the workers possessed to call attention to their plight and they struck 293 times between 1911 and 1920. In the face of such conditions the founding of a university at Concepción (1919), more public schools, better qualified teachers, a free press, and greater availability of printed matter did little to alleviate popular discontent.

The discontent of the working class was. in fact, increased by developments in Europe, where new ideas had wrought havoc with the social fabric. The new social consciousness found expression in Chile in 1918. an election year. Control of the lower house of congress was at stake. Many different elements of the population — wage-earners suffering from inflation, small businessmen pinched by both inflation and high interest rates, and discontented intellectuals joined forces in the Liberal Alliance to unseat the vested interests. Arturo Alessandri Palma (*q.v.*), lawyer, politician, demagogue and "Lion of Tarapacá," served as the cohesive force that held the discontented groups and the social romantics together during the campaign. Directing his appeals to the newly articulate elements of society, Alessandri hammered home his argument that the economic problem had become the fundamental political problem.

The Liberal Alliance won a striking victory at the polls and captured control of the lower house, which was then organized under Alessandri's directorship. In victory, Alessandri was unable to hold together the diverse forces within the Liberal Alliance and his ministry was forced from office. But the election of 1918 was nevertheless a landmark in Chile's political development. Politics had been forced out of the "smoke-filled room" and into the street, where the voices of the depressed elements could be heard.

7. Reorientation of a System. — Politically ambitious middle groups and working elements had come to the surface in 1918. For the next two decades a bitter political war waxed and waned between the new elements and the entrenched privileged groups. In the process the national welfare was sacrificed to the interests of political parties. The use of force as a means of settling political differences was revived. There was a pronounced trend toward state intervention in the economy. Collectivism as a social philosophy assumed greater stature. Nationalism was lifted to new heights as a political ideology. The church-state pact was broken. These developments threatened rather than destroyed established institutions and values. Democratic-republicanism continued to be the objective of all but a narrow fringe of extremists. There remained a wide area within which the free enterprise system had full rein and the private ownership of property mas strongly defended — land monopolists went almost untouched. The Catholic Church continued to be the interpreter of social values for a large and influential sector of the population.

Discontented voters elected Alessandri to the presidency in 1920 in a close election that was finally decided by a "court of honour." The old ruling element, however, remained predominant in the senate. From there it offered tenacious opposition to reform measures sponsored by the president. Economic distress, caused largely by a depressed world demand for Chilean nitrates and copper, served the interests of the opposition, as did the president's failure to resolve the Tacna-Arica dispute with Peru.

Stalemated at nearly every turn, Alessandri made a determined effort to win a working majority in the legislature, and used questionable methods in intervening in the elections of 1924. He carried both houses and won approval of an advanced labour code, but the legislature soon fell to bickering and failed to act on his other recommendations. At this juncture, unrest in the army over salaries that were in arrears and the general instability of society culminated on Sept. 5, 1924, in the institution of a military junta to direct national affairs. By decree-laws the junta enacted some of Alessandri's social program. The junta's interest in reform was short-lived, however, and its members had turned to the right before they were removed early in 1925 by a group of young officers headed by Maj. Carlos Ibáñez del Campo.

The new junta invited Alessandri to return to the presidency, and he did so on March 20, 1925, but only on condition that the executive branch of government would be strengthened in relation to the legislative. This issue and others raised by the constitution, which many considered outmoded, led to the writing of a new constitution that was approved by a plebiscite in Sept. 1925.

The constitution of 1925 gave the president considerable independence from the legislature, the stronghold of the reactionaries. The church and state were separated but, thanks to both religious and secular authorities, this was done in a manner that did not leave angry resentments. In providing for greater state participation in the labour and welfare fields the constitution gave recognition to the reorientation of the nation's thinking away from its former *laissez faire* position and toward the collectivist aspirations of the lower middle-income groups and the working elements, who were becoming increasingly articulate.

Under fire from both conservatives and reformers and unable to relieve the economic depression that blanketed the republic, Alessandri was forced from office in Oct. 1925. The *coup d'état* was engineered by Ibáñez, minister of war in the Alessandri cabinet and dictator-president from 1925 to 1931. When Ibáñez had a presidential election called, Emiliano Figueroa Larrain emerged the victor and replaced acting president Luis Barros Borgoño in Dec. 1925. But Ibáñez ruled Chile arbitrarily until he forced Figueroa Larrain to resign and had his own power legalized in an election held in May 1927.

Ibáñez was aware of the transformation that the republic was experiencing, and under him progress was made in welfare and labour legislation. The nation maintained an economic climate that invited foreign loans and investments needed to speed industrial production. Meanwhile, Ibáñez was careful not to arouse the rural aristocracy by tampering with the nation's landholding system. Creation of the Compafiia de Salitre de Chile (Chilean Nitrate company, known as COSACH), a nitrate monopoly whose control was shared by foreign and domestic capitalists and the Chilean nation, was one of the most daring moves in the direction of state intervention in business in Latin America up to that time.

A steady flow of foreign capital into the republic made for a spurious prosperity. Public works projects kept the working groups occupied and provided a market for local manufactures. Growth of public and private bureaucracies and a significant expansion in the field of education offered new opportunities for the intellectual element. By supporting lams directed against the employment of foreigners and offering protection to domestic commerce and industry the dictator gave his stamp of approval to an intensification of economic nationalism. Meanwhile, the final settlement of the Tacna-Arica dispute in 1929 served to silence the agitators who had kept Chile and Peru on the brink of war throughout the decade.

The world depression that struck in 1929 emphasized basic weaknesses in the Chilean economy and aggravated latent social discontent. The nation's sources of foreign exchange dried up. It was forced off the gold standard and defaulted on its external debt. By Dec. 1931 mining output, having dropped steadily after early 1929, was down to 52% of the 1927–29 average. Deprived of foreign exchange, the republic's international trade nearly ground to a halt. Unemployment and underemployment were widespread. Of 91,000 men employed in mining at the end of 1929 only 31,000 continued in employment at the end of 1931. A third of the population lived in substandard quarters. When Ibáñez discharged public employees and tried to raise taxes, dissatisfaction over his dictatorial methods burst forth. Students at the University of Chile revolted. They were joined by medical doctors and other professional men. Restless mobs added their disapproval. On July 26, 1931, Ibáñez tendered his resignation

and left for Buenos Aires, plunging Chile into a violent 18-month-long civil conflict, made worse by the misery and suffering which accompanied economic stagnation.

During the period of civil strife, Chile was led first by Conservative Juan Esteban Montero, who unsuccessfully sought to restore constitutional government. He was forced from office by a military clique, and Socialist Carlos Dávila was placed in the presidency. His 100-day rule was too short to implement a program, but he advanced ideas of social welfare and state intervention that had lasting influence. "Responsible" elements, frightened by the "excesses" that Dávila tolerated from the working groups, demanded a return to order and stability. Dávila was ousted by the military group in September and after an election Arturo Alessandri returned to the presidency in Dec. 1932 for a second term.

Alessandri, who had more or less stood still as social and economic thinking in Chile moved to his left, won the election with support from the right and centre of Chile's political spectrum—especially important was his acceptance by the Radical party. Under him, Chile began its slow recovery from the depression as mineral and industrial output rose from their 1931–32 low points and tax concessions gave rise to a notable expansion in the construction industries. The budget was balanced, COSACH was reorganized, and payments on the interest of the foreign debt were resumed.

When it became apparent that Alessandri was more devoted to constitutionality than to reform, the Radical party withdrew its support (1934). This party, dating from the 1860s, had been the personification of individualism until 1918 when it associated itself with the emerging urban groups. By the 1930s, although its leadership had remained tightly in the hands of southern landholders and the new wealthy class in commerce and industry, it had become the champion of democratic government, social reform, and economic diversification through industrialization.

8. The New Order.—The Radical party, torn by internal dissension, vacillated for approximately two years after withdrawing its support from the Alessandri government. Then in 1936 it gained control of the alliance of parties of the centre and left known as the Popular Front. The origins of the Popular Front have not been definitively established, but the consensus of scholars seems to be that it was formed at the urgings of the Chilean Communist party, which had been founded in 1921. The Popular Front temporarily provided a common ground for most segments of society whose objectives were becoming steadily more difficult to reconcile with traditional values. It also proved to be a springboard from which the Radical party was propelled to national leadership under three presidents whose terms extended from 1938 to 1952.

Pedro Aguirre Cerda, educator, member of the Radical party and standard-bearer of the Popular Front, won the presidency in 1938. His narrow margin of victory, only about 4,000 out of a total of 440,000 votes, probably was provided by Nazi elements who threw their support to the Popular Front when, following an unsuccessful armed uprising organized by former dictator Ibáñez and Nazi leader Jorge Gonzalez von Marées, 62 of the revolutionaries were shot by government troops after they had surrendered.

In office Aguirre Cerda devoted himself to implementing the Popular Front program. He aided and protected organized labour. The popular masses mere urged to become more politically conscious. Educational facilities and health and welfare programs were expanded significantly. Industry was given strong state support. The Corporación de Fomento de la Producción, or Development corporation, was chartered to funnel public capital into basic areas of the economy that were not attractive to private investors and to provide private enterprise with relatively low interest-bearing loans. Funds from the Export-Import bank helped to capitalize the Corporación de Fomento.

Juan Antonio Rios succeeded to the presidency (1942–46) after Aguirre Cerda died in office (1941). Rios in effect traded the extreme left support that Aguirre Cerda had courted for backing from the Catholic-oriented Social Christian element. A wealthy businessman from Concepción, Rios was not a strong leader. He did not need to be, as the course of World War II largely dictated his decisions. Fearing that Chile could not protect its long coast line against a possible Axis attack. Rios associated his nation with the Allies but did not break relations with the Axis until Jan. 1943, and did not declare a state of belligerency until Feb. 1945. In the face of the foreign threat he had little trouble rallying the nation behind him, especially in view of the fact that Communist agitation against the United States and its allies had been stilled by Hitler's invasion of Russia in June 1941. A strong demand at favourable prices for Chilean copper. a high level of employment, and lend-lease aid from the United States further eased Rios' efforts at "moderation." In this atmosphere the president was able, with a minimum of friction, to shift the ideological base of his government to favour industrialization.

When Rios died in office in 1946 it was evident that by putting a lower priority on social reform he had satisfied only the industrial element among those to whom the Radical party looked for electoral support. The party's choice of Gabriel Gonzalez Videla as its presidential candidate was an obvious effort to improve its standing with the low-income groups that Rios had alienated. González Videla, a self-made man from La Serena and a prominent lawyer, had early associated himself with the left wing of the party. During the campaign he openly sought Communist backing, and the Communist party responded by instructing its members and followers to vote for him.

As president, González Videla proved a disappointment to his popular following. He began his term with Communists in his cabinet but within a few months he removed them. In 1948 the Law for the Defense of Democracy made the Communist party illegal, and so it remained until 1958, when it was again given legal status. Gonzalez Videla's break with the Communists was apparently prompted by two considerations. He seemingly became convinced that Chile had to industrialize at all costs and apparently also became satisfied that Chilean national welfare depended upon close and friendly relations with the United States.

The president's decision to throw the weight of his office behind industrialization involved a calculated political risk. There were three major political considerations: 1) Faster industrialization would require an increasing share of new investment capital at a time when the agricultural sector was lagging and the purchase of foodstuffs from abroad was requiring more and more of the nation's foreign exchange; 2) industry would have to assume primary responsibility for providing employment for the approximately 50,000 persons who were entering the labour pool each year; and 3) industrialization would have to be financed in large part by inflation, thereby placing added burdens on the already hard-pressed working elements. Gonzalez Videla's political gamble did not pay off. Industry failed to respond as expected; industrial employment in 1949 was actually below the 1947 level, and the workers revolted against what they considered their undue exploitation by the wealthy.

The administration succeeded in maintaining republican institutions and a free press, and in expanding educational opportunities. Chile's literacy rate was exceeded only by Argentina's and Uruguay's, and perhaps Costa Rica's, among the Latin-American republics. But these successes paled before the failure of the administration's economic policies. The president's successes in promoting Chile's international interests and prestige were also probably undervalued. He perhaps assumed the role of a demagogue in his efforts to strengthen Chile's claims in Antarctica, but he showed considerable restraint before breaking relations with the U.S.S.R. and its satellite, Czechoslovakia (Oct. 1948). He was circumspect in dealing with the meddling Perón regime across the Andes. The representatives he sent to the United Nations, the Pan American Union and international congresses in general reflected credit upon Chile. His relations with the United States served the purposes of the Chilean people, at least to some extent. His government obtained loans and other forms of assistance, including funds and technological aid without which the integrated iron and steel plant at Huachipato, near Concepción, formally opened in 1950, probably would not have become a reality. It is

still not clear to what extent his sponsorship of the mutual assistance pact (approved in April 1952) adversely affected the political interests of the Radical party in the presidential election of that year.

Carlos Ibbiiez, erstwhile dictator and plotter, succeeded González Videla as president in 1952. Ibbiiez, who ran as an independent without the organizational support of any major party, personalized in the eyes of many voters the repudiation of discredited political machines. He made "Larger Loaves of Bread" the symbol of the need for a more equitable distribution of the national income. To the propertied groups he proposed a reexamination of the economy with a view toward integration of agriculture, mining and industry. He crossed socioeconomic lines by appealing to national pride and national sovereignty. One of the significant results of his campaign was that he aroused the agrarian workers. That group served notice that it was about to enter the already confused political picture as an independent force.

The president's erratic conduct and a continuing deterioration of the economy brought on by a serious decline in the price of copper were major considerations which prevented Ibáñez from successfully resolving any of the problems that he pointed out before his election. Like his Radical predecessors, he resisted the methods advocated by extremist supporters. He left the land redistribution problem to some future administration with the result that 75% of the arable land remained in the hands of 5% of the landed proprietors. He continued state intervention in the economy but also invited private capital to supplant the state in certain industrial and commercial ventures. His attitude toward foreign capital did not discourage U.S. companies from expanding their investment in mineral enterprises. Political freedoms were generally respected.

When Ibáñez ended his term in 1958, Chile's record in the defense of democratic institutions was unsurpassed in Latin America. The military group remained discreet in its concern over political and economic developments. Public morale, however, was low. A bitter political campaign had kept open old and angry wounds. The republic teetered on the edge of economic disaster. It had no untapped sectors of its economy capable of providing further immediate basic development. Economic instability invited political instability and made short-term solutions attractive.

For Ibbiiez' successor, conservative, free-enterprising businessman Jorge Alessandri Rodriguez, inaugurated on Nov. 3, 1958, the primary political problem was the same one that his twice-president father. Arturo Alessandri, had delineated as early as 1918—the creation of a viable economy. By the end of his first year in office the new president could report that inflation had been checked and the nation's budget balanced, but labour disputes clouded the economic picture. (J. J. J.)

V. POPULATION

The racial composition of the Chilean population is predominantly white. This is the result of heavy mortality among the Indians during the colonial period—from both disease and warfare—and of extensive migration from Europe in the 18th and 19th centuries. The 18th-century migration came chiefly from Spain and was mostly Basque. The 19th-century immigrants came from Germany, Italy and England. Such Indian groups as remained at the end of the 19th century were small and were limited to specific areas of northern and central Chile.

The 1952 census classified 127,151 Chileans as Araucanian Indian. (See ARAUCANIAN.) Most of these were concentrated in the provinces of Cautin, Malleco, Arauco, Valdivia and Bio-Bio.

In the extreme south there are remnants of the Fuegians, an indigenous people of extremely primitive culture. In the coastal region of the north there are some Changos, who may represent survivors of an original, indigenous racial stock. Throughout most of the territory there is a generous sprinkling of English, Irish, Scottish. German, Italian, Yugoslav and French settlers who still carry the names of their immigrant forefathers. The immigration of these groups has never been of major proportions but the process has been a relatively stable one.

Provinces and Population

Province and capital	Area in sq. mi. 1952	Population

Antarctica territory	. .	87	202
Total	286,396	5,932,995	7,339,546

*Preliminary.

The 1960 census showed a population of 7,339,546 as compared with 5,932,995 in 1952; 5.023.539 in 1940; 4,287,445 in 1930 and 3,731,573 in 1920. The density of population per square mile in the whole country was 25.6 in 1960 and 20.7 in 1952 but there was a wide range of density between regions. The northern desert region, with more than one-third of the total area, had 6½% of the population and a density of less than 4 per square mile. The central region, with only 18% of the national area, had 65% of the total population and a density of 76 per square mile. The mainland forest region, with 13% of the area, had 26% of the population and a density of 38 per square mile. The archipelagic zone of the forest area, with 27% of the total area, had only 2% of the population and a density of little more than 1 per square mile. Atlantic Chile, with 7% of the area. had only 1% of total population. Most of its inhabitants were in the city of Punta Arenas.

Chile has one of the highest birth rates in the world. Just before 1930 the annual rate mas about 40 births per 1,000 population. Although the rate decreased somewhat after 1930 it was 35.4 in 1960. Approximately one-third of all births were recorded as illegitimate in 1917; this percentage had declined to 17.1% in 1960.

The death rate in Chile progressively declined after 1900, due largely to improvements in child care practices, but remained high in the cities. It was at a low of 11.9 deaths per 1,000 population in 1960. This gave a survival rate (births minus deaths) of 23.5 for 1960, a rafe sufficiently large to double the population in slightly more than one generation.

Like most other Latin-American populations, that of Chile has shown strong tendencies toward urbanization. The 1952 census classified 60% of the population as urban as compared with 52% in 1940.

Major cities (1960 municipal pop.) were: Santiago (646,731); Valparaiso (259,241); Concepción (167,468); Viña del Mar (126,441); and Antofagasta (89,114). (O. E. L.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government.— Chile is a unitary or centralized republic and has always had this type of government except for a brief and unhappy experiment with federalism in the mid-1820s. Responsibility is centred in the president, who is elected by direct vote of the people for six years and cannot immediately succeed himself. Beginning in the early 1890s Chile had a semiparliamentary form of government but this led to serious political difficulties. The new constitution of 1925 reverted to the presidential type.

The constitution provides for direct elections, suffrage for both men and women, citizenship without class distinction, separation of church and state, and a strong executive branch. The legislative

and judicial branches have considerably more independence of the executive than in most Latin-American governments.

If no presidential candidate receives a majority of the popular vote a choice between the top two candidates is made by the congress, which normally follows the practice of electing the one receiving the plurality of the popular vote. The Belgian system of proportional representation is used for legislative elections. The electorate in the 1950s included over 1,000,000 persons. of whom nearly one-third were women; full woman suffrage was adopted in 1949.

The president, who must be native-born and at least 30 years of age, freely appoints and removes cabinet members, although party pressure sometimes exerts an indirect but considerable influence on appointments to and resignations from the cabinet. Presidential appointments of diplomatic, high military and some administrative officials must be approved by the senate. The cabinet normally includes 14 positions although at times two or more portfolios are in the hands of one minister. In case of a vacancy in the presidency the office is temporarily filled by the minister of the interior, who is required to call a new election within 60 days; the president chosen at this election fills a full six-year term. The president can propose legislation and can veto bills passed by congress, but the congress by a two-thirds vote can override a veto. The president has broad appointing power, directly or indirectly, in the administrative subdivisions of Chile; he names the *intendentes* (chief administrative officials) of the provinces, the governors of departments, and the *alcaldes* (chief local administrative officials) in municipalities of more than 100,-000 inhabitants.

The national congress consists of a senate and a chamber of deputies. The former is composed of 45 members, five from each of the nine groups of provinces into which the republic is divided for such purpose. Each senator holds office for eight years, and half the seats are renewable each four years. Senators must be at least 35 years of age. The chamber of deputies numbers 147 members, one for each 45,000 persons. The members are elected for 4-year terms. No alternate senators or deputies are elected, as is done in several Latin-American countries; in case of vacancies special elections are held. Ordinary sessions of the congress last from May 21 to Sept. 18. It passes on the budget but the president may alter items within the limits therein prescribed. The senate has 12 standing committees and the chamber of deputies 13. Members in each chamber are seated in a semicircular arrangement according to the political complexion of their parties, as in France. The system of proportional representation results in the election of representatives from many parties. Members of the cabinet may not hold seats in the congress but may speak in its sessions.

The judiciary is headed by a supreme court of justice of 13 members appointed by the president from panels proposed by the court itself. Members must be at least 36 years of age and must have had at least 15 years' experience as attorneys or judges. Lower levels of the judiciary include nine courts of appeal and 139 *jueces letrados,* or certified judges (of first instance). The president cannot remove judges but is empowered to transfer them, when necessary, within the jurisdictions to which they belong. Judges are removable by a two-thirds vote of the supreme court.

The largest unit of local government is the province, of which Chile has 25. Provinces exist for administrative rather than political purposes, and the *intendente,* who heads each province, is primarily an administrative agent and a political representative of the president. Each province has a provincial assembly, the members of which are chosen by municipal councils; powers of the assemblies are narrowly restricted, however, both in law and in practice. The next largest subdivision is the department, each province having from one (in Aysén in southern Chile) to six (in Santiago) departments; the usual number is three or four per province. The chief departmental officer is the governor, who is appointed by the president. Departments are divided into subdelegations and the latter into districts. The president has broad power of removal of lower administrative officials and the administration is both hierarchical and highly centralized.

Political parties in Chile are more important than in most Latin-American countries. This has been true since the late decades of the 19th century; during the time of the semiparliamentary regime beginning in the early 1890s governing was largely on the basis of deals worked out among the party groups in the national legislature. Since the restoration of presidential government in 1925 the chief executive's power has been relatively greater than before but it is still true that a political figure's allegiance to his party may sometimes be greater than to the president, even if the former happens to be a cabinet member.

The party picture in Chile bears many similarities to that in France. Proportional representation makes a multiparty system almost inevitable and at times more than 30 parties have been registered for an election. There is necessarily a good deal of flux in the number, composition and alignment of parties, although the Radical, Liberal and Conservative parties are all some decades old; the "Liberal" party is, in fact, a conservative grouping and the "Radical" party is moderate. Two more recent parties that bid fair to become significant in Chilean politics are the Christian Democratic and the National Popular parties. The former was organized in 1957 by a union of the National Falange (not similar to the Spanish Falange) and the Social Christian Conservative party. The National Popular party was formed at the end of 1958 by an amalgamation of the Agrarian Laborite and the' National parties. The National Popular party by 1960 had the fourth largest representation in the congress.

Party coalitions have sometimes been organized. Thus, in the 1930s the Popular Front was an influential grouping composed of leftist and left-of-centre parties. By the late 1950s the Popular Action Front (commonly referred to by its initials as F.R.A.P.) had become an active and influential coalition; it did not include the Radical party. Communists were theoretically banned from action as a party by the Law for the Defense of Democracy (1948). It ineffectively suppressed them for about a decade but was repealed late in the administration of President Ibáñez. Communists have claimed a hard core of about 50.000 voters in Chile. The often frenetic activity of Chilean political parties, especially during electoral campaigns, has resulted in a relatively high degree of urban political participation. In rural areas, however, apathy prevailed.

2. Taxation. — The Chilean tax structure responds in part, but only in part, to social organization and pressures. Thus, in 1953, consumption taxes that bore proportionately more heavily on low-income groups accounted for only about one-eighth of all tax revenues in Chile; this was one of the lower ratios of the kind in Latin-American countries. Indirect taxes in general are significantly lower in Chile than are direct taxes. All taxes are levied by the national congress. The three most important types are the income taxes, sales taxes and taxes on imports and exports.

3. Labour. — Chile is marked by great disparity in personal incomes. For large numbers of people wages are low, employment is uncertain and housing is inadequate. The importance in the national economy of copper and nitrate production means that when production declines — whether because of insufficient markets, low prices or for other reasons — workers are released in the producing areas and quickly drift back to Santiago. As unemployed *rotos,* they constitute a socially and politically volatile and potentially explosive element.

Labour organizations before the 20th century, beginning with the Typographical union established in 1853, were of the mutualist type that emphasized insurance features and educational, cultural and social activities. The mining and shipping industries gave impetus to the formation of a formal labour movement late in the 19th century, and by 1903 *sindicatos* (workmen's associations or trade unions) had about 63,000 members centred in the province of Valparaiso; membership grew to 92,000 by 1910. The Labour Federation of Chile was organized in 1909 and adhered to the third international in 1921. It thereafter sponsored a frankly Communistic program, much of which was embodied in the social legislation of the mid-1920s.

The depression of the early 1930s, which, so far as the nitrate industry was concerned, had begun years earlier, stimulated the

conversion of the labour movement into a popular mass activity. Rival labour organizations in Jan. 1937 created the Confederacibn de Trabajadores de Chile (C.T.C.H.), which included about half of all Chilean industrial workers and a larger proportion of miners. It was controlled by Marxist ideology and adopted a lengthy program of action. After World War II a rift occurred between Communist and other elements in the organization, with the coal-mining unions supporting the Communist element, nitrate and railway workers being more or less divided, and copper-mining unions and most of the important manufacturing unions of Santiago backing the Socialists. The confederation withdrew from the Confederación de Trabajadores de América Latina (C.T.A.L.; Confederation of Latin-American Workers) in June 1947 on the ground that that organization had succumbed to Communist influence. Important agricultural and other semiautonomous unions also exist in Chile. By the early 1960s the chief labour organizations were the Central Única de Trabajadores Chilenos (C.U.T.C.H.; Single Centre of Chilean Workers) and the Confederación Nacional de Trabajadores (C.N.T.; National Labour confederation), both of which engaged actively in politics as rivals.

The development of the Chilean labour movement, one of Latin America's most important, was accompanied by much violence and many strikes. A bitter general strike occurred at Santiago and Valparaiso early in the 20th century and in 1907 a strike at Iquique resulted in the death of 1,000 persons. Strikes were prevalent in the 1920s and 1930s and the severe post-World War II inflation caused many crises. From 1945 onward the operations of a number of foreign interests, including copper and nitrate companies, were seriously hampered by protracted labour disputes, work stoppages and strikes. The Labour code provided that no work stoppage could occur in any establishment employing ten or more workmen or employees until the code's provisions for conciliation had been exhausted.

Inflation continued to be a major factor in causing labour unrest and strikes up to the end of the Ibáñez administration in 1958, despite strenuous but sporadic attempts to introduce an austerity program and hold down the price level. The cost-of-living index increased 2,200% between 1945 and 1958. In the decade ending with 1958 money in circulation increased 3,000% but production only 50%; it therefore proved necessary for President Ibáñez to borrow heavily from social welfare funds. During 1959 and 1960 Pres. Jorge Alessandri achieved some success in checking inflation but encountered strong protests from labour groups.

4. Welfare Services. — Chilean labour and social legislation is among the most extensive in Latin America. Although there were some earlier enactments, labour legislation had its formal beginnings in the decree-law of Sept. 8, 1924, which, with supplemental legislation, was codified as the Labour code of 1931, the first such code to be promulgated in Latin America. The Chilean code, in contradistinction to the Mexican (with which it shares a position of international influence), distinguishes between workers and white-collar employees and contains separate provisions for each category. The code regulates in detail employer-employee contracts, hours and wages, vacations and holidays, and uorkmen's compensation; it also provides for compulsory profit sharing by labour and places on the employer basic responsibility for work accidents and diseases.

The Chilean system of social insurance, begun in 1926, covers almost the whole working population under a number of social welfare organizations. The basis of the system is a compulsory caja, or guild structure, related to the type of employment. The system is financed by employer, employee and government contributions. The law applicable to manual workers provides family allowances and sickness, invalidism, old-age and elements of unemployment insurance; that applicable to salaried employees also provides for other benefits, including dismissal wages, medical benefits and borrowing privileges.

As a result of progress made after 1925 in public health and sanitation the death rate dropped sharply. Birth and death rates in the 1950s were respectively about 35 and 12 per thousand of population. Life expectancy for males at birth was approximately 50 years. The number of Chileans per physician was 1,900, the third most favourable ratio in South America. Just over half of all Chilean dwellings had one or two rooms, 31% had three or four rooms, and 18% had five or more rooms; 54.5% had a piped indoor water supply, 35.7% had baths, and 54.5% had electricity.

5. Education. — Chilean education in the colonial period was limited and was conducted by the church. The first public educational system was organized about the middle of the 19th century. A program of school building was inaugurated during the prosperous years of the 1880s and was continued into the 20th century, but it was not until 1920 that primary education between the ages of 7 and 15 was made compulsory. The principal stimulus to education in the 19th century was given by Andrés Bello, the eminent Venezuelan teacher, who spent most of his adult career in Chile and was primarily responsible for organizing the educational system.

The educational system is organized on three levels — primary, secondary and university. Official sources reported in 1957 the operation of 6,886 primary schools with over 1,000,000 students and 389 secondary schools with over 163,000 students. Agricultural, commercial, technical and evening school education was considerably expanded in the 1950s. The University of Chile (the official university, founded at Santiago in 1842) in the 1950s reported more than 8,000 students; the Catholic University of Chile at Santiago 2.700; the University of Concepción 1,800; and the University of Valparaiso 1,200. School attendance in 1952 was only 42% of those of school age. Literacy of those over ten years of age was estimated in 1952 at nearly 80%; this was an increase from an estimated 50% in 1920.

6. Defense. — The armed forces were reported in the late 1950s to have a total strength of about 33,500 officers and men — 23,000 in the army (including conscripts and a labour force), 13,000 in the navy and 7,500 in the air force. The army and navy differed considerably in tradition, the former having been trained, beginning in the 1880s, by German military missions, and the latter inheriting an English naval influence. These differences were reflected politically in an important way in the fact that in the civil war of 1891 most army elements supported the president but the navy aligned itself with the congress. By the 1950s, however, Chile was one of a minority of Latin-American countries in which the armed forces were relatively apolitical. On April 9, 1952, Chile signed a military assistance pact with the United States, pledging free access to raw materials and armed support in defense of the western hemisphere. (R. H. Fi.)

VII. THE ECONOMY

Before World War I the Chilean economy was based primarily on agriculture and mining. There was little manufacturing although the food and beverage industries were active. For finished products Chile relied heavily on imports, but during World War I shortages of goods and of shipping forced Chile to produce more for herself. This trend continued after the war and added breadth to the Chilean economy. Agriculture was also encouraged to provide for an expanding population and to improve the diet of those who were insufficiently fed.

A. Production

1. Agriculture. — The Spanish brought to Chile the traditional Spanish attitude that land was valuable in and of itself and that its ownership carried social and political prestige. Hence, during the colonial period the productive land in central Chile was divided into large estates, whether by grant, seizure, fraud, purchase or marriage. After independence, there were frequent attacks on the concentration of agricultural land in the hands of the few. Despite criticisms, the system persisted so that about 10% of the farms in modern Chile include about 86% of all the agricultural land in the nation. By the middle of the 20th century there was little evidence that the situation would be altered.

The bulk of the farmland is located in the central valley, an area about 30 mi. wide that lies between the coastal range and the Andes mountains and reaches from La Serena to Puerto Montt. The largest properties are near Santiago. The southern part, settled

by Germans after the 1840s, has smaller units. A landed aristocracy occupies the large estates. Labour is supplied by *inquilinos,* who reside permanently on the land, and by *afuerinos,* migratory workers who are employed during busy seasons. The latter are a miserable lot, poorly paid, illiterate. diseased and often alcoholic. About one-third of the people in Chile are engaged in agriculture.

Chilean agriculture has failed to provide enough food for the nation. The acreage is limited, but there are nevertheless about two and one-half productive acres per capita, more than many European states possess. One reason for inadequate production is that the land is not farmed by the most modern methods. Fertility is restored by rotating the fields, a practice that restricts cultivation. Cheap labour is used instead of machines, and modern techniques are ignored. Inadequate rainfall, especially in the north, makes irrigation imperative. During the colonial period, private associations were formed to canalize the rivers. These associations continued during the 19th and 20th centuries, and the government has given assistance to irrigation projects. Even so, irrigation has not kept pace with the growth of the population. Projected agricultural colonies on unoccupied lands have yielded barren results.

The major crops are wheat, barley, oats, rye, corn. potatoes, peas, lentils, beans and a wide variety of fruits, for which Chile is justly famous. Rice, previously a major import, became a significant crop after 1937. Near the cities, the artichoke, strawberry, radish, asparagus, lettuce, tomato, onion and other truck crops are cultivated in abundance. Chile imports uheat, sugar, coffee, tea, bananas and cotton.

Some horses, goats and hogs are raised, but cattle and sheep are most important. The cattle industry is inadequate, for about 35% of the nation's beef requirement must be imported from Argentina. The dairy industry supplies butter and cheese, but not nearly enough milk. South of Puerto Montt, sheep provide wool and mutton for domestic consumption and for export, mainly to the British Isles.

Wine has been produced since the time of the conquest, but until 1850 quality was ignored. Vines and expert wine makers were then brought in from France and Spain, and Chile began to produce wines of better quality. Beginning in 1875 Chilean wines appeared at international expositions, and by 1900 enjoyed a wide reputation. Vineyards are found throughout the central valley but are most numerous in the Santiago area. The fact that Chileans are accustomed to drinking wine with meals assures a stable domestic market. In addition, exports range from 5,000,000 to 8,000,000 l. annually.

Beginning in 1939, the government adopted a policy of encouraging the production of more food and borrowed funds from abroad for the purpose. Pedigreed stock were imported. New irrigation systems were built and old ones improved. A general plan for the development of agriculture and transportation mas adopted in 1954. Agreements were signed with the United States in 1955 and 1956 to import U.S. surpluses with the provision that funds from their sale should be loaned to the government to promote agriculture.

2. Forestry.— In 1946 a team of U.S. forestry experts estimated that about 10% of the total area of Chile was covered with commercial timber. This amounted to about 2.5 ac. of commercial timber per capita as compared with 1.4 ac. in the United States. Unfortunately, a great part of this rich resource lies in the inaccessible southern third of the country and economic exploitation is difficult because of the profusion of varieties. There are both hard- and softwoods adeauate to meet national needs but a plentiful supply of heavy structural timber is lacking.

Before World War I Chile's lumber industry was both inefficient and wasteful. The mills mere small; exact dimensions and proper seasoning u-ere ignored. Imported woods from the United States dominated the market, especially in northern Chile where the mines created a large demand. After 1914, the domestic lumber industry began to grow. Tariff protection and propaganda in favour of the national product helped. Eventually an industry embracing between 600 and 700 sawmills emerged. These were small, portable mills that cut from 5,000 to 7,000 bd.ft. per day. As a result, the importation of lumber has virtually ended. Chile also manufactures veneer. plywood and wood pulp. The forestry experts mentioned above recommended a plan to preserve this rich resource and part of the plan has been put into effect. Reforestation, proper cutting and fire prevention have been emphasized, along with efforts to produce briquettes, prefabricated houses, wood alcohol, protein feed and other by-products. This industry has yet to attain its full potential. Essential to that end is improved transportation to the southern reserves.

3. Mining.——Mining, especially of nitrates and copper, has been of major importance to Chile since the first half of the 19th century. Without nitrates and copper, the northern third of the country would have little economic importance. It was the struggle for nitrates that provoked the War of the Pacific and gave to Chile a world monopoly of natural nitrate production. Copper and silver mining began on a small scale during the colonial period, but copper production became of real economic importance only with the entrance of U.S. capital and technical skill on a large scale in the 19th century. Despite its importance to the national economy, mining employs only 10% of the population.

There are various theories to account for the deposits in Chile of *caliche,* the grey, rocklike substance containing sodium chloride. sodium nitrate and iodine salts. *Caliche* is found in a narrow strip about 10 to 50 mi. wide between latitudes 19° and 25° S., along the eastern slope of the coast range. The deposits vary in thickness from a few inches to several feet. It is uncertain who first realized that nitrate had commercial value, whether the Jesuit priests or Thaddeus Haenke, the German explorer. With recognition of its value as a fertilizer and in the manufacture of explosives, exportation began in the 1830s; by 1860 a flourishing business had been established. The industry, developed mainly by foreign capital, prospered until 1920, and taxes on exports supplied about 60% of the Chilean budget. After 1920 the Haber-Bosch process for the manufacture of synthetic nitrate presented serious competition. The depression curtailed the market even more. The price of nitrate in 1932 was less than 40% of the price before 1920. Employment and tax revenues both declined.

To meet this competition the Guggenheim process was developed to replace the old Shanks refining technique. The new system, highly mechanized, reduced labour costs, increased efficiency and processed ores of lower grade. Each of two new plants erected at María Elena and Pedro de Valdivia in 1926 and 1930 was capable of producing more than 500,000 tons annually, These two plants, along with a third built at Victoria in 1944 with Chilean and some foreign capital, account for about 90% of all Chilean nitrate production. The industry is directed by a government agency, the Nitrate and Iodine Sales corporation, established in 1933 to succeed the unsuccessful Chilean Nitrate company. This bureau was permitted to allot quotas and market the product. The export tax was revoked. It was agreed that the industry should be reimbursed for the cost of production plus $1.50 per metric ton. The difference between this amount and the market price was defined as profit, of which the operators were to receive 75% and the government 25%.

Iodine, a by-product of nitrate refining, was once a virtual Chilean monopoly. This monopoly, too, has been challenged. Chile now produces about 2,000,000 lb. per year, about 75% of the world's needs.

Production of copper increased slowly after independence until Chile became the world's leading producer in the latter half of the 19th century only to fall behind as deposits in the United States were exploited. After World War I, production increased again so that an annual average of about 200,000 tons was maintained from 1920–30. With the depression, production fell to 103,173 tons in 1932. . World War II stimulated production to about 500,000 tons per year.

Foreign competition alone was not responsible for the decline toward the end of the 19th century. Part of the trouble stemmed from failure to adopt improved techniques. There were also heavy freight charges. It was the foreigner, principally the North American, who invested the capital, restored the industry, and won control of 90% of it. The Braden Copper company was the

first; it acquired El Teniente near Rancagua in 1904 and began production in 1911. In 1915 control passed to the Kennecott Copper company. This mine produced about one-third of the national total. The Guggenheim company purchased Chuquicamata. northeast of Antofagasta, in 1912 and then in 1915 sold it to the Anaconda company, which began production that year. Chuquicamata produces about half the national supply. A smaller mine. Potrerillos. inland from Chafiaral, was acquired by Anaconda in 1927 and produced about one-sixth of the national output. At the mid-20th century rate of exploitation it was estimated that copper production could be sustained for at least another 50 years.

Chile produces more coal than any other South American country, but the product is of poor quality, either semibituminous or lignite. Coal mining began in 1840 at Lota on the Bay of Arauco and has been carried on at that point since. The original development was due to the need to find coal for the first steamship brought to the Pacific. Other mines in the same area are at Coronel and Lebu. These produce about 2,000.000 tons per year. The mines are adjacent to the coast and some reach out under the sea. Before the construction of the Panama canal, Chile did a profitable business in bunker coal. With completion of the canal in 1914 and conversion of ships to oil that business was lost. The outlook for the future is not bright as the reserves are limited and operation is costly.

Iron deposits in Chile are rich and abundant. The best ore contains as much as 70% iron and is virtually free of impurities that are difficult to remove. The first property to be developed, El Tofo, about 40 mi. N. of La Serena, was owned by a French company until 1913 when it was leased to the Bethlehem Steel company. Bethlehem then invested about $40,000,000 to modernize the operations, both at the mine and the port. Cruz Grande, where modern loading facilities were installed. In 1930, 1,500,000 tons were exported. By 1960 the high-grade ores at El Tofo practically had been exhausted, although low-grade ores remained. A second premium deposit, El Romeral, near Coquimbo, was producing in quantity. Ores were exported to the United States and were also shipped to the Chilean steel mill near Concepción. There were additional important iron deposits in Atacama province.

Small mines, widely scattered but mostly in the north, yield gold and silver; these metals are also obtained as by-products in copper refining. In addition, Chile has deposits of lead, mercury, zinc, borax, sulfur and manganese. The sulfur and manganese deposits have commercial potential. Some molybdenum results from the processing of copper at El Teniente. Native limestone supports a cement industry.

Beginning about 1910 there were halfhearted attempts to locate oil and a few dry wells were drilled. Interest then lagged until 1940 when a geologist from the United States reported indications of oil in the southernmost regions. A successful well was drilled in 1945 and production increased phenomenally until in 1960 it was exceeding 70,000 metric tons monthly—still not enough, however, to meet national requirements. The nation's oil reserves and oil industry are controlled by the government.

4. Fisheries.— Even during the Spanish period it was known that the coastal waters abounded in edible fish and crustaceans. There are also marlin and swordfish to attract the sportsman. Despite knowledge of this rich resource there was no systematic effort to develop a fishing industry before 1930. Chile even imported fish. But after 1930, with government encouragement, a gradual change was made so that the tuna, congrio, corvina, sardine, hake and sierra came to be marketed. Cheaper fish are made into meal for use as fertilizer and livestock food. A whaling industry was founded before 1900 and oysters, crabs, clams, locos (scallops) and *erizos* (sea urchins) are caught.

5. Industries.— Handicraft industries such as weaving, leather work, food production and shipbuilding were established before independence. During the 19th century the food industry expanded; flour was exported; gas lighting was introduced; breweries, foundries, textile mills and shoe factories appeared; and wine was produced on a commercial basis. Notable among the industrial pioneers were people of Basque, English, German and Italian origin. These early factories were often little more than workshops. The Sociedad de Fomento Fabril was founded in 1883 by leading manufacturers to encourage industrial growth, and there were fairs or expositions as early as 1894 to emphasize the quality of domestic goods. Agitation for a protective tariff failed until 1928 when the moderate prevailing rates were increased.

When World War I interrupted imports, the development of industry was stimulated. The depression encouraged industry again to provide jobs and also materials that could not be imported because of the lack of foreign exchange. Exchange control, adopted in 1931, favoured domestic goods over imported commodities. A further stimulant came in 1938 with the election of Pres. Pedro Aguirre Cerda whose government was committed to a policy of industrial and agricultural self-sufficiency. Largely because of Aguirre Cerda's insistence, La Corporación de Fomento de la Producción (Chilean Development corporation) was organized in 1939. This government agency was directed to formulate plans to expand the national economy and raise the standard of living, and was authorized to contract foreign loans. The basic law stipulated that the corporation should be directed by a council drawn from the executive and legislative branches of the government, the various professional societies, financial institutions and the national federation of labour. It could undertake projects alone or assist private agencies. About five years were required to formulate a basic plan and to catalogue the national resources. The corporation's chief projects were the development of power, especially hydroelectric power, and the development of basic industries such as iron, steel and paper to reduce imports.

The bulk of Chilean industry is located in and about Santiago and Valparaiso. A third major area is Concepción with the nearby Pacific Steel company plant that has virtually freed Chile from dependence on iron and steel imports. Near Concepción are the fresh water, coal, labour force, access to water and land transportation, and room for expansion which the steel industry demands. Iron ore arrives by sea from northern Chile. Because oil resources were limited, coal of poor quality and imported fuel expensive, the planning officials gave high priority to hydroelectric projects. The country was divided into seven districts to be developed separately and then integrated. Investigation disclosed that from Arica to Puerto Montt there was a 6,000,000 kw. potential of which only 145,000 kw. were used in 1942.

From foundations laid in the early national period or developed since, modern Chile manufactures most of its metal goods, including tin plate and copper products that were formerly processed abroad. From timber milled domestically comes furniture, cartons, veneer, plywood and paper products. Brick, ceramics, tile and glass are manufactured at home. Little processed food is imported. A relatively new industry is the manufacture of edible oil from sunflower and other seeds. Textile requirements are met domestically. Few shoes are imported. A chemical industry supplies most of the dyes, paints, insecticides and drugs required by the national market.

B. Trade and Finance

1. Trade.— The movement of goods within Chile is marked especially by the shipment of foods from the central area to the north and the shipment of oil, coal, mutton and wool from the south to the central region. Manufactured goods move from the centre to all parts of the country.

Minerals dominate the export trade. Before 1932 nitrates headed the list, but copper later became the undisputed leader, followed by nitrates, iron, iodine and other minerals. Agricultural exports consist mainly of dried and canned fruit, wine, wool, hides, mutton and some metallurgical products. Leading imports are petroleum, machinery, railroad and maritime equipment, automobiles, sugar, cotton, coffee and tea, beef and some long-fibre wool.

Before World War I most Chilean exports went to Great Britain and other European countries. The two world wars and the change in the character of mineral exports diverted European commerce to the western hemisphere. The United States became Chile's foremost trading partner. The neighbouring states of Argentina, Bolivia, Peru and Brazil also exchange goods with Chile. The nation's trade balance is usually favourable, but because of the large

foreign investment in Chile the favourable balance is needed in part to meet interest payments.

2. Currency and Banking. — For many years Chile's national monetary unit was the peso, which was divided into 100 centavos. In 1931 the peso was established at 12.17 cents U.S. currency. After 1931 its value greatly depreciated. When exchange control was abandoned in 1956, the peso on the free market was sold at over 1,000 to the dollar. In Jan. 1960 a new monetary unit, the escudo, equal to 1.000 pesos or about 95 cents, was introduced. The Central Bank of Chile, established in 1925, resembles the U.S. federal reserve system and supervises the nation's other banks. By 1960 the budget had been balanced, inflation had been checked and the Central bank had begun issuing notes in terms of the new monetary unit.

C. Transport and Communications

1. Railways and Roads. — Because of its location, topography and latitudinal expanse. Chile is at a disadvantage in creating an efficient land transportation system, but it has one of the best railway systerns in South America. The first rail line in South America, reaching 50 km. inland to Copiapó from Caldera, was completed in April 1851. It was built by William Wheelwright (*q.v.*), a U.S. engineer. From that modest beginning, a national railway network of about 9.000 km. has been built, about two-thirds of it controlled by the national government. The national lines include the longitudinal line from Pisagua to Puerto Montt (a distance of about 1,500 mi.), the Arica-La Paz line that gives Bolivia access to a seaport, the Trans-Andean line from Los Andes to Mendoza, Arg., the Valparaiso-Santiago line and the Antofagasta-Salta line, completed in 1948. The state also operates a small fleet of ships from Puerto Montt to southern ports. There are numerous short feeder lines that connect the longitudinal lines with the various ports. A short line from Arica to Tacna is controlled by British capital. The Antofagasta-Bolivia railway, formerly controlled by British capital, is operated by the Bolivian government. Serious problems result from the multiplicity of gauges and the maintenance of obsolete equipment. To overcome the fuel problem, considerable sections of the state railways in the central zone have been electrified. The relatively good railroad network, mostly state-owned, is often blamed for Chile's failure to develop better highways. Modern hard-surfaced roads in the mid-1950s formed only 5% of all highways. Country roads are often rough, dusty in the summer and almost impassable during the rainy season. The few good roads in the north are maintained by the mining companies.

2. Shipping. — There is virtually no freight or passenger traffic on the rivers of Chile, for the streams are shallow and reach but a short distance inland. The long coast line provides few natural harbours. Only a few ports such as Antofagasta, Valparaiso, San Antonio and Puerto Montt have modern dockside facilities. Antofagasta and San Antonio with copper and Tocopilla and Iquique with nitrates lead in exports. Valparaiso leads in imports.

Coastwise shipping became a national monopoly in 1917 although the law was relaxed in 1939. By the early 1960s Chile had about 100 ocean-going vessels, about 85 of which were engaged in the coastwise traffic. All of these vessels were small and most of them were old. Foreign ships carried most of Chile's export trade. The Grace Line (U.S.) was most important, followed by ships from Great Britain and the Ketherlands.

3. Air Transport. — The development of air transport has been of outstanding importance to Chile because of its geographical situation. Between the late 1930s and the mid-1950s there were enormous increases in traffic on both domestic and international routes. Santiago was the terminus of several international routes, and the number of passengers entering and leaving Chile by air exceeded that of all other means of transport combined. Routes of the National Air Line (L.A.N.) covered the whole length of the country and extended to Buenos Aires. Airfields were numerous but the number suitable for large four-engined aircraft was limited.

4. **Telecommunications.**—The internal telegraphic service was largely government-controlled; international telecommunications service was provided largely by All America Cables and Radio, Inc. and an affiliate of Cable and Wireless, Ltd. The internal telephone service, under control of private companies, was not highly developed; there were less than 150,000 telephones by the mid-1950s, about 90% of which were served by the Chile Telephone company. Commercial radio broadcasting was highly developed. See also references under "Chile" in the Index volume.

Current history and statistics are summarized annually in *Britannica Book of the Year.*

(J. J. J.)

CHILEAN CIVIL WAR. This conflict, which grew out of political disagreements between the president of Chile, J. M. Balmaceda, and his congress (see Chile: *History*), began in Jan. 1891. Unable to win congressional approval of his budget, Balmaceda declared that he would rule without congressional sanction. On Jan. 6, at Valparaiso, the political leaders of the congressional party went on board the ironclad "Blanco Encalada," and Capt. Jorge Montt of that vessel hoisted a broad pennant as commodore of the congressional fleet. Preparations had long been made for the naval pronunciamiento, and in the end few vessels of the Chilean navy adhered to the cause of President Balmaceda. The rank and file of the army, however, remained faithful to the executive. The first shot was fired on Jan. 16 by the "Blanco Encalada" at the Valparaiso batteries, and landing parties from the warships engaged small parties of government troops at vari-

ous places during January and February. The president's principal forces were stationed in and about Iquique, Coquimbo, Valparaiso, Santiago and Concepción. Full-scale military operations began with a naval descent upon Pisagua followed by an advance inland to Dolores. The congressional forces failed at first to make good their footing (Jan. 16–23) but they brought off many recruits and a quantity of munitions of war. On the 26th they retook Pisagua, and on Feb. 15, the Balmacedist commander, Eulogio Robles, who offered battle in the expectation of receiving reinforcements from Tacna, was completely defeated on the old battlefield of San Francisco. Robles fell back along the railway, called up troops from Iquique, and beat the invaders at Haura on the 17th, but Iquique in the meanwhile fell to the congressional fleet on the 16th. In the battle of Pozo Almonte, fought on March 7, Robles was killed and his army dispersed. After this the other Balmacedist troops in the north gave up the struggle.

The congressional leaders now established in Iquique prosecuted the war vigorously, and by the end of April the whole country, from the Peruvian border to the outposts of the Balmacedists at Coquimbo and La Serena, was in the hands of the "rebels." In command of rich nitrate ports, the congressional forces were in position to wage a prolonged war if necessary. In a few months the arrival of new ships from Europe reopened the struggle for command of the sea and the congressional party felt compelled to attempt to crush the dictator at a blow. Del Canto was made commander in chief of the congressional forces and an ex-Prussian officer, Emil Korner. chief of staff. By the end of July they had done their work as well as time permitted, and early in August the troops prepared to embark, not for Coquimbo but for Valparaiso itself.

The expedition by sea was admirably managed, and Quinteros, north of Valparaiso and not many miles out of range of its batteries, was occupied on Aug. 20, 1891. Balmaceda's forces were surprised, but acted promptly. The first battle was fought on the Aconcagua river at Concón on the 21st. The eager infantry of the congressional army forced the passage of the river and stormed the heights held by the presidential forces. The killed and wounded of the Balmacedists numbered 1,600, and nearly all the prisoners, about 1,500 men, enrolled themselves in the rebel army, which thus more than made good its loss of 1,000 killed and wounded. The victors pressed on toward Valparaiso, but were soon brought up by the strong fortified position of the Balmacedist General Barbosa at Viña del Mar. Del Canto and Körner now resolved on a daring step. Supplies of all kinds were brought up from Quinteros to the front and, on Aug. 24, the army abandoned its line of communications and marched inland. The flank march was conducted with great skill, little opposition was encountered, and the rebels finally appeared to the southeast of Valparaiso. There, on the 28th, took place the decisive battle of La Placilla. The government army was practically annihilated. Valparaiso was occupied the same evening and Santiago soon afterward. So great was the effect of the battles of Concón and La Placilla that even the Coquimbo troops surrendered without firing a shot. Balmaceda claimed asylum in the Argentine legation where he committed suicide Sept. 19, 1891. A parliamentary government was formed to guarantee congressional supremacy. (J. J. J.)

CHILI (CHILE), the pods of several kinds of peppers, notably the capsicum, used as a condiment. A dish of meat and beans, called chili con carne, highly flavoured with chili, is popular in the United States; it is generally, though erroneously, believed to have originated in Mexico. In tropical countries chilies are used in many ways to flavour foods.

CHILIASM (MILLENARIANISM), the belief that Christ will return to earth to reign for a thousand years (from Gr. *chilioi,* "a thousand") before the end of all things. It is based on Rev. xx, 1–5. See MILLENNIUM.

CH'I-LIN (KI-LIN), one of the four symbolic creatures that in Chinese mythology is believed to keep watch and ward over the celestial empire. It is a unicorn portrayed in Chinese art as having the body and legs of a deer and the tail of an ox. Its advent on earth heralds an age of enlightened government and civic prosperity. It is regarded as the noblest of the animal creation and as the incarnation of fire, water, wood, metal and earth. It lives for a thousand years, and is believed to step so softly as to leave no footprints and to crush no living thing.

CHILLÁN, a city and the capital of Ñuble province and Chillán department in the southern part of central Chile, 246 mi. S.S.W. of Santiago by rail and about 56 mi. direct (108 by rail) N.E. of Concepción. Pop. (1960) 82,947 (mun.). Chillán is one of the most active commercial cities of central Chile, and is surrounded by a rich agricultural and grazing country. The city was founded by Ruíz de Gamboa in 1580. Its present site was chosen in 1836. The original site now a suburb, known as Chillán Viejo, was the birthplace of the liberator, Bernardo O'Higgins. Chillán was severely damaged by an earthquake in 1939. The hot sulfur springs, Termas de Chillán, known since 1660, are about 45 mi. E.S.E. They issue from the flanks of the Volcán Viejo, about 7,000 ft. above sea level. The highest temperature of the water issuing from these springs is a little over 135° F. The principal volcanoes of the Chillán group are the Nevado (9,528 ft.) and the Viejo. After a two-century repose, the former erupted violently in 1861 and 1864 and slightly in later years.

CHILL HARDENING, the process of hardening the surface of a metal by rapidly cooling it while it is molten or at a very high temperature. Usually the chilling is done by plunging the object in a bath of water or oil. In the case of railway and other wagon and car wheels, a "chill mold" is used, consisting of a sand mold with the outer part (which forms the rim) made of cast iron. When the wheel is cast, the rim cools very rapidly because the iron part of the mold absorbs and conducts away the heat and the consequent chilling hardens the rim. Chill hardening is sometimes combined with case hardening. See FOUNDING; HEAT-TREATMENT; IRON AND STEEL; SURFACE HARDENING.

CHILLICOTHE, a city of southern Ohio, U.S., on the Scioto river, about 50 mi. S. of Columbus, is the seat of Ross county and a trade centre of a wealthy agricultural area. It has extensive paper mills and many smaller industries which help round out a sound economy. A gaseous diffusion plant built in the nearby area increased the city's rate of growth and expansion.

Founded in 1796, Chillicothe was the first capital of the eastern section of the Northnest territory in 1800–03 and the first capital of Ohio in 1803–10 and 1812–16; thus it has considerable historical background and many tourists visit its three museums. Ross County Historical Society museum, Adena museum (the restored home of Gov. Thomas Worthington) and Mound City Group National Monument museum (a restored group of ancient mounds). Many of the early settlers were from Virginia and the older homes in the city show influences of Greek Revival (antebellum) architecture. The name Chillicothe is an Indian word meaning "large town." The city has a council-manager form of government, in effect from 1959. For comparative population figures *see* table in OHIO: *Population.* (D. K. WE.)

CHILLINGWORTH, WILLIAM (1602–1644), English divine, was born at Oxford in 1602. While a fellow at Trinity college he was converted to Roman Catholicism through the efforts of the Jesuit theologian and controversialist "John Fisher" (Fisher the Jesuit; 1569–1641). Thereupon he went to the Jesuit seminary at Douai. His godfather, William Laud (*q.v.*), who had been engaged in a running controversy with Fisher, raised enough doubts in Chillingworth's mind about the correctness of his change to return him to England. Back at Oxford, Chillingworth devoted several years to a reconsideration of the question of authority in religion, and on the basis of this reconsideration he rejoined the Anglican Church in 1634. Three years later he published his most famous work, The *Religion* of Protestants a Safe Way to Salvation, in which he set forth the argument for which he is best known: "the Scripture · · · contains all the material objects of faith [and] is a complete and total, and not only an imperfect and a partial rule" of faith. He took part for a while in the Civil War on the Royalist side; during the war he took ill and died, sometime in Jan. 1644.

See *The Works of William Chillingworth,* 3 vol. (1838); J. D. Hyman, *William Chillingworth and the Theory of Toleration* (1931). (J. J. PN.)

CHILOE, province of southern Chile bisected approximately by lat. 43° S., was reduced to its present size in 1937 when Llanquihue province (*q.v.*) was created. Its 9,052 sq.mi. area embraces the insular components of Chiloé, Chauques and Guafo islands, and the Guaitecas islands (northern part of the Chonos archipelago [q v.]) which are structurally part of the coastal range; and a rugged Andean continental segment which extends from Estero Comau to the Palena river. Volcanoes (Huequén, Minchimávida, Corcovado) arise on the mainland. In both segments evidence of glaciation is general. Summers and winters are cool and humid. Temperate forests of broadleaf evergreens cloak much of the land, but for centuries subsistence farmers, and lumbermen since the early 19th century, have deforested large areas. The predominantly agricultural population (98,662 in 1960) is concentrated on eastern Chiloé and adjacent islands. Most families own small tracts on which potatoes, wheat and a few head of livestock are raised. Fishing and shellfish gathering are important. There are a number of small lumber mills. Economic opportunity is limited so emigration is common: *chilotes* predominate in the labour forces in southern Chile and southern Argentina.

Castro, founded in 1567 and capital until 1834, is centrally located in the province. Ancud, the capital, formerly San Carlos de Ancud (pop. [1960] 18,207 mun.), founded in 1769, is to the north. A narrow-gauge railway and a road join them; both have airfields. Castro (pop. 18,262 mun.) has steamer service to Puerto Montt (*q.v.*), but most of the intercourse with the mainland is by nonscheduled launch or ship. The area suffered from a severe earthquake in 1960. (J. T.)

CHILON (6th century B.C.), Spartan statesman, listed by Plato as the seventh of the Seven Wise Men of ancient Greece, was the son of a certain Damagetus. Either in 560 or 556 B.C he was ephor (an office which he is sometimes even said to have founded). The sayings traditionally attributed to him, which include "Nothing in excess" and "Know thyself" (though he is not the only claimant to these), are sometimes truly laconic; e g, "Give no trouble" and "Do not hope for the impossible."

BIBLIOGRAPHY.—Diogenes Laërtius, i, 68–73, is the main source for Chilon's life and work For lists of the sayings *see* also F W Mullach (ed), *Fragmenta philosophorum graecorum,* vol i, book 2 (1860), and Diels-Kranz, *Fragmente der Vorsokratiker,* vol ii, 7th ed. (1954).

CHILPERIC, the name of two Frankish kings, of the Merovingian dynasty.

CHILPERIC I (539–584) was the son of Clotaire I by Aregund, sister of his queen Ingund. On his father's death (561), fearing that his half brothers would set him aside as a bastard, he seized the royal treasure and tried to set himself up in Paris. but was ejected by the brothers, who allowed him only the kingdom of Tournai, the poorest share in the inheritance. After his half-brother Charibert's death (567). however, he received the country later known as Normandy, Maine and Anjou, together with Rennes, as well as Limousin, Quercy, Toulouse and much territory south of the Garonne.

Already in 562 Chilperic had tried unsuccessfully to take Reims from his half-brother Sigebert of Austrasia, who was then fighting the Avars in the east. Next, in 568, Chilperic had his wife Galswintha, sister of Sigebert's wife Brunhilda (*q.v.*), murdered so that he could marry his mistress Fredegund (*q.v.*). Sigebert then exacted Galswintha's marriage settlement (Bordeaux, Limoges, Quercy. Bigorre and Béarn) from Chilperic as compensation. Resenting this, Chilperic in 573 sent two of his sons. Theudebert and Clovis, to attack Sigebert's southwestern territories. Sigebert then sought help from the Germanic tribes beyond the Rhine, and Chilperic, though his half brother Guntram of Burgundy was now supporting him, was driven back to the Seine and had to restore all his conquests (574). When he advanced as far as Reims in 575 he was again defeated and would have lost his kingdom to Sigebert but for the timely assassination of the latter. In 581, however, when all his own sons were dead, Chilperic adopted Sigebert's son Childebert II. He then turned against Guntram, but this attack came to nothing (583). Shortly after the birth of a last son (the future Clotaire 11), Chilperic was assassinated at Chelles in Sept. or Oct. 584.

Gregory of Tours called Chilperic the Nero and the Herod of his age. He was indeed a typical Merovingian despot, unbridled in his rapacity and ambition. He sold bishoprics, levied crippling taxes and seized the property of the rich. Dissolute, sadistic and superstitious, he was stirred by echoes of classical learning and of Roman splendour. He composed Latin verse, ordered the addition of four Greek letters to the Latin alphabet and constructed amphitheatres at Soissons and in Paris. He also dabbled in theology, forbidding orthodox trinitarian belief. He attempted to extend to women the right of inheritance denied them by Salic law.

CHILPERIC II (*c.* 675–721), king of Neustria. As the alleged son of Childeric II he was taken from a monastery (where he was living under the religious name of Daniel) and made king in 715. Utterly subservient to Ragenfrid, mayor of the palace, he accompanied him on a campaign against Austrasia which took them as far as Cologne Returning, they were defeated by Charles Martel, the Austrasian mayor of the palace, at Amblève, near Liège, in 716. They then sought help from Eudes, duke of Aquitaine, but were again defeated, near Soissons, and Chilperic fled to Aquitaine in 719. Within that year, however, the weakling king of Austrasia, Clotaire IV, died, and Charles Martel. needing a Merovingian to lend legality to his power, restored Chilperic, who now became king of the entire *regnum Francorum.* He died at Soissons in 721.

See F. Lot, *et al., Les Destinées de l'empire en occident de 395 à 888* (1928), in G. Glotz (ed.), *Histoire générale (Histoire du moyen âge,* vol. i). (JE. H.)

CHILTERN HILLS, a range of chalk hills in England extending from southwest to northeast through parts of Oxfordshire, Buckinghamshire, Hertfordshire and Bedfordshire. Considerable areas are cared for by the National trust. The Chilterns form a well-marked escarpment facing northwestward, with a long south-eastern slope, and run from the Thames in the neighbourhood of Goring to the headwaters of its tributary the Lea between Dunstable and Hitchin, the crest line between these two points being about 55 mi. These hills are part of a larger chalk system, continuing the line of the White Horse hills from Berkshire, and themselves continued eastward by the East Anglian ridge, a series which represents the edge of the chalk rising from beneath the Eocene deposits of the London basin. The greatest elevation in the Chilterns is Coombe hill (852 ft.) in the vicinity of Wendover. Toward the Thames gap to the west the elevation falls away only a little, but eastward the East Anglian ridge seldom exceeds 500 ft. Several passes through the Chilterns are used by roads and railways converging on London. The hills were formerly covered with beech, which is still the characteristic growth and the main raw material of the chair and furniture manufactures of High Wycombe.

CHILTERNHUNDREDS, an abbreviation of "the stewardship of the Chiltern Hundreds," an ancient office in the gift of the crown An old principle of English parliamentary law declared that a member of the house of commons. once duly chosen, could not resign his seat. This rule was a relic of the days when the local gentry had to be compelled to serve in parliament. The only method therefore, of avoiding the rule came to be by accepting an office of profit from the crown. The Succession to the Crown act of 1707 provided that every member accepting an office of profit from the crown should thereby vacate his seat. but should be capable of re-election, unless the office in question had been created since 1705, in which case the holder was disqualified from membership failing express statutory provision to the contrary. Before this time the only course open to a member desiring to resign was to petition the house for its leave, but except in cases of incurable ill-health the house always refused it Among the posts of profit held by members of the house of commons in the first half of the 18th century are to be found the names of several crown stewardships, which apparently were not regarded as places of profit under the crown within the meaning of the act of 1707, for no seats were vacated by appointment to them. The first instance of the acceptance of such a stewardship vacating a seat was in 1740, when the house decided that Sir W. W. Wynn, on inheriting from his father, in virtue of a royal grant, the stewardship of the lordship and manor of Bromfield and Yale. had *ipso facto* vacated his seat. On the passing of the House of Commons (Disqualification)

act of 1741, the idea (possibly suggested by Sir W. W. Wynn's case) of utilizing the appointment to certain crown stewardships as a pretext for enabling a member to resign his seat was carried into practice. These nominal stewardships were eight in number, but only two survived to be used in this way in contemporary practice —namely, the offices of steward or bailiff of the three Chiltern hundreds of Stoke. Desborough and Burnham, and of the manor of Northstead. These were carefully preserved by the House of Commons (Disqualification) act of 1957 which clarified the extremely confused state of the law relating to offices of profit and repealed much previous legislation. A stewardship was first used for parliamentary purposes in 1750, the appointment being made by the chancellor of the exchequer It was laid down in 1846 that the Chilterns could not be granted to more than one person on the same day, but this rule has not been strictly adhered to. Modern practice is to grant the Chiltern hundreds and the manor of Northstead alternately, so that two members may vacate their seats at the same moment. Each new warrant expressly revokes the grant to the last holder, the new steward retaining it in his turn until another is appointed. **A** member who vacates his seat in order to test electoral support at a by-election or to contest another constituency may take his seat if re-elected even though he still holds a stewardship.

See parliamentary paper, *Report* From *the Select Committee of House of Commons on the Vacating of Seats (1894).* (JK. W G)

CHI-LUNG (KEELUNG; Japanese, KIIRUN), leading port and city of northern Formosa (Taiwan), located 18 mi. N.E. of T'ai-pei at the mouth of the Chi-lung river. The otherwise excellent deep-water harbour is exposed to the northeast winds of ninter, which bring heavy rains. Chi-lung (pop. [1956] 194.006) was developed by Chinese settlers during the 18th century following previous efforts by the Spanish and Dutch to establish a trading post there. Partly because of its proximity to T'ai-pei and partly because of Formosa's unbalanced international trade, Chi-lung's foreign and domestic imports are much greater than exports. It is a major fishing centre, with freezing factories, a marine products school and a meteorological station. Closely associated with coal and power, Chi-lung's industries include fertilizer factories, several shipbuilding yards, a grain elevator, a flour mill and a bicycle plant. (N. S. G.)

CHIMAERA, in zoology, the common name for any cartilaginous fish (Chondrichthyes) of the small order Chimaerae (sometimes given family rank as the Chimaeridae). "Chimaera" or "chimera" (although the latter spelling usually indicates a genetic mosaic animal or plant; see Chimera), from the Latin meaning "monster." refers to the grotesque form of these, for the most part, deep-sea species. See CHONDRICHTHYES.

CHIMALTENANGO, a department in the highlands of Guatemala; area 764 sq mi.; pop. (1957 est.) 145,948. The capital of the department is also named Chimaltenango (pop. 7,814). The higher part, along the Pan-American highway, is occupied by Maya Indians who grow maize, beans and wheat. The lower areas (below 5,000 ft.) are divided into private estates that grow coffee and sugar cane and pasture cattle and hogs. Access to Chimaltenango is by the highway from Guatemala City about 20 mi. to the east. (P. E. J.)

CHIMBORAZO, a province in highland Ecuador, bounded west by Bolivar. north by Tungurahua, east by the Oriente and south by Cañar province. Area 2,379 sq mi ; pop. (1960 est.) 288,-400. The province includes Mt. Chimborazo in its northwest corner, the highest mountain (20,702 ft.) in Ecuador. A large part of its area is in the zone of the paramos, or high mountain grasslands. Chimborazo includes parts of two intermontane basins in which the people are concentrated: the basin of Riobamba and the basin of Alausi. The capital is Riobamba (*q.v.*). At the higher altitudes the land is used mainly for grazing sheep; in the basins much land is used for the pasture of dairy cattle. The crops include maize, wheat, barley, potatoes, fruit and fibre plants. In the towns of Riobamba and Alausi there are textile mills that produce woolen goods and clothing.

The province is served by the railroad that connects Guayaquil and Quito and by the Pan-American highway, which passes close to Riobamba and through Alausi. (P. E. J.)

CHIMERA. In Greek mythology the Chimera was a fire-breathing female monster resembling a lion in the fore part, a goat in the middle and a dragon behind. She devastated Caria and Lycia until finally she was slain by Bellerophon (*q.v.*). In art the Chimera is usually represented as a lion with a goat's head in the middle of the back. as in the bronze Chimera of Arezzo (5th century). The word is now used generally to denote a fantastic idea or fiction of the imagination. Chimera, or *chimère*, in architecture, is a term loosely used for any grotesque, fantastic or imaginary beast used in decoration.

CHIMERA. Biologically, chimera is defined as a mixture of tissues of different genetic constitution in the same part of an organism.

In ichthyology the term chimera, or chimeroid, is commonly applied to primitive sharklike fishes of a group typified by the genus Chimaera. See CHONDRICHTHYES.

In botany certain types of plants were formerly regarded as "graft hybrids." Graft hybrid suggests a plant produced by the fusion of vegetative cells derived respectively from two plants grafted together. It is true that plants composite in nature and having some of the characteristics of the two plants employed may result from an operation of grafting, but these arise without the fusion of cells that would justify the appellation of hybrid. The term graft hybrid has been replaced in general by "plant chimera" or simply "chimera." (See also GRAFTING [IN PLANTS].)

Many of these plants have been long known in gardens, being grown as curiosities rather than for their decorative value. The earliest to be described in scientific literature was the Bizzaria orange which appeared in a garden in Florence in 1644, arising as an adventitious bud from the region where a scion of sour orange (Citrus *aurantium*) had been grafted on a stock of citron (Citrus *medica*). Others are the so-called *Crataego-mespilus* forms, arising in a similar way following the grafting of medlar (*Mespilus* germanica) on hawthorn (Crataegus monogyna); the *Pyro*-cydonias from the grafting of pear (Pyrus communis) on quince (Cydonia vulgaris); and, best known of all, Laburnum *adami* (or Cytisus adami) from the grafting of the small purple-flowered broom (Cytisus *purpureus*) on the common laburnum (Laburnum vulgare). In all these instances the history of origin is the same; the plants at present in existence have been derived by vegetative propagation from an adventitious shoot that arose at the junction of scion and stock.

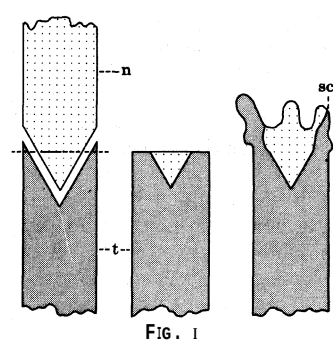

FIG. 1

Stages in the production of a chimeral branch; Winkler's method. Dotted line indicates position of cut. n, nightshade; t, tomato; sc, sectorial chimera

While all the examples mentioned above originated as the result of a horticultural operation, their production was unintentional. Knowledge of the subject passed into a new phase with Hans Winkler's experiments in 1907, deliberately designed to produce graft hybrids. In these experiments black nightshade (*Solanum* nigrum) was grafted on tomato (Solanum *lycopersicum*) (see fig. 1).

After the graft had taken, a transverse cut was made through it at the junction of the stems. From the exposed surface! numerous buds developed which grew into new shoots, all of which were shoots either of nightshade or of tomato except one; this, arising at the junction of the two tissues, had the characters of nightshade on one side and tomato on the other. Winkler called this shoot a chimera, since it was partly of one species and partly of another. In the following two years large-scale experiments were carried out resulting in the production of many thousands of shoots from decapitated grafts. Most of these were either pure nightshade or pure tomato, some were chimeras of the kind already described but in addition there were a few shoots sho ing characters intermediate between the scion and stock. These differed among themselves as to the extent to which they resembled scion or stock and

Winkler gave them special names, believing them to be true graft hybrids.

In 1909 Erwin Baur published observations on variegated plants, in particular the garden geranium *(Pelargonium zonale).* In such plants branches sometimes occur in which one side is green and the other colourless, corresponding structurally to the tomato-nightshade branch to which Winkler first applied the term chimera. In the present instance the distribution of the two kinds of tissue constituting the branch is dramatically obvious because of the difference in colour. Such a branch, called by Baur a sectorial chimera, when cut through transversely usually presents an appearance as shown in fig. 2(A). The nature of any lateral shoot arising from it depends on the place of origin; shoots arising at a and b will be pure green and pure white respectively, while one arising at c will possess a sectorial structure like the parent branch. If a shoot arises as at d where, as often occurs, a superficial strip of one component overlaps the other, a periclinal chimera will result

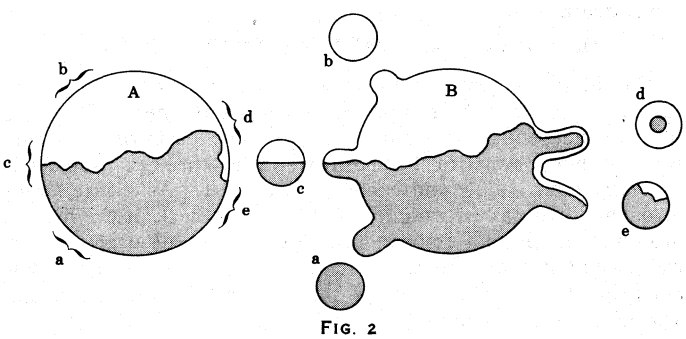

FIG. 2

(A) Diagram of a cross section of the stem of a sectorial chimera consisting of green and colourless tissue; the line of junction between the two tissues is often very irregular. (B) Illustrating how there may arise from such a stem pure green (a), pure white (b), sectorial (c), periclinal (d) or mericlinal (e) branches, depending on the position of lateral bud formation

—an arrangement in which a "core" of green tissue is invested by a "skin" of colourless tissue, one, two or more cell layers thick, depending on the thickness of the overlap, or vice versa.

If the bud arises at the extreme edge of the overlap, as at e, the superficial "skin" may occupy only part of the surface of the shoot, a condition described as mericlinal. Thus, a branch having a sectorial structure gives rise during growth not only to occasional sectorial branches like itself but to branches that are pure for either component, periclinal or mericlinal. In contrast to this instability, a branch that has once acquired a periclinal pattern shows very great stability of structure during growth, producing lateral branches that are all periclinal chimeras like the parent branch.

Baur's experiment with these chimeras of *Pelargonium* composed of green and colourless tissue led him to suggest that Winkler's so-called graft hybrids between nightshade and tomato were in reality periclinal chimeras, and he provided cogent evidence that two of the plants to which Winkler had given special names were built up of a core of tomato with a skin of nightshade one and two cell layers thick respectively, and two of the others of a core of nightshade with skins of tomato one and two cell layers thick. After some hesitation Winkler fully concurred with Baur's interpretation.

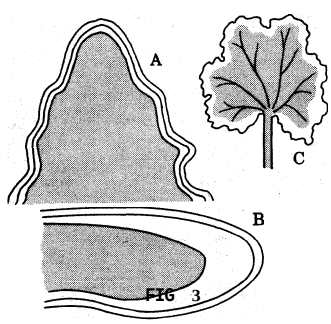

FIG 3

(A) Longitudinal section through the growing point of a periclinal chimera in which the cells of the central core possess potentially green plastids while in the two outer cell layers the plastids lack the capacity to become green; (B) transverse section near the edge of a leaf derived from such a growing point. Because the whole of the marginal tissue, apart from the epidermis, is derived from the second layer of the growing point, the leaf has a white margin. (C) Superficial appearance of a leaf from such a periclinal chimera. The central part of the leaf, as well as the stem, appears green since the green core tissue shows through the two enveloping layers of colourless cells

Attention was then turned to *Laburnum adami* and the other long-known "graft hybrids." Opinion became general that these also are periclinal chimeras: *Laburnum adami,* for example, consisting of a core of laburnum invested with a one-layered skin of *Cytisus purpureus,* the *Crataego-mespili* having a core of hawthorn covered with skins of medlar differing in thickness in the different forms. and so on.

Because of the fact that in flowering plants the reproductive cells arise from the layer second from the surface of the growing point, seedlings from periclinal chimeras are all pure core if the skin is but one cell layer thick, and all pure skin tissue if the skin consists of more than one layer; they are never periclinal chimeras like the parent plant. Also, while stem branches or stem cuttings reproduce the periclinal condition, root cuttings yield invariably plants of core tissue only because of the endogenous manner in which lateral roots are formed.

Apart from being an occasional product of grafting, chimeras also arise in nature, most frequently, no doubt, as the result of a sudden mutation in some cell or cells of a growing region. The new kind of tissue may be conspicuously different from the old as when it is colourless instead of being green, but far more commonly the difference is evident only on special investigation as when the number of chromosomes is altered. Thus chimeras are of far greater frequency than the readily recognizable examples met with might suggest.

In contrast to the graft-hybrid interpretation which predicates a blending of the two components, the chimera hypothesis regards the components as maintaining their identity, but arranged in a definite pattern at the growing point; the manner in which vegetative growth occurs in flowering plants is responsible for the way this pattern is transferred from the growing point to the mature tissues.

The whole behaviour of these plants in reproduction and vegetative growth, as well as in the nature and arrangement of their mature tissues, accords well with the supposition that they are chimeras.

The alternative graft-hybrid hypothesis cannot be said to be theoretically impossible, but it may be regarded as improbable in view of what is known of plant behaviour and as lacking positive supporting evidence.

Nevertheless, it still has its supporters, few though they may be, as exemplified by T. D. Lysenko and his followers.

While in no sense conclusive, it is at least significant that variegated foliage as described above for *Pelargonium zonale* is commonly met with in flowering plants of all kinds. but never occurs in groups such as the ferns with a single-celled growing point. This is what would be expected if such variegation is correctly interpreted as a consequence of the possession of a growing point having a chimerical structure, for which a multicellular growing point is a necessity.

CHIMKENT, the capital city of the South Kazakhstan *oblast* in the Kazakh Soviet Socialist Republic, U.S.S.R., lies 380 mi. W. of Alma-Ata. It was formerly a caravan centre, Isfijab, captured from the Arabs by the Russians in 1864. The population was 153,000 in 1959, having increased more than sevenfold since 1926. Before 1917 Chimkent nas a centre of the santonin industry and it now possesses a large chemical and pharmaceutical works. In addition it has an important lead works, cotton gins, flour mills and fruit canneries. Chimkent is an important railway centre, being the junction of the Arys. Dzhambul and Lenger lines.

A cultural centre. with more than 30 schools and 70 libraries. Chimkent has a pedagogical and a building industry institute.

(*G.* E. WR.)

CHIMNEY, a structure or portion of a building constructed to carry away smoke and gas from fires. It is intended to induce and maintain a draft providing a supply of fresh air to the fire.

It will also act as a ventilator facilitating the change of air in a room. Chimneys range in height to over 300 ft. for some industrial stacks.

HISTORY

The Romans developed elaborate vent and chimney systems in connection with the furnaces and hot-air heating chambers built under the doors and in the walls of their villas, baths and libraries. However the brazier, which they used for domestic purposes, was adopted by southern Europeans for heating. Only in northern Europe, where the smoky wood fire was the usual heat source, was the chimney given architectural emphasis in building exteriors. The custom of maintaining the hearth at the centre of the communal room and allowing the smoke to escape through vents or louvers in the roof or gable ends goes back to prehistoric huts of the northern peoples.

Characteristic chimney forms appeared in medieval times, when the development of masonry techniques allowed the construction of a hearth with a fireproof backstop and flue. Some of the oldest chimneys extant (12th century) are tubular, the shape considered most efficient Some have ingenious conical caps with hooded side vents. Where masonry materials or techniques were lacking, expedients ranged from a barrel with both ends removed to carry smoke through a thatched roof, to the rectangular wooden chimney constructed of notched branches and lined with a coat of clay plaster. This type was used on the American frontier. As rooms became numerous, fireplaces did also, and rectangular flues were grouped to carry them through the roof in a rectangular mass of masonry. Steep-roofed French châteaux required tall chimneys, the late Gothic and early Renaissance examples being elaborately decorated with carvings, pilasters, niches and inlays to form an important part of the architectural ensemble. In English chimneys of the time each of the dues emerging at the roof line was treated as a separate columnar structure with base, cap and polygonal or twisted shaft, generally of elaborately shaped bricks. Some 16th-century examples appear as incongruous miniature classical columns against the sky line.

Chimneys of the 17th and 18th centuries were rectangular. Generally the top courses were projected to form protective caps. The more massive early chimneys were often decorated with bevels or pilasters. In America this type was used as the central feature of the colonial New England farmhouse; the end position was customary for chimneys in the warmer southern colonies, allowing for better air circulation through the house and less retention of heat by the chimney. In the 18th century end placement of fireplaces, which could easily be combined to form fireproof party walls, became standard for row housing everywhere.

In the later 18th century coal became a readily available fuel and the principles governing the operation of domestic fireplaces and chimneys were investigated. Benjamin Rumford established the definitive forms and proper relationships of the essential parts of the chimney. These included the fireplace, the throat, the smoke chamber and the flue. Benjamin Franklin invented a portable cast-iron hearth, evolved from the traditional fireback, used to protect the wall behind the fire and increase the heat reflection from it. The Franklin stove could be inserted in existing overscaled fireplaces or used freestanding when connected by a stovepipe to a chimney flue. In the 20th century new models of this type, intended to supplant the traditional masonry fireplace, were prefabricated in steel.

FIREPLACE AND CHIMNEY CONSTRUCTION

The chimney is generally the heaviest part of a construction and must have ample footing to prevent uneven settlement. It should be built independently and not support other parts of the structure. In North America the masonry substructure of a fireplace is generally built hollow and encloses an ash pit. Ashes are swept through a pivoted cast-iron dump plate at the back of the hearth. drop into the pit and are removed through a small airproof cast-iron clean-out door. In Europe a raised fire grate is more commonly used with some form of shallow tray for ashes beneath. The fireplace has a back hearth of firebrick, while the part extending in front of the chimney is intended largely as a precaution against sparks and may have a more finished masonry surface. The front hearth is laid on a reinforced concrete slab or brick trimmer arch supported by the chimney and bounded by the headers framing the opening in the door.

Dimensions and Shape.—If the fireplace is the only source of heat its size should be proportional to the size of the room, the severity of the climate and the insulating efficiency of the building. Fireplaces have become smaller as design has improved and fuel costs have increased. More heat can be obtained from the open

fireplace if it is modified to heat the air entering the room or if a supplementary air-circulation system is added. Most fireplaces depend in part for combustion on cold air drawn through cracks in floors and around door and window casings. They will not operate satisfactorily if the room is too well sealed or if too much air flows through it.

If air coming from the outside can be drawn through a series of pipes or ducts in the rear wall of the fireplace and heated before it is discharged into the room above the fireplace opening, a more even and economical heating of the room will. result. Where a circulator is used, a double-walled metal heating chamber forms the back and sides of the fireplace. Cool air is drawn from the room at floor level, is warmed in the chamber and delivered to the same or adjoining rooms or to the floor above by means of ducts and registers. Baffles in the chamber may increase efficiency, and if a fan is added, the heating capacity of the system will be further increased. When made of masonry the walls of the fireplace should be of firebrick laid in fire-clay mortar. The side walls should splay in plan, so that the back wall is narrower than the opening, and the upper part of the back wall should slope to reflect heat into the room. A depth of 16 or 18 in. is usual, although fireplaces as shallow as 12 in. work well when the throat is properly constructed. The opening into the room should be wider than it is high. Its area will govern the flue size required, being approximately ten times the area of the effective cross section (discounting the corners) of the flue.

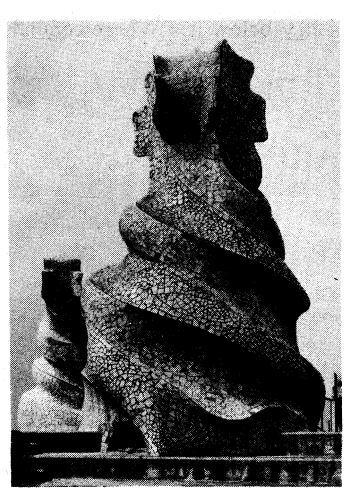
The Throat. — The throat is placed toward the front of the chimney and centred over the fire. The internal surfaces of the throat — especially the entrance to it under the front lintel or arch — should be rounded and smooth to provide a streamlined passage. The throat usually narrows to about four inches deep, and should extend six or eight inches above the top of the fireplace opening to the level of the smoke shelf at the bottom of the smoke chamber, where a damper, or valve plate, should be installed. The damper, which must be adjustable to regulate the air flow, should hinge at the back and extend the full width of the throat.

The smoke shelf is the horizontal surface formed by setting back the masonry at the top of the throat to the line of the back wall of the flue. It serves to deflect downdrafts which would otherwise force smoke and soot into the room. Where there is no damper it is sometimes built with a slight concavity to direct the cold air upward again before it encounters the rising warm air.

The Smoke Chamber. — The space above the shelf is the smoke chamber. It is constructed by sloping the masonry of the side and front walls uniformly toward the centre to meet the bottom of the flue lining. As it should have smooth surfaces it is convenient to build it around a metal form. The smoke chamber slows down drafts and acts as a reservoir for smoke trapped in the chimney by the pressure of gusts of mind across the chimney top. Wind pressure interferes with the normal motion of the column of warm air in the chimney forced upward by the heavier cold air outside, and the danger of poor chimney action is increased. This danger also arises when the fireplace itself is open on more than one side or when there are openings in the wall on either side. The draft in a fireplace without a back may be improved by the use of parallel dampers, while the construction of a fireplace open on three sides or on two adjoining sides may be aided by the installation of an asymmetrical metal smoke chamber to carry the smoke over to a point under the flue. In some old houses the smoke chamber of a large central chimney is accessible through a small door and is equipped for curing meats.

Height. — Since height as well as differential of temperature inside and outside the chimney determines the velocity of air motion within it, short chimneys and chimneys whose outlets are in areas of high wind pressure are also likely to be smoky. Nearby obstacles such as a steeply pitched roof, a tree or another building may deflect the wind, producing pressure or suction over the chimney top. Thus a chimney which need only extend two feet above the ridge when it passes through it should probably rise three feet above the ridge when built elsewhere on the roof. Dimensions of flues and chimneys are usually specified by local building ordinances.

Except in large structures with specially designed central flues, each fireplace or appliance will have a separate flue of a height and size appropriate to its heat output and to the volume of air circulation which it requires. As gas appliances burn at relatively low temperatures and do not produce soot, their flues can be smaller and constructed of concrete block or asbestos cement units.



WAYNE ANDREWS

A CHIMNEY DESIGN AS ART. CHIMNEYS OF THE CASA MILÁ, BARCELONA, SPAIN (1905–07), BY ANTONIO GAUDÍ

Lining. — Each flue should have a fire-clay lining. Unless it is made of dense concrete or specially cast concrete units, an unlined flue will develop leaks as a result of the action of hot gases and weathering. This will increase the disintegration of mortar and spalling of brick caused by moisture in the chimney freezing in cold weather. Flue linings should be carefully cemented and the space between lining and masonry filled with mortar. Traditional pargeting (plastering with lime cement mortar) of the inside of a brick flue, if clear of debris. will generally provide a satisfactory substitute for the lined chimney.

The pargeted chimney must be constructed with a slightly larger cross section (to take care of the same volume of gas) because of

greater friction. Where masonry is to be avoided, economical lightweight chimneys of tubular form can be suspended from the framing of the building. A smoke test should be made on each flue beiore any appliances are connected. (A smudge fire is built and the top of the flue covered tightly. Smoke will be seen escaping through any openings.)

The pipes used to connect appliances with masonry flues should end at the edge of the lining where they discharge into the flue and be sealed in place.

Precautions. — Flues should be vertical except where bends are required to collect them in a stack. Although bends reduce rain splash down the flue, they restrict the flow of gases. Therefore care should be taken that there is no reduction in the cross-sectional area of the flue at the bend and that it slopes at an angle of at least 45°, and preferably more than 60°. Where flues are grouped together they should be separated by at least four inches of masonry to the top of the stack. The danger of warm air siphoning into a neighbouring unused flue. resulting in condensation and damage to interior finish, can be avoided by carrying the partition, or withe, between the flues higher than their outlets or by varying the heights of the flues. Usuallv the flue lining is carried a few inches above the masonry of the chimney and a cement bevel sloped up to it. Baffles, hoods, cowls, chimney pots or spark arresters may form part of the chimney top to control venting, while a capstone will keep rain out of a seldom used flue.

ISOMETRIC DRAWING OF FIREPLACE AND CHIMNEY

Usually the flue linings project above the weatherproof chimney cap, which is made slightly larger than the stack to protect the masonry below it. Where condensation from slow-burning materials may deposit acids or tars on the flue, additional air must be allowed to enter to increase the velocity of the gases, or a means of collecting and removing the condensate must be provided at the base of the flue.

INDUSTRIAL CHIMNEYS: AN ELECTRIC GENERATING STATION. NEW YORK CITY

Fire hazard may be reduced by cleaning partially obstructed flues. removing combustible soot by suction or brush. All combustible building materials should be kept away (nine inches) from flues or fireplace openings, and the space left around the chimney where it passes through the framing of a wooden floor should be packed with fireproof insulation. Where the chimney passes through the roof, flashing and possibly dampproof masonry courses will be necessary to avoid staining of the chimney breast.

Larger Chimneys. — Industrial chimneys are usually freestanding single flues with radial firebrick cores and outer jackets of steel, brick or reinforced concrete. Often there is an insulating air space to allow for differential expansion and contraction. Brick chimneys are generally tapered and reinforced with an iron or steel ring at the top, while concrete chimneys may be built with fire-clay linings. Similar freestanding chimneys are built within or alongside multistory office, hotel and apartment buildings, but are anchored laterally at suitable intervals to ensure stability.

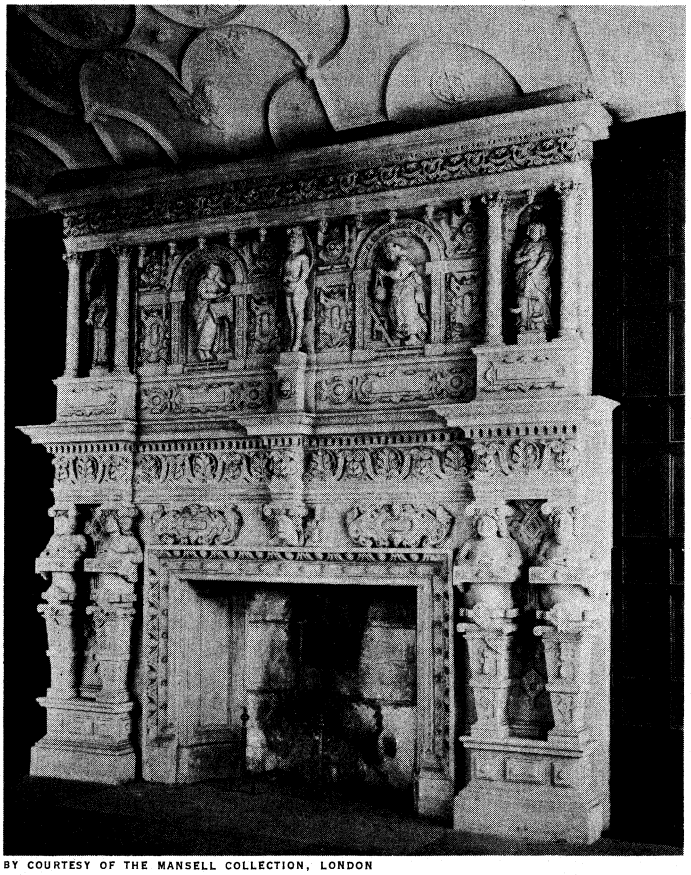
CHIMNEY PIECE, in architecture, was originally a hood, projecting from the wall over a grate, built to catch the smoke and lead it up to the chimney flue. Later, the term was used for any decorative development of the same type or for the same purpose, as a mantel or mantelpiece. Like the chimney (*q.v.*), the chimney piece was essentially a northern medieval development. Its earliest form, a simple hood, sometimes with shafts below, at the wall, is seen in the king's house at Southampton and at Rochester castle, England (12th century). Later, the spaces under the ends of the hood were made solid, so that the fireplace became a rectangular opening, and in some cases the fireplace was recessed into the wall. Late medieval fireplaces were of great size and richness; *e.g.*, the triple fireplace in the great hall of the Palais des Comtes at Poitiers.

During the Renaissance fireplace openings were decorated with columns, pilasters and entablatures, and occasionally the front of the wall or hood above the overmantel was enriched. North Italian palaces have numerous examples of great delicacy. In France the fireplaces at Blois and Chambord are famous. In England the same formula appears in naive and complex types, with the usual Elizabethan and Jacobean mélange of misunderstood classic and Flemish motifs — strapwork, gaines, etc. In France, after a brief classicism under Henry II and Henry IV, the chimney piece reflected the baroque and rococo design trend. Although the opening



BY COURTESY OF THE MANSELL COLLECTION, LONDON

ELABORATELY CARVED CHIMNEY PIECE OF SOUTH WRAXALL (ENG.) MANOR HOUSE

was usually smaller, the decoration was rich. and commonly characterized by elaborate overmantel treatments. The detail assumed the classic extravagance of the Louis XIV style, the swelling curves of the Louis XV and the distinguished restraint of the Louis XVI styles, but almost always retained the same general proportions and overmantel enrichment. German design largely followed that of France; chimney pieces were less numerous there, however, because of the use of porcelain stoves.

In England the Renaissance chimney piece was at first treated, with simple architraves, frieze and cornice. in such as way as to serve as mantelshelf, occasionally with rich paneling above, and much breaking or keying of the moldings. Later. consoles, caryatids and columns were used, although occasionally a bolection molding of sweeping profile replaced the architrave, and the shelf was omitted. In the latter half of the 18th century the characteristic English chimney pieces, in the style of Robert Adam, owed much to Louis *XVI* influence. In American colonial work there was a close following of English precedent, and occasional examples can be traced to specific plates in English architectural books. (J. G. VANDI.)

CHIMPANZEE, one of the anthropoid apes of the family Pongidae. An inhabitant of tropical Africa, it is distinguished from its congener and neighbour the gorilla (*q.v.*) by its smaller size, large outstanding ears and more lively disposition. Males range up to 5 ft. and 150 lb.; females are slightly smaller.

Chimpanzees dwell in small family parties in the rain forest belts of Africa from Gambia to the Congo region; inland the range extends north of the Congo river eastmard to Lake Albert and Lake Victoria and thence southward to northwestern Tanganyika.

Although the general colour of the coat is invariably black with some white hairs on the face and around the anus, examples from so wide a range naturally exhibit considerable variation in size, distribution of hair and skin pigmentation. Consequently many varieties have been described; but. in view of the changes shown by captive animals in passing from youth to maturity and the differences due to sex, it is now felt that the majority of them are invalid. In the early 1960s it was not possible to state precisely how many valid forms exist. but those mentioned below are certainly recognizable, though whether as species or subspecies is a moot point.

1. The masked chimpanzee (Pan *satyrus* verus) of upper Guinea has a pale muzzle bearing short, white hairs, while the brows and upper face are blackish from birth. Ears are large, pale and prominent. fingers and toes pale, palms and soles brownish (never black), body skin pale.

2. The choga (P. s. *satyrus*) occurs in the same area as the next form; *i.e.,* in lower Guinea east of the Dahomey gap. Black-faced throughout life, its nose is not swollen; the body skin is black, including that on hands, feet and ears. Ears are rather smaller than in *verus* and placed somewhat higher, The skull in the male shows a sagittal crest.

3. The koolo-kamba of Nigeria and the western Cameroons region is distinguished by its gorillalike swollen nose, resembling a squashed tomato. The face is blotchy and the hair long and coarse.

4. The long-haired or eastern chimpanzee (P. *s. schweinfurthi*) has the face completely pallid at birth, but with age it becomes a dirty brownish-pink; ears, hands and feet are also pink. This form comes typically from the eastern part of the range, *i.e.,* Tanganyika and Uganda, but extends thence westward into the Congo, a few stragglers even reaching into the Cameroons.

5. The pygmy chimpanzee (P. *paniscus*) is a very distinct, dwarfish animal, confined to the south bank of the Congo river. It deserves full specific rank and has even been promoted to a new genus (Bonobo) by some authors. Its limb proportions somewhat recall those of the gibbon (*q.v.*).

In contrast to the other great apes, chimpanzees are temperamentally extrovert and endowed with considerable intelligence. involving even a degree of insight. They are consequently educable, though attention is inclined to wander if a particular problem eludes them, whereupon they are liable to tantrums. However, they show great individual variability in personality.

In nature chimpanzees move in small family parties led by an adult male. On the ground they walk on all fours in a semierect attitude, but in the trees they use their arms for swinging from branch to branch. When walking, they lean on the knuckles of their hands. In an erect position, their arms reach just below the knees. Females produce a single offspring after a gestation of 32–34 weeks. There is no special breeding season. Full growth is attained by the 11th year and the life span is around 35 years. The chimpanzee's food includes fruit, plant shoots and occasionally insects and birds' eggs.

See PRIMATES; see also references under "Chimpanzee" in the Index volume. (W. C. O. H.)

CHIN, a group of tribes of Mongoloid race occupying the southernmost part of the mountain ranges separating Burma from Assam, numbering some 260.000 in the late 1950s. They are closely related to the Lushai to the west, the Haka and Lakher tribes to the south, and the Kuki to the north. Their history, traceable to about A.D. 1600, is a long sequence of tribal wars and feuds; they also raided the neighbouring areas, such as Chittagong in 1777 and Manipur in 1856. The first British expedition into the Chin hills in 1889 was soon followed by annexation. Previously there had been head-hunting and slave raiding, and much effort had to be devoted to defense. The villages, often of several hundred houses, were self-contained units, some ruled by councils of elders. others by autocratic headmen. There were also hereditary chiefs, exercising political control over large areas and recognized as "lords of the soil," receiving tribute from the cultivators.

Agriculture is the basis of the economy; land is cultivated in rotation, consecutive cultivation for between three and six years being followed by reversion to forest. The land is worked by hand with hoes; rice, millet and maize are the main crops. Hill slopes are cultivated from top to bottom with variations of height between individual fields of up to 6,000 ft. Domestic animals are kept mainly for meat, and are neither milked nor used for traction. The mithan (Bos frontalis), the main sacrificial animal, is a symbol of wealth and prestige. Pigs, goats and fowls are also sacrificed as well as eaten. Prowess in hunting has religious significance, and the slayer of much game is believed to enjoy high rank in afterlife. Equally important for the attainment of a desirable fate after death is the giving of lavish "feasts of merit." Social advancement too is achieved by means of feasts, and much of the Chins' material resources is devoted to payments and ritual connected with marriage, birth, death and illness.

Traditional religion comprises a belief in numerous deities and spirits, accessible to propitiation by offerings and sacrifices. Christian missions have made many converts, and in a late cult known as Pauchinhau indigenous and Christian religious concepts have been mingled. The area inhabited by Chins is also claimed by the Kuki, Lushai and Lakher as their original home, and ethnographically these tribes conform to a similar pattern: they speak related Tibeto-Burman languages, and common to all is the rule by chiefs, the division of society into patrilineal, exogamous clans, polygyny and the levirate; a system of patronage amounting to serfdom enables a chief to build up a powerful following. These tribes have retained their identity, and Burmese cultural and linguistic influence has remained limited. See BURMA.

CHINA, a vast country of eastern Asia, bordering the U.S.S.R. and the Mongolian People's Republic for more than 6,000 mi. on the north and west; it is flanked by Korea on the northeast; the Yellow sea, East China sea and South China sea on the east; Vietnam, Laos and Burma on the south; and the Karakoram and Himalaya ranges on the southwest. Including Manchuria. Sinkiang and Tibet and numerous smaller islands, but excluding Formosa (Taiwan), China has a total area of 3,691,502 sq.mi. with a population (1953) of 582,603.417; (1957 est.) 646,530,000. After the victory of the Chinese Communists and the flight of the Nationalist government to Formosa (Dec. 8. 1949), China was divided into two political entities: Communist China on

the mainland and the Nationalist government on Formosa

The People's Republic of China (Chunq-hua jen-min kung-ho-kuo), capital at Peking, which was formally inaugurated in Oct. 1949, was founded on the principles of Marx, Lenin and Stalin and of Mao Tse-tung's New Democracy. The Nationalist government in T'ai-pei, Formosa, was based on Sun Vat-sen's Three Principles of the People and the five-power constitutional system; its official name is the Republic of China (Chung-hua-min-kung-ho-kuo).

Following are the main sections of the article:

I. INTRODUCTION

Traditionally, China has been considered as comprising five separate cultural and economic regions. China proper, Manchuria, Mongolia, Sinkiang and Tibet. To these in the second half of the 20th century must be added a sixth, industrial China.

Less than half the country's total area is essentially Chinese. Its civilization has always rested upon agriculture, and Chinese culture has extended as a dominant institution only into those areas where cultivation is possible. The majority of political China is either too dry, too hilly or too cold for farming; these vast spaces, while relatively empty and hence relatively easily incorporated into the Chinese polity. are inhabited for the most part by non-Chinese people whose cultures and economies are markedly distinct from the human patterns of agricultural China.

The interaction between agricultural China and the outer areas of political China is in part a measure of their differences, but equally of the attractive power, wealth and prestige of Chinese civilization Despite the distinctions outlined below, "greater China" is a living entity, with a degree of unity that belies its regional distinctiveness.

1. China Proper. — "China proper," as the agricultural area commonly is called, consists of 18 provinces — Anhnei, Chekiang, Fukien, Honan, Hopeh, Hunan, Hupeh, Kansu, Kiangsi. Kiangsu, Knangsi, Kwangtung, Kweichow, Shansi, Shantung. Shensi. Szechwan and Uunnan — bounded by the sea to the east, the mountains to the south and west and the desert to the north. In early Han times only a few areas near the capital were clearly delimited, and the more distant military and civil zones or districts were but loosely designated. Under later dynastic rulers the units changed steadily in number and general area, but slowly the number of closely delimited areas increased, particularly in the north The final shaping of the 18 provinces occurred during the 15th and 16th centuries, under the Ming rulers. at which time there were 15 provinces. Anhwei had not been separated from Kiangsu. Hupeh and Hunan had not been divided, Kansu still was a part of Shensi, and the limits of several provinces had not yet been settled. By 1760, under the Manchus, only Hupeh and Hunan remained undivided (though recognized), some other lines were still under final adjustment, and the western boundaries of Szechwan and Yünnan still were ill-defined. Detailed adjustments in fully precise boundaries have continued, and the Szechwan-Tibetan border still is subject to repeated change. Despite these late adjustments in details the basic political patterns have been intact for several centuries. and they express a kind of integrated regionalism toward which administration has long been moving, so that political boundaries have been recognized by all as far more than mere administrative lines. Strikingly, the political divisions were developed on land form and drainage criteria in almost all cases, but they have become important historical and cultural boundaries that the Chinese have recognized and compounded in many ways. The historic identification of provincial birthplace. and the banding together of fellow provincials, has been one of the strongest social attributes of the Chinese.

The Great Wall. completed, from earlier walls, as a continuous unit by the emperor Shih Huang Ti in the 3rd century B.C., still serves to mark a line between farming and grazing along the desert border of agricultural China in the north and northnest. Not all of the area of the 18 provinces is arable. however, and in fact mountains, hills and climate, especially in the nest and south, combine to keep almost three-quarters of it out of cultivation (*see* below). In many of the areas — for example, the southwest — there still live many non-Chinese people. Agriculture also increasingly spread out beyond the limits of China proper after the middle of the 19th century as population pressure mounted Manchuria and the moister parts of Inner Mongolia have in particular been increasingly settled by north China farmers. But the 18 provinces of China proper do contain the bulk of the agricultural land. the great majority of the Chinese people and the roots and body of Chinese civilization.

2. Manchuria. — Manchuria was sparsely settled before 1900. Chinese political claims to it were weak but were made effective by the mass immigration of farmers. Southern Manchuria has rich resources of broad, level land, coal, iron, timber and water power, which mere largely developed by the Japanese during their period of control from 1931 to 1946. This process continued under Chinese Communist control after 1947 and made Manchuria into a major industrial area. Manchuria's current distinction from China lies to a considerable degree in the commercialized and industrialized nature of its economy, a reflection of accessible resources and of heavy Japanese and Russian investment in railways and manufacturing betneen 1890 and 1946. The name Manchuria is no longer officially used, and the area is known simply as the Northeast. (See also MANCHURIA.)

3. Mongolia.—Mongolia is a vast steppe bordering on the desert of central Asia. The moister southern sections, now the Inner Mongolian autonomous region (formerly Ningsia, Suiyüan, Chahar and Jehol — not part of the 18 provinces), especially since the end of the 19th century have been infiltrated by Chinese farmers and drawn more firmly under Chinese political control. The remaining drier sections, known as Outer Mongolia and sparsely though almost exclusively occupied by Mongols. are oriented to the Soviet Union. Outer Mongolia's independent status as the Mongolian People's Republic was recognized by both the Nationalist and Communist governments of China in agreements with the Soviet Union. (See also MONGOLIA)

4. **Sinkiang.**—Sinkiang is the westernmost extension of political China, a desert corridor betneen the two arms of the mountain mass of central Asia. the Tien Shan (Chinese. *shan;* English, "mountain") and Kunlun ranges. Its earlier name of Eastern or Chinese Turkistan reveals its non-Chinese culture, as well as the reason for the repeated assertion of Chinese control: it is the traditional overland connection with the nest. Most of Sinkiang's people belong culturally to the Turkish group, and life centres in the scattered string of oases from east to west along the base of the mountain escarpment. These oases, following both the northern and southern margins of the desert basin, nourished the old silk route from China to Europe and the middle east. At Kashgar and Yarkand passes lead out of the desert basin and across the Pamirs into Russian Turkistan and Afghanistan. Another route westward runs north of the basin through the oases of Hami and Urumchi into the steppe of Dzungaria, which is also included in the province of Sinkiang. Chinese authority in Sinkiang tended to be increasingly nominal after 1900, and Russian influence grew. The Chinese Communist government established its control in Sinkiang in late 1949; and in 1956 renamed it the Sinkiang Uighur autonomous region, giving it special status. (See also SINKIANG.)

5. Tibet. — Tibet, like Mongolia, has two parts. though it is less usable from a human point of view. The terms "nearer" and "farther" Tibet record this division, the first referring to the borderland areas in the east fronting on agricultural China and low enough or nith a series of narrow river valleys to permit farming. About 80% of Tibet's cultivated area and the majority of its population are there. Most of nearer Tibet used to be included in the Chinese provinces of Sikang and Tsinghai (not part of the 18 provinces), reflecting not only the penetration of agriculture but the need for a buffer against nomadic raids from farther Tibet. In late 1955 the province of Sikang was abolished, and the area annexed to Szechnan. Most of farther Tibet is too high, rugged and cold for agriculture. It is extremely thinly occupied by a non-Chinese population whose support comes largely from nomadism based on the yak, from the raising of barley in a few favoured places, and from the trade routes connecting India, China and central Asia which pass through the country. with their most notable focus at Lhasa, the capital.

Chinese sovereignty over all of Tibet usually has accompanied the rise of a strong dynasty in China. As central authority in China weakened during the 19th century the theocratic govern-

ment at Lhasa became increasingly independent. Though Great Britain and Russia recognized China's suzerainty by treaty in 1907, Tibet remained very loosely attached until the Chinese Communist government carried out a military occupation as far as Lhasa in 1951 and obtained an agreement conferring on Peking all control of foreign affairs, currency and defense.

6. Industrial China. — The growing industrialization of China in the second half of the 20th century significantly alters the limits of the old, agricultural China. Road, rail and air transport is unifying the whole of greater China in a way never before accomplished. Many of the newly located mineral resources lie in areas marginal to the old centres of population and economic power. As the industrial program matures the formerly marginal and nonagricultural sectors of the political state, except for farther Tibet, will become productive areas vital to the economy of the whole. In the expanding economic development of the first and second five-year plans the regional dispersal of Chinese, of industrial processes, industrial plants, internal trade routes and economic forces serves to enlarge the areal economic structure of China more nearly to fit its political limits. Though the process had only begun, by the 1960s it already had altered the regionalism of China.

II. PHYSICAL GEOGRAPHY

The eastern Asian mainland, containing China proper and its outlying segments, possesses tremendous variety and complexity in its physical make-up. There are to be found ancient hard rock surfaces (north China and Manchuria), a zone of recent wind-blown sediments masking the underlying surface (the loesslands of the middle Yellow [Huang] river system), some of the world's youngest and loftiest mountains (Himalayas, Kunlun and Tien Shan), one of the lowest spots on earth (Turfan depression). a dramatic region of karst land forms (Kwangsi and Kweichow). two of the world's great rivers (Yellow and Yangtze) and two alluvial lowlands subject to serious flooding (north China plain, Yangtze valley). A land form profile drawn westward. south of Shanghai. passes over a series of low mountain ranges interspersed by lowland basins, each unit set a step upward until the last great step onto the Tibetan plateau. Across Manchuria and into central Asia the easternmost portion of the profile is similar to that in the south, but the western portion drops away to the Turfan depression. China proper, with Manchuria, forms the eastern sector of this varied zone, wherein the elevations are lower, and most of the land forms less spectacular, than those of Tibet. China proper, however, is one of the most irregular large areas of the world, with lowland basins. rugged hill and low mountain country, and intricately developed drainage systems arranged in a complex pattern that seems at first glance to have little order.

A. Geology and Structure

1. Structural Features. — The geological pattern of China and its dependencies is determined by two widely spaced series of structural axes, one extending eastward out of central Asia and the other trending northeast-southwest across Manchuria and China proper. The older axial elements are broad but discontinuous hard rock massifs forming low mountains and blocks of rugged hill country that constitute drainage divides, whereas the more recent elements are marked by more imposing mountain ranges that still are undergoing mountain building.

The east-west axes, from north to south, are (1) the Tannu Ola-Kentei-Khingan range system on the Siberian border; (2) the Yin Shan ranges just north of the great bend of the Yellow river: (3) the Tsinling system of ranges extending from the Kunlun eastward across central China and tapering out in the southern north China plain; and (4) the Nan Ling Shan in south China forming the divide between the Hsi Chiang (Chinese, *chiang;* English, "river," "basin") and the Yangtze river.

The northeast-southwest axes are (1) the Fukien massif fronting on the China sea; (2) the discontinuous system of ranges and blocks extending from Hainan Island off the south China coast northnard through the Shantung and Liao-tung peninsulas into coastal Siberia; (3) the Great Khingan-T'ai-hang system of ranges whose southern ends lie buried in the east front of the Yünnan plateau, trending north across central China to the Siberian border; and (4) the Ala Shan, a short series of hilly mountain roots just west of the great bend of the Yellow river. South of the Kunlun the eastern ends of the Tibetan mountain systems curve southeastward toward southeast Asia to form the spectacular Chinese-Tibetan borderland, whose geological composition and structure are still imperfectly known.

The several axes intersect and interfere with one another in much of China proper, produce local structural complexities and contribute to the complicated physiography of China. Between the axial trends are located the structural basins, platforms and plateaus which show up either as alluvial lowlands now being filled by the rivers of China, or as lowlands, platforms, elevated basins or plateaus now undergoing denudation by stream processes, karst processes, wind erosion or some combination of these.

(R. M.; J. E. Sr.)

2. Geologic History. — The earth movements, involving both folding and faulting, responsible for the present geological structure of China began in very ancient times and have continued at intervals to the present. The most important were: (1) Pre-Cambrian (widespread, in several stages); (2) post-Silurian (minor except in south); (3) post-Devonian (in southeast); (4) Upper Carboniferous (in southwest and in Nan Ling Shan, where granite intrusions are numerous); (5) mid-Permian (Kunlun mountain axis and its extension into central China. lava flows in southwest); (6) post-Triassic (general uplift of eastern Asia. folding in southwest and east central China); (7) post-Jurassic (widespread. most important in Tsinling axis of central China); (8) post-Cretaceous (widespread, lava flows in Manchuria and southeast China, igneous intrusions in the south with which metalliferous deposits are associated); (9) Late Tertiary (particularly in north China and Mongolia); and (10) Recent (central Asian highlands).

3. Distribution of Strata. — Because of structural complexity, rocks of all geologic ages are widely but irregularly distributed, and the only considerable areas of comparatively undisturbed strata occur in the basins. The total thickness of sedimentary rocks is very great. but in a country of such size the thickness and also the lithologic nature of beds of equivalent age vary greatly in different areas.

The Pre-Cambrian rocks constitute three great systems: T'ai Shan (oldest), Wu-t'ai and Sinian (youngest). The first consists of highly metamorphosed sedimentary and igneous rocks. mostly gneiss and schist, and the second is made up of less metamorphosed sediments. The last is mainly sedimentary and consists of arkosic clastics below grading up into thick cherty limestone; it also includes sedimentary iron ore, tillite and local lava flows. These are unmetamorphosed except where involved in much later mountain-forming disturbances and generally resemble overlying Paleozoic formations.

The Paleozoic succession begins with Lower Cambrian sandstone and grades upward into thick later Cambrian and Ordovician limestone. Toward the end of the Ordovician period all China north of the Tsinling axis was gently uplifted, and subsequent deposits are absent from that region.

Silurian. Devonian and Lower Carboniferous strata are confined to south China and include graptolite-bearing shale (Silurian), plant-bearing nonmarine beds (Devonian) and much limestone. The lower parts particularly were deposited in very shallow water.

Upper Carboniferous strata overlap extensively onto Ordovician and older rocks in north China, and Permian strata are almost equally extensive. In south and central China these beds are mainly limestone. but in the north they include the most important coal deposits of the country, and red beds become conspicuous in the upper part.

Sinian and Paleozoic sediments accumulated in a broad depression extending northeast-southwest and connecting with similar east-west depressions on either side of the Tibetan region. Successive mountain uplifts encroached upon these depressions and reduced in size and multiplied in number the depositional basins

of later times, which shifted to some extent with respect to each other.

Nonmarine strata become progressively more important in the Mesozoic, and thick red beds are present in many areas. Rock salt occurs in the Triassic of Szechwan, coal in the Jurassic and gypsum in the Cretaceous.

Tertiary strata, mostly nonmarine red beds, occur especially in the north, where they are many thousands of feet thick. They include some lignite, gypsum, fresh-water limestone and lava flows. The youngest of these beds are nearly horizontal except adjacent to very recently uplifted mountains. Oil is produced from the Tertiary in the northwest.

Deposits of Pleistocene and Recent Age include thick piedmont gravels in central Asia, the loess of north China and extensive alluvium in the Yellow, Yangtze and other river valleys.

(J. M. WR.)

B. PHYSIOGRAPHY

The land forms of China are complex, varied and developed around the structural framework described above. Essentially there are a series of elongated zones of hill and mountain country with intervening erosional or depositional basins. In north and central China the pattern is fairly clear, but south China has few basins and a larger share of hill country. Stream erosion and its associated denudational processes have been the primary forces shaping the upland landscape, and stream deposition has created the critically valuable alluvial basins and deltas. Aeolian processes have been important in the northwest; glaciation has played an active role in the higher mountain regions, notably in the Chinese-Tibetan borderland; and solution processes have been important in parts of south China.

1. River Systems.—There are four major and several smaller river systems that drain China proper and Manchuria, serving both to reduce upland areas and to fill the lowland basins and the shallow coastal waters. Primarily the drainage net is guided by the structure. Northern Manchuria is drained by tributaries of the Amur river, of which the Sungari system is the largest, draining the northern portion of the Manchurian plain and its surrounding mountains northward away from the rest of China. Southern Manchuria is drained by the smaller Liao river. The Yellow river (Huang Ho) taps a 486,486-sq.mi. sector across north China, between the Yin Shan and the Tsinling Shan. The northern end of the north China plain carries a series of smaller streams. whereas some 64,000 sq.mi. of the southern part of the plain is drained by the Huai Ho (Hwai river; Chinese, ho; English. "river"), into which the Yellow occasionally breaks when in major flood. The Yangtze (Ch'ang Chiang) river system drains a 756,498-sq.mi. zone across central China, between the Tsinling and Nan Ling mountain systems, forming the major drainage basin of eastern Asia. It has several large tributaries within China proper. In the east the Kan joins from the south through P'o-yang Hu (chinese, hu; English, "lake"), the Han joins from the north at Hankow, the Hsiang comes in from the south through Tung-t'ing Hu. the Wu joins from the south at Fou-ling, the Chia-ling joins at Chungking from the north, and the Min comes in from the north at I-pin, in western Szechwan. The Hsi Chiang (West river) system, as a whole, drains 170,000 sq.mi. of south China. The Fukien coastal zone is drained by a series of small rivers that are mountain streams rather than lowland rivers.

The Sungari tributaries of the Amur are normal high latitude rivers, subject to winter freezing and spring floods, and though they are degrading most of the basin they do not operate in spectacular fashion. The Yellow river is a typical arid-land river system, with few permanent tributaries, highly variable water flow, a very high silt content when in flood, silting of its bed in its lower course, and frequent changes of course across the north China plain. Its drainage of the loess highlands region of China, subject to easy erosion, provides an abnormal potential load of sediment in flood season. The historic diking of the lower course of the Yellow has prevented the natural distribution of the sediment load and has caused the upbuilding of the river bed and natural levees many feet above the plain. This has led to major breakouts during unusual flood periods, resulting in disaster on a large scale. The Yellow's lower course seldom has been constant for more than a century during the whole of historic time, and it has been the major builder of the north China plain. In 1938 the Chinese cut the dikes and diverted the Yellow to a course south of the Shantung peninsula in an effort to delay the Japanese armies, and it was not returned to its northern course until 1947.

The Liao river is also an arid-land stream, but one that freezes in winter. It is degrading most of its basin, but it carries a small volume of water and a lesser sediment load than the Yellow, so it is not rapidly building its delta margins. The Huai Ho, on the arid margins of north central China, has too small a basin and regular flow volume fully to maintain its course to the sea, and ends in the Hung-tse Hu, though flood control outlets are again being developed to drain off to the sea its frequent summer flood volumes. The Yangtze is a normal humid-region stream, with an intricate system of tributaries and a large flow at all times, but it is very subject to seasonal flooding in some portions of its basin. The western and outer margins of the basin are under active erosion, and its lower portion and delta zone are areas of active alluvial deposition. The main branch of the Hsi Chiang flows chiefly through a region of karst land forms, and though the region is humid the river has fewer than the normal number of tributaries and a fairly even flow.

2. Relief.—Mountains.—East of the Tibetan borderland only the western Tsinling mountains and a few ranges in Yiinnan and Kweichow reach really high elevations, yet most of China proper is rough and rugged hill and mountain country of high local relief, and much of the west and most of south China appears as a jumbled sea of mountains. Of the roughly 2,000.000 sq.mi. area of China proper, Inner Mongolia and Manchuria, about 1,400,000 sq.mi. could be described as hills and mountains, leaving only about 600,000 sq.mi. in areas of subdued to smooth surfaces. Most of the physical landscape, therefore, is a denudational landscape with large amounts of bare rock exposure. The historic processes of deforestation and soil erosion have added to the amount of bare rock, or to the gullying and roughening of much of the surface, despite the amount of terracing done by the Chinese, for there have been periods in which civil unrest has interfered with terrace maintenance. In areas of hard bedrock, such as the Shantung peninsula, the T'ai-hang Shan, the Fukien hill country or the karst mountains of Kweichow and western Kwangsi, the stripping off of thin soil covers has created broad expanses of bare rock that no amount of careful maintenance can restore to usefulness.

Few of the mountainous areas form well-defined mountain ranges, and none within China proper or Manchuria form real barriers to internal transport of some sort. The Tsinling ranges from eastern Kansu to central Honan form perhaps the sharpest physical divide, of climatic as well as topographic significance, separating the dry loesslands of the north from the green hills of the south. Elsewhere the mountainous districts serve chiefly as watershed divides or zonal separations of the lowland basins.

Around the margins of most of the structural basins the flexures, faults and folds created locally coinplex patterns that have been roughened by the developing of headwater drainage networks to make many of the basin margins zones of acutely developed land forms of high local relief. In these zones terracing, historically, has been extensive and effective in the prevention of serious erosion, but exceptional rains or periods of civil unrest often have caused widespread deterioration of agricultural areas.

Loess Region.—Much of Shansi, northern Honan, most of Shensi and eastern Kansu are overlain by a mantle of fine-grained wind-deposited alluvium, or loess, between 25 and 250 ft. thick, masking the detailed relief of the underlying surfaces. Loess was deposited beyond these suggested limits in smaller amounts mixed into the water-laid deposits. Within the main loess region the rich, soft soil was very important to early Chinese agriculture, but loess is highly subject to erosion by gullying. Though terracing is both old and widespread there has been general increase in total erosion, so that by modern times the region contains many areas of high local relief, lessening the modern agricultural utility of the farm landscape.

Basins.—The Manchurian basin is a degrading zone rather than a depositional area, but the structural smoothness and the climatic regime have been such that most of the basin presents subdued relief and broad open surfaces. Such surfaces also are characteristic of much of Inner Mongolia, though in this area the aridity is so great that stream drainage is almost entirely sporadic, local and internal within the broad structural basins. The Szechwan basin, pitched well above the level of most of eastern China, is a zone of active denudation. Chiefly horizontal sediments of soft textures have been intricately dissected by stream drainage, so that most of the basin presents a surface of low hills, whose tendency to natural terracing has been easily and highly amplified by agricultural occupance.

Plateaus.—The Yunnan and Kweichow plateaus are not good examples of plateaus. for dissection has etched them deeply. The margins of the Yünnan plateau are very deeply cut by the great rivers of southeastern Asia, though a few portions of the main upland region present broad surfaces located around structural depressions containing mostly shallow lakes. The Kmeichow plateau, in reality, is no longer a plateau at all, but a deeply dissected upland region of hills. canyons, valleys and karst land forms. Eastward of the Ydnnan plateau these karst land forms are more highly developed. and the Kwangsi platform shows a variety of physical features. In the west the rock outcrops are numerous and the solution basins tend to be ragged in outline, whereas to the east the rock outcrops are but remnants, the open surfaces are broad, and relief is generally more subdued.

Lowlands.—Several lowland basins present smooth depositional land form features. These are the best portions of China wherein the mass of the population is concentrated. The north China plain, the Yangtze delta (properly a filled estuary, which merges into the southern north China plain), the Tung-t'ing basin, the P'o-yang basin and the Canton estuary lowland are the largest of these. Seasonal flooding, alluvial deposition, frequent changes in local minor land forms, the presence of natural levees, river terraces, old channel lines and other flood plain features are normal. Except in the northern north China plain there are many natural and artificial lakes and ponds. The historic procedures of dike building. the canalizing of natural streams and artificial canal building, however, have continuously interfered with natural physiographic processes, and the Chinese have been engaged in a long and difficult struggle to control the precious lowlands. The periodic high floods repeatedly have broken through dike systems to cover local areas with sediments that sometimes obliterate the previous detail of the land surface. The Yellow river has been more difficult to control than the Yangtze, whose several basins and tributary valleys afford temporary storage for flood waters draining from some other sector of the river system. As the inland depositional basins progressively are being filled. the north China coast line is being built outward steadily at a rapid rate.

Coast Line.—North of Hangchow bay the alluvial coast line provides almost no natural harbours except for those around the rocky Shantung and Liao-tung peninsulas Shantung, originally an island in the Yellow sea, has been tied to the mainland through the growth of the north China plain River-mouth harbours increasingly are turned into artificial harbours. South of Hangchow bay the submerged coast has many deep inlets and offshore islands as far south as Canton, and excellent harbours are plentiful, but west of Canton the coast again is a smooth coast, though not an active depositional one, and there are only a few good harbours, nith shallow waters offshore.

C. Climate

For China proper and Manchuria eight major climatic regions can be distinguished. Their general locations and principal characteristics are as follows:

1. Northern Manchuria.—Thenorthern sector of Manchuria. including both the north end of the basin and its surrounding mountains, is a subarctic region with too short a summer for agriculture. the growing season everywhere being under 140 days per year. The winter is very long, cold and dry except for a little snow. and the summer has warm weather and light rains. Total precipitation is about 20 in. per year.

2. Northwest China.—The northwestern fringes of China proper share the arid climate of the Mongolian region, with steppe to desert conditions and local variations according to relief and exposure. This includes Kansu, northern Shensi, northern Shansi and Inner Mongolia. Precipitation is everywhere under 20 in., and often under 10. Though rain occurs chiefly in summer, the distribution normally is erratic as to timing during the year, as to amount in any one year and as to local distribution. Frost-free growing periods everywhere are under 200 days.

3. North China.—This region includes the southern section of the Manchurian basin, the Jehol and T'ai-hang mountains and most of the loess highlands area. It is a somewhat transitional zone in that the growing season and the annual precipitation lessen from the south to the northwest. Growing seasons range from about 225 days in the south to about 150 days in central Manchuria and the Jehol mountains, and the precipitation total ranges from about 30 in. in the south to about 15 in, in the northwest of the region. Any given summer season may bring both drought and flood: either to the whole region or to some portion of it, for this is a zone of extremely variable and erratic. rainfall, and the optimum seasonal distribution needed for maximum agricultural production does not often occur over the whole climatic region. Really good climatic years produce good harvests, but bad years produce disaster in some portion of north China.

4. Yangtze Valley.—Central China south of the Tsinling mountain line, east of Szechwan, into the Tung-t'ing and P'o-yang basins, and as far south as Hangchow bay, comprises a climatic region of mild winters and hot summers. It is a zone of 225–280 days' growing season, with intermittent periods of freezing weather and light falls of snow during the winter months. The summers are very humid and hot, with a peak rainy period in June and July. Total precipitation varies from 45 in. to around 80 in., depending upon location and exposure. Some of the hill margins have cooler conditions in summer.

5. South China.—The southeast coast and the southern hill areas have milder winters than the Yangtze valley, with rain instead of snow, and freezing conditions only during short periods in exposed localities in the higher mountain areas. The growing season for most lowland localities ranges from 300 to 350 days, and slightly less than this in upland exposed localities. The summers are long, hot and humid, except in coastal localities or in the uplands, where cooler temperatures prevail. May. June! July and August each normally have heavy rainfall, the month with the most rainfall! varying with the locality. Though there is adequate rain in every month, the summers receive the largest amounts, and totals range from 50 to over 80 in. The coastal zone is affected by typhoons which occasionally produce heavy rainstorms and destructive winds during summer and autumn periods.

6. Szechwan Basin and Northern **Kweichow.**—For an inland location this is an unusual climatic region in that it has an all-year growing season, with frosts only in upland exposed localities. The area is protected from cold northerly winds by the high western sector of the Tsinling mountains, and from the mid-latitude sweep of the westerly wind storm belt by the Tibetan plateau. During the autumn, winter and spring this is a region of stagnating air and quiet conditions, and the gradual cooling of the still air up to 6,000 or 7,000 ft. produces a thick blanket of cloud that covers the Szechwan basin and northern Kweichow, normally, from late October until about the end of March. During this period the thermometer hovers a few degrees above freezing for weeks at a time. the sun being seen only occasionally. The Szechwan proverb "The dogs bark when the sun shines" applies to this uncomfortable, depressing set of winter conditions. There is little real rain during the winter, though it often barely drizzles for days at a time. The low temperatures and lack of sun reduce evaporation and permit winter growing of hardy crops. Summers are hot, humid and rainy in the main Szechwan basin, though its margins and northern Kweichow are less uncomfortable. Annual rainfall varies from just over 30 in. in the north to about 60 in. in southern exposed localities. Within the main basin much of the midsummer rain results from local thunderstorms.

7. Southwest China.—The western and southern portion of Kweichow, and the Yiinnan plateau, in respect to human comfort, have the most enjoyable climate of all China. The higher elevations reduce maximum temperatures during the day, and the protected location prevents any really cold winter weather, except in the mountain ranges that rise above the plateau. Most of the region has a growing season that is almost yearlong. The winters are rather Sunny and dry, with brief showers of rain accompanying cool. cloudy spells from late November through April, the nights being cool and the days delightful. Summers are relatively cool, with few uncomfortably hot days, and there is a peak period of rainfall in July. Total annual precipitation normally amounts to about 40 in. in the north and 60 in. in the south. Yünnan is famous for its magnificent cumulus clouds and bright blue sky (the name may be translated as "south of the clouds" or "southern cloud land").

8. Tropical South Coast.—Hainan Island and the south coastal zone of China, to a point north of the Canton lowland, is a region of tropical climate, with an all-year growing season and with rather high temperatures at all times of the year. There is rain in every month, but in most localities the period from November through February is relatively dry, the maximum rainfall occurring in May through August. Precipitation totals for the year vary from one part of the region to another, but range between 45 and 85 in., so that there are sections that are humid tropical and others that are dry-margin tropical. In this region rice and other crops may be planted in any month of the year, though planting normally follows the rain cycles. It is the only region that traditionally has double-cropped rice and where tropical fruits and flowers flourish. (J. E. Sr.)

D. Vegetation

The natural vegetation of China ranges from boreal taiga to rain forest and from barren tundra and desert to the littoral vegetation of the coral islands in the tropical seas. In general, the entire territory of China is dominated by two great plant formations: the grassland-desert of the northwestern half of China and the woodland of the southeastern half.

Six major forest types are recognized:

1. The mixed northern hardwood forest is best developed in the northeastern provinces. A similar type appears also in the higher elevations of the northern provinces above the deciduous oak belt. The primary components are maple, linden and birch. intermixed with Korean pine (*Pinus koraiensis*), oak, walnut, elm. *Maackia, Phellodendron, Kalopanax* and other trees of minor importance.

2. The deciduous oak forest is the major type of the northern provinces. Relics of natural forest indicate that the primary components are *Quercus aliena, Q. liaotungensis, Q. dentata* and *Q. variabilis.* The common associates are ash, hornbeam, elm, *Pistacia, Prunus,* walnut and hackberry. Pine (*Pinus tabzilaeformis*), arborvitae and juniper grow on exposed ridges. The denuded slopes are covered with *Vitex, Zizyphus, Lespedeza,* grasses and thickets of *Cotinus, Deutzia, Spiraea,* wild roses and lilacs.

3. The mixed mesophytic forest of the Yangtze valley is richest in composition of all the deciduous forests. Preserved in this

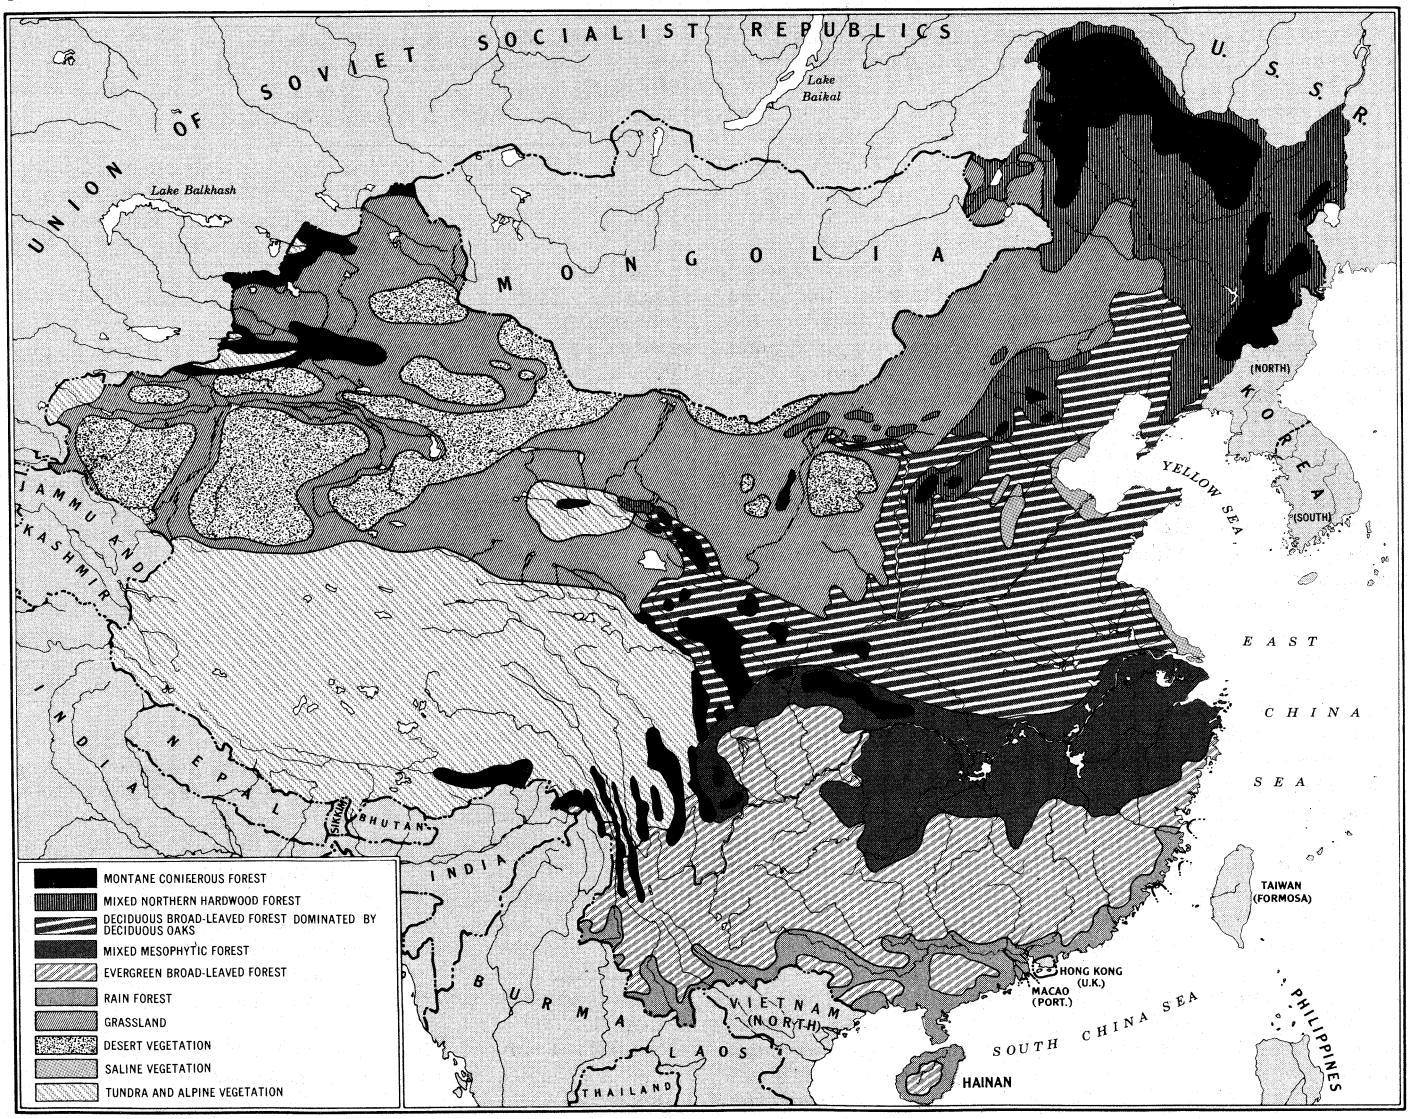

FIG. 1.— DISTRIBUTION OF MAIN TYPES OF NATURAL VEGETATION OF CHINA, MONGOLIA. KOREA AND JAPAN

temperate clime are a number of relics of Tertiary flora (notably *Ginkgo, Metasequoia*) of more than *60,000,000* years ago, and polytopic genera which are represented also in North America (*e.g*, *Liriodendron, Sassafras, Cladrastis, Gymnocladus*) The forest components include: *Aesculus, Aphananthe, Carya, Castanea, Cephalotaxus, Cercidiphyllum, Cryptomeria, Cunninghamia, Cupressus, Daphniphyllum, Diospyros, Ehretia, Emmenopterys, Eucommia, Fagus, Fraxinus, Halesia, Idesia, Magnolia, Nyssa, Paulownia, Pseudolarix, Pseudotsuga, Quercus, Torreya, Trema* and *Zelkova*

4. The evergreen oak forest extends over the hilly areas of the southern and southwestern provinces. Taiwan and Hainan Island. It is composed of more than 150 species of evergreen cupuliferous trees (*Quercus, Lithocarpus, Castanopsis, Castanea*) and numerous evergreen trees of the Lauraceae, Theaceae, Magnoliaceae and Hamamelidaceae. Bamboo and secondary growth of *Pinus massoniana* and *Liquidambar* cover large areas south of the Yangtze.

5. Rain forest occurs only along the southern fringe of China from the Yünnan-Assam border to the lowlands of Kwangtung, Hainan and Formosa.

6. The montane coniferous forest of the Greater Khingan range is essentially of larch *(Larix gmelini),* but spruce *(Picea obovata, P jezoensis*) and fir *(Abies holophylla, A nephrolepis*) form dense forest on the eastern rampart bordering Korea. The montane coniferous forest of the southwestern plateau is composed of many conifers, including spruce, fir, hemlock, larch and *Pseudotsuga.* Montane coniferous forests appear also on the high peaks of the northern provinces *(Picea asperata,* P. *neoveitchz, Abies nephrolepis*) and Sinkiang *(Picea schrenkiana*), and on Formosa *(Picea morrisonicola, Abies kawakami),* which lies on the Tropic of Cancer.

A vast expanse of grassland extends from the plain of the northeastern provinces westward to the Tien Shan, interspersed nith salt lakes *(nor),* gravel desert and sand dunes Thick clumps of grass *Stipa splendens* are the most conspicuous feature. The arid areas support only xerophytes and halophytes. Orchards, vineyards and luxuriant groves of poplar and elm, however. thrive in the oases. Marshes of cattail and *Phragmites* teem with nesting geese. ducks and s ans in summer. The vegetation of the Sidzang plateau (Tibet) is scanty, consisting only of scattered cushion plants with thick rootstocks. But the Tsangpo (upper Brahmaputra) valley is well wooded. *(See* also ASIA: *Physical Geography: Vegetation.)* (W.)

E. ANIMAL LIFE

Profusion of vegetation and variety of relief have fostered the development of a fauna of great diversity and have permitted the survival of animals elsewhere extinct. Notable among such survivals are the great paddlefish (*Psephurus gladius)* of the Yangtze, the small species of alligator in east central China and the giant salamander (related to the Japanese giant salamander and the American hellbender) in western China. The diversity of animal life is perhaps greatest in the ranges and valleys of the Tibetan border, to which region the giant panda is confined. The takin or goat antelope, numerous species of pheasants and a variety of laughing thrushes are to be found in all the Chinese mountains. China seems to have been one of the chief centres of dispersal of the carp family and also of old world catfishes.

The regional affinities of the Chinese fauna are complex. In the northeast there are relations with the animal life of the Siberian forests. The mongolian deserts bring animals from central Asia into suitable steppe areas in northern China. The life of the great mountain ranges is Palearctic, but with distinctively Chinese species or genera. To the southeast, the lowlands and mountains alike lead directly into the oriental region. This part of China presents a complete transition from the temperate zone Palearctic life to the nealth of tropical forms distinctive of southeastern Asia. Tropical types of reptiles and amphibians and of birds and mammals aredominate in the southernmost Chinese provinces. *(See* also ASIA: *Physical Geography: Animal Life.)* (K. P. S.)

III. GEOGRAPHICAL REGIONS

A great many different kinds of regionalisms may be recognized in China by the application of differing scales and types of criteria. This section describes only a few of them.

The simplest separation of China into parts is the distinction of north China from south China along the Tsinling mountain system. Such a division separates the cold and drier north—the culture hearth of China, the wheat-millet eating area, the northern plant and animal areas and the seasonally dull brown landscape—from the mild and humid south—the region of colonial expansion, the rice-eating area. the southern plant and animal zone and the perennially green landscape. This division overgeneralizes some elements, for northeast Manchuria is not really dry or brown at any season, and Manchuria also is a zone of recent expansion of settlement. The rice-wheat dietary division actually is a zone extending across the northern portion of the Yangtze drainage system, and the northern plant and animal zone extends south of the Tsinling along the Tibetan borderland.

A more detailed zonal division of China would suggest six regions. south, west, east, north, northwest and northeast. In these terms (1) south China becomes the region roughly south of a line from Hangchow bay to Tung-t'ing Hu and east of Kweichow and Yünnan; (2) the west comprises Szechwan, Kweichow and Yunnan; *(3)* the east covers the central and lower Yangtze valley region; *(4)* the north includes Shantung, the north China plain and that portion of the Yellow river drainage system roughly east of the great bend of the Yellow; *(5)* the northwest comprises Shensi, Kansu and the Inner Mongolian fringe; and (6) the northeast covers Manchuria.

These regional divisions involve climatic. crop, ethnic, linguistic, historical and many other cultural factors, and are often used by the Chinese themselves. They have about the same validity for China as regional divisions labeled New England, the south or the midwest have for the United States.

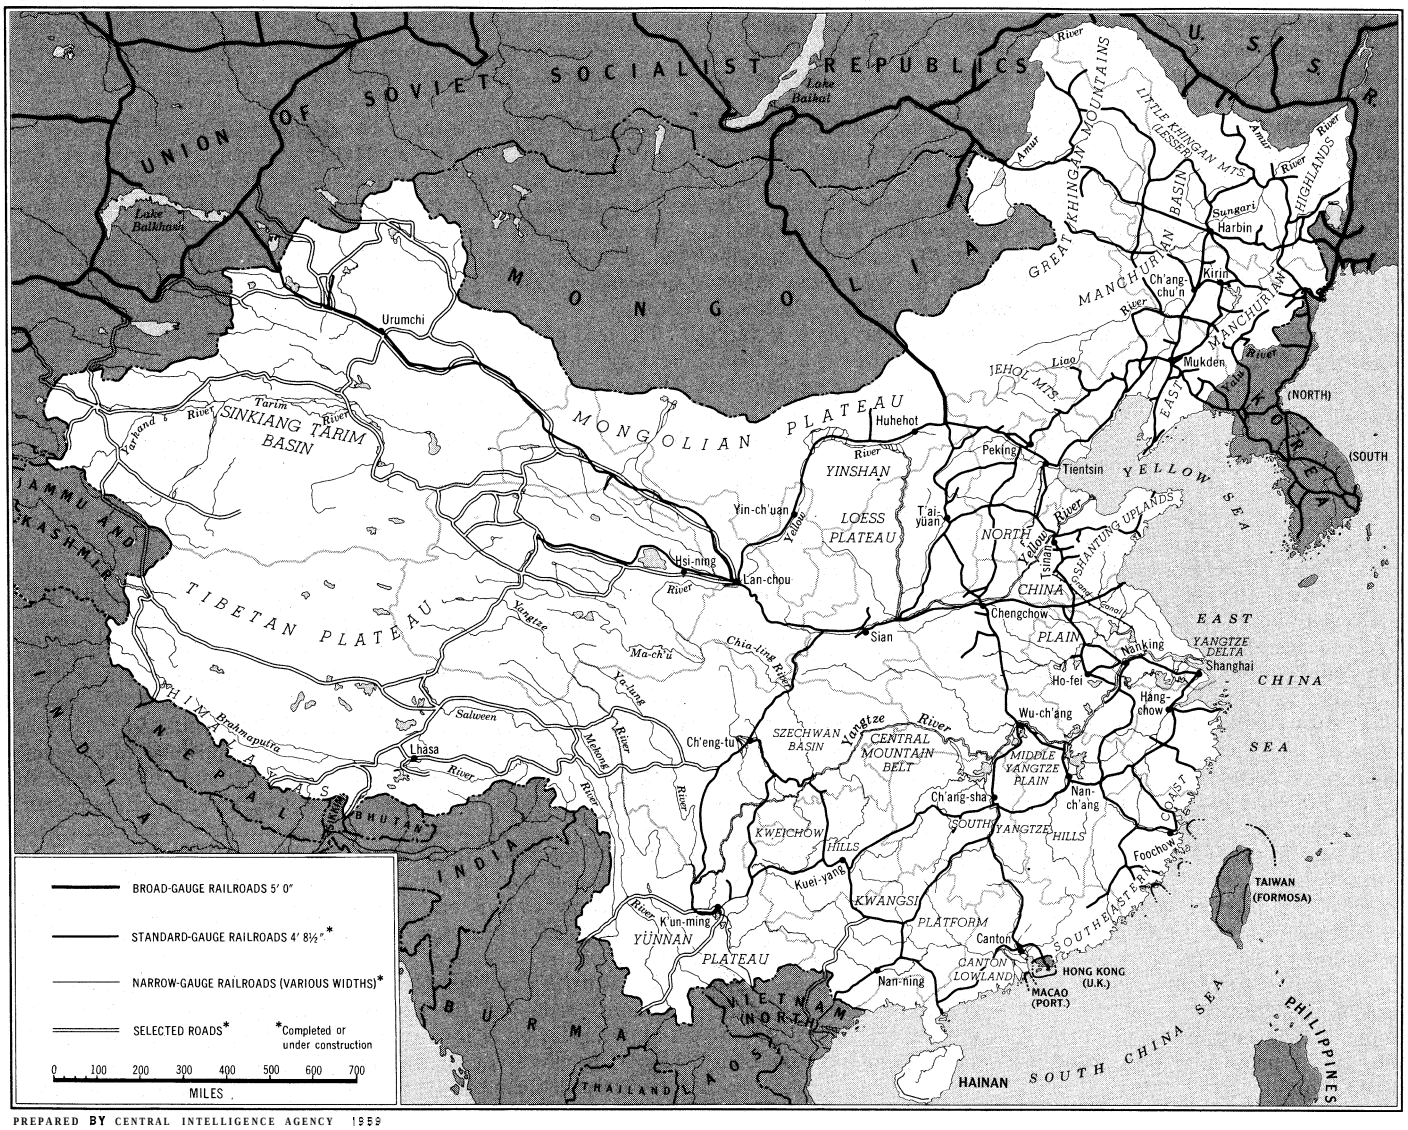
A wide variety of other criteria may be used to distinguish the parts of China, resulting in a varying number of regions of major significance. Physiographically China proper and Manchuria can be described as comprising 19 major regions, with a large number of subregions identifiable in a more detailed study *(see* below). Climatically there are eight major regions and about that many more subregions *(see* above, *Climate).* There is general agreement on nine agricultural regions *(see* below). The major vegetation regions are described in the section *Vegetation,* above; *see* also fig. 1. The *18* traditional political provinces of China proper (prior to the manipulation of boundaries for tactical political and military purposes that has marked China since *1900,* and that goes on in Communist China) go far beyond distinguishing political areas for administrative purposes *(see* above, *Introduction).*

A. PHYSIOGRAPHIC REGIONS

The major regions are developed on the structural framework (see *Geology and Structure* and *Physiography,* above). Subregions occur in localities in which structure, drainage or physical processes have given rise to special land forms. Starting in the north, the major regions and their chief characteristics are as follows:

1. East Manchurian Highlands.—These are rounded to rugged ranges of hills and mountains trending north-south along the east margin of the Manchurian basin. with the highest elevations near the Korean border, reaching *9,003* ft. in Ch'ang-pai Shan. but elsewhere much lower. Many deep entrant valleys of locally low relief, several internal structural basins and little severe erosion make this region relatively usable. The northern end approaches the east end of the Little Khingan, with the Sungari river passing between the two. The southern end of the region tapers off into the Liao-tung peninsula, a drier, more barren and hard-rock landscape suffering from soil erosion. The total area is about *120.000* sq.mi.

2. Little Khingan Mountains.—The Little Khingans are several low (under *3,000* ft.), little-known mountain ranges that close off the northern end of the Manchurian basin and that merge into the Great Khingan on the west.



PREPARED BY CENTRAL INTELLIGENCE AGENCY 1959

FIG. 2.— PHYSIOGRAPHICAREAS OF CHINA WITH BROAD AND STANDARD GAUGE RAILWAYS AND SELECTED ROADS. MAY 1959

3. Great Khingan Mountains. — These north-south trending ranges present steep, rugged and dissected escarpments to the east above the Manchurian basin, but appear as low ranges of hills when viewed from the Mongolian side. The southern zone is lower and less dissected, and there is a broad gap affording access between the Manchurian basin and Mongolia. The area, including the Little Khingan. is about 170,000 sq.mi.

4. **Jehol** Mountains. — This is a rugged, complex region of dissected hills and mountains located at the crossing of two structural lines. The northern portion, in the west, has surface lava flows and is raised only slightly above the Mongolian plateau; in the east it is more rolling. The region was long an imperial Manchu hunting area; its opening to settlement after 1911 brought short-term occupation, destruction of the forests and culturally induced soil erosion that greatly increased the bare rock exposure on the naturally steep slopes of the southern sector. Maximum elevations are just above 5,000 ft. in the central section. The area is about 40,000 sq.mi.

5. Manchurian Basin. — A broad open structural basin everywhere below 1.000 ft. elevation, it is in its central zone a gently rolling plain, with little entrenchment of the stream net. Toward either end the Sungari river in the north and the Liao in the south have lightly entrenched their courses, and river terraces and flood plain features are evident near the channels. The Sungari (1.215 mi. long) is navigable by river steamers for about 600 mi. during the summer, and some of its tributaries also are navigable by shallow-draft craft. The Liao Ho (835 mi. long) is generally shallow and navigable for a short distance only by shallow-draft boats.

The total area of the physiographic region is about 170,000 sq.mi., though only about 130,000 sq.mi. is normally considered to constitute the Manchurian plain.

6. Yin **Shan.**—A series of discontinuous ranges of bare rocky hills and mountains, the Yin Shan separates the Mongolian plateau from China proper. Several breaks permit passage to and from Inner Mongolia. The total area is about 27,000 sq.mi.

7. Loess Highlands. — An irregular region comprises the area from the Ala Shan and the Yin Shan to the Tsinling mountain system and eastward to the north China plain in which fine wind-blown loess forms a thin to deep veneer over the underlying surfaces, with water-laid deposits locally intermixed. The higher original surfaces project through the loess cover as local hill and mountain ranges. There are several alluvial basins and river valleys with normal valley features of stream-process origin within the region, chiefly located in Shansi province. The northern end of the region is of low general relief, with varied deposits of coarser wind-blown sands and, near the Yellow river, of flood plain alluvium that often is quite saline. This portion lies outside the Great Wall beyond the zone of permanent Chinese occupation. Where the loess is deep it often has suffered intricate dissection, frequently increased by agricultural soil erosion despite the terracing, so that many areas are quite rough and of locally high relief.

The whole region suffers frequent earthquakes, which, where

steep slopes and river bluffs occur, cause serious landslides in the soft-textured loess. The total area of the loess region is a little over 200.000 sq.mi., though the loess surfaces themselves amount only to about 120,000 sq.mi.

8. North China Plain. — This gently sloping plain, nearly 600 mi. long, has elevated river channels that mostly spill onto but do not drain the plain itself. Local drainage is not effective, and there are a number of low areas in which floodwaters pond. The plain is marked by minor land forms only, and the dike lines built across it often are of greater proportions. The western margins are close to 400 ft. in elevation. Most of the rivers flow across the plain on elevated beds that are considerably above the interstream regions. The surface of some part of the plain is built up every time a flood escapes the channel of any of the streams flowing onto the plain, and the seaward margin is extending as rapidly as a mile per decade. Variations in soils are numerous. ranging from sands and recent alluviums to older and heavier lakeland soils in which flbod ponds occur, and to local areas of saline soils.

None of the northern streams is navigable unless dredged, and Tientsin has an artificial port and water connection with the sea. The Yellow river and some central channels are navigable only by rafts and very shallow-draft craft. In the south there are more watercourses, and the Huai Ho is navigable most of the year by launches and native boats for over 400 mi. All ports along the shallow alluvial coast must be dredged. The area of the plain is about 130.000 sq.mi.

9. Shantung Uplands. — Rolling to rocky and steep low mountains of high local relief, with large areas of bare granites and limestones exposed in the higher areas, the Shantung uplands reach 5,069 ft. in T'ai Shan, China's most sacred mountain, located near the western margin of the region. Else here elevations seldom exceed 3,000 ft. The uplands are irregular in outline and much broken by fault zones, the largest of which cuts a broad lowland gap through the uplands from the northwest to the port of Tsingtao on the south coast. Many fault zones carry shelves of sediments and soils, and a thin veneer of loess covers locally exposed surfaces, derived from the north China plain. Soil erosion has increased the bare rock exposure, despite terracing. Some of the best ports in north China occur in the rocky inlets of the peninsular portion of the upland. The area is about 30.000 sq.mi.

10. Central Mountain Belt. — This region normallv is taken to include the Tsinling proper, the Ta-pa Shan to the south, the more southerly mountains between the Szechwan and Tung-t'ing basins, and the eastward extensions known by several names that reach into the southern edges of the north China plain. The Tsinling proper is a series of high parallel ridges with steep fault and erosional scarps above deep canyons. Maximum elevations in the west exceed 15.000 ft.; the eastern portions become lower in elevation. The Ta-pa Shan is lower and less spectacular in relief.

Between the Tsinling and the Ta-pa Shan the Han river flows in a narrow alluvial valley eastward into the northern end of the Tung-t'ing basin. South of the Ta-pa Shan are round-shouldered hills and mountains with deep narrow canyons, through which the Yangtze river flows in a spectacular series of gorges and canyons. Eastward from the Tsinling and Ta-pa Shan the general trend is to lower elevations and local relief, with one broad gap between northwestern Hupeh and southern Honan. The eastern sector of this mountain belt is a confused mass of low hills. where structural lines meet, that is rather deeply etched by streams, and whose final eastern ends appear as remnants buried in the fill of the north China plain-Yangtze delta. The total area involved is close to 125,000 sq.mi.

11. Middle Yangtze Plain and Yangtze Delta. — Sometimes separated into two units, this riverine lowland is a region of active deposition and seasonally changing water expanses under 100 ft. in elevation. Dike building, canalizing and lowland terracing have obstructed natural sedimentation, but the permanent water area of the region has been decreasing over the centuries. particularly in Tung-t'ing basin. Some long-protected areas of the lowland are below mean river level. During low-water periods the water area, exclusive of canals, may be no more than 3,500 sq.mi., whereas during flood stage the normal water area is close to 8,000 sq.mi., and severe floods that break numerous dikes may cover up to 35.000 sq.mi. The Yangtze itself is navigable by ocean-going ships as far as Hankow during the summer, and regular river steamers reach I-chang, at the foot of the Yangtze gorges, all year. Many tributaries are navigable for considerable distances by launches, and native craft penetrate deeply into the basin hinterlands. In the delta thousands of miles of canalized streams and canals provide water transport to every village and locality.

The port of Shanghai is on a tributary of the Yangtze that must be kept dredged to afford entry of larger ocean-going ships. Though its site is poor, its situation at the mouth of the greatest river in eastern Asia affords Shanghai the largest single trade hinterland. The total area of the whole region is about 105,000 sq.mi.

12. Szechwan Basin. — The basin is surrounded on all sides by mountains of rugged surface and high relief. Its floor is just under 800 ft. in elevation, and its outer margins lie at about 2,000 ft. The country rock is composed of clay and lime shales in generally horizontal structure, with a tendency to natural terracing that has been increased by terrace building. The intricate stream network is entrenched into the basin floor, so that the whole of the basin is very hilly, except for a narrow flood plain along the main Yangtze river above the city of Chungking, and the small alluvial basin in the northwest corner around the city of Ch'eng-tu. Locally structural folds have produced low ranges of sandstone hills, chiefly aligned north-south. Though a degrading and hilly basin the country rock is soft enough that it weathers rapidly into rich soils.

Within the basin the Yangtze and several of the tributaries are navigable for varying distances by launches and for longer distances by native craft. The area of the basin normally is taken at 75,000 sq.mi.; it is surrounded by perhaps 30,000 sq.mi. of hill country.

13. South Yangtze Hills. — The hill country that rims the southern portions of the Yangtze river system east of Kweichow is an irregular zone that surrounds the southern sections of the Tung-t'ing and P'o-yang basins and separates the two. It is an intricately dissected area, with deep entrant valleys penetrating the hill country. Only the crest lands show much bare rock exposure or have really high local relief, and the lower zones of gentler gradient are terraced to make much of the region usable in agriculture. Maximum elevations are around 4,000 ft., but most of the region is considerably lower. At the southern extremity two easy passes afford access to the Canton lowland: Che-ling pass at 1,400 ft. leading out of the Tung-t'ing basin, and Mei-ling pass at 1.000 ft. leading out of the P'o-yang basin. Total area is about 150.000 sq.mi.

14. Southeastern Coast. — The region between Hangchow bay and the Canton lowland has a rocky irregular coast with about 3,000 offshore islands and many deep inlets that provide the best harbours on the whole China coast. Several mountain streams empty into the sea along this coast. but they carry little sediment and there are only a few small alluvial lowlands along the coast. Inland the hills grade into mountains of high relief and much hard rock exposure, with maximum elevations that exceed 5.000 ft. The ridge trends are northeast-southwest. and the streams in the central zone have developed trellis-type drainage systems. Valleys are narrow with steep gradients, and there is little flat land anywhere except at the northern and southern ends of the regions, where elevations taper off, relief is subdued and the stream valleys widen out. This is one of the poorest agricultural regions of all China. The total area is close to 70,000 sq.mi.

15. Canton Lowland. — The small estuary fill at the mouths of the Tung, Pei and Hsi rivers covers only 3,000 sq.mi., but it is the largest depositional fill in all of south China. Rocky hills project above the alluvial fill throughout the delta region. former islands in the embayment. Other islands lie farther out, not yet attached to the mainland by filling. The delta is a watery

landscape whose lower river reaches are tidal channels. Canton is located on the Chu (Pearl) Chiang, a short lowland stream at one side of the alluvial lowland.

16. Kwangsi Platform. — West of the Canton lowland lies a limestone zone that has been developed by solution processes and is a zone of karst landscapes. The easterly section of the whole zone forms the Kwangsi platform, pitched at a few hundred feet above sea level and drained by the Hsi river system. The Hsi Chiang has relatively few tributaries, particularly in its headwater zone (a characteristic feature of karst landscapes). The present platform lies across one of the main structural lines of China. The eastern portion of the platform (about 20,000 sq.mi.) presents old karst land forms in which broad open surfaces are present, erratic limestone remnants are scattered, and stream channels and flood-plain features exist in sparse arrangement. The Hsi Chiang is navigable by steamers and launches for about 250 mi.. and shallow craft can go farther on the main river. Progressively, to the west and north, elevations increase, the karst topography shows younger stages, and the country becomes rougher. The western portion of the platform exhibits very rough country of high local relief, a minimum of flat land, and much bare rock in erratic and ragged conical hills and rock piles. There streams are few and seldom continuous, and solution basin patterns dominate the landscape, so that transport is difficult. It is from this general region that some of the motivation for Chinese landscape painting is drawn, and bizarre forms do exist somewhat as painted. Southward the platform grades off into a smooth, sandy coastal littoral of low relief and shallow offshore water. The total area of the platform is close to 60,000 sq.mi.

17. Kweichow Hills. — West and northwest of the Kwangsi platform elevations and relief increase, and the karst land forms are in the mature stage of development. This is one of the roughest parts of China, from close to the Yangtze river on the north to the Indochina border on the south. Long streams are not numerous, but locally stream action combines with solution processes, and dissection by master streams has cut deeply into the region. It frequently is labeled a plateau, since it is pitched close to 4,000 ft. elevation, rising to about 7,000 ft. in the west where it adjoins the Yunnan plateau, but the Kweichow region is no longer properly a plateau, since there are few broad upland surfaces. Much bare rock is exposed in steep slopes, and there is almost no large area of level land. The originally folded limestones do present some massive mountain sections still, particularly in the north and west, but most of the country is of karst land form pattern. Soil erosion has added to the amount of bare rock exposure, and this is the poorest physical region of all China. Its area totals about 100.000 sq.mi.

18. **Yünnan** Plateau. — The Kweichow hills grade westerly into the Yunnan plateau, with general increase in elevation to about 6,000 ft. A number of folded and fault-block mountain ranges stand above the plateau, the northern ranges reaching 17.000 ft. Within the plateau there are many structural basins containing shallow lakes, and the southeastern sector presents other basins that are in the early stages of karst development, in which the solution cycle has not yet produced the spectacularly rough landscapes found in Kweichow and western Kwangsi. Most of the basins and some of the plateau crest lands carry deep though leached soils, and are generally areas of agricultural utility. The southern margins of the plateau have been cut deeply by streams, and the southwest margins are carved into tremendously deep and narrow canyons. The area of the plateau is close to 125,000 sq.mi., excluding about 300,000 sq.mi. of the mountain-and-canyon Tibetan borderland.

19. Hainan Island. — The roughly circular island off the south coast has a coastal plain that is widest on the northern and eastern sides, but narrow or discontinuous on the south and west. A central mountain core with radially outward drainage has numerous peaks above 6.000 ft., and is a dissected region of high relief. Its area normally is given at 13,124 sq.mi.

B. Agricultural Regions

Though dozens of field crops, a very wide variety of vegetables and a large number of fruits are grown in the different parts of China, a relatively few crops are the dominant elements in agriculture, and there is a distinctly regional pattern to their distribution. The nine major agricultural regions, their primary crop associations and their distinctive characteristics follow.

1. Manchurian Spring Wheat-Soybean-Sorghum-Millet Region. — The Manchurian basin is a zone of recent settlement, apart from the southern littoral, and farms there were larger than farms in old China. Manchuria is a zone in which agricultural production exceeds local consumption demands. Japan long had a strong economic interest there, initiating a degree of mechanization and developing foreign trade in agricultural products. Communist control furthered the industrialization of agriculture, with the establishment of tractor stations and mechanized farms. Only one crop can be grown per year, and the crop pattern is closely related to the length of the growing season. Spring wheat, maize (corn) and tobacco are the first crops planted in April, quickly followed by sorghum (kaoliang), soybeans, millet, barley and cotton. Some of these drop out northward, being replaced by white potatoes in the far north. Some fruit is produced in the south. and Korean settlers raise rice in the upland valleys of the eastern margins of the basin. Yields per acre are less than those in old China, since Manchurian agriculture is extensive rather than intensive. This is the only part of China in which the land can absorb a larger population (at the risk of losing its production surpluses), but even there the best land is in use and the reserve is chiefly marginal. Around 70% of the lowland main basin is in use.

2. Northwestern Spring Wheat-Millet Fringe Zone. — The aridity and the long winters of the northwest fringe of China enforces a pattern of one crop per year, spring wheat and drought-resistant millets being the chief crops, with some spring barley, oats and buckwheat. In this region there always is a gamble with dryness, frequent crop failures occur, and there is a considerable fluctuation of the frontier of agricultural settlement. Dry periods force it back into China, and moist periods bring expansion toward Mongolia. Many farmers raise some livestock. Locally where water is available for irrigation the variety of crops increases. and such fruits as apricots, peaches, cherries and plums, and grapes and melons, plus many vegetables, become important. Less than 20% of the land normally is in crop.

3. Loessland Winter Wheat-Millet-Sorghum Region. — Roughly south of the Great Wall the spring planting of wheat shifts to autumn planting for winter wheat. Millets, sorghums and spring barley are the other basic crops. Where water is available such fruits as persimmon, jujube, apricot and peach, and melons, cotton, tobacco, maize, white potatoes, sesame, peas and even a little rice may be grown. Just over 20% of the land normally is in crop.

4. North China Winter Wheat-Soybean-Sorghum-Cotton Region. — The north China plain. its western mountain margins and the Shantung uplands form a region in which farms were fairly small and often fragmented; Communist reorganization of agriculture has made marked changes in land control. Farming uses about a dozen crops per year to take full advantage of local variation in soils and weather conditions and to minimize the problem of crop failure. In the northern sector wheat is still spring planted, but in the central and southern areas winter wheat or barley share the land with spring plantings of other crops. In all parts of the region millets, sorghum, soybeans, cotton, maize, sweet potatoes, tobacco, broad beans, sesame, peanuts, peas and a variety of vegetables are grown. Excellent fruit, including apples, peaches. pears, plums and persimmons, is grown in the Shantung uplands. In the past only vegetable gardens normally were irrigated. but the Communist government expended much effort in broadening the facilities for irrigation. A significant amount of crop loss to flood also has been normal, and Communist efforts at flood control have been region wide. Well over 60% of the lowland is in crop, but in the uplands the percentage drops.

5. Szechwan Basin Rice-Wheat-Sweet Potato Region. — This is a region of highly integrated cropping systems that often produces four and five harvests in two years. Its yearlong grow-

ing season permits growing both northern and southern crops, and the basin has almost the widest range of crops of any part of China. Summer rice dominates the lowlands and the lower terraced lands to which water can be delivered, and sweet potatoes. maize. sorghum, rape, millet, cotton, tobacco, soybeans, peas and a wide variety of vegetables are summer crops on the nonirrigated higher terrace fields. Winter wheat, barley and broad beans. plus hardy vegetables, are the chief winter crops, using all kinds of fields. Sugar cane often is integrated into a cropping cycle spanning both seasons. Mulberry and tung oil trees are scattered over the dry upland fields. and a wide variety of fruit is gro n in small volume. In many favourable areas citrus fruits become dominant orchard plantings. In the rougher lands of the basin margins white potatoes enter the cropping cycle and, with maize and sweet potatoes, form the basic crops. In the main part of the basin the cultivated area exceeds 60% of the land, but toward the drier north and the rougher east the percentage drops. A high degree of terrace building has made possible an unusual degree of cultivation of a hilly region.

6. Yangtze Valley Rice-Winter Wheat-Winter Barley Region.—Over most of the Yangtze valley rice is the dominant summer crop, with winter wheat and winter barley being important alternates, particularly north of the Yangtze river. The southern boundary of the region is not far south of the Yangtze river, though in the east it includes the Hangchow bay hinterland. Summer cultivation involves important acreages of peanuts, maize, soybeans and sesame on nonirrigated lands. and cotton appears in the coastal districts. The aquatic crops such as lotus and water chestnut. in addition to duck raising and pond-fish culture, are important in the delta zone. Mulberry plantings for silk production are common in the eastern sector. Near the cities market gardening has become commercialized. Well over 60% of the Yangtze delta zone is in crops, but elsewhere the percentage is somewhat lower. This is a food-deficient region, owing to its heavy urban population and its annual flood problem.

7. Southeastern Rice-Tea Region.—The southeastern coastal area and a broad zone west to the Kweichow hills comprises a region in which a somewhat different agriculture is practised. The winter wheats and winter barleys and the millets, soybeans and cotton largely drop out, as do many of the northern fruits such as plums, cherries, apples, peaches and pears. Tea, the bamboos and the more subtropical fruits enter the cropping pattern significantly. Rice is by far the dominant basic food crop, and the southern Tung-t'ing and P'o-yang basins produce rice surpluses. There the Communist regime is pushing the double cropping of short season rices. Sweet potatoes. beans and peas are widely grown in the hill area. This is the traditional area of tea production, with regional specialization in variety as a cash crop on hill fields. The tung tree is important as a hill crop away from the coast. Citrus fruits are a regional specialty in the lower areas, and the southeastern coastal zones produce the best tangerines and pomelos in the whole of the orient. Locally forest cropping of both timber trees and bamboos on the hill lands is significant to the agricultural economy. The degree of land use varies widely, from about 10% in the rougher areas to as much as 60% in some lowland localities.

8. Southwestern Rice-Maize Region.—In the southwestern portion of China, including most of Kweichow and all of Yiinnan. rice is the dominant crop wherever flat land or terraces can be provided with water. Maize is an important crop grown on dry and unterraced lands. In the hill country maize and white potatoes, supplemented by yams, become the chief crops. A little winter wheat, winter barley and winter broad beans are grown in some localities. Tea and fruits are locally important, as are tobacco, rape and a variety of vegetables. In the high zones above the plateau walnuts and chestnuts are important food crops, and in the lower hill country sectors of Kweichow the tung tree is widely grown. This was the last region in which the opium poppy was a standard crop, and agriculture has not recovered its balance after the general cessation of poppy growing. In the past the Chinese came to oan the better lands, including most of the rice lands, whereas the non-Chinese tribal populations were restricted to the rougher hill country. In some areas shifting cultivation still is locally important as a relict system. Well under 20% of the total land is under cultivation. The concentration of population on the areas that can be cultivated means that the agricultural density of population is about the highest in China.

9. Tropical South Coast Double Crop Rice Region.—The southern littoral and much of the territory south of the Nan Ling Shan and east of the Kweichow hills is almost tropical. There rice lands long have borne two crops per year. Sugar cane is the only crop normally competing with rice for land, except in the eastern urban fringes where market gardening is important. In the hill areas sweet potatoes, maize, tobacco, ginger root, cassia, mulberry and a wide range of tropical fruits are auxiliary crops. In the delta region pond fish and aquatic crops also are important. Hainan Island grows rice on the coastal lowlands, and is the only portion of China able to grow coconuts (an old crop) and rubber (a new crop). Much of the island interior still is used in shifting cultivation by non-Chinese tribal peoples. In broad terms the percentage of land in crop is well under 20. but this varies greatly from the Canton delta to the western littoral and the interior of Hainan. (J. E. Sr.)

IV. THE PEOPLE

A. Ethnic and Language Groups

China is a multinational country made up of a large number of ethnic groups. This point was emphasized after the advent of the Communist regime in 1949. The official nationality policy of the Nationalist regime was assimilationist; for example, Chiang Kai-shek in his book *China's Destiny* (1947) presents the idea that China is inhabited by a single nation. According to this Nationalist thesis, China includes only a single "Chung-hua nation" or "Chinese nation" (Chung-hua min-tsu), subdivided into various "stocks" of common blood, such as Mongols and Tibetans. The Communists, on the other hand, have sought to apply a nationality policy based on Soviet practice. This policy is based on Stalin's definition of a nation or nationality as "a historically evolved, stable community of language, territory, economic life, and psychological make-up manifested in a community of culture." On the basis of this definition, Chinese Communist theoreticians have concluded that China is a state inhabited by diverse nationalities. The Communist government has put this view into practice by identifying the country's diverse nationalities, delimiting national autonomous areas of several types on the basis of the geographical distribution of the nationalities, and encouraging the development of national languages and cultures within the limitations of overall policies.

Foremost among the nationalities in China is the Chinese nation or Chinese people, also called the Han nation or Han people. The English use of the expression "Chinese people" is confusing because it may refer to three different Chinese terms used in Communist China. The first, Chung-hua min-tsu, is commonly used as a collective name for the various nationalities of China. (*Chung-hua* is a some hat flowery term for China or Chinese, and *min-tsu* means "people," "nation"). The second, Han tsu, refers to an ethnic or cultural group that is considered to be a distinct nationality because its members speak Chinese, have a distinct Chinese culture and otherwise contrast with other distinct national groups like the Mongols and Tibetans. (In the following discussion. the term "Chinese people" will be used in the sense of this ethnic group.) Finally, there is a third term, Chung-hua jen-min or Chung-kuo jen-min, which refers to the people. or population, of China as a political unit.

According to the 1953 census, the Chinese (Han) nationality made up 93.9%, or 547,283,057, of the country's total population, representing thus the overwhelming majority among the diverse nationalities. However, being concentrated in traditional China proper and in Manchuria, the Chinese inhabit only two-thirds of China's total area, while non-Chinese minorities, numbering only 35.320.360 in 1953, are settled in the remaining third of the country's total territory.

The Chinese and the non-Chinese minorities of China are best classified into linguistic families, branches and groups generally

recognized for classifying the languages of the world. China's ethnic or linguistic minorities, as well as the Chinese themselves, belong mainly to two of the world's great language families—the Tibeto-Chinese and the Altaic. The Tibeto-Chinese family, formerly called the Indo-Chinese family, includes Chinese and Tibetan and is by far the larger of the two linguistic families represented in China. It is divided in turn into three branches—the Chinese-Thai (T'ai), Tibeto-Burman and Miao-Yao.

1. Chinese-Thai Languages. — Chinese. — Chinese is the principal language of the Chinese-Thai branch. Although Chinese has a universal written form, in which characters (ideographs) represent words or ideas, its spoken forms display marked regional differences. The diversity of dialects, however, has been much exaggerated. There are probably not more than eight mutually unintelligible dialects, most of which are spoken in the coastal belt of southern China stretching from Shanghai to Canton.

By far the most important Chinese dialect is the Mandarin (*kuan-huah,* or official language), which is spoken by more than 400,000,000 persons throughout the Chinese-language area, except along the southern coast. There are three varieties of Mandarin: (1) the northern variety, of which the Peking dialect is typical and which is spoken in north China, northwest China and Manchuria—in fact, anywhere north of the line formed by the Tsinling Shan and the Huai Ho; (2) the western variety, also known as Ch'eng-tu or Upper Yangtze variety, which is spoken in Szechwan and adjoining parts of southwest China; and (3) the southern variety, also known as Nanking or Lower Yangtze variety, which is spoken in Anhwei and northern Kiangsu.

Related to Mandarin are the Hunan dialect, spoken by 25,000,000 persons in central and southern Hunan, and the Kiangsi dialect, used by 15,000,000. The Hweichow dialect, spoken by 7,000,000 persons in the Tunki area of southern Anhwei, forms an enclave within the southern Mandarin area.

Less intelligible to speakers of Mandarin are the coastal dialects extending south from Shanghai to Canton. (1) The most important of these is the Shanghai, or Wu, dialect, spoken by about 45,000,000 persons in southern Kiangsu and in Chekiang. (2) This is followed southward by the Foochow, or Min, dialect of northern Fukien, which is spoken by 10,000,000 persons in the drainage basin of the Min Chiang; and (3) by the Amoy-Swatow dialect of southern Fukien and easternmost Kwangtung, with 15.000 000 speakers. (4) The Hakka dialect of southernmost Kiangsi and northeast Kwangtung is spoken by almost 20,000,000 persons. (5) Probably the best known of these southern dialects is Cantonese, which is spoken by at least 35,000,000 persons in central and western Kwangtung and in southern Kwangsi, a dialect area where a large proportion of overseas Chinese originated.

In addition to the Chinese (Han) proper, the Communist regime distinguishes two national minorities that speak Chinese. They are the Hui (Chinese Muslims) and the Manchus. The Hui. also called Dungans in Russian sources, are descendants of Chinese who adopted Islam when it penetrated into China in the 7th century. Before the Communists, the Hui group was usually included with all Muslims living in China, most of whom were non-Chinese of the Turkic language branch. According to the 1953 census, there were 3,559,350 Hui in China, out of a total of 10,000,000 Muslims. (Pre-Communist estimates of the total number of Muslims in China ranged as high as 50,000,000.) Most of the Hui people live in northwest China, where the Ningsia Chinese Muslim autonomous region was ordered established in 1957 and formally inaugurated in 1958. Other Hui communities are organized as autonomous chou (districts) in Kansu and Sinkiang, and as autonomous hsien (counties) in Tsinghai, Hopeh, Kweichow and Yiinnan.

The basis for identification of the Manchu nationality is unclear. According to the 1953 census there were 2,418.931 Manchus, who apparently declared themselves as descendants of the Manchu warriors who invaded China in the 17th century and founded the Manchu (Ch'ing) dynasty (1644–1912). Ancient Manchu is virtually a dead language, and the Manchus have been assimilated completely into Chinese culture. They are found mainly in north China and Manchuria, but form no separate autonomous areas above the hsiang (township) or commune level.

Chuang-Thai. — In addition to Chinese, the Chinese-Thai language branch includes three language groups represented in China. They are the Chuang-Thai group, which includes the Chuang, Thai, P'u-yi and Nung minorities; the T'ung-Shui group, and the Li people.

The Chuang, with 6,611,455 persons in 1953, are China's largest minority group. More than 80% of them live in Kwangsi, which was converted in 1957 into the Kwangsi Chuang autonomous region. The Chuang also are represented in national autonomous areas in neighbouring Yiinnan and Kwangtung. The Thai people of China are concentrated in Yiinnan province. Numbering altogether 580,000, the Thais of Yiinnan are constituted as two autonomous chou (districts): the Hsi-shuang-pan-na chou, whose population is related most closely to the Thais of northern Thailand; and the Tehung chou, whose Thais are related to the Shan people of Burma. The P'u-yi people, formerly known as Chung-chia, number 1,247.883 and are concentrated in southern Kweichow, where the P'u-yi share an autonomous chou with the Miao people. The Nung minority, the smallest of the Chuang-Thai language group, has 170.000 persons living on the border of North Vietnam in southeastern Yiinnan.

T'ung-Shui.—The T'ung-Shui group is represented in the Kweichow-Kwangsi-Hunan region. The T'ung people, numbering 690,000, are settled in small communities in Kwangsi and Kweichow and share with the Miao people an autonomous chou set up in southeast Kweichow in 1956. The smaller Shui minority. with 150.000 persons, lives in the karst district of southern Kweichow, where an autonomous hsien (county) was set up for them in 1957 at Santu.

Li.—The Li people of the island of Hainan form a separate group of the Chinese-Thai language branch. The Li number 330.000 persons and share with about 30,000 Miao people a joint autonomous chou in southern Hainan.

2. Tibeto-Burman Languages. — The Tibeto-Burman branch of the Tibeto-Chinese language family falls into three groups: the Tibetan. the Yi (formerly called Lolo) and the Kachin (or Chingpo).

Tibetan. — According to the 1953 census, there were 2,775,622 Tibetans in China. They were distributed over the entire Tibetan highland area, including 1,273,969 in Tibet proper, 800,000 in Szechwan (including former Sikang), 450,000 in Tsinghai and 200,000 in Kansu. Tibet proper, which includes the Chamdo area, was placed in 1955 under a governmental committee which led to the establishment of a Tibetan autonomous region. Outside Tibet proper, Tibetan minorities are constituted in autonomous *chou* and autonomous hsien. There are five Tibetan autonomous chou in Tsinghai, two in Szechwan, and one each in Yiinnan and Kansu.

Among small splinter groups closely related to Tibetans are the Chiang people, 70.000 strong, who were established as an autonomous hsien in 1958 in the Mao-hsien and Wen-ch'uan area of Szechwan; and the Nu (12,000) and Tulung (2,400), who had a joint autonomous hsien in northern Yiinnan after 1956.

Yi.—The Yi language group is limited almost entirely to Yünnan province and adjoining areas. The Yi proper (formerly called Lolo) numbered 3,254,269 according to the 1953 census. Their principal concentrations are in the Liang-shan Yi autonomous *chou* of Szechwan province, with about 800,000 Yi, and in the Tsuyung Yi autonomous chou of Yiinnan province, with 385,000 Yi.

Among lesser minorities within the Yi language group are the Lisu, Nasi (former Moso), Hani and Lahu, all of which are set up as autonomous areas within Yiinnan province. Also part of the Yi group is the Pai (former Minchia) minority, with 480.000 persons, constituted in 1956 as an autonomous chou in the Ta-li area of Yiinnan.

Kachin.—The Kachin people, who live mainly in Burma. have a community of 110,000 persons just across the Burmese border in western Yiinnan province. There they share the Te-hung Thai autonomous chou with the Thai minority.

3. Miao-Yao Languages. — The Miao-Yao branch of the Tibeto-Chinese linguistic family is geographically one of the

most uidespread in southern China. The 2,511,339 Miao people are settled in Kweichow, Hunan, Kwangtung, Kwangsi, Yunnan and Szechwan provinces. Two-thirds of the Miao minority is concentrated in Kweichow, where it shares two autonomous *chou* with the Tung and P'u-yi peoples. The Yao people, numbering 640.000, are concentrated in the Kwangsi-Kwangtung-Hunan border area.

4. Tungusic Languages. — While the minorities of the Tibeto-Chinese language family are thus concentrated in southern and southwestern China, the second major family — the Altaic — is represented entirely by minorities in northwestern and northern China. The Altaic family falls into three branches: Turkic, Mongolian and Tungusic (or Manchurian).

The easternmost and least significant numerically is the Tungusic branch, which extends into northern Manchuria from Siberia where it is widely represented. The Tungusic branch falls into two groups, Manchu and Tungus. The Manchu group includes the virtually dead ancient Manchu language, with the related languages of the Nanay (also known as Gold in Russian and as Hoche in Chinese) and the Sibo. The Nanay of northeasternmost Manchuria. numbering fewer than 5.000, live in the marshy watershed near the Amur-Ussuri confluence. The Sibo, of whom there are 20,000, are descendants of 17th-century Manchu warriors who were garrisoned in the I-li valley of western Sinkiang along the Russian border. The Tungus group includes the small primitive Orochon (Olunchun) and Evenki (Solon) tribes of northern Inner Mongolia and Heilungkiang province.

5. Mongolian Languages. — The Mongolian branch of Altaic has 1,462.956 speakers in China. About 1,100,000 Mongols live in Inner Mongolia, 150,000 in Manchuria and 200,000 in northwest China (Kansu. Tsinghai, Sinkiang). The Mongols are constituted in two autonomous *chou* in Sinkiang, a joint chou with Tibetans and Kazakhs in Tsinghai, and several autonomous hsien, as well as in the Inner Mongolian autonomous region.

Also regarded as members of the Mongolian language branch are three minorities of the Kansu-Tsinghai border area. They are the Muslim Tunghsiang (140,000 members) and Paoan (4,000) and the Buddhist Tu (60,000), all of whom speak Mongor, a variety of Mongol. Also counted with the Mongolian branch is the Dagur (Daur) minority of Inner Mongolia and Manchuria. (See DAGUR.) This group of 50,000 persons is of Tungus origin but has been heavily mongolized.

6. Turkic Languages. — The Turkic language branch is by far the most numerous of the three Altaic branches, with a total of 4,500.000 speakers. The largest Turkic minority is the 3,640,125-strong Uighur group of the Tarim basin of Sinkiang. which furnished the basis for the establishment of Sinkiang in 1955 as the Sinkiang Uighur autonomous region. Other Turkic minorities in Sinkiang are splinter groups of nationalities of Soviet central Asia. Sinkiang includes 470,000 Kazakhs, who are mainly nomadic herders in Dzungaria (northern Sinkiang), where they are constituted as the I-li Kazakh autonomous *chou;* 80.000 Kirghiz, in westernmost Sinkiang, where they form the Kizil Su Kirghiz autonomous *chou* adjoining the Kirghiz Soviet Socialist Republic of the Soviet Union; and 13,000 Usbeks, settled chiefly in the I-li valley. In Kansu are 3,000 Yuku (Yugur or Sary-Yugur), nho unlike the other Muslim Turkic minorities are Buddhists The easternmost Turkic minority is the 30.000 Salars of northeast Tsinghai, who are constituted as an autonomous hsien at Shunhna (Hsun-hua).

7. Others. — A few linguistic minorities in China belong to neither of the two main language families. The Tajiks of westernmost Sinkiang, numbering 15,000, are related to the population of the Tadzhik Soviet Socialist Republic and belong to the Iranian branch of the Indo-European family. The 280,000 primitive Kana (Wa) people of the Chinese-Burmese border area belong to the Mon-Khmer branch of the Austroasiatic family. Finally, the Koreans of Manchuria, who number 1,120.405 and form the Yenpien Korean autonomous *chou* in Kirin province, cannot be assigned nith certainty to any of the standard language classifications.

(For further information on the ethnic groups and languages of China, see the various articles on languages—*e.g.,* CHINESE LANGUAGE; MONGOLIAN LANGUAGE; TURKIC LANGUAGES; etc.—and on peoples—*e.g.,* MIAO; KACHIN; YAO; etc.)

8. Language Reforms. — In an effort to spread literacy, the Chinese Communists engaged in a major effort to reform the Chinese written language and to devise new written languages for non-Chinese minorities. The Chinese language reform proceeded along three lines: (1) simplification of the present Chinese characters; (2) teaching of a common standard spoken language throughout the country; (3) gradual introduction of an alphabetic script.

Simplification *of* Characters. — This has been a continuing process in the evolution of the Chinese written language. In the past. however. simpler forms crept into the writing of the language one by one without formal recognition or official acceptance. Conservative officials and scholars, who looked with reverence upon the traditional ideographs, opposed any systematic attempts at character reform according to officially formulated sets of principles. With the coming to power of the Chinese Communists, the situation changed radically. Intent on transforming China into one of the world's leading powers, the Communist regime gave unprecedented priority to mass education and to language reform as an indispensable tool of such mass education.

Many of the Chinese characters are clumsy and unwieldy. Of the 2.000 commonest characters only 28% have fewer than 8 strokes, the rest containing from 9 to 27 strokes. Learning to read and write this elaborate ideographic script is very difficult. Although the Communists looked to the introduction of an alphabet as the ultimate solution of the written-language problem, they approached such a drastic overhauling cautiously and favoured a period of transition in which the existing written language would be made as simple as possible. Accordingly, a language reform committee devised lists of simplified characters, the first 230 of which went into effect in Chinese Communist publications as of Feb. 1, 1956. The complicated forms of these characters were excluded from use by government decree, except in reproductions of ancient classics.

Spoken Language. — Achievement of uniformity in the spoken tongue throughout Chinese-speaking areas is an essential prerequisite for the establishment of a phonetic alphabet. The Chinese Communists therefore stressed national linguistic unity as a step toward their ultimate goal of complete literacy of the population. The Peking (Peiping) variety of Mandarin, being the most widespread Chinese dialect, long had suggested itself as a basis for a national language. In Chinese usage the term Mandarin (*kuanhuah*), with its connotations of imperial officialdom, gradually mas dropped after the 1911 revolution that set up the Chinese Republic. Instead. the Nationalists used the term *kuo-yü,* meaning "national language," to describe the standard Peking dialect. After 1949, under the Communists, the term *kuo-yü* in turn was replaced by *p'-u-t'ung hua,* meaning "generally understood language." By the early 1960s it was estimated that more than 70% of the Chinese people already understood and used *p'u-t'ung* hua, and increasing efforts nere being made to teach and publicize the use of this standard speech in other dialect areas.

While the trend toward a national spoken language continued, a similar revolution took place in the written language. Before the 1911 revolution, Chinese literature was written in the old concise classical literary language (*wênyen*), which may once have corresponded to common speech but had gradually deviated from the spoken language as speech had evolved over the years. In a literary revolution which got under way in the 1920s the popular vernacular (*paihua*) partly replaced the literary style in the new literature. However, the classical style continued to be used in government documents. business correspondence and newspaper articles even under the Nationalists. Under the Communist regime, after 1949, the new colloquial style based on the living language completely replaced the old classical language in all writing. (See also CHINESE LITERATURE.)

Alphabetic Script. — The ultimate goal of the Communist regime appears to be the use of an alphabetic script, nhich alone is held to be suitable for the achievement of universal literacy and the establishment of a modern industrial state. Alphabetization is

not a new idea in China. Over the years transcription systems were developed as an aid to learning the difficult ideographs and to render such characters in western alphabets. Such systems never obtained governmental support, however, and deep-rooted conventional thinking prevented their being put into general use. The Communist government was committed to the reform of the written language and began to study proposed alphabetic systems soon after coming to power. After long consideration of alternative proposals, the first draft of a new alphabet plan was published in Feb. 1956. The alphabet of 30 letters included 25 letters of the Latin alphabet and 5 special characters. As a result of nationwide appraisal of the first draft, the five non-Latin characters were eliminated and a number of other revisions were made. The final alphabet, consisting of all 26 letters of the Latin alphabet, was approved by the national people's congress on Feb. 11, 1958. This alphabet, for the time being, was not intended to replace the Chinese characters. Its main uses were in the phonetic transcription of the characters. By using this alphabetic transcription, the Communists hoped to speed the spread of a standard spoken language throughout the country. The alphabet also was expected to speed the end of illiteracy among the Chinese masses. It is used in teaching Chinese to the national minorities and in devising alphabets for the language of the non-Chinese minorities. The alphabet had important uses in the rendering of international scientific and technical terms in Chinese and in many other applications related to the building of a modern industrial society. In short, for the period immediately following its introduction, the alphabet was to be used as an auxiliary tool side by side with the traditional characters, whose progressive simplification continued to be stressed.

Of the 50-odd minority languages, only 20 had written forms before the coming of the Communists. Only relatively few written languages (for example, Mongolian, Tibetan, Uighur, Kazakh, Thai and Korean) were in everyday use. Other written languages were used chiefly for religious purposes and by a limited number of persons. The Latin alphabet, partly adapted by missionaries, was used for Kachin, Lahu and Kawa in Yiinnan province; the Arabic alphabet was used for Uighur and Kazakh in Sinkiang; Tibetan, Mongolian, Korean and Thai had their distinctive alphabets. Communist efforts were directed to reforming existing written languages to make them more serviceable or to devise entirely new written forms. In general, Latin alphabets were used for this purpose. Such alphabets mere devised, for example, for the large Chuang minority of Kwangsi and for the Yi people of Yiinnan and Szechwan.

B. Religion

For untold years writers have spoken of the Chinese as having three major religions: Confucianism, Taoism and Buddhism. This is a misconception. Westerners usually adhere not only to one faith but to one denomination or even to one branch of a denomination. Members of different churches of the same sect have a sense of rivalry. Such phenomena are unknown to the Chinese. The average Chinese tends to have something to do with any or all religions but adheres exclusively to none.

The most universal system of belief in China is ancestor worship (*q.v.*). Under that traditional belief, it is part of the filial duty of sons to provide for their parents before and after death, for the dead are believed to have the same needs as the living. Like the father-son relationship within the family. the relationship between the departed ancestors and their living descendants is also reciprocal. The conduct of the living affects the welfare of the dead. and the actions of the latter in the spirit world continue to help the living.

Ancestor worship, however, is part of a wider belief system of the Chinese. The departed ancestors are spiritual beings closest to the living descendants, but each descendant also is affected by a tremendous hierarchy of nonancestral gods. The hierarchy ranges from the Supreme Ruler of Heaven down to local gods, whose temples are found in nearly every Chinese village and town. It is in this hierarchy of gods that Confucianism, Taoism and Buddhism find their places. To the ordinary believing Chinese. Confucius and his many disciples, Buddha and his followers, and the spirits of Taoist origin are merely intermediary between the Supreme Ruler of Heaven and man. In public prayer meetings called to deal with emergencies such as drought, earthquake or epidemic, it is not unusual to find the tablets of Mohammed and Jesus Christ placed side by side with those of Confucius, Buddha and Lao-tzu, all in a position subordinate to that of the Supreme Ruler of Heaven.

While the great majority of believing Chinese adhere to these eclectic religious mixtures, most non-Chinese ethnic minorities follow one or the other of the main Asian religions. Although pre-Communist estimates of the number of Muslims in China ranged as high as 50,000,000, the 1953 census reported only 10,000,000 Muslims. The largest Muslim groups are the Turkic-speaking Uighurs of Sinkiang and the Chinese-speaking Hui (Chinese Muslims), each community numbering more than 3,500,000. Other Muslim minorities are the Kazakhs, Kirghiz, Salar and Tunghsiang. All except the Mongor-speaking Tunghsiang, who are related to the Mongols, belong to the Turkic language family. The Tibetans and the Mongols, though belonging to two different linguistic and cultural groups, share the same branch of Buddhism (*see* Tibetan Buddhism). The small Turkic-speaking Yuku people and the Mongor-speaking Tu people of the Tsinghai-Kansu region are also Tibetan Buddhists. The Thai people and related minority groups in southwestern China are predominantly members of the Theravada branch of Buddhism.

The disintegrating effect of modern influences inevitably invaded the religious sphere. Even before the Communist regime there was some change in the attitude toward religion, and the traditional observances were greatly weakened. Of the three historic religions of China, Taoism in its later phases has been little more than a collection of superstitions that was bound gradually to lose its vitality. Moreover Taoist belief frequently has been associated with secret societies, which played a role in the overthrow of dynasties in the past. The Taoists' belief in magic, divination and secret organization made them a natural target for the Communists. Taoists were persecuted as counterrevolutionaries, and it is probable that Taoism will cease to have any importance in China.

Confucianism, although it has a religious aspect, denotes a social code and an attitude. Although weakened by the changed conditions of a modern society, it retained a large part of its vitality under the Nationalists. It formed the mental background and in part oriented the lives of many educated Chinese who held no definite religious beliefs. Under the Communist regime, however, the shift of emphasis from family loyalty to loyalty to the state and party signified an attack on the entire Confucian pattern of family life and ancestor worship. Although the Communists engaged in no organized campaign against Confucianist beliefs as such, Communist propaganda against undesirable "feudal" aspects of traditional Chinese civilization was implicitly directed against some of the teachings and practices of Confucianism.

To the extent that Buddhism, in both Theravada and Tibetan forms. was identified with non-Chinese minority groups, the Communist regime proceeded slowly against the Buddhist religion. This was true particularly in the case of the tightly organized religion of Tibet. However, the role of Buddhist monasteries in everyday life was greatly limited. Monastery lands were seized and redistributed among landless peasants during the land reforms. Many temples and shrines were converted into recreation centres. Similar restraint was adopted by the Communists toward the Muslim minorities.

Although less than 1% of the Chinese population was converted to Christianity (mainly Roman Catholicism), the influence of Christianity proved considerably greater than the relative smallness of the number of its adherents would indicate. Under the Communist regime, Christianity came under heavy attack, largely because it is identified in Communist doctrine with western imperialism in China. Foreign missionary enterprises were nationalized and almost all missionaries were compelled to leave. Yet an indigenous Christian church. subservient to the regime, was not discouraged. This was especially evident in the case of the Roman Catholic Church, which was forced to break all

ties with the Vatican but was permitted to function under the supervision of the Communist state.

See also BUDDHISM; CONFUCIANISM; TAOISM.

C. Civilization and Culture

China during the 20th century experienced the most momentous transformation in its history, affecting every aspect of life: economic, social, political, intellectual, ethical and cultural. Changes were at first sporadic, the automatic result of infiltration of alien ideas and foreign commodities. Then under the modern-minded Nationalist government and particularly under the Communist regime there occurred a purposeful, co-ordinated remolding of the society and the economy and a systematic attempt to refashion the habits and even the ethics of the entire people.

Traditional Chinese civilization was based on the family system. The sanctity of the family was the cornerstone of Confucian teaching. It extended to elaborate rites connected with marriage and death. the maintenance of ancestral halls, family reunions at fixed seasons and countless other symbolic acts. Marriage, for example, was a contract arranged between two families without reference to the individuals concerned. The association of families in a community in turn provided a system of local government enabling village and district life to maintain an effective organization even during periods of political anarchy. The village attempted to avoid relations with officials of the central government or to reduce them to a minimum. Any dealings that were necessary with higher state officials mere handled by the village elders.

Even before the Communist regime began its effort to reduce the control of the family in favour of that of the state, many influences were at work in modern China to destroy the traditional structure of Chinese society. One of these was the gradual introduction of modern industry. This in turn led to the rise of a trade-union movement that broke down the old guild system. which was similar to the family organization. The advent of a modern educational system in the 1920s played an important role in disrupting the traditional society.

The forces that began to come into play under the Nationalists were greatly fostered after the coming of the Communists in 1949, but were at the same time channeled into a pattern of tight totalitarian control unprecedented in China. Borrowing Soviet techniques of political organization and manipulation, the Chinese Communists effectively brought the entire population under political. social and psychological controls in a way that many students of the Chinese national character would have believed to be impossible. Virtually every person in China has been brought into Communist-controlled mass organizations, which the regime regards as communication intermediaries between itself and the masses. These organizations, established on the basis of specific social and economic groups (peasants, women, urban labourers, children, youth, students, etc.), conduct frequent meetings, indoctrinate their members and direct activities of many sorts. Through them the energies of active supporters of the regime are put to work, while others are subjected to constant, organized social pressure to conform.

Under this social and cultural revolution, changes of tremendous significance have taken and are taking place. The role of the family in society has been disrupted. Women, formerly regarded as inferior, have been given complete equality with men in all phases of life. Political pressures have created an entirely new pattern of individual and group behaviour. Education has been radically changed, training youth for socialism and for service to the state. Using these and other tools, the Chinese Communists are mobilizing the nation's population in a program of economic development aimed at transforming China from an agricultural nation into one of the world's leading industrial powers.

(T. SD.)

V. HISTORY

A. Prehistory and Archaeology

To the Chinese scholar up to the 20th century, archaeology was a discipline closely linked with historical and literary studies. Archaeological materials were valued according to whether they verified or illustrated the past as encompassed in the classics and annals. Epigraphy, therefore, naturally became all-important. while objects without inscriptions were neglected. Thus the documents of the scriptless prehistoric past remained practically outside the sphere of scholarly research in China until westerners began to organize explorations in the field from about the early 1920s onward. Their activities, soon shared by the Chinese themselves, resulted in geological, paleontological and archaeological discoveries of the utmost importance. After a hiatus caused by the Japanese invasion of 1937 and World War II, field work was conducted with renewed vigour and on a large scale under the Communist authorities, and a good deal of the rapidly accumulating material was published in journals and monographs.

1. Paleolithic in North China.—The famous site of Chou-k'ou-tien, 30 mi. S.W. of Peking, was first investigated in 1921 and in part excavated between 1923 and 1939, and again after 1949. It is a limestone hill with fossiliferous deposits ranging from the Miocene to the end of the Pleistocene. The remains of *Sinanthropus pekinensis* and his primitive industry came from two strata of the deep fissure of Locality I, which was sealed by red clays and stalagmitic formations still of Middle Pleistocene Age. *Sinanthropus* is a hominid that ranks in age with the closely related *Pithecanthropus* of Java. Its discovery had added significance because skeletal fragments and artifacts were found in association. The latter consist chiefly of cracked pebbles and splinters of vein quartz, monotonous and accidental in character. Hand axes are absent. The geologically oldest identified artifact came from the red clays in Locality 13, estimated to date about 500,000 years back in time; it is a chert chopper reminiscent of the early Soan (Sohan) industry of north India. An advanced stone technique appears in flaked tools made of various rocks such as those found in the deposits of Locality 15, deposits consisting of red clays still of preloessic age but containing a fossil fauna that points to a geologically younger period than those of Localities 13 and 1. Whether these superior tools also were made by *Sinanthropus* is a question that for lack of skeletal evidence cannot safely be answered.

A nide gap separates the finds of the so-called Upper Cave of Chou-k'ou-tien from the preceding finds. Instead of the red sediments there appear the yellow ones typical of the Late Pleistocene loess formation. Four human skulls found there revealed the presence of what has been termed an early Homo sapiens asiaticus. Cultural remains, poor and atypical in regard to the stone implements, include perforated stone beads and animal teeth, a bone needle and polished objects of bone and antler, which taken together suggest a burial place of some stage comparable with the Magdalenian.

In 1954 another Lower Paleolithic site was found at Ting-ts'un in Shansi. The artifacts—large pebble flakes (some of which exhibit secondary trimming), nuclei and hammerstones—as well as the osteological remains represent a stage comparable with that of Locality 15 at Chou-k'ou-tien.

2. Ordos Industries.—Several important Upper Paleolithic sites have been discovered along the southern fringe of the Ordos steppe, the area skirted by the great bend of the Yellow river. They belong in their entirety in the Late Pleistocene, the time of the formation of the yellow earths (loess), but vary in age. None of them yielded skeletal remains of man. A series of very hard quartzite implements, mostly made of round pebbles chipped along one edge, as well as some flakes, came from the basal gravels underneath the loess, the maximum thickness of which does not exceed 50 m. according to Pierre Teilhard de Chardin, and often is far less. Finds of this category were reported from a number of other sites. In the loess stratum itself, two dwelling places and workshop sites were explored: Shui-tung-k'ou, close to the Yellow river opposite Ningsia, and Sjara-osso-gol, southeastern Ordos.

Shui-tung-k'ou.—This is a loess-filled depression, stretching east-west for 10 mi., where five hearths with ashes and a great number of artifacts were located at various depths in a stratum of loess measuring 15 m. A rich and diversified stoneworking industry comprising such types as scrapers, points and gravers suggests a stage more developed than that of the aforementioned group; yet

tools of the primitive "Soan chopper" variety occurred in the same assemblage. The materials used, chert and silicified limestone, were taken from the gravel of streams embedded in the yellow loam that later were buried under renewed deposits of wind-carried loess dust.

Sjara-osso.—The site of Sjara-osso is remarkable on two accounts; namely, the extraordinary depth of the fossil-bearing beds of dune sands and lacustrine clayey sediments overlying the Paleolithic floor, and the smallness of the stone implements, chiefly scrapers and points, made of small siliceous pebbles such as are available in that area. Typologically, this "micro-industry" is considered by Henri Breuil as advanced beyond the Shui-tung-k'ou stage. However, it is separated from the Neolithic horizon of the same site by no less than 55 m. of deposits, sands and sandy clays rich in fossils.

The absolute age of Shui-tung-k'ou and Sjara-osso is about 100,000 years and separated from the final phase at Chou-k'ou-tien by a gap of another 100,000 years, more or less; the Upper Cave of Chou-k'ou-tien follows much later, about 25,000 B.C.

3. South China.—Except for some isolated finds of probably Late Pleistocene stone implements, south China has offered little beyond promises of future discoveries. Reported finds include: some flakes collected from loess deposits in the area of Ta-tien-lu (western Szechwan); a chipped flinty tool found at the surface of the Yangtze terraces near Wan-hsien (Szechwan); strongly weathered chipped quartzite implements embedded in conglomerates of limestone and river gravels in the Yangtze gorges above I-ch'ang; and a quartzite chopper, heavily rolled and apparently reworked by Mesolithic cave dwellers of Kwangsi, which has some claim to be the oldest implement so far encountered in south China.

4. Mesolithic Phase.—A Mesolithic phase comparable with that of post-Pleistocene Europe has not been identified in China proper. In the southerly province of Kwangsi, however, a possibly Mesolithic culture was discovered in cave deposits of perhaps still Late Pleistocene Age but devoid of remains of extinct animals or any strongly fossilized bones. It is a pebble industry including crude types of choppers, scrapers, hammerstones and, occasionally, perforated stones. Polished or only partly polished stone implements and pottery are absent. The stage is comparable with, and probably related to, the early Bacsonian of neighbouring Tongking (Vietnam).

In the northern borderlands—Mongolia and Manchuria—geographic and climatic conditions of the postglacial period apparently favoured the development and spread, over millenniums, of a culture of hunters, and later of primitive farmers, who have left abundant traces of their culture in microlithic tools made of fine minerals such as jasper, agate. carnelian, chalcedony and flint. The commonest shapes among those tools are small and slender flakes and the conical cores, or micronuclei, from which these flakes were obtained. The foremost site in Mongolia is that of Shabarakh-Usu in the Gobi desert. Widely diffusedto the east, into Manchuria, and southward (Ordos), and no doubt related to Siberian microlithic cultures, this Shabarakh or Gobi culture corresponds to the Tardenoisian and Azilian of Europe, but differs from the latter in that the "geometric" silices are wanting. In regard to China it should be observed that microlithic chipped implements are not encountered to the south of the line of the (much later erected) Great Wall; it appears as though this gigantic line of fortification followed a cultural borderline of hoary age and remarkable stability.

5. Neolithic Stage.—This northern orbit seems to have undergone a gradual transition toward a primitive Neolithic culture of sedentary farmers and husbandmen. This can be observed at two sites in Ch'eng Te, Lin-hsi and Ulan Hata (Ch'ih-feng), discovered by Emile Licent and Teilhard de Chardin in 1924. The artifacts at Lin-hsi were found either embedded in a post-Pleistocene layer of black earth on top of Quaternary white sands above ancient schist, or exposed on the sand where the black earth had been blown away. Crude rhyolithic pebble tools and blades as well as nuclei of fine siliceous rocks occurred side by side with grinding stones and pestles usually made of granite. A few hoelike implements and perforated round pebbles were recovered. Polished implements were rare, and true axes or celts were absent. The pottery encountered in the stratum of black earth was a handmade, poorly fired ware. Bones of the domesticated horse, ox and sheep, but none of wild game, were found.

Geologically and archaeologically similar conditions prevail at the site to the south of the "red rock," which gave Ulan Hata its name. In addition to the Lin-hsi inventory mentioned above, however, this site yielded rather advanced types in stone as well as pottery, the later age of which seems unquestionable but could not be ascertained stratigraphically.

The "Mongolian Neolithic," typified by the presence of microliths, agricultural tools and some pottery such as are known from Lin-hsi, expands north into north Manchuria, where it assumes or retains a character that has been described as Maglemosian, since the finds speak of a stronger dependence on fishing and hunting there; farther west it was traced in the Gobi (later Shabarakh) and southwest in the Ordos. This culture, which must have comprised the wide territories to the north of the yellow clay or loess of China proper and to the south of the Siberian forest zone, seems to have vanished without further local developments, presumably because of an increasing desiccation and the desertlike conditions resulting therefrom. Some traces of it were found in sites spreading between western Kansu and the Gulf of Liaotung, where—similar to what was noted in Ulan Hata—a new Late Neolithic culture with painted pottery and polished stone tools supervened. These "mixed sites," on the whole, have to be understood as evidence of an expansion of the new culture into the southern fringes of the territory previously and perhaps still held by the makers of the microliths.

The rare case of what appears to be an intrusion of north Eurasian Kammkeramik in a south Kansu site (Ch'i-chia-p'ing) visited and described by Andersson, a ware with comb stamped ornaments entirely foreign in China, probably belongs in the period preceding the appearance of the painted pottery.

6. Yangshao Painted Pottery Culture.—The period between the Late Paleolithic of the Upper Cave at Chou-k'ou-tien and the appearance of the Painted Pottery or Yangshao culture in north China, a period of many millenniums, is (in contrast with Mongolia) archaeologically obscure. Except for a series of limestone and quartzite artifacts of Paleolithic character collected by C. C. Young and W. C. P'ei at Yang-shao-ts'un in 1934, there are no finds to shed light on that long period. But this is an isolated and puzzling case that does not go far in altering the apparent fact of an archaeological blank, Andersson's "Neolithic hiatus." Climatic conditions may account largely for this hiatus. The final Pleistocene, when the loess formation was still in progress, was a cold and semiarid phase; afterward, in postglacial times, the river valleys and plains may have been swamplands.

Then suddenly, at the very end of the Neolithic, at a time only four thousand years distant from our own, the hitherto seemingly empty land becomes teeming with busy life. Hundreds, not to say thousands of villages occupy the terraces overlooking the valley bottoms. Many of these villages were surprisingly large and must have harboured a considerable population. Their inhabitants were hunters and stock-raisers but at the same time agriculturalists, as is evidenced by their implements and by the finding of husks of rice in a potsherd at Yangshao-ts'un. The men were skilled carpenters and their womenfolk were clever at weaving and needlework. Their excellent ceramics, with few or no equals at that time, indicate that the then inhabitants of Honan and Kansu had developed a generally high standard of civilization. There must have been, by some means or other—new inventions or the introduction of new ideas from abroad—a rather sudden impetus that allowed the rapid spread of a fast growing population. (From J. G. Andersson, *Researches Into the Prehistory of the Chinese,* Bulletin of the Museum of Far Eastern Antiques, no. 15, p. 297 [Stockholm, 19431).

It was in 1921 at Yang-shao-ts'un (Mien-ch'ih-hsien, western Honan) that Andersson discovered the culture so succinctly described in his above-quoted words. Further explorations revealed that this culture had covered the wide area between western Kansu and northern Honan, with extensions into Szechwan, Ch'eng Te and Liaoning, and that the ancient settlements were close to the rivers Hsi-ning, T'ao-erh, Wei, upper Chia-ling and Han and to the Yellow where it flows eastward after the great Ordos bend. The surprising and basic fact arising from this discovery is that

China falls in line with west Asian and Indian sequences. For not only does there appear in China a painted ware, but, exactly as in the west, this ware is gradually replaced by a burnished black ware. This is, or was, however, a complicated process, far from being clarified by field work. The observations made are summarized briefly below.

Stratigraphy.—In most of the dwelling sites explored, the cultural stratum was rather shallow, but in two very large ancient villages, Hsi-yin-ts'un (southwestern Shansi) and Yang-shao-ts'un, partial excavations revealed cultural strata varying between 2.50 to 4.00 m. and 2.50 to 3.00 m., respectively. However, judged by the occurring types of pottery shards, no clear subdivision or stratigraphic sequence was seen in either place. Andersson stated that Yangshao represents one single cultural stage comprising both painted and burnished black wares. The only stratigraphic change noted by P. L. Yüan, Li Chi and Liang Ssu-yung at Hsi-yin-ts'un in 1926 was a slight increase in the percentage of the black shards as compared with the painted shards in the upper layers, while the percentage of the cruder pottery, gray and reddish, with or without cord impression, remained constant throughout.

In a few northern Honan sites, on the other hand. excavated by staff members of the Academia Sinica in 1931 and 1932. a stratigraphic sequence of painted pottery overlaid by black pottery and, topmost, gray Shang pottery was observed. In other sites in northern as well as western Honan, however, black pottery associated with, or overlaid by, gray pottery but with no trace of painted pottery was found to be a recurring and typical assemblage. Field observations made in the upper Wei valley by W. C. P'ei in 1947 tended to show that the ceramic wares in the many prehistoric sites of that area—the main route from Kansu to Honan—suggest three stages, early, middle and late, characterized by painted pottery first of good style, then of degenerate style and finally by utter decay and disappearance. From Kansu came the finest of the painted ceramics but little of stratigraphic interest.

Some inferences can be drawn. In Honan and Shensi, the painted ware preceded, but apparently overlapped with, the black pottery, and the latter in turn preceded a Bronze Age gray mare. In Kansu. where the black pottery seems to be almost absent, only a very few shards being reported. the Yangshao ware is older than the Hsin-tien ware of the beginning metal age and older than the (unpainted) Ch'i-chia mare. which is unknown in Honan.

Painted Pottery Styles.—The phenomenon of clearly differentiated styles of ornament was observed only in Kansu. Named after type sites in Kansu, most of these styles suggest an evolutionary sequence and, consequently, relative dates: (1) Pan-shan; (2) Ma-ch'ang; (3) Hsin-tien; and (4) Sha-ching.

The Pan-shan style is distinguished by an amphora type, of noble shape and with exquisitely painted ornaments, among which a design of rotatory S curves running horizontally round the vessel predominates. Other common patterns are rhombic chequers, diamonds, zigzags and a gourd motif. One tomb of this phase that Andersson was able to excavate at Pien-chia-kou (Pan-shan hills, T'ao-erh valley) contained the skeleton of a man of about 40, in a flexed position and sprinkled with ochre. The Ma-ch'ang wares are of reddish clay and are painted, sometimes carelessly, with black ornaments such as large concentric circles, rhombic T hooks and large meander bands consisting of parallel lines; the beautiful dynamic spiral patterns have disappeared.

It was with the pottery of the following Hsin-tien stage that some minor bronze objects came to light, none of them, by the way, typically Chinese (Shang). These Hsin-tien nares retain the meander as the predominating motif of their sparse decoration, while their shapes mark a departure from the Pan-shan-Ma-ch'ang tradition. Sha-ching, the fourth phase, appears to have derived from Hsin-tien.

More closely comparable with the repertory of ornamental designs found in Shansi. among which stand out large, flowerlike, sweeping patterns, are decorations known from minor find spots in south Kansu. The exact relationship of these latter styles to those of the above-described sequence is not fully clarified, but it appears likely that they postdate the Pan-shan style; they presuppose the spiral motif, which here is transformed into free and asymmetrical curvilinear patterns foreign to the geometric development of the Ma-ch'ang phase.

Ma-chia-yao and Lo-han-t'ang in central Kansu, two large dwelling sites, exhibit designs that may well stand midway between Pan-shan and these south Kansu styles.

As new material is uncovered, however, the picture of the Yangshao culture becomes increasingly complex, necessitating continuous reappraisals. The excavations carried out in 1953 and 1955 at the site of a large Neolithic village at Pan-p'o-ts'un (Shensi). for instance, brought to light some previously unparalleled pottery designs, in addition to rich architectural remains, including kilns, which for the first time give evidence of a long-continued occupation.

The range of ornamental patterns known from Shansi and Honan is comparatively narrow; to put it in the briefest interpretive statement, it may be said that after a splendid manifestation in Shansi (Ching-ts'un and Hsi-yin-ts'un) decline set in in west Honan (Yang-shao-ts'un), followed by a rapid decay in north Honan, so that a loss of diversity and freshness becomes the more noticeable the farther east we move.

Stone Implements.—The following four tools are, according to Andersson, characteristic of the Pan-shan phase: heavy axes of rectangular cross section with rounded-off corners, flat adzes, small adzes and rectangular or trapezoidal knives with one or two perforations. There are pendants and beads of jade, amazonite, turquoise and marble and perforated disks of jade, which in more regular shapes reappear in Shang and Chou times. The techniques of sawing and drilling hard stones thus were familiar to those vase painters. The occurrence of composite tools such as bone knives set with small flint blades points to connections with the Gobi microlithic cultures.

7. Lungshan Black Pottery Complex.—It was noted above that a black ware is associated with the painted ceramics in Shansi and Honan. In the eastern provinces of Shantung, Kiangsu. Anhwei and Chekiang, however, only the black wares are found, without any traces of painted pottery. The existence of a culture or cultural phase traceable through this black ware became known through the excavation in 1930 and 1931 of Ch'eng-tzu-yai, in west Shantung.

The typical black pottery is a very thin ware with a blackish or brownish body and a burnished, shiny. black surface. The shapes are distinguished by angular silhouettes that bespeak the potter's wheel. Save for some occasional incised geometric design of great simplicity, there is no decoration. Among the vessels are found types not known in painted pottery, such as tripods, spouted vases with bulbous hollow legs and, most characteristic, bowls on high ringed stems. Specimens of these stemmed bowls were unearthed not only in Shantung but also as far south as the Hangchow bay and in westerly Szechwan. Sparse occurrences of black pottery have been reported from outlying regions such as northwest Kansu, south Szechwan and Port Arthur. The centres of the black pottery culture appear to have been located in Shantung and the Huai Ho valley, areas held by tribes that as late as the Chou dynasty had not yet been assimilated.

It is certain that the Lungshan culture preceded the Bronze Age level of An-yang (north Honan), site of the last Shang capital, and that several Lungshan features live on in the Shang culture: bone oracles, shapes of vases (in gray Shang pottery and in bronze) and tamped earth structures.

It appears, moreover. that the pottery of the later Lungshan phase was barely distinguishable from the typical Shang ware, a thick-walled gray ware made with pad and beater (wound with cord), but whether this was due to an internal evolution or an assimilation to the powerfully emerging Shang culture with dissimilar potting traditions is an open question. The fact that the known early Shang sites always overlie Lungshan settlements argues in favour of continuity.

8. Chronology and Western Connections.—An earlier Lungshan I without metal was found to be separated by a thin, sterile, sandy layer from a later Lungshan II with scarce bronze objects at Ch'eng-tzu-yai. It is likely that Lungshan II belongs in the early Shang period (from about mid-16th to early 13th cen-

tury B.C.), and that Lungshan I accordingly dates from the first half of the 2nd millennium, beginning perhaps around 1800 B.C. Consequently the painted pottery must be placed, in its beginnings in Kansu. around or shortly before 2000 B.C., because its secondary styles in Shansi and Honan overlap with the black pottery.

Both the painted Yanshao and the black Lungshan ceramics point to early contacts with western Asia, where possible prototypes of similar shapes, ornamentation and techniques are widespread. In the case of the painted pottery, moreover, an apparent want of archaic forerunners, hence the phenomenon of a sudden unfolding, make it almost necessary to think of outside stimuli. These may have come from Iran, where similar shapes of tripods, urns and steamers occur, dating from around 2000 B.C., or from south Russia, where both the shapes of the urns and their décor of running spirals offer striking parallels to the Chinese types. For the black pottery, close similarities to north Iranian and east Caspian types of stemmed bowls dating from about 2000 B.C. seem to warrant actual connections through cultural transmissions or, possibly, migrations. Even a type of tripod with hollow legs, widely regarded as uniquely and specifically Chinese, occurs as far west as Xnatolia.

The approximate dates of the relevant western Asian and European material agree fairly well with the rough estimates permitted by the Chinese evidence.

9. Late Neolithic of South China. — The beginning of exploration dates only from about 1932, along the coast between Hong Kong and Swatow, an area that under the ancient Yüeh had remained independent until as late as 111 B.C., when it was finally subdued by Han Wu Ti. Field observations made by J. Shellshear, D. J. Finn and R. Maglioni (which led to the recognition of several Late Neolithic and chalcolithic cultures) were summed up by Maglioni in an attempt to arrive at a coherent if preliminary and admittedly obscure picture. This included three Neolithic stages, termed — after a district in Kwangtung—Hoifung (Mandarin: Haifeng) I (Sov), Hoifung II (Sak) and Hoifung III (Pat), and a chalcolithic and bronze period that is only a continuation of the Pat culture modified by the acquaintance with metal. The various stages are differentiated on the basis of the ceramic wares and stone or bronze tools as well as the sites discovered. In most cases these sites revealed objects of only one of the three cultures; among more than 20 sites in the Hoifung district, only two or three showed a mixture of remains of two different cultures.

Numerous reconnaissances undertaken during the 1950s make it clear that south China was lagging behind the north. The evidence collected from no fewer than 159 sites along the lower Yangtze river shows that as late as Western Chou (1027 [1122 or 1111 or 1050]–771 B.C.) these parts had not advanced beyond a Chalcolithic phase. The commonest ceramic ware of the epineolithic Hu-shu culture (after the eponymic site of Hu-shu-chen, about 20 mi. S.E. of Nanking) is a coarse sandy red ware in shapes which reveal influences from the north, as do the sparser blackish wares. The later phase is distinguished by a hard-fired grayish ware with stamped patterns derived from Chou bronze ornaments. This stamped ware is found throughout the coastal provinces, in Chekiang, Kiangsi, Fukien, Kwangtung and Hong Kong during the centuries of Eastern Chou to Han (771–202 and after).

Most of the stone implements current in north China occur in the south also. Occasionally a stone imitation of some typical Shang or Chou bronze weapon is encountered in a seemingly Neolithic assemblage (ko halberd from She-chu, Kiangsu). The shouldered ax, which is less common in the north, is found in many sites between Nanking and Canton. Most typical is the stepped adz with a tang of elliptic cross section distinctly set off from the angular body. a boatbuilders' tool that forms one important link with Neolithic Formosa, the Philippines and Polynesia, while it seems to have remained unknown in northern China.

10. Early Bronze Age in North China. — Until the excavations at Chengchow, concepts of the early Bronze Age were dependent on the material excavated at several sites near An-yang in northern Honan, known as the Ruins of Yin (Yin-hsü). Yin mas the last capital of the Shang dynasty (whose dates are still debated) and it lasted from 1300 to 1028 B.C., according to the chronology of the Bamboo *Annals* (or 1388–1122 in the computation of Liu Hsin, 7 B.C.). The year 1300, therefore, was the archaeologically safe upper limit for the Bronze Age chronology of Shang China. Scanty occurrences of primitive metal objects from several painted pottery sites in remote Kansu and Ch'eng Te (Jehol) (bronze buttons, bell-shaped pendants, armlets, simple knives, tubes, arrowheads and the like) which probably are older than 1300 B.C. shed little light on what happened in the Shang domain before An-yang, say between 1500 and 1300.

The discovery at Chengchow (Honan, south of the Yellow river) of the remains of an older Shang city (identified with the ancient Ao) in no fewer than 24 scattered localities, excavated from 1951 onward by the Archaeological Research institute of the Chinese Academy of Science, brought certainty with regard to the pre-An-yang bronze phase as a fact, its nature and its limitations. Four Shang levels have been recognized at Chengchow, preceded by a Lungshan level, at least in some of the sites. The latest level corresponds to the An-yang horizon from 1300 and after; but in the main the Chengchow strata end where An-yang begins. Thus it appears that at Chengchow was a large Shang settlement, indeed a walled city. whose flourishing period fell to the earlier phase of the dynasty, more precisely the period of the tenth Shang king, nho made Ao his capital. and his successors down to P'an-keng who abandoned the city in favour of Yin.

Of the architectural remains, the ancient city wall, built in layers of pounded earth and about 20 m. in its greatest width at the base, is most impressive. Within and without the wall were numerous pits for dwelling and storage, as well as foundations of houses, which by their stratigraphic positions and varying designs suggest occupation through many successive generations. Ceramic factories and kilns, workshops of bone carvers and several bronze foundries were found there. The Erh-li-kang site of Chengchow yielded oracle bones, but only two of them were inscribed; it would appear, therefore, that writing was practised on a limited scale and not until toward the end of the pre-An-yang period. The bronze objects and vessels from Chengchow compare with those of early style from An-yang. More primitive than the typical Shang bronzes, the vessels are still close to pottery shapes, and their decoration is of an archaic cast, with geometric designs of unevolved or nascent animal motifs.

The bulk of the finds consists of ceramic wares, the typically gray, heavy, cord-marked Shang wares, sometimes with elaborately carved patterns like those of the bronzes. It is on the basis of the typological correlation of the pottery that finds made at other localities such as Lo-yang (Honan), Hsing-t'ai (Hopeh), Liu-li-ko in Hui-hsien (Honan) are considered contemporary, that is, pre-An-yang. Bronze is always rare in these early settlements. (See also below, Beginnings of tlze *Chinese* Civilization: *Shang*, or *Yin*.)

Measured by the wealth and character of the finds made at An-yang, however, the foregoing stages amount to little more than vague promises of a breaking away from the Neolithic traditions with their parallels in western Asia and in Europe, anay from their "international" aspect. During the last three centuries of Shang rule in Yin, Chinese civilization appeared for the first time in history. distinct from other ancient civilizations, in a process which, if no longer unheralded, seems sudden and unpredictable. Even so, some of the Shang people's most significant cultural possessions were paralleled in the west and ultimately may have come thence: the horse-drawn war chariot, the idea of a script and the technique of bronze casting as such. The form they took, however, is uniquely Chinese.

The excavations carried out by the Academia Sinica in 15 campaigns between Oct. 1928 and June 1937, in an area stretching more than three miles along the Huan river to the west of the city of An-yang, revealed a considerable number of individual sites of varying age and importance.

Clear links with older cultures exist in the case of the gray pottery, which in a coarsened fashion continues the black pottery traditions. They exist also in the case of many types of bronze vessels, the shapes of which were dependent on then-current pottery prototypes. To ceramic traditions points also a limited but common repertory of geometric ornaments such as diapers, angular

meanders and T hooks, found on gray pottery and bronzes as well as on a peculiar new kind of ceramic ware, the Shang white pottery. This is a heavy, hard-fired, whitish ware distinguished by its carved décor.

The same white pottery, on the other hand, marks a new departure, being carved in a technique foreign to the Neolithic potters and decorated also with animal images of the abstract, heraldic style that is one of the Shang novelties in archaic bronzes as well as on carved bones and ivories. A bone carver's tradition looms as the uniting agency behind the abstract animal imagery in all those mediums including wood, but the origins of this tradition are unknown. Another new feature is small animal sculptures in jade; they have no precursors in Neolithic sites, while in a general way they are reminiscent of much earlier animal amulets in stone such as were unearthed at Ur, Erech (Warka), Tepe Gawra and Khafaje in Mesopotamia.

Among the magnificent bronze weapons of the Shang there are types of tanged axes that appear to be autochthonously Chinese. Others are suggestive of foreign connections. Some rarer types of shaft-hole axes recall designs current in Mesopotamia, Luristan and Persia. The spearheads, socketed celts and certain kinds of daggers and knives, on the other hand, have close analogies in east Russia, Siberia, Mongolia and the Ordos steppe inside the great bend of the Yellow river. Conditions thus would seem to repeat a pattern observed when dealing with the Neolithic painted ceramics, which likewise point toward south Russia and the ancient near east as centres of diffusion.

The true standard of Shang culture, however, was attained in the sacrificial bronzes such as they were developed in the few centuries at An-yang. The technical excellence and the monumental designs of these vases, which were used in the ancestral temples of the aristocracy, are unmatched in the ancient world. (See CHINESE BRONZE.)

11. Ordos.—On the evidence of numerous stray finds of bronze objects made there, the Ordos region and adjacent Inner Mongolia form part of the geographical and cultural continuum of the Eurasian steppe belt, an area that was to remain alien to that of the Chinese culture. The Ordos bronzes have close affinities in the Bronze Age inventory of central and south Siberia and south Russia, and after they became known in the 1920s mere rightly recognized as related to Scythian art. However, older, pre-Scythian strains also are present in Ordos art. In fact, it seems that the Bronze Age sequence established for Siberia is fully answered by the Ordos bronze material so far known, whereas correspondences with Shang art appear to be limited to the types mentioned above. These types belong, in Siberia, in the periods called Andronovo (c. 1500–1300 B.C.) and Karasuk (c. 1300–700 B.C.). It is the influence of these cultures, including early Ordos, that in the author's opinion accounts also for the lesser bronze finds in several Kansu and Ch'eng Te painted pottery sites.

The Karasuk phase is archaeologically important in that it offers early examples of what is known as the Eurasian animal style. This culture has been explained as the result of an amalgamation with Mongoloid elements which, absent in the older Andronovo population, were traced in the skeletal remains of the Minusinsk area of southern Siberia. Even so, most of the Karasuk inventory, whether metal tools or pottery, is linked with Andronovo, and the animal sculptural adornments of daggers and knives (which might be taken as testimony of influences from An-yang or the Shang cultural sphere at large) agree so well with older Siberian animal sculpture in stone, antler and bone that there is little need to look to China for their origin; particularly since the comparable specimens from An-yang appear to be novelties with no background of native traditions. A grave disadvantage in an attempt at disentangling these Bronze Age Chinese-Siberian relations is the lack of excavations in the Ordos region. Evidence rests with stray finds of metal tools and chronology. Taking this latter fully into account, it can only be assumed that metallurgy came to China from the northwest, ultimate filiations with Mesopotamia notwithstanding.

Perhaps no other single factor so aptly illustrates the degree of obscurity prevailing in regard to the pre-An-yang period (before 1300 B.C.) as does the Chinese script. Appearing in the archaic but essentially developed system of the oracle inscriptions on tortoise shells and animal bones found in one of the An-yang sites, this script, an eminent achievement of Chinese civilization, undoubtedly presupposes some span of time prior to An-yang for its evolution. Yet the only trace of ideographic writing known from before An-yang is that found on the two inscribed oracle bones unearthed at Chengchow and dating from near the end of the pre-An-yang period. It is justifiable, therefore, to conceive of the creation of the Chinese script some time during the obscure two centuries or so before An-yang, a creation which save perhaps for the basic idea of writing was entirely indigenous. (M. L.)

B. Beginnings of the Chinese Civilization

1. Origins.—The origins of the Chinese people and their civilization are still undetermined. It need not be assumed, indeed it is unlikely, that the people were of one original stock or that the civilization spread from one centre either within or outside the modern boundaries. It appears more likely that many different ethnic groups and many separate centres of primitive culture gradually merged and mingled to produce the civilization that has been continuously unfolding and spreading over this continental region. The Neolithic culture revealed by archaeology in numerous sites in China bore fundamental resemblances to the Neolithic in many parts of the Eurasian continent but also had some distinctive features. In different parts of China, moreover, there were from early times regional variations. There was apparently a continuity of population from Neolithic times into the historic period. and there are some evidences of cultural continuity as well. But the sources of information available allow no simple conclusion about the complex question of the connection between the civilization of China and other ancient centres to the west.

The oldest Chinese historical literature, that in the Shu Ching (Book or Classic of History or of Documents)—parts of it the so-called "ancient text," a late forgery—and the earliest extant collection of ancient songs and poems, the Shih Ching (Book or Classic of Odes or of Songs), cannot be depended upon for information earlier than the 1st millennium B.C., and much of that is by no means uncontested. The earliest documents in even these books show a civilization that is already far removed from primitive conditions and contain no certain proof of either a native or a foreign origin for the Chinese. Archaeological researches in central Asia have disclosed extremely ancient seats of culture east of the Caspian and suggested the possibility of migrations from what is now Sinkiang and Mongolia and possibly from farther west, and also the possibility of very early transmission of some art forms from western Asia and southeastern Europe. The excavations in China proper described above (under Pre-history and Archaeology) have revealed, in this regard. only that clear glimpses of what can be called with assurance Chinese culture are caught first in the present area of Honan, Shantung and Shensi, that at the time from which we have remains it was already old, and that it and the people who possessed it were probably the result of several strains from different parts of Asia. Much and perhaps all of Chinese culture may have developed in China itself.

2. Legends.—The Chinese. like every other people, have legends about their earliest times. These, however, are not of much use for history, since they come from late literature that may have been modified for political or social purposes. Of ten figures of most ancient times, cited in the 1st millennium, only three are of real significance: Fu Hsi, Shen Nung and Huang Ti. Fu Hsi and Shen Xung were sages as well as rulers, and sacrificed on T'ai Shan, a mountain of hoary antiquity even in the time of Confucius. who lived in its shadow. Fu Hsi taught people to hunt, while Shen Nung cultivated the five grains. invented the plow and established markets. Huang Ti, also ruler and sage. stands out most prominently, for during the period of the Chou (see below) men both in the royal house and in the feudal states revered him as primal ancestor. He too sacrificed on T'ai Shan. His inventions included boats and oars and the fire drill. With fire he cleared the hills and the plains of their trees and brush, and he rid the country of wild beasts, making cattle breeding possible. He even

instituted music among his officials. Two royal houses before the Shang are mentioned in the texts—Yii and Hsia—but their historicity has not been determined. If they did exist they may be considered to have been roughly contemporaneous with the Late Neolithic stage. The traditional dates for Hsia are 2205–1766 B.C., but one prominent Chinese scholar revised this to 2183–1751, and another (following the oldest text of the Bamboo Annals, or *Chu* shu *chi nien*) put them at 1994–1524.

3. Shang, or Yin (*c.* 1766-*c.* 1123 B.C.).—In this age, though made more secure by archaeology, the dating is still uncertain. The orthodox school puts it at 1766 to 1123, Tung Tso-pin at 1751 to 1112, and others either at 1558–1051 or 1523–1027. It is the spade that has brought this period into the light, and continuing discoveries may be expected. Settlements of the Shang have been identified all the way from Sian in the west to Tsinan in the east.

Chengchow.—According to early literature the royal house successively occupied several seats, and archaeology seems to support this tradition. One of the royal seats may have been at modern Chengchow, Honan, where a walled town, about $1\frac{1}{4}$ by 1 mi. in size, has been revealed. The walls were made of tamped earth measuring 19 to 55 ft. thick at the base. In addition to tombs, workshops of several kinds distinguish the area. Notable among these are pottery kilns of vertical type, with round or oval oven chambers some four feet in diameter. Clay stamps for impressing decorated designs were located in the debris. The patterns included many that were to remain popular for a long time: glutton, dragon, trellis and squared spirals. These same designs occur on pots and shards. Some of the pottery pieces show indications of having been made with the potter's wheel. Most of them are gray. No painted ware, like that of nearby Yang-shao-ts'un of several hundred years earlier, has turned up. The *li* tripod is common, and some black pottery occurs, but none of it is as fine as that discovered at Lung-shan, west Shantung, in a Late Stone Age site (see above). White pottery is completely absent, but there is glazed ware with a brownish body, which must have been fired at high temperature.

Shops for the casting of bronze also existed. Here mere fashioned such objects as arrowheads, knives, fish hooks, socketed axheads, awls, ritual vessels. In the tombs lay examples of the ko, or halberd—a chief weapon of the Shang—hairpins, washbasins and vessels for liquor. Other objects were artifacts made of bone, stone, shell, ivory, jade and gold. Among the first, made of bone of oxen, were some pieces used for oracular purposes; so too were a few tortoise carapaces. Other bones with incised characters may well represent the first appearance of script in China. Obviously this was an important city, but though it reveals the first certain beginnings of the use of bronze in China, its cultural level is below that which is yet to come.

An-yang.—Some time around the 14th century (1401 B.C. according to orthodox dating, 1397 or 1315, etc., according to others) one Shang ruler named Pan (or P'an)-keng is said to have moved his capital to Yin by the Huan river near modern An-yang, and there he and his successors remained for over two and one-half centuries. The town and its tombs have yielded evidences of a civilization brilliant and barbaric. Bronze had come into its own, as had glazed pottery and a fine white ware bearing impressed or incised designs similar to those found on bronze ritual vessels. Woodcarving too was probably advanced, for the bronzes seem to have been based on wood originals. Carving in stone, jade, marble, bone and ivory was far advanced. Objects of bronze and bone sometimes were inlaid with turquoise or mother of pearl.

While the poor may have continued to live as their ancestors did, the patricians put up large timber houses with roofs supported on rows of wooden pillars with stone or bronze bases. Palaces, government offices and ancestral shrines also a-ere erected. The craft of building must have been well advanced, for numerous architectural terms are found in contemporary inscriptions.

The tombs, many of the finest probably for members of the royal house, are magnificently constructed and furnished. One such tomb—26 ft. long, 39 ft. wide. 26 ft. deep—with 17 sacrificial pits, had two sloping passages opening out from its north and south walls. The pits contained bodies of decapitated human beings, dogs and horses. Its grave furniture included ceremonial vessels of bronze, stone and pottery, bronze weapons and bridle fittings, stone, jade and bone ornaments, and a musical stone or chime of gray limestone with tiger design on its face. Other tombs revealed occasional chariot burials. (See also above, Prehistory and Archaeology: Early Bronze Age in North China.)

Social.—The royal house that ruled from this city over the countryside was obviously one of importance. At its apogee the kingdom was probably bounded by the sea on the east, the Yangtze river on the south, Shensi on the west and southern Hopei on the north. The king was not alone in government but was assisted by a hierarchy of nobles. His state was largely a kind of tribute-collecting machine; hence the numerous wars with peoples on its borders. Succession to the throne was irregular; of 38 successions, 19 were from father to son, 14 from elder brother to younger brother, with 5 deviations from both practices. Queens were of some consequence, particularly the one who bore the heir apparent, who after her decease might be awarded her o n shrine in the family temple and be worshiped as an ancestress. The kings, with one or two exceptions, were not war leaders but intermediaries between man and unseen powers. The king's ancestors were ostensibly the real power; he consulted them through his diviners and sacrificed to them. Ti was the supreme god, whose aid was invoked indirectly for good harvests and success in war. Other lesser divinities, such as the god of wind (called Ti's messenger), of the river (Yellow), of earth, of the sun (worshiped at sunrisej, of the moon, of the six clouds, of Yüeh (T'ai Shan), were worshiped. Whether ancestor worship went beyond the royal house has not been determined.

Calendar.—The calendar was important to the Shang, for the chief industry of the people was agriculture, and the king must inform them as to the right times for sowing and reaping. The appropriate functionaries understood lunation; the character for month is the moon. The month was normally 30 days in length, two months making a 60-day cycle, and 360 days a year. Intercallation was practised. In the time of Wu-ting (orthodox dates of reign, 1324–1266 B.C.) an intercalary month was added when necessary at the end of the year, and called the 13th month. Tsu-chia, his third son by his third queen (traditional dates, 1258–26 B.C.), evidently a less superstitious and more forward-looking prince, placed the intercalary month after any month when it was required, and called it the same as the month just preceding. It was an awkward but a stable calendar. One Chinese scientist has ascertained from study of a period of 152 years (1313 to 1161, according to his reckoning) that the mean length of a solar year was $365\frac{1}{4}$ days. In the time of Wu-ting days were divided into seven, but in Tsu-chia's into ten. This is interesting as one of several indications that the Chinese leaned toward the decimal system from earliest times, and with remarkable consistency carried it forward in measurements of all sorts. As a result of this concern for calendrical reckoning the chief astrologer and recorder of events (for long he was the same man) came to have an important place, and the recording of lunar eclipses, considered a portent of evil, and other celestial phenomena began. Eclipses of the moon were reported to the capital even from distant states, and several stars and planets (Jupiter, for example) are mentioned in the inscriptions.

Warfare.—In warfare the nobles led armies of 3,000 to 5.000 men, but there are notices of 23.000 and 30,000 men conscripted for service. The nobles, armed with bronze spears and halberds, and protected by shields and helmets, rode in chariots drawn generally by tno horses, though four-horse vehicles are not unknown. The troops or conscripts were supplied chiefly with composite bows that shot arrows tipped with points of bronze, bone or stone. One inscription on a bone dated in the 12th century tells of a successful military campaign against a state on the western marches in which the booty included 1,570 prisoners, 2 chariots, 180 shields, 15 pieces of armour and a few arrows.

Industry and *Commerce.*—In farming the peasantry used hoes and mattocks, shod with stone or shell, spades and a foot plow. Millet, apparently the only common cereal indigenous to China, was the chief crop; wheat and some rice may have been introduced about this time. In addition to domesticated animals known

earlier, goats and fowl were added to the economy. Tamed elephants were brought in to assist in heavy building operations. Some irrigation was practised. Commerce may be taken for granted, since much of what has been found at the An-yang site and much of what the people required came from elsewhere. Seashells and salt probably derived from the Shantung coast; some of the tortoise shells came from the Yangtze valley and beyond, possibly as far south as the Malay peninsula; tin and lead and some copper as well were imported from the south and southeast; cinnabar (a principal ingredient of red paint) was produced in Szechwan; and turquoise derived from outside the Shang sphere. More conspicuous examples are jade, probably mined in Khotan, and cowrie shells—chief medium of exchange—which may have come from as far distant as the Maldive Islands. Shang tradesmen were so well known that the name Shang jen ("Shang man") became standard for merchant. Textiles included silk and hemp cloth. Names for these and such words as dress, shawl, fur, silkworm and mulberry are given in the inscriptions, and traces of silk have been identified in wrappings for precious weapons. Names for a number of musical instruments (mostly wind and percussion) also are known, as are a few examples of stone chimes, ocarinas and bells.

Script.--Of highest importance among the archaeological discoveries are the bones and tortoise carapaces employed both for sacred and profane use. Over 162,000 of these are scattered in public and private collections around the world. The biggest discovery came in 1936 when 17,096 were located in a single pit. A few bones lay among a great mass of tortoise shells, 300 of them complete. The inscriptions on a large percentage were incised against a scorched area, but some also were written with a brush, using cinnabar or black fluid. A number of the inscriptions reveal a king consulting the oracle and getting replies that at times are signed by the diviner. For example: "Kuei-ch'ou day. (Question) What about this year's rice crop? (Answer) Greatly favourable. (The oracle made in) the 8th moon of the 8th year." There are also, besides oracle inscriptions, records of receipts and historical records dealing with events of the royal court; these are not scorched. The diviners wrote sometimes from right to left, sometimes left to right, probably to suit the "oracle signs"; the recorders or archivists, however, wrote in the same way as at present, from top to bottom. About 3,000 different characters have been identified but only 1,400 or so are readable. Whence comes this script, found incidentally on bronze and other hard surfaces as well? The idea of script, long known in Babylonia and Egypt, may have come from outside, but the Chinese examples except for the simplest pictograms are conspicuously different from the writing of the people of the Tigris and Euphrates and Nile valleys and of the island of Crete. Chinese characters of the Shang period may be divided into three types: pictographs, ideograms and phonograms. By 1100 B.C. they had already developed over a stretch of several hundred years.

4. Chou (*c.* **1122–256 B.C.**).—There is a tradition that in the reign of Ti-hsin, last ruler of the Shang, there was a period of extreme drought: a portent indicating failure on the part of the king. Doubtless also the house had lost its power to govern; after about 270 years in the same locale (about average for a long-lived dynasty) its line may well have become effete and its bureaucracy inefficient and corrupt. In any event the most powerful of the march states, the Chou, on the western frontier—long a battleground between the settled folk and the nomadic invaders—led by King Wu, seized this opportunity to strike. Forming a coalition with eight other states it gradually (in about 20 years) overwhelmed the Shang and ruthlessly destroyed its capital. Blood, it is said, flowed like a river at the battle. Survivors fled in every direction and may well have served as culture bearers to places as far removed as Hunan in the south and Manchuria and Korea in the north and northeast. A scion of the royal family together with members of his court eventually was installed in a small state called Sung, near modern Kuei-teh (Shang-ch'iu) in Honan, and there allowed to continue the ancestral rites. The Chou made a centre, called Hao (near Sian), their capital and parceled out the conquered territory to near of kin and favoured generals, thus instituting a Chinese type of feudal control. These fiefs, said to have numbered 1,773 at the start, were small, thus precluding at the outset any danger of a massive attack such as the Chou themselves had delivered against Ti-hsin of Shang.

For two and one-half to three centuries (the dating at the beginning is uncertain: 1122 or 1111 or 1050 or 1027) ending in 771 B.C. a succession of 13 Chou kings ruled from Hao, only to be ejected by enemies from without and a breakdown of authority within. The ruling king was slain, but surviving members of his clan, together with the court, succeeded in fleeing to a secondary capital on the Lo river, where the dynastic line was re-established but never ruled with power. From this point until, in 256 B.C., the last prince was eliminated, the royal house observed certain rituals and held court for visiting dignitaries, but its domain grew smaller and smaller. Even near the beginning of its existence near Lo-yang it was subjected to attack (by Cheng in 707), and to a large extent it was ignored by states growing in military strength. For example, between 722 and 481, princes of the state of Lu had only two audiences with the kings of Chou, and paid a ceremonial visit to the capital but once. They stopped their material gifts as well. At this time there were 170 states but by 403 B.C. all but seven were swallowed up. In 221 B.C. one man, from the state of Ch'in, could pronounce himself master of all China. The five centuries then, from the 8th to the 3rd, were characterized by almost ceaseless struggle, political chicanery and aggrandizement, and diplomatic jockeying, as well as by the beginnings of higher forms of artistic expression, literature and thought.

Who were the Chou? In all probability people ruder and less cultivated than the Shang, but nonetheless Chinese. The royal line traced its ancestry to Hou Chi, 14 generations earlier, who held a fief about 50 mi. W. of Ch'ang-an. Later the tribe shifted its base 50 mi. to the north, and still later 75 mi. to the southwest, following attacks by northern "barbarians," to a place called Chou or Chou Yüan (Chou plain), whence the name. From this point their chief, Tan Fu, according to tradition, gave up barbarian ways, threw up walls about his seat of residence and began to imitate the Shang. His grandson achieved sufficient stature to take a Shang lady to wife, to increase his domain and to give himself the name of Hsi Po ("chief of the west"). In due course this chief, known to posterity as King Wen, bested all other contenders for power in his vicinity. It was his son, King Wu, who finally displaced the Shang.

Political *and* Social.—To govern so huge a territory was no easy matter for him and his successors. Roads must have been execrable, the Yellow river every summer flooded the plain, and wild animals and even aboriginal folk who clung to remote regions in his domain may have made communications hazardous. An early description of the countryside near modern K'ai-feng relates that "all one sees is only woodland, marshes, lakes. There the king shot birds and hunted. In the second month of winter, in a hunt near Shen-kuan, he took 420 stags of different kinds and wild boar, and killed two tigers and nine wolves." Nevertheless the Chou monarchs traveled widely, living off their vassals, drawing their subsistence from them on the spot. They were assisted by various officials—administrators, inspectors, subordinate officers, scribes and pages. Their lords also returned the king's visits and went to court. When they showed signs of insubordination he dispatched expeditionary forces to bring them to heel. At his capital were altars, temples and palaces. But each successive king, at least at the beginning, incurred the considerable expense of abandoning the palace of his predecessor and putting up a new one.

The lords themselves developed tiny courts of their own with a bureaucracy rivaling that of their master. At the top was an intendant, or more than one if the lord had several domains. Below him were superintendents of forests and cultivated lands. A supervisor of roads and bridges, a chief of engineers, a controller of merchants, a justice (whose writ was subject to the royal judge), a controller of prisoners or of brigands and a director of horses to look after military needs also are mentioned in surviving inscriptions and early literature. In fact, each vassalage was a kind of state in miniature, copying royal institutions. The king-

dom was only more complex and demanded more manpower. It also needed archives where the pronouncements of the king and his acts were duly recorded and preserved. This office was presided over by the grand scribe; he was charged in addition with the calendar and with intercallation.

In the years from 771 to 222 B.C. (usually known as the Eastern Chou from the location of its capital), the royal house, with priestly, ritualistic and diplomatic functions but diminishing authority, slowly sank out of sight as the nobles struggled with each other for power. Survival took no little skill, as it soon became evident that only coalitions with one or another neighbour would save anyone from extinction. Each needed wealth as well from produce of the land, the forests and the rivers and from manufactured commodities. To effect this, many drainage operations, canals, dikes, reservoirs, roads and the like had to be undertaken, often on an interstate or multistate basis. Long walls too were thrown up as means of protection not only against each other but also against aboriginal or nomadic tribes. In the latter part of the period one or more states saw the wisdom of creating monopolies in such universally needed staples as salt, iron and even liquor. Merchants and artisans began to assume some significance. Bureaucrats—so necessary in maintaining large undertakings—started to supersede the patricians. The first canal mentioned, possibly dug before the 720s, is the Hung Kou ("Great Ditch"); it connected with the Yellow river at a point in central Honan and ran eastward past K'ai-feng and thence southeast to join the Huai river tributaries in northwest Anhwei. The earliest reservoir recorded (it had a circumference of about 40 mi.) was built around the year 600 at the order of the prince of Ch'u, near Shou-hsien, in northern Anhwei, the site of one of his seats of power. It irrigated approximately 1,000 sq.mi.. of land. Dikes were thrown up in the 4th century by the states of Ch'i and Chao and Wei, all of which bordered the Yellow river. The Ch'i also constructed a wall east and west across the Shantung peninsula, the northern face serving as an embankment against the overflow of the Yellow river, while the southern fortified the border against the rising state of Ch'u. In 487 B.C. the state of Wu, centred around Soochow, dug the earliest canal connecting the Huai with the Yangtze. At a later but uncertain date the same state constructed canals to reach the "three branches" of the lower Yangtze and the five lakes (the present T'ai Hu). This marks the beginnings of the Grand canal, and testifies to an increase of farming in this area, which was to become the grain centre of China, and to a marked growth in population. Ssu-ma Ch'ien, the grand historian, who visited the region befpre 100 B.C., was to write:

> All the canals were used for boats; and if there was sufficient water they then would be used for irrigation. Peasants enjoyed the benefit; wherever the canals passed, the peasants made use of the water. There were tens of thousands of ditches—nay, an incalculable number of them—to lead the water from the canals to the fields (translation of Chi Ch'ao-ting, *Key Economic Areas in Chinese History,* p. 66; George Allen & Unwin Ltd., London, 1936).

At the very end of the Eastern Chou, possibly around 300 B.C., the great plain of the Ch'eng-tu area was irrigated. Two main channels, subdivided eventually into 158 and 130 canals, respectively. led the water that pours down at certain times from the melting glaciers of the Tibetan massif to enrich this region in Szechwan, another of China's great grain-producing sections. These and other examples that might be cited tell of the backbreaking activity of the peasants in this creative period when the Chinese were coming of age.

Commerce and Industry.—The capitals of the states of this time were not only political but also commercial and industrial centres, known variously for their production of copper, textiles, salt, fish and, after 500 B.C., iron. One passage of the Odes, placed in the 8th century, suggests that profits could be triple the investment, yet nobles were supposed to be above engaging in trade. But were they? The first noble to receive the fief of Ch'i (in Shantung) "promoted its silk textile industry, perfected its skilled handicrafts, and opened up production and trade in fish and salt." As a result, "both people and goods came to it. They arrived carrying babes on their backs and converged on it like the spokes of a wheel. Consequently, Ch'i provided the world with hats, sashes, clothes, and slippers" (translation by Wang Yü-ch'uan, Early Chinese Coinage, p. 32; New York, 1951).

One scholar has estimated that by the year 300 B.C. or thereabouts the city of Lin-tzu had a population of not less than 370,000. Such wealth was possible not alone of a state on the coast. Around 550 B.C. in the northeastern state of Chin, "the rich merchants of Chiang (the capital) could decorate their carriages with gold and jade and have their clothing embroidered with flowery patterns." Besides, "they could distribute gifts to the feudal lords" (translation by Wang Yü-ch'üan, Early Chinese Coinage, p. 35; New York, 1951). The patrician class might scorn the thought of trade, but they fattened on it nonetheless. To their deserving officers they must give large donations; the bronze inscriptions tell of gifts of horses, land, slaves, weapons, strings of cowries, jade, chariots, cattle. red shoes, silk banners and millet liquor. The nobility craved palaces and pleasure houses and lavishly furnished tombs in addition to a following of servitors.

Far to the south, too, wealth was increasing. In the year 597 a minister reported that in Ch'u "neither the merchants, the farmer, nor the artisans have shown any relaxation in production." Archaeology supports this testimony. The areas around Ch'ang-sha and Shou-hsien, both important in Ch'u, have revealed the magnificence of material culture in these times.

While bartering must have been common, industrial developments led to a money economy. Though cowrie shells and their imitations continued for some time in use, metal coins, simulating the commonest tools or objects, came into circulation: knives in Ch'i and spades in the middle regions of the Yellow river valley (both cast in copper), and gold plates in Ch'u. Quantities of these of pre-3rd-century date have been found far removed from their places of origin, especially the knife coins of Ch'i, which have been discovered in Ch'eng-te, Liaoning and Korea on the east and Koko Nor on the west. This speaks volumes for the enterprise of the merchants and the confidence in Chinese money on the part of non-Chinese.

Intellectual Life.—All this indicates the need for literate people, sufficiently literate at least to serve as judges, diplomats, scribes, archivists, temple priests, teachers and the like. Education indeed advanced steadily through the time of Eastern Chou. Even before the 770s there was a certain amount of literature produced, but little besides some of the odes of the people and the court and part of the annals of the royal house has survived. By the 6th and 5th centuries and on to the end of the Chou there was a steady increase in writing: poetry, historical anecdotes, belles-lettres, political theorizing, laws and works on music, mathematics, medicine, divination, agriculture, arboriculture and horticulture. Some of the greatest minds that China has ever produced wrote and taught and argued about the way to solve the problems of their day.

Most of the thinkers seem to have been associated with the government. Certainly the problem that chiefly engaged their attention was the welfare of society. Cosmogony did not greatly concern them. To their minds, however, the disorder that attended the breakdown of the central government and the division of the country into warring states dominated by autocratic rulers was of great moment, and they sought to build a new order that would bring happiness to all. More is said elsewhere of the teachings of the Chou philosophers (see CHINESE PHILOSOPHY). It is sufficient here to state that Confucius (551–479 B.C.) sought to save society by a return to the way of the ancients. This he believed to involve an emphasis upon ethics—especially upon moral education—and upon ceremonies. By the leadership and example of the educated, and by the careful regulation of society by the ceremonies which had come down from the past, he would bring in a golden age (see CONFUCIANISM).

In his train and approving his solution came others. chief among them Mencius (*q.v.*), who stressed the essential goodness of human nature and the right of subjects to revolt against a persistently unjust ruler. Another school, Taoism (*q.v.*), had as its foundation classic the Tao-te *Ching* and attributed this to Lao-tzu who is said to have been an older contemporary of Confucius. The authorship and the dates of Lao-tzu are highly doubtful. The

solution for the woes of mankind offered by the Tao-te Ching was conformity to the way of the universe. The way of the universe was believed to be the absence of all man-made restraints and freedom from elaborate regulations and from what passed for civilization. This solution obviously was quite different from that advocated by Confucius, and members of the two schools engaged in frequent controversy. Belonging to the school of the Tao-te Ching — Taoism — were many other thinkers, notably Chuang-tzu (*q.v.*; d. c. 300 B.C.). A book bearing his name is a witty exposition of the Taoist view that happiness may be achieved only by the free development of man's nature and that the best way of governing is through nongovernment.

Mo Ti (*q.v.*), who lived between the times of Confucius and Mencius and who was the precursor of two schools that for several centuries were to have great vogue but were eventually to disappear, taught that institutions should be submitted to the pragmatic test — were they of benefit to society? He was deeply religious, believed that T'ien (Heaven) loved men and that all men should love one another. It mas his doctrine of universal love as the basis of ethics that brought against him the vigour of Mencius' dialectic. Yang Chu, a contemporary of Mencius, declined to trouble himself about society, maintained that death ended all and held that each man should live for himself and for his own pleasure. Hsun-tzu (*q.v.;* 3rd century B.C.) denied immortality and the existence of spirits and held that man, although bad by nature, could be improved by regulations and ceremonies. The legalists, as their name indicates, wished autocratic rule through the enforcement of law rather than the Confucian influence of moral example.

These and others show how diverse and vigorous was the thought of the age. Never again was Chinese philosophy to be so creative and so untrammeled by the past. Systems then begun were to persist until modern times.

Arts *and* Artifacts. — The last centuries of the Eastern Chou, so famous for their conflicts that they are called the period of Warring States (Chan Kuo; approximately 450–221 B.C.), are highly significant too for their native developments and foreign importations. Iron came gradually into use to displace the more expensive bronze for weapons and tools. The *Kuan-tzu,* a book of the 4th century B.C., tells of farmers needing plowshares, hoes, sickles, sledges and scythes; cartwrights needing axes, saws, wheelnaves, drills, chisels and wheels; women needing knives, awls. long and short needles. Archaeology has confirmed the accuracy of these details and has made clear how far ahead of the rest of the world the Chinese were in casting iron. For the cutting of jade the craftsmen of the 4th century had available the rotary wheel, the wire saw and the diamond drill. Bone and wooden chopsticks were added to kitchen and table. Ink and brush for the scholar and painter underwent improvements. The use of lacquer was perfected, preserving many articles that would otherwise have disintegrated: shields, scabbards, trays, bowls, cups, caskets, wooden figures, musical instruments, many of them decorated with delicate designs. Silk, sometimes (then as later) used as a surface for painting, has appeared in 4th-century tombs. Invention of the crossbow, one of the important weapons of the Chinese against their neighbours, is placed in the same century.

To these and other developments may be added what seem to be importations from outside. Objects of glass — undoubtedly made in China, for some at least contain barium while those of the west do not — are strikingly similar in design to examples from the rim of the Mediterranean. The two-humped camel, long known in central Asia, appears in the latter half of the 4th century and was to become essential for trade across the barren stretches of the continent. Mules and donkeys followed. Horseback riding, probably unknown in China before 33'0, penetrated the states of the northwest and revolutionized the art of war. No longer could a charioteer or his master survive against a galloping mounted bowman. Chariots, except for ceremonial use, began to disappear in China just as they did after Alexander's time in western Asia.

This is not all. Ideas too may have trickled into Asia over the routes of trade: geographic ideas, astronomical notions, musical formulas, even a few philosophical concepts, carried by caravan owners and passed from person to person to such a market as that which grew up near Lanchow (in Kansu) around 300 B.C. Before and around this time the Chinese seem to be aware of more of the Asian world than just the Middle Kingdom, and show an awakening knowledge of regions from the islands of Japan to the mountains of the west. Finds in the Altai of Chinese silk of the 4th century B.C. attest to the range of some of their goods. Calendrical science and ideas about the 28 resting places of the moon may have been stimulated by activities of the Babylonians in these fields, though proof of this is lacking. The Chinese were themselves careful students of celestial phenomena and by the 4th century had mapped 1,464 individual stars (200 years before Hipparchus and one-third more than his number). They were also making lists of solar eclipses, comets, meteors and shooting stars, for these were taken to be signs and portents. The division of the octave into 12 semitones of the untempered chromatic scale, derived from studies of string and wind instruments and bells, appears in a book completed in 238 B.C., and may have been touched off by Babylonian stimulus. In the oldest book on mathematics, which includes some late Chou material, the Pythagorean geometrical theorem is stated; in addition there is much that shows how the Chinese computed measurements, both celestial and earthly. They used the gnomon, sighting tube, circle and square, and measured heights and distances. They talked of the sun's shadow and estimated its differences in length at different latitudes. They calculated the annual movements of the sun. They took account of fractions, and knew how to multiply and divide them and how to find common denominators. Square roots were known. Counting rods were used from at least c. 400, and doubtless led to the Chinese use of place value, apparently ahead of any other people. Geometry became a special study in one of the schools, that of Mo Ti, about the same time as Euclid in Greece, but disappeared as that school ceased to exist three or four centuries later.

The Chou period closed as one after another of the larger states succumbed to superior craft and might. Wu submitted to its southern rival Yüeh in 474. Ch'u in 334 enveloped Yueh and in 286 Sung (in Anhwei), thus dominating the Yangtze from the Gorges to the sea. Ch'in in the northwest by 318 subdued a coalition of states in the north; in 316 and later it reduced Shu and Pa in Szechwan. This brought Ch'u and Ch'in face to face for a life and death struggle that has been compared with the contest for supremacy between Rome and Carthage at about the same time. The discipline of the Ch'in troops and their mobility as mounted archers may well have helped them win the day. Ch'u was eliminated in 223; Chao, Wei, Yen and Ch'i between 228 and 221.

C. Middle Period

1. Ch'in (221–207 B.C.). — The prince who became supreme in 221 B.C. called himself the first emperor (Shih Huang Ti). Indeed he deserved the name, for China was now in fact an empire. No longer was there a cluster of states with nobles s earing (but not observing) fealty to their liege lord. Shih Huang Ti divided the country, stretching from the great bend of the Yellow river to certain areas south of the Yangtze, into 36 commanderies, adding 5 or 6 as other territories came under his control. Each commander had officials subject only to the emperor. He shifted people without regard for local loyalties; the most powerful families were brought to the capital to remain under his eye. Brigands and ne'er-do-wells were transported to the marches to keep the nomads at bay. In 214 the first emperor connected such defensive walls as lay in the north into a single system and threw up watchtowers to guard the bulwark and to send signals — smoke by day and fire by night — to his capital at Hsien-yang, near Sian. A 100-mi.-long canal was dug in Shensi, in the valley of the Ching, in 246, during his minority, enriching the metropolitan area. Another was cut in 219 in the deep south, through mountainous terrain, making water transport from the Yangtze to the Hsi Chiang possible for the emperor's troops. Roads, 50 paces wide in the north, 5 ft. in the southwest, built between the years 220 and 215, supplemented the system of canals. Standard dimensions for cart and chariot axles were imposed. The script was standardized.

Unification of laws, weights and measures took place. Books and philosophies at variance with the thought of Ch'in were eliminated (the celebrated "burning of the books" of 213 was designed to assure the supremacy of legalism; see CHINESE PHILOSOPHY). Condign penalties were imposed on learned men who refused to be subservient.

Actually the reforms of Shih Huang Ti were not new. What was new was their application not to a single state but to an empire. Ch'i and Wei had experimented with some of them 200 years earlier. A native of Wei had carried them to Ch'in in 352 and had persuaded the prince there to put them into practice. The fact that he did accounts for the discipline and single-minded concern for conquest that occupied the princes of Ch'in for over a century thereafter. The first emperor died in 210, and with removal of his strong hand the dynasty crumbled. It was extinguished in 207. For five years various military officers contended for supremacy. Two emerged as rival leaders, with Liu Pang victorious after a severe struggle.

2. Han (202 B.C.–A.D. 221).—*Former Han.*—This period began with a rough and ready general and military officers who included a dog butcher, an undertaker, a silk dealer and a cart puller in the seats of authority. It is to the credit of Liu Pang (posthumously knoun as Kao-tsu) that he was finally persuaded to call in the bureaucrats and seek their help in administering his vast empire. He made the mistake, however, of assigning the administration of various distant regions to favoured members of his personal and official family. This blunder almost led during the next 50 years to the breakup of the realm. until the power of the "seven kings" was broken (154 B.C.) and civil service examinations were instituted for the selection of some of the officials in the imperial service in 124 B C. Equally dangerous to Han rule were the nomads of the north and northwest, the Hsien-pi and the Hsiung-nu. Each, with a reputed 200,000 archers, constantly menaced the northern marches. Indeed, one of the purposes of the Great Wall was to impede their horsemen, and its watchtowers kept incessant guard. For the first century and a half it was the Hsiung-nu who provided the greater worry. At the very start of Liu Pang's reign they almost destroyed him, trapping him in a northern citadel in the year 201 and forcing him to pay subsidies of silk, wine. grain and food to gain release. The handing over of a palace maiden in marriage then (and frequently later) was another part of the agreement. Not till the days of the emperor Wu (reigned 141–87 B.C.) were the Hsiung-nu subdued, first by an attempt to gain allies against them and then by daring raids deep into their own territory.

The attempt to gain allies led to a memorable embassy. A people called the Yiieh-chih, who had once occupied part of the Kansu corridor, were forced out of this region by the Hsiung-nu in 161–160; three decades later they arrived in Bactria. After numerous adventures a Han envoy, Chang Ch'ien (*q.v.*), reached Bactria (in 129–128) to try to persuade them to assist the Han in confounding their mutual enemy. His mission failed, but the data he collected and brought back to his emperor persuaded Wu to embark on numerous military and diplomatic forays. In 121 one army attacked the Hsiung-nu at Kuei-hua and killed or defeated 19,000 of them, also capturing a vast herd of sheep. Another went 700 mi. farther west and seized 80 Hsiung-nu chiefs. In 115 the envoy returned to central and western Asia, this time with 300 men; from then on diplomatic connections with a score of states developed. Far to the south, in Kwangtung and Tongking, which had once been absorbed by Ch'in but whose colonizers had declared their independence of Han, Wu dispatched another force in 111, taking over the administration of the region. In 108 he turned his attention toward the east, to northern Korea, where many Chinese had settled following the rise of Ch'in. Here again his army and his fleet were successful. Four commanderies were set up in the occupied territory.

Han was now an empire rivaling if not exceeding Rome in size and probably also in wealth, power and prestige. Its envoys, officers and merchants could and did roam far afield, some apparently even voyaging across the Indian ocean in the 1st century B.C. Almost certainly they stopped at Kancheepuram (old name Kanji) on the southeast coast of India, traveling by foreign vessel. They stimulated the export of goods and tribute by land and sea to Ch'ang-an, the capital city, now a place of grandeur. The historian Pan Ku in the 1st century A.D. wrote of the imperial park of Ch'ang-an:

> In the suburbs to the west are the parks of the emperor, private gardens, groves, forests at the foot of the mountains, lakes and pools, basins and marshes. They . . . are surrounded by a long wall more than a hundred miles in circumference. The independent palaces and separate pavilions are thirty-six in number; supernatural springs and marvellous pools are encountered at every turn. In the interior are unicorns from Annam, horses from Ferghana, rhinoceroses from Kanchi, and birds from Chaldea.

The name of no individual foreign merchant is known until A.D. 181, but that such people came is hardly subject to doubt. A song of the time runs:

> The itinerant foreigners, whence do they come, and what do they bring from their various lands? Rugs and carpets and frankincense, rosemary, camphor, and thorough-wort (translation of Arthur Waley, History Today, p. 92; 1953).

As merchandise and plants and animals and even disease traveled westward, so did Chinese goods and products make their way across the Asiatic continent. The Romans, after conquering Syria in 64 B.C., came to prize Chinese silk and set up a market for it in the Vicus Tuscus in Rome. Patricians in distant Spain, Gaul and Britain demanded silk. Chinese bronzes and jades and lacquer goods followed in the trail of silk, but were in less demand.

Interim.—With the death of the emperor Wu (or Han Wu Ti) came a gradual decline in power and prosperity and increasing corruption in high places. The consort families acquired such authority that eventually one of their number, Wang Mang, then first minister, after a bloodless and well-managed coup, took over the empire changing its name to Hsin (A.D. 9–23). A great controversy has raged over this man ever since. Though many of the reforms he instituted were overdue, he operated under difficult circumstances. The peasants in the east, already impoverished, were affected by a major shifting of the bed of the Yellow river (twice: c. 1 B.C.–A.D. 6 and A.D. 11). The government tried to ameliorate their condition, but the numbers of dispossessed increased. The bureaucracy co-operated at best without enthusiasm. Merchants took advantage of the situation. The government became discredited, and soldiers finally stormed the capital and slew the monarch.

Later Hun.—It was two years before a scion of the house of Han restored the dynasty, now to be known as the Later Han. Actually, however, not until A.D. 36 was the country again at peace. It then set about recovering its former colonies. The commanderies in Korea were not a problem, but the southland (Tongking) had to be recovered (this was done in 42) and the northern tribes in Manchuria and Mongolia pacified. In 73 Pan Ch'ao was selected to win back the chieftains of the oases of the Tarim basin and dislodge the Hsiung-nu, once more independent, who bestrode the Altai and blocked the trade routes to the west. With expert use of both force and treachery he cleared the way and by the year 94 was supreme as far as the Pamirs, exacting tribute (*c.* 90) even from the Yiieh-chih, who had themselves erected a flourishing empire known by the name of Kushan.

This feat brought the Chinese face to face with Buddhism, the greatest missionary force in Asia. The religion penetrated slowly but effectively, first befriended, then spurned by the Taoists, steadily gaining ground as the Han tottered again to its fall in the last 40 years (c. 180–220). Conflicts among the consort families, the eunuchs, powerful families in the capital and in the provinces, and the military, plus another serious uprising of peasants (184), brought misery all around. In the end the military gained control and divided the country into three dominions.

During the Han dynasty China came of age. Its earliest historians, Ssu-ma Ch'ien (writing about 100 B.C.) and Pan Ku (A.D. 32–92), set the pattern for the majestic series of annals that are one of China's glories. Agriculture, mathematics, astronomy, belles-lettres, music and industry took forward steps. The skeptical writings of Wang Ch'ung (1st century A.D.) punctured the superstitious theology of Tung Chung-shu (2nd century B.C.).

Education so flourished that by the middle of the 2nd century A.D. there were 30,000 students in the capital (then Lo-yang) alone. Paper was invented and began to displace wooden and bamboo surfaces for writing. The first important dictionary, explaining about 10,000 characters, was published; likewise the first important pharmacopoeia. The alchemists began to make discoveries useful in medicine and industry; the proto-porcelain of the last decades of the Han may be the result of their experimentation.

3. Six Dynasties (221–589).—From A.D. 221 to 589, the Chinese, particularly those of the north, suffered division and turmoil. Split at first into three states, Wei in the north, Wu in the middle and lower Yangtze valley, and Shu in the Szechwan area, China was united for a few decades by the Tsin (265–317), only to be broken by invasions of Hsiung-nu, Hsien-pi and other ethnic folk who penetrated passes in the Great Wall at will. While non-Chinese ruled mainly in the north, a series of native houses held sway in the south, thus preserving much of the Chinese heritage. In fact, the south was becoming more "Chinese" all the time as exiles poured in across the frontier to escape the exactions and discomforts of life under alien conquerors. In addition to the above-mentioned state of Wu, these houses were the Eastern Tsin (317–420), the Former Sung (420–479), the Southern Ch'i (479–502), the Southern Liang (502–557) and the Southern Ch'en (557–589), all of which had their capital at Nanking; hence the oft-used term "Six dynasties" for the period, in utter disregard for what was transpiring elsewhere in China. In the north the most important dynasties were the Northern Wei (ruling from 386 to 495 at Ta-t'ung in northern Shansi, and for the next 40 years at Lo-yang), the Eastern Wei (at An-yang from 534 to 550), the Western Wei (at Ch'ang-an from 535 to 556), the Northern Ch'i (at An-yang, 550–577) and Northern Chou (at Ch'ang-an, 557–581).

Troubled as those centuries were, they did not pass without significant developments. Indeed they cannot rightly be compared with the dark ages into which Europe sank after the fall of Rome. The period was essentially one of transition in civilization. Many of the invaders adopted Chinese culture, but they could not but modify it. Buddhism now achieved popularity, perhaps in part because with the breakdown of central authority the Confucian school could not offer the resistance that it could under the Han. Many of the monarchs espoused the foreign cult, missionaries came in numbers, and Chinese, the best known of whom was Fa-hsien, went on pilgrimages to the sacred sites in India and returned with Buddhist scriptures.

By the time the empire was once more united, Buddhism had become an integral part of its life and was having profound effects upon other religions, popular thought, literature and art. The Buddhist sculptures of the period are noteworthy. During the last years of disunion and during the first century or two of the union that followed, Buddhism was more prosperous than it was ever again to be in China. The many new sects that arose within it testified to its vigour. Taoism, too, under the stimulus of Buddhism, developed and became a great popular religion.

Though it was a period of disunion and turmoil, the 3rd to 6th centuries showed great increases in knowledge of medicine, mathematics, astronomy, botany and chemistry. Through foreign missionaries and returning pilgrims, merchants and embassies, the Chinese became much better informed about the outside world. Sea connections and commerce between China and southern Asia increased. The lower Yangtze region became more highly developed economically and culturally.

It was during this age that P'ei Hsiu (224–271), who produced a large map of China in 18 sections, laid down specific rules for the use of the grid system in cartography, each gradation corresponding to 100 *li* (about 30 mi.). During the Six dynasties, too, a start was made on the writing of local histories or gazetteers for specific parts of the Chinese world. A work to be noticed is an account of the southern regions that gives, inter ***alia,*** the first notice of biologic control through use of insects in the culture of oranges and lychees. A book on agriculture, horticulture and animal husbandry, produced before 550, so excelled other works in the field that it went through more than 20 editions after it was first printed in the years 1023–31. Tea was introduced, possibly from Burma, in the 3rd century. The practice of welding hard and soft steels to make the blades of weapons, probably derived from central Asia, and wootz steel, imported from India, appeared in the 3rd and 5th centuries respectively. Mica came to be widely used for lanterns, screens and windows and for decorative purposes in the 3rd century. Water mills, ships, the wheelbarrow and the stirrup came into general use in those centuries. The value of π in mathematics was developed with great accuracy by a mathematician of the 5th century. In studying the heavens the astronomers of the Tsin made a list of 28 solar halos between the years 249 and 420; not until the 17th century did anyone in Europe record such phenomena.

4. Sui (589–618).—A long time had elapsed since the days of empire, but the historically minded Chinese had never forgotten that all China had once been ruled by a single house. The Sui dynasty that finally achieved unity did not hold power for long, but its monarchs laid the foundations for the T'ang to follow. The Sui rulers actively patronized Buddhism and embarked on domestic construction at home, much of it extravagant, and recovery of territory and prestige abroad. Perhaps nothing so served to unite the country politically and economically as the improvement and extension of the waterways that formed the Grand canal. The two capitals, Lo-yang and Ch'ang-an, at prodigious cost in *corvée* labour and other expenditures, were now linked to the lower Yangtze valley and Hangchow bay in the south, and to a point close to Tientsin in the north. The Great Wall was rebuilt to protect the northern flank. The forays abroad were only partially successful. The Chams and the Chen-la kingdom in Indochina were forced to pay tribute and Taiwan (Formosa) was raided, but excursions into Korea (611–614) and against the T'u-chüeh (or Eastern Turks) in Mongolia were a failure. Rebellions begun in 613 ended in 618 in the murder of the second emperor. He was succeeded by a general of his northwestern command who established the house of T'ang—as memorable a dynasty as that of Han, and ruling for a time the largest and strongest empire on the globe.

5. **T'ang (618–906).**—After consolidating their hold at home the first emperors reopened the war with Korea, but they did not annex the whole peninsula until the 660s. Contacts with Japan, begun under the Sui, continued under the T'ang until the 9th century, with students, envoys, merchants and monks coming to the capital or to the ports and monasteries for stays of considerable duration, a few even remaining for life. At the same time Chinese missionaries and teachers carried Buddhist, Confucian and Taoist thought and ritual to the Koreans and Japanese. The second emperor, T'ai-tsung (or Li Shih-min), who regarded himself as a worthy successor of the Han emperor Wu, carried his arms into central Asia, defeating the T'u-chiieh (both Eastern and Western Turks) in Mongolia and beyond as far as Ili, by 648 achieving mastery of the whole Tarim basin. Princes of Bokhara and Samarkand recognized his suzereignty. At his death in 649 his tomb was protected by statues of 14 vassal kings, from the khans of Turkestan to the king of Champa (Annam). Less successful in his struggle with the rising power in Tibet, he at least was able to crush a Tibetan attempt at invasion and to improve relations by sending a Chinese princess to Lhasa as consort of Songtsen Gampo.

At home the central administration was organized so well that the pattern stood, with few changes, up to 1912. Confucianism again began to flourish, growing strong especially in educational circles, with the Confucian canon required study for all candidates for civil office. Schools at the capital attracted students from many lands. Foreign missionaries preaching Mazdaism, Nestorian Christianity and Manichaeism established temples and translated their sacred works, while Buddhist Chinese eager to make contact with the wellsprings of their faith continued to make long journeys to India and Ceylon. A great map of the Chinese world, measuring some 30 by 33 ft., which treated in addition seven great trade routes from China to other parts of Asia, appeared in 801. Even under the Sui a landmark in dictionary making was published (601), to be followed by other scholarly

works under the T'ang, such as the first historical encyclopaedia (801). Astronomy and mathematics made marked advances, partly as a result of increased contact with Buddhist and Manichaean scholars from abroad. One government-sponsored research project is one of the most remarkable studies carried out anywhere in the world in those days: in 721–725 nine stations, ranging from a point near Hué in Annam to the Great Wall in the north (over 2,175 mi.), were set up to make simultaneous measurements of summer and winter solstice shadow lengths. At the same time investigators mapped the constellations of the southern hemisphere. Wealth and peace brought leisure and a renascence of the arts. Calligraphy and painting, poetry and belles-lettres touched new heights. With the demand for multiple copies of literature of all sorts, from almanacs to sacred scripture, the art of printing arose.

In spite of its vigorous start the course of the T'ang dynasty was not smooth. Through palace intrigue a former concubine of the second emperor succeeded not only in becoming empress but also in calling herself emperor (the only female emperor in Chinese history) and in changing the name of the dynasty for a time (690–705) to Chou. A half-century later worse was to come, with the chiefs of Nan Chao in full cry against the T'ang (751–754), defeat of its army by the Arabs in western Asia (751) and a rebellion by dissatisfied generals at home (755). The emperor and his court fled ignominiously, leaving the two great capitals to be sacked by the Uighurs and Tibetans respectively (763). The Tibetans and the Uighurs withdrew in due course, but the latter, with an empire stretching across Mongolia to the Altai, became a dangerous and burdensome ally for the next 80 years.

The T'ang court returned to Ch'ang-an, but it never again exercised suzerainty over so vast a territory. Military officers and eunuch favourites took over in many areas of control, though the country at large continued to be administered with a high degree of efficiency. In 842–843, because of the collapse of the Uighurs who patronized the followers of Mani in China, Manichaean monasteries were closed, their priests sent north or slain, their property confiscated and the religion proscribed. Two years later, for political and economic reasons among others, a similar disaster befell the Buddhists, affecting, according to the decree, 4,600 temples and all their lands and precious treasures, 40,000 shrines, and 260.500 monks and nuns. The Nestorian and Zoroastrian religions too were proscribed. Buddhism recovered in some measure, but never again was it to assume the major place in Chinese life that it had held between the 5th and the first part of the 9th century. Zoroastrianism, on the other hand. was destroyed, and Christianity died a lingering death; Manichaeism survived, more or less surreptitiously, for a few more centuries.

Fifty years later the country began to fall apart as powerful generals assumed control of areas under their command. The T'ang bowed to the inevitable in 906. (See also T'ANG.)

6. **Five Dynasties and Ten States (907–960).**—The years assigned traditionally to this period are 907–960, but actually the state of Ch'ien Shu in Szechwan broke away from T'ang in 890 and that of Pei Han in Shansi was not made part of the Sung empire until 979. Politically these decades were chaotic, with two Chinese and three non-Chinese houses laying claim to empire around the ancient cities of Lo-yang, K'ai-feng and Ch'ang-an, and with the rest of China parceled out among self-appointed despots. Even this was not all, for the Khitan, a people of Hsien-pi descent and Mongol tongue who were based on Jehol and Liaotung, swept into the area around Peking in 938 and maintained their hold for nearly 200 years, ruling under the name of Liao.

The picture is not all black, however, for this is the era of printing. Between 932 and 1019 the entire Confucian (130 volumes), Buddhist (5,048 rolls) and Taoist (4,565 rolls) canons were carved on wood blocks and the resultant works distributed far and wide. In addition there were printed all the dynastic histories up to that time and numberless other books, both official and unofficial. In the meantime one ambitious general, Chao K'uang-yin, gained the upper hand after the death of his emperor in 959 and established another dynasty that was to lend distinction to China for over 300 years.

D. Early Modern Period

1. Sung (960–1279).—The establishment of the Sung dynasty inaugurates the period that has been described rightly as early modern. It was modern in government, with the appearance of political parties with differences in policy. A certain modernity also may be seen in the decline of aristocracy and rise of the status of commoners; in the development of the system of civil service examinations to serve more genuinely as a device for the discovery of talent; in the growth of a money economy (paper currency was resorted to in 1024); in a sensible willingness to admit more than one interpretation of the Confucian canon; and in the rise of new media in fiction, drama and art. Perhaps even more striking is the fact that, due to the now wide availability of books, the level of general education rose and in many fields there was a close approximation of the spirit of science.

The Sung faced major difficulties on its frontiers from the start and never overcame them. To the north of the Yellow river were the Khitan, with whom they fought an exhausting war from 986 to 1005; this ended with the Sung being compelled to pay a sizable annual indemnity. In the west were the Tangut of Tibetan ancestry who established themselves athwart the Kansu panhandle and demanded costly tribute every year after 1043. Annam in the south and Nan Chao in the southwest sealed off the southern frontier. In 1122–23 the Khitan were displaced by the Jurchen. a people ancestral to the Manchus, who founded the house of Chin; they crossed the Yellow river and descended in force on the Sung capital, taking prisoner the entire court (1126). One prince escaped and set up temporary capitals in a number of places before reaching Hangchow, where the capital remained from 1135 to 1276. Meanwhile the Jurchen menaced the entire area north of the Yangtze. Not until 1215 were they compelled to withdraw from Peking and in 1233 from K'ai-feng, to be entirely destroyed the following year by the Mongols.

Ringed around as they were, the Sung were forced to develop their domestic economy and take to the sea. These steps they took with conspicuous success. Great cities were built, generally according to plan. K'ai-feng, the first capital, rebuilt after 1078, had an area within its walls of over 16 sq.mi., and its population, including suburbs, was estimated at 1,200,000. Soochow was about its equal in size and Huchow was even larger. These cities, together with Hangchow and Canton, were among the greatest urban centres of the age, catering to almost every need. The main streets were wide, and public baths, street cleaning, street lighting and fire protection existed. Fairs and markets, eating places and amusement centres enlivened them by day and doubtless far into the night. City officials also ran orphanages, homes for the aged, first-aid stations, granaries and schools. The coastal regions from Yangchow to Canton grew increasingly prosperous, due to foreign trade. Native craft became perhaps the finest and safest ships on the high seas thanks to the development of watertight compartments, balanced rudder and wave-resistant superstructure, and to the invention of the magnetic needle. Ports such as Ch'üan-chou (Chin-chiang) and Canton had large non-Chinese settlements where Indians, Arabs and other foreigners lived and erected their temples and mosques. The Chinese shipped silks and porcelains to Japan in the east and Egypt in the west, receiving in exchange spices, incense, ivory, jewels, pearls, steel, cotton and precious woods. Revenue taken by the government on imports around 1200 amounted yearly to 65,000,000 strings of cash. For defense the Southern Sung, in 1127, created a navy; by 1237 it had 20 squadrons armed by nearly 52.000 men.

In an age such as this the Chinese made advances in almost every field. Use was made of explosive power in fire arrows, flame throwers, bombs, grenades, proto-muskets and cannon. They experimented with movable type. They developed human inoculation against smallpox. One medical author wrote the world's first treatise on legal medicine; a pharmaceutical author insisted on the need for investigation of any doubtful drug.

The first astronomical clock was realized—a technical achievement of the first order. The zero (from India?) made its first appearance. The introduction of cotton and sorghum and green lentils from India and drought-resistant rice from Champa brought

about a mild revolution in Chinese agriculture. In political economy statesmen of the 11th century developed enduring principles in arguments before the court, and carried them into practice. One statesman, while out of office, wrote one of the great histories of China, covering the long period from 403 B.C. to A.D. 959, a work in 294 chapters plus 30 additional chapters in which he gave special attention to divergencies in the records he used as sources. Buddhism. though no longer the power that it once had been, had nonetheless unconsciously affected the thinking of scholars; the resultant thought, a synthesis of the ethics of older times and a new metaphysics, was the theme of countless discussions and writings, culminating in the formulations of Chu Hsi (*q.v.*). (See also SUNG.)

2. Yüan (1280–1368).—Temujin (born between 1155 and 1167, died 1227), after a youth spent largely in overcoming tribal enemies, became supreme over the Mongols in 1206 and was proclaimed Genghis Khan. Invading Kansu, he conquered the Tanguts (1209) and pushed on into north China, taking the Chin capital (Peking) in 1215 after a bitter siege. In 1234 his successors annexed the Chin empire and followed up this campaign by penetrating Szechwan. Later Genghis' grandson Kublai established the Yuan dynasty, beginning in 1260, though it was not until 1280 that all China was invested. During the reign (to 1294) of Kublai, Peking, again the capital and rebuilt by a Muslim architect, succeeded Karakorum as one of the principal centres of world attention. There the storytelling of the Sung period and the puppet and marionette shows of earlier days developed into maturer fiction and drama. The Grand canal, running now from Hangchow to the suburbs of Peking, was restored for travel and commerce; so too were the waterways in Kansu. Imperial roads were put in condition, and postal stations with relays of 200,000 horses were installed for imperial service. Government funds and even ships were lent to private traders to stimulate overseas commerce; maritime trade bureaus were established first at Ch'üan-chou (1277) and later at Ningpo, Shanghai and other ports. Crops and the food supply were checked periodically, and grain was stored away against shortage.

Failing in 1274 to conquer Japan with a Mongol army transported across the straits by a Korean fleet, Kublai assembled two other fleets, one Korean, one Chinese, but failed again in 1281. Other marauding adventures to Champa (1282–83), Annam (1257 and 1285), Burma (1287) and Java (1293) were hardly more successful, but the kingdom of Nan Chao (in modern Yunnan) was forced to submit (1253) and in 1274 came under the governorship of a Muslim. Other Muslims followed. establishing flourishing communities there and in other western provinces. Nestorian Christians, forced out of Sung China not long after 1000. though holding on precariously in the north, came back in strength under the Mongols, to be followed by Roman Catholic missionaries and traders and Greek Catholic guardsmen—the Alans, who eventually (1336) asked to be accepted into the church of Rome.

Through his brother Hulagu in Persia Kublai received models of astronomical instruments and even a terrestrial globe. Of more significance perhaps were the instruments—designed by a Chinese engineer and astronomer and erected in the imperial observatory—with which officials of the observatory were able to ascertain facts of primary concern. China during the 13th century had what may have been the most advanced mathematics and astronomy of the age. Kublai also promoted a search for the source of the Yellow river. A map of the then known world, published after 1330, included the whole of Asia, Europe and Africa.

With Kublai's passing the dynasty gradually declined. Tribute to Peking dwindled, but the costs of supporting public enterprises, the Mongol nobility and Buddhism and Taoism continued. Metallic currency was drained away into the west. A study of the issues of paper currency shows rapid inflation, until government notes became valueless; in 1356 printing of them was discontinued. In 1351 the Yellow river overflowed its dikes, causing great distress. Grain transportation to the north, necessary because of the insufficient supply of farm produce in the metropolitan province, fell away after 1342, and famine faced the court. The region south of the Yangtze, which had suffered only moderately in the time of Mongol conquest and which had been allowed even to maintain many of its bureaucrats, became a breeding place for rebellion. Starting in 1325 numerous uprisings broke out. How much they were directed against the Mongols and how much the several leaders were struggling with one another is not clear, but by 1368 all but one of the leading insurrectionists were eliminated, and so were most of the Mongols.

3. Ming (1368–1644).—The founder of the Ming dynasty. Chu Yüan-chang (reign title Hung Wu). like Liu Pang of the Han came of humble origins. Instead. however, of adopting a policy of reform that might have benefited the people of his own kind, he upheld the landholders, suppressed all differences of opinion, even deleting large segments of antiautocratic pronouncements from the text of Mencius, and became as much of a despot as ever sat on the dragon throne. Perhaps this was the policy required during his reign. The people had to be coerced into accepting his rule, dikes and walls rebuilt. the peasants coaxed back to the farms. Having depended heavily on ships during his rise, he created a navy, with supporting stations on the coast, to patrol the littoral. Secret societies, widespread during the time of rebellion, were suppressed, a new code was authorized, and attempts were made to establish a safety zone around the empire. Mongolia and Korea at the time were too weak to resist; the princes of Liuchiu (Luchu Islands) and certain oasis states of central Asia acknowledged China's suzerainty; Japan, however, brushed aside Chu's threat of war, and, knowing that his fleet might have no better success than had those of Kublai, he had to accept the situation. He at least started the land off to a long period of material prosperity. The population, estimated at 65,000.000 in his day, rose to 150,000,000 before the dynasty fell. The country's sea and land frontier suffered frequently from raids during these $2\frac{1}{2}$ centuries, but the interior remained relatively undisturbed throughout.

A crisis over the succession disturbed the peace after Chu's death, but in 1402 a grandson was eliminated and a son (Chu Ti) came to the throne (then at Nanking) behind a seasoned army to reign under the title Yung-lo (1403–24). Besides the problem of gaining allegiance from a people irate over his bloody march from Peking to the Yangtze, and from the scholars disturbed over his unfilial act in upsetting his nephew, whom his father had made emperor, Chu Ti had constantly to repel the restless chiefs of Outer Mongolia and the Japanese marauders on the coast. His interest in the navy, as keen as his father's had been, led to the equipping and dispatching of well-armed "treasure boats" with attendant supply ships nearly halfway around the world. Six expeditions went out from Chinese ports during his reign, and one afterward (1433), to countries of the South Seas, Annam, Ceylon, the near east and Africa. The ships mere armed with cannon, and forced the payment of tribute when necessary. A prince in Sumatra and a king of Ceylon, both of whom gave resistance, were seized and transported to the capital. Mecca and many other states acknowledged China's might. Tribute often came in money; also imported were horses, sulfur, copper ore, timber, drugs and spices. In exchange China gave paper money (when possible), silk and porcelain. Remnants of the last still are found in faraway places, while a stele in Ceylon, inscribed in Chinese, Persian and Tamil and dated 1409, bears witness to Chinese aggressiveness and enterprise during these decades. One of this emperor's last major acts was to transfer his capital to Peking (1421) and there, on the ruins of cities put up by the Khitan, Jurchen and Mongol invaders, to construct an imperial city of his own.

The following reigns show no comparable interest in foreign adventures. The navy was reduced in strength, patrolling of the coast ceased, and merchants were discouraged from going abroad. One ill-advised monarch in 1449 permitted himself to be captured by a small detachment of Oirat (western Mongol) horsemen, a fraction of the size of his own army. A spirit of isolationism spread in court circles. The following century saw repeated encroachments on Chinese soil: the Portuguese in the south in 1521, Japanese pirates along the coast (1525–63), and Altan Khan, prince of the Ordos, in the northwest after 1542. Certain Muslims, allied to coreligionists in central Asia, also caused frequent trouble, especially in Kansu and Shensi. A serious threat was an

attempted invasion by Japanese armies via Korea; these nearly reached China's northeast border during the final decade, being checked in 1598 partly by Chinese arms and partly by lack of supplies from the home islands. By this time China's economic strain was becoming evident, imperial leadership was relaxed, and morale at the capital and in the field deteriorated. When the Manchus rose in strength north of the Great Wall they were able to expel the Chinese from the basin of the Liao (1621) and eventually take Peking away from a bandit chief who had just broken through the city's gates after ravaging much of the west.

In spite of generally inept emperors, the Ming was a period of marked accomplishment. The Grand canal was deepened and improved; the Great Wall was repaired; and most of the city walls, paved highways, bridges, palace and temple structures that stand today were erected by architects of the Ming. Beautiful paintings and porcelains date from this period, as do excellent textiles, rugs and furniture. There was craftsmanship of the highest order in bookmaking, and encyclopaedic works appeared in a variety of fields, such as military science, technology and medicine, in addition to the huge Yung-lo ta *tien* in 11,095 volumes. Reprinting of many ancient books preserved what other ise might have disappeared irrevocably. Fiction and drama continued to delight and distract the multitudes. In philosophy the dispute between Chu Hsi and Lu Chiu-yuan, his contemporary of the 12th century, blossomed again between the followers of Chu and the great disciple of Lu, Wang Shou-jen (1472–1529), who insisted that the moral judgments of a man should spring from his own intuition. Academies sprang up in many parts of the country, especially in the south, encouraging freedom of expression within the Confucian tradition. The province of Kiangsi alone had 241 academies by the mid-16th century. The members of one academy in Kiangsu dared challenge the eunuch-ridden court, with death the end result for many of them. There was no dearth of literate and able men.

Into this atmosphere appeared a small and dedicated group of Roman Catholic missionaries, led by Matteo Ricci (*q.v.*), who, in addition to their work of evangelization, undertook to introduce western culture. Their influence was immediate and consequential, leading to useful advances in many fields. For the first time in history western and eastern science began to flow in one channel. The discovery of the Americas brought not only knowledge of a wholly new world to the Chinese but also new crops that were added rapidly to their farms (maize, sweet potato, peanuts, tobacco), a new coin (the Spanish peso, minted in Central or South America) and a new disease (syphilis). Under less blind and venal leadership at the court China might have gone on to great advances, but with rebellions in the west, ending in the seizure of Peking, and a fresh and hardy foe to the north, the dynasty of the Ming came to an end. (See also MING.)

4. Ch'ing (1644–1912).—With the consent of a Chinese general who was blocking the passes of the Great Wall, the Manchus poured through Shan-hai-kuan to aid him in ejecting the bandit foe from Peking. This done they saw no reason to retire, and within a year had pushed south and driven the retreating Ming survivors from Nanking. Though they now had all north China to the Yangtze, this was only the beginning of a prolonged struggle. Ming princes and their supporters continued to resist not only on the mainland but also on Formosa, where Cheng Ch'eng-kung (called Koxinga [*q.v.*] by contemporary Europeans) finally based himself (1661–62) by driving out the Dutch. Not till 1683 was the Chehg insurrection crushed on the island and across the straits in Fukien. Meanwhile a revolt of three high Chinese officials appointed to govern the southland broke out in 1674 and lasted to 1681.

The Manchus at last were in control. To make their domination clear to all they imposed the partly shaven head and queue on every man. Chinese and Manchus together staffed the principal offices of administration at the capital, but frequently Chinese alone governed the provinces. At important cities throughout the provinces were stationed guardsmen drawn from the eight Manchu banners or divisions. The first Manchu emperor to reign at Peking was little more than a figurehead. With the second, however. the Ch'ing came into its own. Reigning under the title K'ang-hsi (born 1654; reigned 1661–1722), he launched a period of achievement scarcely equaled before, certainly not afterward. Of all the reigning monarchs of the time—Aurangzeb in India, Peter the Great in Russia, Louis XIV in France—K'ang-hsi was the most enlightened.

Peace, beginning in 1683, made possible careful administration and judicious control. Foreign adventurers were repressed. The Portuguese were allowed to remain in Macao but were not permitted elsewhere. The Russians pushing out across Siberia challenged the Manchus in their northern homeland, but in the treaty of Kerchinsk (1689) agreed to desist from argument by force. An agent of the tsars and a branch of the Greek Orthodox Church were allowed to settle in Peking. The Mongols in 1691 accepted junior status. Tibet, disturbed because of the Manchu forced selection of a dalai lama, was invaded in 1720 by imperial armies and compelled to allow the stationing of Manchu garrisons. Of all foreigners those most tolerated at the court were members of the Society of Jesus. They were men of scholarship, well versed in both the Chinese and Manchu languages, who introduced the emperor to certain branches of European learning. They performed numerous services as well, assisting as interpreters in state business involving Europeans, preparing elaborate maps, establishing the calendar, serving in the bureau of astronomy and even curing the emperor of malaria with cinchona bark newly procured from members of their order in South America. A shadow came over these friendly relations with the church when papal and imperial authority clashed over the Chinese name for God and the acceptability of Chinese rites (the so-called rites controversy). With the Chinese literati the emperor was always the patron, promoting compilations of books dealing with painting, literary expression, poetry and finally the whole field of knowledge—an encyclopaedia actually published a few years after K'ang-hsi's death. A dictionary named after his reign, the K'ang-hsi *tzu-tien,* is still standard in its field. Scholarship independent of the throne also flourished, and at Ching-te-chen (Kingtehchen) was inaugurated another period of superb porcelain manufacture.

The reign of the following emperor, who came to the throne by questionable means, lacked in distinction, being occupied largely with keeping the Mongols and others in the west at bay or under control. His successor, however, known under the reign title of Ch'ien-lung (1736–96), continued in the tradition of his grandfather. The empire's boundaries were pushed to their farthest limit, to the Ili valley and Kashgar (1755 and 1759). Korea and Annam remained as vassal states. Tibet, Burma and Nepal were invaded severally (1751, 1765–69, 1792). In spite of these military successes abroad and an extended era of peace at home there were signs of growing dissatisfaction. The Pai-lien chiao (or White Lotus society) in Shantung (1774), the Muslims in Kansu (1780s), the native population in Formosa (1786–87) and the Miao tribes in Kweichom (1795–97) all broke out in rebellions, which were put down often ruthlessly. An accumulated reserve in the national treasury, amounting to over 70,000,000 taels as of 1781, was dissipated by the end of the reign. The emperor, who besides his skill in administration was genuinely interested in learning and scholarship and eager to leave behind him a monumental literary compilation that would outshine all others, ordered to that end the dispatch to the capital of all rare books in public and private possession (1772–81). This action brought to light over 2.600 works critical of his dynasty and of its predecessors from the north. Such criticism he found intolerable. Over 2.300 were listed for total suppression, and the rest for partial deletion of a few lines or paragraphs. A number of scholars suffered the extreme penalty; the rest limited themselves to works of textual criticism. local histories, commentaries on the Confucian canon and on the earlier histories. The imperial compilation when completed (seven copies in manuscript only) was nonetheless an important as well as gigantic work, its catalogue *raisonné* (which did appear in print) being a necessary tool for every scholar. The emperor, when well along in age, allowed one corrupt guardsman, Ho-shen, to win his confidence and corrupt the civil service. Not until after the emperor's death in 1799 was Ho-shen put down and his vast and illegally derived fortune confiscated.

E. 19TH CENTURY AND REVOLUTION

The dynasty from this point on deteriorated s iftly. Revolts broke out in the years 1796–1804 and again in 1813. The trade in Indian opium, the sale of which was forbidden in 1729 and importation in 1800, grew alarmingly after 1820, with both foreign and Chinese connivance. By this time French, Dutch, British and U.S. ships were to be found in Macao harbour and carrying their goods up the Hsi Chiang to Canton, where the supercargoes would buy tea, silk and cotton goods in exchange for specie and opium. The purchase of the latter meant an unfavourable trade balance.

Foreign tradesmen, eager only to buy and sell on their own terms and turn a quick profit, were irked by various restrictions—the necessity of dealing solely with an officially designated group of merchants (the Co-hong; *q.v.*), the absence of fixed tariff charges, the exactions of venal officials, the unwillingness of the Manchus to permit official intercourse on the basis of equality, the prohibition against a Chinese teaching a foreigner the language, the subjection of the foreigner to Chinese laws and courts. The Russians received slightly better treatment than did the other foreigners, perhaps because they had long had contact with the peoples of Asia and the Manchus and Chinese understood better how to deal with them. Their second treaty with the Manchus (that of Kyakhta, 1727) provided for trade, diplomatic intercourse and the extradition of criminals. The western Europeans wanted even more favourable terms. Portuguese, Dutch and British embassies traveled to Peking (notably those of the British in 1793 and 1816, led respectively by Lord Macartney and Lord Amherst), but to no avail. The Chinese, and in turn the Manchus, had never been accustomed to dealing with other governments on the basis of equality and regarded all foreign envoys as bearers of tribute.

1. First War With Great Britain and First Group of Foreign Treaties (1839–44).—Such a condition of affairs could not endure. The industrial revolution had inaugurated a period of renewed expansion of the west, and it desired admission to China to market the products of its factories and to obtain raw materials. This was also the period of the important clipper ship trade between the United States and China.

Pressure first came from Great Britain. On demand from British merchants, the monopoly of the China trade by the English East India company was abolished (1834), and friction between the English and Chinese increased. Lord Napier was appointed the first "superintendent" of British trade in Canton (1834), but Chinese officials looked upon him as merely a head merchant and refused to deal with him as an equal. Lord Napier died while still in this anomalous position, and his successors were unable to effect any improvement in the situation. Armed conflict was all but inevitable. British merchants were insisting upon more privileges than the Chinese were willing to concede, and British and Chinese ideas of international intercourse were fundamentally at variance—the one government being accustomed to a family of equal nations, the other knowing only an empire and subject peoples. Conceptions of law differed, the Chinese, with their emphasis on group responsibility, holding the entire British community liable for the misdemeanour of any of its members and the British contending that upon the individual and not the community should be placed the responsibility for misdeeds.

The conflict reached its climax over the question of the importation of opium. This had long been prohibited by the Manchu government, but foreign merchants brought it in ever-increasing quantities and corrupt Chinese and Manchu officials connived in the trade. After many futile attempts at enforcement, Peking at last took vigorous action and dispatched a special commissioner, Lin Tse-hsii, to stamp out the trade. Lin arrived at Canton in 1839 and promptly set about his task. Foreign merchants were compelled to surrender their stocks of opium for destruction, and pressure was put upon them to give bond not to engage further in the importation of the drug. The British objected to what seemed to them highhanded measures, and in Nov. 1839 hostilities broke out. The Chinese were repeatedly defeated. The war dragged out until 1842, however, for the British contented themselves largely with attacks on centres south of the Yangtze, and their victories alternated with unsuccessful attempts at negotiation. Finally, when Chen-chiang—at the intersection of the Yangtze and the Grand canal—was taken and Peking's communications with the south were threatened, the imperial authorities were frightened into concessions, and on Aug. 29, 1842, the treaty of Nanking was signed.

This document provided for the cession of the island of Hong Kong to Great Britain, for the opening to foreign residence and commerce of five ports (Canton, Amoy, Foochow, Ningpo and Shanghai), for liberty to appoint consuls at each port, for communication between British and Chinese officials of the same rank on the basis of equality, for an indemnity to the British, for the abolition of the Co-hong and for a "fair and regular tariff." In 1843 regulations for trade were agreed upon and published, and a supplementary treaty was signed that fixed the tariff rates, assured to the British most-favoured-nation treatment and contained the beginnings of extraterritoriality.

Other western nations took advantage of China's defeat. The U.S. sent a commissioner, Caleb Cushing, who negotiated a treaty that conceded, in general, the same commercial privileges to Americans which had been granted to the British and that, among other things. removed U.S. citizens engaged in the opium traffic from the protection of their government, elaborated extraterritoriality and provided for the revision of the treaty at the end of 12 years. In 1844 the French obtained a treaty that had much the same provisions for trade and official intercourse as were guaranteed by the British and U.S. documents. At the instance of the French, imperial edicts were issued providing for the toleration of Catholic Christianity and for the restoration of the church property that had been sequestered in the persecutions of the previous century. In the next few years the Belgians and the Swedes were also given treaties.

2. Second Foreign War and Second Group of Treaties (1856–60).—The years between 1842 and 1846 were in effect a period of troubled truce. The treaties of 1842 and 1844 were satisfactory neither to foreigners nor to Chinese. From the standpoint of the foreigner they did not grant enough. No provision was made for travel in the interior, for residence in places other than the five open ports or for direct diplomatic intercourse through representatives resident in Peking. The Chinese, on the other hand, believed that the treaties conceded too much, and, since they had been extracted by force, the authorities were not disposed to abide by them any more than they were compelled to do. The Chinese were no further inclined than formerly to treat western "barbarians" as equals. Clashes were frequent. Moreover, the British treaties said nothing about opium, and the traffic in the drug continued, a constant source of friction.

While the Americans, the British and the French were demanding that revision of the treaties which had been promised in the documents of 1844, war between the British and the Chinese broke out over a comparatively minor incident—as is often the case in times of international tension—the violation by the Chinese of a British flag and the arrest of the crew, all Chinese, on a Chinese-owned but British-registered craft, the lorcha "Arrow" (Oct. 8, 1856). The French, then closely associated with the British through the Crimean War, found in the judicial murder of a Roman Catholic missionary in Kwangsi (Feb. 29, 1856) an occasion for joining in the conflict.

The two powers did not at first press the war, for they were just emerging from the struggle in the Crimea; also, difficulties with Persia in 1856–57, and the Indian mutiny, which blazed out in 1857, engrossed the attention of the British. Late in 1857, however, the British and French took Canton, and in the following year their squadrons went north to Tientsin, thence to threaten Peking into submission. The Taku forts, commanding the entrance to Tientsin, were captured, and to save the capital the Chinese granted the desired treaties. The Russian and U.S. representatives, although not in the war, were on hand to profit by the French and British successes and also obtained treaties. The Russians obtained all the Chinese territory north of the Amur.

The treaties of Tientsin (1858) in general contained the following provisions: (1) the tariff was modified, and by the fixing of

a rate for opium the importation of that drug was legalized; (2) the residence in Peking of diplomatic representatives of the powers was promised; (3) foreigners were to be permitted to travel in the interior; (4) the activities of Christian missionaries were sanctioned, and Christians, both foreign and Chinese, were guaranteed freedom in the practice of their faith; (5) foreign merchant vessels were allowed on the Yangtze; (6) several additional ports were opened to foreign residence and trade, including Chefoo and Ying-k'ou in the north, one on Hainan, two on Formosa and four on the Yangtze; (7) extraterritoriality was further elaborated; (8) regulations for trade, including the collection of customs, were developed; and (9) indemnities were promised.

When, in 1859, the envoys came to complete the ratification of the treaties and to take up their residence in Peking, they found the road by Tientsin blocked. The Chinese, moreover, proposed the reconsideration of the treaties. The British and French attempted to force their way past the Taku forts and were repulsed. The two powers accordingly renened the war and in 1860 fought their way through Tientsin to Peking. Peking was captured, the emperor fled to Ch'eng-te, and the British, in retaliation for the violation of a flag of truce and the death of some of its bearers, set fire to such of the summer palace as had escaped marauding Chinese troops. Both French and British joined in looting it. The Chinese were now constrained to sign conventions by which they agreed to observe the treaties of 1858, to pay an additional indemnity, to open Tientsin to trade and to permit—more definitely than agreed upon in 1858—the permanent residence of foreign ministers in Peking. The British were ceded the Kowloon promontory opposite Hong Kong, and through the French was obtained treaty sanction for what had been promised earlier. the restoration of confiscated Catholic Church property. In the Chinese, although not in the official (French), text of the French convention was also permission for French missionaries to lease or buy land and build houses in the interior. The Russians, still fishing in troubled waters, obtained a modification of their frontier by which the territory east of the Ussuri was a arded to them. This territory had a long stretch of coast that included the site of Vladivostok.

The treaties of 1842–44 and 1858–60 defined the legal basis on which intercourse between the occident and China was to be conducted. They were later modified in details, but until 1943 in their main outlines they were the basis of the legal status of foreigners in China.

While at the time they seemed to solve a troublesome situation, they weakened Chinese sovereignty and threatened the existence of the state—partly by removing foreigners from Chinese jurisdiction, partly by their regulation of the tariff and partly by making Christian communities *imperia* in *imperio*.

3. T'ai P'ing Rebellion and Other Revolts.—The Manchu government was confronted by serious internal problems in addition to the problem of occidentals. By 1800 the population was twice as large as it had been at the beginning of the Ch'ing. Agriculture, industry and commerce had not been able to expand with equal rapidity. There were frequent revolutionary outbreaks following the attempt by the followers of one secret society to seize Peking in 1813.

In south China, particularly in Kwangtung, a number of additional factors stimulated disorder. The Hakka, an ethnic group which had migrated centuries before from north China and settled in Kwangtung and Kwangsi, were in frequent conflict with the longer-established local population, and when economic troubles grew these conflicts increased. Secret societies with an anti-Manchu purpose mere strong in south China. The illegal opium trade, carried on by smugglers, encouraged gangsterism and piracy, which became linked with the underground secret societies. After about 1820 opium was beginning to drain silver from China, which disturbed the economy, particularly that of Kwangtung. The first Anglo-Chinese war was a blow to the prestige of the Manchu dynasty. It also broke the government's naval power and weakened its ability to maintain order in Kwangtung against the league of pirates, gangsters and secret societies. During the 1840s in Kwangtung and Kwangsi the people suffered severe famines. Banditry increased; disorder was spreading. Conditions—both general and specific—made an uprising almost inevitable. The outcome was the T'ai P'ing rebellion, one of several that shook the imperial structure to its foundations.

During the T'ai P'ing rebellion the imperial government, in desperate straits for revenue, resorted to likin (internal transit taxes on commerce) and, the crisis once past, continued it. During the rebellion, too, as a convenience for the imperial authorities, was begun the system of collecting the maritime customs through the agency of foreigners. This expedient was first adopted in Shanghai but proved so acceptable to both Chinese and foreigners that it mas extended to other ports. The imperial maritime customs service so developed was placed in 1863 under the direction of Robert Hart, and through his genius was officered by an able foreign staff and became not only a dependable source of revenue but an agency for the charting and lighting of the coasts and the inauguration of a postal system.

Other rebellions threatened the power of the Manchus, especially in Shensi, Kansu and Sinkiang, but these were all suppressed. The Manchu dynasty, indeed, for the moment took on a new lease of life. Able Chinese came to its support. The empress dowager, Tz'u-hsi. who had had the good fortune to bear the heir of Hsien-feng, ruled as coregent during the minority of her son, the emperor T'ung-chih—and was dominant not only during his boyhood but after her nominal retirement (1889). Unscrupulous but vigorous, she probably prolonged the life of the dynasty.

4. Increasing Foreign Pressure (1860–94).—The years between 1860 and 1894 were marked by no major crises in China's foreign relations, and Chinese life and culture went on nearly unaltered by the presence of the westerner. Pressure was steadily accumulating, however, occasional minor clashes occurred, and the stage was being set for revolutionary changes.

From time to time new ports were opened, and through these and those previously available foreign commerce was growing. As before 1860, the British continued to lead. In the treaty ports foreign colonies arose, and in some of them special districts were set aside, usually either as "concessions" or "settlements" (some of them dated from before 1860), which, as a development of extraterritoriality, were under the administration of the foreigners, through the consuls, and some of them with a council elected by the foreign taxpayers.

Christian missionaries, both Roman Catholic and Protestant, rapidly increased in number. The first Protestant missionary, Robert Morrison, of the London Missionary society, arrived in 1807, and under the impulse of the vigorous new life of Protestantism in Europe and the United States during the ensuing century representatives of many societies followed—British, American and European. Protestant missionaries emphasized the translation and distribution of the Scriptures and of religious and secular literature, preaching, schools, medical relief and the formation of churches. They were largely responsible for China's first contacts with western education and medical science.

Roman Catholics reinforced their missionary staffs, emphasizing the winning of converts and the care of children in orphanages. By 1890 Protestant Chinese numbered about 50,000 and Roman Catholic Chinese about 500,000.

The growing pressure of the west began slowly to take effect. Before 1895 no startling changes in the structure of Chinese life occurred, but here and there were indications that China would not remain as it had been. In the first place, it somewhat grudgingly began to enter into the diplomatic life of the world. In 1866 a Manchu was sent to Europe with Robert Hart to observe and report. In 1867 Anson Burlingame, who was retiring as United States minister in Peking, was asked to head a mission to present China's case to the governments of the west. Burlingame went first to the United States and there negotiated a treaty (1868) which among other things promised respect for the territorial integrity of China and freedom of immigration of Chinese labourers to the United States and reciprocal rights of residence and travel. From Great Britain and France the mission obtained assurances that pressure would not be applied inconsistent with the independence and safety of China. In 1870, after

visiting several courts, and while in St. Petersburg, Burlingame died and his colleagues returned to China. The mission was much criticized, especially for Burlingame's optimistic speeches, but—with the exception of a much earlier one to Russia (1733)—it was China's first formal embassy to that west with which it must henceforth deal.

Before 1880 resident envoys had been appointed to most of the leading capitals of the world. In 1873 and again in the early 1890s the foreign envoys in Peking were given audience by the emperor, but always with a subtle suggestion that they were considered as coming from tributary states. Not until 1894 were they received on the basis of full equality.

In the 1870s the Chinese government sent several scores of youths to the United States to be educated, but in 1881 they were recalled. Two government schools were founded to train men for diplomatic service. By 1895 telegraph lines and a few miles of railway were built, and some attempts were made to reorganize China's naval and military forces and to construct coast defenses according to western models.

5. Chinese-Japanese War and Beginning of Rapid Change.—China could not hope long to remain semi-isolated. The occident was continuing to expand, Japan, at China's very doors, was rapidly adopting and adapting western culture, and China must sooner or later adjust itself to the new world.

The beginning of rapid change was brought by war with Japan. Korea had long been in an ill-defined position of vassalage to China, which Japan refused to recognize. The two nations came to blows over the dispatch of troops by both to put down an insurrection in Korea. War was declared Aug. 1, 1894, and China was quickly and overwhelmingly defeated. By March 1895 the Japanese had successfully invaded Shantung and Manchuria, had captured Wei-hai-wei and Port Arthur, fortified posts which commanded the sea approaches to Peking, and the Chinese sued for peace. By the resulting treaty (of Shimonoseki) China recognized the independence of Korea, ceded to Japan Formosa, the adjoining Pescadores Islands and the Liaotung peninsula (in Manchuria), agreed to pay an indemnity of 200,000,000 taels, opened four more ports to trade and promised a satisfactory treaty of commerce. Russia was not disposed to see Japan make gains which would threaten Russian ambitions in the far east, and, backed by its ally, France. and by Germany—which professed fear of the "yellow peril"—protested against the cession of the Liaotung territory. Japan had no other recourse but submission, and the retrocession to China was made in return for a face-saving increase in the indemnity. The war had demonstrated the utter failure of Chinese attempts at "self-strengthening" during the past three decades. Its "modern armies" had proved incapable of defending the country and its western-style navy had been destroyed (see also CHINESE-JAPANESE WAR).

The victory of Japan was the signal for a scramble among the powers for leases, concessions and special privileges. The weakness of the Manchu dynasty had been unmistakably disclosed and for a few years it looked as though the powers, driven by earth hunger and fear of one another, would partition it. Russian, French, British and German bankers angrily contested for shares in the loans through which China was to pay the Japanese indemnity. In 1895 Russia obtained permission to carry the Trans-Siberian railway directly across Manchuria instead of by the longer all-Russian route of the Amur and Ussuri. France secured a "rectification" of the frontier in the Mekong valley and railway and mining privileges in China. Great Britain, alarmed, demanded and received concessions on the Burmese frontier. Rumours were soon afloat (1896) of further grants to Russia in Manchuria and of a promise to that same power of a lease on Kiaochow bay (Chiao-chou Wan) in Shantung. Russia, too, extended its influence in Korea. In Nov. 1897 German forces seized Tsingtao, giving as an excuse the murder of German missionaries in Shantung, and the following March that port and land controlling Kiaochow bay were leased to Germany for 99 years, and railway and mining concessions in Shantung were assured. Russia made the German seizure of Tsingtao the signal for the occupation of Port Arthur and Dairen, and in March 1898 a portion of the Liaotung peninsula which included these two ports was leased to Russia for 25 years. Within a few weeks France was given a 99-year lease to Kuang-chou Wan in Kwangtung, and Great Britain acquired Wei-hai-wei "for so long a period as Port Arthur shall remain in the occupation of Russia." Great Britain also acquired a 99-year lease on an additional portion of the Kowloon promontory, opposite Hong Kong.

Concurrently with the seizure of these leaseholds, the powers delimited "spheres of interest," by which they meant by implication, prior rights to provide capital for the development of mines and railways, and the promise of nonalienation of territory to another power. In case China should be partitioned, spheres of interest might become formal annexations. In 1897 France secured from China a "declaration of nonalienation" of Hainan to any third power. In 1898 Great Britain obtained a similar declaration for the provinces adjoining the Yangtze, France for the provinces bordering on Tongking and Japan a promise that none of Fukien would be alienated to any power whatsoever. Germany laid claim to Shantung as its sphere and Russia the territory north of the Great Wall. In 1899 Russia and Great Britain agreed not to interfere in each other's preserves. Great Britain, too, exacted from China a promise that the inspector-general of the maritime customs should be of British nationality, at least so long as the trade of Great Britain exceeded that of any other country.

Still another form of the struggle over the country was the competition for the privilege of providing capital for railways. The details of the story are extremely complicated, but in general the results were that Russia acquired a monopoly on railway building in Manchuria; Belgian financiers—behind whom France and Russia were suspected to stand—provided the money for the road from Peking to Hankow; Germans furnished the capital for lines in Shantung and for the northern section of the road from Tientsin to P'u-k'ou (on the Yangtze, opposite Nanking), Britons for the southern half of the road and the line from Shanghai to Nanking, and France was granted concessions for railways in its sphere of interest—Kwangtung Kwangsi and Yiinnan. A U.S. syndicate was given the concession for a road from Hankow to Canton, but the Belgians later acquired a controlling interest in the company and the Chinese, irritated, bought back the grant. The French got from the Russo-Chinese bank the contract for a road connecting T'ai-yüan with the Peking-Hankow line, and a Franco-Belgian syndicate the contract for a line from K'ai-feng to Lo-yang. Mining concessions also were obtained by various foreign groups.

6. Attempts to Prevent Disruption.—To prevent the threatened disruption of China three major and widely different efforts were made. One was by the United States. In the autumn of 1899, John Hay, the U.S. secretary of state, asked from England, France, Russia, Germany, Japan and Italy assurances that within their respective spheres of interest they would not interfere with any treaty port or vested interest, that no preferential harbour dues or railway charges would be given their subjects and that the Chinese government should collect the customs duties and only according to the Chinese tariffs. This "open-door policy" was not, strictly speaking, new but was founded upon the most-favoured-nation clauses. Nor was it entirely disinterested. The United States held aloof, to be sure, from the scramble for leases and concessions. but this was partly because the United States was too engrossed in developing the virgin resources of its own land to engage in ventures abroad. On its acquisition of Hawaii and the Philippines, however, the United States had awakened to a livelier interest in eastern Asia, and did not wish doors to be slammed in the faces of its merchants and bankers. All the powers assented to the U.S. note, although Russia did so with slight reservations.

The other major efforts to save China were by the Chinese themselves. After the war with Japan clubs sprang up advocating "reform"—organization on the occidental pattern. That, so the members urged, had been the secret of Japan's victory. The great viceroy Chang Chih-tung came out with a widely read pamphlet, *Learn,* urging reform, although without the abandonment of the best of China's heritage. Some of the extremists, notably the

brilliant but erratic K'ang Yu-wei and his disciple Liang Ch'i-ch'ao, a master of Chinese style, obtained the ear of the emperor, and for a little more than three months in the summer of 1898 edict after edict poured forth from Peking ordering some of the changes which the radicals desired. Compared with what was to happen in the next 25 years, these were moderate enough, but at the time they seemed revolutionary.

The civil service examinations were to be reformed; new schools with western as well as Chinese subjects were to be founded; western military methods and equipment were to be introduced and steps taken looking toward a national army based on conscription; reforms in the courts of law were projected; a government bureau to translate foreign works and a ministry of arts, commerce and agriculture were to be established; patent and copyright laws were to be introduced and rewards offered to authors and inventors; annual budgets of receipts and expenditure were sanctioned; and many sinecure offices were abolished.

Skilled statesmen might have succeeded in carrying through these reforms without provoking a major crisis, but the young emperor knew little of the world of men outside his palace walls, and his radical advisers had little or no experience in government. The inevitable storm, therefore, was intensified, and in Sept. 1898 the empress dowager suddenly intervened and inaugurated a third effort to save China—by a return to the conservative status quo. The coup *d'ktat* was precipitated by the emperor's plan to thwart the reactionaries by placing restrictions on the empress dowager and executing her most loyal henchman, Jung-lu. Information seems to have come to Jung-lu through Yuan Shih-k'ai. and Tz'u-hsi acted promptly. On Sept. 22, 1898, she reassumed the reins of government. She kept the emperor a virtual prisoner and but for the powers might have had him assassinated. As many reformers as could be apprehended were executed, and most of the reform decrees were annulled. Tz'u-hsi attempted to restore the government as it had been and to strengthen it to resist foreign encroachments.

7. Boxer Uprising (1900).—On the heels of the conservative reaction, and in part as a consequence of it, came a blind attempt, largely popular but sanctioned by the extremists, to oust the foreigner once and for all. In 1898 and 1899 unrest was widespread, induced partly by the talk of reform, partly by the aggressions of the powers and partly by the vigorous reaction led by the empress dowager. The government, in an attempt to provide for the national defense against foreign aggression, ordered the revival of the village trainbands or militia and put the plan into effect first in the northeastern provinces. Into these trainbands came many of the local rowdies, and here and there disorderly secret societies affiliated with them. The members practised rites which they believed would make them invulnerable to bullets and came to be known to foreigners as "Boxers"—a loose translation of the Chinese name for the bands, I Ho T'uan or I Ho Ch'uan, "Righteous Harmony Bands" or "Righteous Harmony Fists."

One of the favourite mottoes of the Boxers was "Protect the country, destroy the foreigner." By the autumn of 1899 the Boxers were beginning to persecute Chinese Christians—as "secondary foreign devils"—especially in Shantung, where the anti-foreign Yü Hsien was governor. The powers, alarmed, brought pressure, and, while they obtained the recall of Yu Hsien, he was soon appointed to the governorship of Shansi and unrest increased. An English missionary was murdered the last day of 1899, and by the following June the attacks on Chinese Christians became more frequent and foreigners were in grave danger.

In early June 1900 an unsuccessful attempt of the powers to throw additional troops into Peking aggravated the situation, and when, on June 17, foreigners seized the Taku forts to open the way to Tientsin and Peking, the storm broke. Against the counsel of saner heads, the empress dowager ordered all foreigners to be killed. The German minister was murdered, and the other foreign ministers and their staffs, missionaries and hundreds of Chinese Christians were besieged in the legation quarter and in the Catholic cathedral in Peking. Scores of Roman Catholic and Protestant missionaries and thousands of Chinese Christians were done to death, principally in Hopeh, Shansi and Manchuria. The powers declared that they were not waging war on China but were simply seeking to rescue their nationals and to suppress the Boxers. The viceroys in the Yangtze valley and the south opposed Boxerism and accordingly remained neutral and endeavoured to repress antiforeign outbreaks within their jurisdiction. That attitude was taken also by high officials in most of the west and north. The disorders, therefore, were confined chiefly to the northeast. An international force captured Peking on Aug. 14, 1900, the court fled to Sian, and the foreign troops proceeded to loot the capital and then to relieve scattered groups of missionaries and Christians who had been standing siege and to disperse the Boxer remnants.

Although the powers had not declared war on China, they deemed a formal settlement necessary to exact reparation and to guard against a recurrence of the outbreak. After negotiations, which were prolonged by disagreements among the victors, in Sept. 1901 a protocol was finally signed.

This document provided for the punishment, by China, of some of the officials held chiefly responsible; for memorial monuments for some of the murdered foreigners; for formal missions of apology to Berlin for the death of the German minister; for the suspension for five years of civil service examinations in towns where foreigners had been killed or mishandled; for the prohibition for at least two years of the importation of arms and ammunition; for an indemnity of 450,000,000 taels, to be paid in 39 years and to be secured by the revenues of the imperial maritime customs; for the fortification and policing by foreigners of the legation quarter, the razing of the Taku forts and the maintenance by foreign troops of communication between Peking and the sea; for edicts against antiforeign agitation; for the amendment of the existing commercial treaties; and for transforming the foreign office (Tsungli Yamen) into the chief of the ministries of state, under the name of the Wai Wu Pu.

8. To the Overthrow of the Manchus (1900–11).—The Boxer year inaugurated momentous changes. The empire was clearly at the mercy of the powers, and foreigners acted as though they were living in a conquered country. With the exception of Manchuria, encroachments on Chinese sovereignty were less marked than in 1898 and 1899. The Russians continued their aggressions. The disorders of 1900 had spread to Manchuria, and thither Russia quickly dispatched large bodies of troops, ostensibly to protect its subjects and investments. The Russian forces ruthlessly suppressed all opposition and occupied much of the three provinces. Late in 1900 an agreement between China and Russia promised the latter extensive control in southern Manchuria and was modified only on protest from the other powers. Both Great Britain and Japan were alarmed, the former because of its general fear of Russia in the east and the latter because of the threat to Korea, where Russian machinations were increasing. In defense against the common foe, the Anglo-Japanese alliance was formed (Jan. 30, 1902). Russia, subjected to pressure from these two powers and the United States, promised to respect the commercial rights of all nations, and agreed with China (1902) gradually to withdraw Russian troops from Manchuria. However, Russia found pretexts for delays and sought from China, in return for evacuation, compensations that would have strengthened its hold on the debated territory.

Great Britain, the United States and Japan sought to check Russia. Japan was especially concerned and strove by direct negotiations with St. Petersburg to obtain recognition of its interests in Korea and the promised evacuation of Russian troops from Manchuria. Russia was obdurate and Japan had recourse to arms (Feb. 1904). In the ensuing months the Japanese captured Port Arthur, drove the Russians out of southern Manchuria and destroyed the Russian fleets. In 1905 Pres. Theodore Roosevelt proffered his good offices, hostilities were suspended, and by the resulting treaty of Portsmouth (Sept. 5, 1905) Russia recognized Japan's interest in Korea; transferred to Japan Russian rights in the Liaotung peninsula; ceded to Japan the southern section of the Manchurian railway and the southern half of Sakhalin. Both powers agreed to withdraw their troops from Manchuria; to use the railways in Manchuria, except those in the Liaotung

peninsula, only for economic and industrial and not for strategic purposes; and not to obstruct "measures common to all countries which China may take for the development of the commerce and industry of Manchuria."

The war merely substituted Japan for Russia in southern Manchuria, and the former was no more scrupulous in respecting China's rights than was the latter. Many Japanese contended, indeed, that having spent blood and treasure for Manchuria they had better rights there than the Chinese. By the annexation of Korea (1910) Japan moved its boundary to the southeastern edge of Manchuria and strengthened its interests in Kirin and Liaoning, the southern two of the three provinces.

The suppression of the Boxer outbreak by the powers and the subsequent war between Japan and Russia seriously weakened China. The governmental machinery, which had worked fairly well as long as China had not been in intimate touch with nations as powerful as itself. proved inadequate to meet the strain imposed by the coming of the occident. The Manchus would have to show unusual ability if they were to save their throne, and the Chinese if they mere to avoid anarchy.

After 1900 and especially after 1905 both Chinese and Manchus set about the reorganization of the country. Even the most conservative could not fail to read the signs of the times, and the empress dowager, doubtless reluctantly and with many misgivings, attempted to direct the reform which she could no longer avert. In 1902 the court returned to Peking and the empress dowager set herself to win the friendship of the foreigners, addressing herself especially to the ladies of the legations.

Much more important was the sanction she gave to decrees that sought to aid and to regulate the introduction of western civilization.

In 1902 orders were issued to remodel public instruction by the creation of new schools and by the introduction of western subjects in the curriculum. In Sept. 1905 a decree was promulgated abolishing that most characteristic feature of the old educational system, the civil service examination. Partly as a result of these orders and partly in consequence of the general movement for reform, schools teaching Chinese and western subjects sprang up by the thousands. The old examination stalls were razed and on some of the sites rose buildings dedicated to the new learning. Many temples were converted for educational purposes. By the end of 1910 there were 35,198 government schools with 875,760 pupils. Protestant mission institutions, once the unpopular representatives of a new learning, were now thronged and new ones were opened. Thousands of students flocked to Japan, there to study in modern schools. and hundreds went to Europe and the United States. When in 1908 the United States announced its purpose to return a portion of its share of the Boxer indemnity, the sums remitted were set aside for scholarships to enable Chinese to study in the United States. With the new schools came a flood of literature treating of western ideas, and publishing houses, notably the Commercial Press, arose to give it circulation.

With educational reform went efforts to put the country in a better state of defense. The foreign drilling of the northern army continued; throughout the country troops were trained in the new ways. greater honours mere paid to military officers, and in 1906 steps were taken toward the creation of a national force as contrasted with the older provincial forces.

In 1910 slavery was abolished, but since that institution was never so prominent in China as in parts of the occident the step did not entail marked revolution. Vigorous efforts were made to stamp out the opium trade, an imperial edict of Sept. 1906 inaugurating the campaign. The British government, under whose protection much of the foreign trade in the drug was carried on, in 1907 agreed to reduce the importation concurrently with the progressive abolishment of the domestic growth of the poppy, at a rate which would extinguish the trade in ten years. The restriction on poppy growing proved so much more rapid than was anticipated that in 1911 Great Britain agreed to the complete exclusion of the foreign drug from the provinces where the culture had ceased.

Governmental reorganization also was undertaken. In 1902 a commission on juridical reform was established and in 1905 reported. recommending the modification of the laws. As a beginning, torture, except in criminal cases, and certain cruel forms of punishment were ordered to be abolished. The reorganization of laws and judiciary mas not sufficiently thoroughgoing, however, to cause the powers to dispense with extraterritoriality. The reform of the currency was discussed, but nothing effective was accomplished, and with the appearance of new coins the previous confusion became worse confounded.

Most important of all the governmental reforms was the attempt to introduce a constitution with representative assemblies. In 1905 a commission was sent abroad to study constitutional methods, and on its return in 1906 a promise was made to introduce a parliamentary form of government. That same year, as a preliminary, changes were made in the organization of the central administrative boards in Peking.

In Aug. 1908 an edict promised the convocation of parliament in nine years, but the death of the emperor and of the empress dowager in November of that year brought postponement. The new emperor, P'u-i, a nephew of the childless Kuang-hsii, was an infant of two and one-half years, and his father, Prince Ch'un, was appointed regent. The new reign was given the title of Hsuan-t'ung. Shortly after its beginning the regency was deprived of the support of one of the strongest Chinese by the forcible retirement of Yuan Shih-k'ai, as a punishment, so rumour had it, for his alleged betrayal of the regent's brother, the late emperor, in 1898.

Constitutional reform was delayed only by the change in rulers, and that briefly. In 1909 provincial assemblies met, chosen by a limited electorate, and in Oct. 1910 the national assembly convened. half of it elected and half appointed by the throne. The national assembly demanded the right to legislate, but for the time could gain merely the promise of the convocation of a parliament with legislative powers in 1913 rather than in 1917.

Along with changes in education and government went other sweeping alterations in the nation's life. Several of the railways authorized before 1900 were constructed, bringing great modifications in transportation. Foreign shipping increased on the coastal waters and the Yangtze, telegraph lines aere extended, and the business of the post office multiplied. Foreign commerce more than doubled in the decade after 1901, and foreign merchandise penetrated to the remotest hamlets. The numbers of missionaries rapidly increased, and both the Catholic and Protestant communities showed a phenomenal growth.

After 1900 a more radical movement looking toward overthrow of the Manchu dynasty began to gain strength among Chinese abroad and to penetrate secretly into the empire. Revolutionary leaders found recruits among the thousands of Chinese students studying in Japan. On their return to China many of these students secured ,positions of influence in education, journalism and the army. hlagazines preaching revolution as well as those urging reform were printed in Japan and smuggled into China.

Merchants overseas contributed funds. Anti-Manchu secret societies in south and west China were rejuvenated. Several short-lived uprisings occurred. Sun Yat-sen and Huang Hsing were but two of many revolutionary leaders.

9. End of the Ch'ing.—In 1912 the rising tide of change swept aside the Manchus. Ever since the conquest in the 17th century most of the Manchus had lived in comparative idleness, supposedly a standing army of occupation, but in reality inefficient pensionaries. All through the 19th century the dynasty had been declining, and in the death of the empress dowager it lost its last able leader. In 1911 the emperor was an infant and the regency utterly incompetent to guide the nation through the stormy waters ahead. The unsuccessful contests with foreign powers had shaken not only the dynasty but the entire machinery of government. The ferment of new ideas was already weakening the ancient wineskins, and only strong and wise leadership could prevent loss to both. Under the circumstances almost any incident might have toppled the Manchus off the throne.

The chain of events immediately leading to the revolution began with the signing (April 5, 1911), with a four-power group of

foreign bankers, of the Hukwang railway loan agreement for the construction of roads in central China. The Peking government decided to take over from a local company a line in Szechwan, on which construction had been barely begun, and to apply part of the loan to its completion. The sum offered did not meet the demands of the stockholders, and in Sept. 1911 the dissatisfaction boiled over into open revolt. On Oct. 10, in consequence of the uncovering of a plot in Hankow which had little or no connection with the Szechwan episode, a mutiny broke out among the troops in Wu-ch'ang, and this is regarded as the formal beginning of the revolution. The mutineers soon captured the Wu-ch'ang mint and the arsenal at Wu-ch'ang, and city after city declared against the Manchus. The regent, panic-stricken, granted the assembly's demand for the immediate adoption of a constitution, and urged Yuan Shih-k'ai to come out of retirement and save the dynasty. Yuan, after much hesitation, accepted on his own terms, and at the end of October took the field at the head of the northern armies. In November he was made premier.

Had Yuan acted vigorously he might have suppressed the uprising and so have delayed the inevitable. He dallied, however, and by the end of the year 14 provinces had declared against the Manchus, in several cities Manchu garrisons had been massacred, the regent had been forced out of office, a provisional republican government had been set up at Nanking, and the archrevolutionist Sun Yat-sen had returned from abroad and had been elected president.

In December Yuan agreed to an armistice and entered upon negotiations with the republicans. On Feb. 12, 1912, the boy emperor was made to abdicate the throne in a proclamation that transferred the government to the people's representatives, declared that the constitution should thenceforth be republican and gave Yuan Shih-k'ai full powers to organize a provisional government. The Nanking authorities agreed that the emperor was to retain his title for life and to receive a large pension. To unify the country, Sun Yat-sen resigned the presidency and Yuan was chosen in his place. Li Yuan-hung, who had come into prominence in Wu-ch'ang in the initial stages of the rebellion, was elected vice-president. A provisional constitution was promulgated in March 1912 by the Nanking parliament, and in April the government was transferred to Peking.

F. The Republic

The republic, established with such startling rapidity and comparative ease, was destined to witness the progressive collapse of national unity and orderly government. The causes for this chaos were, in the main, three. In the first place, traditional processes were being repeated. The demise of every dynasty had been followed by civil strife, in which rival military chieftains struggled for the throne. The disorder usually lasted for decades, and once, after the downfall of the Han dynasty, was prolonged for nearly four centuries.

The peaceful transfer of power to Yuan Shih-k'ai under the guise of a republic for a time mitigated the struggle and even seemed to have averted it. Yuan, however, did not prove strong enough to hold the country together. The country was broken up into ever-smaller fragments, most of them ruled by military chieftains. After Yuan's death (1916) the political map was seldom the same two years in succession.

In the second place, the chaos was accentuated by new ideas from the west. The governmental machinery which on the whole had worked better over a longer period than any other ever devised for so numerous a people was being abandoned. It was ill-adapted to the new conditions, and theoretical radicals, imbued with occidental ideas, and militarists tended to ignore it or to modify it more greatly than at any time since the Han. Such thoroughgoing political experimentation meant chaos, and new institutions were not quickly evolved for so enormous a section of mankind.

In the third place, the disorder was increased by the interference of foreigners. Japan was vitally concerned in the fate of its huge neighbour. The Japanese population was steadily increasing, no adequate relief could be had through emigration, and Japan's only recourse mas to add to its income by engaging in industry and commerce. If it were to do this. it must have access to raw materials, including coal and iron, and to markets. For these it most naturally looked to the adjoining continent and especially to China. Japan's life depended. therefore, upon keeping open the trade with China, and it is not surprising that it sought to control portions of the republic and at times meddled in Chinese politics. To Japan were added other powers, especially the Soviet Union. Beginning about 1922, but especially after 1925, Russian Communists sought to extend their influence into China and to foment the kind of revolution that had been achieved at home.

It must be noted, however, that activities of foreigners helped to bring union as well as disunion. Resentment against the foreigner mas the one issue on which the vocal elements of the nation could unite; railways and telegraph lines — both of foreign origin — helped to bind the country together, and the foreign-controlled customs service and the foreign-organized postal system were the only governmental agencies that continued to function over all the country.

1. Under Yüan Shih-k'ai.—For four years Yuan Shih-k'ai was able to delay the further disintegration of China. He faced no easy task. The radicals. who in Aug. 1912 took the party name of Kuomintang, regarded him with suspicion, and, obtaining a majority in the parliament that assembled in 1913 under the provisional constitution of 1912, demanded a type of government in which the legislature should be supreme and the president a figurehead. Rival military leaders were beginning to appear, and grave financial difficulties faced a government whose fiscal machinery, already decrepit, had been disturbed by the revolution. The confidence of the powers, moreover, was not yet given the new regime.

In the face of all these difficulties Yuan for a time achieved marked success and gradually restored in the provinces the authority of the central government. In April 1913, after prolonged negotiations, he concluded a "reorganization" loan with a financial group representing Great Britain, France, Russia. Germany and Japan. The loan, a large one, was secured by a lien on Chinese revenues, chiefly on the income from the salt monopoly — now put under foreign supervision. His financial position and the moral support of the powers thus assured, Yuan proceeded to defy the members of the Kuomintang. The latter had sought to block the loan and saw in its conclusion grave danger to themselves. They continued obstructionist policies, and, as Yuan still prevailed, in the summer of 1913 some of them, including Sun Yat-sen and Huang Hsing, declared a "punitive" expedition against him and for a while held Nanking. Yüan promptly put down the rebellion, and, after obtaining the ratification of the articles of the "permanent" constitution which had to do with choosing the president, and being elected under them (Oct. 1913). he outlawed the Kuomintang (Nov. 1913) and unseated its members of parliament. A few weeks later he disbanded what remained of parliament, replacing it with an administrative council selected by himself. In March 1914 the provincial assemblies were dissolved. A new constitution, framed by a body controlled by Yuan, was promulgated in May 1914. The president's power was greatly strengthened, his term was lengthened to ten years, and he might be rechosen by the council of state or control the election of his successor. In 1914 Yuan performed the imperial ceremonies in the Temple of Heaven at the winter solstice. He seemed to be winning against the opposition and in 1915 prepared to take the further step of having himself formally chosen and proclaimed emperor.

However, opposition developed both within China and among various foreign powers, particularly Japan, which was supported by its wartime allies Great Britain, France and Russia. A rebellion broke out in Yünnan and spread to other provinces of the south. The Kuomintang established a rival government at Canton. Opposition mas so formidable that Yuan rescinded the monarchy in March 1916; on June 6 he died. (*See* also YÜAN SHIH-K'AI.)

With Yuan removed, the country appeared quickly to unite. Li Yiian-hung, unopposed, succeeded to the presidency; Tuan

Ch'i-jui, appointed by Yüan in the last few weeks of his life, continued as premier and brought to the support of the new government some of the northern military chiefs. The parliament of 1913, reassembling, brought back to Peking many of the Kuomintang. The government seemed to be further strengthened by the election to the vice-presidency of Feng Kuo-chang, dominant in the lower part of the Yangtze valley.

The very strength of the new government however, was its weakness, for it was made up of elements that were fundamentally discordant and that any crisis might set at loggerheads. This crisis was to grow out of international reactions in which China was inextricably involved.

2. Foreign Relations (1911–17).—The revolution did not immediately bring marked change in China's foreign relations. Tibet and Outer Mongolia, at best never very firmly attached to the empire, took the opportunity afforded by the shift in governments to effect their virtual independence, and Great Britain in the former case and Russia in the latter were not slow to attempt to extend their influence over territories that abutted so directly upon their own. China recognized the autonomy of Outer Mongolia in return for the acknowledgement of Chinese suzerainty, but it was less pliant in yielding to British ambitions in Tibet. On the whole, the powers made little objection to the establishment of the republic.

The outbreak of World War I, however, brought serious difficulties. With Europe absorbed in internecine strife, Japan saw a golden opportunity to extend its power in China. The Anglo-Japanese alliance afforded it a welcome excuse for seeking to eliminate Germany from the far east. Accordingly, in Aug. 1914 Japan dispatched an expedition to Shantung and, with the cooperation of a small British force, captured Tsingtao and the other German possessions in the province.

This was only a beginning. In Jan. 1915 Japan presented 21 demands that, if accepted, would strip China of its suzerain power and hand over to Japan railway, mining and other rights in Shantung, thus placing the Japanese in complete dominance. Japan attempted to keep the demands secret, but they became known and a wave of indignation swept over China; criticism also was expressed publicly and vigorously in Great Britain and the United States. The Japanese were constrained to make important concessions, but they had the upper hand; they presented an ultimatum to which China, helpless, had to submit. Early in 1917 Japan made secret arrangements with Great Britain, France and Italy nhereby those powers assured their support of Japanese demands at the peace conference for the former German holdings in Shantung.

As World War I progressed, pressure was brought upon China to enter the struggle on the side of the Allies. In Feb. 1917 the United States invited the Chinese government to follow its example in protesting against Germany's submarine campaign and severing diplomatic relations, and the Franco-Japanese secret notes of March 1, 1917, promised Japanese support to the effort to induce China to take the step. On Feb. 9 the Chinese foreign officesent warning to Germany and on March 14 broke off diplomatic intercourse. The question whether China should actually declare war precipitated a contest among the principal contenders for control of the government. The step was taken on Aug. 14, 1917, when China formally declared war on Germany.

The country had already begun to disintegrate politically. The Kuomintang members of the dismissed parliament denounced the Peking government as illegal, and, under the leadership of Sun Yat-sen, in Sept. 1917 organized a provisional government, which they declared to be the only constitutional one in China. The powers did not grant it recognition, however, and it maintained a precarious existence, usually with headquarters at Canton. In the north Tuan Ch'i-jui and his supporters, the so-called Anfu group, were for several years in the ascendant.

3. World War I and the Peace Conference.— In the meantime World War I was drawing to a close. China's internal discord and financial straits were such that the country could take no active part in the struggle, although recruiting of about 175,000 Chinese citizens for labour battalions was permitted.

China gained slightly by its entry into the war. It took over the German and Austrian concessions in the ports, canceled the unpaid portions of the Boxer indemnities due its enemies and was permitted to suspend payments on the sums due to the Allies. China was assured a seat at the peace conference.

In contrast with these gains, however, was an increased control by Japan. In Nov. 1917 the United States, in an effort to adjust its difficulties with Japan, entered upon the Lansing-Ishii agreement (terminated March 30, 1923), by which it recognized that because of "territorial propinquity . . . Japan had special interests in China," and so seemed to have delivered China over to Japan. The Anfu clique around Tuan Ch'i-jui concluded agreements with Japan for the construction of railways in Shantung, Manchuria and Mongolia (Sept. 1918) and borrowed extensively from the Japanese on the security—some of it extremely dubious—of railways, mines, forests, telegraphs, taxes and bonds.

To the peace conference that terminated the war the Chinese sent an able delegation representing, by a strange but characteristic anomaly, both the Peking and the Canton governments. The delegation asked not only for the restoration to China of the former German properties in Shantung but also for the cancellation of spheres of influence; withdrawal of foreign troops, post offices and nireless and telegraphic communications; abolition of consular jurisdiction; tariff autonomy; relinquishment of leased territories; and restoration of foreign concessions and settlements. China was doomed to disappointment. The U.S. delegation favoured the restoration of the Shantung properties, but against it were the agreements of 1917 between Japan and the European Allies. By the treaty of Versailles. therefore, Japan was confirmed in the possession of its holdings in Shantung. The remaining questions were held not to come within the purview of the conference.

When news of the Versailles settlement reached China there was immediate widespread protest. On May 4, 1919, students in Peking began a demonstration against the pro-Japanese government. This patriotic movement spread rapidly to other cities and won the support of other groups in the population. The Peking government had to instruct the Paris delegation to refuse to sign the treaty with Germany. A very effective nationwide boycott against Japanese goods was also instituted by patriotic groups. This patriotic outburst, known as the May 4 movement, had wide ramifications. It developed under the leadership of western-trained professors and their university students into a broad movement for reform and rejuvenation of Chinese life in all aspects.

China was not to emerge from the war without some gains, however. It obtained membership in the League of Nations by signing the treaty with Austria, for that document did not contain the objectionable Shantung clauses, and in its separate treaty with Germany the German share of the Boxer indemnity and German extraterritorial privileges were canceled. A significant breach had been made in the wall of foreign "rights" in China.

4. Washington Conference **(1921–22).**—After the war the U.S. continued its active participation in Chinese affairs by bringing about (1920) a financial consortium whose purpose was to assume international control of all further foreign loans to China and so to prevent the granting of special privileges to individual nations.

In 1921 and 1922, moreover, the United States called the Washington conference, and China again had the opportunity to lay its case before the world and to ask for the elimination of the special privileges that foreigners enjoyed within its borders. Not all the agreements and treaties that resulted from the conference affected China, but the Chinese question loomed larger than any other except possibly that of disarmament. The most important actions, in so far as they concerned China, were as follows:

1. The treaty limiting naval armaments and fortifications confirmed Japan in the domination of the northeastern coast of Asia. No sea power could now hope easily to penetrate by force through the islands to the coast of China, as the United States and Great Britain found during World War II.

2. Nine powers agreed by treaty to respect the sovereignty, independence and territorial and administrative integrity of China, to give China opportunity to develop a stable government, to maintain the

principle of equal opportunity in China for the commerce and industry of all nations and to refrain from taking advantage of conditions in China to seek special privileges that would abridge the rights of subjects or citizens of friendly states.

3. The customs schedule of duties was within four months to be raised to an effective 5%, and provision was made for the convening of a special tariff conference and for the periodical readjustment of the customs tariff.

4. A board of reference was to be established in China to which questions connected with the enforcement of the "open door" and equal railway rates could be referred.

5. A resolution expressed the sympathy of the powers with China's desire to see removed "immediately or as soon as circumstances will permit existing limitations upon China's political, jurisdictional and administrative freedom," and provided for the early establishment of a commission to inquire into the practice of extraterritoriality in China and the progress in judicial reforms.

6. On Jan. 1, 1923, foreign postal agencies in China were to be abolished.

Several other resolutions expressed the good intentions of the powers toward China. (See also WASHINGTON, TREATIES OF; WASHINGTON CONFERENCE.)

The Washington conference also afforded Japan and China an opportunity to come to an understanding over the Shantung question. Following the signing of the treaty of Versailles, Japan had made attempts to adjust the dispute, but always on conditions that had been rejected by the Chinese. Now, however, Japan adopted a much more conciliatory attitude, and an agreement was reached whereby the former German holdings in Shantung were to be returned to China. However, the Japanese retained a share in some mines in the province and large commercial interests and landholdings in Tsingtao.

Several of the promises made to China at Washington were carried out. The foreign post offices were discontinued at the designated time. A special conference on the tariff convened in Peking in Oct. 1925 and. going beyond the assurances previously given, permitted the consideration of the entire question of tariff autonomy. Because of the disintegration of the Chinese government, the gathering broke up before a treaty was framed. but the foreign delegates agreed to the removal of tariff restrictions and consented to the putting into effect of the Chinese national tariff law on Jan. 1, 1929. The Chinese for their part promised to enforce the national tariff law and to abolish likin, long obnoxious to foreigners, on the same date.

Japan, moreover, continued conciliatory. While it declined to accede to the Chinese demand, made in 1923, for the abrogation of the agreements of 1915, until 1931 it entered upon no new marked aggression.

The powers also seemed about to remit the unpaid portions of the Boxer indemnity. The United States acted finally in Rfay 1924, and Great Britain, France, Japan and the Soviet Union took preliminary steps looking toward the same end. All plans for remission, however, called for the allocation of the funds to educational or other cultural projects.

5. Domestic Politics.—While China was making progress toward regaining the special privileges that had been wrested from it by the powers, internally its government was rapidly disintegrating.

At the close of World War I Hsü Shih-ch'ang was in the presidency and Tuan Ch'i-jui was in control. A separate government was maintained at Canton, largely by members of the Kuomintang, under the leadership of Sun Yat-sen. For a time Sun was ousted from Canton by a Kwangsi faction, but he was restored and in April 1921 was elected "president of the Chinese republic" by such members of the parliament of 1913 as could be got together. However, Sun secured only a precarious foothold in Canton and a part of Kwangtung. Most of southern China was a medley of petty factions and quarreling war lords.

Conditions were little better in the north. In 1920 the outstanding leaders were Wu P'ei-fu, his titular superior Ts'ao K'un, and Chang Tso-lin, the master of wealthy Manchuria. In the summer of 1920 these three united to drive Tuan and the Anfu leaders out of power. Wu P'ei-fu and Chang Tso-lin could not long co-operate, and in 1922 Wu defeated the latter and drove him back into Manchuria.

Wu now took steps which he hoped would unify the country. Hsü Shih-ch'ang resigned the presidency, Li Yüan-hung was reinstated in that office, and the parliament of 1913 was recalled to Peking. Thus the last officers around whom the entire country had seemed to unite were reinstated.

Hopes for a unified China proved illusory. Funds were insufficient, cabinets unstable, parliament venal and militarists intransigent. The disintegration that had set in after the death of Yuan Shih-k'ai became complete. China was torn by rival military factions that year after year launched campaigns against each other, conscripted troops, levied burdensome taxes and disrupted the economy.

6. Nationalism **and** Communism.—During the early years after World War I two interrelated developments of great significance occurred: the rise of nationalism and the emergence of the Chinese Communist movement. The Communist party was founded by a group of intellectuals, some of them leaders in the May 4 movement, who had turned to Marxism for a possible solution to China's weakness and political instability. With the help of an adviser from the Comintern, the party was organized in July 1921, though there were then only a few score members. The party devoted itself at first to organizing labourers and publishing propaganda journals. In Moscow the Communist international at its second congress in July-Aug. 1920 had adopted a strategy with respect to colonial peoples that called in the first place for cooperation between Communists and other parties in movements for national liberation. Applied to China, this strategy was interpreted to require an entente between the Communist party and the Kuomintang. It took several years for Comintern agents to convince both parties of the desirability of this program. By the summer of 1923, however, the details had been worked out and the U.S.S.R. had promised help to Sun Yat-sen, who was attempting to establish a government in Canton.

In Sept. 1923 Mikhail M. Grusenberg, better known as Mikhail Borodin (*q.v.*), arrived in Canton and soon became Sun Pat-sen's adviser in a program of reorganizing the Kuomintang into a strong, disciplined and centralized party. Communists were to be admitted to the Kuomintang as individuals and to assist in an attempt to reunite the country and free it of foreign encroachments. Russian advisers, money and arms flowed into Canton to aid in the creation of a Nationalist army. After Sun's death on March 12, 1925, his party glorified him as a national hero and made his Three Principles of the People—nationalism, democracy and livelihood—a bible.

In the latter part of 1925 the Nationalist movement was directed sharply against Great Britain, the occasion being a sequence of clashes between British authorities and Chinese in Shanghai and Canton during which many Chinese were killed. Hong Kong was tied up for months by boycott and widespread strikes. Patriotic students flocked to the Kuomintang and many into the Communist party as well. Communist members of the Kuomintang were particularly active in the anti-imperialist movement and in organizing labourers and poor peasants to demand better economic conditions. The movement at Canton under the leadership of Borodin and some of Sun's more radical lieutenants veered increasingly to the left. In the meantime the new Nationalist army was consolidating the power of the Kuomintang in Kwangtung.

Not all leaders of the Nationalist party approved of the Communists, but some hoped to use them to achieve Nationalist aims. The Communists likewise hoped to use the Kuomintang. Great tension existed within the coalition.

In the summer of 1926 the Nationalist armies, led by Chiang Kai-shek. began a triumphant march northward, and by winter they had driven Wu P'ei-fu into Honan and practically eliminated him, were in possession of the Wu-han cities—Hankow, Wu-ch'ang and Han-yang—and the Kuomintang had moved its capital to Hankow.

The victories had been achieved as much by skilful propaganda as by force of arms. Wherever the Nationalist forces came, trained agitators directed popular sentiment against the treaties and foreign merchants and against Christian schools, churches and hospitals as imperialistic. Kuomintang agitators also organ-

ized labourers and peasants to make exorbitant demands of employers and landlords, and in some places, notably Hunan and Hupeh, a reign of terror followed in which many of the propertied class were dispossessed and even executed.

Educated Chinese, weary of the long civil strife and smarting over China's feeble position among the nations, hailed the advance of the Kuomintang, which continued with amazing rapidity. By March 1927 the Chinese had taken over the British concessions in Hankow and Chiu-chiang; British and U.S. merchants and missionaries were being evacuated from much of the Nationalist territory; Sun Ch'uan-fang, recently strongly entrenched in Chekiang and Kiangsu, was in full flight, his armies a disorganized rabble; and only strong forces of foreign marines kept the Nationalist armies out of the foreign settlements in Shanghai. The northern military chiefs. alarmed, had put themselves under the direction of Chang Tso-lin to stem, if possible, the oncoming flood.

The radicalism of the Communists during the northern expedition inevitably produced a reaction. Merchants, landlords, army officers and many other groups who found themselves menaced offered support to conservative leaders in the Kuomintang if they would rid the party of its radical wing. With victory in sight, tension between right and left grew sharper. Chiang Kai-shek became the centre of the anti-Communist movement. In March 1927 Nationalist troops, entering Nanking, looted foreign dwellings, robbed foreigners and killed several of them, until further loss of foreign lives was prevented by the fire of British and U.S. gunboats in the Yangtze river. One effect of this incident was to widen the breach within the Kuomintang.

In the Chinese section of Shanghai, labour unions under leadership of the left wing had risen in a general strike, disarmed police and driven out some of the northern troops. On April 12, shortly after the Nationalist army arrived in Shanghai, Chiang Kai-shek instituted a bloody purge to stamp out the Communists and leftist Kuomintang elements in the city. The purge quickly spread to other regions under control of conservative military commanders. Chiang then set up a government in Nanking as a rival to the one in Hankow. The irreconcilable cleft between Communists and Nationalists dates from this period.

The Nationalist advance was halted by these internal dissensions, and the party continued to divide. By autumn 1927 the anti-Communist reaction was under way, Borodin and other Soviet advisers were evicted from Hankow, and in many places Chinese Communists were being hunted down and executed.

In 1928 the Nationalists, reorganized under moderate and conservative leaders and with headquarters at Nanking, began a new northward advance. Chiang Kai-shek led, in co-operation with Feng Yu-hsiang and Yen Hsi-shan. A serious clash with Japanese troops occurred in May in Tsinan, and a partial reoccupation of Shantung by Japan followed. In spite of this, however, the Nationalists pushed on and in June entered Peking. Chang Tso-lin was killed by a bomb as he was retiring into Manchuria, and his son, Chang Hsueh-liang, succeeded to the command of his forces. Because of Japanese opposition, Manchuria did not formally join the Nationalists, but Chang Hsueh-liang was given a place on the chief council of the Nanking government. The major armed opposition to their rule having been eliminated, the Nationalists moved the capital from Peking (now renamed Peiping, "Northern Peace") to Nanking and in October set up an administration reorganized to conform to Sun Yat-sen's program, with Chiang Kai-shek as the ranking official.

7. Domestic Events (1928–37).—In domestic politics the years 1928–37 were stormy, but, on the whole, progress toward a more stable regime was made. Throughout the period the most prominent figure in the central government was Chiang Kai-shek. So vigorous a man inevitably had his enemies, but he retained his control of the army and accordingly continued the dominant leader. More serious was the recalcitrancy of the south and west. Only slowly, and then largely because of the necessity of presenting a common front against the Japanese, did Kwangtung. Kwangsi, Yunnan, Kweichow and Szechwan fall into line with Nanking.

The greatest domestic menace to Chiang Kai-shek and the Kuomintang was the Communist movement. After the purges of mid-1927 the Communist party turned to armed force to overthrow its rival. Only gradually was it able to create armed bands of peasants and deserting soldiers, seize control of inaccessible bits of territory and begin to create soviet districts. It appealed to tenant farmers, landless labourers and others upon whom the existing rural order bore most heavily. Terrorism was widespread, and persons of property were dealt with cruelly. In essence the movement depended on peasant revolt. By 1930 the Communist army had become a sizable force and Soviet regions covered large areas in Kiangsi, Fukien, Hunan and Hupeh.

The Nanking government launched five campaigns between Dec. 1930 and Oct. 1933 in an attempt to destroy the Communist army and capture the Soviet bases. Finally by Oct. 1934 the main Communist forces were driven out of their chief base in southern Kiangsi. They executed a long retreat, marching and fighting through most of the southern and western provinces of China, arriving in north Shensi one year later. In the meantime Japan had seized Manchuria and was seeking to detach north China (see below). The Communists skilfully employed the rising patriotic sentiment to blunt the Nationalist attacks against themselves, urging an end of civil war and a united front of all parties and armies against Japan. This program appealed especially to the Manchurian troops of Chang Hsueh-liang who were being used to fight the Communists in north Shensi. When Chiang Kai-shek went late in 1936 to Sian to push the campaign, he nas seized by Chang Hsueh-liang, who demanded the end of the civil war against the Communists, a reorganization of the government with more toleration for the opposition and, above all, a united front against Japan.

Although Chiang Kai-shek was released without publicly acceding and Chang Hsueh-liang was technically punished, in effect the dramatic incident was the precursor to the easing of the war against the Communists and to the eventual co-operation of the latter in the defense against Japan.

In many ways advances were being registered by the Nationalist government: officials of modern training were being introduced; education throughout the country was undergoing improvement at all levels; public health measures to cope with contagious disease were being widely adopted; one post-office administration, one customs service and one system of coinage extended throughout the country. Painfully and with occasional lapses China was advancing toward unification and a better and more stable government.

The improvement in internal order must not be exaggerated, however. Much of it depended precariously upon the life of one man, Chiang Kai-shek. Dissension among leaders had not been eliminated. Over several provinces even of China proper Nanking exercised no effective control. In the outlying dependencies, only in Sinkiang, in portions of Inner Mongolia and here and there on the borders of Tibet did Nanking exert even a shadow of power. The world-wide financial depression brought embarrassment, especially beginning in 1934 with a rise in the price of silver and, accordingly, a fall in other price levels. In the autumn of 1935 the government felt itself forced to nationalize all the silver and to go officially on a managed currency. Yet nearly every year witnessed some gains. Even those provinces that did not tolerate the interference of Nanking in their internal affairs usually permitted the Nationalist government to speak for them in relations with other nations.

For more than two years after 1928 China seemed to be making progress toward emancipation from the "unequal treaties." In 1929 the British returned to Chinese administration their concession in Chen-chiang and the next year their concession in Amoy. In 1929 Belgium consented to the cancellation of its concession in Tientsin. In 1928 and 1929 nearly all the western powers and in 1930 Japan formally assented to the resumption by China of its tariff autonomy. On Feb. 1, 1929, accordingly, the Chinese government put into effect a schedule of duties determined by itself. Moreover, effective Chinese control over the customs administration increased.

China also seemed to be making headway toward the abolition of extraterritoriality. Several of the smaller powers assented to

the jurisdiction of Chinese laws and courts over their citizens. In July 1928 the Nanking government announced that all "unequal treaties . . . which have already expired shall *ipso facto* be abrogated" and that it mould take immediate steps to end those "unequal treaties which have not yet expired and conclude new treaties." A number of the powers against which China adopted specific measures protested. Eventually several assented, but only on certain conditions. However, Great Britain. Japan. France and the United States, together with some of the smaller countries, held out. In Dec. 1929 Kanking announced that extraterritoriality would come to an end on Jan. 1, 1930, but postponed putting the order into effect pending suitable provision for the trial of cases involving foreigners. The needed regulations were framed and were announced to be operative on Jan. 1, 1932. Before that day arrived, however, events in Manchuria precluded carrying out the plan.

For several years after 1927 the relations of Nanking with Moscow were much of the time either strained or decidedly unfriendly. The Kanking government had been established in an anti-Communist reaction and could scarcely be expected to look upon the U.S.S.R. with cordiality. The joint operation by Russians and Chinese of the Chinese Eastern railway, in Manchuria, made for irritation. In 1929, indeed, the Chinese dismissed and arrested the Soviet officials associated with the railway. In Jan. 1930 a Russian invasion forced the Chinese to assent to the restoration to the Soviet Union of its former share in the control of the line. The U.S.S.R., moreover, had Outer Mongolia in its orbit and appeared to threaten the remnants of Chinese authority in Sinkiang. By the end of 1932, however, Russo-Chinese relations became much more friendly, especially since both nations found common cause in their apprehension of Japan.

8. Japanese Aggression.—It was from Japan, as has been suggested, that the greatest external menace arose to the territorial integrity and independence of China. Since the Washington conference the attitude of the Japanese government toward China had usually been one of moderation and restraint.

In Manchuria, however, a serious conflict was developing. There the Chinese were especially restive under the privileges held by the Japanese. Chinese formed the vast majority of the population, and the legal title of the region was held by China, yet Japan controlled much of south Manchuria through its railways and its leasehold on the Liaotung peninsula, and in other ways compromised Chinese sovereignty. The Chinese began building a series of railroads that would in part encircle the Japanese lines, debouch at Hulutao, a port which the Chinese were developing, and make them partially independent of the Japanese. Chang Hsüeh-liang, the ruler of Manchuria, was disposed more and more to ally himself with Nanking and to sympathize with the Kuomintang and its desire to rid China of foreign control. The Japanese, on the other hand, had large investments in Manchuria.

In the summer of 1931 the friction expressed itself in minor incidents. Those in control of the main body of Japanese forces in Manchuria believed that the time had passed for temporizing and compromise, and on the night of Sept. 18–19, 1931, alleging that Chinese had blown up part of the track of the South Manchuria railway near the city, seized Mukden.

In the next few weeks the Japanese occupied other cities in Manchuria and demolished Chang Hsüeh-liang's power north of the Great Wall. Having destroyed the only effectiveChinese rule in Manchuria, the Japanese, compelled to preserve order to protect their own interests and not disposed to annex the region outright, stimulated native leaders, largely Chinese, to set up local governments. Early in 1932 these were organized, with Japanese direction, into a new state called Manchoukuo, which on Feb. 18, 1932, declared its independence and called to its head P'u-i. the last Manchu emperor of China. Later in the year Japan accorded Manchoukuo official recognition and entered into a defensive alliance with it.

Nanking, unable to offer effective armed resistance to Japan, presented its case to the League of Nations, which attempted to induce Japan to withdraw its troops to the zone of the South Manchuria railway, and in time appointed a commission, headed by Lord Lytton, to investigate. The commission's report, made in the autumn of 1932, in the main found Japan to be at fault and proposed a procedure for settling the dispute that would preserve China's sovereignty. On Feb. 24, 1933, the assembly of the League took action against Japan, recommending a method of effecting an adjustment that Japan would not accept. Soon thereafter Japan announced its resignation from the League.

The United States. at times acting in close co-operation with the League, attempted to induce Japan to keep the peace and declined to recognize Manchoukuo. The U.S.S.R., while deeply interested. was not disposed to go to mar to keep Japan out of the Russian sphere of influence in northern Manchuria.

The Chinese, powerless to oppose effective military resistance, had a weapon in the boycott, which they invoked at great cost to Japanese trade. The Japanese objected, friction became acute and fighting broke out in Jan. 1932 at Shanghai; in the ensuing warfare Japanese forces laid waste a large portion of the city. The Chinese offered a much sturdier defense than had been expected, but eventually were driven back. Due in part to the good offices of the League. fighting ceased in March 1932.

Chinese anti-Japanese activities continued in Manchuria, largely through irregulars. Chang Hsueh-liang, for a time with his headquarters at nearby Peiping (Peking), was a source of irritation. The Japanese, too, wished to add the province of Jehol (now Ch'eng-te) to Manchoukuo. In Jan.–Feb. 1933, Manchoukuoan-Japanese forces occupied Jehol, and Chang Hsueh-liang. his prestige badly damaged, soon resigned and left for Europe. When he returned. it was to a post in Hupeh and then in Shensi. In April 1933 the Japanese, annoyed by raids from south of Jehol, advanced within the Great Wall. The Chinese were forced to withdraw and on May 31 Nanking found it advisable to enter into a truce, setting up a demilitarized zone south of the Great Wall, in the northeastern part of the province of Hopeh. Strangely enough, however. in all this time war was not officially declared and regular diplomatic relations were maintained between the two governments.

The truce of May 1933 established a modus vivendi that was in effect a treaty of peace and that tacitly (although not explicitly) acquiesced in the Japanese occupation of Manchuria. The articulate among the Chinese, however, remained unreconciled to the existence of Manchoukuo. Moreover, for a number of years only two foreign powers besides Japan (Italy and El Salvador) formally recognized the new state.

Japan, however, persevered in consolidating its position in Manchoukuo. It acted against banditry and entered upon a vast program of railway building that opened up more of the land and connected it with Korea. In 1934 P'u-i was officially crowned monarch of the new state (*see* also MANCHURIA).

After long negotiations, moreover. Japan obtained the sale of the Russian interest in the Chinese Eastern railway and thus eliminated the last legal trace of the former Russian sphere of influence.

Japan was not content with confining its control of China to regions north of the Great Wall. In the spring of 1934 a pronouncement from Tokyo in effect declared all China to be a Japanese preserve in which no power could take important action without the consent of the island empire. In 1935, moreover, Japanese forced the withdrawal from Hopeh and Chahar of any officials and armed forces and the disbanding of any organization that might prove unfriendly to Japan. The provinces of Hopeh and Chahar passed partly into Japanese control, and Suiyuan, Shansi and Shantung were threatened. Chiang Kai-shek dared not offer open opposition.

In July 1937 what proved to be a life and death struggle broke out between China and Japan. The opening incident was a minor clash between Chinese and Japanese troops not far from Peiping on the night of July 7. The conflict soon ceased to be localized. The Japanese came to feel that since Chiang Kai-shek and the Nationalist government would not yield to their wishes they must be eliminated. To the Japanese, the rising tide of nationalism in China, directed, as much of it was, against them, had become intolerable.

9. Chinese-Japanese War (1937–45).—The war, which remained undeclared until Dec. 9, 1941, may be divided into three phases—a period of rapid Japanese advance until the end of 1938, a period of virtual stalemate until 1944, and the final period when United Nations counterattacks, principally in the Pacific and on Japan's home islands, brought about Japan's surrender.

In July 1937 practically all Chinese regional military and political groups rallied to support the Nationalist government and Chiang Kai-shek in their decision to oppose Japan by every means. The Communists, who had urged a united front against Japan since 1935, pledged their support and put their armies nominally under command of the government. From a strictly military point of view, however, Japan was so much better prepared than China that its armies achieved rapid initial success.

Within the course of two years Japan obtained possession of most of the ports, of the majority of the chief cities as far west as Hankow and of the larger part of the railways. Peiping and Tientsin were occupied in July 1937. After fierce fighting, the Chinese armies were driven out of the Shanghai area by the middle of Nov. 1937. Nanking fell in mid-Dec. 1937. The capital was moved west to Hankow. The Japanese followed and took that city in Oct. 1938. In the same month, the Chinese lost Canton. The Japanese pressed northward and westward from Peiping along the railway lines into Shansi and Inner Mongolia. They dominated Shantung. They took possession of the Peiping-Hankow, Tientsin-P'u-k'ou and Lung-hai railways and of the lines in the lower part of the Yangtze valley. They had complete command of the sea. Always superior in the air, before many months they had all but destroyed the Chinese air force and bombed Chinese cities at will. The loss of life, particularly to Chinese, both soldiers and civilians, was enormous.

Yet the Chinese did not yield and the war was prolonged far beyond Japan's expectations. Chiang Kai-shek moved his capital to Chungking, in Szechuan, at the western end of the Yangtze gorges. Much of China's leadership migrated to the far west, to Szechwan and Yunnan. Unoccupied China prepared for piolonged resistance. In occupied China, Japan was unsuccessful in inducing many Chinese of standing to take office in the governments that it endeavoured to set up. Even there Japan's control was confined to the cities and the railway lines; outside these it was challenged, often successfully, by guerrilla bands that professed allegiance to the Nationalist government. The Communist regime was particularly successful in using guerrilla methods to resist Japan. The rapid Japanese advances broke down the established patterns of politico-military control. Communist troops and organizers moved into the vast rural areas behind Japanese lines. They organized village self-defense units, created local governments and expanded their own armies, the 8th route army operating in the mountains and plains of north China and the new 4th army in the lower Yangtze valley.

During the stalemate phase of the war, beginning in 1939, Japan tried to subdue Chinese resistance by blockade. China's main seaports were occupied, from the south to the north. In at least one, Foochow, the occupation was only intermittent, but in most of them it was continuous. When, in 1940, France fell to the Germans, Japan took the occasion to advance in French Indochina and block the railroad that led from the coast to K'un-ming (Yünnanfu) and the crude highways from the Indochinese coast to the interior. For a time Japan induced the British to close the road that led from Burma to K'un-ming in Yiinnan. After a time the British reopened the road *(see* BURMA ROAD).

Then, following years of increasing tension, came the sudden outbreak of war between the United States and Great Britain on the one hand and Japan on the other. The Japanese, taking advantage of their preparedness and of their favourable geographic position, quickly made themselves dominant on the coasts of east Asia. Their capture of Hong Kong and of Burma in 1942 shut doors by which goods had moved in and out of unoccupied China. The only routes that now remained to connect the Chinese with their friends abroad were the long and poorly constructed roads across Sinkiang and the air passage from Assam. Through the venality of Japanese officials and the skill of blockade runners, some goods trickled through the Japanese lines along the coast.

During the war China was divided into three regions—Nationalist China under control of the government, Communist China and the regions occupied by Japan. Each was pitted against the other two.

Nationalist China had serious economic and social problems. The relatively backward western provinces, with almost no modern industry or transport facilities, were strained to support the huge armies and the government. The region was crowded with refugees and some of its cities were bombed. The shortage of manufactured goods and the costs of war brought on inflation, which was intensified by the government's fiscal policy and which caused great hardship and encouraged hoarding, speculation and graft. The army, unable to take the offensive against the superior Japanese forces, steadily deteriorated. In the schools and colleges a shortage of books and equipment, malnutrition and attempted regimentation by the government all had a deteriorating effect.

The government, too, was deeply affected by the war. It had lost its industrial and financial base in east China and the flower of its armies. The strong public support it had enjoyed during the early years of resistance waned and turned to apathy or hostility. The government was blamed for the ills of inflation, corruption and heavy taxation. When the Communists began to reappear as rivals rather than subordinates, the Nationalist government retaliated with repressive measures, which it applied also to other groups. Essentially an authoritarian regime, it tended to become more repressive and less efficient as the war dragged on. Yet with all these difficulties, the Chinese under Chiang Kai-shek's leadership refused to surrender or negotiate with Japan.

The scattered areas controlled by the Communist party and its armies grew during the war until near the end they covered large parts of north and east China *(see* below, *Chinese Communist Party)*. In these "border regions" and "liberated areas" the regime was. by nearly unanimous report, popular with the people. This was partly the result of economic and social reforms, which improved the conditions of the peasantry, and partly the result of the system of local government, which encouraged wide participation of the public through mass organizations even though control was held firmly by the party. The army was also popular because of its good discipline and close relations with the common people upon whom it depended for existence.

During the stalemate period relations between the Nationalists and the Communists were embittered by many military clashes for which each side blamed the other. The Communists did everything possible to strengthen themselves, while the Nationalist government tried to keep them confined by blockade and other means. In effect the civil mar was merely submerged, after 1938, in the larger war with Japan.

In the occupied regions Japan tried to win support and lessee its military burden by setting up a puppet regime at Nanking (1940). To head this, it obtained Wang Ching-wei, once an intimate companion of Sun Yat-sen, who professed to be carrying on the latter's tradition. Japan also went through the motions of restoring to Chinese administration the French concession and the international settlement in Shanghai, which it had taken over after the attack on Pearl Harbor.

Yet Japan was no more successful than it had been before in inducing many Chinese of ability and integrity to serve in these administrations. Obviously, too, no important step could be taken by these regimes without the approval of the Japanese authorities.

In the last phase of the war, from early 1944 to Aug. 1945, some help was beginning to come to China from the outside, chiefly from the United States. War matériel was being flown from India, and Chinese pilots and mechanics were being trained. Japanese strongholds were bombed by U.S. and Chinese planes. The United States also was training and equipping in India Chinese forces that had taken refuge there after the fall of Burma. Yet the main theatre of war was far from China, whose armies by then were too debilitated to play an important part in the final campaigns.

The Nationalist government had been seriously undermined by seven years of war and inflation, while Communist strength had grown. As Japan withdrew divisions to fight in the Pacific islands,

the Communist armies were able to move in and organize more "liberated areas." The danger of fratricidal war after Japan's defeat became obvious. The U.S. government was drawn into China's domestic crisis since the United States provided the main external supports—financial, military and diplomatic—for the Nationalist government and since the U.S. wished China to take a place as a stabilizing influence in the far east after the war. In various ways United States representatives in China tried to bring about a reconciliation between the Kuomintang and the Communists. A fundamental difficulty—besides the bitter distrust and intransigence of both Chinese parties—lay in the United States' position of trying to mediate between them while supporting one side, the Nationalists, as the government of China.

G. China After World War II

1. Civil War.—Within five years of the victory over Japan the Nationalist government had been driven from the mainland by the Communists, who then became masters of the country. Japan's defeat set off a struggle for control of occupied China, from Manchuria in the north to Canton in the south. Nationalist troops, transported by the U.S. army air force and navy, were able to take over key cities and most railway lines in east and north China. But Communist troops, moving out from their guerrilla bases, occupied much of the hinterland in the north and in Manchuria. The stage was set for renewal of civil war.

For more than a year the U.S. government attempted, through its ambassador, Patrick J. Hurley. and then through Gen. George C. Marshall, to mediate and prevent this conflict. During Jan. and Feb. 1946 it appeared that agreements laying the basis for peace had been reached. On Jan. 10 the Nationalists and Communists concluded a cease-fire agreement to be administered by a tripartite committee (Kuomintang, Communists and the United States) which would send out truce teams to stop conflicts that arose. A Political Consultation conference representing all parties, meeting Jan. 10–31, worked out plans for an interim coalition government to function until a new constitution should be adopted by a representative national assembly. On Feb. 25, 1946, a military reorganization plan worked out with the help of General Marshall, to merge and consolidate the hostile armies, was agreed upon by representatives of the government and of the Communist party. Within a few months, however, these agreements were undone. During all of 1946 the U.S. government, acting through General Marshall and his aides, strove for peace. The hostility, ambition and distrust of both Chinese parties made peace impossible.

The civil war lasted from 1946 to 1950. In that period the great strategic advantage of the Nationalists was reversed. During 1946 and early 1947 they succeeded in taking most of the railways and in recapturing important cities in the north. As Soviet troops withdrew from Manchuria the Nationalists sent in their best armies to try to hold the vital railways and industrial centres. But they were overextended. Communist forces, retrained and reequipped with Japanese arms, gradually shifted from guerrilla warfare to large offensive campaigns. In 1948 they destroyed the Nationalist armies in Manchuria and won impressive victories in north China. By the end of the year the Nationalist government was in desperate straits: its armies were disintegrating; inflation was destroying the economy; the Kuomintang was torn by factional strife; and the public was withdrawing its support.

In 1948 the Communists began a southward march. They captured Nanking, the Nationalist capital, on April 24, 1949; the substitute capital of Canton, on Oct. 15; then Chungking, the wartime capital to which the government had returned for final refuge, on Nov. 30. On Dec. 8, 1949, T'ai-pei in Formosa was declared to be the Nationalist capital.

2. Formation of the People's Republic.—During 1949 the Communists laid the foundation for a national government. In September the Chinese People's Political Consultative conference, a body having the appearance of a constitutional convention, met in Peiping to establish a new government. The conference included representatives of many parties, professions, organizations and ethnic minorities, but their selection was determined by the Communist party, which dominated the gathering. The climax of its meetings was the announcement of the formation of the People's Republic of China on Oct. 1, 1949. The Central People's government of the People's Republic of China was established at Peking (renamed by the conference). While having the appearance of a coalition government, it was essentially a Communist dictatorship.

Government was only one of the agencies employed by the Communist leaders to control the country and carry out their policies. Other agencies included the party itself, numerous mass organizations and the armed forces. The Communist party, a highly centralized and strongly disciplined organization, had from 6,000,000 to 7,000,000 members at the time when the People's Republic was formed. Its central committee, or a smaller group within it, determined party policy, carried out by a network of regional, provincial, municipal and lesser committees. The party structure paralleled and party officials controlled each level of the government, of the army and of the mass organizations. The rank-and-file members provided the motive force for carrying out the party's will in factories, villages, street associations and army units throughout the country. After coming to power the party established many types of mass organizations and extended those it had previously created. Associations of peasants, youths, women and labourers enrolled millions or scores of millions of members. Every ptofession and occupation was organized. Each of these bodies served as an agency to mobilize support for the regime and its programs. At the same time they provided the Chinese people with greater opportunity for participation in government, particularly local government, than they had ever before known.

The party, through the government, established a monopoly of all organs of information—radio, press, motion pictures, etc.—and the entire educational system. All coercive bodies such as the army, the police and the courts came under its control. The government did not hesitate to use terror, including widespread executions and forced labour, to eliminate or control potential opponents. It was through these means that the new regime, with a large measure of popular support, was able to unify the country more completely than any other had done since the height of Manchu power.

3. Foreign Relations.—In foreign policy the regime was firmly in the world Communist camp. The government was quickly recognized by the Soviet Union and its satellite countries. A treaty of friendship, alliance and mutual assistance between the People's Republic of China and the Soviet Union was signed in Moscow on Feb. 14, 1950. By the terms of a supplementary agreement, the U.S.S.R. promised to transfer to the People's Republic of China before the end of 1952 all its rights in the Chinese Ch'ang-ch'un railways (the former Chinese Eastern and South Manchuria railways) and to withdraw its troops from Port Arthur and turn over the naval base to China's control; Dairen was also to be returned. The U.S.S.R. also extended a five-year credit amounting to U.S. $300,000,000. Subsequent treaties and agreements bound the two countries closely together. Communist China's entry into the Korean conflict toward the end of 1950 tightened this alliance and tended to isolated China from the non-Communist world.

But the course of mainland China's relations with the U.S.S.R. has not always run smoothly. During the summer of 1960 strain began to appear when some leaders of the two countries were openly critical of each other and when the U.S.S.R. withdrew most of its technicians from China. In the autumn of 1961 China sided with Albania in its struggle with the Soviet Union, and even lent Albania money and diverted wheat shipments (sorely needed by the Chinese people themselves) to Albanian harbours. For several years China's foreign trade had shifted from Japan and the west to the Soviet Union and its satellites, but in this area, too, signs of change appeared. In 1961 alone the Peking government purchased 6,000,000 tons of grain from Canada, Australia and France.

The non-Communist governments of the world were divided over the issue whether to recognize the new Chinese government or continue to deal with the Nationalist government on Formosa. Burma, India, Pakistan, Indonesia, Sweden, Denmark, Finland and Switzerland quickly established relations with the new government. Great Britain and certain other countries offered recognition, but

the Communist regime made no effort until 1954 to establish relations. In that year Peking and London exchanged chargés d'affaires with diplomatic status and China agreed to formalize its relations with Norway and the Netherlands. Diplomatic relations between China and Yugoslavia mere established in Jan. 1955, five years after Yugoslavia had offered recognition to Peking. A series of agreements on greater trade and closer relations were concluded between the People's Republic of China and Indonesia, Burma, Vietnam (North), North Korea and Outer Mongolia in 1955 and relations also were established with Afghanistan and Nepal. Relations also were established with a number of the newer countries in Africa, and in Latin America Cuba became an outspoken ally. These understandings resulted in China's making grants and loans to Burma, North Vietnam and Guinea, supplying Ghana with machinery, and aiding Morocco in the planting of tea.

The question of which Chinese government should represent China in the United Nations also was a matter of controversy. On this issue, the United States supported the Nationalist government position, and in March 1956 the secretary of state, John Foster Dulles, declared that the United States had consistently recognized and supported the government of the Republic of China as the only government of China. In July of the same year, the U.S. congress declared in a resolution that it was unequivocally against the seating of Communist China in the United Nations.

India and the U.S.S.R. continued to introduce resolutions at sessions of the United Nations general assembly calling for the admission of the People's Republic of China. The proposals were defeated. however, by votes of 42–12 in 1955 and 48–27 (with 6 abstentions) in 1957. In 1958 a U.S. proposal to exclude any proposals for a change in the representation of China for another year was passed by a vote of 44–28 with 9 abstentions. In 1959 the vote was 44–29 with 9 abstentions. When a resolution was introduced in 1960 it was defeated by a vote of 42–34 with 22 abstentions. By that time, however, the United States realized that the number of votes it could count on was dwindling. The U.S. delegate in 1961 backed a New Zealand-sponsored resolution to consider China's membership "an important question." The African delegates agreed to vote against Communist China's becoming a member provided that the U.S. would agree to the entry of Outer Mongolia and Mauritania. This the U.S. was willing to do, and, with some difficulty, persuaded the Nationalist Chinese delegate not to veto the proposal in the Security council.

Tibet was brought back under Chinese control through a military campaign beginning in Oct. 1950 and through negotiations during April and May of 1951. The Central People's government promised Tibet "national regional autonomy under the unified leadership of the Central People's Government" but assumed control of the country's defense, communications and external relations. The agreement was signed on May 23, 1951, in Peking and was ratified by the dalai lama in October. In a treaty between India and China signed April 29, 1954, India recognized China's full sovereignty over Tibet and gave up certain privileges previously acquired there by Great Britain. One position India clung to, however, was the maintenance of the line drawn by Sir Arthur Henry McMahon early in the 20th century, indicating the boundary of India in the north. This boundary, agreed to by representatives of Tibet and British India in 1914, apparently was accepted also by the Chinese government; certainly it was not at any time protested. When therefore the Chinese Communists, late in 1959, started over the highways constructed to the borders of Bhutan, Sikkim, Nepal and Kashmir, to cross the line and dispose their armed forces at strategic points within the line, the Indians protested, and Prime Minister Jawaharlal Nehru refused to have any dealings with the Chinese premier, Chou En-lai, until the troops had been withdrawn.

Relations between India and China dropped to a new low as a result of the border dispute. On Feb. 24, 1961, India issued a white paper condemning China as an aggressor and accusing the Chinese of occupying 50,000 sq.mi. of Indian territory in the border area. Though India still favoured the admission of Communist China to the United Nations, Indian newspapers left no doubt that the country had lost much of its enthusiasm for the Chinese regime. The Indian government also was tried by events occurring in Tibet in 1959. when the Chinese began to suppress harshly the restlessness among the people and by so doing caused thousands of Tibetans, the dalai lama among them, to flee for refuge into India. The panchen lama was summoned to Peking and made titular head of the Tibetan state. (See also TIBET.)

The ruthlessness of Chinese Communist actions in Tibet and their significance for other states in Asia were not lost on the peoples of other border areas and beyond. Resettlement of many Communist Chinese in China's peripheral areas was observed. About 2,000,000 were settled in the decade 1950–60 in Inner Mongolia, Ningsia, and Sinkiang. In 1959–60 over 10,000 were sent into Yunnan province, the beginning of a migration that was expected to relocate 100,000 people. An anti-Chinese attitude was observed in Indonesia, Malaya, Burma and Pakistan after the conference of Asian and African nations held at Bandung in 1955.

4. Domestic Reforms. — After winning control of the country, the Communist regime launched a series of nationwide reforms that attempted to refashion nearly every aspect of Chinese life. Of fundamental significance was the land redistribution program, which undertook to expropriate the land of all landlords and "opponents of the state" and distribute it to farm labourers, tenants and poorer peasants. Within a few years, throughout a territory larger than Europe, ownership of land was redistributed and landlords were eliminated as an economic class. This mas only the first step toward collectivization. Other intermediate stages were mutual-aid teams and agricultural co-operatives, which were gradually developed throughout the land. Marketing and distribution of most of the products of Chinese agriculture was brought under co-operatives and state trading companies. These and other measures were designed to increase the nation's agricultural output and place it at the service of the state for its program of economic development.

China's economic development was planned and controlled by the state. The first several years after 1949 were devoted to rehabilitation and to establishing the mechanism of economic controls. Communication facilities were restored, inflation was halted, and state banking and state trading companies were established. The mar in Korea prevented much new capital construction except of railways and flood-control systems, but in 1953 the government launched the first five-year plan and announced a "high tide of construction" to transform China from an agricultural to an industrial country.

In 1955 a food shortage on the mainland was reportedly acute, partly because of floods and droughts. The decision to re-examine the five-year plan and to tighten the food ration reflected these conditions and, in an attempt to increase food production and reduce the number of city dwellers who must be fed, the government took steps in July to send large sections of the population in Shanghai and other large cities back to their native villages to take up farming. By the latter 1950s the agricultural economy was largely collectivized and industry and commerce were almost completely transformed into enterprises jointly owned and operated by the government.

Despite these facts and Peking's claim of achievement in accelerated socialization, there were, in 1957, repeated officialand unofficial reports of food shortage, further reduction of cotton-cloth ration, student unrest, peasant revolts and severe punishment against "counterrevolutionary gangs." At the eighth Chinese Communist party congress in Sept. 1956, Premier Chou En-lai had reported that because of floods and drought and difficulties encountered in the process of socialization the targets for some industrial and agricultural production would not be attained at the end of the five-year plan in 1957. An outline for a second five-year plan (1958–62) was adopted by the party congress, proposing a 50% increase in national income through a rise of 100% in industrial output and 35% in agricultural production, as compared with the lower rates of increase oi 90% and 23%, respectively, under the first five-year plan. The new plan, among other things, called for a long-range effort to surpass Great Britain in the output of steel and coal within 15 years.

The new plan's first year, the first year of the "great leap for-

ward," was made notable by establishment of the people's communes. In spite of setbacks due to mistakes and floods and other forces beyond its control, the government continued to announce gains in production. In 1959 only grain production failed to reach its quota, though the total actually exceeded the 1958 figure by 8%. Steel production rose from 8,000,000 metric tons in 1958 to 13,350,000 in 1959. Pig iron production, at 20,500.000 metric tons represented an increase of 115% over 1958, though some of this may have been of poor quality because it was produced in temporary furnaces and converters. Coal production was 347,800.000 metric tons. exceeding 1958 production by 29%. Crude oil production remained small; in 1959 it was 25,900,000 barrels, a little more than three days' production in the United States. Cotton output for 1959 was 2,410,000 metric tons, an increase of 14.76% over 1958, and the mills turned out 8,250,000 bales of cotton yarn, 35% more than in 1958. Electricity rose 51%; cement 32%; timber 18%; chemical fertilizer 64%; machine tools 40%; paper 31%; sugar 26%; and salt 6%.

Late in 1960 government news sources began to report that various natural disasters plaguing the country during that year had, according to the Red Flag magazine, "not only affected the fulfillment of our agricultural plan for 1960 to a great extent but also inevitably created certain unfavourable conditions for the production of both heavy and light industries." The natural calamities that had visited the agricultural regions included drought (affecting almost every province except Tibet and Sinkiang), typhoons and floods (20 provinces), insects, pests, plant diseases, hailstorms and frost. Western observers speculated that the seriousness of the disasters might have been exaggerated in an effort to account for a decrease in production that had come about because of the commune system, which had met with widespread discontent, sabotage and resistance that reached their climax in 1960. The result, in any case, was famine, and food grains had to be imported.

The Communist regime actively extended education, which was brought completely under state control. Schools and colleges operated by western missionaries were confiscated. In the revised system emphasis was laid upon expanded educational facilities, ideological uniformity and technical training. A central purpose of the new system was to bring education within the reach of all workers and peasants, one device being the use of simplified characters, together with a phonetic system based on the western (and Russian) alphabet (see above, The People). Mass education to eliminate illiteracy was pushed vigorously. The government stated that in the year 1958 alone 100,000,000 persons among the young and middle-aged learned to read, so that the striking figure of 80% literacy was reached. In 1960, according to reports of the government, 86,400,000 children were enrolled in primary schools, while 8,520,000 were attending middle school, and around 660.000 (not including research students) young people were in institutions of college grade. Teachers were retrained through "ideological remolding campaigns," and new textbooks, much influenced by Soviet books, were produced. Secondary and higher education became increasingly technical in order to train engineers. agronomists, medical personnel and technicians; nearly 1,500,000 students were enrolled in technical schools in 1958. All students spent part of their time in manual labour. Carefully selected students were sent annually to the U.S.S.R. for special training.

The emancipation of women from their inferior position in the old society was announced as another aim of the Communist regime, carrying forward a movement that had been developing during the first decades of the 20th century. Legislation strengthened women's rights in property ownership, employment and health insurance. The marriage law promulgated in May 1950 made child marriage and concubinage illegal, and stressed the right of young women to choose their own husbands. Women were given franchise equal to that of men. At the same time, however, like their sisters in the U.S.S.R., they were also required to work as hard.

During 1953–54, elections were held throughout China for "people's congresses" at village, county, municipal, provincial and national levels. To prepare for elections a population count was made as of June 30, 1953 (see Population, below). On Sept. 20, 1954, the new national people's congress adopted a constitution of the People's Republic of China, the first constitution since China came under Communist control. In April 1959 Mao Tse-tung resigned from the chairmanship of the congress, being succeeded by Liu Shao-ch'i. Mao continued as chairman of the party's central committee and of the Politburo, while Chou En-lai served as premier and Chu Teh as chairman of the standing committee of the national people's congress.

5. Nationalist Government on Formosa. — The Nationalist government meanwhile maintained itself on Formosa, which had reverted to Chinese control upon Japan's surrender in Aug. 1945. When the island became the government's last refuge late in 1949 it was necessary thoroughly to reform the inefficient, "carpetbag" administration that had operated there during most of the civil war period. The Kuomintang party was reorganized with a view to its revitalization. The government bureaucracy superimposed upon the provincial administration was reduced and rationalized. The armed forces that had fled from the mainland were reorganized and, with help from a United States military mission and large U.S. financial grants. were revived into a more effective fighting force to defend the island and, according to Nationalist hopes, to lead in a reconquest of the mainland. In these efforts to establish a secure base Chiang Kai-shek took the lead as head of Kuomintang, president of the republic and commander in chief of the armed forces. His power within the regime became absolute.

An attempt was made to provide Formosa with an efficient administration having due regard for the welfare of the people. This was necessary in order to restore confidence in the Nationalist government both at home and abroad. Elections in 1950–51 for magistrates, mayors and councils introduced a measure of local self-government. Similar elections were repeated periodically; in 1957, 83% of over 4,250.000 voters participated. The councils, however, were given only advisory, not legislative, power.

In the civil service the proportion of Formosans, especially in higher positions, was increased. The former Japanese educational system was completely reorganized and extended so that more than 93% of children of elementary school age were in schools by 1957. In 1959 there were 22 institutions of higher learning (including 7 universities) as compared with 6 in 1949. Twelve Chinese institutions of higher learning overseas (11 in Hong Kong and one in the Philippines) were approved by the ministry of education. The Chinese language completely superseded Japanese throughout the school systems.

The island's economy was soon brought back to the productive levels of the prewar Japanese administration, and in every known instance improved. During the years 1949–53 the Nationalist government peacefully carried out a land reform program including reduction of land rents to 37.5% of the yield, sale of land to cultivators and government purchase of land and resale to tenant cultivators. As a result 5,800,000 ac. of land were transferred to tenants, and the percentage of Formosan farm land cultivated by owners increased from 50.5% to 75.4%. With the help of the Joint Commission on Rural Reconstruction, composed of Chinese and Americans, significant improvements were made in irrigation, cropping methods, animal husbandry, organizing of farmers' associations and agricultural extension. In Oct. 1959, at the conclusion of 14 years of occupation, the Nationalist government reported that the industrial production index had risen ten times, and the number of workers nine times, from 23,000 to 207,000. The textile industry rose from 20,000 spindles to more than 240,000. Steel output rose from almost nothing to 227,000 metric tons; cement from 78,000 metric tons to the neighbourhood of 1,000,000. The number of factories increased from 5,600 in 1951 to 12,100 eight years later. Privately owned plants rose from 2,300 in 1945 to 19,315 in 1959. Many new industries emerged: motor vehicles, diesel engines, machinery, electric appliances, glass, timber processing and synthetic products. Formosa's exports in 1959 totaled about U.S. $160,000,000, of which sugar and rice accounted for U.S. $77,000.000. The island's government launched one four-year economic development plan in 1953 and another in 1957. It came close to or exceeded its goal in every respect, in spite of devastating storms and the distractions of military defense.

The chief problem was the support of the armed forces of the

Nationalist government, numbering some 600.000 men, and a constant influx of refugees from the mainland. Only with extensive economic aid from the United States was that possible. (See also FORMOSA.)

On April 28, 1952, the Nationalist government on Formosa and the government of Japan signed a separate peace officially ending the mar which had begun in fact on July 7, 1937.

6. Conflict Between the Two Chinese Governments. — The two Chinese political regimes — Nationalist and Communist — which had been at war most of the time since 1927, confronted each other across the Formosan strait in a continuation of the contest for support of the Chinese people and the nations of the world. In Sept. 1954 Peking increased its attacks on the islands lying in the strait between Formosa and mainland China and nominally under the control of the Nationalist government. Heavy air attacks on the Ta-ch'en Islands in Feb. 1955 led to their abandonment by the Nationalist government. The islands of Quemoy and Matsu also were harassed by artillery fire, and beginning on Aug. 23, 1958, they were subjected to a heavy and sustained bombardment for several weeks. The U.S. 7th fleet during this period convoyed Nationalist supply ships to Quemoy, bringing forth charges that the U.S. fleet had violated territorial waters, and denials from the United States. Thereafter the attacks were resumed, but the Nationalist forces, supported by the United States, held fast, and an inconclusive series of engagements continued. The Communists kept up a nuisance shelling of the offshore islands on odd-numbered days, though the bombardment became massive only on June 17 and 19, 1960, when Pres. Dwight D. Eisenhower made a state visit to Formosa. There was little damage to the heavily fortified defense works and casualties were few. See also FAR EAST: RELATIONS WITH THE WEST. (K. S. L.; C. M. W.; L. C. G.)

VI. POPULATION

The prolonged uncertainty, especially among western scholars, about the total size of China's population was finally resolved by the census taken by the government in 1953. It was generally accepted outside China as an accurate head count, conducted with care and precision between July 1953 and March 1954 but referring to June 1953. It gave a total mainland population, including Manchuria (called simply the Northeast after 1949), Inner Mongolia, Tibet and Sinkiang, but excluding Formosa, of 582,603,417. Inner Mongolia accounted for 7,338,000 of this total, Tibet for 1,273,969 and Sinkiang for 4,873,608. Figures released by the statistical bureau in 1957 placed the total mainland population at 646,530,000 (excluding Formosa), including Inner Mongolia (9,200,000), Tibet (1,270,000) and Sinkiang (5,640,000).

Earlier estimates, by Chinese and westerners, of the country's total population had ranged from as little as 250,000,000 to as much as 600,000,000. The huge population of China is very unevenly distributed, however; most of it is concentrated in the following regions:

1. The central portion of the north China plain around the convergence of the provinces of Hopeh, Shantung and Honan and a section of the valley of the tributary Wei river.

2. The triangular tract of the Yangtze delta with its apex at Nanking.

3. A relatively narrow coastal belt extending southward from the mouth of the Yangtze through Chekiang, Fukien and Kwangtung to the Hsi Chiang or Canton delta, where it widens considerably.

4. The central (Hupeh) basin with the Wu-han cities (Hankow, Han-yang, Wu-ch'ang) as its node and extending up the radial valleys converging on it (Han, Siang, Kan, etc.).

5. The Red basin of Szechwan, isolated far in the west beyond the Yangtze gorges.

The northern belt of maximum population is essentially one of peasant farmers, depending upon the land; large manufacturing cities are only beginning to grow up in the western sections, apart from established eastern centres such as Tientsin. In the Yangtze delta, the coastal zone and the Canton delta, agriculture greatly predominates, but in addition there are old and new industries and active river and maritime commerce. Despite cold-war limitations on maritime trade, Shanghai retained its place as by far the largest city and manufacturing centre. New centres are growing rapidly in the west, southwest and northwest, but the coastal plain, the plain of eastern north China, and the middle and lower Yangtze valley still contain the bulk of China's people.

Outside these regions, population is dense only in isolated valleys or small basins. In the provinces of the loess plateau (Shensi and Shansi) the density is moderate and the population fairly evenly distributed. The same may be said of the south China plateau as a whole. In both, well-peopled valleys contrast with sparsely occupied highlands.

The southwestern provinces (Kweichow, Yiinnan and Kwangsi), Kansu, the provinces of Inner Mongolia in the northwest and the Manchurian provinces in the northeast all have distinctly low densities. The possibility of lessening the pressure of population depends upon developing industries and new agricultural techniques, internal migration and gradual changes in reproduction patterns.

1. Migration. — The Chinese throughout their history have been a colonizing people, but movement from congested and overpeopled regions to sparsely occupied areas was constantly held in check by the great reluctance, for reasons connected with their social philosophy, to leave their ancestral homes. This is least true of southeast China. There has long been a stream of Chinese emigrants from Fukien and Kwangtung, with their densely peopled coasts, to the rich peninsulas and islands to the south, where they helped to develop the far eastern tropics.

In Malaya Chinese form approximately one-half the total population. In the Philippines, in Java and many other parts of Indonesia, in Thailand (Siam), in Indochina and in Burma their vigour, frugality and tenacity make them a prosperous and progres-

sive commercial element. These same qualities often constitute a menace to the economic prospects of the less commercially minded local peoples. Resentment and discrimination against the Chinese in these countries of southeast Asia where they form such a critically important group have become political issues, especially when the national loyalties of the Chinese may be ambiguous.

The peoples of the congested districts of the north in Shantung, Hopeh and Honan were until relatively recently somewhat less adventurous. The rich grasslands of Manchuria beyond the Great Wall became available for agricultural settlement only under the Manchu dynasty, and economic development was very slow until after the Russo-Japanese War of 1904–05. With the rapid development of railways and new industries, Manchuria became a very attractive field. North China, on the other hand, was devastated by famines and the ravages of civil war. The almost intolerable conditions of life in many districts so weakened old prejudices that a tremendous mass movement toward Manchuria set in, no longer a mainly seasonal migration of males but rather a movement of entire families. The increase of population in Manchuria in the four years 1923–27 was estimated at 2,000,000 and the exodus from north China during the summer of 1928 at 40,000 a week. During the period of Japanese control of Manchuria, migration was slow but steady. After the area came under control of the Communist regime, it was developed as an agricultural-industrial base, and migration, particularly of skilled workers and technicians, was encouraged.

To this field of colonization in the north must be added the adjacent districts of Inner Mongolia on the Chinese side of the Gobi desert, with very considerable pastoral possibilities which the Peking-Pao-t'ou-Lan-chou railway made accessible. However, this is a marginal region in which the small and fluctuating rainfall makes settlement and livelihood precarious. In spite of climatic limitations, northern China has thus had a "land of promise" along its whole northern border, but except for some sections of Manchuria this has nearly reached the saturation point. The Communist regime attempted by a drastic reorganization of the society and economy to solve the fundamental problem of overpopulation, but a generation at least mill be necessary to assess the results. If no slowing occurs in growth rates, China should have 1,000,000,000 people well before the end of the 20th century; it is doubtful that total production can match such an increase.

2. Demographic Characteristics. — In the years after the 1953 census, the population of China was reported to be increasing at a rate of 2% a year. This rate of natural increase was based on birth and death rates derived from a sample survey of 30,000,000 persons, or about 5% of the total population. The survey showed births at a rate of 37 and deaths at 17 per 1,000 population.

The 1953 census showed the Chinese population to be a rather young one. The census reported 15.6% of the total population under 4 years of age, 25.5% between 4 and 17 years, and 58.9% 18 years and over. China thus had a much larger proportion of its population in the younger ages than, for example, the United States, where in 1953 the age group of 18 and over included 67.4% of the population.

The 1953 census reported that men outnumbered women by 107.5 to 100. This situation contrasts sharply with that in the United States, where at the same period (1953) there were only 98.9 males per 100 females. Chinese population counts have traditionally disclosed a predominance of men over women, partly explained by the former practice of undercounting girl babies in population registers.

3. Urban Population. — According to the 1953 census, 13.3% of the country's population, or 77,257,282 persons, were classified as urban. At the time of the census, more than 1,600 places in China were listed in the urban category. The great majority of these were small market towns, engaging in trade and handicrafts. There were only 103 (121 in 1957) cities with a population of more than 100,000 each, a relatively small number for a country as large as China. However, these large cities alone accounted for 63% of the country's total urban population. Among the large cities, 9 had a population of more than 1,000,000 (14 in 1957), 16 had a population from 500,000 to 1,000,000 (20 in 1957), and 78 (90) had a population of 100,000 to 500,000 (see Table II).

*Municipality.

Urban population as a whole rose by 40% in China between 1950 and 1953 as a result of renewed industrial activity in the cities under the Chinese Communist regime. Urban increases were most marked in cities where industrial development progressed. At the same time cities were being built around industrial construction sites and newly developed mines.

The urbanization trend in China continued at a rapid pace after the 1953 census as the Communist regime intensified its efforts to convert China into a powerful industrial nation. By 1956 the country's urban population was estimated to have risen to 89,150,000, or 14.2% of the national total. By late 1957, Shanghai's population had risen to an estimated 6,900,000; that of Peking to 4,010,000 (largely as a result of territorial expansion of the city limits), and that of Tientsin to 3,220,000. (T. SD.)

VII. ADMINISTRATION AND SOCIAL CONDITIONS

A. CHINESE COMMUNIST PARTY

1. Party Development. — The Chinese Communist party (C.C.P.) was formally established at the first National Party congress in Shanghai, July 1, 1921. National Party congresses were held thereafter at irregular intervals: Shanghai (1922), Canton (1923), Shanghai (1925), Wu-han (1927), Moscow (1928), Yenan (1945) and Peking (1956, 1958). Between 1921 and the early 1960s the C.C.P. increased from 57 to nearly 18,000,000 members, becoming the world's largest Communist party. During the first united front with the Kuomintang, during the 1920s, C.C.P. members were admitted to membership in the Kuomintang, but the party retained full organizational and programmatic independence during the second united front during the Japanese war period (1937–45). The C.C.P. controlled the Chinese soviet republic in Kiangsi and Fukien provinces (1931–34) and the Shensi-Kansu-Ningsia border area government (1936–45), in addition to large guerrilla areas within the Japanese lines. It achieved national power on Oct. 1, 1949, by a process of territorial expansion from large rural base areas that remained under its control after the cessation of hostilities in World War II.

Under the successive leaderships of Ch'en Tu-hsiu, Li Li-san and Ch'en Shao-yii, between 1921 and 1935, the C.C.P. was torn by internal and factional differences over such questions as: relations with non-Communist elements, relations with the Soviet Union and the Communist international: political-military strategy and tactics, and a number of ideological issues, such as the

respective roles of the urban proletariat and rural peasantry in the revolutionary process. An extraordinary party conference at Tsunyi (Kweichow province) in Jan. 1935, during the course of the march from south to northwest China. established the leadership of Mao Tse-tung (*q.v.*). Party dissidents were disciplined by Mao Tse-tung and his principal lieutenant, Liu Shao-ch'i; and the *cheng-feng* or rectification movement of 1942–43 had the effect of consolidating Mao's leadership and of establishing his interpretations of Marxism-Leninism as the basic ideological guide for the party's subsequent revolutionary action.

The revised party constitution of Sept. 26, 1956, defined the C.C.P. as "the vanguard of the Chinese working class, the highest form of its class organization," and set forth the principal objectives of party policy with respect to social revolution and reconstruction, economic development, relations to other classes and minority groups, and foreign affairs. It declared that "the C.C.P. takes Marxism-Leninism as its guide to action"; that it "adheres to the Marxist-Leninist world outlook of dialectical and historical materialism"; and that it "upholds the principle of integrating the universal truths of Marxism-Leninism with the actual practice of China's revolutionary struggle." These and other party pronouncements emphasized the principle of the "continuing revolution," by which the party was wholly committed to "the achievement of socialism and communism in China." The C.C.P. has its own constitutional and administrative systems, which are rigorously distinguished from those of the state, and it looks upon the state apparatus as but one of the several forms of organization available to it for attaining its objectives.

2. Organization and Structure.— In accordance with the principle of "democratic centralism," the capstone of the C.C.P. hierarchical structure is the National Party congress, a body formally endowed with plenary authority to control the constitution, organization and policies of the party. Members of the congress are indirectly elected by party congresses of lower levels for five-year terms. The party constitution of 1956 stipulated that the congress should normally hold annual sessions within the five-year term of its election, in sharp contrast to the previous practice of convening single-session national congresses on an ad *hoc* basis. Congress sessions are of short duration, and in practice are almost entirely concerned with endorsing proposals laid before them in the name of the central committee.

The National Party congress elects a central committee of about 100 members to exercise full authority over party affairs in the long intervals between its sessions. In turn, the central committee elects the principal functionaries of the national party organization: a chairman, five vice-chairmen, a secretary-general, a Political bureau, a standing committee of the Political bureau, a secretariat and a Central Control commission. The number of members of the collegial organs varies at the discretion of the central committee. During intervals between the prescribed semi-annual plenary sessions of the central committee, which are actually convoked less regularly, its powers and functions devolve upon the Political bureau and its standing committee, which issue orders and directives in the name of the central committee. The latter organs comprise the core of the party leadership.

Under direction of the Political bureau and secretariat, the continuing apparatus of the central committee consists of administrative departments, each normally headed by a central committee member. which exercise policy and staff functions connected with the formulation and enforcement of party programs, the internal business of the party and liaison and direction of lower-level party organizations and committees. The most active departments of the central committee have been the organization department, finance department, united front work department, rural work department, industrial and communications work department, propaganda department, social affairs department, women's department, youth department and military affairs committee. Parallel activities, with more limited scope, are maintained by analogous departments of provincial and local party committees.

Membership in the C.C.P. is open to persons above the age of 18 who are qualified and willing to perform the duties prescribed in the party constitution, to accept party discipline and "to place the interests of the Party and the State . . . above their personal interests" (party constitution, art. 2). The ne member is admitted to a one-year probationary status by a local party branch. Once qualified for regular status, the member may voluntarily withdraw or, as a disciplinary measure, may be reduced to probationary status or expelled. The Communist Youth league (formerly the New Democratic Youth league). the junior organization directly controlled by the C.C.P., maintains at all levels an organizational apparatus paralleling that of the party, and is the principal source of recruitment for new party members. At the time of the eighth party congress (1956) the party membership was identified. by social status, as follows: workers, 14%; peasants, 69.1%; intellectuals, 11.7%; others, 5.2%. About 10% of the party members are women.

The C.C.P. also controls and directs nonparty mass organizations, which are considered as the party's principal links with the masses and serve as "transmission belts" for party policies, and whose "activists" may become candidates for party membership. Such organizations include the All-China Federation of Trade Unions, All-China Federation of Democratic Women, All-China Democratic Youth, All-China Federation of Industry and Commerce, Sino-Soviet Friendship association, All-China Federation of Literature and Arts. All-China Student federation, and others. Their total membership exceeds 100,000,000, and many of them maintain active affiliations with such international Communist organizations as the World Federation of Trade Unions, World Federation of Democratic Women, International Student union, and others.

3. Party Control of **Government.**—In C.C.P. doctrine, the party assumes the role of leadership in transforming ownership of the means of production, in establishing the socialist society and in preparing for the transition to Communism. In principle, the party anticipates the "elimination of classes, state authority and party" (Mao Tse-tung, June 30, 1949). During the pre-Communist phase, it considers the "state institutions of people's democratic dictatorship and its lams" as "superstructure" which plays a role in socialist transformation (Mao Tse-tung, Feb. 27, 1957) necessarily subordinate to the transformations it assists the leading party to achieve. Consequently, the C.C.P. exercises complete control over the government, directly or indirectly formulating its policies.

Several channels for controlling the government are available to the C.C.P.:

1. Although party membership is not prerequisite to employment by the state, the most responsible governmental personnel at all levels are invariably important members of the party hierarchy. The party constitution stipulates that three or more party members of the leading bodies of state organs or people's organizations should form a "leading party members' group," with responsibilities for assuring that policies and actions of the leading bodies conform to the policy decisions of the party.

2. The state constitution itself acknowledges the leadership role of the C.C.P. within "a broad people's democratic united front," and incorporates a statement of the directions of state policy corresponding to the party's objectives.

3. Basic constituent and legislative acts, such as the state constitution of Sept. 20, 1954, are preliminarily drafted within the party apparatus before submission for formal action by an appropriate constituent or legislative body of the state.

4. From time to time, the party central committee joins with the state council, or its ministries, to issue joint orders. directives or regulations equally applicable within the party and state hierarchies.

5. The indirect system used in electing members of people's congresses and governments at different levels of the state apparatus permits the C.C.P. to maintain strong electoral control, indirectly, over party and nonparty officeholders.

6. Through its propaganda department. the party directly employs and controls all media of mass communications (press, publications, radio) and cultural and educational facilities, to stimulate broad mass support for policies it seeks to popularize.

7. Through its united front work department, the party exerts leadership over all "democratic parties and groups," ensuring their conformance with party policies.

As a consequence of full utilization of such means of control, the actions and pronouncements of the party take priority over state actions and enactments as expressions of the principal directions of public policy. Jurisdictional debate does not occur, and certain "rightists" who in 1957 voiced objection to the "party empire" were purged from public life. In sum, the party employs the state apparatus to carry out party policies considered appropriate for governmental action, but at its option it may employ mass organizations and other nongovernmental agencies, or act directly. Thus, the sweeping program for the establishment of people's communes in 1958 was completed entirely under direct party leadership, without authorizing legislation or subsequent official confirmation by state authorities.

B. State Constitution and Administration

1. Constitution. — The constitution of the People's Republic of China (abbreviated hereafter C.P.R.), adopted by the first national people's congress on Sept. 20, 1954, supplanted the organic laws of the Chinese People's Political Consultative conference of Sept. 1949 as the basic constituent instrument of the C.P.R. The state constitution consists of a programmatic preamble and 106 operative articles grouped in four chapters.

Ch. i (art. 1–20), "General Principles," defines the C.P.R. as "a people's democratic state led by the working class and based on the alliance of workers and peasants," and sets forth the basic policies for "the gradual abolition of exploitation and the building of a socialist society." Ch. ii (art. 21–84), "The State Structure," defines the organs of state administration, including the national people's congress and its standing committee, the office of chairman, the state council, local people's congresses and government councils, the special regimes for autonomous areas, and the people's courts and people's procuratorates; ch. ii was implemented, in detail, by a special series of organic laws. Ch. iii (art. 84–103), "Fundamental Rights and Duties of Citizens," and ch. iv (art. 104–106), "National Flag, National Emblem and Capital," complete the document.

The constitution entered into force immediately upon its adoption. The national people's congress may amend the constitution at any time by a two-thirds majority vote. Broad powers to interpret the constitution were subsequently assigned by the congress to its standing committee. The supreme people's court, which is politically responsible to the congress and reports to it, has none of the functions of a constitutional court.

2. Central Government. — The governmental system of the C.P.R. is based on the unitary principle. The national people's congress, "the highest organ of state authority," exercises complete legal control over provinces, national autonomy areas and local governments and administrations. All state organs observe the principle of "democratic centralism," which nominally renders people's congresses (and government councils elected by them) responsible to the lower-level congresses that elect them ("democracy") but which actually permits higher-level congresses and their governments to prescribe mandatory policies for lower-level organs ("centralism"). Within the central government, the powers of the national people's congress nominally extend over all other organs, whose personnel are elected by the congress and are subject to recall by it. The principle of unity of power, rather than separation, governs the assignment of particular functions to the chairman of the C.P.R., the state council, the supreme people's court and the supreme people's procuratorate.

The national people's congress (1,226 members, pending the "liberation" of Formosa) is a unicameral body whose members are indirectly elected for four-year terms by people's congresses of successively lower levels. In 1959 there were 150 women deputies and 179 from national minorities. The franchise is held by all men and women aged 18 and above, "except insane persons and persons deprived by law of the right to vote" (constitution. art. 86). The latter provision has been employed during the period of voter registration to exclude "counterrevolutionaries" and politically hostile elements. The individual right to vote, however, is exercised only in elections of people's congresses at the basic levels of hsiang (rural township) or *ch'ü* (urban wards or precincts), where the balloting occurs secretly or by show of hands according to local practice. The ballot is cast for a slate of names equal to the number of seats allotted to the basic-level congress, which has been approved by an election committee appointed by higher authority. Deputies elected to basic-level congresses elect the members of the *hsien* (county) or municipal people's congress, who in turn elect members of provincial people's congresses. The national people's congress is elected by provincial congresses, or their equivalent, on the basis of a slate of names proposed by the higher-level national committee of the Chinese People's Political Consultative conference.

The national people's congress has formal authority over all important matters affecting the life of the nation. It approves the national economic plan, examines and approves the state budget and financial report, decides on general amnesties and on questions of war and peace and exercises such other functions and powers as the congress considers necessary. The standing committee of the national people's congress exercises the functions of the congress during the intervals between its annual sessions, and in 1959 was authorized to amend the lams enacted by the congress. The chairman of the standing committee yields precedence only to the chairman of the C.P.R. The nationalities committee of the national people's congress submits for approval to the standing committee matters concerning various nationality autonomous areas. The bills committee studies bills or draft decrees. The budget committee is responsible for examining and reviewing the budget as well as the final accounts of state expenditure.

The chairman of the C.P.R. is elected by the national people's congress for a four-year term. He performs the formal and representative functions of chief of state, commands the armed forces and presides, ex officio, at sessions of the Supreme State conference and the National Defense council. Although the constitution provides for election of a single vice-chairman, the second national people's congress in 1959 elected two vice-chairmen of the C.P.R., without regulating the order of their succession to the chairmanship.

On recommendation of the chairman, the national people's congress elects the premier of the state council; and, on his recommendation, elects the vice-premiers, ministers and chairmen of commissions. The state council is the "highest administrative organ of the state," and exercises the characteristic functions of a national administration, with broad powers for the appointment of personnel and for issuance of orders, decisions and regulations. Its precise composition and that of its organs vary frequently as changes are made in the number of ministries and commissions.

3. Local Administration. — For administrative purposes, mainland China is divided into 21 provinces, five autonomous regions and two municipalities under direct central control (see Table I). The provinces of ancient China have their own deep historical and cultural traditions, and provincial separatism frustrated the efforts of the Manchu dynasty and Nationalist government to modernize the country. The C.C.P. has developed explicit policies calculated to destroy provincialism, but incurs criticism by reason of the predominance of Hunanese in its higher echelons. The national autonomous regions reflect the C.C.P. policy of seeking to minimize "Great Han" nationalism and to accord cultural autonomy — but not political independence — to areas in which national minority peoples predominate (see also above, The People).

In their turn, the provinces are basically divided into approximately 175 municipalities and some 2,000 units of hsien (county) level, many of which also have independent traditions. At the next successive lower level, the municipalities are divided into almost 400 municipal districts, and units of hsien level are divided into approximately 100,000 hsiang (administrative villages) and *chen* (villages). People's congresses and governments are set up at each of the three indicated levels, although hsien- and hsiang-level apparatuses are relatively less complex than provincial struc-

PREPARED BY CENTRAL INTELLIGENCE AGENCY, 1959

FIG. 3.— ADMINISTRATIVE UNITS OF CHINA SHOWING DEMARCATED INTERNATIONAL BOUNDARIES AND POPULATION DENSITIES. MARCH 1959

tures. Integral mergers of hsiang and hsien governments with people's communes of the same areas were prescribed late in 1958, when the traditional patterns of local administration began to collapse.

For the administrative convenience of higher-level governments, intermediate administrative combinations of subordinate areas frequently are found. Hsien are grouped into subprovincial administrative areas, and hsiang are grouped into sub-hsien administrative districts. Such areas and districts are, in effect. branch areas under control of the higher authority, and do not themselves have status in the system of people's congresses and governments. They permit higher-level governments to maintain closer scrutiny over governments of lower level, and permit adaptations of government policy to special local circumstances.

C. Social Revolution and Transformation

1. Socio-Political Objectives.— In On People's Democratic Dictatorship (June 30, 1949), Mao Tse-tung clearly defined the immediate and long-range socio-political objectives of the C.C.P. For the short range,

> Our present task is to strengthen the apparatus of the people's state, which refers mainly to the people's army, the people's police and the people's courts, for the defence of the nation and the protection oi the people's interests.

As for the long-term,

> When this condition is met, China will be enabled to advance steadily, under the leadership of the working class and the Communist Party, from an agricultural to an industrial country, from a new democratic to a socialist society and communist society, to abolish classes and to achieve world communism.

By "the people," Mao explicitly meant "the working class, the peasant class, the petty bourgeoisie and the national capitalists." as distinguished from their explicit enemies, "the landlord class, the bureaucratic-capitalist class, the Kuomintang reactionaries and their henchmen." By the "people's democratic dictatorship," Mao meant the basic social integration of the four elements constituting "the people," who. "under the leadership of the working class and the Chinese Communist party," formed "their onn state" to maintain dictatorship over non-co-operating social classes.

Mao's formulation reflected the class-war concepts of Marx and Engels. Lenin's "dictatorship of the proletariat" and his own interpretation of the need for "continuous revolution" under the special conditions found in China.

Mao's immediate objective of strengthening the power of the people's state was broadly achieved between 1949 and 1953, when the state army. police and courts destroyed the principal class enemies. The properties of "bureaucratic-capitalists" (*i.e.*, capitalist elements identified with the Kuomintang. especially the "four families" of Kung. Soong. Chiang and Ch'en), were confiscated and placed under direction of new economic ministries, thus providing the new regime from the beginning with a state-social-

ized, urban-centred industrial economy. Under the Agrarian Reform law of June 28, 1950, properties of rural landlords were confiscated and redistributed in the spirit of a political struggle to free China of "semifeudal" elements. Land reform, except in isolated minority areas, was completed by the end of 1952, and the economic power of the landlords was destroyed. The Regulations for the Suppression of Counterrevolutionaries (Feb. 20, 1951) legitimized continuing police action against other dissident elements whose "counter-revolutionary" character was ascertained from their reluctance to accept C.C.P. direction. During the same period, several nationwide campaigns (the "3-Anti," "5-Anti," "democratic reform" and others) had the effect of disciplining, indoctrinating and isolating politically the middle-class elements in private industrial and commercial circles. The "Aid-Korea, Resist-America" campaign exploited the patriotic themes of the Korean war to excite the people's loyal allegiance, and to expose class enemies as national traitors. During the same period. the network of C.C.P. controls was vastly expanded and decisive action was taken against carefully selected social and political targets.

A second phase of social policy, now in pursuit of the longer-term objective of the "transition to socialism," was initiated in 1953—the year of the first five-year plan and the Korean armistice. Following the substantial socialization of all means of economic production by 1957–58, the C.C.P. embarked upon the program of people's communes, considering these as an organizational prototype for the eventual transition to Communism. High levels of political and organizational tension were consciously sustained throughout the entire period; the masses were continually exhorted to act in a spirit of militant struggle to destroy all remaining class enemies and establish, in succession, the socialist and Communist societies. Progress toward those goals was specifically measured by successes in destroying anti-working-class elements, suppressing the theory and practice of private ownership of the means of production, and identifying and purging "rightist" elements. A great campaign against the "rightists" was waged in connection nith the all-encompassing "rectification movement" of 1957–58. At the same time. the growing economic power of the state-owned sectors of the national economy was deliberately employed to overwhelm the dwindling private sectors of the economy (industrial and commercial); and, in the countryside, the massive weight of collectivized agricultural production was employed to make economic life untenable for individual landowning peasants.

2. Rural Transformation. — While the land reform movement successfully removed the landlord class, it left unsolved the technical problems of increasing agricultural productivity and did not basically alter the social status of rich. middle, poor and landless peasants. To meet these objectives, the C.C.P. central committee issued a series of directives on Dec. 15, 1951, Feb. 15, 1953, and Dec. 16, 1953, contemplating the gradual. "voluntary" creation of agricultural producers' co-operatives following a preparatory campaign for the organization of permanent and temporary mutual-aid teams. The mutual-aid teams were organizations of several rural households for the common employment of tools, farm implements, draft animals and labour power during the spring and autumn sowing and harvest seasons and in rimes of natural adversity, which did not affect private ownership of the peasant's land or possessions.

Thus habituated to mutual effort, the peasant was next encouraged to pool his land with that of his neighbours in a lower-level agricultural producers' co-operative, from which he derived compensation in proportion to the share of his land (retaining a theoretical right to withdraw his property from the co-operative). By the end of 1954, nearly 10,000,000 mutual-aid teams with a total membership of around 70,000,000 households had been established; there were also 115,000 co-operatives with a membership of 2,300,000 rural households. Following Mao Tse-tung's July 1955 report on agricultural co-operatives, the C.C.P. central committee on Oct. 11, 1955, directed an acceleration of the movement. Between Oct. and Dec. 1955, the number of lower-level co-operatives increased from 630,000 to 1,900,000, with a membership of 75,000,000 rural households (65% of the total). In that phase of rural transformation, the primary social target was the "rich" peasantry.

The Supreme State conference convoked by Mao in Jan. 1956 decreed a completion of the lower-level co-operative movement and an intensification of the establishment of "advanced" agricultural producers' co-operatives by merger and consolidation of lower-level co-operatives. The social target of the ensuing "high tide of socialization in the countryside" was the middle peasant class, with the objective of reducing all peasants to a common system of wages. By the end of May 1956 the basic transformation had been completed: 110,000,000 rural households (91% of the total) had been encompassed in co-operatives—75,000,000 households (62% of the total) in advanced co-operatives and 35,000,000 households (29% of the total) in lower-level co-operatives. The process of consolidating lower-level co-operatives proceeded at a rapid rate for the rest of 1956, and the end of the year 95% of all rural households had been organized into 750.000 advanced agricultural producers' co-operatives.

Model Regulations for Agricultural Producers' Co-operatives (lower-level) were issued on March 17, 1956; Model Regulations for Advanced Agricultural Producers' Co-operatives were issued on June 30, 1956. A comparison showed that members of advanced co-operatives were called upon to assign title to their lands to the co-operative, without right of recovery, and to receive thereafter compensation in the form of wages based upon their actual hours and days of labour for the co-operative. The political blow to the middle peasantry, formerly the mainstay of the countryside, was struck by the party policy of requiring advanced co-operatives to accept the membership of "small" and "landless" peasants with equal right to daily and hourly wages even though they brought no land into the collective effort.

By the end of 1956, therefore, the Chinese countryside was substantially organized into semisocialist collectives; the private ownership "guaranteed" by the Agrarian Reform law of 1950 had ceased to exist, except for small garden plots; and the new system of party-controlled co-operative management brought most of the agricultural production of the nation within the framework of the planned national economy.

Concurrently with the advanced co-operative movement. the C.C.P. brought about a co-operative organization of handicrafts and side industries. rural credit and commercial and marketing agencies. Private speculations in grain, foodstuffs and industrial products (cotton, in particular) were halted. As a consequence, nearly all agricultural processes were managed and controlled by the collectives and their co-operative satellites—from the physical reconstruction of the rural land to the application of advanced agricultural techniques, the financing of rural agriculture, the semiprocessing of agricultural products and their sale and distribution. The mass of peasants had been reduced to the common level of a rural proletariat. The processes of merging and consolidating co-operatives of all types continued through 1957–58, paving the way for the establishment of people's communes late in 1958 (see below).

3. Industrial and Commercial Transformations. — The Common program of 1949 had theoretically safeguarded the private property interests of industrialists and merchants untainted by "bureaucratic-capitalism" or "foreign imperialism." Gradually, through such pressures as were exerted during the "3-Anti" and "5-Anti" movements of 1951–52, private industrialists and merchants were brought under higher degrees of party, state and trade-union control of their operations. At the same time, the rapid growth of state-owned industry made private industry increasingly dependent on state allocations of raw materials and manpower, and the development of state-owned trading agencies sharply reduced the operational sphere of private commerce. Late in 1955 the C.C.P. decided to bring private industry and commerce into contractual relationships of a "joint state-private management" type; in Jan.–Feb. 1956, the overwhelming majority of private industrialists and merchants were induced to "voluntarily" accept new arrangements in which, in return for a short-term payment of "interest" on the state-appraised value of their prop-

erties, former private owners might continue to serve as salaried managers of their enterprises. Political conformity with C.C.P. objectives was enforced. and the device of joint state-private operation brought nearly all industry and commerce within the scope of the state-managed planning system. The transformation was more drastic in industry than in commerce. As a result, at the end of the first five-year plan period in 1957, less than 0.01% of Chinese industry remained in private hands. and private commercial transactions were reduced to 3% of the total internal commerce. The "national capitalists" had been eliminated as a social class by measures as effective as those employed in the elimination of private ownership in the countryside. Mao Tse-tung could therefore say, with some accuracy, that "socialist relations of production have been established" (Feb. 27, 1957). The ensuing decision of the C.C.P. was to set new targets for "socialist production" (as distinguished from former emphasis on "socialist construction"), to complete the socialization of the small remaining spheres of private economy, and to move—through people's communes—to the Communist society.

4. People's Communes.—The C.C.P. Political bureau's Resolution on the Establishment of People's Communes in Rural Areas, of Aug. 29, 1958, visualized the establishment of people's communes as "the fundamental policy to guide the peasants to accelerate socialist production, complete the building of socialism ahead of time, and carry out the gradual transition to communism." The agricultural collectives, with their average memberships of fewer than 200 households, were considered to have been outmoded by the march of events. Initially, therefore, the Political bureau directed that all collectives within a particular *hsiang,* averaging 2,000 peasant households, should be amalgamated to form larger and more comprehensive people's communes—without bar to the merger of all collectives within a *hsien.* Where the former collectives had been engaged exclusively in agricultural activities. the people's communes absorbed all other forms of co-operative activity in the communal area and became multi-purpose production units embracing peasants, artisans and handicraftsmen, local merchants, students and local militia. The commune thus became the sole form of economic and social organization for large rural areas, including many consolidated *hsiang,* with responsibility for single direction of agricultural, industrial, commercial, educational, defense and other social-productive activities.

Experimental communes had been set up in Honan province early in 1958, and between hlay and August 1958 that province was wholly communalized while pilot communes were being established elsewhere. By Dec. 1958, 123,250.000 peasant households (99.1% of the total households) were reportedly organized into 26,578 people's communes, with average membership of 4,637 households (18.000–20,000 persons). On Sept. 30, 1958, communalization was complete in the rural areas of Hopeh. Shansi, Liaoning, Kirin, Heilungkiang, Shensi, Kansu, Tsinghai, Shantung, Anhwei, Chekiang, Honan, Hunan and Kwangtung provinces, in Kwangsi Chuang autonomous region. and the suburbs of Peking and Shanghai; more than 95% completion was reported from Kiangsu, Fukien, Hupeh and Szechwan provinces and in the Inner Mongolian autonomous region.

Such a transformation, on so vast a scale and affecting so many people, was doubtless without parallel in the history of mankind. It did not take place without opposition. During 1959–60 reports of widespread resistance to the program appeared. In July 1960 the *People's Daily* said that peasants had devastated some 10% of the total cultivated land in Shantung, Hopeh, Kiangsu, Shansi, Heilungkiang, Honan and Shensi; next month it reported that one-third of the cultivated land in Shantung was overrun with weeds because of neglect. Hog raising had been hindered by acts of sabotage; land had been carelessly harvested and thousands of tons of grain left in the fields. On Nov. 1, 1960, the *People's Daily* reported that party and government leaders had gone to the fields to supervise harvesting because of distrust of local commune leaders and peasants in general.

During the initial phases of the commune movement in 1958. drastic modifications in the regular patterns or' Chinese rural life aere introduced as a consequence of the extreme actions of the party's organizing cadres. A substantial retrenchment was prescribed by the central committee resolution on Some Questions Concerning the People's Communes, of Dec. 10, 1958. and subsequent actions in 1959–61 sought to restore the precommunal systems. The extreme changes in rural life observed in 1958 included the following:

1. The new communes, as productive units, were integrally merged with the governmental apparatus of the *hsiang,* district or *hsien,* becoming "the basic organization of socialist state power." The management committees of the former collectives and the people's congresses of merged *hsiang* were dissolved and replaced by a single communal people's congress and communal administrative committee for the exercise of governmental and production activity. C.C.P. organizations were reconstructed to ensure effective party leadership of the enlarged effort. The peasant, who could formerly deal face-to-face with the local political and production authorities, thereafter was obliged to deal indirectly with authorities more remote from his native village.

2. The vastly larger areas and populations of the communes led to more specialized forms of production organization. The labour power of the commune, male and female, was organized into a new hierarchy of production brigades. battalions, companies and sections (or "production teams"). The woman, "freed from household drudgery" so she could participate in economic production, might be assigned to the paddy fields; the man might be assigned to an irrigation construction project miles distant from his nife. Communal kitchens and mess halls, staffed by special teams, provided the food for workers too occupied to prepare their own; cominunal nurseries took charge of the children nhile the mother worked the fields; and systems of boarding schools were started to provide for school-age children. A profound effect was exerted in these and other ways upon the traditional relations of family members.

3. In principle, all private property of the peasant was abolished and merged into the communal holdings, but in Dec. 1958 the central committee at least temporarily relaxed the full enforcement of the policy for the personal possessions of the peasant. Where the land system of former collectives was based on the principle of collective ownership by the members, the communal land system at least partly reflected the nationalized principle of "ownership by the whole people." In many localities, however, the "production team," corresponding to the co-operative, remained the basic unit for agricultural production and continued the principle of "collective ownership"; while new activities at the communal level generated capital accumulations and investments said to reflect the principle of "ownership by the whole people." Actually, then, the communal system in the "transition period to communism" was to be characterized by a mixture of ownership systems.

4. The former system of wages by which members of collectives had been compensated was replaced by a combination of (lower) wages and "free supply" of food, clothing and other services. Ideologically, the wage-and-supply system was considered a step in the direction of the Communist principle ("to each according to his needs") and an advance over the socialist principle ("to each according to his labour")—but the central committee emphasized that the full adoption of the Communist principle, which also would require replacement of collective ownership by ownership by the whole people, would require 15, 20 or more years, and would need to anait a vast increase in the total economic production of the country.

5. The face of the countryside was physically changed as the separate lands of former collectives were merged into larger fields better suited to mechanized agriculture and more advanced technology; as road nets, irrigation systems and water-impounding structures mere reconstructed; and as burial mounds were leveled, new schools and nurseries constructed and many small villages removed or reconstructed.

6. Emphasis was placed on communal industrialization taking advantage of the raw materials and energy sources available to the commune, partly to enlarge the total national industrial pro-

duction, but also—by bringing industry to the countryside—to minimize the economic differentials between the rural and urban workers.

7. New state fiscal arrangements were necessitated by the loss of turnover and commercial taxes from the movement of commodities within the commune. At the same time. the communes were held responsible for maintaining their own capital construction projects, school construction and public norks on the basis of their own manpower and capital surpluses, thus reducing financial subventions from the state budget for local operations. Communes were required to enter into contractual relations with higher authorities for the delivery of capital accumulations in lieu of former taxes, and pressures were exerted to increase the total payment to the state from the rural areas. Closely associated with these developments was the central government's necessary policy of devolving a large share of responsibility for economic planning and development upon the localities.

8. Communes were obliged to maintain their own schools, including "Red and technical universities." in accordance nith a further policy of educational decentralization. All education was to be combined with "productive labour." to heighten socialist consciousness and to make workers of all intellectuals.

9. Heavy emphasis mas placed on labour discipline to mobilize communal labour power "as in a factory or the army." but lip service was paid to the necessity for combining discipline with mass-line democratic procedures of discussion and criticism. Especially intensive labour effort and discipline were required in the autumn-winter period of 1958–59 in support of the massive communal projects of public works and capital construction and reconstruction.

The entire communal program was executed by C.C.P. leadership without specific state legislative authority. The entire development occurred with surprising rapidity. especially in view of the fact that no apparent discussion of commune policy occurred in the national party congress deliberations of May 1958, where the 12-Year National Program for Agricultural Development (1956–67) was approved in revised draft without mention of communes. Party cadres often used ruthless working methods in their haste to complete the work; as peasant complaints increased late in 1958. the party directed its cadres to respect a normal work day not exceeding 10–12 hours and to grant all rural workers two free days each month. The national people's congress was officially apprised of the communal transformation only when Premier Chou En-lai referred to the communes in a passing paragraph of his report of April 18. 1959, in which he attributed the movement to "the demands of the broad masses of peasants."

By the early 1960s, however, the system of rural people's communes was in full retreat. Successive years of decline in agricultural production (1959–61), officially attributed to natural calamities of drought and flood, were also explained by nidespread resistance of the peasantry. In Aug. 1959 a "three-level system of onnership" was instituted, and rural means of production were distributed between the three levels of commune, production brigade (corresponding to the former collective) and production team (corresponding to the former lower-level co-operative), with ownership at brigade level designated as basic. By 1961. after difficulty had been experienced in reactivating peasant initiative at the collective level, measures nere taken to restore the co-operative level and to protect production at that level from undue encroachment on the part of the production brigade. The functions of the commune management committee were reduced to those of general planning and supervision, and many of the nonagricultural functions of the communes were permitted to atrophy. Rights of private ownership of plots of land and other property were restored to peasants within the co-operative system, and they were encouraged to sell or barter their surplus products and the products of family handicrafts in rural fairs. A nen system of wages was intended to compensate rural norkers on a differential basis, according to the special skills required in different types of labour and according to the actual volume of work produced. and the system of "free supply" was largely abandoned. In principle, the system of communes survived (and could be reinvigorated at a more opportune time); in practice, however, the measures of retrenchment recognized a substantial collapse of even collective agriculture and were designed to salvage the systems of private and co-operative agriculture originally instituted in 1953–55.

The more difficult problem of creating urban communes was tentatively approached by providing some "street and block" mess halls and nurseries and by preparing urban workers to accept a new system of equal wages (with bonuses) in place of the incentive wage differential used since 1949. In some newly established industrial centres, such as the Wu-han iron and steel complex efforts were made to employ industrial workers on part-time. small-scale garden plots in the vicinity to prepare for urban communes with agricultural components. The enlarged program of urban communes undertaken in 1959–60 placed more emphasis upon full employment of men and women in small and medium-size industrial establishments designed to replace small handicraft enterprises; in the larger cities, the new organization was based upon districts and sections rather than upon the municipality as a whole.

D. Justice

"The law of the people's state is a weapon . . . to be used to punish subversive elements of all sorts" (People's ***Daily***, March 25. 1952), and "people's courts" are politically responsible to and report to, the people's congresses which elect them at different levels. The Organic Law on the People's Courts (Sept. 21, 1954) assigns final appellate jurisdiction to a supreme people's court. which also exerts judicial control over local people's courts. intermediate people's courts and such "special people's courts" as may be appointed for specific purposes from time to time. Until it was abolished in April 1959, the ministry of justice was the principal agency concerned with the administrative assignment of judicial personnel, staff and "people's assessors," but these functions thereafter were centralized under the supreme people's court. People's courts exercise criminal and civil jurisdictions so as "to safeguard the people's democratic system, maintain public order, protect public property, protect the rights and legitimate interests of citizens and ensure the smooth progress of the Socialist construction and Socialist transformation of the country" (Organic Law, art. iii). The courts are assertedly "independent" (Organic Law, art. iv), but an official report in 1959 declared that they "work under the leadership of the (Chinese Communist) Party and the State, . . . adhere to the mass line and carry out the policy of combining judicial work with productive labour. . . ."

Public prosecutions are maintained by the supreme people's procuratorate (Organic Law of Sept. 21. 1954), under a procurator-general elected by the national people's congress. The procuratorial organization is self-contained and self-administered. and procuratorates at lower levels are controlled directly from the centre and may not be interfered with by local state organs (state constitution, 1954, art. xcvi). The supreme people's procuratorate exercises procuratorial authority over all departments of the state council and corresponding administrative organizations at lower level. and may also review the work of the people's courts. The state constitution guarantees citizens from arrest "except by decision of a people's court or nith the sanction of a people's procuratorate" (art. lxxxix), but no published regulations control the absolute discretion of the procuratorates. Their essentially political character was suggested in the report of Chang Ting-cheng, procurator-general, to the national people's congress on April 24. 1959. when in a review of the work of his agency during the preceding four-year period (1955–58) he pointed out that of all arrests and indictments during that period "70 8% involved active sabotage activities, nhile the remaining 29.27, involved counter-revolutionaries." The ministry of public security maintains a national police organization. which is supported by rural and urban militia and the garrison forces of the People's Liberation army, and together with the procuratorates and people's courts forms the backbone of the police state apparatus.

The "six codes" of the former Kuomintang government were annulled in 1949, but no subsequent codification of criminal and civil law was promulgated. People's courts rely on "people's

assessors" and informal methods of inquiry to administer "people's justice" in accordance with the mass-line policies of the C.C.P. Public hearing of cases is the rule, except in cases "involving state secrets, the private matters of the parties concerned. or crimes committed by juveniles . . ." (decision of the standing committee, national people's congress, May 8, 1956).

E. Education

During the first five-year plan period (1953–57), over-all enrollment in Chinese educational institutions at all levels reportedly increased about 33% from 54,000,000 to 71,000.000. In 1958 the total rose to nearly 100,000,000: 86,400,000 primary-school students, 8,520,000 middle-school students, upper and lower, and 660.000 in institutions of higher education and 1,470,000 in comprehensive and technical universities, normal schools, technical schools and colleges. Educational policy is generally directed by the propaganda department of the C.C.P. central committee, but the principal administration is vested in a ministry of education.

Educational policy strongly reflects the political objectives of the C.C.P. Mao Tse-tung asserted, on Feb. 27, 1957: "Not to have a correct political point of view is like having no soul . . . Our educational policy must enable everyone who gets an education to develop morally, intellectually and physically and become a cultured (*i.e.*, literate), socialist-minded worker." Following a central committee Conference on Educational Work in 1958, Lu Ting-yi declared:

> Our state is a proletarian dictatorship, a socialist state. Our education is not bourgeois, but socialist education . . . The educational policy of the Chinese Communist party has always been that education should serve the politics oi the working class and be combined with productive labour; and to apply this policy, education must be led by the Communist party . . . We believe there are only two kinds of knowledge in the world. One is knowledge of the class struggle. . . . The other kind of knowledge is the knowledge of the struggle for production, that is, the knowledge men gain in their struggle against nature. . . . The philosophy of dialectical materialism provides men with a correct way of thinking.

In 1957–58 strong emphasis was placed upon compulsory "socialist education" at all school levels, and for all elements of the population, under a special curriculum prescribed by the propaganda department. Extensive indoctrination was maintained concerning the necessity for combining "redness" with "expertness"—in large part to overcome rightist and "bourgeois" tendencies in educational and intellectual circles. Especially after 1958, students and faculty in all educational institutions were required to engage in productive activity, either establishing their own factories and workshops or being assigned to work in factories, on farms and in other enterprises. As summarized by Lu Ting-yi:

> Education divorced from productive labour is bound to lead, to a degree, to the neglect of politics and of party leadership in educational work, thus divorcing education from the realities of our country and eventually causing right deviationist and doctrinaire mistakes.

The assignment of educational responsibility to the communes was designed to keep the student in the closest possible relationship to productive activity.

F. Defense

The Chinese People's Liberation army (P.L.A.) is the unified organization, under a single command, of all mainland land, sea and air forces. Known as the Red army (until 1937), and as the 8th route army and new 4th army (and 18th army group) during the Japanese war (until 1945), the P.L.A. adopted the new name when the civil war resumed in 1946. The history of the P.L.A. is officially traced to the Nan-ch'ang uprising of Aug. 1, 1927; the army fought under the "8–1" red flag until 1949, and Aug. 1 is regularly celebrated as P.L.A. day. The P.L.A. developed as the armed force of the C.C.P., whose People's Revolutionary Military committee exercises continuing political control, and Mao Tse-tung's military lectures and essays of 1936–38 strongly influence its military and political doctrines. A system of political commissars, with full military status, is maintained throughout the P.L.A.; and seven of the ten marshals first appointed in 1955 were serving as regular members of the C.C.P. Political bureau in 1959.

The P.L.A. is recruited on the principle of compulsory military service (law of July 30, 1955), which requires such service of all male citizens who attain the age of 18. Women may register for medical, veterinary and other technical services. The year of the military call up runs from March 1 to the end of February, and eligible men are required to register before July 1 of the year they attain the age of 18. Basic service is for a three-year period, which is extended for noncommissioned officers. Since the total size of the P.L.A. is estimated to be about 3,000,000 officers and men, the annual call up is fewer than 1,000,000 men. perhaps only one-twentieth of all eligible men. Technical information concerning the operation of the system is carefully restricted. Demobilized servicemen are carried in a ready reserve, which is reinforced by a standby reserve of civil and Korean war veterans and the urban, rural and communal militias.

The P.L.A. officer system, adopted on Feb. 8, 1955, specifically follows the Soviet model, with four officer levels: (1) two grades of marshal: supreme marshal, marshal; (2) four grades of general officers, corresponding to: general, lieutenant general, major general, brigadier general; (3) four grades of field officers: senior colonel, colonel, lieutenant colonel, major; and (4) four grades of company officers: captain, senior first lieutenant, first lieutenant, second lieutenant. Commanding officers and political officers are assigned to specific branches of service: infantry, cavalry, artillery, armoured corps, engineers, railway corps, signal corps, technical troops, public security force, air force, navy and air defense. (Naval ranks extend from admiral of the fleet to warrant officer.) Officers in certain professional classifications have special rank designations: technical officers, quartermasters, medical officers, veterinary officers, judge advocates and administrative officers. Art. 25 of the regulations concerning officers specifies: "Selection of officers and assignment of officer duties shall be based on political quality and professional ability." During the rectification campaign of 1957–58, and as a means of advancing party concepts of the proper relations that should exist between officers and men, senior officers were temporarily detailed to company duty as enlisted men. Officers are ordinarily held accountable for maintaining a party-type mass-line association with their juniors.

The modernization of the P.L.A. took place with Soviet military advice, and weapons systems and armaments were based on Soviet models. Increasing amounts of armaments, including ships and aircraft, are produced in China; it is generally understood that production of military matériel is a responsibility of the second ministry of machine building.

The chairman of the C.P.R. is commander in chief of the armed forces, and is chairman of the National Defense council. Under a chief of staff, the P.L.A. maintains a general political department, a general training department, a general personnel department, a general inspectorate, a general logistics department, a finance department and special command organizations for the navy and air force. Several department heads serve concurrently as vice-ministers in the ministry of national defense, which was established in 1954; nearly all are also members of the C.C.P. central committee. The Scientific and Technological commission of the state council, constituted in 1958 and initially placed under the chairmanship of Marshal Nieh Jung-chen, is understood to have responsibility for the military applications of advanced science and technology. (H. A. S.)

VIII. The Economy

In examining the economy of China it is necessary to distinguish between plans, practices, goals and operators. There first existed two patterns, that of the Nationalists and that of the Communists. Both planned the industrialization of postwar China, and both administered portions of China during the 1940s. The Communist pattern in 1949 became that operative for mainland China, and the Communists inherited a shattered economy, initially executing many Nationalist projects. Within the Communist pattern, however, after 1949, plans, practices and goals were altered so frequently that assessment of conditions at any one time is difficult. Chinese Communist economic policy is marked by inventive expediency, skilful improvisation, willingness to depart from classi-

cal Marxist theory and a sense of timing. Chinese Communist economy by the 1960s had become a mixed and transitional economy, no longer that of the traditional orient, but neither that of the occident nor of the Soviet Union.

The economy during the 1950s went through revolutionary changes, some of them truly basic and some chiefly organizational. Though a revolution has been in progress, the Chinese economy involves such a large population that intensive operations and a large amount of human labour per production unit continue to be a primary characteristic. Intensive agriculture, handicraft manufacturing and traditional transport all expanded during the very period in which agricultural mechanization, big-factory industry and modern transport were being fitted to the economy. In the reorganization of the economy, private activity gradually but largely mas eliminated, state control of primary and secondary production being relatively complete as the second five-year plan went into operation in 1958. Only in the non-Chinese areas of southwest China, in Tibet, in Inner Mongolia and in Sinkiang was state control less than complete. Though the production index increased, much of the product was either plowed back into expansion or was consumed by a growing population, so that the living level of the great majority of the population rose very little. Though party members profited from events, almost all Chinese were deprived of their private property and their freedom to operate individually, and millions of people were forced to work at public works projects under conditions amounting to slave labour. The economy of China is growing steadily, and the traditional focus on agriculture is changing, but agriculture remains dominant, with basic growth taking place in all other areas of the economy.

A. Production

1. Agriculture.— China proper and Manchuria form a region extending through several climatic regimes from Hainan Island to the Amur river. The region long has had a complex double pattern of agriculture, to nhich was added a third pattern in Manchuria after 1900. In the south has been a subtropical to tropical agriculture, based on rice, silk and tea and supported by a wide range of minor crops; the use of hill terracing, water in crop growing, and double cropping on small farms has been normal. In the north was found a midlatitude to cold climate and a dry climate agriculture based on wheat, millet and kaoliang (sorghum), supported by a wide but different range of minor crops; use of water in crop growing and double cropping have been minimal. In Manchuria after 1900 there developed on larger farms a commercial agriculture based on wheat and soybeans, plus several minor crops, contributing a large foreign trade volume by utilizing the good transport network. In all three zones there have been localities in which minor crops assumed major proportions, based on climatic, soil, ecologic or cultural factors. In the Yangtze valley the two southern patterns overlapped, and the two northern patterns overlapped in south Manchuria. (For a more detailed discussion of the agricultural regions, *see* above, *Geographical Regions: Agricultural Regions.)*

Traditional Chinese agriculture was distinguished primarily by its intensity. The use of human energy was basic, leading to a high development of co-operative labour patterns both locally and regionally. Local processing and fabrication of agricultural raw materials into simple manufactured goods has given most of the agricultural population a variety of secondary handicraft skills. The subordination of animals to crops led to the subordination of animal to human energy in farming operations, this in turn keeping tools simple and farms small in size.

Chinese agriculture. as a whole, has been practised on lands held under private ownership, so that tenancy has been traditional, though varying both regionally and historically. Regional self-sufficiency in products has been traditional but not total. The Chinese seldom purposely exported agricultural produce in earlier periods, yet since before the 19th century a large annual export of agricultural products has occurred and since the establishment of the People's Republic agricultural exports have been the chief means of paying for purchases abroad.

The agricultural landscape has expanded slowly over the centuries, and the number of farm families has increased. The agricultural population long comprised about 80% of the total. Farms generally mere small, and though the large amount of human labour available enabled high yields per acre, this meant a low yield per man-day and, therefore, a low per-capita income. As the population increased after the 1850s the per-capita farm area actually decreased steadily, resulting in a slow decline in the per-capita income. Though the Chinese farmer was perhaps the world's most skilled user of fertilizers, the volume available never was adequate to the need. The gradual disappearance of former Chinese monopolies (such as natural silk. tea, soybeans, pig bristles and tung oil) caused disruption and deterioration of regional sectors of agriculture. since government services to the farmer never developed.

The Communist agrarian revolution was designed to cure the ills from which rural China suffered. It consisted of the abolition of landlordism and, initially, the distribution of land to the landless peasantry to win their support, proceeding to agricultural co-operatives and thence to vast rural communes (described above under *Social Revolution and Transformation: Rural Transformation*).

Increase in yields is being sought through the extension of the cultivated area, the extension of irrigation, flood control. field drainage. disease and pest control, improved plant breeding and supply and use of chemical fertilizers.

2. Fisheries.— China has rich and varied sea and fresh-water fisheries, and a widespread pattern of pond breeding of fish to supplement the total. The whole of the China coast is a shallow-water sea-fishery zone, with tropical species important in the south and cold nater forms in the north. The Shantung and Chekiang-Fukien coastal sections are leading sea-fishery areas. Prior to 1950 there were few modern facilities for handling large volumes of fish. and fishing fleets were not mechanized. Almost every stream, lake and canal in eastern and southern China produces fresh-water fish in wide variety. In the lowlands of south and eastern China the pond raising of carp and other breeds of fish is an important auxiliary occupation. In southwest, west and northwest China fresh-water fisheries are not productive in any form, and fresh fish are a rare food.

3. Forestry.——Most of China proper and Manchuria were once forested. For many centuries, however, the Chinese have prevented nature from reproducing the natural plant cover and gradually have depleted most of the forest resources. Afforestation has been practised repeatedly. Extensive forest plantings of the early 1930s mere being cut for commercial timber in parts of south China during the late 1950s. Cnder Communist control reforestation is under way, and by the early 1960s around 7,000,000 ac. of shelter belt forests and other local forests had been planted in north China. Manchuria and other localities. Though much of this would not yield forest products for several decades, it should have more rapid results in flood control and prevention of soil erosion.

The heavily populated parts of the Yangtze valley, north China and southern Manchuria are extremely short of all kinds of wood products. Northeastern Manchuria is the only real source of large timber, with commercial lumbering one of the important industries. From the Yangtze valley southward there are scattered patches of forest, with many scattered trees found throughout the agricultural landscape. Lumbering there is small in scale and secondary to agriculture. However. south of the Yangtze river bamboos grow nidely and provide a substitute for true wood products. Bamboos grow rapidly and produce large volumes of marketable material annually, so that in the 20th century there has been greater use of bamboo than of true wood products everywhere in southern China. Whereas China as a whole formerly was an exporter of wood and forest products, its supplies by the 20th century had become inadequate to its total need, and China became an importer of wood products. *(See* also above, *Physical Geography: Vegetation.)*

4. **Mining.**—In the early 19th century China was thought to be a tremendous mineral storehouse. By the 1930s the estimates had been revised sharply downward, as surveys revealed shortages. Surveys carried on by the Communist government, however, par-

ticularly in the outer areas of greater China, have been revising the totals upward again, both in quantity and in variety.

Coal.—Coal is China's greatest mineral resource, the country ranking fourth in world coal resources, assessed in 1954 at 445,000,000,000 tons. The coal varies in type from anthracite to lignite. Most of the reserves, and the greatest annual production, are located in north China and southern Manchuria, though coal is mined in every province (but not in Tibet). South China, however, is not well off, the coal resources being smaller and more costly to mine than those of north China and Manchuria.

The annual production of coal in 1938 was 38,900,000 tons; that of 1942 was 56,300,000 tons; that of 1954 was 79,928,000 tons; and by 1959 a production of 347,800,000 (metric) tons was said to have been reached. Communist effort centred on the two open-pit basins at Fu-sung and Fou-hsin, south Manchuria; on the Kailan mines near the port of Ch'in-huang-tao, Hopeh; the new Ta-tung area of north Shansi; and the Hwainan area of northern Anhwei, with development at other coal basins at lesser rates.

Petroleum.—Petroleum prospects for China were small and scanty in reserve until 1955, when important finds were made in Sinkiang. Manchurian oil shales, located near the major coal sources, produce oil also. Production of oil in 1944 was only 116,000 tons (minus Manchurian oil shale production), that for 1954 was 824,000 tons; by 1959 it reached 3,300,000 tons, still a small figure in comparative world terms.

Iron.—Iron ore of some sort is to be found in every province of China, but the known deposits of workable, high-grade ores formerly were scattered and rather small. New sources have been found in a number of areas in surveys conducted by the Communist government, and the program of iron and steel manufacturing is expanding rapidly. Though Chinese iron ore reserves are neither huge nor high in quality, there is sufficient ore, adequately distributed, to advance the country's industrial status, and new sources of satisfactory ore continue to be found.

Others.—China is known to possess a wide variety of other minerals in quantity adequate to its needs in the near future. The shortages in copper, aluminum-producing minerals, some ferro-alloys, and other minerals critical to industrialization have come to appear less serious than they formerly did.

5. Power.—In power resources China long depended upon coal and charcoal. The programs in petroleum exploration, and those in hydroelectric power development, supplemented by thermal-electric development, were expected to yield results by the end of the second five-year plan. A long-range program of multipurpose dams in the Yellow river basin eventually will yield large power returns. The total electric power capacity in 1958 stood at 2,500,000 kw. and the government reported that 41,500,000,000 kw.hr. were generated in 1959, reaching the goal for 1962 under the second five-year plan.

6. Industry.—Manufacturing is very old in Chinese economy. In the premachine age handicraft manufacturing was carried on in countless small units organized by guilds. Handicrafts persisted into the 20th century as the prevailing method of manufacture, though some were weakened by competition with foreign machine-made goods or, in cottons, by modern factories in China itself. Factory development was mainly, although not exclusively, in the manufacture of cotton textiles. There also were established silk filatures, flour mills, match factories and some steelworks. Industrial development was retarded by civil strife and foreign wars, since both domestic and foreign capital were reluctant to invest extensively in equipment that might be destroyed by contending armies.

Before the war with Japan began in 1937, industry had been developed mainly in the lower reaches of the Yangtze valley. After 1937 industrial development made rapid progress in the interior provinces. The Japanese in Manchuria, after 1931, developed industry and the return to China of Manchuria promised an active industrial region. Its stripping by Russia during 1945 and 1946 made the process of postwar economic reorganization difficult. The first five-year plan almost amounted to an initial plan for the development of industry in China, though it did have as support many previous plans, a number of plants in going condition, many inoperative plants, mines, a skeleton transport network and a small complement of skilled labour.

Facing economic blockade from much of the world, the Communist government turned to the Soviet Union for aid. The industrial program was divided into two segments, namely modern, powered, big-factory industry, and traditional handicraft, workshop industry. Both segments are under expansion, the first designed to develop basic heavy industry and power, the second to supply consumer goods until the maturing of the modern industrial pattern. Institutional changes made by the Communist regime were in the direction of transfer of control of all industry from private hands to the state. (See above, *Social* Revolution and Transformation: Industrial and Commercial Transformations.)

For the first five-year plan about 3,000 industrial projects were set up, of which 694 were classified as "above norm," meaning that major state financing would be required for each, whereas the other 2,300 projects were smaller items into which the state expected to put only minimal capital investment funds. The "above norm" group was expanded to 800 prior to the completion of the first five-year plan in 1957. Some of the 800 projects were not scheduled to begin until late in the period. Forty-eight projects were planned for the already operating An-shan iron and steel complex, whereas in other cases a single project involved a complete operating complex.

As the second five-year plan began in 1958, many projects of the first plan were not yet operative, and many long-term complexes were designed for completion only by the end of the second period. Owing to changing bases of statistical reporting, the changing of base dates for production indexes, and other technical changes, the actual accomplishment is difficult to assess. Industry is growing and is turning out producer's goods that can promote further industrialization. The government reported that in 1959 steel production reached 13,350,000 tons, as compared with 8,000,000 tons in the preceding year; these figures do not include the poor product of small native-style plants. An automobile truck factory began operation in 1956, and electric generators, electric motors, machine tools and other producer's goods are actually being turned out.

Formerly most industry was concentrated near the seaboard. During the war years, 1937 to 1945, it was dispersed all over interior China proper. The locational focus of the first five-year plan lay in north China and southern Manchuria, with Shanghai and its hinterland an important auxiliary zone, but with industrial beginnings in Inner Mongolia. Later planning indicated considerable decentralization around the newer finds of mineral resources.

B. Trade and Finance

1. Trade.—Though local and regional self-sufficiency was marked in traditional China, it never was complete; interregional trade in a wide variety of products is almost as old as Chinese culture. But as the occident developed its modern passion for interregional trade China maintained its older patterns, neither developing the complicated organizational machinery nor the consuming interest in commodities that marks the modern economic history of the occident. (For the origin and nature of the system by which the foreign trade of China was organized after the middle of the 19th century, see above, History: 19th *Century* and Revolution.) The Chinese interest in trading, though it has grown slowly, does not yet equal that of the occident. After about 1930 Chinese interest in foreign goods shifted gradually toward raw materials, tools, machinery and other production goods. Communist trading policy is political in nature, the exports and imports of the People's Republic reflecting centralized planning and political intent rather than popular will or interest.

Domestic.—The earlier internal trade of China was made up of two types of exchange: purely private trade on a local to national basis; and movement of grains and other commodities from local areas toward government administrative centres as tax payments. The latter expression of exchange ceased in 1911, but government agricultural collection as tax payment was reinstituted by the Com-

munist government in 1949. In Communist China domestic trade is handled by a variety of state-controlled agencies for large inter-regional trade, and by local co-operative organizations for purely local commodities, these latter groups engaging in both wholesale and retail trade. The volume growth of internal trade has been slow, but corresponds closely to improvements in transport. By the early 1960s internal trade mas increasing rapidly as large volumes of raw materials and manufactures moved between rural areas and urban industrial centres; the very population of China requires a large amount of exchange.

Foreign.—Since the mid-19th century the foreign trade of China has grown larger with the changes in the economy. An important feature of this foreign trade has been the considerable excess of imports over exports, characteristic up to 1955, but not thereafter. There has always been some government participation in foreign trade, since early "tribute" missions operated between governments. Under the Communist government, state trading organizations took over the entire handling of foreign trade. Summary returns are not published, making a full analysis of trade since 1949 impossible.

After 1949 the direction of foreign trade shifted markedly, reflecting the altered international situation. In Dec. 1950 the United States announced the prohibition of transportation or discharge by U.S. ships or aircraft of strategic materials shipped from or transshipped through the United States to the Chinese mainland, Hong Kong and Macao. Most west European countries followed this ban to some degree until about 1955, after which date they increasingly relaxed their restrictions. Consequently China's trade with the Cnited States ceased and that with the Soviet Union and eastern European satellites came to be dominant. Trade with the Soviet Union was only 0.4% of total trade in 1936 and 8% in 1949. Trade agreements were signed with the Soviet Union in February and April 1950. In 1950 the Soviet Union accounted for 20% of total imports and 27% of total exports; in 1951, 45% of total imports and 52% of total exports. Trade agreements were also signed with eastern European countries, among them Poland, Czechoslovakia, Hungary and eastern Germany. These countries accounted for slightly over 1% of total imports and 4% of total exports in 1950; in 1951 for 25% of total imports and 26% of total exports. Imports from the Soviet Union and eastern European countries consisted mainly of industrial raw materials and industrial machinery, equipment and parts. Exports to those countries consisted of soybeans, silk, tea, wool and agricultural by-products, which increasingly were more highly processed. From 1952 through 1958 trade with Communist countries amounted to almost 80% of China's foreign trade.

China also made trade agreements with other countries with which no large trade previously existed, and between 1953 and 1957 agreements were made uith west European countries that resulted in the growth of significant trade with Europe. In most of these cases China was seeking particular raw materials, such as rubber and cotton, or such manufactured goods as machine tools, electrical equipment and chemicals. Trade agreements with Japan encountered political obstacles, but by the late 1950s China's trade with Japan was greater than that with any non-Communist country.

2. Banking and Currency.— China's traditional currency consisted of copper coins, known as "cash" to foreigners, used for small transactions only, and unminted silver bullion for larger transactions, the amounts specified by varied weight measures. Domestic banks were chiefly merchant trading houses, though these sometimes received deposits and made loans. After European trade began, Spanish and Mexican silver dollars were imported and circulated, and in the 19th century some foreign banks, chiefly British, established branches in China. After 1900 the "cash" slowly disappeared, Chinese minted silver dollars and copper coins, on a decimal system, replaced the foreign coins, but paper money, based on silver, provided the main medium of exchange. Chinese private and government western-type banks appeared, replacing the older merchant trading houses. Silver was nationalized in 1935, and paper money issued by government banks became the exchange medium. The period from 1937 to 1950 saw heavy inflation and several new paper currencies, both Nationalist and Communist.

Communist abolition of these currencies, and replacement by the *jen-min-pi,* issued only by the People's Bank of China, was complete by the end of 1951. All private banks were taken over by the end of 1952, and all government banks were reorganized to be replaced by six government banks, each of which finances different sectors of economic activity. After all banking became state controlled, several thousand branches were established throughout the country. The currency became a controlled one without specific gold or silver backing, and a compulsory savings system was developed for the accumulation of state controlled capital funds. Most of the government banks engaged in short- and medium-term loan programs to government agricultural and handicraft co-operatives and to industrial corporations. Almost annual fluctuations take place in credit, loan and investment programs, reflecting changing economic planning, rapid or slow economic development, and success or failure in loan recoveries.

3. National **Finance.**—Normally the Chinese imperial government's income was derived from a variety of levies, among which the land tax, duties on both foreign and domestic trade, the salt tax and "tribute" levies of commodities drawn from all over China were the chief producers of income, supplemented by a wide variety of minor taxes. Public works were largely performed by unpaid drafted labour. After about 1860 the foreign trade customs dues increased greatly but regularly were mortgaged for foreign loans. During the 1930s the salt tax produced much of the unmortgaged national income, the land taxes financed provincial governments and regional military groups. In the 1930s income, profit, corporation and other occidental-type taxes were introduced, along with more complete budgeting, accounting and auditing systems. However the Nationalist government operated partially upon the basis of foreign loans. The Communists were supported by a variety of local and regional taxation until after 1949.

Communist national finance differs from earlier patterns. After 1953 most state revenue was derived from receipts from state enterprises, the proportion of national income so derived in 1958 being estimated at 84% of the total budget, with the remaining state-controlled private enterprise yielding about 1.5%, communes yielding some 13.7%, and purely private enterprise taxation yielding only about 0.5% of the national budget. Soviet financial aid to China has been significant, but is roughly balanced by Chinese aid to such governments as Outer Mongolia, North Korea, Communist Vietnam and Nepal.

Capital formation during 1951–57 represented chiefly profits from state enterprises and compulsory savings, with domestic bond subscriptions and other sources contributing smaller proportions. The introduction of the commune simplified the problem in the sense that state control of income became almost total, as shown by the 1958 figures given above. The annual rate of capital formation is rising above 20% of annual income (in 1958 being estimated at 28%), a rate which can be enforced by the almost complete state control of the economy. The rate of investment in expansion of the economy has exceeded the rate of capital formation, producing inflationary pressures and causing cutbacks in expansion during 1957 and 1958.

The published total budgets of income and expenditures moved slowly upward until 1958, when the budget jumped from 30,000,000,000 Yuan (balanced) to 41,000,000,000 Yuan with the 1959 budget set at 52,000,000,000 Yuan. The allocation of expenditures during the first five-year plan were roughly: industry, close to 40%; agriculture, forestry and water conservancy, about 10%; transport, telecommunications and postal services. about 12%; trade, about 4%; culture, education and public health, about 15%; and defense, nearly 20%. In 1959 the allocation to industry was increased to about 50%, with a decrease in defense to about 11%.

C. Transport and Communication

For centuries the human carrier, using the shoulder pole and a peculiar bouncing gait, treading narrow paths that become step trails in the uplands, has been the chief transport agency. Royal courier trunk roads for government agents were wider and often

stone-paved, but were not suitable for wheeled vehicles. In the north the wheelbarrow, the animal cart and the pack animal were supplementary, as were also, in central and south China, water navigation by boats and rafts on rivers, streams, lakes and canals. In the southwest the pack train again was supplementary, and in Tibet and most of central Asia the pack train was dominant. Along the coast the sailing junk was a dominant and highly developed agent of transport. Communication for all levels of society was chiefly by courier. Passenger traffic used all forms of transport, though the upper classes traveled chiefly by sedan chair. Not until the latter part of the 19th century did other forms of transport or communication come into use, but slowly China has adopted most of the modern devices, though the human carrier and the other traditional agencies remain much used in contemporary China. In 1949 the ricksha and the sedan chair were legally prohibited.

1. Roads. — After 1915 modern roads were constructed in various parts of China, though many areas, such as Szechwan province, were without roads until the 1930s. All forms of wheeled traffic have been growing steadily. The bicycle, the wheeled cart, automobiles, motor trucks and motor buses spread all over China proper, into Manchuria and into central Asia. By the early 1960s greater China had a total of 275.000 mi. of wide road open to wheeled vehicles, though of this only about 180,000 mi. could be termed highways open to automotive truck and bus traffic, the balance being usable by carts, bicycles and other light wheeled traffic. Of these totals, about 80% (and 90% of the automotive highways) lay in China proper and Manchuria. The claim was made, at the end of 1958, that only 54 counties out of just over 2,000 could not be reached by some kind of wide road. There are few statistics for the vehicles themselves, but the total of light wheeled vehicles of all kinds at the end of 1958 was well over 1,000,000, whereas the automotive equipment is restricted, the 1959 total being approximately 105,000.

2. Railways. — Railway construction started in 1895 (see **History** above), made fair progress during the early years of the 20th century, stopped during the civil wars of the 1920s, resumed during the 1930s and World War II, and made progress after 1950. The older lines formed a skeleton system in the Yangtze valley and north China. The Russian- and Japanese-built Manchurian lines formed a good system linking the Russian Siberian system to that of China. All railways prior to 1926 were built by foreign companies on economic concessions, giving rise to much international difficulty and becoming a sore issue to the Chinese. Since 1930 new lines have been Chinese built and controlled. Construction by the Communists has been both strategic and economic, and is aimed at spreading the rail network over the whole of greater China and at connecting to the Soviet and Vietnam systems at several points.

The total mileage of lines in 1937 was about 6,850, excluding Manchuria, and that in 1948 after the recovery of Manchuria was about 16,000, though by 1951 only about 8,750 mi. had been reopened to traffic, owing to military destruction and deterioration since 1937. New construction to the end of 1959 totaled about 4,500 mi., which, with the completion of restoration of older lines, produced a total of about 20,500 mi. of operating line, with construction in progress on a few hundred miles. The chief new construction was in north China. Mongolia, the central Asian corridor and south est China. The only significant double trackage in 1952 was the Peking-Mukden and other Manchurian lines, but by the end of 1959 about 1,900 mi. of double-track line were in operation.

Railway rolling stock suffered severely during the war years. In 1959 there were in operation about 4,700 locomotives, 128.000 freight cars and 4,800 passenger cars, with annual additions being made. The second five-year plan, 1958–62, called for significant additions to all aspects of the railway system, in both line construction and rolling stock. The rail system is China's economic mainstay in the program of industrialization, and represents the cheapest form of inland transport available.

3. Maritime Shipping and Inland Waterways. — The fleet of motorized seagoing ships, barges and tugs available to the Communists in 1949 numbered under 350, with a tonnage of about 200,000, of which only a very few were seaworthy cargo ships, the balance of a rather large fleet either having been destroyed during the war years or taken to Formosa by the Nationalists. The fleet grew considerably, totaling by the early 1960s about 600,000 tons, in addition to a considerable tonnage of chartered British ships. Its utility is coastwise and on the lower reaches of a few rivers, except for the tug fleet, which chiefly is used on the inland waterways. The tonnage of about 300,000 native junks in 1958 was about 4,000,000, about one-third of which could work both the coastal zone and the major inland waterways, the balance being purely inland craft. Their carrying capacity was less than the tonnage would suggest, owing to their slowness. There are in the vicinity of 70,000 mi. of rivers and canals navigable to all kinds of watercraft, about two-thirds of this being limited to small craft and rafts, or to seasonal traffic. The distribution is chiefly within the Yangtze basin and south China, except for a very few navigable streams in north China and Manchuria. Waterborne traffic formerly amounted to between 10% and 15% of all freight carriage, also accounting for a significant share of the passenger movement, but in 1959 it handled about 20% of all freight moved.

At the end of the war many of the ports were in poor shape, and the navigational services largely inoperative. These subsequently were restored to their former quality, Shanghai resuming its dominant position in all forms of water movement of cargo and passengers.

4. Air Transport. — When the People's Republic was established a large number of airfields were available. With Soviet aid, equipment and personnel a civil air line was established in 1950, which became a state-controlled company in 1955 with, by then, dominantly Chinese personnel. About 20,000 mi. of passenger and freight routes are flown regularly, connecting the major Chinese cities, and linking up with Soviet air services.

5. Postal Services. — The Chinese postal service began operations in 1879, and was increasingly improved and extended over the years. All foreign powers withdrew their postal agencies from China in 1923. During the varied civil wars of the 1920s and the period of military conflict from 1937 to 1949 the postal services operated with surprising efficiency, delivering mail through military lines. During the 1920s there were maintained about 11,000 post offices and postal agencies, several hundred of which included postal savings bank facilities. The number of offices has been greatly increased under the Communist governments, reaching over 60,000 in the late 1950s.

6. Radio and Telecommunications. — Telegraph lines began to be privately built in China during the 1880s, became government controlled in 1908 and have gradually expanded to a fairly complete network covering all of greater China with a mid-1950s mileage of about 120,000 mi. of line. The telephone developed more slowly, except in urban areas, but by the late 1950s the total line mileage was close to 90,000, and trans-China long-distance service was in operation. A network of international telecommunications also was established, with centres in Peking and Shanghai connecting more than 80 countries. Radio, of course, is much younger, but has developed even more highly than either the telegraph or telephone systems. During the 1930s many private concerns and government agencies installed their own radio systems for trans-China communication. Under the Communists the radio communications have been further developed, both for message work and for general broadcasting. The broadcast network completely covers the country and, by the device of the fixed-tuning village and community centre loudspeakers, can completely blanket the country to bring almost the entire Chinese population into rapid and effective contact with central and regional officialdom.

Current history and statistics are summarized annually in *Britannica Book of the Year.*

CHINA (ware): *see* CHINAWARE.

CHINABERRY *(Melia azedarach),* a member of the Meliaceae or mahogany family and also known as China tree, pride of India and Indian lilac, is a spreading, mostly deciduous tree that may reach a height of 50 ft. The leaves are twice pinnate, the fragrant, purplish flowers are in open panicles four to six inches long, and the fruit is a globular, yellow, smooth drupe to three-quarters of an inch in diameter, hanging after the leaves fall. Although native to Asia it has become naturalized in tropical America and is much grown in the southern United States from southeastern Virginia to Texas. It grows with great rapidity and forms a desirable, dense shade. The variety *umbraculiformis,* known as the Texas umbrella tree, has drooping foliage and radiating branches which give the tree the appearance of a giant umbrella. (J. M. **BL.**)

CHINA CLAY: see KAOLIN.

CHINANDEGA, a department and city in northwestern Nicaragua. Population of the department (1959 est.) was 112,526. of which 57.5% was rural; area 1.776 sq.mi. Chinandega is important agriculturally and is the leading sugar area of the nation, manufacturing about two-thirds of the high-grade sugar of the country. It is also important in the production of corn, beans, sesame, rice, cotton and fruits, and in raising beef cattle on natural savanna pastures.

Chinandega, the departmental capital (pop. [1959 est.] 18,667), is in the centre of a rich agricultural district. Near the city are large modern sugar centrales and in it are cotton textile mills, ironworks, and plants for the manufacture of furniture, leather goods, cheese and vegetable oils. Chinandega has wide streets and many attractive buildings, which were built after the centre of the city was destroyed by fire during the 1927 revolution. It is connected by highways and the Pacific railway of Nicaragua with Managua (*q.v.*), 75 mi. S.E., and with Corinto 13 mi. S.S.W. on the Pacific coast.

Corinto (pop. [1959 est.] 6,776), also in the department, has a large excellent natural harbour and is the most important port in the country. Through it passes about 50% of the total foreign trade of the country. Corinto is also famous as a seaside resort because of its excellent bathing beaches. (C. F. J.)

CHINA SEA, part of the Pacific ocean (*q.v.*) off the coast of China. The China sea, which has a total area of 1,377,700 sq.mi., is divided by the island of Formosa (Taiwan) into the East China sea in the north and the South China sea in the south.

East China Sea.—This portion of the China sea, called Tung Hai by the Chinese, is bounded by the China mainland in the west, Formosa in the south, the Ryukyu Islands in the southeast, and Japan's Kyushu Island and Korea in the northeast. The East China sea, which has an area of 482,300 sq.mi., includes the Yellow sea (Huang Hai), which is an embayment between Korea and the north China mainland. The East China sea communicates through the Korea strait with the Sea of Japan, through the Formosa strait with the South China sea, and through the several straits between the Ryukyu Islands with the Philippine sea, also a section of the Pacific. Most of the East China sea is occupied by a continental shelf, on which the water depth ranges from 100 ft. in the west to 600 ft. in the east. The easternmost part adjoining the Ryukyu Islands is a deepwater trench reaching a depth of 9,126 ft.

The climate is dominated by the monsoonal system of east Asia, in which the steady cold, dry winter monsoon from the northwest alternates with a feeble, irregular, warm, moist summer monsoon from the southeast. Typhoons, which are tropical storms typical of east Asia, occur during the warm season and number three to four storms a year on the average. January temperatures over the East China sea range from 40° F. in the northwest to 60° in the southeast; July temperatures average 80°. Annual precipitation ranges from 45 in. in the west to 90 in. in the east. The eastern part of the sea is dominated by a strong warm northward current, which is a continuation of the north equatorial current of the central Pacific. The current enters the East China sea through the straits of the southern Ryukyu Islands and, flowing north, branches into a northern arm that enters the Sea of Japan through the Korea strait and a southern arm that skirts the south coast of Kyushu and becomes the Japan current (Kuroshio). In the shallower western section of the East China sea, currents shift seasonally with the monsoon, flowing southward in the winter and northward in summer. In view of the vast volume of sweet water carried by the Yangtze river, the chief inlet of the sea, its salinity, which is normally 34.5 per thousand, drops to 10 or even 5 per thousand in the vicinity of the Yangtze estuary. Water temperatures range in the winter from 45° in the northwest to 60° in the southeast; in the summer they are generally 80°. Below a depth of 5,000 ft. the water temperature is uniformly 36.5°. Tides reach 20 ft or more along the China mainland, notably at Hangchow, but drop to 4 or 5 ft. in the Ryukyu Islands. Fishing is an important branch of the economy of China, Formosa, Japan and Korea, and their fishermen make rich catches of sardines, milkfish, tunas, sea breams. croakers and other species, as well as shellfish and seaweeds. The principal ports on the East China sea are: Foochow, Wenchow. Ningpo, Shanghai, Sinhailien, and the Yellow sea ports of Tsingtao, Tientsin, Ch'in-huang-tao and Dairen in China; Chinnamp'o and Chemulpo in Korea; Nagasaki in Japan; and Chi-lung in Formosa.

South China Sea.—This portion of the China sea, known by the Chinese as Nan Hai, with an area of about 895,400 sq mi., is bounded by the southeast Asia mainland in the west. Borneo in the south. the Philippine islands of Palawan, Mindoro and Luzon in the east, Formosa in the northeast and the China mainland in the north. It receives several major streams of southeast Asia, such as the Hsi Chiang (West river) of southern China, the Red river of North Vietnam, the Mekong of Laos, Cambodia and South Vietnam, and the Menam Chao Phya of Thailand. The mainland shore line is fairly regular and contains only two major indentations: the Gulf of Tonkin and the Gulf of Siam. Most of the South China sea is underlain in the west and south by the continental shelf with depths of less than 500 ft. Only in the northeastern section do depths exceed 15,000 ft. Unlike the East China sea, which is devoid of islands, the South China sea is speckled with a vast number of islands and reefs. These are part of the Pratas group (Tung-sha), the Paracel (Hsi-sha Ch'ün-tao group), Macclesfield (Chung-sha bank), and the Spratly (Nan-sha group), all of which are claimed by the People's Republic of China. In the far south. the Natuna and Anambas islands are part of Indonesia.

The South China sea is subject to submarine earthquakes and volcanic eruptions that effect changes in the surface relief of the sea bottom. Like the East China sea. it is dominated by the monsoon climate with alternating seasonal winds. However, in view of its lower latitude, the South China sea has high winter temperatures. ranging from 60° in the north to 80° in the south near the equator. Annual precipitation averages 100 in. Warm-season typhoons are more common than in the East China sea. with as many as 15 occurring in August in the northern portion. Currents shift seasonally, with a predominant southward flow in the winter and a northward flow in the summer. These seasonal currents are especially strong in the western part of the sea and are counterbalanced by weaker currents moving in the opposite direction in the east. Tides reach 20 ft. in the Gulf of Tonkin. Tuna, sardines and mackerel are among the most important commercial fish in the region. The principal ports are: Hong Kong, Canton and Chan-chiang (Tsamkong) in China; Haiphong in North Vietnam, Saigon in South Vietnam; Bangkok in Thailand; and Manila in the Philippines. The South China sea is a major sea lane for all ships passing from Europe through Singapore to the far east. (T. SD.)

CHINAWARE, a term used as early as the 17th century to describe ceramics imported into England from China. Since then, it has come to be used almost synonymously with porcelain to designate most of the finer ornamental and useful ceramic wares, particularly table services.

The types of chinaware discussed in this article will be confined to the translucent, vitreous ceramic wares such as American household china. American hotel (or restaurant) china and English bone china. These ceramics are made with a high first, or bisque, fire at about 1,250' C. to 1,300° C, and a second, or glaze, fire at a lower temperature, about 1,100° C. to 1,200° C., followed by decorating firings at temperatures lower than the glaze firing.

These wares resemble true porcelain as made by the Chinese, which is also a translucent, vitreous ceramic. However, Chinese porcelain is made by a reversal of the firing process described above, having a low bisque fire (or none at all) followed by a high glaze fire during which both body and glaze mature together at about 1,350° C. to 1,480' C. All vitreous ceramic wares are resonant and ring when struck.

The nonvitreous, opaque earthenwares, which are often called china in a broad application of the term, are manufactured by processes similar to those used for translucent wares. However, earthenwares have different clay body formulas and lower firing temperatures and would be absorbent if left unglazed. (See POTTERY AND PORCELAIY; EARTHENWARE.)

Principal Raw Materials of Chinaware.— Clay is the basic essential ingredient of chinaware. It is formed by the decomposi-

tion, due to weathering or pneumatolytic action, of igneous rocks such as granite, gneiss and pegmatite. This process began ages ago with the cooling of the earth's crust and is continuous, so that more clay is constantly being formed.

Ceramists define clay as hydrous silicate of alumina; *i.e.*, a substance composed largely of aluminum oxide (Al_2O_3), silicon dioxide (SiO_2) and combined water. A theoretical formula for one form (kaolinite; *q.v.*) of pure clay would be $Al_2O_3.2SiO_2.2H_2O$. However. pure clay is practically nonexistent in nature. All clays contain impurities. usually compounds of iron and magnesium, which sometimes must be removed, depending on the type of ware to be made.

Geologists divide clay into two main classes: (1) primary, or residual, clays, which have remained where they were formed; and (2) secondary, or sedimentary, clays, which have been transported by erosion or other processes of nature to a place sometimes far distant from the original site of the parent rock. Secondary clays are much more prevalent, and more plastic, than primary clays.

It is possible to make some types of pottery, such as coarse earthenwares. from clay as it is found in the earth. In order to provide the attributes desired in finished chinawares, they must be made from special clays plus other ceramic materials. This mixture of clay and other substances is called the chinaware body, clay body or batch.

Kaolin, or china clay, constitutes about 40% to 50% of the chinaware body. This is the only type of clay from which a white, translucent, vitreous ceramic can be made. It is classed as a primary or residual clay, although some kaolins are sedimentary. Kaolin is 2 refractory clay, which means it can be fired at high temperatures without deforming; because of this characteristic it forms the framework of the chinaware body. It is a "white burning" clay, which means it imparts whiteness to the finished ware.

The early discovery of kaolin in China enabled the Chinese to produce true porcelain from about the 9th century A.D. After kaolin was found at St. Yrieix. near Limoges, France, and also in Aue. Ger., and Cornwall, Eng., Europeans began to produce fine porcelains and chinawares. In the United States, the principal sources of kaolin are in North Carolina, Georgia and Florida. (See KAOLIN.)

Ball clays, which constitute about 10% to 15% of the chinaware body, are sedimentary, refractory clays with a high degree of plasticity, and are added to make the body more workable. They also aid in the fusing, or vitrification, thus strengthening the ware. They fire to a creamy colour and cannot be added in amounts exceeding 15% without noticeably altering the whiteness of the finished china. Ball clays are more widely found than kaolins. Devonshire and Dorset in England, and Kentucky and Tennessee in the United States are important sources. Ball clays were so named because they were first marketed in the form of balls weighing several pounds each.

Flint, or pure silica, is a most important ingredient of American commercial china. although it is not used in English bone china. Its addition to the batch lowers the shrinkage of the body before firing and adds hardness and strength to the fired ware. Flint is made by grinding crystalline quartz or quartzite sand to powder. It is plentiful and can be obtained easily in most parts of the world. In the United States, it is mined extensively in Illinois, West Virginia and Pennsylvania.

Feldspar is needed in chinaware to act as a flux, that is, it melts first during the firing, thus helping to dissolve the other body materials and fuse them into a vitreous mass. As the ware cools, the feldspar hardens and forms a binding element that increases the hardness and translucency of the fired ware. Feldspars, or "spars" as they are called in the industry, vary in composition. There are two general types: (1) potash spars. such as orthoclase, which contain potassium and have the theoretical formula $KAlSi_3O_8$; and (2) soda spars, such as albite, which contain sodium and have the theoretical formula $NaAlSi_3O_8$.

Commercial feldspars are mixtures of potash and soda spars and are made to order to meet the requirements of the manufacturer. A mixture having a high content of potash is used in the chinaware body. North Carolina produces a large percentage of the feldspars used in the United States.

Cornwall stone (Cornish stone), or china stone, is a unique feldspathic material found at Cornwall, Eng. It forms 20% to 30% of the body of English bone china, in which it acts as a flux. It is also used in glazes and bodies of other chinawares.

Bone ask is a calcium phosphate made by calcining (roasting) bones of cattle and grinding them to a fine powder. Some authorities consider bones of oxen best for this purpose. This material forms from about 25% to 45% of the body of English bone china, in which it acts as a flux and imparts translucency. When added in large amounts, it acts as a refractory along with the kaolin in keeping the ware from deforming during firing.

Other supplementary ingredients are added in small percentages to the body to facilitate production. Dolomite provides calcium and magnesium; bentonite increases plasticity; talc (steatite) and nepheline syenite act as fluxes.

Formulas. — A typical formula for U.S. household china body is: kaolin, 40%; ball clay, 10%; feldspar, 30%; flint, 18%; dolomite, 2%.

This ware is given a bisque firing of about 1,270" C. and a glaze firing of from 1,100" to 1.200° C.

A typical U.S. hotel china formula is: kaolin, 29.5%; ball clay, 13%; feldspar, 21%; flint, 35%; lime, 1.5%.

This ware is given a bisque firing of about 1,270" C. and a glaze firing of about 1,150" C.

Bone china was made experimentally at several English factories, including Bow and Chelsea, as early as the mid-18th century. However, it was perfected and first marketed in quantity in England by the second Josiah Spode (1754–1827) about 1800. So successful was his venture that many other factories in north Staffordshire began to make similar ware and thus created the great English bone china industry. Spode's original bone china formula was: kaolin. 3½ parts; Cornish stone, 4 parts; bone ash, 6 parts.

A modern variation of the bone china formula as used by some English manufacturers is: kaolin, 40%; Cornwall stone, 20%; bone ash, 40%.

Preparing the Body. — After the formula for the chinaware body has been determined, the ingredients must be thoroughly mixed, purified and processed to the form and consistency necessary for shaping the ware. The steps in this process vary with the factory and type of ware, but in general are as follows:

1. Blunging—the term used in ceramics for mixing the batch with water in a tank called a blunger.
2. Grinding—reducing the body materials to the necessary degree of fineness. This is usually done in a ball mill, a cylindrical tank lined with porcelain and containing a "charge" of flint pebbles. It is sometimes possible to mix and grind simultaneously in ball mills, thus eliminating the need for blungers.
3. .Screening--passing the batch through a series of screens, usually varying in fineness from 80 to 100 meshes to the square inch, to remove coarse particles left from the grinding.
4. Magnetic separating—passing the batch over strong electromagnets to remove iron impurities that would discolour the white body of the china during firing or that appear as brown or black spots in the bisque ware.
5. Filter pressing—removing the surplus water and forming the body into soft, plastic clay slabs for storage or processing to the appropriate consistency for shaping the ware.
6. De-airing—eliminating bubbles that would cause defects in the finished ware.

The ceramic industry in the 20th century has notably accelerated the development of machinery to facilitate these operations and decrease costs. Machines have been developed that will blunge, grind, purify. filter, and de-air the chinaware body automatically and deliver it in the form of slip for casting, or soft plastic clay of the proper consistency for jiggering or pressing.

Forming the Ware. — Most useful and ornamental chinaware is produced by one of the following methods: (1) wheel throwing; (2) jiggering; (3) slip casting; or (4) pressing.

Wheel throwing is a process in which the potter. who must be highly skilled, forms the ware with his hands on a revolving disk, or wheel, mounted on a vertical shaft; the wheel may be driven

by mechanical power or by the potter. This process is better suited to the making of individual pieces than to mass production. After the mare has been formed, it is allowed to dry to a "leather-hard" state, and the feet and any other unfinished parts are completed by turning (see below).

Jiggering, or jollying, is the mechanical adaptation of wheel throwing; it is used in chinaware factories and in many studios where mass production or duplication of the same shape is reauired

Hand jiggering is done by placing a plaster of paris mold shaped like the outside of the object, such as a cup, on the jigger head (which is essentially the throwing wheel). A piece of clay of the size and shape necessary to form the object is put into this mold. As the jigger rotates, a metal template shaped like the inside of the cup and fastened to an adjustable arm is slowly lowered into the revolving mold and clay; this action gradually smooths and shapes the clay to the profile of the template and completes the forming of the object. The cup handle is applied later.

In forming shallow objects, such as plates, the mold is shaped like the inside of the plate and the template forms the foot and underside. It is possible to jigger oval shapes by using an eccentric rotating gear.

Automatic jiggering machines have made it possible for factories to produce more than 240,000 table services per day.

Slip *casting,* or molding, is the simplest of all the clay fabricating processes for producing more than one piece of a particular kind of ware. It is especially useful in producing pieces, such as teapots, that cannot be formed easily by other methods. In the slip casting process, the ware is formed in molds made of plaster of paris and shaped to the contour of the outside of the object. Considerable skill is required in making these plaster molds.

Once the mold is ready, the clay body is mixed with water to a creamy consistency called slip; the slip is then poured into the mold until its level is at the top of the mold. The mold, being porous, rapidly absorbs the water from the slip, causing a coating of clay to form on the surface of the mold in the shape of the object desired. The thickness of the ware is determined by the length of time the slip is allowed to remain in the mold. It may be necessary to add more slip from time to time to maintain the slip level; otherwise the level will drop as the mold absorbs water from the slip. When the ware is of the desired thickness, the excess slip is poured out and the mold inverted to drain and to allow the clay to harden slightly.

As soon as the clay has hardened sufficiently, usually in about half an hour, the ware is removed from the mold and finished by trimming the mold fins. filling any holes left by air bubbles, and turning or smoothing the top and foot, if necessary. Extra parts that have been molded separately. such as handles for cups, are applied and the ware is ready for firing.

Figurines and other sculptured forms are especially adapted to casting when more than one of a kind is wanted. These are cast in several "piece molds" and the parts assembled and put together by a "repairer" while the clay is still somewhat moist.

Pressing of clay wares is done in plaster of paris molds. The clay body can be used wet, semidry or dry. In the past, automatic pressing techniques have been more generally used for tiles, bricks, electrical wares and other industrial products than for artistic wares. However, the trend in chinaware factories in the 1960s was toward increased use of the newer and faster automatic techniques, such as ram-pressing.

Turning. — Turning is the process of finishing the green (unfired) ware, after it has dried to a leather-hard or air-dried state, by shaving and paring the surface with a variety of metal tools. This technique is used to smooth and finish foot rings on wheel-thrown wares or undercut places on molded or jiggered pieces. It is usually done on the potter's wheel or jigger as the ware revolves, although a lathe, similar to that used for metal or wood, can be used. Turning requires great dexterity and skill.

Firing the Bisque (Unglazed) Ware. — Setting *the Kiln.*— Placing the ware in the kiln in preparation for firing is called setting the kiln. This operation requires great care and specialized knowledge of packing and supporting the clay wares so that they will not warp or crack when subjected to heat. Bisque wares can be set in rings, placed in other specially designed supports called kiln furniture or bedded in silica. Some wares are packed in boxlike containers called saggers (or saggars) to prevent breakage or to avoid direct exposure to the kiln atmosphere.

Whenever conditions permit, the ware is placed on shelves made of silicon carbide and separated by posts made of the same material. This is called open setting and is preferred because it lessens weight and conserves space and heat. Silicon carbide in the early 1960s was replacing fire clay as the material for kiln furniture, especially shelves, because of its superior strength in relation to weight.

Temperature Indicators. — The temperatures inside the kiln and inside the wares are measured by pyrometers or pyrometric cones. The pyrometers show the temperature of the kiln atmosphere, while the cones indicate the temperature of the ware. which, because of its thickness, may be lower at some periods than the temperature of the kiln atmosphere. The cones are slender pyramids, about 2″ high by $\frac{1}{2}$″ wide at the base, made from ceramic materials that will melt at predetermined temperatures. The 60 cones in a standard series have melting points ranging from 605° C. to 2,015" C.

Usually three cones are selected; the first melts a few degrees below the maturing temperature of the ware; the second melts at or near the maturing temperature; and the third melts a few degrees above this temperature. These cones are set in a row, with each cone at a slight angle, in a flat piece of soft clay and are then placed in the kiln so they can be observed through a peephole. When the cones begin to melt and bend, the ceramist knows that the maturing point of the firing cycle has been reached. The fire is usually cut off before the last cone deforms, and the kiln then is allowed to cool.

The Firing Process. — The soft, dull-coloured clay body is transformed to brilliant white translucent chinaware by the firing process. In the firing, the claywares are heated to the temperatures necessary to mature the body, glaze and decorations. These temperatures vary from about 600" C. for soft bisque pottery to 1.480" C. for Copenhagen porcelain, and to over 2,000° C. for high-fired industrial and scientific wares.

Kilns. — In modern ceramic practice, there are two basic types of kilns: periodic kilns and continuous or tunnel kilns.

In periodic kilns, the ware is placed in a cold kiln and the temperature is gradually raised to the degree necessary to mature the ware or glaze; the kiln then is allowed to cool and the ware is removed. These kilns are useful in studios and factories where production is not continuous.

Tunnel kilns are constructed in straight or circular form and are lined with refractory bricks. As the ware moves through the tunnel on kiln cars or movable trays, it passes through a series of zones of different temperatures, gradually increasing to the maximum temperature. and then cooling again as the ware approaches the exit. The firing cycle for bisque wares often takes several days. The glaze firing for china is usually shorter.

The sizes of the tunnel kilns vary greatly according to the type of ware produced. In the larger factories, where kiln cars are used, the kiln opening is 4 to 5 ft. wide and about 6 to 8 ft. high. The average length is about 275 ft.

Oil and natural or manufactured gas are the fuels most commonly used for firing kilns, although coal and wood are still employed in some localities. Electricity is an excellent source of heat, particularly for decorating kilns.

Glazing. — Chinaware, in common with other ceramic products, can be covered with a glassy coating called a glaze. Glazes have the same characteristics as glass, and may be shiny or matte, coloured or colourless, and transparent, translucent or opaque.

Glaze Composition. — Glazes are made from silica (one of the basic materials used in making glass) combined in most cases with either soda, lead, lime or borax, or combinations of these materials. Silica, if melted alone, will make a glass but it cannot be used as a glaze because its melting temperature (1,710° C.) is higher than the melting points of chinaware or porcelain bodies. When soda or the other metallic oxides mentioned above are

added to the silica, they act as fluxes and cause the silica to melt with them at temperatures low enough so that the silica-oxide mixtures can be used as glazes for ceramic wares. A small amount of alumina has to be added to most glazes to keep them from running off the vertical surfaces of the ware.

A number of other glaze materials, such as zinc, barium and magnesia (magnesium oxide), also act as fluxes. Sometimes these substances contain more than one of the ingredients needed in the glaze. For example, commercial feldspars, the principal material for producing high-fired glazes, usually contain soda, potash, alumina and silica.

Ceramists often refer to the various types of glazes by the names of the materials that are added to the silica and alumina as the flux. Thus, when soda is added, the glaze is called a soda glaze; when lead oxide is added, it is called a lead glaze; a glaze with feldspar as the chief ingredient is called a feldspathic glaze:

Most chinawares are glazed with a lead-borosilicate glaze, which is a mixture of lead oxide, boron oxide, silica and alumina.

Preparation.— In preparing the glaze for application, the ceramist grinds the ingredients to a powder and then mixes the powder with water. The grinding is done with flint pebbles in a ball mill.

Since glazes are usually mixed with water during their application as well as during their preparation, it is desirable to use ingredients that are insoluble in water so they will not dissolve and be lost or, if toxic, such as lead, so that they will be less injurious to the worker. When a glaze is composed of ingredients that are insoluble in water, it is called a raw glaze; its components are mixed, ground and applied without any further processing.

Soluble ingredients can be melted, under controlled conditions, with silica and other necessary components into a glass called a frit. After cooling by quenching, this frit can be ground to powder and used as an insoluble glaze ingredient. Glazes of this type are called fritted or frit glazes. Most glazes used on chinawares are fritted glazes.

Glazes can be coloured by adding metallic oxides, alone or in combination, to the glaze formula. Some oxides give more than one colour depending upon the amount used, the glaze combination and the firing conditions. Some of the oxides and the colours they produce are: cobalt for blue, chromium for green, manganese for red-violet, copper for blues and greens, iron for brown and tin for opaque white.

Application.--After the glaze is prepared it is applied to the ware by one of three basic methods: (1) dipping, in which the ware is immersed in the liquid glaze; (2) spraying, in which the liquid glaze is sprayed on with a spray gun as the ware revolves on a turntable under a ventilating hood; this method gives better control of glaze thickness and produces excellent results when more than one colour is used, or when shaded or stenciled pattern effects are desired; (3) painting, in which the glaze is applied to the ware with a brush; textured and other decorative effects can be produced with this method.

Firing the Glaze.— After the bisque ware or the green (unfired) ware has been coated with glaze, it is placed in the kiln and fired to the temperature necessary to melt the glaze and fuse it into an impervious coating on the ware. Glaze firing can be done either in periodic or tunnel kilns as described for the bisque firing process. It is necessary, however, to place the ware in the kiln in such a manner that the melted glaze will not fuse to other pieces or to parts of the kiln. This is accomplished by using various types of supports made from fire clay such as stilts, pins, spurs, saddles and other pieces of kiln furniture. These supports are designed to leave a minimum of marks on the finished ware. Marks from stilts can be found on the underside of the rim or foot of plates or similar pieces. They often appear as three marks or pits in the glaze where the three points of the stilt contacted the ware. If the base of the foot ring is not glazed, it can be set directly on the kiln shelf with no stilt for support. This eliminates the stilt mark but leaves a "dry foot" on the ware.

Decorating the Ware.— Decorations on chinaware can be applied either under or over the glaze coating.

Underglaze decorations are more lasting because they are protected by the glaze covering, but the colours are limited because they must be fired at the same temperature as the glaze. Many colours will "fire away" and disappear at the temperatures required for chinaware glazes. The materials used for colour pigments in underglaze designs are usually oxides of iron, cobalt or copper, which are mixed with fluxes and refractories, such as flint, to keep them from running and blurring under the glaze.

Overglaze decorations are applied on the glazed ware after it has been fired and cooled. The colours used are called enamels and are actually glazes with the ingredients so proportioned that they fuse at whatever temperatures are desired, usually at about the softening point of the glaze or slightly lower, and thus attach themselves to the glaze surface or even sink into it during the firing. These colours are usually opaque or semiopaque and are made by grinding together a glass (or frit) with small amounts of clay, tin oxide and one or more of the colouring materials such as the oxides of cobalt, iron, copper, chrome, nickel and manganese. After they are applied to the ware, they are fired in the decorating kiln.

Transfer printing or decalcomania is the process by which a large proportion of commercial chinaware is decorated. Decalcomania prints, or decals, also known as transfers, are designs printed in overglaze enamel colours on a special paper that has been coated previously with a gelatinous material. When these decals are used for overglaze decoration, the ware, which has already had the bisque and glaze firings, is coated with varnish that dries to a semihard or tacky consistency. The printed side of the decalcomania paper is placed against this varnished surface and rubbed with felt or bristle rubbers until the printed colours have adhered to the varnished surface. The paper is removed by washing in water, leaving the design on the ware. The decorated ware is then fired at about 850° C. This burns away the varnish and fuses the enamel colours to the glazed surface of the ware. When decals or other, transfer prints are used for underglaze decoration, the techniques must be adapted to substances and colours that can be used under the glaze.

It is usually possible to distinguish a transfer decoration from one that has been hand painted by examining the object with a magnifying glass. If under magnification the pattern appears stippled, or if no brush strokes can be seen, it is probably a transfer pattern. Sometimes it is possible to see an overlap, or joint, where the paper on which the decal was printed was cut in matching sections of the design. This is particularly evident when a border design intended for a ware of one size has been folded or trimmed to adapt it to a ware of smaller or larger diameter.

Hand-painted decorations can be placed either over or under the glaze. The colours used are the same enamels as described above. These colours are ground to a powder and mixed with oil of turpentine, linseed oil, or similar vehicles that allow them to be painted on the surface of the ware with brushes. Combinations of hand-painted and transfer decorations are often used. The outline or other part of the decoration is put on with a transfer print, then parts of the design such as leaves, flowers, clothing or water are painted in.

Gold or gilded decoration is usually fired at a lower temperature than the enamel colours. It ranges in quality from pure gold, which must be burnished after firing, to the diluted liquid gilt decorations, which contain so little metal that they are actually lustres. Because of its low-firing temperature, pure gold decoration is very soft and will usually wear away much quicker than enamel colours.

Factory Marks.— A factory mark on chinaware is the monogram, seal or trade-mark usually found on the underside of the ware. This mark can be over or under the glaze and is usually painted or printed, although some marks are impressed or incised in the soft clay before the bisque firing. These marks are to china what hallmarks are to silver, except that china manufacturers do not have to state whether the object is porcelain, earthenware or some other ceramic body; neither do they have to state the content of the various ingredients. Incised, impressed or painted letters and numerals that occur at random are called work-

men's marks and sometimes indicate a dating, or maker, in code. Usually they are without meaning unless explained in factory records, and do not help in identification.

Chinaware that has the country of origin indicated in the trademark is generally found to have been made after 1891, the year the United States began requiring that imported ceramic wares be marked with that information. But this is not an infallible rule for dating ceramics because some wares are marked with paper stickers that can be removed; also, ceramics made for use and sale outside the United States would not need to comply with this regulation.

There are a number of books that give the date and origin of factory marks. Since rare marks are often forged, it is advisable to consult museum curators or reputable dealers when identifying problem pieces.

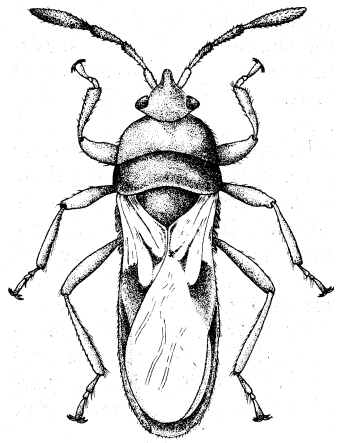
CHINCHA ISLANDS, a group of small islands in the Pacific ocean, about 12 mi. off the coast of Peru. in Ica department, opposite the town of Pisco, and 106 mi. from Callao. The largest of the group. known as the North Island or Isla del Norte, is only four fifths of a mile in length, and about a third in breadth. They are of granitic formation and rise from the sea in precipitous cliffs. worn into countless caves and hollows. Their highest points attain an elevation of 262 ft. The islands have yielded a few remains of the Chincha Indians. They were noted for vast deposits of guano (*q.v.*), but the supply was exhausted in 1874, The Peruvian government enforces strong regulations for the protection of the sea birds, and the cliffs are repaired with cement as needed to ensure the continuance of guano deposits. In 1853–54 the Chincha Islands were the chief object in a contest known as the Guano war between Pres. Juan Martin Echenique and Gen. Ramón Castilla; and in April 1864 they were seized by Spain, in order to bring the Peruvian government to apologize for its treatment of Spanish immigrants.

CHINCH BUG, a North American hemipterous insect (*Blissus leucopterus*) occurring in most parts of the United States, but particularly destructive to grain crops in the valleys of the Mississippi, Rlissouri and Ohio rivers (see HEMIPTERA). A most destructive native insect, it has frequently damaged crops to the extent of many million dollars in a single year. It was first noticed in North Carolina, at the close of the Revolutionary War, and was first described and named by Thomas Say in 1831.

Originally, the chinch bug fed upon wild grasses, but when cultivation of wheat reached its native haunts it multiplied enormously and soon became a pest of the first importance on many cereal grasses. In 1934, in the U.S. alone, the damage to grass crops, especially corn (maize). wheat, oats and barley, was estimated at $55,000,000. Federally supported and organized programs conducted to protect crops from the insects have been successful. In one year, for instance, it mas estimated that through a combined federal and state expenditure of $1,212,776 in a cooperative effort to control the chinch bug, at least $25,500,000 worth of corn was saved from destruction.

It is a small. black and white to gray and white (early immature forms reddish) insect: about one-sixth of an inch long, which, when full gromn, has a long-winged and a short-winged form (considered by some investigators to be a separate species). The adult bugs hibernate in sheltered places, usually clustering about the roots and bases of grassy plants. In the spring they lay their yellowish, cylindrical eggs behind the lower blades of the grain or in the ground around the plants.

The young, when hatched, are bright red in colour. and begin at once to suck the sap of the plants. They grow rather rapidly, become dark in colour and shed their skins five times, the adult being the sixth stage. By the time the majority are full gromn, or even before. the wheat has become too hard to suck, or harvest begins. and they are then compelled to migrate in search of food. The cropping systems prevalent in the middle west at once offer new sources of food; corn, usually young and succulent at this time, provides an excellent host.



BY COURTESY OF THE AGRICULTURAL RESEARCH SERVICE, U.S. DEPARTMENT OF AGRICULTURE

CHINCH BUG (BLISSUS LEUCOPTERUS), LONG-WINGED FORM

In seasons of abundance the bugs march in throngs from the wheat to the corn. The full-grown individuals do not generally take wing but walk along the ground. Occasionally, however, at this time they take wing and scatter. There is generally a second generation on corn, the adults of which appear in the autumn and fly back to their winter quarters at the roots of wild grasses or other sheltered places.

The chinch bug is most susceptible to weather conditions, and with wet weather in the late spring and toward the end of July the young are either destroyed by the water or develop an epidemic fungus disease.

In dry weather, however, they flourish. Seasons in which they occur in great numbers are rarely consecutive. Outbreaks have lasted for two or three years. but. in the same locality, years of abundance are apt to be separated. Serious damage may be obviated by proper cropping of farms, reducing the acreage of small grains and using the land for immune crops. Resistant varieties of grains have also been found.

Control measures often effective in small areas are the spraying of seriously infested crops with nicotine sulfate, and, in summer, the trapping of the crawling bugs in chemical barriers (ditches or lines of creosote, DDT, etc.) as they migrate from ripening wheat to young corn.

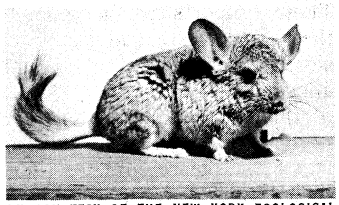
CHIN-CHIANG (CH'ÜAN-CHOU or TSINKIANG), a seaport on the coast of China, Fukien province, between Foochow and Amoy. Pop. (1953) 81,200. This city was a leading south China port during the early centuries of the Christian era and as late as Mongol rule during the 13th century. Much of the early and medieval trade with southern Asia passed through it, and the town became known to Europeans as Zaiton, Zayton or Zaitun. Most of the passenger traffic with southern Asia used Chin-chiang; Marco Polo referred to it and possibly departed from there on his return voyage. The silting of the Tsin river and the rise of alternate ports reduced the town's importance. During the Ming dynasty it had lost its dominance, and when modern European contact began, Chin-chiang no longer was a leading south coast port, having been eclipsed by Amoy and Foochow. However, it still is the natural outlet of a considerable drainage basin. Many overseas Chinese of southeast Asia originated in Chin-chiang and its surrounding towns and villages. The city is a centre of light industry and a processor of agricultural products. (J. E. SR.)

CHINCHILLA, a small rodent resembling a long-tailed rabbit but with smaller ears. The best-known and commonest member of the species, *Chinchilla laniger*, is the Chilean or coastal variety. These animals are about 14 in. long, including the hairy, tufted, 5-in. tail. The fur, about one inch long, is exceedingly soft and of a beautiful pale gray colour with dusky overtones; a black streak runs the length of the tail above and below. Rudimentary cheek pouches are present. Chilean chinchillas occur in loose communities among the rocks in the warmer foothills and valleys along the western base of the Chilean Andes. They live in burrows and are active above ground in the morning and late afternoon. At the least alarm they scamper to the safety of the burrow only to emerge, impelled by curiosity, a few moments later.



BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

CHINCHILLA (CHINCHILLA LANIGER)

They feed about sunset, sitting on their haunches and manipulating their food with the forepaws. They are vegetarians, feeding on seeds, fruits, grains, herbs and moss. Usually two litters of two young each are produced each year; gestation is about 110 days.

The Peruvian or royal chinchilla, which once inhabited the higher elevations of the western slopes of the Peruvian Andes, is virtually extinct because of having been hunted intensively for its fur. The Bolivian variety, which inhabits the eastern slopes and plateaus of the Andes in Bolivia and northern Argentina, is still fairly numerous.

Chinchilla fur is exceedingly valuable, the most costly being that of the rare royal chinchilla. The use of chinchilla fur dates back at least to the Incas, who also prized the animals as food. The Chilean chinchilla is raised extensively in captivity and presents no difficulties save for its sensitivity to humid conditions. The first breeding stock was introduced into the United States about 1923 and the progeny, together with a few subsequent introductions, have given rise to a flourishing industry. Little fur was being produced commercially in the early 1960s; instead, the animals were being reared primarily as breeding stock. Efforts to raise the very rare royal chinchilla at that time had not been notably successful. (See FUR: *Fur Farming.*)

The viscacha (*q.v.*) of South America is a related but much less valuable fur bearer. (K. R. KN.)

CHIN-CHOU (CH'INCHOW), a city on the Peking-Mukden railway, in southwest Liaoning province, China, at the northern entrance to the corridor connecting Manchuria to the north China plain, not far from the head of the Gulf of Liaotung. The population was 352,200 by the 1953 census. Though an old settlement, it became important only when the Japanese constructed branch rail lines to exploit regional coal deposits, and turned it into an industrial and rail centre during the early 1930s. By the second half of the 20th century, the city was an expanding industrial centre engaged in the manufacture of chemicals, synthetic fuels, textiles and paper, and in food processing. (J. E. SR.)

CHINDWIN, a river of Burma, the largest tributary of the Irrawaddy, is called Ningthi by the Manipuris. Length about 650 mi. It is formed by the junction of the Tanai, the Tawan and the Tarôn or Turông, but there is doubt as to which is the main stream. The Tanai rises on the Shwedaung-gyi peak of the Kumôn range, 12 mi. N. of Mogaung, and flows due north until it reaches the Hukawng valley, when it turns to the west and meets the Tarôn or Turông river. The last-named flows into the Hukawng valley from the north. Its sources are in the hills to the south of Sadiya, rising from 10,000 to 11,000 ft. above sea level. Below the Hukawng valley the Chindwin is interrupted at several places by falls or transverse reefs. At Haksa goods have to be transshipped from large boats to canoes. Not far below this the Uyu river comes in on the left bank at Homalin and from this point downward steamers ply for the greater part of the year. The Uyu flows through a well-cultivated valley, and during the rainy season it is navigable for a distance of 400 mi. from its mouth by steamers of light draft. Below Mawlaik the only considerable affluent of the Chindwin is the Myittha, which drains the Chin hills. The Chindwin rises considerably during the rains, but in March and April is so shallow in places that navigation is difficult even for small launches. Whirlpools, narrows and sandbanks also cause considerable trouble. The extreme outlets of the river are 22 mi. apart, the interval forming a succession of long, low, partially populated islands. The most southerly mouth of the Chindwin is, according to tradition, an artificial channel, cut by one of the kings of Pagan. It was choked up for many centuries, until in 1824 it was opened out by an exceptional flood: *See* also IRRAWADDY. (L. D. S.)

CHINESE ARCHITECTURE. The art of building in China has always been closely related to the deep feeling of the Chinese people for the perfect harmony and order which is reflected in the world of nature. The general arrangement and planning of Chinese structures were rooted in religious and philosophical ideas of long standing and the basic plans, as well as the principles of construction, have remained the same during many centuries. The principal building material was wood, and a timber-support unit of column and brackets was basic to a constructive system which limited the depth dimension of a building, its height dimension somewhat, its length dimensions not at all. The story of Chinese architecture is that of the development of this timber construction technique and its expressive elaboration in a traditional society.

Historical and cultural information about the periods mentioned in this article will be found in CHINA. BUDDHISM also gives relevant background material. The principles of architecture are treated under ARCHITECTURE. Material on Chinese religious buildings appears in TEMPLE ARCHITECTURE. The development of architecture in other areas of the orient is discussed in JAPANESE ARCHITECTURE and INDIAN ARCHITECTURE. See also CHINESE SCULPTURE and CHINESE PAINTING.

This article is divided into the following sections:

I. HISTORY

1. Carpentry Techniques.—A Chinese building may be described as a complex of posts and beams tenoned together to support a massive roof and to define the planes of enclosing walls. Substantial columns afford the primary support and rest freely on individual foundation stones whose upper surfaces have been carved to form dowels that are socketed into the bottoms of the columns. Wall beams and tie beams are tenoned into or through the upper ends of the columns. Upon this framework rests the structure that forms the steeply sloping roof. The roof truss repeats on a smaller scale the post-and-beam construction of the main support and by means of an internal arrangement of beams establishes the curvature and slope of the roof.

Each tie beam of the main support carries a pair of short posts, placed some distance in from each end, which together hold a shorter transverse beam. Into this beam is socketed another pair of posts supporting an even shorter beam. By means of such units, each a little shorter in length than the one immediately below, a stepped truss is raised until the required height of the roof at the head of the kingpost is gained. The kingpost stands immediately below the ridge beam and in the centre of the uppermost beam of the truss. Some additional support to the roof framing may be given by extra posts placed at strategic points along the beams. Roof purlins rest on or above the heads of the posts, whose various heights may be regulated to shape the contour of the roof precisely. The deep overhang of the eaves may be supported by extending the tie beams beyond the wall columns to catch the eaves purlins situated some distance out from the walls; or the eaves may be carried by an arrangement of cantilevers, or brackets, springing from the columns or rising above them. It is this elaborate technique of eaves support that distinguishes Chinese architectural form and contributes significantly to the visual unity and variety of Chinese buildings.

In one system, the brackets are socketed into the column itself and rise in a sequence of regularly increasing lengths until the topmost and longest bracket reaches the eaves purlin. In other arrangements, the brackets extend from a capital that is socketed into the top of the column or into the wall beam at a point immediately above the column. In such a system, the capital is fitted with a longitudinal arm holding three regularly spaced bearing blocks and a transverse arm with a bearing block at its free end. Such an arrangement may be considered the standard bracketing unit basic to most Chinese bracketing systems. This basic unit may be repeated, vertically, with the transverse arm

regularly increasing in length until the eaves purlin is reached. The longitudinal arm grips a wall purlin from which rises the capital block of the next bracket unit. The transverse arm supports the corresponding member of the bracket unit above.

Often. the uppermost bracket arm is a slanting lever tethered at one end in the framework of the roof and sloping toward the eaves purlin at an angle parallel to that of the common rafters. This slanting arm is braced either by the horizontal bracket arm immediately below it or by a second parallel slanting arm, shorter and slightly below. Sometimes the stay for the slanting arm is the extension of an interior beam incorporated into the bracket unit. The slanting arm also may function as a true lever, with the inner end freed from its moorings in the roof framing and giving direct support to the aisle purlin. With the wall beam as fulcrum, equivalent thrusts on either side are held in balance.

Extra supports in the wall plane may take the form of struts braced between the wall beams and wall purlins at points in-between the column axes. Sometimes the strut is a simple post; at other times, it is a double brace, looking something like an inverted V. Support to the eaves at points between the column axes comes from one or more intercolumnar bracket groupings at the same level as and often exactly like those springing from above the columns.

Since walls had no supporting function, they could be made of unsubstantial materials such as mud plaster. The roofs of buildings of the first rank invariably were sheathed in tiles. The buildings themselves were set off from the ground by means of raised platforms.

2. Earliest Times.—The earliest known dwellings in north China were pits or caves which were covered with domed-up shells of sod. A more highly developed type, square in plan, with sunken floor, smoothed and plastered walls and a central fire pit, either followed or existed alongside of the rude pit dwelling. Other simple houses were roughly arched or gabled shelters of wood and thatch and mud. Platform houses, raised shelters of poles and brush, were apparently used in warm weather and were designed to overcome the discomforts of flood and the peril of marauding animals.

The city culture of the ancient Shang capital, An-yang (1300–1028 B.C.), in Honan. developed a style of building mhich was already recognizably Chinese. Wood was the chief structural material. Large oblong halls were raised upon tall rammed-earth (*q.v.*) platforms. Rows of wooden columns, somewhat symmetrically disposed, supported roofs of thatch. Some important buildings were oriented toward the south. A city wall, made of rammed earth and surmounted by lookout towers, enclosed the city proper. These were some of the traits characterizing the traditional building style which was to evolve in the millenniums to follow.

3. Chou Dynasty **(1122?–256 B.C.).**—The ballads of the "Poetry Classic," *Shih Ching,* often extolled the princely ancestral shrines and royal palaces raised by the rulers of the Chou states. These were invariably buildings which were awesome in size. with huge raised platforms, strong supporting pillars, wide-spreading roofs and rammed-earth walls.

Architectural forms and ornament seem to have been allotted according to rank or social status. as was to be always the case in later imperial times. The *Li Chi,* a standard compendium of Chou etiquette, states that "the pillars of the Son of Heaven are red, those of the feudal princes blackish, those of high officials blue-green, and those of the other gentry yellow." 4 commentator to the *Ch'un Ch'iu* remarked that "the rafters of the shrine of the Son of Heaven are to be hewn, rubbed smooth, and polished with a fine stone. Those of the princes are to be hewn and rubbed only, and those of high officials merely hewn."

Architectural ornament could have been either painted or carved. Richly sculptured walls and elegant. costly carving became more and more the vogue during the later years of Chou rule. Thatch was the usual roofing material until the 8th century when tile roofs began to be used in monumental structures.

A dynastic ode of the royal house recounted the foundation of the first Chou city by the chief Tan-fu; the plan was roughly symmetrical with one set of rammed-earth ramparts around the perimeter and another girdling the palace compound. These walls were broken by lofty and strong gates. In every part of the city design, left balanced right with big and little plots methodically measured out and related to each other.

The typical Chou mansion seems to have been planned with courtyards along a dominant axis. The main building stood at the rear of the major courtyard on a high platform and was subdivided into numerous symmetrically disposed areas. Along the front was a porchlike space called the *t'ang.* Behind the *t'ang* was the main room called the *shih;* this was flanked by smaller rooms, *fang, hsu, chia.* Sometimes a second *t'ang* spread across the rear or north side. The entire building may have been contained within a rectangle or may have had projecting wings on either side.

In this plan, the central axis, though dominant, was not pronounced with the clarity of Iater times. The building was approached by parallel front stairs and thus maintained a left and right balance of the elements.

The Late Chou rulers were notoriously extravagant and had a passion for building lofty lookouts called *t'ai* which, when associated with parks and artificial lakes, served as talismans, designed to win strength and prosperity for the state. The *t'ai,* park and lake combination had already become a classic pattern for imperial architecture by the end of Chou. The name *t'ai* probably referred to all kinds of towers regardless of specific form or method of construction. A *t'ai* was usually an elevated platform built of rammed earth which might have been sheathed in plaster and decorated. A separate superstructure sometimes capped the platform. Other *t'ai* had wood superstructures built over rammed-earth bearing walls and incorporated actual interior spaces.

Another curious feature of Chou princely architecture was the *Ming T'ang,* a royal hall whose specific form and function still remain enshrouded in mystery. Whatever its appearance in Chou times, it was considered of magical necessity to the sovereign and fired the imaginations of imperial architects for hundreds and hundreds of years.

4. Ch'in **and** Han **(221 B.C.–A.D.** 2211.—When Ch'in Shih Huang Ti subjected the lords of Chou and brought all of China under one rule, he made possible the development of a genuinely national architecture which was more grand than any that had existed before. The magnificent palaces with which he adorned the new capital, the Great Wall and the network of military highways which he had built were as remarkable as the fantastic power of his warriors and the wealth of his treasury. The varied regional styles of Chou architecture were fused into a single imperial style, which was looked upon as an impressive symbol of national greatness. Under the "First Emperor." monumental architecture was thought to be indispensable to sound government.

The Han emperors. who succeeded Shih Huang Ti. also believed that a great architecture was necessary to stable government. They considered great size and overpowering beauty as the appropriate means for inspiring awe.

Ch'ang-an (Sian), the capital of Western Han, was used for many generations and suffered much irregular expansion motivated by necessity rather than a sense for order. It nevertheless betrayed something of the customary Chinese regard for symmetry and regularity in its general layout. The walled city was surrounded by a moat. Three monumental gateways opened each face of the enclosing wall; nine major avenues running each way dominated the network of streets. There was, however, after the initial expansion. no major palace on axis and the arrangement of government offices and major places of worship was all too often haphazard.

The reign of Han Wu Ti (140–87 B.C.) saw the erection of countless pleasure palaces more sumptuous than those of the Ch'in, and a number of architectural constructions designed to establish contact with the supernatural world. In 109 B.C. the emperor had built a *Ming T'ang* on an ancient site in Shantung. This structure had a single apartment with a broad porch on four sides and a wide overhanging roof of thatch. A moat encircled the shrine precinct. Then there was a double ring of walls surmounted by wooden towers. The approach was from the southwest, the direction appropriate to the "Yellow Emperor," and the shrine precinct was

called K'un-lun after the fabulous paradise mountain of Taoist myth.

The usurper Wang Mang (A.D. 8–23), who momentarily replaced the Han line in the royal seat, used architecture to establish his claim to rule. Like the sage-kings of legend, he built a succession of monuments of the sort traditionally associated with kingship: a *Ming T'ang*, a *Pi-yung* lakeside hall, a *Ling T'ai* and a ninefold ancestral shrine. All of these were overpowering in size and, therefore, quite appropriate for an emperor. Wang Mang also built the first *Ming T'ang* in the imperial capital. This was a two-story building, "round above and square below." with eight windows and nine chambers. The magical number system which determined these arrangements extended also to the participants in the rite performed there. The whole was meant to embody a particular cosmological concept. This temple was burned when Wang Mang fell from power, but one comparable to it was erected at Lo-yang in A.D. 59. Among the other architectural wonders for which Wang Mang was responsible was an important shrine to the "Yellow Emperor" which was, as usual, gigantic in size and took the form of a Greek cross in plan.

When civil war destroyed most of Ch'ang-an, the Eastern Han line that came to power did its best to repeat its beauties at the new capital in Honan. Lo-yang, however, was distinctly more regular in design. The imperial palace compound, together with its great park, occupied the rear centre of the city and the axial boulevards were clearly marked by the principal government offices.

Palaces, mansions and public edifices followed a plan which was to become routine later on. A succession of courts, each more private than the one before. were aligned along a major axis. The building blocks were assembled in the courtyards with left balanced against right and the main hall on axis at the rear. There were the inevitable front and side gates; a major gate on axis was itself a proper building with interior chambers. Sometimes galleries leading back to the main hall bordered each court.

The major hall with its platform and left and right stairs was often two storied. On the east and west sides of the hall were areas called *hsiang*, which were partitioned off from the main chamber only by light screens or curtains. A surrounding aisle completed the unit. Sometimes all of the elements were covered by a single roof; in buildings of considerable size, the *hsiang* were roofed separately and had the appearance of wings. Another architectural type current in Han times was the *hsien*, which took the form of a raised porch attached to the front of a hall.

Single-story buildings often were ceiled; buildings set apart for imperial use had their coffered ceilings embellished to symbolize the "dome of Heaven."

The official architecture was lavishly decorated. It was habitually enhanced by sculpture and painting to a degree unknown before. Human and animal caryatids, brilliant polychromy, gilding, jade and bronze ornamentation enriched all architectural surfaces and forms. (See CHINESE SCULPTURE.)

Han palace complexes were filled with magnificent buildings of various sorts. Park annexes, moreover, had artificial lakes and hills, were set out with fine groves and strangely shaped rocks, and were stocked with rare birds and beasts. The largest buildings, the halls of state, were grandly colossal; many of them were as large as 400 ft. by 110 ft. in plan. Next to the halls of state. the most impressive features of the Han palace compound were towers of various sorts. Most of these were like the ancient *t'ai* in form, being raised on bearing walls of rammed earth which were faced with stone for greater beauty. Gateways were marked by paired towers called *ch'ueh* which were sometimes so modified that they took the form of monumental masonry pillars flanking an entranceway. A new type of high building, the wood-framed *lou*, became popular during Han. The *Lou* was sometimes only two stories high and at others soared through many levels. The *ch'ueh* of the Ch'ien-chang palace were cylindrical and were topped by bronze acroteria in the shape of phoenixes. The Cloud *t'ai* at Lo-yang, which was destroyed by fire in A.D. 185, was used as a storehouse for rare books and other objects and must have been built with rooms and a wooden superstructure. Another tower, the *t'ai* for "communication with Heaven," was distinctly magical in function and was supposed to serve as a lure for Taoist Immortals. Another tower, which was furnished with chambers decorated with paintings of Heaven and Earth, the Supreme Unity and various supernatural beings. was equipped with sacrificial utensils to allow contact with the spirits of Heaven. An entire precinct, Ming-nien, "the radiant year," was composed of 5 walled areas and 12 wood-framed *lou* towers, and clearly embodied cosmological ideas.

Under Eastern Han, Buddhism made a partial penetration of China Its first recognized temples were probably erected by the state and took on a simple form similar to that of secular halls. A building erected in A.D. 190, however, described as a Buddha shrine, was a two-story pavilion surmounted by a finial with nine bronze disks. Inside the pavilion sat a human figure fashioned out of gilt bronze. The shrine was surrounded by galleries and, like the stupa-ghara of India, was a forerunner of the later Chinese pagoda.

The Han style survived the second collapse of the dynasty and flourished as late as the 5th century when the Tatar rulers of Northern Wei, in tribute to the Chinese past, sent architects south to Lo-yang to survey its ruins. The Tatar capital later was transferred to Lo-yang and it was rebuilt on Eastern Han lines.

5. The Six Dynasties (221–589).—This period was marked by political instability and, for a long time, official architectural commissions were carried out on a smaller scale and in the still dominant Han style.

In the early 6th century, under the Northern Wei and Liang rulers, building activity took on new vigour, motivated primarily by the new religion. Buddhism. As soon as official interest turned to the new faith. Buddhist precincts began to be "dignified" in the traditional Chinese way, with walls, high gatehouses, galleries and monumental halls. More and more, costly materials and cunning craftsmanship were invested in Buddhist establishments of impressive size. The traditional forms had been given new meaning and the monastery was in architectural style often little different from the palace. Only the pagoda, fully developed as an architectural form, was specifically Buddhist; it was the only alien element in an utterly traditional way of building.

The best examples of the Six Dynasties style in wooden architecture are found in the halls, galleries and gatehouses of the Japanese monastery of Horyuji. These are characterized by an effective simplicity and a strict symmetry about both axes. The *kondo* still reflects an ultimately Indian notion in the disposition of its interior. The altar is in the centre with its images oriented toward the four directions; all are surrounded by a processional aisle. Chinese examples of the style may be found at the rock-cut cave-temples of Tun Huang in Kansu, Yun Kang in Shansi and Lung Men in Honan.

6. Sui and T'ang Dynasties (589–906).—The reunion of China under the Sui ushered in a second imperial age whose archi-

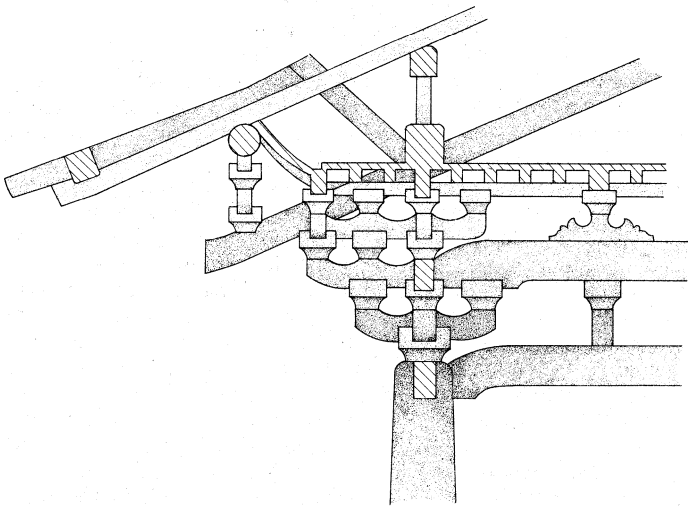


FIG. 1.— BRACKETING SYSTEM ON THE KONDO OF TOSHODAI-JI. JAPAN. T'ANG STYLE

tecture rivaled and surpassed the splendour of Han. In a tremendous burst of energy, a new capital city of Ch'ang-an mas laid out. new palaces were raised and countless Buddhist temples were restored or newly founded. The new style developed rapidly, molded by new and better building techniques and a more mature aesthetic.

The Sui court placed a high premium on the science and fine art of building and heaped honours lavishly upon the skilled builders gathered in the capital. The names of four outstanding men of genius who contributed most to Sui operations have come down to us.

Yang Su was an expert designer of gigantic naval yachts who also helped to lay out the new city of Lo-yang and direct its construction. Yu-wen K'ai was an architectural historian who undertook an exhaustive study of the *Ming T'ang* prior to designing an intricate version of his own. He was also a hydraulic engineer who constructed, for the pleasure of the second Sui ruler, a rare rotating pavilion which was operated by an ingenious mechanism beneath its platform. Ho T'ai, a connoisseur of old pictures and *objets d'art,* was a most distinguished military engineer who designed an assault bridge to span rivers and, also, a demountable castrum complete with ramparts and towers which was capable of being set up overnight. He constructed a mausoleum for the dowager empress and designed the imperial insignia, robes and vehicles; he also staged the state festivals and other ceremonies. Yen Pi, a painter and calligrapher, was famous for his pleasure-palace designs and for the construction of a long canal waterway which served the Sui armies fighting in Korea. He was also commissioned to restore the Great Wall.

The T'ang dynasty continued the developments begun in Sui times and brought the empire to its full flowering. The perfect combination of talent, wealth and demand coincided with a stable and long-lived regime to allow for the refinement of building techniques and the maturing of the architectural style. T'ang design was marked by regularity and a pronounced spaciousness: and was dominated by a few massive elements. It gave an impression of great vigour and the repeated stress on the horizontal produced a feeling of solemnity and dignity.

The capital city of Ch'ang-an, laid out by the Sui and inherited and developed by the T'ang, was characteristiccllly huge. It was bounded by the usual high ramparts and ordered by the traditional checkerboard of streets and avenues with an unprecedented regard for strict symmetry and formal order. The imperial enclosure, on axis toward the rear of the city, embraced all of the government offices as well as a lavishly laid out palace. There was a second, larger palace compound just outside the city limits to the northeast which became a favourite imperial residence and went by the name Ta-ming. Each palace was developed around an arrangement of three large halls on axis, a formula which was later often repeated. This three-part scheme was ultimately derived from the Chou ritual books which insisted that the Son of Heaven rule from three courts. It manifests at Ch'ang-an a classicistic revival of what was thought to be a very ancient form.

Buddhist architecture flourished under the early rulers of T'ang, as it had under the Sui, but after the reign of Ming Huang (Hsuan Tsung; 712–756), Taoist influence became so strong as to effect the gradual decline of Buddhist building.

Sui and T'ang temples and shrines have suffered much from the ravages of war and the action of time, and little remains to reflect the magnificence which once was theirs. However, the Todaiji monastery in Nara, Japan. built in the mid-8th century to rival and surpass the most glorious of T'ang temples, preserves for us a goodly number of the features characteristic of the T'ang imperial style. Designed to impress by reason of size, both precinct and buildings are astoundingly spacious and grand. The imposing Buddha hall, actually a throne hall in religious dress, dominates the scheme. The Chinese ideal of order is especially manifest in the doubling of the pagoda, thereby maintaining the perfect symmetry of the layout. The double-pagoda scheme may also indicate the enormous accumulation of wealth in the early days of the second empire which allowed the foundation and construction of such grandly impressive shrines.

The only wood-framed building of T'ang date still extant in China is the mid-9th century main hall of Fo-kuang-ssu on Wu-t'ai Shan. It witnesses clearly to the strength, dignity, forceful simplicity and massiveness which characterized T'ang architectural form. A concern for the impressiveness of ideal proportions and for the visual interest of plain surfaces contrasted by richly carved details is everywhere evident. Its hipped roof, dignified, stable and stressing the horizontal, was a form which was much preferred in T'ang times. The interior of the hall was axially subdivided. All spaces were covered by reticulated ceilings, the chancel being higher than the aisles. The altar images were no longer oriented toward the four directions but a-ere assembled like an emperor flanked by courtiers.

A new type of building which became very popular in T'ang times was the *ko,* a pavilion which was lower than the pagoda, but broader, and higher than the throne hall. The *ko* pavilion was used in a number of ways. It was at times the culminating feature of a compound, placed squarely on axis; sometimes it was used in pairs which flanked the axis.

The empress Wu (late 7th century), a passionate patroness of Buddhism, was responsible for a considerable number of bizarre and colossal structures among which was a 100-ft. stone *lou,* a magnificent confection of openwork masonry. In 688 she commissioned a *Ming T'ang,* at Lo-yang, as big as any previous one and more extraordinary. It was three tall stories high; the lowest was square, each face coloured appropriately to symbolize one of the four seasons. The top two stories were polygonal and were separated by a cylindrical unit with a balcony which was supported by nine dragons. The whole structure was capped by a round cupola and topped by a huge iron phoenix. Running up the core of the building was a massive wooden shaft, symbolic of the great pillar which separates earth and heaven, according to the prevailing cosmology. She commissioned also an equally tremendous five-story tower to house a colossal Buddha image. From its third floor one could look down on the peak of the *Ming T'ang* to the south.

During the golden age of Ming Huang, pleasure seems to have been the ultimate aim. All of his commissions were characterized by costliness and ingenuity. Perhaps it was in emulation of the "warm" and "cool" apartments of Han palaces that T'ang Ming Huang had erected pleasure kiosks which were cooled by artificial rains falling on the roof and massive marble halls, large enough to include warm-water pools with miniature islands and pleasure boats. In the Ta-ming palace there was a triangular hall in which the emperor loved to feast.

This kind of ostentation and costly display was considered to be the privilege of the great in the T'ang society whose rigid building codes were ordered according to social status. It stood, however, in marked contrast to the earlier austerity affected by T'ang T'ai Tsung (627–649), who ordered that the buildings of his mountain palace should be roofed in thatch.

After the civil war of the mid-8th century, T'ang power steadily decreased. Yet the patronage of the crown, the bureaucracy and religion were secure and money was reasonably abundant. The wars and the proscription of Buddhism in 845 led to the destruction of much fine architecture. Those who followed and attempted a recovery were all the more stimulated to build on the customary grand scale. Late T'ang buildings incorporated more complicated and interrelated bracketing and increased the decorative embellishment of the structural members.

7. The Five Dynasties and the Sung Dynasty (907–1279). —The period of the Five Dynasties was much too short and chaotic to have had any lasting effect on the development of a national architecture. In those parts of China which were relatively undisturbed by political conflict and economic instability, a significant amount of expert building was undertaken. The middle coastal region, where the rich princes were still ardent patrons of Buddhism, saw the erection of many splendid buildings.

With the rise of the Sung house, the country was brought under a single rule and the diverse talents of China were once again collected at the court. Among these was an architectural genius, Yu Hao, whose treatise on carpentry proved to be both valuable and influential.

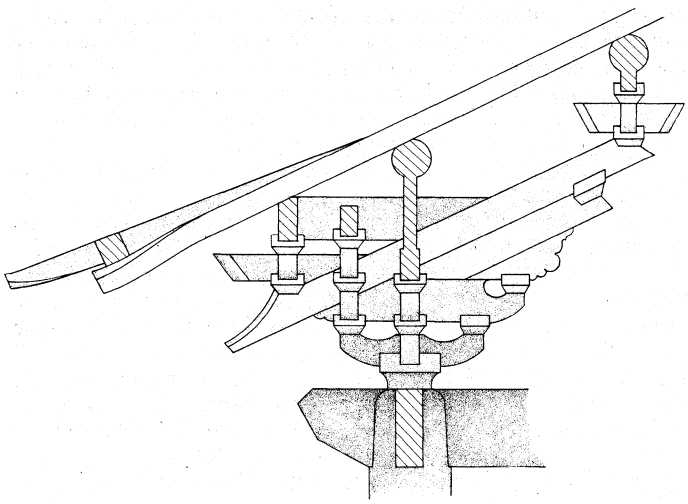

FIG. 2.— BRACKETINGSYSTEM FROM THE CH'U-TZU-AN, SHAO-LIN-SSU, SUNG STYLE

The Sung sovereign had to tackle the usual job of recreating a capital city and building a palace. The Sung capital was built at Pien-ching, now K'ai-feng, Honan, on the basis of an already large T'ang city. Successive enlargements of this T'ang city were made until the appropriately imperial dimensions were realized. The city plan was manipulated until a reasonable regularity was achieved and the metropolis took on the classic formation of a square. The Sung palace was modeled directly after the T'ang examples at Lo-yang but with an even stricter adherence to symmetrical layout and precise balance of the elements. Axes were clearly marked and halls and gateways were perfectly aligned so that the whole could adequately reflect the perfect morality of the sovereign. Some of the T'ang remains, notably those buildings associated with the reinstated temple of Hsiang-kuo-ssu, set the styie for the new buildings.

Sung buildings, however, were less overwhelming than those of T'ang in size and sheer vigour. The inventiveness of Sung designers was invested in the refinement of traditional forms and in the evolution of an elegant, subtle and ideal beauty. There was also a marked preference for the picturesque.

Sung taste evidently ran in the direction of high buildings; numerous accounts of the capital city testify that it was a city of towers. Pagodas, high gateways, *lou* towers and *ko* pavilions were liberally used; sometimes the upper stories of neighbouring high buildings were connected by balconies.

The Japanese pilgrim Jojin visited Pien-ching in 1072 and described the spectacle of the city in lavish terms. He mentioned the usual gold and silver ornamentation of important buildings as well as the use of jewels in architectural embellishment. A curious feature of Sung interior decoration, a scheme to be much repeated later, also came to his notice. This was the use of miniature buildings in varying degrees of relief as a form of architectural enrichment.

The great Buddha hall of the imperial Ch'an headquarters, Fu-sheng-ch'an-yuan, had a ceiling which was generously adorned with miniature treasure halls. The libraries of a number of Ch'an monasteries featured miniature pavilions as crownpieces for the book cabinets. The fascination with reduced architecture brought about the fashion of enshrining anything valuable in some kind of architectural container.

Another achievement of the Sung age with regard to architectural décor was the mastery of the art of glazing roof and floor tiles with sumptuous colour. Much of the splendour of Sung structures must have been due to the brilliant coloristic effects thus obtainable.

A manual of architectural procedure, immensely popular in its own time and happily still extant in a not-too-much-disfigured form, the *Ying-tsao Fa Shih*, was composed by a state architect, Li Chiai, and was presented to the throne in 1100. Part of the book is devoted to architectural history of a sort and a discussion of architectural terms used by the ancients. The rest of the book deals with the more practical aspects of building: the laying out of a plan. the foundation, stonework, décor, etc.

Among the many forms recommended in this manual is a platform type which in Sung times was new to architecture. The so-called *Sumeru* platform with its widely projecting cap and base and narrow waist had long been used in image pedestals. During Sung times it was widely used for stone terraces which literally enthroned whole buildings.

When the capital was moved to Hang-chou, under the Southern Sung, the official Pien-ching style moved with it. It developed there. under the auspices of the strong Ch'an sect, into a new official style which was exported to Japan in the late 13th century along with Zen Buddhism, and which became known there under the name of *Karayo*, or "Chinese style." This represented in many ways a conspicuous softening and dissipation of the vigorous forms inherited ultimately from the T'ang. Southern Sung architects also exploited that baroque play with projections and heights, the innumerable variations of masses, which animated the best pleasure-palace designs of Northern Sung.

Another style of building contemporary with the *Karayo* of Southern Sung was the so-called "Indian style," *Tenjikuyo*, which survives primarily in some late 12th-century structures in Japan. It was distinct from the official style in the power and directness of its forms. The design allowed for no play with subtleties or superficial enrichment. The great south gate of Todaiji remains as a prime example of the masculine power of this mode of building. and the twin pagodas at Ch'uan-chou (Chin-chiang), Fukien, witness its influence upon the masonry styles of the day.

The Sung temple at Lung-hsing-ssu, Cheng-ting-hsien, western Hopeh, preserves a good deal of its earlier form. Its general plan is long and narrow, widening out to make a courtyard in the rear. A strictly defined axis dominates the plan which differs from T'ang usage in that there is none of the grand spaciousness common to T'ang designs and there is a greater complication of building forms. The conventional oblong hall seems to have been abandoned in favour of more varied and picturesque types which place an unusual stress on height.

The Shrine of the Saintly Mother, Sheng-mu-miao, at Chin-tz'u, T'ai-yuan-hsien, Shansi, presents an unusual combination of two separate halls; a large, closed, main hall and an open offering hall. The plan of the main hall betrays a new and greater freedom in establishing interior spaces. An open porch, doubly wide in front, surrounds a closed sanctuary; the front portico was made more spacious by the omission of four centre columns in the middle line. In the Wen-shu-t'ien at Fo-kuang-ssu on Wu-t'ai Shan, the traditional chancel and aisle scheme with its essential 18 supporting pillars had given way to a freer, more unified space with only four interior columns. The transition from the four supports to the framing of the roof was made by an ingenious arrangement of extra girders and beams.

The structural daring and ingenuity of Sung architects was matched by an increased interest in the aesthetic impact of functional forms. A greater preoccupation with delicate and rich ornamentation is seen in the Ch'u-tsu-an chapel, Shao-lin-ssu on Mt. Sung, Honan, where the stone pillars were delicately sculptured. The wooden main hall of the Taoist Yuan-miao-kuan in Soochow, rebuilt in the late 12th century, used both functional and fictitious bracketing units to further animate the design.

8. Yüan Dynasty (1280–1368).—The Sung style continued as the official style of the Mongol Yuan line as the barbarian conquerors reconstructed the ruins of China with the help of architects and craftsmen who had earlier served the Sung rulers. With little cultural tradition of their own, the Mongol warriors were helpless before the sophistication of the Chinese society they now controlled. and had little choice but to imitate carefully those whom they had vanquished. They exceeded their Chinese models only in size and costly display; the basis of their art was still that of the examples of Sung times. A two-story main hall of the Taoist Shrine of the Northern Peak at Ch'u-yang-hsien, Hopeh, remains as the most impressive remnant of Yuan splendour and this clearly imitates the Southern Sung official style in every detail.

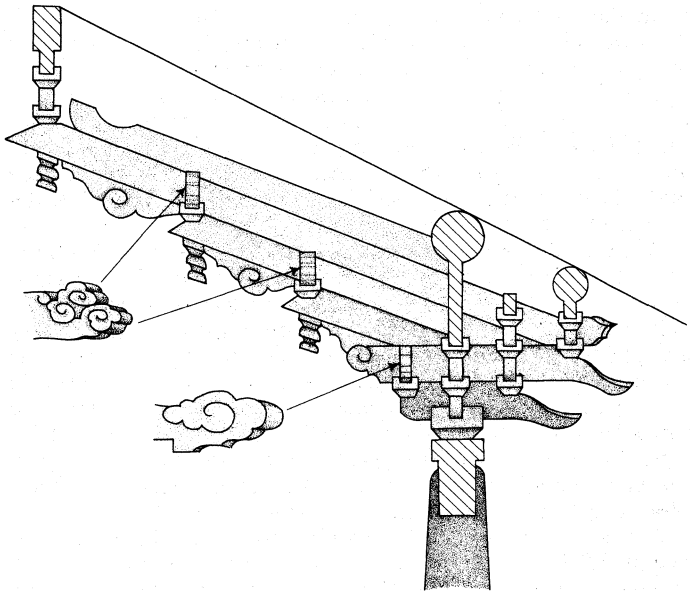

FIG. 3.— BRACKETING SYSTEM FROM A PAVILION AT THE CONFUCIUS TEMPLE AT CH'Ü-FOU, YUAN PERIOD

9. Ming and Ch'ing Dynasties (1368–1912).—The story of architecture under the Ming and Ch'ing rulers must necessarily stress the prolonged decadence of the art of fine building. The Ming style at its best was little more than a modification of the Southern Sung mode. The Manchus were even more satisfied than were the Mongols to ape their Chinese predecessors. Under the Ch'ien-lung emperor of the 18th century, a great deal of monumental building was done and a considerable amount of refacing of earlier structures was undertaken. In the best of this work, the underlying monotony is broken by the majesty of big halls, courtyards and gates and by the charm of the pleasure quarters.

The typical Ming or Ch'ing building was rather small in scale, a simple oblong in plan, and had interior columns arranged according to the old aisle and chancel convention. An enclosed porch at the front or the rear may have had a separate roof, and there may or may not have been extensions in the form of wings. Pillars and large beams did the work of supports; the bracketing systems, greatly diminished and nestled together, were little more than ornamental. Gorgeous decorative effects, gained through tile work, sculpture and polychromy, invested the architecture with a certain distinction.

Some examples of the use of structural vaulting exist. The great city gates of Peking (early 15th century) incorporated tunnel vaults in their construction. Two large temple halls, built late in the 16th century, were made entirely of brick and were tunnel vaulted. These are the temple at Shan-t'a-ssu, T'ai-yuan, and the "beamless hall," Wu-liang-tien, in Soochow. Some curious structures built in an adaptation of the late European baroque style were among the exotica laid out in the gardens of the Ch'ien-lung emperor's summer palace west of Peking.

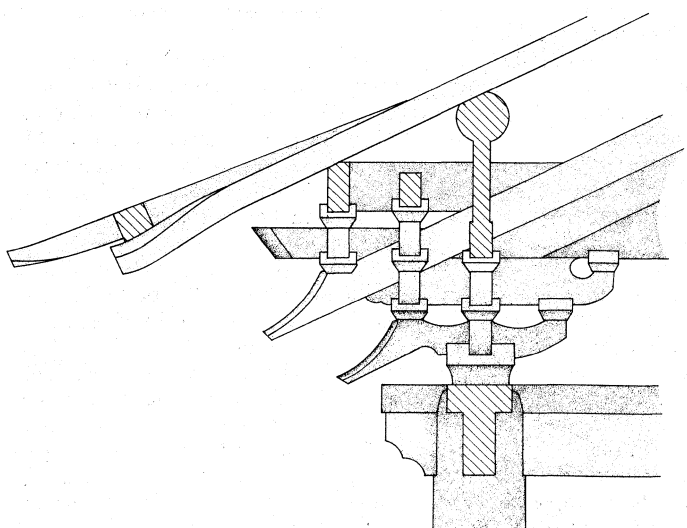

FIG. 4.— BRACKETING SYSTEM ON BELL TOWER AT SHAO-LIN-SSU, YUAN PERIOD

The "Tatar city" of the capital betrayed an attempt to follow superficially the prescriptions of the ancient Chou ritual books. The plan of the city approximated a square form and had the imperial palace placed near the centre.

The "forbidden city" was partitioned off into a number of major walled-in areas, the most imposing of which was the series of audience courtyards and halls which were strung out along the grand axis. This precinct was followed by a somewhat smaller one, the imperial living quarters, which repeated in many ways the schema of the larger group. The grand audience group was unique in Ming and Ch'ing building in the massiveness of its building blocks, in their dramatic heights and powerful proportions, and was enlivened by magnificent coloristic effects achieved in tile and paint. The major court, square and about 200 yd. across, was broken toward the rear by a massive tripartite stepped terrace upon which rose, in succession, three splendid halls. The first, the T'ai-ho-tien, a massive throne hall, was oblong in plan and had a monumental hipped roof above a skirting penthouse. The smaller middle hall, the Chung-ho-tien, which served as a waiting place, was square and capped by a pyramidal roof. The Pao-ho-tien, used for state banquets, was a smaller version of the throne hall and was distinguished by a hip and gable roof.

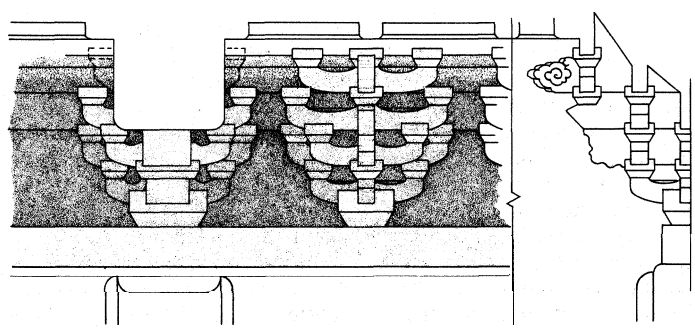

FIG. 5.— BRACKETING SYSTEM OF CHIEN CH'ING KUNG. "FORBIDDEN CITY." PEKING. CH'ING PERIOD

The three-part scheme clearly insisted upon here and in the imperial living quarters, as well as in the shrine to the imperial ancestors, the T'ai-miao, must have been derived from the ancient Chou prescription that the Son of Heaven rule from three "courts" or ch'ao.

The architectural remains of Peking have suffered much modification, rebuilding and remodeling in the course of history, and all too often decadence and tasteful design were hopelessly intermingled. The last gasps of a dying tradition, however, occasionally produced remarkable gems. The circular Hall of Annual Prayers, Ch'i-nien-tien, at the Altar of Heaven in the "Chinese city," was built at the very end of the 19th century and manifested, in a surprising way, the pure geometrical order and coloristic splendour which we have come to associate with the Chinese mode.

II. THE PAGODA

The predilection of the Chinese for towerlike buildings and the requirements of Buddhism led to the development, in the Six Dynasties period, of the pagoda (*q.v.*) form. It derived ultimately from the stupa of ancient India, which was a domical funeral mound erected over the remains of a holy man or king. Perhaps the most celebrated pagoda in India was the multistoried tower erected by Kanishka I near Peshawar to enshrine a notable collection of the Buddha's relics. This famous tower, built in the 2nd century of the Christian era, was the inspiration for the pagodas of China. where the design always consisted of the repetition of a basic story unit (circular, square, polygonal) in regularly diminishing proportions. Each unit had its own projecting roof

and the whole pile was topped by a prominent mast and disks. (See INDIAN ARCHITECTURE.)

The pagoda, like the stupa, was at first thought of as an architectural diagram of the cosmos. The great pillar which ran up the core of the building was symbolic of that invisible world axis which joins the centres of the earth and heaven. The separate stories, diminishing in size as they mount upward, were thought of as the many terraces of the mythical world mountain. The disks of the finial corresponded to the various heavens of the gods. The cosmic diagram, thus fixed in architectural form, was thought to be animated by the precious relics which were enshrined within. The history of the pagoda in China may be illustrated by a fairly large number of extant monuments.

Just as the principal monument of Indian Buddhist establishments had been the stupa, the pagoda was the dominant feature of early Chinese Buddhist temples. As the principal centre of worship, it rose isolated in the courtyard, on axis. Behind it was placed a Buddha hall with an altar set out with images. Another large building closed off the courtyard at the rear; this was the lecture hall where the monks met to study the scriptures. A major gate building shut off the court in front of the pagoda and smaller galleries surrounded it.

1. The **Six** Dynasties. — During the Six Dynasties period, the number of pagoda stories varied from three in the 4th century to nine in the 6th century. An occasional outstanding monument had 12 stories.

The greatest early pagodas were built by the Northern Wei. In 467 there was built for the Yung-ning-ssu temple in the capital city a seven-story pagoda which was lauded as the tallest then on earth. At the same time, a great stone three-story pagoda was raised to a height of 100 ft. After the capital was moved to Loyang, a new and more splendid Yung-ning-ssu (begun 516) was built. The pagoda of the new temple was square in plan, about 400 ft. high, lavishly studded with gold ornaments and strung with myriad gold bells. Its doors and windows were lacquered in brilliant red.

Examples of the square, multistoried pagoda may be found in the rock-cut cave shrines at Yun Kang and Lung Men. Full-scale examples in wood have been preserved in Japan: the 7th-century pagodas in Horyuji, Hokiji and Horinji. In this type, the number of openings on each side ranged from the three doors and six windows of the Yung-ning-ssu pagoda to the one door of Horyuji. The architectural details of the Yun Kang examples were borrowed from the north Indian prototypes.

Certain 6th-century brick pagodas in north China represent other designs which were used during the Six Dynasties. The Sung-yueh-ssu pagoda on Mt. Sung, Honan, was built in the 520s in emulation of an Indian Gupta model. Its dodecagon plan is unique in the far east. It has a high plain plinth above which is a piano nobile with corner columns. Then follows a succession of eaves which gradually diminish in size. At the top are the usual mast and disks. The details are purely Indian. An arched recess decorates each cardinal face of the main story and miniature arches are spaced around the eaves. Each secondary façade is filled by a representation in relief of a square, single-story pagoda whose pedestal is underlined by lion busts and whose dome rises out of foliated acroteria.

A structural example of the square, single-story type is found in the small four-doored pagoda, Ssu-men-t'a, of Shen-t'ung-ssu in Shantung (544). The tomb-pagoda of Fa-ting at Ling-yen-ssu has a similar form slightly elaborated by a double row of corbeled eaves. The ancient pilgrimage temple of Fo-kuang-ssu on Wu-t'ai Shan, Shansi, has two hexagonal stories of which the lower is plain except for a single arched doorway leading to the core of the structure. The upper story has squat, indianizing columns at its corners; each column is banded with three rings of lotus petals. On the axis is a small arched door; each other face has a simulated lattice window. The plinth and eaves are faced with tiers of small overhanging lotus petals and the spire was once ornately formed.

2. T'ang Dynasty. — Almost all extant T'ang pagodas rise from square plans and are made of brick. The octagonal plan, which was to dominate pagoda design from the 10th century on, was infrequently used during T'ang times. The basic unit in T'ang pagoda design was a cube with a simple corbeled cornice and a roughly pyramidal superstructure nhich was crowned by some sort of spire.

In the monument to the dhyana master Fa-yuan (died 791) raised on Mt. Sung, the basic form was used. manifesting T'ang taste in the slight elaboration of it. The roof was made to simulate tiling; the door was given a pointed arch frame and was flanked by a pair of guardian deities. Standard examples of the type are those pagodas found at Lai-shui-hsien (712) and Yun-chu-ssu on Mt. Fang, both in Hopeh.

In slightly more involved versions of this basic type, the cube was crowned by a series of closely set eaves, from 7 to 16 in number. At this period the proportioning of the pagoda was excellent; the silhouette tapered upward across the horizontals in a long graceful curve following the early T'ang instinct to design in big, clear, sweeping forms. The Small Gander pagoda, Hsiao-yen-t'a, of Chein-fu-ssu at Sian (Hsi-an) in Shensi was built in the beginning of the 8th century and rose to a great height through 15 eaves. It is a good example of the strength and grace of early T'ang design undiluted by elaboration. The simple multiroofed type was carried to a height of 330 ft. through 16 eaves in the giant tower at Ta-li in Yunnan (9th century).

During the T'ang period, pagoda design as a whole was dominated by the habits of building in wood and the aesthetic standards evolved in wood construction prevailed throughout China no matter what materials were being used. The big brick tower of Hsian-chi-ssu near Ch'ang-an (late 7th century) has a separate story between the eaves which is marked by paneling. Wood construction is recalled in the regular spacing of simulated column capitals just under each of the eaves. This tendency is more marked in the Great Gander pagoda. Ta-yen-t'a, of Tz'u-en-ssu. Seven clearly marked stories were stepped back to diminish as regularly as in a wooden pagoda. The walls were divided by tall flat pilasters and decorated with simulated beams, intercolumnar struts and capitals. This pagoda was first built by Hsuan Tsang in 652 and was extensively renovated in 701–705. A more thoroughgoing imitation of wood effects is seen in two late T'ang pagodas, the one built over the ashes of Hsuan-tsang in the monastery of Hsing-chiao-ssu, and the unique pagoda of Master Lang at Shen-t'ung-ssu in Shantung.

The octagonal plan appears in the low tomb-pagoda of the dhyana master Ching-ts'ang (died 746) at Hui-shan-ssu on Mt. Sung, Honan. Here, too, the design simulated features of wooden construction in masonry brick. False doors and windows. quasi-octagonal pillars, projecting beam ends running through capitals, intercolumnar V-shaped struts — all useless to brick construction but fundamental to wood — appeared as more or less ornamental features.

In the Wu-t'ai Shan temple of Fo-kuang-ssu there are the remains of still another type of pagoda dating from T'ang times. This is the Treasure pagoda, a single-storied, cylindrical and domed structure which was surmounted by a series of octagonal corbeled eaves. This type derives directly from Gupta India. It seems to have been brought to China with the newly fashionable Tantric sect. In the early 9th century this form was adopted in Japan under the name of Tahoto.

The T'ang style may be clearly seen in some of the wooden multistory pagodas of Japan, notably those of the Yakushiji, Taimadera and Daigoji monasteries.

During T'ang times, Buddhism became more and more sinified, and the pagoda. once of primary importance in the temple complex, was gradually subordinated to the Buddha hall. It became the fashion to move the pagoda from the axis of the courtyard, sometimes doubling it. sometimes placing it behind the Buddha hall, alnays putting it in a position secondary to that of the Buddha hall.

3. Sung Dynasty. — With the rise in power of Ch'an Buddhism during Sung times the building of pagodas suffered a gradual decline, for the devotees of Ch'an had as little use for the pagoda as they did for the rest of the traditional trappings of the developed Buddhism of the day. A number of remarkable towers

were constructed, however, and their splendour was recorded in political and religious history. Perhaps the most famous of the pagodas was that erected at Pien-ching in 989 to house the famous reliquary stupa of Asoka from Ningpo. This tower was octagonal and had 11 stories. It was burned in 1037 and rebuilt with nine stories and the remarkable feature of being open all the way up inside. The pagoda of the pilgrimage temple on the Huai river, called P'u-ch'ao-wang-ssu, was octagonal and 13-storied. Each story had a roof of yellow tiles and was covered with myriad niches containing images of bodhisattvas and minor deities. Inside was a spacious chapel glitteringly furnished with gold and silver fittings. Above the interior columns were gilded busts of bodhisattvas; the partition beam ends took the form of angels.

The typical Sung pagoda had a serviceable interior in which images were often enshrined.

The extant brick pagodas of Sung times all run true to a single type. Almost all are hexagonal or octagonal and strictly continue, in elaborated form, the T'ang multistoried formula. The northern examples are, on the whole, more conservative in design and are distinguished by a special mode of eave enrichment which consists of corbel blocks closely spaced in two regular tiers. This device is seen in an elaborate form in the pagoda at Tsou-hsien in Shantung and on the 11th-century Iron-Coloured pagoda, T'ieh-t'a, at K'ai-feng (old Pien-ching). In each case an obvious attempt had been made to imitate wooden bracketing. It was also the style to encase whole towers in richly decorated square, glazed tiles; sometimes each tile was centred with a round image niche.

A large number of southern brick pagodas were not only designed to simulate wood construction but actually incorporated wooden rafters to hold the tiled roofs and balconies and sometimes even had wooden brackets. The Pei-t'a at Soochow in Kiangsu is just such a pagoda.

This tower is characteristically tall and slender, and has an unusual small masonry cupola. which rises from an octagon to a circle. Each corner of the octagon holds a two-tier bracketing unit, the top of which helps to support the rim of the circle. In addition, a stone rib runs between each opposite pair of bracket tops and the four ribs meet at a capstone.

Some southern pagodas were made of iron and were consequently small in scale and extremely slim in appearance. The one at Kan-lu-ssu in T'an-tu-hsien. Kiangsu, and that at Ching-chou in Hopeh were each set upon an elaborately designed pedestal ornamented with waves and peaks. Early Sung pagodas were relatively simple and sturdy in appearance; the eaves curved up only at the corners. In the course of 100 years, the style moved toward a fragile richness; the bracketing systems became small and crowded and the eaves acquired sweeping continuous curves.

The pair of pagodas at Ch'uan-chou in Fukien, built of brick in the mid-12th century and encased in stone in the mid-13th century, each have five stories which are squat and wide. The bracketing is bold and uncomplicated. Only the sweeping curves of the eaves and the consistent imitation of pillar and beam forms mark the style as southern.

4. The Barbarian Empires. — The barbarian emperors of Liao and Chin, who were the constant adversaries of the Sung house from the 10th century through the 13th century, patronized a brand of Buddhism which created a distinctive pagoda type. Octagonal in plan, its elevation had three stages which were sharply differentiated. The base was fairly high and was subdivided into courses enriched with sculpture. The shaft was relatively plain, being decorated only by Buddhist groups in relief and some kind of corner accent to maintain the verticality. The crown was a series of close-set roofs, usually 13 in number. The bottommost eaves were bracketed in imitation of Chinese carpentry; the others were simply corbeled out. The whole multiple crown diminished until it joined the form of the spire.

The Liao octagonal pagoda differed from the Sung examples in the baroque exuberance of its design. It represented a peculiar combination of T'ang and Northern Wei characteristics and can probably be traced back to some distant Indian original. The octagonal ground plan was a clear reflection of Tantric Buddhism, the cosmological pattern of which was subdivided into eight compass points instead of four. The Liao pagoda, then, mystically embodied the mystery of the eightfold pattern. A group of four pagodas near Ch'ao-yang, Chin-chou, Jehol, is unique in that each structure retains the square plan. The earliest of these served as the model for the rest. It was originally a T'ang construction but was refaced in the middle of the 11th century when the status and privileges of Ch'ao-yang were raised by the patronage of a Khitan ruler. The four major wall areas served to display relief representations of enthroned Tantric Buddhas attended by bodhisattvas. Each trinity was in turn flanked by a pair of small square pagodas. This scheme brought together the Tantric Buddhas of the Four Quarters and the Eight Great Stupas of Mahayana tradition. According to Tantric theology, the buddhas of the directions were simply manifestations of the Supreme Buddha, Vairochana, who was therefore symbolized by the pagoda itself. The Four Buddhas also appeared on hexagonal and octagonal pagodas, where some adjustment had to be made with the extra faces.

The standard octagonal pagoda was adorned with representations of the Eight Great Buddhas, or the Four Buddhas with the Four Bodhisattvas. For the great pagoda of Ta-ming-cheng, another canonical favourite, the Eight Great Bodhisattvas, was used.

The typical base for the Liao pagoda incorporated grotesque caryatids at the corners. In three examples, there appear the foreparts of a huge lion protruding from each face. There, the lion, as the Tantric vehicle of Vairochana, appropriately supports the symbolic body of the primal lord.

The Liao standard plans and elevations permitted several variations. In smaller buildings. the number of sides was reduced to six and the number of roofs to nine or seven. Several examples have imitative bracketing under all the eaves.

A less common Liao type, found chiefly in Hopeh, was not adorned with reliefs. The South pagoda of Yun-chu-ssu, Mt. Fang, was erected in 1117 and was adorned with doors and windows only. Another example, at T'ien-ning-ssu, just outside of Peking, has sculptured ornament only in the form of door guardians. This type of unadorned building implied the presence of major images within the shrine.

The bracketing systems in Liao pagodas created areas of rich visual interest. The details of contemporary carpentry were carefully imitated. Comer bracketing was always the most complex and visually fascinating, and the eight-sided plan allowed for twice the usual number of corners set closer together. The Liao architects deliberately exploited a variety of forms. No single scheme seems to have been repeated.

One wooden pagoda, erected in 1058 at Fo-kung-ssu, Ying Hsien, Shansi, has survived. This building has five stories, each of which is very squat. The whole silhouette is so broad that it resembles a *ko* pavilion as much as it does a pagoda. The eaves have that characteristic emphatic projection which demanded a more developed bracketing.

A few curiously exotic works were among the productions of the barbarian kings. The Northern pagoda, Mt. Fang, has a dome and masonry spire which recall a peculiarly Tibetan form of the stupa. The dome and cone superstructure also appears in relief representations of pagodas which are accompanied by mystical Tantric spells.

The most unusual pagoda is one which was built during Chin rule. This is the Hua-t'a of Cheng-ting Hsien, the first story of which is a large octagon. On the alternate faces of this story are hexagonal, single-story wings. The top of the structure was thickly encrusted with an extraordinary collection of sculptured forms: miniature stupas resting on lion or elephant protomes, grotesque caryatids and lion heads. The general plan of the building reproduced the four-around-one scheme of the Tantric mandala.

Nearly all the Liao and Chin pagodas rose singly, on axis and behind the major hall.

Very few of the Yüan pagodas that have survived offer anything new. A particularly baroque tower, in a park in Seoul, Korea, was a gift of the last Mongol emperor on the occasion of the marriage of his favourite granddaughter with the Korean king.

CHINESE BRONZE. Bronzes have been cast in China for about 3,500 years. Except for a few categories described below, this article is concerned only with the products of about 1500–300 B.C., roughly the Bronze Age in China. Most bronzes of this period may be described as ritual vessels, intended for the worship of ancestors, who are often named in inscriptions on the bronzes. Many were specially cast to commemorate important events in the lives of their possessors, and their inscriptions constitute valuable social and historical documents. The vessels were also meant to serve as heirlooms, and the inscriptions often end with the admonishment "Let sons and grandsons for a myriad years cherish and use."

The ritual bronzes of ancient China include some of the loveliest objects ever made by man, and as a group they represent possibly the most remarkable achievement in the whole history of metalcraft before modern times. No one can say how many ancient Chinese bronzes survive; more than 12,000 have been counted.

Traditional Chinese scholarship assigns the ancient bronzes to the period known as the Three Dynasties. Of these the first! the Hsia, may have been historical, but confirmatory archaeological evidence is lacking. The second, variously called Shang-Yin, Shang or Yin. is known by a rich accumulation of material remains from sites in Honan province in northern China. The third, the Chou, also is well represented by material remains, while its extant writings form the inheritance of classical Chinese literature.

Known bronzes belong to the second and third of these dynasties, The widely accepted revised chronology of the Shang-Yin puts its dates at c. 1500–1027 B.C. (according to the orthodox school, 1766–1123 B.C.), but most known Shang-Yin bronzes were made after the founding of the last or next last capital, near the modern city of An-yang in northern Honan, during the 14th century B.C. Shang-Yin bronzes were being taken from the An-yang site as early as the 11th century A.D., and systematic excavation in the 20th century uncovered many more; of all Chinese bronzes they are the finest. The Chou period (1027–249, or 1122--256, B.C.) saw two successive major changes in style, as well as the development of regional traditions and a certain deterioration from the standards of Shang-Yin bronze art. Chou bronzes, too, were being collected in the 11th century A.D., and considerable hoards of them continue to come to light.

Beginning of the Bronze Age.—Bronzes of the Shang-Yin and Chou periods fit roughly into three stylistic and chronological phases, using the nomenclature and dating of W. Perceval Yetts: (1) first phase, 13th–10th century B.C.; (2) second phase, 9th–6th century B.C.; (3) third phase. 5th–3rd century B.C.

In 1937 Bernhard Karlgren demonstrated the existence of A and B styles concurrent within the first phase. Many A-style vessels have a single decorative composition covering the main body of the vessel; in B-style vessels the decoration is invariably disposed in horizontal registers. Further, the commonest design element, the *t'ao-t'ieh* (see below), is in the A style a coherent and easily distinguishable form, whereas in the B style it is disintegrated and its animal nature cannot easily be perceived. Lastly, the A style presents a variety of animal motifs—t'ao-t'ieh, vertical dragons, cicadas—all more or less decipherable, whereas the B style tends to favour formal geometrical motifs such as lozenges, interlocked T's, circle bands and massed vertical ribs. Coexistence of two separate styles within the first phase might be taken to imply an even earlier period during which the art presented a unified style.

Karlgren's study of the way in which the motifs are distributed within the two styles indicates that whole classes of vessels were restricted to one or another of the two styles; he cites as an example the li-ting (see below). Evidently by the time these vessels were made (c. 1300–900 B.C.) prescriptive rules already existed which the bronze designer felt bound to obey, and the art, despite its nonderiully rich vocabulary, had acquired a certain conventionality. Karlgren concluded that the bronze art of An-yang must have had a long antecedent history in China. "an era with a freer high bronze art, with a whole array of vessel types, décor motifs and ornamental constellations not yet bound by fixed conventional rules," intervening between it and a more primitive period.

Of this hypothesized preceding era of high bronze art there is not the least trace. On the other hand, excavation during the 1950s at the sites of Liu-li-ko and Erh-li-kang in Honan revealed a culture with unmistakable early Shang-Yin characteristics. including oracle bones used for divination and a number of bronze vessels that can fairly be described as the rude forefathers of those known from An-yang.

The forms of Chinese ritual bronzes probably were based originally on ordinary domestic utensils made of clay and perhaps other materials, such as horn or gourd; bronze vessels from Liu-li-ko and Erh-li-kang demonstrate this relationship much more clearly than do those from An-yang. In other words, they seem to belong to a period nearer in date to the time when bronze vessels were first made in imitation of Neolithic domestic prototypes. They display features that may rightly be regarded as primitive in Chinese bronze art: thin walls; the legs of ting short, conical and hollow, like those of certain prehistoric pottery *ting;* bottoms of *chüeh* and ckia vessels flat instead of rounded; the *ku* goblet of stout proportions and standing on a squat base. A bronze fing from Liu-li-ko is very much like one made of pottery from Erh-li-kang; a bronze *ku* from Liu-li-ko has features in common with an ivory cup found at Erh-li-kang; while *chüeh* goblets resemble pottery examples.

These bronze., perhaps dating from as much as a century and a half before An-yang, throw fresh light on the controversial question of the origin of metallurgy in China: Was it a cultural importation, or did it originate and develop in China? The importation theory depends mainly on the similarity of a group of curved bronze knives with animal heads and ring handles, found at An-yang, to another group belonging to the Yenisei Bronze Age culture of the area around Minusinsk, U S S R. There is some historical connection between the two groups, but absolute dates for the Karasuk culture, to which the Siberian knives belong, are lacking; indications are that it opened at least a century after the founding of An-yang.

The shapes of the ritual bronzes, for the most part, are distinctive to China; they combine with the amazing *décor*—sometimes amounting almost to an iconography—to produce forms for which no-parallel exists in any other part of the world. If metallurgy had been introduced to China from outside, one would expect to find some stylistic trace of foreign antecedents. If, on the other hand, the origins of the Chinese Bronze Age are to be sought in China itself. then the rather crude bronze vessels from Erh-li-kang and Liu-li-ko represent precisely the sort of early stage it might be expected to have gone through. In short, these vessels provide evidence in favour of the view that bronze casting was an independent Chinese invention.

Materials of Bronze Casting.—Few reliable analyses of the metal used for casting ancient Chinese bronzes have been made. One. done on part of a Shang-Yin bronze. showed the following constituents, copper 82.39; tin 15.42; lead 0.45; gold 0 38: iron 0.09; sulfur 0.115; residue 1.20. Perhaps because of this it has been supposed in the west that lead entered very little into Chinese bronze alloys Lead is usually introduced to temper the metal—in Mediterranean bronzes, for example, in proportions varying between 3% and 11%, in south Indian examples up to 25%—and it seems certain that the Chinese followed the tradi-

tional practice. Lead is present in proportions as high as 20% in bronzes of the early Chou period onward, and an analysis of part of a vessel dating probably from the Shang-Yin shows copper 75.5; tin 12.6; lead 6.5. While there is no reason to suppose that Chinese founders were incapable of distinguishing one metal from another, as is often said, the formula no doubt varied from one foundry to another.

Abundant remains of foundry products, including malachite, charcoal slag. molds and crucibles, were found at both An-yang and Erh-li-kang. Usable copper and tin ores today come mainly from far southwestern China, but there is a local tradition that both were formerly mined in the vicinity of An-yang.

Methods of Bronze Casting.—Flat objects such as weapons and tools were cast directly by means of temporary molds or "flasks" made of loamy sand or clay composition, one mold for each side of the object to be cast. Among many such molds found at Erh-li-kang is one bearing negative impressions of arrowheads, set slantwise and connected by a central channel, forming a pattern like the veins of a leaf. Hollow vessels. or undercut relief, could not be cast by this method but needed a much more complicated technique.

It is generally believed in the west that ancient Chinese bronze vessels were cast by the *cire* perdue, or lost wax, method (see SCULPTURE TECHNIQUE: Casting and *Finishing*), which is capable of yielding extremely fine castings, its disadvantage being that once the outer mold has been formed upon the wax model it cannot subsequently be inspected for possible flaws—the vessel must be cast come what may. The mold cannot of course be used more than once.

In 1935 **O.** Karlbeck described a series of piece molds recovered in course of excavation at An-yang. These bore negative impressions of typical bronze designs and had smooth, right-angled edges fitted with lugs, so that the pieces could be accurately assembled. Minute particles of bronze found in the negative relief strongly suggested that these molds were used for direct casting of bronze vessels. Many similar piece molds were later found at Erh-li-kang. Evidence is thus accumulating to show that many first-phase bronzes, probably the majority, were cast directly with the aid of sectional molds. By this process, molds in three or four sections would be cast from a model made either of wax or clay. In the Victoria and Albert museum, London, is a solid pottery object in the shape of a hu, bearing traces of shellac, such as would have been applied to its surface to prevent adhesion of a clay envelope, and vertical scratches that may have been made by a knife in separating off the mold sections. This, then, may have been a permanent positive model for casting piece molds. Alternatively, piece molds may have been taken from a temporary wax model built up on an inner clay core. Sectional molds allowed the caster to inspect and retouch his mold before casting. Though a sectional mold could not have been used more than once, a number of sets of sectional molds could have been taken from the positive model. Probably this was not usually done; no two first-phase bronzes exactly alike are known.

Classification and Nomenclature.—The first systematic classification of ancient bronzes is to be found in the great catalogues of the Sung dynasty (A.D. 960–1279). Their compilers found that many of the bronzes were self-named in the inscriptions they bore, while others could be identified from descriptions given in the classics; with few exceptions, the classes thus established have stood the test of time. Rfany problems of nomenclature nevertheless remain to be solved, nor is the question as to what constitutes a separate vessel class always easy to decide. A list of 25 distinct vessel classes published by Yetts in 1929 usually is accepted as a model. For purposes of this article the number can be reduced further to 21, which includes the vast majority of extant bronze vessels found in museums and private collections or known through photographs.

Sacrifice to ancestors involved the offering of food and drink; ritual vessels thus can be further classified as food and wine vessels, together with a small class for ceremonial ablutions.

Food Vessels.—These may be subdivided into cooking vessels (*li*, ting, li-ting, hsien) and containers (kuei, tou).

The four classes of cooking vessels are all modeled on tripod domestic cooking pots such as have been found at Neolithic sites throughout northern China. *Li* and *ting* differ in that the three legs of the former are hollow and bulbous, joining imperceptibly with the lower part of the body, whereas those of the ting are solid and more or less cylindrical and their articulation with the body is abrupt. Li and ting were perhaps the first vessel classes made in bronze. Examples are found among bronzes made before the foundation of An-yang, and throughout all three stylistic phases. while their forms mere reproduced in bronze and other materials during almost every subsequent period. Both classes are self-named in their inscriptions.

The li-ting is intermediate in form between li and ting, for while the lower part of its body, like that of the li, has three lobes or hollow depressions, its legs are solid and cylindrical like those of the ting. A Neolithic pottery prototype inherits features of pottery li and ting and is, in turn, the ancestor of the pottery tripod, chia. The bronze li-ting is not as a rule admitted as a separate class of vessel, most examples being classified as ting. In fact, however, a stylistic gap separates the two; for instance, scarcely a single li-ting with B-style decoration can be adduced, whereas B-style ting are common.

The *hsien* is a composite vessel; the lower part resembles a li, the upper is bowl-shaped. Food put in the upper part is cooked by steam heat rising from the lower. Hsien may be cast as one vessel or as two, but in either case a grille divides the two portions. Neolithic pottery prototypes are known, and the vessels were made during all three stylistic phases. Some hsien are self-named in their inscriptions.

The kuei also was made during the three phases. Basically it is a round bowl standing on a wide and slightly flared foot, and is clearly descended from a pottery prototype. But shapes are often highly elaborated, and second-phase examples have a decidedly flamboyant, "baroque" appearance. Some kuei are self-named in their inscriptions.

The pottery tou, shaped like a cake stand and mounted on a tall, hollow and often perforated flared foot, is common in the Neolithic pottery cultures of northern China but seems not to have been cast in bronze until the third phase. One bronze variety has a bowl-shaped body and a domed lid which could be reversed to serve as an accessory vessel. Tou are not self-named.

Wine Vessels.—These comprise containers (*tsun*, yu, *hu*, fang-i, lei), goblets (chih, ku, *chüeh, chia*) and vessels for heating wine or mixing it with water (ho, kuang).

In bronze inscriptions the word tsun serves to designate ritual wine vessels generally and it cannot therefore properly be used to name any particular class. A class of tall, massive wine vessel, shaped rather like a very fat *ku* but too large to have been used as a drinking goblet, was nevertheless called tsun by the Sung cataloguers and is generally still so labeled. On the other hand, the classics frequently speak of wine vessels called *hsi* tsun, hu tsun and hsiang tsun, meaning containers cast in the shape of sacrificial animals, tigers and elephants; and such vessels, realistically modeled to represent animals such as sheep, oxen, hares, buffalo and elephants, are fairly common among known Chinese bronzes. A famous example in the Musée Guimet, Paris, no less than 38 in. long, is fashioned in the shape of an elephant and would therefore correctly be called a hsiang tsun.

Of the other wine containers, yu may be described as covered buckets with swing handles. They were made during the first phase only and none is self-named. Yu show a definite shape relationship with hu, for both are usually oval in section and have sloping shoulders and a low-slung belly. A few *yu* are modeled in the shape of a bird, evidently some sort of owl.

Hu, some of which are self-named in inscriptions, were made during all three stylistic phases, but the finest examples belong to the third phase, after which their handsome forms were imitated in glazed pottery of the Han period. They are large vessels, sometimes provided with stoppers, and invariably with a pair of small ring handles, or tubular "ears," through which could be passed a cord or chain for carrying. Hu are usually oval in section, sometimes circular, occasionally square.

Fang-i are not self-named in their inscriptions and do not persist beyond the first phase. They are square in section and their form is distinctly architectural, the shape of the cover suggesting a high-pitched. fully hipped roof, while a base is often marked off from the body, recalling the platform that was an integral feature of palace architecture from Shang-Yin times onward.

Lei were used for serving wine. The class is an ancient one, examples being found at Erh-li-kang, but does not seem to have been made after the end of the first phase. No example is self-named. Lei are tall and capacious, characterized by a high shoulder and gradually narrowing body below. They have the same sort of cover as the *fang-i.*

Chih are morphologically related to *hu,* though very much smaller and lacking ring handles or "ears." They are typically oval in section. The class is not self-named and the Sung identification cannot be guaranteed correct. *Chih* were made during the first phase and again, with what seems to have been an archaizing impulse, during the third.

The tall and slender ku, with its long, flared mouth and foot, is one of the most memorable of the bronzes. It is an ancient class, being represented at the pre-An-yang sites and disappearing completely after the first phase. The ku may have evolved from a pottery ancestor of tou type, as J. G. Andersson supposed, but more probably derives from one made of horn or similar material. A squat ivory cup found at Erh-li-kang (see above) may be such a vessel. Toward the base it has a single cruciform perforation shaped exactly like the diametrically opposed pair of perforations seen just below the middle horizontal zone of many ku, which have not been explained. The class is not self-named.

Chiieh and *chia* are related, both perhaps descending from a Neolithic pottery vessel of li-ting type, from which stage intermediate pottery forms lead down to the mature bronze types found at An-yang. Both vessels stand on three long, lance-shaped legs and both are provided with side handles and with a pair of small capped pillars mounted on the mouth rim. In addition, the *chüeh* has a long, troughlike spout and a tapering tail extending from the mouth rim. These several features give it an elegance and poise not matched elsewhere among the bronzes. Primitive versions of both chueh and *chia,* very similar to contemporary pottery examples, have been found at sites older than An-yang. so that the record of their formal evolution seems nearly complete. They were made throughout the first phase, but never subsequently. Neither class is self-named.

Ho, used for mixing wine with water, are like teapots, being provided with spouts, side handles and lids which are usually connected to the body by a short chain. They are generally mounted on three or four legs and the basic shape of the body is that of the *li* or ting. Ho are self-named in some inscriptions and persist through all three phases. A Neolithic pottery prototype is known.

The name kuang was given to a group of first-phase vessels looking like sauceboats with covers modeled in the shape of an animal head, often that of an ox. There are, however, good reasons to doubt the identification. *Kuang* are not self-named; in shape, they closely resemble the water ewer, *i,* which in many cases is self-named, the only difference being that the *i* usually lacks a cover.

The Sung cataloguers made no distinction between kuang and i, assigning all such vessels to the latter class. If they are one, this would account for the fact that so-called *kuang* are restricted to the first phase, i to the second and third. A vertical partition running across the short axis in some examples is perhaps evidence that kuang were used for mixing wine with water.

Water Vessels.—These include containers (*chien, p'ou*), basins (p'an) and ewers (i).

Chien provide self-named examples, the graph showing a person bending over a bowl, apparently looking at his reflection in the water. One of the meanings of *chien* is "mirror," and it is possible that this bowl was used as such, but references in the classics indicate that it was normally filled with ice and used to preserve sacrificial food in hot weather. *Chien* are among the largest bronze vessels, one in the Musée Cernuschi, Paris, measuring 40 in. across the mouth. *Chien* were not made before the second phase.

There is some doubt as to whether *p'ou* were used as containers for wine or for water. They are large jars. usually provided with covers, and were made during all three phases and reproduced subsequently in glazed pottery of the Han and Six Dynasties periods. This class is not self-named.

P'an are large shallow bowls that were used for washing other ritual vessels or for ceremonial ablutions. The class is self-named. Examples occur among bronzes older than the An-yang culture and throughout the three phases to Han times. The flat inner surface of *p'an* particularly fits them for long inscriptions.

The water ewer, i, probably descends from the so-called *kuang.* The class is self-named and is found only in the second and third phases. Most *i* lack covers; early examples often have the spout enclosed above by an animal mask. the vessel being supported on three or four legs. Later the mask disappears and the legs may then be replaced by a hollow, spreading base, but many other variations occur.

Stylistic Phases.—Two radical changes in the style of the ancient bronzes occurred, one about the beginning of the 9th century B.C., the other approximately four centuries later. Three stylistic phases thus may be discriminated. These changes were not cataclysmic: decorative elements persisted from one style to the next, so that many vessels display features common to both and resist classification into either. Nevertheless a typical first-phase bronze is very different from one typical of the second, just as one typical of the second phase differs radically from one belonging to the third.

The art of the first phase may be qualified as hieratic, for its motifs seem to have a real iconographic import, less evident in the later phases. The *t'ao-t'ieh* mask, set in a background of squared spirals, is its main subject, supplemented by an astonishing array of other animal motifs. There is a tendency, more pronounced in the case of vessels in A style, for decoration to cover the entire surface. Often the shapes of such vessels are almost submerged beneath the profusion of symbolic form.

The second phase expresses a simpler and less tense spirit. Animal forms hare all but vanished and the t'no-t'ielz is reduced to little more than a geometrical pattern. Decoration is used for its own sake. the design being carefully placed in horizontai registers. The shapes of the vessels are freely modified and show great beauty. The whole phase manifests unusual delicacy and good taste.

The third phase marks a return to the exuberance of the first and the use of many first-phase motifs, although the hieratic quality is missing and the mood is light and even playful. Rich effects are sought and much use is made of costly inlays. Designers drew on many sources for their motifs—the art of the northern nomads, for instance—so that the phase may be designated as hybrid in origin and synthetic in style.

First Phase (*13th–10th Century* B.C.).—Among the style criteria distinctive of the first phase are rectangular ting, *li-ting,* yu,

fang-i, ku, chiieh, chia and *kuang;* cylinder legs; an animal's head on the upper part of *ting* legs; vertical, segmented flanges and lid knobs as opposed to disks. A dominant feature is the deep bowl shape of *ting,* and vertical handles, or "ears," are mounted on the mouth rim, not on the body of these vessels.

The most important motif, the *t'ao-t'ieh,* is a mask seen in front face, composed of two confronting animal forms seen in profile; what it is or what it signified is not known. Resemblances to it in the art of Mycenae and of pre-Columbian America must be regarded as chance. Its earliest-known occurrence in Chinese art is on a steep-sided pottery bowl recovered at the Neolithic site of Shih-chia-ho in Hupeh province (1955).

Almost as universal as *t'ao-t'ieh* are the creatures called by the Chinese *lung,* "dragons"; indeed the two halves of the *t'ao-t'ieh* itself may for practical purposes be regarded as a pair of dragons in profile. Though the form is highly stylized, a beaked jaw, snout, forehead. crest, horn, eye, body, tail and leg or legs usually can be recognized.

Many more familiar animals occur on first-phase bronzes, a cicada being one of the commonest, usually incorporated in the tall, tapering motif called by Karlgren "rising blade" or "hanging blade," according to whether it points upward or downward.

Most of the geometrical motifs are restricted to vessels decorated in the A style. They include massed round bosses, massed compound lozenges, lozenges with central spikes, massed vertical ribs, circle bands, interlocked T's and the *ling hua,* "flower of the water chestnut." The commonest geometrical motif, however, in A style as well as in B, is the squared spiral. Its significance is unknown, but the Sung cataloguers called it lei *wen,* "thunder pattern," probably because of a chance resemblance to the ancient written character for "thunder."

Second Phase (9th–6th Century B.C.).—A group of bronzes, assigned to the early 9th century, shows many typical second-phase motifs but none typical of the first. A *ho* found with other vessels and a bell at P'u-tu Ts'un in Shensi province (1954) has an inscription naming King Mu, who ruled in the middle 9th century; the vessels are typical of the second phase. The latest examples that can be approximately dated are the hoard of bronzes (eight vessels and a bell) found at Hsin-cheng in Honan province in 1923. perhaps made in the middle 6th century. By the beginning of the 5th century the third phase was in full swing, and it is likely that second and third phases were coeval for a century or more.

The second phase is marked by total disappearance of the vessel classes distinctive of the first phase—a fact difficult to account for. *Kuang* probably survived into the second phase as *i.* Characteristic changes in the shape of other vessel classes took place. *Ting* become much shallower, the "ears" L-shaped and mounted on the body, the legs thin, splayed and cabriole-shaped. Li are also shallow, with flat spans between the legs. *Kuei* often are cast together with a massive square stand, have lobed handles representing animals or birds, a lid and a lid knob looking like a crown. *T'ao-t'ieh* and dragons are among the few first-phase motifs to survive, but their forms are so fragmented as to be almost unidentifiable, and the first-phase animal forms have been practically banished. Prominent among new motifs is the continuous wavy band with faulted sides, called by the Chinese *pan yün,* "undulating cloud." Another is the horizontal fluting characteristic of the Hsin-cheng bronzes, which may have been an innovation from the near east. A third is the scale or imbricated pattern, in which the scales may hang vertically side by side to form a band, or else are massed together either vertically or horizontally to cover a wide area.

Third Phase (5th–3rd Centuries B.C.).—The first reliable date for a vessel in third-phase style is probably that afforded by inscriptions on a pair of vessels, the Huang-chih *hu,* referring to events that happened in 482 B.C. Again, in 1955, 485 miscellaneous bronzes were recovered from the tomb of a marquess of Ts'ai at Shou Hsien in Anhwei province, part of the ancient state of Wu; the rulers of Ts'ai were refugees in Wu between 493 and 447 B.C., during which period the bronzes were probably made. A third *point de repère* is provided by a group of bronzes found in 1923 at Li-yu, near the Great wall in northern Shansi. Some of the bronzes excavated in 1953 at T'ang Shan in northern Hopeh, in the territory of the state of Yen, show a style and decorative treatment similar to these Li-yu vessels. whereas the Shou Hsien bronzes, with the Huang-chih *hu* and a set of 13 bells found in a tomb at Hsin-yang in Honan in 1954, belong to a style associated with the southern state of Ch'u. Some of the feudal states, in other words, seem by this time to have developed their own conventions within the main phase.

The lower limit of the third phase has been fixed at the end of the 3rd century B.C., mainly on the strength of the sudden disappearance at that time of certain categories of bronze mirrors. Undoubtedly the breakup of feudal China and the founding of the Han dynasty marked the end of the phase in most parts of China. In the south, however, Ch'u continued to enjoy some political independence as late as 122 B.C. Dozens of tombs have been excavated in the vicinity of the Ch'u capital (modern Cha'ng-sha), and while many of these date from the 3rd and possibly 4th century B.C., some belong to the early Han period. The third-phase bronze style is here expressed in other materials, for example lacquer, and the family likeness of these objects, possibly made over a period of three centuries, clearly demonstrates that in this region at least the stylistic break was not sharp.

The phase is marked by a revival of certain Shang-Yin motifs, including a freely treated *t'ao-t'ieh,* climbing dragon handles, rising and hanging blades, interlocked T's, the circle band, the square *ting,* the *chih* goblet, the use of turquoise as an inlay. Other motifs, such as the *pan yiin,* are taken over from the second phase. Nomad art made an important contribution. Modeled animals, such as adorn the covers of certain third-phase *ting,* often have small pear-shaped cells on their bodies. These are vestigial on the Chinese bronzes, but in nomad art were used as *cloisons* to hold turquoise and other inlays; indeed the whole conception of these animals is borrowed from the nomads. The practice of inlaying, while known in first-phase art, was probably stimulated during the third phase by contact with the nomads. A variety of rich materials is used—jade, glass, lacquer, silver, gold, copper, turquoise and malachite—and naturalistic subjects such as hunting scenes are finely rendered, usually on the bodies of *hu.* Many motifs seem to be original, among them the twisted and plaited cord pattern separating horizontal registers, the comma-shaped hook and the free ring handle depending from an animal mask.

Bronzes Other **Than** Vessels.—Among other ritual bronzes,

bells constitute an important group. Perhaps the oldest class is the small clappered bell called *ling,* which occurs among the bronzes older than An-yang; but the best known is certainly the suspended, clapperless bell, *chung. Chung* were cast in sets of eight or more, to form a musical scale, and were probably played in the company of string and wind instruments. The section is a flattened ellipse and on each side of the body appear 18 blunt spikes or bosses, arranged in three double rows of three. These often show marks of filing and it has been suggested that they were devices whereby the bell could be tuned to the requisite pitch, by removing small quantities of the metal. The oldest specimen recovered in a closed excavation is one from P'u-tu Ts'un, dating from the 9th century B.C.

Vast numbers of secular bronzes were cast during the three phases and later. These include weapons, such as the *chih* and ko dagger axes and the short sword; chariot and harness fittings; trigger mechanisms for bows; weights, scales and measures; belt hooks; mirrors. The last appear in great numbers from the third phase onward. They are flat disks, with a central perforated boss by which they could be mounted on a stand. Their backs are covered with a maze of intricate relief designs and feature a diversified series of well-defined subjects.

Karlgren's C and D category mirrors, which disappear at the beginning of the Han period, bear typical third-phase motifs such as interlocked T's, comma pattern, granulated band and continuous compound lozenge band. They also feature a composite creature called "bird-dragon" by Karlgren and a device in which a dragon is combined with an open lozenge. Karlgren's F category appears in the 2nd century B.C., and features a magical mountain landscape peopled with fantastic beings, probably a Taoist subject. About 100 B.C. the Animals of the Four Quarters first appear on mirrors of TLV type, so called because they are decorated with simple geometrical forms resembling those letters. TLV mirrors are often very complex in design, with several concentric zones of ornamentation. and carrying inscriptions naming the 12 signs of the zodiac and the 28 Stellar Mansions; for this reason they are also sometimes known as cosmic mirrors.

An important type of mirror, called by the Chinese "sea horses and grapes," appears in T'ang times. It reproduces a late antique motif of vine trails bearing bunches of grapes intermingled with various animals and birds and is probably derived from Sassanian Persian metalwork.

Later Bronzes.—By Sung times archaistic versions of the ancient bronzes were being plentifully made, but from this stage onward the art, if not the technique, so degenerates that it no longer holds interest. Between Han and Sung, however, quantities of small votive Buddhist images were cast in bronze, and in fact the oldest Chinese Buddha image known, a Sakyamuni inscribed with the date A.D. 338, is such a piece. This period, that of the Wei, Sui and T'ang, was one of vital achievement in Chinese sculpture and the lovely bronzes reflect prevailing stylistic trends.

CHINESE CLASSICS. The Chinese word *ching,* commonly translated "classic," is used in Confucianism, Taoism and Chinese Buddhism to designate the canonical works of these schools. It is above all the *ching* of Confucianism. however, that are usually thought of as *the* Chinese classics. Originally, *ching* meant the "warp" of a fabric; applied to literature, it conveys the idea that the works provide mankind with enduring "threads" or guides for human behaviour and morality.

Strictly speaking. only some of the Confucian classics are actually "Confucian" in the sense that they were written by Confucianists and expound an explicit Confucian philosophy. Several antedate Confucius (551–479 B.C.), while others, though written later, are nonphilosophical in subject matter. All, however, have become Confucian in the sense that, beginning in the and century B.C. when Confucianism achieved orthodoxy, they became basic in the Confucian-oriented system of education. In later times, with the development of the examination system for recruiting government personnel, a knowledge of these classics became an indispensable requirement for almost anyone aspiring to government position.

Though, generally speaking, it is correct to describe most of the classics as products of the Chou dynasty period (12th–11th century to 256 B.C.), a more precise dating is often difficult. On the one hand, portions of some have been traditionally attributed to periods as early as a millennium before the beginning of the Chou. On the other hand, it is known that they, as well as other texts traditionally dating from the Chou itself, underwent considerable editing at the hands of scholars of the Han period (202 B.C.–A.D. 221), particularly during its first two centuries. The direct stimulus for this activity was the loss and dispersion of literature suffered under the preceding Ch'in dynasty (221–207 B.C.) in 213, when, eight years after its forcible welding of the Chou principalities into a unified empire, it deliberately attempted to erase memories of the past by officially ordering a "burning of the books." To what extent the Han scholars, following the downfall of the Ch'in, may have altered or added to the literary materials which they collected is a matter of dispute.

Most scholars believe that probably no classic, irrespective of its traditional attribution, was written more than a few years before the beginning of the Chou; that other texts, though traditionally ascribed to early Chou, probably actually date only from the latter centuries of that dynasty; and that the Han scholars, when they recovered the old literature, often added substantial rationalizations, idealizations and reconstructions of their own. The frequent failure of both Chinese and western students to take due account of these many factors has led to innumerable gross misconceptions concerning early Chinese history and society.

Following 136 B.C., when five of the classics were singled out by the Han government for educational purposes, others were gradually admitted to the Confucian canon until in the 12th century A.D. its present standard number of 13 was reached. Following is an enumeration of these works, among which numbers 1 through 4. 6. 7, 10 and 13 are of primary importance (as already indicated, the dating of certain items can be tentative only):

(1) *I Ching* ("Book" or "Classic of Changes"): a divination text of the beginning of Chou. centred around the figures of divided and undivided lines known as the 8 trigrams and 64 hexagrams. Appended to this original corpus is a series of philosophically important "wings" or appendixes, probably of the 3rd or 2nd century B.C. (2) *Shu Ching* ("Book" or "Classic of History"; "Document Classic"): a collection of speeches, decrees and other political documents, of which the authentic sections date from the beginning of Chou to the 6th century B.C., but others (including

those allegedly antedating the Chou) were written only in late Chou or during the Han. The unraveling of the different strata of this work has been a major problem in Chinese scholarship. (3) *Shih Ching* ("Book" or "Classic of Odes," "Songs" or "Poetry"): a collection of 305 love songs, peasant ballads, religious odes, political satires and other forms of poetry; generally accepted as a genuine product of early Chou down to about the 7th century B.C. (4) *Chou Li* ("Chou Rites" or "Rituals"), (5) *I Li* ("Book of Etiquette and Decorum") and (6) Li *Chi* ("Book" or "Record of Rites"): these three ritualistic texts provide valuable information about the ceremonial behaviour, both religious and secular, of the Chou aristocracy, and about their political organization. All, however, were edited in Han times and must be used with great caution; number 4 is primarily political, number 5 describes factually the ritualistic behaviour of the individual aristocrat and number 6 is important philosophically as well as factually. (7) *Ch'un Ch'iu* ("Spring and Autumn Annals") and *Tso Chuan* ("Tso Commentary"): the *Ch'un Ch'iu* is a brief year-by-year chronicle, 722–481 B.C., of events in Confucius' native state of Lu (it is probably contemporary with the events it records, though traditionally ascribed to Confucius); the *Tso Chuan* is arranged as a commentary on the *Ch'un Ch'iu* and covers the same period. It is a wonderfully detailed and vivid history of all the Chinese states, probably compiled in the 3rd century B.C., with Han accretions. (8) *Kung-yang Chuan* ("Kung-yang Commentary") and (9) *Ku-liang Chuan* ("Ku-liang Commentary"): two briefer commentaries on the *Ch'un Ch'iu,* moralistic and ritualistic in nature and much less significant historically than the *Tso Chuan* (probably 3rd or 2nd century B.C.). (10) *Lun Yu* ("Analects"): sayings of Confucius, as recorded by his disciples of the first and second generation; it is the most important single source for the ideas of Confucius. (11) *Hsiao Ching* ("Classic of Filial Piety"): a short treatise, probably 3rd century B.C., of secondary philosophical importance, in which filial piety is exalted as the highest virtue. (12) *Erh Ya* ("Literary Expositor!"): the first primitive Chinese dictionary, probably 3rd century B.C. (13) *Meng-tzu* ("Mencius"): the conversations of this important follower (371?–289? B.C.) of Confucius, as recorded by his disciples.

In the course of the Han editing of the classics, sharp controversies developed, for the settling of which the government on two occasions convened special councils of scholars (51 B.C. and A.D. 79). Of major importance was the controversy between the *Chin Wen* ("New Text") and *ku-wen* ("ancient style") schools. Here it is impossible to enter into its many ramifications: other than to say that each school had its own particular works, or variant versions of the same works, which it championed, and that the differences between the two extended to ideology as well as textual criticism. In general, the New Text scholars tended to interpret the world in terms of portents and fortunetelling, whereas the ancient style school arose as a rationalistic reaction against this world view. During most of the Han dynasty (with the exception of a brief period about the time of Christ), the New Text school remained officially favoured. By the end of the dynasty (A.D. 221), however, it suffered a decline from which it never recovered save for a momentary revival toward the end of the 19th century.

From Han times onward, the text of the classics, together with a growing volume of exegesis, has been faithfully preserved. On seven occasions emperors ordered various groups of classics to be engraved on stone tablets, initially in 175–183 (9 classics; fragments still extant), and most recently in 1791–94 (13 classics, the tablets of which are preserved in Peking). In 932–953, 12 of the classics (all except the *Meng-tzu,* which did not become canonical until the 12th century) were for the first time printed from wooden blocks. See also CHINESE LITERATCRE; CONFUCIANISM.

BIBLIOGRAPHY.—Of the 13 classics, all except no. 8, 9 and 12 have been translated, notably by James Legge into English (no. 1–3, 6–7, 10–11, 13) and by Séraphin Couvreur into French (no. 2–3, 5–7, 10, 13). See also French translation by Edouard Biot of no. 4; German and English translations by Richard Wilhelm of no. 1; English translations by Bernhard Karlgren of no. 2 and 3; by Arthur Waley of no. 3 and 10; by John Steele of no. 5; and by William E. Soothill of no. 10.

Detailed scholarly studies have been made by Edouard Chavannes, Paul Pelliot, Henri Maspero, Bernhard Karlgren, H. G. Creel and others. For summaries and (in the case of Tjan) much valuable further information, *see* Charles S. Gardner, *Chinese Traditional Historiography,* esp. ch. 3 (1938); Tjan Tjoe Som, *Introduction to Po Hu T'ung,* vol. i (1949); Lien-sheng Yang, *Topics in Chinese History,* pp. 41–45 (1950).

(D. BE.)

CHINESE-JAPANESE WAR (1894–95). This war grew out of a conflict between China and Japan for supremacy in Korea. China, on the one hand! was bent on strengthening its position, which it could no longer take for granted in the face of western and Japanese imperialism. As early as 1880 China began to tighten its hold on this most important of its "tributary kingdoms" by means of a trade agreement and special commercial agents, by taking over the Korean telegraph, by appointing the able Yuan Shih-k'ai as Chinese resident in Korea, and by urging Korea to shore up its military forces.

Japan, for its part, emerged from two centuries of isolation in 1868 with the fundamental aim of increasing its national strength and making itself a respected world power in the face of western pressure that threatened its independence. Asserting influence in Korea was one aspect of this goal. As early as 1874 Japan sent an expedition to Formosa, ostensibly to seek redress for the murder of some Ryukyu islanders by Formosan aborigines but in fact to test China's attitude toward this dependency. Upon receipt of an indemnity and under pressure from Britain, Japan withdrew its troops. In 1879 Japan annexed the Ryukyu Islands, which had been in the ambiguous position of being tributary to both China and Japan.

But Japan was particularly interested in Korea because of its natural resources, especially coal and iron, in which Japan was poor, and because of its strategic position. which may be compared with the Low Countries in relation to England. For some years Japan's objective was Korean independence, for such independence would allow trade relations and economic penetration. In 1876 Japan was more or less successful in this connection when it signed an agreement with Korea that opened three ports for trade and declared Korea to be an "independent state." China, however, continued to speak of Korea as "our tributary kingdom." The international status of Korea during these years remained confusing. In the 1880s it negotiated treaties with various western nations as if it were independent but at the same time declared itself dependent on China.

Factional strife in Korean politics added impetus to Chinese-Japanese rivalry after 1880. In 1882 one Korean group, headed by relatives of the queen, backed by Japan and favouring intercourse with the west, clashed with another group, headed by the regent, backed by China and pro-Chinese in sentiment. In the righting the Japanese legation was attacked and both China and Japan sent troops to the scene. Two years later there was a similar clash in which Yuan Shih-k'ai's forces overcame Japanese troops and put down the revolt. The pro-Chinese group was left in control of the government with Yuan as the virtual ruler of Korea. Japan, it is apparent, did not want war at this time. The so-called peace party, which may be distinguished from the war party in that it was willing to make haste somewhat more slowly, was then predominant in the Japanese government.

But when another crisis arose nine years later (1894). Japan used it as a cause for war to eliminate China from Korea. Chinese troops entered Korea at the request of the Korean government to put down a serious rebellion. Japan dispatched troops to Korea as a countermove. When the uprising was under control: China suggested that both sides remove their troops; Japan replied that this would be unwise because the situation was too unstable. It proposed instead the formation of a joint commission to compel drastic reform of the Korean government, and added that if China declined to participate it would proceed alone. Japan was reasonably sure China would not accept this proposal because Chinese influence depended on keeping the *status quo;* any reforms would have meant admitting at least some of the pro-Japanese faction into the government. China's counterproposal, refused by Japan, was that Japan's reform proposals be discussed after a mutual withdrawal of troops. With the diplomatic situation thus stalemated, the occasion for war occurred in Aug. 1894, when Chinese

naval vessels fired on some Japanese ships.

From the outset of the conflict, China had little confidence in victory and its misgivings proved correct. The Chinese government and armed forces were unable to cope with the small but effective Japanese legions. and within six months China was sending missions to Japan in search of a settlement. By March 1895 the Japanese had gained control of Wei-hai and southern Manchuria, and an assault on Peking was in sight. At this juncture, Li Hung-chang. China's leading statesman, himself made the humiliating journey to Japan to sue for peace.

The outcome was the treaty of Shimonoseki of April 17, 1895. which included the following provisions: (1) China was to pay an indemnity of 200,000,000 taels to Japan; (2) China was to recognize the complete independence of Korea; (3) China was to cede Formosa. the Pescadores Islands and the Liaotung peninsula in south Manchuria to Japan; and (4) China was to draw up nith Japan a commercial treaty opening up four new treaty ports and allowing the establishment of factories under foreign ownership and management. The severity of this treaty was somewhat modified by the triple intervention of April 1895 by Russia. France and Germany. In the name of "friendship" for Japan, they "advised" Japan to relinquish its claim to Liaotunq. Faced with such an array of power. Japan had no choice but to acquiesce.

The war had important consequences. The west had expected a Chinese victory but the fighting exposed China's weakness for all to see; as a result, the next five years were a period of imperialism par excellence in China. China's poor showing in the war also was a decided boon to the revolutionary movement within the country, to which the Manchu regime succumbed in 1912.

Japan's victory established that country among the ranks of the great powers. By 1899 it had regained its sovereignty in full through renegotiation of the unequal treaties, something China did not achieve in full until 1943. In 1902 Japan was accepted by Britain as a partner in a full-fledged alliance And. finally, the war put Japan unmistakably on the course of expansion in east Asia.

CHINESE LANGUAGE. Chinese, the principal language of eastern Asia. is spoken by more people than any other language in the world. Though speakers of Chinese live in all parts of the world — from Singapore to New York city — and though small minorities within China speak non-Chinese languages — Miao-Yao, Thai, Turkish, etc.—more than 95% of speakers of Chinese live in China and more than 95% of the population of China speaks Chinese. Chinese is therefore essentially the national language of one country, as contrasted with English. the second most spoken language of the world. which is an international language of several countries. Chinese is one of the five official languages of the United Nations.

In linguistic stock Chinese belongs to a family of languages known variously as the Indo-Chinese, Tibeto-Chinese or Sinitic languages. Besides Chinese the other main branches are the Thai, Miao-Yao and Tibeto-Burman subfamilies of languages. There are three characteristics that all these languages share to various degrees: (1) they all tend to use monosyllabic meaningful units; (2) they all tend to develop a system of tones, uhether original or evolved out of earlier consonantal features; (3) earlier voiced initial consonants tend to become unvoiced in the modern forms of the languages.

PHONOLOGY

The phonetic system of modern Standard Chinese, or Mandarin, is comparatively simple and regular.

Sounds **of** Mandarin. — The accompanying list gives the sounds of Mandarin, as represented in the Wade-Giles system of romanization, commonly used in books in English on Chinese subjects Initial consonants do not go beyond the following list (where two approximations are given; the first one is easier to make and the second more accurate as to phonetic value). Thus, every word begins either with one of these consonants or consonant groups, or with an open vowel, and anything beginning with, say, sl-, *pr-* or shm- cannot be Chinese.

There are three high vowels, *ɿ* (police), u (rule) and *ü* (Ger. iiber); three mid-vowel qualities, e (yen), *ê* (up, lengthened) and o (horse); and one lou vowel, a (father). The high vowels also serve as semivowels in forming diphthongs and triphthongs, such as *ia,* ai, uei, except that *ü* never occurs as the ending of a syllable. Sometimes a word consists of an initial of the (1) ts, ts', *s* type or (2) the ch, *ch',* sh, *j* type, followed by a vocalization with the tip of the tongue remaining in the same position as the consonant. To remind one of the buzzing quality of the vowel of type (1), the whole syllable is rewritten, in the Wade-Giles system, as *tzŭ, tz'ŭ, ssŭ* (or *szŭ*), the breve sign indicating not so much brevity—the vowel being no shorter than any other vowel—as that it is not really the *u* but the *z* that gives the quality of the vowel. In type (2), ch, ch', sh, j, which already have an r-like quality, the prolongation is indicated by the digraph *-ih.* Thus, a word like *shih* is pronounced something like shr. These two vowels, *ŭ* and *ih,* have been described in some detail here because they occur with great frequency and because those who try to learn them usually make too much effort, whereas the essence of their quality is zero, and the method of producing zero consists in doing nothing.

Blodern Chinese is like Italian in having few consonantal endings. The only common ones are *-n* and *-ng*. The ending *-r,* though frequent in occurrence as suffix, is limited to a very few roots. When a word ends in *-m,* there is almost always an alternate form with *m* folloned by a vowel. Hence one can say that there is practically no final *-m* in Mandarin.

Tone. — As has been indicated above, Chinese has the element of tone as a word-forming constituent. The otherwise identical syllable *t'ang*[1], pronounced with a high level tone, is the word for "soup"; *t'ang*[2], with a tone rising from medium to high pitch, is the word for "sugar"; *t'ang*[3], with a low dipping circumflex tone, is the word for "lie down"; and *t'ang*[4], with a wide drop from high to low pitch, is the word for "hot." Tonal distinctions are sometimes, but not usually, correlated with grammatical or etymological distinctions. For example, *shu*[3] "to count": *shu*[4] "number"; chung[3] "seed". chung[4] "to plant"; ltang[2] "cool": *liang*[4] "to cool, to air." Such instances are of comparable frequency or rarity to that of similar uses of vowel modulation in English like get. got or tooth: teeth. By and large, words with the same consonants and vowels but different tones are quite as unrelated as are English pin. pen, pan, pun, or peat, beat, meat, feat.

Stress. — Stress accent in Mandarin plays an important part to the extent that a difference in stress often makes a grammatical or semantic difference. though not usually in etymological identity. Thus, *mai*[3] mai[4] is a phrase meaning "buy and/or sell," but *mai*[3].*mai*[4] (where the dot indicates a loss of stress and loss or weakening of tone on the following syllable) is a compound noun meaning "trade."

Again, both *ta*[4]-*i*[4] and *ta*[4].*i* are compounds, made up of ta[4] . "great," and *i*[4] "idea," but while the former means "main ideas." the latter means "careless." These cases can be compared with such pairs in English as con-

p as in bore or spore
p' as in pour
m as in me
f as in fine

t as in door or store
t' as in tore
n as in night
l as in let

k as in gore or score
k' as in core
h as in high or Ger. mache

ch(*i,ü*) as in jeep
ch'(*i,ü*) as in cheap
hs as in sheep or Ger. Eiche

ch(*ih,* or other vowels) as in dray or stray
ch'(*ih,* or other vowels) as in tray
sh as in shred
j as in between ray and French je

ts as in loads of
ts' as in tsetse fly or it's hot
s as in say

y as in yes
w as in wide

tract *v.* cóntract or a blàck bird *v.* a blbckbird.

GRAMMAR

It is a common belief that Chinese has little or no grammar. This is true insofar as grammar is taken in the narrow sense of having inflections of person, case, number, tense, voice and the like. But there is as much orderly organization of parts into wholes in Chinese as in any other language. There is, as will be shown, regular structure in word formation; there is functional significance in word order: adjective-noun, verb-object, subject-predicate; there is distinction of parts of speech: *t'ien*[1] "sky!' is a noun, *lai*[2] "come" is a verb, *hung*[2] "red" is an adjective (which in Chinese can also act as a predicate), *wo*[3] "I, me" is a pronoun. In other words, Chinese has grammar.

Another common belief is that Chinese is a monosyllabic language. There is, again, a sense in which this is true. Ninety-nine per cent of syllables in Chinese sentences consist of meaningful monosyllabic units, called *tzŭ*[4] in Chinese. This is the kind of thing that a mother teaches her child to say, that one learns to read and write in school, that one is charged for "so many of" in a telegram and on which one makes slips of the tongue. If one fails to get an answer to a question, one says "He didn't say a *tzŭ*[4]." This unit is, therefore, the exact social counterpart of the word in an English-speaking society, and it is with good idiomatic reason that occidental sinologists have translated *tzŭ*[4] as "word." or any of its other European equivalents. This tendency of making every *tzŭ*[4] mean something is so strong that even for the relatively few originally unanalyzable dissyllables, both the scholar and the popular etymologist have never ceased to try to put meanings into the separate parts.

But if one looks for those units in Chinese sentences and phrases which can be uttered independently and can be rearranged and combined with a great deal of flexibility in the way English words can, then these turn out to be not always monosyllables but quite often polysyllabic units. Examples of such units, which may be called syntactic words, are: *ch'ih*[1] "eat," *nien*[2]*-nien*[2] "yearly," "every year," hao[3]-k'an[4] "pretty," "good-looking."

Derivation. — Since Chinese has no inflection, syntactic words, apart from free monosyllables which are already words, are formed by derivation and compounding. Of the derivational processes. phonetic modification, such as *chien*[4] (from *kian*) "to see": *hsien*[4] (from g'ian) "to appear'! and *ch'ang*[2] (from *d'ian*g) "long": *chang*[1] (from *tian*g) "to extend," has never been active in historical times. Reduplication with various functions is a very active process: with distributive sense, *jên*[2]*-jên*[2] "everyman"; *ko*[4]*-ko'r*[4] "everyone"; to express liveliness, *t'ou*[1]*-t'our*[1] "stealthily"; to form certain nouns, *pa*[4]*.pa* "papa," *ma*[1]*.ma* "mamma," wa[2].wa "baby," *ch'ü*[1]*.ch'üêr* "the cricket."

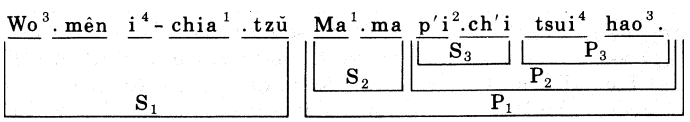
Affixes. — Prefixes and infixes are rare, but suffixes, though few in variety, are extremely frequent in occurrence. The diminutive suffixes *-tzŭ* and *-r* (the last not forming a separate syllable) are attached to a great many roots to form nouns. Verbs often take aspect suffixes: *-lê,* perfective, *-chih,* durative, and, if reduplication may be regarded as an affix, the second k'an may be regarded as a "tentative" suffix in k'an[4].k'an "just look." The single most important suffix in Chinese is the subordinate suffix *-tê* (with a reading pronunciation of ti[4]), which makes the word to which it is attached a modifier of what follows. For example, *chin*[1]*.tê ch'ien*[2] "gold kind of coin"—"gold coin"; *ch'ang*[2]*.tê hsien*[4] "long kind of thread[H]—"long thread"; *ni*[3]*.tê* pao[4] "your newspaper"; fei[S] *ch'ang*[2]*.tê ch'i*[4] "un-usual-ly angry."

There is a small but important class of suffixes which, though closely joined to whatever happens to precede them, do not belong to the word immediately preceding but to the whole phrase or sentence. These are called particles or final particles. For example, Ni[3] *pu*[4] *nêng*[2] *chiu*[4] *tsou*[3] *.eh!* "You can't just leave!" where the untranslated atonic *eh* expresses the mood or attitude of the speaker toward the listener, with the force of "you see?" or "don't you know?" Some particles overlap in form and function those of suffixes for single words. For example, *Chê*[4] *hua'r*[1] *tei*[3] *ch'ang*[2] *chiao*[1] *shui*[3] *tê* "This flower must often be watered," where the subordinate particle *tê* indicates that this is the kind of situation. Used with parts of sentences, this particle has the function of "who," "which," "of" or "'s." *Na*[4] *san*[3] shih[4] *kên*[1] *wo*[3] t'ung[2] *tsou*[3]*.tê* hsiao[2] chieh *tê* "That umbrella is with me together go's lady's." Compare the American "That umbrella is the young lady I go with's." (H. L. Mencken, The American Language, 4th ed., p 461, New York, Alfred Knopf, Inc., 1936). The only difference here is that while the English is something of a curiosity. it is the typical construction in Chinese.

Compounding. — The most important process in Chinese word formation is compounding. A compound may consist of parts in various grammatical relationships. It may consist of subject and predicate. For example, from the sentence *Hsin*[1] *t'êng*[2] "The heart aches," one can form a compound transitive verb *hsin*[1]*.t'êng*[2] "to have a heartache for[v]—"to be solicitous for" as in Shei[2] *pu*[4] *hsin*[1]*.t'êng*[2] *tzŭ*[4]*-chi*[3] .tB *êrh*[2]*.tzŭ?* "Who is not solicitous for his own child?" A compound may have parts in coordinate construction, with parts meaning similar or opposite things, as *ch'ing*[1]*.ch'u* "transparent-distinct"—"clear"; *hêng*[2]*-.shih*<*hêng*[2]*-shu*[4] "horizontal vertical[c]—"anyuay"; lai[2]-wang[3] "come-go"—'(checking (account)." The first part may be subordinated to the second, as wu[4]-li[3] "things-principles"—physics"; "*hsin*[1]*-li*[3] "mind-principles[n]—"psychology"; *nan*[2]*.jên* "male person"—"man"; *nü*[3]*.jên* "female person[x]—"woman." There is one class of subordinate compounds which deserves special mention because of its great productivity. They are formed by putting words of location, or localizers, after a noun. Thus, *t'ien*[1]*-hsia*[4] "heaven('s) below[n]—"the world"; *hai*[3]*-shang*[4] "sea('s) above[n]—"on the sea"; *ch'êng*[2]*-li*[3] "city('s) inside[n]—"downtown"; *ch'êng*[2]*-.li* "city('s) in '—"in the city." Because these localizers usually translate into English prepositions, they are sometimes called postpositions. It should be remembered. houever, that these compounds are substantive words and not adverbs, as English prepositional phrases are apt to be.

The practical significance of the syntactic word as a unit can be seen from the fact that while anybody can put words together by following the relatively simple rules of syntax and the result will be at least grammatical, the formation of new derived and compounded words from *tzŭ*[4], apart from the few very productive types already noted, cannot be trusted to the hands of any but highly literate persons. Otherwise the result would be felt as solecisms and described as being *shêng*[1]*-ying*[4] "raw and stiff."

Syntactical Division. — The main syntactical division in a Chinese sentence is between subject and predicate. The connection betneen them is, both formally and semantically. much looser than between similar parts in an English sentence The subject is literally the subject matter and the predicate is any comment one makes about the subject. For example, *Chê*[4] *ti*[4] fang k'0[3] *i*[3] *t'iao*[4]*-wu*[3] "This place can dance[H]—"as for this place, one can dance[n]—"one can dance here." A very interesting corollary of this is that after announcing a subject (often with a pause, or pause particle a, ne or me) one often starts again uith a more specific part of the general subject matter as a second subject, so that the latter, together with its predicate. forms a clause-predicate to the first (main) subject, and this may go on after the manner of box within box of a Chinese puzzle. For example:



"We the whole family (S_1), Mamma (S_2), the temperament (S_3) is most good (P_3)"—"Mamma is the most good-natured member of our family." Now the addition of "the" in the above translation is not done gratuitously, merely to make the English smoother, because it actuallv translates an element of the Chinese sentence. namely, position in the sentence. In general, an initial or an early position in a sentence tends to imply definite reference, whereas a late position, especially after a verb. tends to imply indefinite reference. Thus. K'0[4] *lai*[2]*.lê* "The guest (nhom I expected or invited) has come," as against Lai[2] *k'o*[4]*.lê* "There has come a guest (whom I have not expected)."

Within the subject or the predicate, if it consists of more than one syntactic word: there may be various other syntactic constructions. Co-ordinate constructions are usually formed by mentioning item after item without any conjunction (with or without pause). For example, *Ni*^{3} *ch'ih*^{1} fan^{4} *ch'ih*^{1} mien^{4}? "You eat rice or noodles?" Fan^{4}, mien^{4} *wo*^{3} *tou*^{1} *hsi*^{3}*.huan* "Rice and noodles I both like." Subordinate constructions are formed in the order of modifier-modified, even though the modifier may be a clause, as has been seen in connection with the particle ti. If a modifier apparently follows, as in *T'a*^{1} *tsou*^{3}*.tê man*^{4} "He walks slowly," the "wrong" word order is in the English translation! since the original sentence is of the construction "He walks 's (manner) is slow." so that man^{4} is not an attributive adverb (as all Chinese adverbs are) but a predicative adjective. Verb and object always occur in that order. Verb-complement constructions are bordering on compounding, especially when they take infixes *-tê-* and *-pu-* to form potential forms, as *nien*^{4}*.tê-wan*^{2} "can finishing reading." nien^{4}.pu-wan^{2} "cannot finish reading"; *sao*^{3}*.tê-ch'ing*^{1} "can sweep clear," *sao*^{3}*.pu-ch'ing*^{1} "cannot sweep clear."

Congruence. — While Chinese syntax has no congruence of number, tense, etc., there is one kind of congruence which is not unlike that of gender. Each noun. according to its nature, usually the shape of the object named, has a specific classifier, which is compounded with the numeral or demonstrative to be used with the noun. A good dictionary will indicate the appropriate classifier under each noun, much as the gender of nouns is indicated for languages with genders. Thus, when a dictionary gives: *ho*^{2} river (t'iao^{2}), it means that one has to say i^{4}-t'iao *ho*^{2} for "a (strip of a) river," and *nei*^{4}*-t'iao* ho^{2} "that (strip of a) river." There are about 100 commonly used classifiers, including the general individualizing classifier *ko*^{4} or *.ko,* which can be used for most nouns for individual things or persons which also have their specific classifiers.

Negation. — Negation is expressed by putting the adverb *pu*^{4} (second tone before another fourth tone) before the word modified, as *pu*^{4} *nêng*^{2} *shuo*^{1} "cannot say"; *nêng*^{2} *pu*^{4} *shuo*^{1} "can not-say"—"can keep silent"; *pu*^{4} *nêng pu*^{4} *shuo*^{1} "cannot but say." The only verb (also used as an auxiliary verb) which takes a different negative adverb, mei^{2}, is yu^{3} "have," as in *mei*^{2}*.yu*^{3} *ch'ien*^{2} "have not money"; *mei*^{2}*.yu*^{3} *lai*^{2} "have (or did) not come."

Questions. — A question is asked by (1) adding an interrogative particle or a special intonation at the end of the statement, as *Shui*^{3} *shên*^{1}*.ma* (or *.pa,* or .a)? "Water deep, huh?"—"Is the water deep?" (2) giving the alternatives to choose from, as *Mi*^{3} kuei^{4} (no pause) *.pu.kuei*^{4} "Rice expensive (or) not expensive?"—"Is the rice expensive?" (3) substituting an interrogative word (what, where, when, why, etc.) in the sentence where the word in the answer will be, as *Ni*^{3} *chiao*^{4} *shei*^{2} "You call whom?"—"Whom are you calling?" *Chiêr*^{1} *hsing*^{1}*-ch'i*^{1}*-chi*^{3} "Today week-how many?"—"What day of the week is today?" (answer *Chiêr hsing*^{1}*-ch'i*^{1}*-liu*^{4} "Today week-six"; *i.e.,* "Saturday"). The rule of word order for such questions is: Ask as you would be answered.

HISTORY AND DIALECTS

Old Chinese. — Old Chinese had a much richer system of sounds than modern Mandarin. In the period which occidental sinologists have called Xrchaic Chinese, covering the five or six centuries B.C. when the great classics were composed. there were as many as four grades of initial consonants: *p, p',* b, *b'; t,* t', *d, d'; k,* k', g, g'—comparable with *p, ph,* b, biz, etc. in Sanskrit. as against the two grades p, p', etc.. in Mandarin. There was also a richer variety of initial consonant clusters. such as kl-, gl-, *pl-,* bl-. For endings there were *-m, -n; -ng,* -r, *-p, -b* (rare), *-t,* -d, *-k* and -g. During this period there were probably three tones.

By the beginning of the 7th century. the language had lost the pure voiced stops b, d and g in both initial and final positions. These had become semivowels *i̯* or *w,* resulting in a poorer system of consonants but a richer system of diphthongs and triphthongs; for example *di̯ad* in Xrchaic Chinese became *i̯äi* in Ancient Chinese, as the language of this period is called by occidental sinologists. The loss of final -d, *-g* and *-b* resulted in. or contributed to, the rise of a new tone class, thus making the full list of the four tones of Ancient Chinese.

Because of the availability of a rich store of source material, it is possible to have a detailed knowledge of Chinese as it was spoken in the 6th or 7th century and to trace the changes from ancient to modern forms. Ancient voiced stops and sibilants have become voiceless. Voiced stops (including affricates: *dz', dź',* etc'.) have become modern aspirated: d'ien to *t'ien*^{2} "field!' if in the even tone. unaspirated if in the other tones: d'ien to tien^{4} "lightning." Ancient palatals become modern retroflexes (cacuminals): *śiän* to *shan*^{4} "fan." Ancient bilabials become modern dentilabials under certain conditions: *pi̯ung* to *fung*^{1} to *fêng*^{1} "wind." Ancient final *-m* becomes modern final -n, thus coalescing with original -n. Ancient final -p, *-t* and *-k* have been dropped. There has so far been no way to reconstruct the exact pitch values of the ancient tones; but one can easily trace the correspondence between the tone classes and their modern correlates. Ancient first tone has become modern first or second tone according as the initial was voiceless or voiced, Ancient second is mostly modem third. Ancient third is modern fourth. Ancient fourth, with its endings *-p,* -t, *-k* dropped. becomes modern 1, 2, 3 or 4.

The Dialects. — The preceding account of the development from ancient to modern Chinese is true, in its main features, of about three-fourths of the area and two-thirds of the population of China. For a country of this size and such antiquity this is remarkable uniformity. From K'un-ming, Yünnan, to Harbin, from Urumchi, Sinkiang, to Nanking. one slightly educated person can talk with another with no more difficulty than people from New York and New Orleans do, although a "slightly educated" Chinese is probably more sophisticated linguistically than a "slightly educated" American. This is the area of Mandarin, in the wide sense. with the pronunciation of Peking as the standard. Though this group is usually divided into Northern Mandarin, Southwestern Mandarin (with Chungking as centre) and Southern Mandarin (with Nanking as centre)! the differences in pronunciation and vocabulary among these is less than between all of Mandarin and any of the other dialects.

The greatest variation in dialects is found in the provinces of the southeast. With Soochow as the cultural and Shanghai as the commercial centre, the Wu dialects are spoken in southeastern Kiangsu and most of Chekiang province. They have kept the ancient three-grade consonant system p, p', b', etc.. and have seven or eight tones, having split each of the ancient tones into two according to voicing of initials. The Min group. marked by preservation of archaic dentals and absence of dentilabials, is split into a northern Foochow type and a southern Amoy type, the latter being spoken in Xmoy, Taiwan, Swatow and by the majority of the Chinese living in the South seas. The Kam-Hakka group is spoken in Kiangsi province and northeastern Kwangtung, with the special feature of aspirating ancient voiced stops for all tones, whereas the Hsiang (Hunan) dialects unaspirate (and sometimes voice) all ancient voiced stops. Finally, the Yiieh (Cantonese) group has kept most of the final consonants -m, -n, *-ng, -p,* -t, *-k* of ancient Chinese. Its speakers live in Kwangtung, part of Kwangsi, and form good-sized speech communities in the South seas and the United States. Dialects differ mainly in pronunciation, secondarily in vocabulary—affecting mostly the high-frequency part of everyday vocabulary—and hardly at all in grammar, if differences in particles are counted as vocabulary.

The Literary Language. — The literary language, or *wênyen,* occupies a more important position in Chinese than the literary language in other countries because (1) it is a common idiom for all dialects; (2) it is based on a common body of literature read everywhere; and (3) it is written in a system of writing which is the same without regard to dialect. It should be understood. however., that *wênyen* is not merely a system of writing, nor the language of ancient books regarded as a concluded corpus of texts. Even from the mouth of an illiterate storyteller, one hears phrases and sentences in *wênyen.* Blind fortunetellers are literally conversant with the literary idiom, which differs widely in vocabulary and to some extent in grammar from everyday speech. It is not a closed-book language, because one learns to

compose in *wênyen* after the model of writers anywhere from the 6th century B.C. to the 20th of this era. While there are, of course, great differences of style from age to age, it is still in *wênyen* that government papers, legal documents, business letters, news dispatches and advertisements are being written in the second half of the 1900s. The Chinese do not learn *wênyen* by visual reading only. but usually by reading aloud; they often compose aloud and even hum the melodic swing of phrases and sentences. Thus it is a living language to many intents and purposes.

A common confusion has been to take *wênyen* to be the same thing as Mandarin. While Mandarin is primarily a type of everyday speech, with a definite system of pronunciation, and is confined to only a part, even though the greater part, of the country, *wênyen* has no single standard of pronunciation, is never used in conversational speech and is not limited in geographical distribution. Nor is *wênyen* the language of Ancient or Archaic Chinese. The Chinese student does not read the Analects of Confucius or the poems of Li Po as an English student tries to read *Beowulf* or Chaucer, but gives the words the frankly modem pronunciation of whatever happens to be his dialect. If a Cantonese reader finds pleasure in Li Po's perfect rhymes. well and good. If a northerner finds Li Po's tones all mixed up, he blames himself for the loss of ancient pronunciation. but would not dream of trying to recover it. He feels that he is truly reading Confucius or Li Po although all the sounds that he utters are really 20th-century Mandarin.

What. then, is it that makes *wênyen* one, if it is neither the language as pronunciation nor the modern dialect of any locality? It lies in the unity of vocabulary and grammar, maintained in history through the unity of the system of writing and its literature and its continued use in modern life. Because *wênyen* was based largely on an older form of the language. with its much greater variety of syllabic types (one dictionary of Ancient Chinese had 3,877 different syllables, as against 1,300 of modern Mandarin), it mas much more nearly monosyllabic in the syntactic sense than most modern dialects. It is significant that Cantonese, with its richer store of 1,800 syllables! uses fewer polysyllabic syntactic words than Mandarin.

SYSTEM OF WRITING

The monosyllabicity of most of the meaningful units of the Chinese language, the *tzŭ*, makes it natural to write *tzŭ* with unit symbols. In high antiquity. in the Shang dynasty (1766?–1123? B.C.) bone and shell oracles. some of the characters were direct representations of things or ideas. But even in those times. most of the characters were already symbols of particular words in the language and not of some different, though synonymous. words. Chinese characters are therefore not strictly ideographs. *i.e.*, symbols of ideas, but logographs, *i.e.*, symbols of words.

Characters.—Traditionally, the Chinese have classified the characters into six categories: (1) pictographs, as 弓 *kung*[1] "a bow," 爪 chao[3] or *chua*[3] "claw," 雨 *yü*[3] "rain," 口 *t'ien*[2] "field"; (2) simple ideographs, as 二 *êrh*[4] '(two" (different from 兩 *liang*[3], which means the same thing but is a different word and has a somewhat different grammatical function), 上 shang[4] "up," 下 hsia[4] "down"; (3) compound ideographs, as 卡 ch'ia[3] "caught in the middle," 止 *chih*[3] "to stop" and 戈 *ko*[1] "arms," together forming 武 *wu*[3] '(military" (*cf.* "war to end all wars"), 不 *pu*[4] "not" and 正 *chêng*[4] "upright" to form 歪 *wai*[1] "crooked," ('awry"; (4) phonetic loans, that is, borrowing the use of a homophonous word for writing something that cannot be pictured or indicated graphically, 來 lai[2] "come" from a homophonous word for a kind of wheat which the character depicts, 其 *ch'i*[2] "his," "her," "its," "their," borrowed from a word for "dustpan" of which the character is a picture; (5) phonetic compounds, consisting of a phonetic, giving the sound, and a signific, giving the meaning, 肌 *chi*[1] "muscle" from 月 *j(o)u*[4] "flesh" as the signific and 几 chi[1] as the phonetic (the meaning "small table" being irrelevant); (6) derivative characters, a very small class about which scholars disagree even as to its membership.

If one leafs through a Chinese dictionary, which is usually arranged by a set of 214 recurring constituents called "radicals." one gets the impression that the vast majority of characters are phonetic compounds, in which the radicals serve as significs. But if one examines closely what look like phonetics, one will find that in the majority of cases they are not simply phonetics, but something more. Take the character 裘 ch'iu[2] "fur (for a coat)," apparently made up of radical 145 衣 i[1] "clothing" and 求 *ch'iu*[2] "beseech," used merely as a phonetic. As a matter of fact, the graph 求 was originally a pictograph of the word for "fur," and then used as a loan character for a homophonous word *ch'iu*[2] "beseech." In order to avoid ambiguity, an additional signific 衣 *i*[1] "clothing" was added to form 裘 for the original word for "fur," leaving the simple pictograph for the abstract word for "beseech." Again, 評 *p'ing*[2] "discuss," "criticize" apparently has radical 149 言 *yen*[2] "to speak" for signific and 平 *p'ing*[2] "level" for phonetic. Actually, the main word is 平 *p'ing*[2] "level," with various extensions of meaning: '(level," "equal," "fair,': so that "to speak fairly" is "to discuss," "to criticize"; with 土 '(earth," "ground" one forms 坪 *p'ing*[2] "plateau," "level ground," "village"; with 艹 "grass" and 氵 "water" one gets 萍 *p'ing*[2] "duckweed," which has level leaves floating on water. All these p'ing[2]'s are therefore really one linguistic word, written differently according to various extensions of meaning. It is as if in English one wrote "slip" for the root meaning, "pslip" for a narrow piece of paper, "dslip" for what is worn under a dress, "lslip" for an accidental error in speech, etc., all pronounced "slip."

As a consequence of this luxury of differentiation, there have developed many more characters than there are words, even if homophones are counted as different words. In the K'anghsi dictionary of 1716, which is still much consulted, there are 40,545 characters. After eliminating obsolete forms and graphic variants, the telegraphic code book—Chinese characters are telegraphed in four figures to the character—still has nearly 10,000 characters, with many differentiations from semantic extensions.

History.—The structure of Chinese writing has changed less since antiquity than the sounds of the language. The most ancient forms of writing are those found on the shells and bones of Shang; then followed the Chou (1122?–256 B.C.) inscriptions on bronzes and stones. In the Ch'in dynasty (221–207 B.C.), under the First Emperor. writing was standardized in what are known as the small-seal characters, still used on seals. Since then, the forms of characters have changed mainly in the style of strokes. and there has

been no basic change in structure. The most commonly used form is the *k'ai*[3] or model form, in which most books are printed. The running hand and cursive hand are used only for personal notes and calligraphic purposes. The preceding diagram gives examples of the chief kinds of characters.

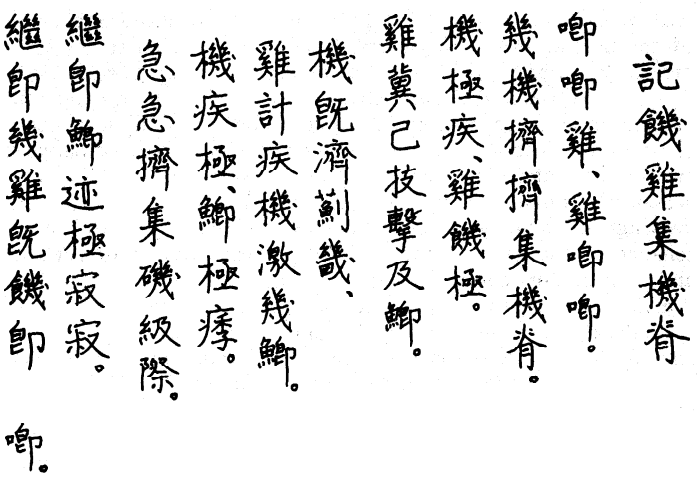
LANGUAGE AND WRITING REFORMS

Language and writing, like other phases of human culture, have always been in the process of being reformed, sometimes more consciously than at other times. The building up of the system of seal characters under the First Emperor, though it was far from being done in a day or by one person Li Ssŭ, was one of those planned reforms. The compilation of the *Ch'ieh yün* of AD. 601, though it was only a semiofficial undertaking, was an organized attempt on the part of a group of specialists, and the resulting dictionary had a greater unifying effect on the language than any other book, insofar as mere books have any influence on the spoken language. During the 20th century there have been three major conscious movements for reform in the Chinese language and system of writing: (1) the vernacular literature movement; (2) the unification of the national language; and (3) reforms in the system of writing.

The Vernacular Literature Movement.—The literary revolution is a movement for writing in the spoken language. While there is some difference in diction and style between speech and writing in all languages of all ages, there was probably not so wide a gap between them in the Chinese of early classical times as there is in modem Chinese. By the time of the T'ang dynasty (618–906), as seen from verbatim records of lectures on Buddhism, there was already a distinct cleavage between the colloquial and the literary language. Writing in the colloquial was, however, extremely rare. Apart from a few novels, plays, and some religious and philosophical writings, everything was written in *wênyen.* It was not until 1917, when Hu Shih started the movement for writing in the vernacular or *paihua* "plain talk," that writing as one speaks became respectable and acceptable. Hitherto, one had to write in a literary idiom different from the speech of any locality, as described above. Now one can write as one speaks, at least for two-thirds of the people, who already speak some form of Mandarin. The rest of the country, Shanghai, Canton, Amoy, etc., will have to learn the Mandarin idiom, which, though different from *wdnyen* and from their own vernacular, is much easier to learn than *wdnyen.* In less than half a century the *paihua* movement has proved to be one of the most definitive changes in the cultural life of China.

The Unification of the National Language.— The unification of the national language, like the use of the vernacular for writing, already had good working capital to start with in the fact that Mandarin was already very widely understood. Formerly called variously *kuan*[1]*-hua*[4] "official speech," whence the term "Mandarin," or *p'u*[3]*-t'ung*[1]*-hua*[4] "general (*v.* local) speech," the movement was officially designated as unification of *kuo*[2]*-yü* "national language," when the program was launched in the 1910s. As aids to the unification of pronunciation, a system of national phonetic letters (1919), consisting of 21 initials and 16 finals, and a system of national romanization (1927) were promulgated. The Communist regime has made some use of the national phonetics and has recently devised forms of romanization or latinization for the same purpose *(see* CHINA: *The People: Language Reforms).*

Writing Reform.— The problem of writing reform is immediately bound up with the preceding problems. *Wênyen* being always pronounced in some modern pronunciation, with many of the ancient distinctions lost, it is not always intelligible to the ear, and *wênyen* written in a modern alphabetic form of writing will not always be intelligible to the eye. A story like the following is in quite idiomatic *wênyen,* so far as the characters go, but when pronounced, the story consists of nothing but a series of repetitions of the syllable *chi* in the four tones. On the other hand. in ancient Chinese, the title of the story *ki kiə kiei dz'iəp kiəi tsiäk,* or, in modern *paihua, chi*[4]*.1u ê*[4]*.tê chi*[1] *chü*[4]*.tsai fei*[1]*-chi*[1]*.tê pei*[4]*.shang* is phonetically quite clear and unambiguous.



Reminiscences of Famished Chickens Assembled on the Ridge of a (Flying) Machine

Chick, chick, chickens! Chickens, chick, chick!
Several chickens squeezed and assembled on the machine's ridge.
The machine was extremely swift; the chickens extremely famished.
The chickens surmised their skill was sufficient to strike some perch.
The machine having crossed the suburbs of Chi,
The chickens reckoned the swift machine should stir up several perch.
The machine was swift; the perch were extremely scared.
Hastily they squeezed and assembled in the interstices of stone steps.
Subsequently the perch's traces were extremely silent, silent.
Subsequently the chickens, since still famished, said chick, chick!

Unless one should revert to an ancient orthography, as has indeed been actually worked out and proposed by some European missionaries in China, an alphabetic system of writing must be based on the *paihua* and not on *wênyen.* Moreover, if one writes as one speaks, then, even within the vast region of the Mandarin provinces, uhich have substantially the same vocabulary, the variation in pronunciation will be great enough to make the same word look quite different, and in the case of Cantonese or Wu the difference will look as great as that between French and Italian or between English and Dutch, thus creating what would look like different languages.

In order. therefore, to make alphabetic writing intelligible to the eye, one will have to write what is auditorily intelligible to the ear, namely, *paihua.* In order to preserve the unity of the language, which has so far been supported by the universality of the characters. this *paihua* must be the *paihua* of standard Mandarin and not the *paihua* of any of the other dialects or even subvarieties of Mandarin. Since, however, unification of pronunciation is only in process of succeeding and has not yet succeeded, the country is not ready for the immediate adoption of an alphabetic writing. In the early 1960s the simplification of the characters was the order of the day. It is significant that the official position of the Communists during the 1950s was exactly that of the Nationalists during the 1930s, namely, to take the national phonetics or the Latin alphabet as aids to (1) the unification of standard pronunciation and (2) the learning of the characters. At the same time. Chinese linguists and educators, in private or semiofficial capacities, have never ceased working toward a system and a program for an alphabetic form of Chinese writing that might become a reality in the reasonably near future.

(Y. R. C.)

CHINESE LAW. Ancient Chinese law had the same influence in eastern Asia as Roman law in western Europe. The first written laws were inscribed on bronze tripods during the second

half of the 6th century B.C. By recording the duties and rights of the people in a lasting form, legislators intended to limit the arbitrary power of princes and feudal lords. Confucius (*q.v.;* 551–479 B.C.) considered these "tables of the law" to be a dangerous change undermining the social order. Thereafter, discord about the character and the very necessity of laws never ceased between two fundamentally different vie\\-points. According to the legalist school of thought a universal, uniform and absolute law *(fa),* unvarying and binding on everybody, was essential for the maintenance of the social order. and only a legal system of rewards and punishments could guarantee the authority of the ruler. The dream of the legalists was realized when the Ch'in dynasty succeeded (221 B.C.) in unifying the Chinese empire under a strong and absolutist state power based on harsh administrative and penal measures. which they considered to be the most efficient deterrent to crime. Against this public law and method of intimidation. Confucianists upheld the norms of proper behaviour *(li),* a kind of particularist and traditional customary law regulating by minute prescriptions not only rites and ceremonial but the whole of social intercourse. If these venerated rules: differentiated according to the social positions of high and low, are carefully respected. there is no need for laws because no crime is committed. *(See* also CONFUCIANISM.)

The struggle between these two theories ended in a compromise. The first known laws. the code of the Han dynasty (2nd century B.c.), had been compiled by legalists. However, the Confucianists. who had accepted law in the meantime as an instrument of state power. maintained that the prescriptions of the moral code were sufficient for the discipline of the upper class, and succeeded during the middle ages in mitigating the rigour of the laws, bringing them into harmony with the *li.* The combination of these two disparate elements resulted in a legal system characterized by principles that were unchanging and rigid (a draconian penal code. collective responsibility of the social group, inequality before the law in favour of the privileged nobility and officials). but which were applied by a flexible and supple procedure that took into account the .special circumstances of every case. Each dynasty had its own code and a huge corpus of ordinances, administrative laws and regulations. The most famous is the still extant T'ang code (A.D. 653), the model of all subsequent Chinese codifications down to the Manchu dynasty (1644–1912) and imitated equally in Korea, Japan and Annam. All codes were arranged in the same way. The general principles at the beginning contained the list of penalties (death, banishment, hard labour, bastinado) and their degrees, the tables of relationship, of awful crimes and of privileged persons. Any offense against the laws, enumerated under different headings, could easily be fitted to the corresponding punishment, the legal sanction being diminished or aggravated by the status of the offender, with each paragraph referring to the tables of relationship. This system enabled the local or provincial magistrate, who had no special juridical training, to judge quickly the lawsuit brought before him. The higher level of judicial administration (ministry of justice, censorate and supreme court of justice) likewise lacked separation of powers. There was no place for lawyers and advocates.

This legal system, lacking precise rulings on civil and commercial law, not to speak of international law (all countries being considered as subject and tributary to China), could not continue beyond the 19th century. Under aestern impact more and more critics demanded a thorough reform Bastinado and penal sanctions for civil-law offenses were abolished and a special committee worked out proposals for new laws based on German and modern Japanese models (1902–10). Nevertheless, these mere only a modernized version of the *Ta-Ch'ing lü-li,* the code of the Manchu dynasty nhich remained in force until 1931. In that year the nationalist Kuomintang government set up a legislative court in order to work out a provisory constitution and a civil code on western lines, but the great output of legal texts was of no practical use in circumstances of civil war and foreign invasion. The People's Republic of China established in 1949. deliberately abandoned the western legal system and began immediately to promulgate a new set of laws accompanied by a far-reaching reform of judicial administration. So far the main legislative acts are the agrarian law (legalizing agrarian reform) and the marriage law (enforcing the equality of the sexes and monogamy), both promulgated in 1950. and the constitution of 1954. Judicial authority is formally set apart at all levels and exercised by the supreme people's court and procuratorate as well as by local and special people's courts and procuratorates. New laws and decrees adopted by the national people's congress are published in official papers and periodically collected in special volumes. *See* CHINA: *History; Administration and Social Conditions.*

CHINESE LITERATURE is not the oldest in the world, but it has the longest history of any written in a single language, continuously producing works of historical, intellectual and artistic interest for more than *2,500* years. The people's speech varied in different areas and changed with time,-but because of the nature of their writing *(see* CHINESE LANGUAGE) and the early standardization of orthography, educated persons could read the national literature no matter where or m-hen it was written.

Writing in the living language was a late development. and although masterpieces appeared in it, for a thousand years they remained outside the four standard Chinese categories of literature. These m-ere:

The Classics.—These refer not to great writings throughout Chinese history but to the heterogeneous scriptures (*ching*) making up the canon of the Confucian school of thought. They derive their status from association (in part actual, in part contrived much later) with Confucius himself (j *jo* or j51–479 B.C.). It is certain that he used some form of the *Shu Ching (Classic of Documents)* and *Shih Ching (Classic of Songs)* in his teachings. less certain that he set great store by the I *Ching (Classic of Divination). He* probably compiled the *Ch'un Ch'iu (Springs and Autumns),* a bare chronicle of his native state of Lu which, accompanied by three early commentaries, accounts for three among the classics. The *Tso Chuan* probably was not a commentary in origin, being largely narrative; its literary interest is considerable.

The remarks of Confucius and some of his students are preserved in elliptical style in the *Lun Yü (Analects).* His later admirer Mencius was similarly immortalized in the more fluent book *Meng Tzu,* which likewise eventually became a classic. Since the 12th century these two texts have been associated with the *Ta Hsüeh (Great Leavning)* and *Chung Yung (Happy Mean)* in a group constituting the four books emphasized by the neo-Confucians *(see* below. *Philosophical Works).* The latter two are really chapters extracted from the *Li Chi,* one of three classic collections of public and private ritual compiled toward the time of Christ. as was the *Erh Ya.*

This is a kind of lexicon. perhaps deriving its canonical status from a Chinese concept of the nature and power of the word—spoken or written—almost as mystical as the Christian concept of the Logos. Last but not least influential of the 13 classics is the spurious *Hsiao Ching (Classic of Filial Piety).* All are accompanied by numerous, sometimes divergent commentaries and sdbcommentaries.

Forming the core of education for government sen-ice (the primary aim of all education in prerepublican China). the classics permeated Chinese life. Their historical and philological importance is great, but except for the *Songs (see* below. *Poetvy)* their intrinsic literary interest is far outweighed by their influence on later writings. which are often incomprehensible without recognition of their allusions to the classics. Chinese literary theory related all subsequently acknowledged literary forms to one or another of the classics. *(See* also CHINESE CLASSICS.)

Historical Writings, Including Biographies, Travelogues, Geographies, **etc.**—Historiography derives from the *Classic of Documents* through the *Springs and Autumns* chronicle. The so-called commentary *Tso Chuan* and other works of its period undoubtedly contain some genuine historical data. The first general history of China was the *Shih Chi (Records of the Historian)* of

Ssu-ma Ch'ien (145/135–*c.* 90 B.C.), who to some extent rationalized legend and proceeded with increasing historicity down to his own Han times. The monumental work was substantially a selection of extant texts, to which the compiler appended his own judgments. His method set the pattern for most subsequent histories, which were divided into (1) annals of imperial reigns; (2) tables of government organization, etc.; (3) treatises on such subjects as the calendar, economy and geography; and (4) biographies. Pan Ku (A.D. 32–92) intended his History *of* the *Han* Dynasty as a continuation of the Records of the Historian. Each later dynasty officially sponsored such a continuation for its predecessor, usually compiled by a committee from the records of the fallen dynasty (*e.g.*, the "Veritable Records" of each emperor's reign). These and Ssu-ma Ch'ien's pioneer work make up the 25 standard histories.

The Draft History of the *Ch'ing* Dynasty, completed in 1928, never received official status. but it remains an indispensable source for the period it covers. The others are of similar value, though none deals in detail with events not connected with the court or government. The same applies generally to the independently written histories; *e.g.*, the celebrated *Tzu* Chih *T'ung Chien* (*Comprehensive* Mirror for *Aid* in *Governing*), a general history by Ssu-ma Kuang (1019–86), of which a later abridgment and various continuations formed the basis of the first European history of China. Aside from formal histories, innumerable other texts—biographical, geographical, technological, miscellaneous—can be used with critical care to fill in the background. Modern Chinese historians have produced many books and studies on currently accepted principles, including those of Marxism.

Philosophical Works other than those considered classics are catalogued together with all sorts of polemical and theoretical treatises and include some works of a religious nature but little on Buddhism, which had its own extensive canon outside the four classifications.

Early attempts to persuade men to courses of action (or inaction), by composition in a written language long based on symbols for concrete ideas and relatively simple extensions of them, were important in developing that language into a flexible medium for expository prose.

Persuasion rather than mere conviction was the aim; philosophy in China has been concerned mostly uith principles for the guidance of human behaviour rather than with metaphysics or systems of logic. Hence it was usually political or antipolitical. Confucius' time was one of disunion and social breakdown; he preached return to a traditional age of sage kings who were in harmony with the Way of Heaven and governed by example. There were now many rival kingdoms, but Confucius maintained that a true king would receive the voluntary submission of all. A subject could at least become a gentleman (the Chinese term meant a prince's son, but the sage gave it a moral sense) with such virtues as humanity, justice and reciprocal fidelity between parents and children, superiors and inferiors.

Confucius emphasized, as manifestations of these qualities and as disciplines in preserving them, strict observance of time-honoured public and private rituals and manners. These ideas can be pieced together from the laconic Analects; they were developed, nith certain divergencies, by similarly oriented teachers such as Mencius and Hsiin-tzu.

To some other thinkers, the existence of political structures, rules of conduct and reverence for the past meant only that men had deviated from the Way (*Tao*), which could only be followed intuitively and could never be embodied in records or words. Yet these mystical Taoists wrote numerous books themselves. The Tao Te *Ching* (Scripture of the Way *and Its* Power) is one of the most frequently and divergently translated Chinese texts. Its alleged author, Lao-tzu (Lao-tse), was supposed to have lived in the time of Confucius, but at least parts of it are later than some of the Teachings of Chuang-tzu. The latter contains passages of brilliant style and wit. Unlike many later Taoist writings, with their esoteric recipes for direct immortality, it more than once counsels accepting death with equanimity.

Few of these early writings were by a single hand, hence they are not always consistent. Taoism and Confucianism, often in conflict, were not mutually exclusive. Many writers classified under one school show elements of the other. Mo Ti stood apart from either in preaching universal love, a beneficent deity, and interceding spirits, while opposing useless ceremony. The legalists put no faith in good intention or example and called for explicit, rigorous law under absolute totalitarianism. Their program achieved the first unification of China, but the Ch'in dynasty (221–207 B.C.) was short-lived, and Confucianism became orthodox under the succeeding Han.

Scholar-administrators fostered acceprance of a textual canon which would be of higher authority than that of changing rulers, and of which they themselves would be the recognized interpreters. Thereafter Confucianism developed mostly through commentary on fixed texts.

Occasional independent philosophers appeared (*e.g.*, the skeptic Wang Ch'ung and the youthful metaphysician Wang Pi). Taoism in one direction degenerated into magic and became a popular religion, which soon had the powerful competition of imported Buddhism. Confucianism, with its noncommittal position on the supernatural and its emphasis on obligations, remained the official standard, but even emperors often favoured one or the other of its competitors.

Eventually the traditionalist philosophy vitiated its rivals by borrowing from them. Neo-Confucianism, as articulated by Chu Hsi (1130–1200) in a feat of syncretism comparable to that of St. Thomas Aquinas, remained grounded on the classics but invested them with an eclectic metaphysic and cosmology. Its conservative ethic dominated Chinese mores, as Chu Hsi dominated scholarship, until modern times.

An influential modifier, Wang Yang-ming (1472–1529), gave the pursuit of knowledge a subjective interpretation suggestive of Zen Buddhism. The school of "Han Learning" from the 17th century sought an objective view of history, but its followers confined their investigations largely to textual problems.

At the turn of the 20th century, conditions brought political theory again to the fore. K'ang Yu-wei and, at first, Liang Ch'i-chao tried to rehabilitate Confucianism as a modernized state religion; Sun Yat-sen attempted to combine the western liberal tradition and some elements of Marxism with Chinese concepts. After 1949 the Communist state imposed an orthodoxy more absolute than Confucianism ever enjoyed.

Of professional philosophers, outside the field of action, the best-known Chinese name at mid-century was that of Fung Yu-lan, whose works show in different phases the influence of neo-Confucianism, western neorealism and Taoist transcendental thought.

Collected Works, as a standard classification, include all the poems, essays, letters and occasional pieces by a given man, but not a single drama or novel.

Until the 19th century the professional author, receiving money for publications, was virtually unknown in China. However, nearly all educated men were professional writers, their ability to compose documents being their primary qualification for civil employment.

Anything else they wrote was incidental, but could hardly be called avocational since proficiency in verse and certain other accepted forms was required for the government examinations as well as by social exigency. Actually a talent for literature often had a great deal to do with a man's reputation and consequently with his advancement. Production of less dignified genres, on the contrary, was harmful to an official career and hence usually unacknowledged.

Poetry in China from the beginning made rhyme as important as rhythm. The ancient *Classic of Songs* is a collection of folk songs (polished by court scribes). ceremonial odes and dynastic hymns, all from north China. Later commentators interpreted even the love songs as moral and political allegories. Similar treatment was inflicted on the next-oldest preserved poetry, which originated farther south in the incantations (often erotic) of male and female shamans. These inspired the melancholy rhapsodies associated with the vague figure of Ch'ü Yüan, central among

which stands the luxuriant, obscure "Li Sao" ("Falling into Trouble"). Partly from these, in turn, came the rhymeprose (fu), with a short prose introduction and strongly rhythmical sections making free use of rhyme. It was characterized by virtuoso piling up of words for cumulative effect, as already in the goddess-haunted "Rhymeprose on Mount Kao-t'ang" attributed to one Sung Yu (third century B.C.?).

Eventually some writers used the fu for more formal or more realistic subjects, as Lu Chi (A.D. 261–303) in his brilliant "Rhymeprose on Literature"—the first systematic Chinese essay on literary form and theory—and Yu Hsin (513–581) in his great "Lament for the South" on the fall of the Liang dynasty. But during Han times, when the fu was the chief rhythmic vehicle for the literati, it remained predominantly descriptive.

Meanwhile the Han imperial music bureau had started writing down the songs of the people for adaptation to court use. These lyrics and ballads (called yiieh-fu poems), more varied in theme and expression than the ancient Classic of Songs, gradually inspired literary men to simpler poetry mixing personal sentiments with folk themes.

The Wei dynasty prince Ts'ao Chih (192–232) raised this combination to poetic heights. Even more individual was the recluse T'ao Ch'ien (365–427), one of China's greatest poets. He spent nearly all his life on a small farm close to nature. which permeates his poems both realistically and philosophically. He also took considerable comfort in wine. Coterie poets of this period of disunion were more self-consciously unconventional, often proclaiming their scorn of official life, celebrating wine and fantasy. Others devoted themselves to erotic themes, praising beautiful women in the ornamental palace style, a pastiche of cliché. After the reaction against this preciosity, poets seldom wrote about sexual or romantic passion, at least for circulation.

The T'ang dynasty (618–906) is often called the golden age of Chinese poetry, because it produced galaxies of major and minor poets and because early in this period was crystallized the verse form par excellence. The regulated poem (*lü-shih*) is so considered because it fully yet compactly exploits the tonal resources of the Chinese language. It consists of a stanza of eight five-word or seven-word lines with a complex pattern of tonal or pitch contrasts. In such brief space there is no place for connectives; the style is inevitably elliptical and allusive. Even more concentrated is the stop-short (*chüeh-chü*) containing only four such lines.

Able poets sometimes violated the rules and often wrote freer "old-style" types of verse; no Chinese literary form, once established, was ever abandoned completely.

T'ang poetry reflects the dynastic glory and sophisticated cosmopolitan life of the period but also the hazards of political careers and the hardships of internal war and disaster. One of history's most lavish patrons of the arts was the emperor Ming Huang (Hsuan Tsung), yet his reign was broken by a rebellion which sent his pensioners scurrying about the empire in search of food and shelter. The insouciant Li Po, once a favoured guest at court, in his wanderings continued to write virtuoso fantasies and heightened evocations of landscape with the same ease as before. A legend grew up that he drowned while drunkenly trying to embrace the moon's reflection. Tu Fu, a man of soberer character, a conscientious minor official and a painstaking writer, put into his poems the hardships and sorrows of his own life and those of the common people.

For his broad humanity coupled with meticulous craftsmanship many Chinese consider him their greatest poet. Some of his and Li Po's poems were messages to each other. Meetings and partings of friends is a ubiquitous subject in Chinese poetry, often treated with deep feeling as between these two, perhaps oftener as a social-literary convention.

In later and calmer T'ang times the ballads and lyrics of a gentler poet. Po Chu-i (772–846), made his name a household word. One of the most appealing of Chinese poets, he is also one of the most translatable. More difficult are the poems of his contemporary Han Yu, chiefly known as a model prose writer. He championed a return to the simplicity characteristic of Chinese prose before it accumulated a set of elaborate rules involving verbal parallelism and verselike regularity. As a poet he wrote largely in regulated verse, but brought to it an unhackneyed vocabulary and employed harsh combinations when he wanted a harsh effect.

Equally original, at about the same time, was the short-lived Li Ho, whose strange satanic poems have been compared to those of the French symbolists.

Toward the end of the T'ang a previously subliterary form, the tz'u, began to enjoy a measure of artistic status. Young men set their own words to songs they heard in the brothels and teahouses, following the rhythm and melody of a given song so that the resulting love poem was often in uneven lines. Some of the loveliest and saddest are by Li Yu (937–978), second and last ruler of the ephemeral Southern T'ang, who died a prisoner of the Sung.

In the Sung dynasty (960–1279) the tz'u was adapted to more varied subjects, and much of the best poetry of the period was in this form, though its origin prevented inclusion in a man's collected works. Sung writers also revitalized the rhymeprose, while making of it less rhyme and more prose; the "prose *fu*" of Ou-yang Hsiu are especially noteworthy. The most popular Sung poet, Su Tung-p'o, reworked as a tz'u one of his two famous fu about his visits to the Red cliff on the Yangtze. The most prolific of all Chinese poets, Lu Yu, especially wrote patriotic pieces urging defense of Sung China against its encroaching enemies. For several centuries after its fall, the finest verse appeared in opera librettos.

Drama or opera evolved slowly from court ballets, street entertainments and variety shows. The theatre as an integral artistic and popular institution emerged in the Yiian dynasty (1280–1368). For its character and history, see DRAMA. Despite or rather because of its great popularity, the drama was not a respected medium for literary talent, partly because the narrative and dialogue parts were written in the language of everyday life. There was little precedent for writing down such language, and doing so could not advance a man's career in an officialdom for which even the entrance examinations were in the terse literary language.

In the Yiian period China was ruled by the Mongols, and the classical examinations counted for little. Apparently some educated Chinese to whom office under the conquerors was either closed or repugnant, having time on their hands, took an interest in the theatre and began to write for it, doubtless not without pay. Verses for the arias more or less remained in the literary language, being made intelligible to the ear through colloquial asides by the performers.

Fiction existed in written form from early times, in the sense of elaborations on history and anecdotes in philosophical writings. Nobody knows how much of the Intrigues of the Warring States or the Tso Commentary is factual. how much hearsay or invention. Even in later times, hero tales and ghost stories were intended to be taken as true reports. The poet T'ao Ch'ien wrote a famous prose allegory, "The Peach Blossom Source," but not until the T'ang period did the literary tale come into its own. From frequent use of the supernatural such tales were called *ch'uan-ch'i*, "narrations of strange things." Many were love stories. They were still written in the scholar's language, and could scarcely be read by any other class; the masses depended on itinerant storytellers in the streets.

These entertainers seem to have kept simple outlines or prompt books in the vernacular, which printers began to bring out in illustrated popular editions, which fell into the hands of scholars who read them in private and polished them for diversion. They expanded the outlines, adding new incidents and subplots, retaining as chapter endings the storyteller's allurement: "And if you don't know what happened then, listen to the next episode."

Thus the novel was born. For centuries it remained outside the pale of recognized literature, unsigned or attributed to a rival, since discovery might ruin the author's official career. Authorship was often composite, different readers making any alterations or additions they liked; numerous variant editions appeared. The Romance *of* the Three Kingdoms, prototype of many novels based on historical characters and themes. existed in fairly extended form as early as the Yuan period, but the present 120-chapter

version probably dates from the 16th century. The Water Margin (retitled All *Men* Are Brothers in one translation) deals sympathetically with the exploits of a band of robbers in the 12th century. The Journey to the West (partially translated as Monkey) by a known author, Wu Ch'eng-en (?1500–80), is a satirical allegory written in the manner of an interminable but amusing fairy tale.

The first novel of everyday life, divorced from legend. history and the street entertainer's conventions, was Chin *P'ing* Mei (completely translated as The Golden Lotus), written anonymously in Ming times. Its theme is the ruin caused by selfish pursuit of pleasure; because of its frequent pornography, probably introduced to ensure readers, it has been especially denounced. Yet it is a truly great realistic novel, complex in plot and convincing in characterization.

The 18th-century Dream of the Red Chamber (Hung Lou *Meng*) is a sentimental but psychologically penetrating love story developed against the background of a large family and its declining fortunes. Ts'ao Chan left this novel unfinished at his death, and Kao E carried it to a conclusion. The death of one of its two heroines has called forth at least as many tears as Samuel Richardson's Pamela, written not much earlier.

Several Ch'ing dynasty novels sharply satirized official corruption and inefficiency. In the last years of the Chinese empire an unsuccessful businessman and reformer, Liu E (1857–1909), wrote the semiautobiographical Travels of Lao Ts'an, which has little plot but is unified by an original personality. It reflects his multiform interests, including the Sherlock Holmes stories, but primarily his anxiety over the future of China, represented in a dream by a floundering ship with an irresponsible and vicious crew.

The colloquial short story developed concurrently with the novel, retaining the oral storyteller's clichés to an even greater extent. Stories of exemplary conduct were rather conventional; love stories showed far more realism and invention. Three definitive anthologies published in late Ming times are known collectively as the *San* Yen.

In the Ch'ing dynasty the literary-language tale of ghosts and marvels was revived, with especial artistry in P'u Sung-ling's Strange Stories from the Liao-chai Studio.

Women Writers, exceptional in premodern China because of educational and social limitations, were by no means unknown. Pan Ku's sister, Pan Chao, contributed substantially to his History of the *Han* Dynasty. It became a convention for men to write love poetry from a woman's standpoint, reserving the masculine first person for poems of friendship; but countless anonymous love poems are traditionally attributed to various women. Known poetesses include Ts'ai Yen, who wrote 18 memorable stanzas about her long captivity by a border tribe in late Han times; Yü Hsüan-chi, a Taoist nun and mistress of more than one T'ang poet; and Li Ch'ing-chao (Sung dynasty), famous for her *tz'u*. Female professional authors appeared in the 20th century (*e.g.*, leftist short story writer and poetess Ting Ling).

The Literary Revolution which followed the political one of 1911 virtually abolished the terse traditional style; the mainstream of literature shifted to an approximation of the vernacular. This change, championed in 1917 by Hu Shih and Ch'en Tu-hsiu amid a storm of controversy, came about largely for practical rather than purely literary reasons.

A modern China must aim at nation-wide literacy, impossible if education should remain divorced from speech patterns. and at assimilation of the theoretical and practical knowledge of the rest of the world. Even in the new paihua ("plain talk") style, officially taught in the schools after 1920, new terms had to be coined, eventually becoming idiomatic.

Authors freely borrowed both ideas and techniques from Europe and America, where some of them studied. Western literary trends reflected in China generally were those of several decades past: Ts'ao Yii's play Thunder and Rain shows the influence of Ibsen, Mao Tun's novel Midnight that of Zola and Tolstoi. Although the high place occupied in European literature by fiction and drama had much to do with the reappraisal of China's own popular literature. the traditions of that literature (other than its use of the vernacular) were more honoured than imitated. The new writings were nearly always bound up with some aesthetic or political program, their authors associating themselves with magazines or manifestoes. Groups dissolved and shifted overnight as iconoclasts became conservatives and aesthetes turned reformers.

Caught between opposing political forces some turned from programs to scholarship, while the most active writers tended more and more to the left. Lu Hsiin (1881–1936), whose brief but bitter Ah Q'is the classic of modern Chinese fiction, was forced into the extreme camp by circumstance rather than by firm conviction, though the Communists later made his works "revolutionary" classics. At mid-20th century the outstanding literary name in Communist China was that of Kuo Mo-jo, an archaeologist, playwright, poet and critic who attained high office as a sort of cultural commissar.

Cut off from the mainland. Nationalist Chinese writers abroad and on the island stronghold of Formosa found it hard to produce creative works rooted in their native soil, but not being bound by an all-pervasive authority they could maintain a higher level of objective literary criticism and scholarship.

Modern Chinese poetry threw off restrictions of form and content, but merely exchanged Chinese models for foreign ones, principally the imagists and Whitman in reverse chronological order. Traditional forms were not completely abandoned---even Communist leader Mao Tse-tung wrote tz'u verses—but no general revitalization of them appeared imminent.

Chinese literature obviously would remain in transition until the nation became sufficiently unified and stabilized to achieve again a homogeneous culture of its own. Whether the novels. plays and poems of the future would be anything like those of the past would depend on whether native traditions were to be reassimilated and transformed. The Communists undertook to reinterpret the whole of China's past literature. for instance revising the still popular traditional plays to emphasize social and economic contrasts in them. But no very individual creative artistry could operate in either traditional or new mediums as long as both were to be rigorously controlled.

Meantime contemporary Chinese literature continued to share one important characteristic aith that of the past. namely its predominantly didactic nature.

CHINESE MUSIC. The types of music of a multinational state, such as China, may well be expected to differ from one region to another, and this account is mainly confined to the music of the *Han-jen*, the "Chinese" in a limited sense.

Melody.— It is not easy to define Chinese melody in such a way that melodies from all periods and styles fall within the limits of the definition. First, however. it may be agreed that it is predominantly five-note melody. provided that the frequency with which it makes use of seven notes is acknowledged. Second. the melodic line tends to break into units of a fourth; so that while chains of fourths (D, G, C'. for example) are not uncommon, broken triads are rare. Third, the fourths are spanned by three notes, spaced as a minor third and a major second (DE G or D FG). Fourth, its rhythms are for the most part binary or quaternary, rarely ternary; and though often momentarily irregular, they are never continuously so, as are the irregular (aksak) rhythms of India. the middle east or the Balkans. Fifth. Chinese tunes do not show sequential structure and are often nonsymmetrical, in spite of their binary rhythmic structure. All these prop-

erties are exhibited in the following example, taken from a folk dance tune that is current south of the Yangtze river in Kiangsu and Anhwei provinces and is called "The golden snake's wild dance."

One structural feature common to western folk song and some Chinese tunes (though much less frequent in China than in the west) is the "answer at the fifth." This is exemplified by tunes consisting of two phrases, A A', where A' is a slightly varied restatement of A at the fifth below.

The impression of unusual intonation that a western listener sometimes receives may arise from either of two causes: from gracing of notes by microtonal on or off glides, or from the non-tempered occasional semitones. Fourths, fifths and octaves are usually perfect. The semitones are chiefly used in modulating from one five-note mode to another, but they also occur as passing notes (see example).

Musical Practice.—Of great importance for the practising musician is the art of "gracing." A fiddler or flautist accompanying a singer decorates a cadence, such as E D̂, for example, as E G D̂, E GE D̂, or EAGE D̂. A lutenist not only graces but fills out sustained notes of the tune with a pattern of repeated notes. In a small band of, say, flute, fiddle and lute, all play the same tune in unison or at the octave, with graces and in a manner appropriate to the properties of each instrument, against a rhythmic framework of percussion—drums and clappers, and single gongs or cymbals, for example. If this ensemble is compared with similar groups from India or the middle east, conspicuous differences are apparent, not only in the specific timbre of instruments and in the predominantly five-note melody but also in the rhythmic framework. The elaboration of "rhythmic modes," so striking in Indian and middle eastern music, is much less conspicuous in China, where rhythmic patterns are simpler and less numerous.

One feature of the instrumental ensemble of the theatre, for which there is no parallel in India or the middle east, is the use of the mouth organ, doubling the melody in parallel fourths. This diaphony is subservient to the purely melodic interest of the tune, but it serves as a reminder that the common view of Chinese music as purely linear does not take into account the practices of folk music. In folk and popular music the mouth organ is used not only to play tunes in fourths or fifths (as far as its structure permits) but also to provide ostinato accompaniments—two chords played in alternation, for example. An analogous use of the mouth organ is found among certain national minorities in the republic, such as the Miao and Yao, as well as south of the border in Vietnam. and there can be little doubt that these harmonic features belong to an ancient musical tradition, modified by contact with ideas and practices coming from central Asia.

Reduced to staff notation and played on an equal-tempered instrument, Chinese music strikes westerners as "Scottish," because of its five-note character. Heard on Chinese instruments. however, it is more strange, because of the peculiarities of intonation and the distinctive timbres of the instruments. The muted tone of the two-stringed fiddle. *erh-hu,* is due to the snakeskin diaphragm on which the bridge rests: the "edge" to the sound of the side-blown flute, ti, is due to the vibration of a thin membrane closing a supernumerary hole; the shrillness of the shawm, *suo-na,* derives from the smallness of the double reed; the "dry" sound of the pear-shaped lute, *p'i-p'a,* depends on the special qualities of the resonator; and among percussion instruments the flat, circular drum, pang-ku, provides an essentially "Chinese" element with its unique and indescribable sound.

Opera and Classical Music.—In addition to the wealth of local folk music related to all aspects of daily life—including such characteristic features as storytelling in rhythmized prose to the accompaniment of a long-necked lute, the *san-hsien*—two major kinds of Chinese music must be considered: opera and classical music. The term opera is eommonly applied to the music dramas, sung throughout, save for brief passages in highly stylized speech where the tonal accent of the syllables is so emphasized that the result sounds like the *Sprechstimme* of Arnold Schönberg.

FIG. 2.—P'I-P'A, FOUR-STRINGED LUTE

Five types of opera can be distinguished: *k'un-ch'ü,* dating from the 16th century, in which the chief accompanying instrument is a flute; *ching-hsi,* the 19th-century style, with a fiddle as the chief accompanying instrument and existing in a number of variants (erh-huang, hsi-p'i, etc.), sometimes referred to as the "classical Chinese theatre"; modern opera (see below); provincial opera, such as is to be heard in the capitals of the different provinces; and folk opera—the last of great interest and still inadequately recorded and investigated. In listening to Chinese opera, the foreigner has first to accept the use of the voice in high falsetto before the richness of melodic invention, the dramatic appropriateness of the music and the artistry of the performers can be appreciated.

The term "classical" is often applied to those solo musics for lute (p'i-p'a), flute (both side blown and end blown) and zither that are preserved as a repertory of scores. The zithers—*ku-ch'in,* or ch'i-hsien-ch'in, and *chêng*—are the oldest Chinese stringed instruments, with a documented history from before the 5th century B.C. The repertory of the former (*ku-ch'in*) includes pieces already printed in tablature in the early 15th century, and is beyond question the greatest musical treasure of the Chinese tradition.

This music is the equal of Chinese painting and ceramics in its universal appeal. The sounds of this instrument are intrinsically beautiful and evocative, even for foreign ears at a first hearing, and the musical structure of the suitelike pieces from the classical repertory is of the greatest interest.

Glancing briefly at the musics of certain groups other than the *Han-jen,* it may be said that while the music of Mongolia often resembles that of north China, there is a striking difference in the abundance of unmeasured song in Mongolia in contrast to China. In Tibet, Lamaist music and the music of the historical music dramas differ profoundly from Chinese music in the characteristics of the melodic line. Finally, in Sinkiang province, and among the Turkic peoples—such as the Wei-wu-erh and Khazaks—seven-note melody is the rule rather than the exception.

History.—Excavation of graves of the Yin dynasty (c. 1523–c. 1027 B.C.) has revealed lithophones (slabs of sonorous stone), bronze bells and globular earthenware flutes, all yielding notes at the same or related pitches, so that there is reason to believe that the Shang people had at that time a standard pitch. At least by the 3rd century B.C., and probably earlier, an arithmetical procedure for generating the note series was known. Starting with a bamboo tube of length x, if other tubes are cut to lengths of $2/3x$, $4/3(2/3x)$, $2/3(4/3(2/3x))$, etc., the first five tubes when

blown will yield five notes of relative pitches C G D A E, that is, the five-note series, C D E G A. It is possible that both Greece and China derived from Babylonia their knowledge of the 1:2/3 ratio between fundamental and fifth. There are reasons for believing that the Shang people, like some of the national minorities in modern China, may have practised a three-note ritual music.

Certain musical instruments entered China from central Asia at an early date. Iconographical evidence establishes that a pear-shaped lute with a short straight neck was known in the later eastern Han dynasty (before 200 A.D.?), and a circular, straight-necked lute is attested by contemporary documents and a figure on a pottery vessel from 260 A.D. The date of entry of the fiddle is still uncertain, but rubbed half-tube zithers were known in the T'ang dynasty (618–906 A.D.). The Persian dulcimer, *yang-ch'in*, associated with popular Cantonese music, entered during the Ming period (1368–1644).

FIG. 3.—YANG-CH'IN, DULCIMER

In T'ang and Sung times the musical influence of central Asia was strong in the entertainments of the court, and seven-note tunes were common in ceremonial music. Some of these tunes survive in the works of Chu Hsi and Chiang Pai-shih from the beginning of the 13th century. Seven-note tunes were also characteristic of the so-called *Northern Songs* of Yüan and Ming times; but on the whole the fundamentally five-note character of Chinese melodies always shows through the seven-note structure.

Modern Music.—In the mid-20th century Chinese composers were experimenting with western instruments and with harmonic and contrapuntal devices adapted to the national idiom. Among many modern works, mention may be made of the *Yellow River Cantata* (for soloists, chorus and an orchestra of Chinese instruments) by Hsien Hsing-hai, and of the impressive opera *The White-Haired Girl* (1945) by a group of composers and writers, perhaps better regarded as a collective work than a work "composed" in the usual sense. Many of its tunes, indeed, are folk and popular songs. The orchestral texture marks a new departure in Chinese music, and there are passages of striking originality and affecting pathos.'

(L. E. R. P.)

CHINESE PAINTING. Chinese painting is to be ranked with major forms of artistic expression throughout the world. As a point of departure, it can be suggested that Chinese painting is permeated by a sense of the wholeness of things. Separate detail is important only insofar as it affirms more universal characteristics. Portraits to western eyes often appear generalized; for while they may record the nature of an individual, they seek at the same time to assess that individuality as an ideal—of, for example, the Confucian scholar. Small objects—a bird, a flower, a fish, bamboo—are seldom depicted without stressing their growing, moving life and hence the implications of their involvement with all living things. The perfection of shape and proportion that is necessary to depict a Buddha is the artist's way of defining a godlike universality. It is no accident that the Chinese artist has so often turned to the art of painting landscape. In what other theme can one find the vision of far horizons, the extension of time that is in the mysterious recurring passage of the seasons, and a chance to express man's involvement with such a wide and universal theme?

Appreciation of Chinese painting, outside China and Japan, came late, but increasingly during the 20th century more and more paintings have become known, important collections have been formed in western museums, and knowledge is expanding and becoming surer. Certain obscurities, however, are inherent in the long history of the art. Although the Chinese have kept careful historical records, countless paintings have been destroyed by war and natural calamity. For what is preserved, the judgment of authenticity has been complicated by the practice of making copies. Hsieh Ho's (*c.* 500) famous six principles of painting enjoin the artist to "copy" the old masters. In this fashion early creativity might be preserved for the admiration of later generations, much as old masterpieces are reproduced and preserved by photography. From such a background, however, it becomes clear that if artists' names are assigned to the finest early Chinese paintings, this need not mean more than that the painting was done according to a well-established tradition connected with that name.

For descriptions of the historical and cultural background of the periods discussed *see* CHINA: *History;* BUDDHISM; CONFUCIANISM. Specific areas of Chinese painting are treated in EMBROIDER~; ENAMEL; TAPESTRY; TEXTILES. *See* also CHINESE ARCHITECTURE and CHINESE SCULPTURE.

TECHNIQUE AND IDEALS

Chinese painting is water-coiour painting with pigments of both vegetable and mineral components. Applied with a binder of glue, colours could be opaque or in semitransparent washes. These were usually added to areas already defined by ink outline, but a free: unoutlined or "boneless" method was also known. Most commonly the surface was a smooth wall or the portable materials silk and paper. Silk was used for painting as early as the 5th to 3rd centuries B.C. Paper, although probably existing earlier, was officially recorded as an invention in A.D. 105. It may have been used in painting, however, several centuries later.

In addition to embellishing walls, Chinese painting from as early as the Han dynasty (202 B.C.–A.D. 221) was often done on standing portable screens. Aside from reflections in Japan, no early Chinese screens have survived. Painting in China tended to three significant forms: (1) the hanging scroll, which was unrolled to hang vertically on the wall; (2) the hand scroll, to be unrolled on a table from right to left, a small section at a time; and (3) the album, a series of separate pictures, assembled like a book and leafed through picture by picture. Such paintings were easily stored. In fact, important masterpieces were shown only on special occasions or to close friends who would particularly enjoy them.

Much of Chinese painting was in ink monochrome. Chinese ink was manufactured in stick form, a combination of pine soot and glue, which was ground in water on an ink stone. The bamboo brushes used to apply the ink or colour could be obtained in an almost endless variety of sizes and qualities, the hardness or softness depending on the kind of animal hair that was used. Even the largest brushes tapered to the finest hairlike point, thus affording tremendous flexibility.

These tools helped create a rather special relation between the artist and what he painted. The brush, which was used as well in writing, had none of the hardness of a pen, and the slightest pressure of the hand caused a marked variation in the character of the brush stroke. The painter thus had to cultivate a most skilful control, a control that was the more remarkable considering that normally the hand that held the brush received no support

and that the whole arm moved free. By this the Chinese affirmed that the inspiration in the mind flowed unfettered down the channel of the arm — almost as an electric current — to record itself on the whiteness of silk, paper or wall.

In practice such spontaneous ease must be qualified. Some paintings took days, weeks, even years to complete. There is sometimes evidence for the use of a charcoal sketch. A type of painting practised as early as the 6th century and apparently of central Asian import was known as "painting in relief." A later example (11th century) involved the application of thick layers of paint until it assumed the proportions of physical relief, certainly a laborious technical process. In the 17th century Wang Yuan-ch'i used an iron to dry water-colour pigment, the more readily to apply individual layers of paint.

But the ideal remained. and the mastery of mind made visible through perfect execution turned the painter into a kind of holy man who, according to Han Cho in 1121, "fathoms the uttermost secrets of heaven and earth and illumines what is not lit by sun and moon." His goal was the attainment of Hsieh Ho's enigmatic ideal of "spirit, rhythm, life movement" — to transcribe directly its four Chinese words. Moreover, legend affirms that the artist was able to perform marvelous feats. Thousands of miles unfolded on a square inch. Dragons flew from the walls on which they were painted: and at the end of his career the artist might paint a cave so real that he could walk into its depths, never to be seen again.

HISTORY

Shang Dynasty **(1766?–1123? B.C.)** and Chou Dynasty **(1122?–256 B.C.).** — Painting of some kind certainly existed far back in China's history. The use of a brush, apparent at least in China's earliest writing (c. 1300 B.C.), is one indication of such antiquity. Only from a much later period (5th–3rd centuries B C). houever. is there a painting which can properly be associated with the long later fruitful traditions of the art. A product of the culture of Ch'u, a powerful southern state during the feudal Chou period, this painting was excavated at Ch'ang-sha in 1949. It affirmed the early use of line and possibly colour on silk.

Han Dynasty (202 **B.C.–A.D. 221**). — According to literary references, the Han dynasty knew both large-scale frescoes and portable paintings on silk. Moreover, the names of several Han painters have been preserved. While no major works have survived. a substantial understanding of the art can be derived from tomb carvings and tomb frescoes, from painted pottery and from lacquer. Much of Han painting was preoccupied with the human figure. but molded tiles from southwest China show landscapes That Han painters were concerned with the spirit world is attested by the appearance of gods and strange imaginative forms When these were painted on lacquer objects, the fluid easy movement of the brush as it described a figure vibrant with life can often be detected. traits of technique and spiritual intent that long remained the aims of the Chinese artist.

Six Dynasties (221–589) and Early **Buddhism.** — Ku K'ai-chih (c. 344–*c.* 406). who worked at the Chin court at Kanking, was the most important early post-Han artist. The scroll coming closest to his hand is in the British museum (London), "The Admonitions of the Instructress to the Court Ladies." Here the artist illustrated a 3rd-century moral treatise recorded in bits of writing ahich divided and explained brief, painted scenes. Elegant postures, careful spacing, telling compositions, refined brushing of a thin sure line, even suggestions of shading in drapery folds proclaim its sophisticated qualities.

In 1950 a complete tomb was uncovered at I-nan in Shantung province. A Chinese writer has claimed relationships between the shallow wall carvings and the art of Ku K'ai-chih, and it is possible that future tomb finds will expand the knowledge of post-Han non-Buddhist paintings. Fine later (early 6th century) examples of this "drawing" on stone may be found in an offering shrine in the Museum of Fine Arts at Boston, Mass., and a sarcophagus illustrating scenes of filial piety in the Kansas City (Mo.) museum.

Both in the north and south of China the imported religion of Buddhism was of great significance. Known to China in the Han dynasty, there are only the briefest sculptured expressions of it at that early date. From the 3rd century it flourished in the lower Yangtze valley. By the early 6th century the most admired artist in the south was Chang Seng-yu, who worked at Nanking for the Buddhist Liang dynasty. A chief aspect of Chang Seng-yu was his ability to paint in a manner referred to as "relief." By this may be inferred, if not actual physical relief, the use of shading techniques imported from India which gave to objects a sculpturesque quality of volume and substance that was to the Chinese a new and marvelous thing.

No Chang Seng-yu paintings have survived, but there are imitations of a relief style in some details from Six dynasties painting in the north at the famous trade route centre of Tun Huang in western Kansu province. Artists first began work there in 366, and the National Art Research institute of Tun Huang has counted as many as 469 caves, 22 of which may be dated in the Six dynasties period. There are Buddhas and their attendants, and popular stories of former lives of the Buddha. The art, as might be expected in such a border region, shows different manners, strains that were related to the mixed environment of Indian, central Asian and Chinese influences.

T'ang Dynasty **(618–906).** — The T'ang dynasty must be accepted as one of the great glories of Chinese history. The main capital of that dynasty, Ch'ang-an (modern Sian), was a great international city, and painting in temples and palaces was a chief adornment of that city.

No great temple survives, but in the west of China, Tun Huang continued to flourish as a caravan oasis, and many wall paintings among its 206 T'ang cave chapels (or temples) can still be seen. In Japan, the Horyuji temple on the outskirts of Nara preserved (until a damaging fire in 1949) a beautiful series of early 8th–century frescoes. However, fine reproductions are extant. So close were they to Chinese ideals that they may well have been done by Chinese craftsmen, and they stand as proof of the international character of Buddhism at that time.

T'ang scrolls ascribed to specific artists are indeed rare. A famous hand scroll, "Thirteen Emperors" (Boston museum), is given to Yen Li-pen (7th century), a favourite of two early T'ang emperors. In some rather damaged hanging portraits of Buddhist patriarchs (Toji. Kyoto) Li Chen (8th century) caught the religious concentration of the followers of the True Word sect. Han Kan (8th century) was a great painter of horses, and one of his spirited animals may have been preserved in a scroll in the David collection in London.

It is often from the sure and skilful copy that the clearest estimate of T'ang art can be gained. Wei-ch'ih I-seng. son of a Khotanese artist, mas sent from central Asia to the Chinese court (*c.* 630). Like Chang Seng-yu of the preceding century, he painted in relief. Something of Wei-ch'ih I-seng's art can be estimated in what appears to be an 11th-century version (by Ch'en Yung-chih), "Buddha Under the Mango Tree," now in the Boston museum. In this hanging scroll, blue and green mineral pigments were applied with such thickness as to stand out physically in relief from the even surface of the silk. Chanp Hsüan's (fl. 713–742) "Ladies Beating and Preparing Silk," a Sung copy, by Emperor Hui Tsung (also in the Boston museum), was beautifully coloured in soft green and gentle orange, blue and rose. It could hardly have come closer to more universal T'ang qualities: dignity and harmony, richness without flamboyancy, a truly "classic" sense of control that contained within it the vibrancy of quiet life.

Of the greatest T'ang artists nothing but shadowy copies remain. In this category must be included the fabulous vigour of Wu Tao-tzu, of whom it was said that "some god must have borrowed his hand"; Wang Wei (699–759), the original symbol of a scholar-painter ideal; and Li Ssu-hsun (651–716), the originator of a highly coloured precise landscape style.

The Five Dynasties (907–960). — Times of trouble in China have traditionally nurtured the independent recluse, and in the post-T'ang uncertainties Ching Hao (c. 900–960) withdrew to the T'ai Hang mountains in eastern Shansi. The ideals he developed — and from them a suggestion of his painting style — are set down in a treatise, *Notes* on *Brushwork*. In part he talked of a just bal-

ance between outward appearance and inner reality: "Truth shows the spirit and substance in like perfection." Concurrently he was affirming a way of life: "Wise men devote themselves to music, calligraphy and painting, thus one by one getting rid of their desires" (S. Sakanishi, The Spirit of *the* Brush, London: John Murray, 1948 reprint, pp. 87–88, in "Wisdom of the East Series").

Ching Hao was only one of several great masters. His home was in the north as was that of Kuan T'ung (10th century), Li Ch'eng (c 940–967) and Kuo Chung-shu (c. 920–c. 977). While the greatest single collection of rare early Chinese landscapes is in China's National Palace museum, the Boston museum attributes a beautiful towering landscape to Kuan T'ung. Here in the complexities of curving crags and soft mists may be experienced the grandeur and mysteries of nature that so stirred the imagination of these early artists.

In the south the elegance of the local court at Nanking was reflected in a figure painting by Ku Hung-chung, "Han Hsi-tsai's Night Revels," of which an important version is preserved in China. To this court were drawn the two great landscape painters so much admired from the Yuan to the Ch'ing dynasties, Tung Yuan and Chu Jan.

From the west at the ancient cultured city of Chengtu. the name Huang Ch'uan (c. 900–965) stands out. Posterity has paired him with Hsu Hsi of Nanking as one of the most skilled early painters of birds and flowers.

Sung Dynasty (960–1279).—Painting of the Five dynasties blended readily into the art of the Northern Sung when China was once again controlled by a single dynasty. Yen U'en-kuei (late 10th century). Hsu Tao-ning (early 11th) and Fan K'uan (c. 990–1030) apparently carried on early traditions well into the 11th century.

Partly because of a famous essay on landscape painting. Kuo Hsi (c. 1020–90) is one of the best-known artists of the Northern Sung. In his essay there is an important passage on the variety and subtle uses to which ink may be put. A dated and lightly coloured "Spring Landscape" (1072) in the Palace museum of China and hand scrolls of "Autumn" (Washington, D.C.) and "Winter" (Toledo, O.) show this dexterity of ink, ranging from the thinnest distant mist-veiled peak to bold swirling ink on foreground rocks to towering imaginative and often cloudlike cliff shapes.

The emperor Hui Tsung (ruled 1101–25) is an important name in the arts of the early 12th century. Politically weak and ending his life a captive in Mongolia (1135), he was one of China's greatest art patrons, maintainer of a painting academy, and himself a skilled painter. His painting catalogue, Hsuan Ho Hua *P'u* (1120), lists 6,396 paintings by 231 artists. Classification by ten subjects gives first place to Buddhist and Taoist themes, second to human figures and only fifth to landscapes.

Artistic ideals had undergone a change; the emperor relegated a whole cartload of Kuo Hsi paintings for use as waste silk. Much of this change must have involved a care and precision in painting technique that is evident in the emperor's own studies of birds and flowers. Leading examples of his art may be seen in the Boston museum ("Five-Coloured Parakeet") and in the Palace museum ("Bulbuls on a Flowering Allspice Shrub" and "Landscape"). While his perfect technique was doubtless something new, as a painter of such tiny things in nature he was actually only continuing 10th-century traditions already upheld in the Sung by Chao Ch'ang (early 11th century) and Ts'ui Po (late 11th).

Because of their significance as exemplars of a persistent Chinese ideal—the ideal of the scholar-painter-poet-calligrapher—an ideal that was so strongly revived in the Yuan dynasty, a group of late Northern Sung artists have special significance. Mi Fei (1051–1107) invented a new technique whereby he built his hills from repeated horizontal dashes or blobs of ink. In a sense no less scholarly and personal were Li Lung-mien's (c. 1070–1106) "plain drawings" (*pai* miao), often of human figures or horses. in a sure sometimes pencillike ink line. Wen T'ung (d. 1079) was the greatest Sung painter of bamboo, while his admirer Su Tung-p'o, a friend of Mi Fei, showed in his skill at calligraphy, bamboo and poetry the kind of personal learned expression for which this scholar class aimed.

When the capital of K'ai-feng was captured (1126) by the Jurchen, Li T'ang, an elderly painter, was credited with reconstituting artistic traditions in the south at Hang-chou (Hangchow) under the patronage of the new emperor, Kao Tsung. Li T'ang's works are best known in China (Palace collection) and in a pair of landscapes in Japan (Daitokuji). There were also many others from the north who continued in the south: Su Han-ch'en, noted for paintings of children; Li An-chung, a painter of birds; Chao Po-chu, who continued the precise manner of the T'ang great, Li Ssu-hsun; and Chiang Ts'an, a perpetuator of Northern Sung landscape ideals. Younger members of a re-established academy grew in stature: Liu Sung-nien, Hsia Kuei and members of a painter family named Ma—especially Ma Yüan and his son Ma Lin.

Because of admiration for them in Japan, and later Europe and America, Ma Yuan and Hsia Kuei have become almost household words to express the character of Southern Sung painting—a brief, yet careful style, in which repeated angular brush strokes ("ax strokes" being particularly important), neatly placed headlands, evenly fading mists, soaring peaks, broad spaces and tiny people presented a picture that was both defined and pregnant with the poetry of suggestion.

Yet another aspect of Southern Sung painting was inspired by Ch'an (Zen) Buddhism. Ch'an paintings attempted to reveal truth by a sudden flash of insight, by quick powerful brush strokes and brief telling areas of wash. These are much admired in Japan, and the best-known Ch'an paintings, especially those by Mu Ch'i and Liang K'ai (both 13th century), are preserved there.

Yuan Dynasty (1280–1368).—This was the era of the Mongol supremacy of the great khans. It is difficult, however, to see any fixed correlation between painting and political control. Some painters were closely connected with the Mongol court at Peking: Chao Meng-fu (1254–1322), Kao K'o-kung (late 13th century), K'o Chiu-ssu (1312–65). Others, shunning official life, prided themselves on independence: Ch'ien Hsuan (1235–90), Huang Kung-wang (1269–1354). Wu Chen (1280–c. 1354), Ni Tsan (1301–74). Wang Meng (d. 1385) held office for a time but was essentially an independent spirit. All had in common a rejection of the ideals of the immediate past.

The famous Italian Marco Polo, who was in China at that time, tells of the continuing glories of the old Sung capital Hang-chou, and there is evidence for the perpetuation under Buddhism of Southern Sung styles. But the great Yuan artists turned elsewhere, chiefly to the Five dynasties and Northern Sung. Wu Chen. in a beautiful painting of fishermen (Freer gallery, Washington, D.C.), was inspired by a later lost Ching Hao work. A Chao Meng-fu hand scroll (Palace museum) is a skeletal reflection of ink landscapes originated by Kuo Hsi. Ch'ien Hsuan is said to have drawn inspiration in his delicate studies of birds and flowers from Chao Ch'ang. Kao K'o-kung worked from the forms of Mi Fei's landscapes.

Labeled as the "four great masters," Huang Kung-wang. Wu Chen, Ni Tsan and Wang Meng were particularly responsible for the glorification of an ideal highly valued in Chinese aesthetics—the ideal of "literary men's painting" (*wen* jen *hua*). For these men painting was neither for money nor for a supporting patron. Painting was self-expression; expression of a self, however, which was allied to time-honoured Chinese ideals—freedom from officialdom. closeness to nature, respect for the past, the simple identification of the learned man with the farmer, fisherman and woodcutter.

Colour was used in Yuan paintings, but painting really communicated its meaning through ink. Landscapes might be empty of people, and enjoyment depended on appreciating the personal quality of the ink brush strokes of which they were made.

On one occasion, Ni Tsan said he did not care whether or not his bamboo looked like bamboo. He was merely expressing his own feelings. Writing such feelings on a painting also became popular at this time, and these moods were often shared by friends whose calligraphy filled the same painting. In this world of personal expression, a fragment, an "ink-play" (mo-hsi), a branch, a

bamboo, a bird, an old rock or something transient was sufficient. Yet this seemingly offhand thing communicated by the skill of its brush and ink the constant nature of the painter.

Ming Dynasty (1368–1644).—In China's long history only three times have the Chinese themselves ruled for an extended period a united China. In this respect the Ming takes its place beside the Han and T'ang periods. Thus, back of much Ming painting was a confident, sure expression that reaffirmed the Chinese way of life. There were two "schools": the Wu (from Wu-hsien, modern Soochow) and the Che (from Chekiang province). Another classification codified past Chinese painting as either Northern (academic and precise) or Southern (individual and free). This period paralleled much of the western Renaissance, but it was hardly an age of exploration. In painting it was more properly a time of confident, sensitive evaluation of what it meant to be Chinese. At its close appeared detailed technical catalogues on painting methods, the writing of which extended into the succeeding dynasty: *Treatise on the Paintings and Writings of the Ten Bamboo Studios* (1633); *Mustard Seed Garden Painting Manual,* i (1679), ii and iii (1701).

Shen Chou (1427–1509), leading spirit of the Wu school, was the ideal scholar-painter-poet. He lived on the family estates near Soochow, but not as a recluse, for friends were constantly coming and going, and he himself was a delighted traveler. His style varied, for he was often imitating one or another of the old masters. Yet despite variety, Shen Chou had a sureness of brush stroke, a positive order to the composition, inventiveness and often delicate colour that told of his own powerful, subtle personality.

Few escaped Shen Chou's influence, yet the Wu school boasted other masters: Wen Cheng-ming (1470–1559), a man of Confucian integrity and Shen Chou's most famous pupil; Wen Cheng-ming's son Wen Chia (1501–83) and nephew Wen Po-jen (1502–75); the often delicate Lu Chih (1496–1576); and the bolder Ch'en Shun (1482–1539 or 1483–1544).

Although not orthodox scholar-painters, two great painters. T'ang Yin (1470–1523) and Ch'iu Ying (16th century), were linked to the Wu school as coming from Soochow. Both studied under the same master, Chou Ch'en, and both were influenced by academic strains of painting, particularly the skilful craftsmanship of Ch'iu Ting.

In the Ming, pure academic traditions were revived in the work of important court artists. The emperor Hsuan Te (reigned 1426–35) painted animals; Lu Chi (fl. 1488–1505), birds and flowers; Li Tsai (15th century). landscapes. The latter was reportedly a teacher of the renonned Japanese painter Sesshu. Tai Chin (15th century), as the acclaimed leader of the Che school, was the greatest talent in this general tradition. He often injected a sparkling vitality into the heritage of Ma Yüan and Hsia Kuei, as in two river scenes in the Freer gallery. His closest follower in court was Wu Wei (1459–1508), while Lan Ying (1578–1660) perpetuated Che traditions. with more personal variations, even beyond the end of the dynasty.

By this time the heart of scholarly painting had shifted from Soochow to Sungkiang and there centred on the personality of Tung Ch'i-ch'ang (1555–1636). Although appointed to high government posts, he and his followers Mo Shih-lung (fl. c. 1567–82) and Ch'en Chi-ju (1558–1639) sought to rephrase the very personal position of the scholar-painter.

Ch'ing Dynasty (1644–1912).—As the Ming was a proud period, its fall occasioned powerful painter reaction. Chu Ta (1626–*c.* 1705), a member of the Ming imperial family, is said either to have gone mad or feigned madness, acts which saved him from the necessity of conforming with the alien dynasty; and the independent, personally distorted forms of landscapes, birds, flowers, fish or rocks confirm this troubled state of mind. Likewise, Tao Chi (fl. *c.* 1660–1710), also a descendant of the Ming house, painted with a self-imposed "awkwardness" in which a conscious nonconformity became his own personal road to beauty. The basis of his aesthetic he described somewhat mysteriously in his writings, *Hua Yu Lu,* as resting on "a single stroke." These two had been monks; so also mas a third independent painter, K'un Ts'an.

Others continued in conformity with political change. The "four Wangs" were famous exemplars of this more conservative tradition: Wang Shih-min (1592–1680). Wang Chien (1598–1677), Wang Hui (1632–1717), Wang Yuan-ch'i (1642–1715). All knew each other. Wang Shih-min, a friend of Tung Ch'i-ch'ang, was the teacher of Wang Hui and the grandfather of Wang Yuan-ch'i. The latter was a great court painter and curator of the imperial collections. All offered endless subtle interpretations and reinterpretations of landscape themes. Wu Li (1632–1718) and Yun Shoup'ing (1633–90) complete a characteristic grouping—the "six masters" of Ch'ing.

The ramifications of Ch'ing painting include other and more individual groups: "eight masters of Nanking" (17th century); "four masters of Anhwei" (17th century); "eight eccentrics of Yangchow" (18th century). Such was the Chinese love for careful classification.

Culture and refinement were maintained among countless other Ch'ing painters, but to the historian seeking meaningful new expression little has yet been revealed. Nor have modern Chinese, however skilled, spoken with an authority to command world-wide attention, and like 20th-century China itself, Chinese painting is linked to the uncertainties that confound an ancient tradition searching for recognition in a new world. (R. E.)

SCREENS

Because of their fragile nature, no screens of great antiquity have survived, but references to them mere not wanting in ancient literature. Folding screens were known in China as early as the 2nd century B.C., at which period glass or mica panelings for them were noted as of much value; their transparent nature afforded both enjoyment of an outdoor view and shelter from the elements. Then, in the century preceding the Christian era. screens carved and inlaid with jade and other precious materials seem to have been produced. Already in this early period the art of painting screens was practised, for it was recorded that '(Figures of Exemplary Women," illustrating the good or evil effects from right- or wrong-doing, were depicted on a screen. The Chinese artist Ts'ao Pu-hsing (3rd century), having dropped ink upon a screen while painting. turned it into a fly which Sun Ch'uan (A.D. 181–252) tried to brush away. Shih Hu (3rd century) made a folding screen covered with silk and painted with hermits, birds and animals, to which he added a long inscription. Chang Mo (4th century) depicted on screens the Buddhist saint Vimalakirti and a scene entitled "Beating Newly Woven Silk."

In passing, mention may be made of a 14-fold screen in the scroll attributed to Ku K'ai-chih (4th century), owned by the British museum, confirming the accuracy of contemporary accounts that screens consisted of numerous leaves. sometimes as many as 40. In the 5th century, Lu T'an-wei painted a lion and Fang Huai-chen the "Paragons of Filial Piety." Landscapes were not unknown in the early centuries as themes for screens for they are referred to in old poems and other writings. Screens of tapestry, embroidery, crystal and lacquer were also recorded in contemporary literature. Moreover, fine calligraphy inscribing moral teachings or auspicious sentiments was executed on screens from the 5th century, if not earlier. It is said that Fang Hsuang-ling (A.D. 578–648) collected precepts from all sources and inscribed them on screens which he distributed among his children as reminders of proper conduct.

T'ang Dynasty.— In the luxurious days of the T'ang dynasty, screens were in constant demand to adorn palaces and mansions. Those which were bedecked nith gold and silver, pearl and tortoise shell. or those of fine textiles noven or dyed, bearing characteristic patterns, must have imparted great splendour to the habitations of rulers and princes.

Horses sent from foreign tributary peoples to the imperial stables furnished themes for screens. and a fabulous animal called *mo,* which was supposed to eat bad dreams, was deemed an appropriate subject for boudoir screens. Then, too, such noted painters as Pien Luan (who treated flowers and birds), Chang Tsao (pines and rocks) and Chou Fang (court beauties) and such accomplished calligraphers as Li Yang-ping and Chang Hsu all decorated screens. Some emperors had about them screens setting forth worthy and moral deeds performed by men of the past, in order that they them-

selves, as well as their subjects, might derive benefit from these constant reminders.

But for actual examples of T'ang art on screens it is necessary to turn to Japan, where, in the imperial repository called the Shosoin, at Nara, were preserved the personal belongings of the emperor Shomu, which were given to the Great Buddha of the Todaiji by the empress Komyo in 756. The list of donations mentioned 100 screens, to which several more were added, at three different times, between 756 and 758. Among this large number of screens were examples of Chinese, Korean or Japanese origin which included paintings of landscapes, palaces, figures and flowers; others of batik and of block-resist dyeing, figuring birds, animals and flowers; and, in addition, some screens on which Chinese ideographs formed the chief decoration. Of these, few remain, in whole or in part, among them no painted screens. Nevertheless. the pictorial accomplishments of the 8th century may be seen in this collection in a sixfold screen, in each leaf of which is shown a figure of a woman standing under a tree. The subject was originally worked in birds' feathers which disappeared, leaving only the preliminary drawings. Despite the sketchy nature of the drawings of the figures, trees and rocks, mature brush strokes may be detected, the importance of which was so much emphasized in the art of painting in the far east. The screen is probably Japanese, yet its conception and execution were based upon contemporary Chinese patterns.

There are also two sixfold screens in this imperial collection, the chief decorative features of which are Chinese inscriptions in large characters. One contains a precept for a ruler, consisting of 48 Chinese ideographs, each written t ice, once in the *chuan* (seal) style and once in the *hsing* (running) style. The backgrounds of this screen are of silk dyed in green and red—alternating in the six panels—bearing designs of conventionalized clouds, birds, animals, trees, plants and rocks, all in white reserve. The screen is very likely Chinese, one of many gifts sent to the Japanese court from China, although it is said that at one time there was discovered upon it a Japanese date corresponding to the year 751—a fact lacking substantiation. In the orient, use of writing for a decorative scheme mas no less common than was employment of a picture for the purpose. Indeed, good calligraphy was considered an art of as great importance as good painting, both being the result of brushwork and both presenting images of mental conception.

Sung, Yüan and Ming Dynasties.— In the Sung period, the practice among prominent masters of painting and inscribing screens was not abandoned. Painters such as Tuan Yuan, Yen Hsiao. Wen T'ung and Hsu Tao-ning are known to have expressed their art thus; and noted calligraphers applied their brushes after the time-honoured custom. The most significant branch of the art of the Sung period was the so-called Idealistic school of painting, which was closely followed by the artists of the Yuan and Ming dynasties. Painters of this school attempted to express in their works certain noble thoughts and ideals. A landscape painting, for example, was an essay which suggested the sublimity of nature and invited the beholder to identify himself with it. The inherent love of nature of the orientals, coupled with the teaching of Ch'an (Zen), produced artists who showed remarkable aptitude for depicting natural phenomena. Artists developed marked individuality and their paintings were characterized by purity and suggestiveness. For their themes, the painters of the Idealistic school chose, besides landscapes, birds, animals and even withered trees and weathered rocks, all of which ordinarily were treated in monochrome with china ink.

Unfortunately there exists no example of the typical art of the Sung as applied on screens, nor are there any screens dating from the subsequent Yuan and Ming dynasties, in both of which it is recorded that painted and inscribed screens were produced. It is possible, however, that some of the paintings coming from these periods, mounted as single hangings, were once panels of folding screens.

Ch'ing Dynasty.— During the Ch'ing dynasty painting on screens was practised, as indicated by the presence of occasional examples dating from the last few centuries. But it is in screens of applied art that the period excels. As already mentioned, the application of the minor arts to screens began in ancient China. The best known among such screens of recent centuries are the so-called Coromandel screens which were made of wooden panels finished with a coat of lacquer, through which designs such as landscapes, figures, flowers, auspicious emblems, etc., were incised and filled uith various thick, opaque water colours—a technique known from the Ming dynasty. A large portion, however, of the existing specimens are of the 17th to 19th centuries. "Coromandel" has no bearing upon their provenance but indicates that these screens of Chinese origin were shipped to European countries from the coast of Coromandel.

Other screens in the category of lacquer are those with lacquered panels (sometimes coated with white oil paint) decorated in gold lacquer; and those of red carved lacquer. Screens of carved teakwood construction set with jade and porcelain plaques, or paneled with silks, tapestries or embroideries, are occasionally seen.

CHINESE PHILOSOPHY. Chinese philosophy involves many systems which have developed within three main periods: the ancient, the middle and the modern.

THE ANCIENT PERIOD: THE CLASSICAL SCHOOLS (TO 222 B.C.)

The most significant development of the ancient period was the triumph of humanism. During the Shang dynasty (1766?–1123? B C) spirits. rather than man, were considered to be the controlling forces in human affairs. There were many kinds of spirits, the highest of whom was the Lord (Ti or Shang Ti); they could dispense rewards and punishments. and many sacrifices were offered to them. Ancestors, who constituted a special class of spirits. served as mediators.

However, during the Western Chou period (1122–770 B.C), man gradually replaced the spirits as master of his destiny. Divination was still common, but spirits were now regulated into a hierarchy and put under the control of sorcerers and witches. The Lord became the nonanthropomorphic Heaven (T'ien). Ancestors rose to become Heaven's "counterparts." The Mandate of Heaven by which dynasties were established and destroyed was no longer dependent on the Lord's pleasure, but on man's virtue. The tide of humanism was definitely rising.

Confucianism.— The triumph of humanism was brought about by Confucius (*q.v.*; 551–479 B C.)—probably the first Chinese philosopher and the most learned man in the first part of the Eastern Chou era (770–256 B C.). He was born in what is now Shantung. north China, into the K'ung family (hence "Grand Master K'ung." or K'ung Fu-tzu, Latinized as Confucius; *tzu,* also spelled *tze* and tse, is the Chinese term meaning "philosopher" or "scholar"). The family had a background of nobility but mas at the time poor. Bereaved of his father at about the age of three, Confucius was brought up by his mother. He was married at about 19, and had a son and a daughter. After holding some minor public offices, he chose teaching as a lifelong career. At about 51, he became prime minister of his native state, Lu. but soon resigned because the ruler failed to carry out reforms which he had suggested. He then started 13 years of travel from state to state. with his pupils, to offer advice and assistance in the cause of reform. Finally, disappointed, he returned home to teach and to write.

Man is the keynote of Confucius' teaching. "It is man that can make truth great," he said. He taught the "three universal virtues" of wisdom, love and courage, which include filial piety, brotherly respect, righteousness, propriety, good faith, liberality, diligence, generosity, sincerity, humility, self-respect, loyalty, eagerness to learn, carefulness in thinking, friendliness in appearance, earnestness in handling affairs and all possible virtues. He called the man of perfect virtue the "superior man" or "gentleman." Hitherto. the term had meant gentleman by birth, but he radically changed it to mean gentleman of character.

According to Confucius, individual goodness is incomplete unless it serves society. The Confucian doctrine of the Golden Mean signifies not merely moderation but the balanced development of the individual and society. **A** gentleman, "wishing to establish his own character, also seeks to establish the character of others. and wishing to succeed. also seeks to help others succeed." This is love (*jen*), Confucius' most discussed subject, which involves both conscientiousness (the individual) and altruism (society). This is the positive side of the Confucian Golden Rule. The negative side was stated by Confucius as "Do not do to others what you do not want them to do to you."

The perfection of both the individual and society, as understood by Confucius' immediate followers, requires the successive eight steps of investigation of things, extension of kno ledge, sincerity of the will, setting the heart right. cultivation of the self, family harmony. national order and world peace. An ideal society is one in which the "five human relations" are fulfilled: affection between parents and children, righteousness between ruler and subordinates, distinction of function between husband and wife, order between elders and the young, and good faith among friends. As for government. he and his followers advocated the restoration of the feudal political structure, but only virtuous and talented men should rule since the Mandate of Heaven was to be seen in the happiness and prosperity of the people, and this could be brought about only by men of virtue. Hence, a ruler should govern by moral examples, like a father, rather than by force. (See also CONFUCIANISM.)

Virtue is not only important but natural, according to the teaching of hfencius (*q.v.;* 371–289? B.C.), who may be said to have represented the idealistic wing of ancient Confucianism. He maintained that man's nature is originally good, for everyone has in him the "four beginnings" of love, righteousness, propriety and wisdom. Therefore man has native knowledge of the good and native ability to do good, as evidenced by a child's natural love for parents. Thus, all men are equal and all could be sages. Moral evils and human failures are due to self-neglect, lack of purpose, bad environment or poor training. Through love and righteousness, especially, human relations can be fulfilled and a "benevolent government" can be established. Evil rulers should be replaced, by revolution if necessary.

On the other hand, Hsün-tzu (*q.v.;* fl. 298–238 B.C.), who may be said to have represented the naturalistic wing of ancient Confucianism, claimed man's nature is originally evil. for man's desires, if unchecked, inevitably lead to greed and conflict. Goodness is acquired. However, the aims of Hsun-tzu and Mencius are the same, namely, a perfect individual and a perfect society; however, Hsiin-tzu did not rely on the moral nature of man, as did Mencius, but preferred discipline through education. rites, law and the "rectification of names." In both cases, as with Confucius, man is the centre and society the circumference.

Taoism. — This humanistic philosophy was diametrically opposed by Taoism (*q.v.*). The goal of Taoism is a peaceful and long life for the individual, it is true; but Taoism frowns upon society. Furthermore, the "way" (*Tao*) of Taoism is not that of man but of nature. The 5,000-word classic Tao-te *ching* probably reflects the basic teachings of Lao-tzu (*q.v.;* 6th or 4th century B.C.; controversy over his dates continued at mid-20th century). It teaches spontaneity, simplicity, unity, purity, constancy, quietude and weakness because these are the characteristics of nature. If one follows nature, that is, observes "taking no (unnatural) action" (*wu-wei*), one will have contentment, enlightenment and peace. Wars, governments, conventions and ceremonies are all destructive; they are not natural.

Chuang-tzu (*q.v.;* d. *c.* 300 B.C.) carried this naturalism to the extreme. To him, Tao is not merely nature; it is "self-transformed" nature. All things instantaneously change and are in opposition to one another. But Tao transforms and combines them into a unity, the One, in which alone harmony and happiness can be found. Therefore the ideal man, the "pure man," will "forget all distinctions," be a "companion of nature" and enter the realm of the Infinite, that is, the life of spiritual freedom. In Taoism, then, the goal is freedom, to be achieved in the realm of nature.

Moism.—The Moists were equally opposed to Confucianism but for a different reason. Like the Confucianists, their interest was focused on human society, but, unlike the Confucianists, they subordinated the individual to the group. Their leader, Mo Ti (*q.v.;* 4702–391 B.C.?), taught "promoting benefits and removing evil," and to this end he praised thrift and denounced elaborate ceremonies. Above all, he condemned war and worked strenuously to prevent it. He also engineered some defense installations. Rather than seek war, one should love the parents and the country of one's fellow men as one's own, for Heaven loves all and benefits all, and one should follow Heaven's will. These doctrines of "universal love" and "obeying the will of Heaven" make Mo Ti the most active promoter of religion in ancient China. Perhaps he even founded a religion, for his followers were organized into a sort of religious and secret society. But "benefits" were always his goal. For this reason he attacked the belief in fate as unbeneficial but approved the belief in spirits because he thought they helped people to behave properly. He believed that, politically, the greatest social benefits are to be derived when people "agree with their superiors."

Legalism. — Like the Moists, the Legalists valued society above the individual, but they considered that man's nature was evil and should therefore be controlled through political measures and "the rectification of names and actualities." Consequently, different Legalists variously advocated law, statecraft or power, and Han Fei Tzu (d. 233 B.C.) synthesized all these ideas. The Legalists emphasized the present, revolted against antiquity and taught the application of objective, standardized, specific and written laws to all without discrimination. They were realists and totalitarians; they put totalitarian measures into practice in the Ch'in state and helped establish the Ch'in dynasty (221–207 B.C.) as the first united empire in Chinese history.

From the preceding it is clear that Taoism overemphasized the role of the individual while both Moism and Legalism overemphasized that of society. Confucianism alone maintained the balance. With the "burning of books" in 213 B.C., Moism virtually disappeared, but other schools carried on.

THE MIDDLE PERIOD: THE DEVELOPMENT OF CONFUCIANISM, TAOISM AND BUDDHISM (221 B.C.–A.D. 906)

Confucianism. — During the first decades of the Han dynasty (202 B.C.–A.D. 221), Taoism, Legalism and Confucianism rivaled each other as the state philosophy, but finally, in 136 B.C., Confucianism became the state cult. This Confucian "supremacy" dominated Chinese government, society, education and literature until the 20th century. However; in philosophy, until the 11th century at least, Confucianism was practically dormant, although for several hundred years Confucianists engaged in lively discussions on human nature. There was also the outstanding Confucianist Tung Chung-shu (179–104 B.C.), who combined, on the one hand, the cosmology of the Yin Yang school which conceived of Yin and Yang as the passive and active principle, respectively, in all existence, and, on the other, Confucian ethics, thus arriving at the theory of correspondence of man and nature. This development was characteristic of the syncretic spirit of Han, Wei and Chin times (206 B.C.–A.D. 419) when Confucianism, Taoism and other currents of thought crossed one another. By the time of Han Yu (768–824), however, Confucianism was so weak that he had to defend the Confucian "way" against that of Buddhism. In this middle period, the light of philosophy did not shine from Confucian quarters. Rather, it came from Taoism and, to a greater extent, from Buddhism.

Taoism. — Taoism (more correctly, Neo-Taoism) flourished under different forms in the 3rd and 4th centuries. There was the fatalistic Taoism in the Lieh *Tzu* and the "Yang Chu" chapter therein, according to which the universe was mechanical and life was transitory and therefore meaningless, to be gone through with pleasure while it lasts. There was the transcendental Taoism of those who sought escape from the troublesome world by engaging in "light conversations" and unconventional living. More positive developments are found in the metaphysics of Neo-Taoism in

which the earlier Taoist concept of Non-being (*Wu*) was transformed into the Originally Undifferentiated or Pure Being, and also was interpreted to mean the real Non-being instead of the Nameless. Significantly. the sage was considered not a person who deserted the world but one who had social and political achievements, that is. "sageliness within and kingliness without." More significantly, Confucius, not Lao-tzu, was looked upon as the model. The spirit of synthesis was at work. Eventually, Taoism declined and became a handmaid to Buddhism.

Buddhism. — Many schools of Buddhist philosophy were introduced into China from India (see BUDDHISM). At first, in the 4th century, Buddhist philosophers interpreted Buddhist thought in Taoist terms in an attempt to "match" Chinese philosophy. From the 6th through the 8th century, various Buddhist philosophies flourished and developed in China. The Middle Doctrine school (Madhyamika), for example, evolved the doctrine of "two levels of truths," namely, "common truth" and "absolute truth," both of which are to be synthesized in the Absolute or Ultimate Void. Again, the Idealistic school (Yogacara) divides the mind into eight consciousnesses, the last of which contains "seeds" or effects of previous deeds and thoughts which affect future deeds and thoughts, thus producing "transformations" until, with perfect wisdom, all transformations are transcended. These and several others were Indian philosophies that grew on Chinese soil. As for indigenous developments, three phases may be briefly related. First, there was the revolutionary doctrine of universal salvation. Hitherto, it was believed that certain people, being evil in nature, could not be saved. But it was now believed that Buddha-nature was all-prevalent; all people had it, and therefore all could be saved. This revolutionary doctrine eventually became the central teaching of Mahayana (*q.v.*) Buddhism in eastern Asia.

The philosophical basis of this doctrine is to be found in the T'ien-t'ai and Hua-yen schools, both indigenous to China. The former school propagated the doctrine of "threefold truth," to the effect that all things are void because they are dependent on causes, but nevertheless they enjoy temporary existence. Being both void and temporary is the mean and all three are really one. The result is a "one-in-all and all-in-one" philosophy, which fully supports the teaching that Buddha-nature is in all. Similarly, the Hua-yen school taught that all things are coexistent and interrelated in a "universe of one truth," all arising at the same time and finally resolving in Thusness, the Absolute Reality, in which fact and principle are harmonized. In short, "one is all and all is one."

However, the most significant development of Buddhism in China was the Meditation school (Ch'an, or Zen [*q.v.*]). Flourishing from the jth through the 9th century, and starting with the two basic propositions that Buddha-nature is in all and that the Buddha-mind is identical with the human mind, it advocates various ways of penetrating the Buddha-mind, especially "absence of thought," "ignoring our feelings" and "letting the mind take its own course." The most important method, however, is meditation, in which one "directly points to the human mind," "sees his own nature and becomes Buddha" and "achieves salvation in this very body." The school was divided into the Southern school which emphasized "abrupt enlightenment" and the Northern school which emphasized "gradual enlightenment." The main point was that the mind should be so clear, pure, quiet and sharp that the great truth of this fleeting universe can be apprehended and that, by seeing the Buddha-mind, salvation can be achieved. This new horizon, simple as it may appear, profoundly influenced Chinese poetry, painting. religion and, above all, philosophy, contributing in no small measure to the emergence of Neo-Confucianism.

THE MODERN PERIOD: NEO-CONFUCIANISM (960–1900)

As popular religions, both Buddhism and Taoism continued to thrive in the 20th century, but as philosophies they disappeared around the 11th century. However, by that time they had left deep imprints on Chinese thought, and their profound metaphysics and subtle psychology had forced Confucianism to find metaphysical and epistemological foundations for its ethics. These new foundations are what make Confucianism new in the second millennium of the Christian era.

The two basic concepts of Neo-Confucianism are "nature" and "principle" — nature, especially human nature, because Confucianism was still primarily concerned with man, and principle because the Neo-Confucianists rejected the Buddhist Void and Taoist Non-being as negative, vague and mystical, and for them substituted principle (*Li*, "law," "reason"), which they regarded as positive, concrete and rational.

The outstanding representative of the Neo-Confucianists in the Sung period (960–1279) was Chu Hsi (*q.v.*; 1130–1200). Before his time Neo-Confucianism was characterized by six major ideas, namely, the Great Ultimate, principle, material force (*ch'i*), the nature of man and things, "investigation of things" and love (jen). All of these were developed, systematized and synthesized by Master Chu.

According to him, the Great Ultimate has no corporeal form but consists of principle. All actual and potential principles are contained in the Great Ultimate; it is complete in all things as a whole and in each thing individually. It is the principle of things to be actualized; and actualization requires, on the one hand, principle, which is incorporeal, universal, eternal, a priori, always good, and, on the other hand, material force, which is corporeal, individual, changing, a posteriori. and involves both good and evil. as reality and function, respectively. Principle and material force are never separated but always work together as one because they are directed by the "mind of the universe," which is the universe itself. In man this mind is divided into the moral mind, which is the principle of man's original nature, and the human mind, which is the principle of original nature mixed with physical endowment and human desires. It is the duty of man to have his nature and desires so harmonized that the human mind is transformed to become the moral mind. Such transformation is possible because all human minds are essentially the same as the mind of universe and because it is the nature of principle to be realized.

The realization of principle depends on the "investigation of things." If things are investigated through both deduction and induction and both objective observation and intuitive understanding, principle will be understood. The understanding of principle leads to the fulfilment of man's nature, which in turn leads to the "establishment" of his destiny.

The greatest understanding to be achieved is that of love. It is the mind of the universe expressed in the unending process of production and reproduction of things. It is the basis of all human goodness. It is the key to individual perfection and an ideal society.

The influence of Chu Hsi's philosophy has been unparalleled in Chinese history save by that of Confucius and Mencius. For many centuries it dominated the intellectual life of China. But strong opposition arose even in his own time, notably from Lu Hsiang-shan (Lu Chiu-yuan; 1139–93). According to Lu, there is no distinction between principle and material force. Man's mind is not the function of his nature but is principle itself. Furthermore, the mind is identical with the universe. It is originally good. Desires are part of it and are, therefore, not different from principle. To investigate things means to investigate the mind. It can easily be seen that he is opposed to Chu Hsi at every turn.

This line of thought was continued and elaborated by Wang Yang-ming (*q.v.*; 1472–1529). Like Lu Hsiang-shan, he equated principle with the mind. As the original mind manifests itself, for example, in filial piety, the principle of filial piety is evident. Thus all men have native knowledge of the good. Therefore, since knowledge and conduct are identical, all men have the ability to do good. It is man's categorical imperative to extend this inborn knowledge by putting it into practice. The ultimate extension is to "form one body with Heaven and Earth." This is love in the broadest sense. In this simple but bold philosophy, Wang rejected the formalistic, narrow and overrationalistic philosophy of Chu Hsi and advocated sincere convictions and forthright action originating from one's own intuitive mind. For about 150 years his school provided China with strong intellectual stimulation and practical insight. Toward the beginning of the 17th century, however, the movement lost its vitality and gradually degenerated.

The reaction against the Neo-Confucian rationalism of Chu Hsi and the Neo-Confucian idealism of Wang Yang-ming was particularly strong in the 17th and 18th centuries. It advanced in three stages. First, it was expressed in the critical spirit of the 17th century when Confucian scholars refused to accept anything, much less orthodox interpretations of Confucianism, unless supported by objective, concrete evidence. Then came the practical emphasis in the teaching of Yen Yuan (Yen Hsi-chai; 1635–1704) and others who stressed the point that theories are empty unless they are put into practice. Finally, Tai Tung-yuan (Tai Chen; 1723–77) carried the movement to the philosophical level. He perpetuated the traditional idea that the greatest characteristic of the universe is production and reproduction, but he insisted that this process involves human desires without which there can be no production. Hence, desires are good and are intrinsic to man's original good nature.

This practical and critical spirit continued to be strong in the 19th century. It was expressed in two directions, namely, in historical and textual criticism and in the new doctrine of "Chinese learning for substance and western learning for practical application." Confucianism was now matched with western thought but was still held to be superior. However, the practical and critical spirit finally led to the radical political reforms of 1898 under the leadership of K'ang Yu-wei (*q.v.;* 1858–1927), the last of the great Confucianists. K'ang maintained that all previous interpretation of Confucianism was wrong, that Confucius was primarily a reformer and that his fundamental doctrine of history was that of progress. Undoubtedly the western tide of reform had reached China and Confucianism could not help but be transformed. Nevertheless, there was nothing new philosophically in 19th-century Confucianism.

In the 20th century, Chinese philosophy involved both the introduction of western thought and the reconstruction of traditional systems. The introduction of western philosophy by mid-20th century had gone through three stages. The first was that of noncritical borrowing. In the first three decades of the century, the works of Darwin, Spencer, etc., were translated and the doctrines of Haeckel, Kropotkin, Nietzsche, Schopenhauer, Bergson, Cucken, Descartes, James and others were successively introduced, especially during the "intellectual revolution" which started in 1917. This revolution, led by Hu Shih (*q.v.;* 1891–1962), led to the second stage, that of critical selection of western philosophies. Hu Shih's own choice was pragmatism. which he strongly propagated. Then in the "polemic of science *v.* life" in the 1920s, leading Chinese intellectuals vigorously debated whether science could form the basis of a philosophy of life. Finally. in the third stage, various western systems were established in China. The strongest of these. of course, was Marxism. Both mechanistic materialism and dialectic materialism were mightily promoted in the 1920s and 1930s. In the 1930s Chang Tung-sun (1887–) formulated his epistemological pluralism on the basis of Neo-Kantianism, which commanded profound respect among Chinese scholars. Similarly, Chin Yueh-lin (1894–), as the outstanding representative of new realism, was looked upon as a brilliant leader of a new philosophy. Along with these developments, different western systems, whether logic, aesthetics, moral philosophy or the systems of Whitehead, Royce or Carnap, were advocated by earnest if small groups with genuine convictions. All these developments were overshadowed if not terminated by the triumph of materialism.

As to the reconstruction of traditional philosophies, it was undertaken by both Buddhists and Confucianists. In the 1920s and early 1930s, Ou-yang Ching-yu (1871–1943) sought to revive Buddhist idealism precisely as it had been about ten centuries before. His opponent, Abbot T'ai-hsu (1889–1947), preferred to transform Buddhist idealism with western thought. Since he was neither a philosopher nor a student of western thought, T'ai-hsu's movement resulted more in practical religious reforms than in intellectual renovation and, along with Ou-yang's, declined in the late 1930s.

At the same time, Confucianism was revived and reconstructed in two different directions and in the 1930s these became the two most extensive intellectual currents in China. One direction was represented by Fung Yu-lan (1890–). Trained in philosophy in the west, he, by the use of western logical propositions, reconstructed the rationalistic Neo-Confucian philosophy of the Sung dynasty. His "new rationalism," as it was called, centred around the two basic concepts of nature and principle, in the sense that being implies reason and that reason pervades the entire universe. To him, it was not a synthesis of Chinese and western philosophies but rather a new philosophy essentially Neo-Confucian in substance but modern in character.

Hsiung Shih-li (1885–), on the other hand, attempted to revive and reconstruct the idealistic Neo-Confucian philosophy of the Ming dynasty. He expressed his "new idealism" in terms of "change," which, in its perpetual expansion and contraction, is, he said, the expression of the Cosmic Mind. A former Buddhist, he was influenced more by Buddhism than by western philosophy. However, his philosophy, being characteristically Neo-Confucian, was diametrically opposed to Buddhist idealism.

With Fung and Hsiung, especially the former, Chinese philosophy was approaching maturity, since they had transformed both traditional and western philosophies into something new. Unfortunately, the growth of their philosophies was hindered by World War II and finally had to yield to communism in 1949. By this time, in China, communism itself had gone from Marxism through Leninism to Maoism and had become the state ideology, thereby opening a new phase in Chinese philosophy. CHINESE SCULPTURE. In China the art of sculpture never received the acclaim awarded to painting or ceramics. For the most part the sculptors were nameless artisans working in hereditary guilds to supply the demands of cult and state. Nevertheless, they created works of art which provided inspiration for some of the greatest monuments of Korea and Japan and could hold their own with the best products of the west.

For a shorter treatment of the general lines of development of Chinese sculpture see SCULPTURE: Oriental. CHINA: History; BUDDHISM; and CONFUCIANISM give pertinent cultural and historical information. Specific areas of Chinese sculpture are presented in IVORY CARVING; JADE AND OTHER HARD STONE CARVING; IRONWORK; TERRA COTTA; WOOD CARVING; and POTTERY AND PORCELAIN. See also CHINESE ARCHITECTURE; CHINESE BRONZE; and CHINESE PAINTING.

(Since the dates of some Chinese dynasties are disputed, the dates in this article are not always the same as those found elsewhere. In each case, the dates suggested by the author of the article are used.)

PRE-BUDDHIST SCULPTURE

Sculpture had its roots far back in Chinese history, although modern knowledge of the art before 1300 B.C. is limited to a few simple animal carvings in jade and stone.

Shang Dynasty (1523?–1028? B.C.).—The earliest examples of historic date came from tombs in the vicinity of An-yang in Honan province, site of the last capital of the Shang dynasty. Of stone, bronze, jade and ivory, they exhibit an artistic quality and technical competence that indicates sculptural traditions antedating by many centuries the founding of this capital. Little is known of pre-Shang or Early Shang glyptic art, and understanding of the closing centuries of the dynasty is incomplete.

Stone Sculpture.—Fragments of monumental stone sculpture have been found, but more common were animals and human figures relatively small in scale. Their salient characteristics were strict frontality and immobility, coupled, even in the crudest examples, with a feeling of sombre power. Animals such as the elephant and water buffalo were often rendered in simple, almost blocklike form that gave the impression of being intentionally unfinished, yet managed to suggest the most essential characteristic~.

Others, like the marble bird at the Academia Sinica, Taiwan,

were composed of carefully integrated carved planes finished with meticulous care. Covering the surface of the marble bird are designs in low relief representing not only feathers but fabulous creatures and geometric patterns. A tigerlike animal appears on the head and back, snakes outline the wings and a stylized animal mask (t'ao-t'ieh) was carved on the breast. These zoomorphic designs were found on both human and animal stone sculptures and on almost all contemporary bronze ritual vessels, which would seem to indicate that the bird and the designs on its surface had a religious rather than a decorative purpose. They may be symbols of protection or appeasement. The deep groove in the back of this and certain other Shang carvings points to an architectural function. While no traces of pigment remain, it is possible that all stone sculpture was once vividly coloured. *(See* Plate II.)

Bronze Sculpture.—Bronze casting during the Shang dynasty reached a level of technical perfection that has rarely been surpassed, Among the bronze ritual vessels were some in animal form which contained all the elements of true sculpture. Like the stone carvings, they were frontal and motionless but showed, to an even greater extent, careful observation of nature.

One of the most splendid of these vessels is in the shape of a two-horned rhinoceros—an animal which once may have roamed central China. Made, it is believed, during the final years of the Shang dynasty, it was modeled with a simplicity and understanding that revealed without unnecessary detail the basic traits of the beast, the ponderous body, wickedly sensitive ears and the small but vicious eyes. It was an art of understatement far more expressive than an accurate portrayal showing every hair and crease (Plate I).

Chou **Dynasty (1028?–256 B.C.).**—For reasons yet unknown, almost no stone carving appeared during the eight centuries that followed the Chou conquest of the Shang dynasty. It is necessary to turn to bronzes for the next phase of Chinese sculpture. The earliest were again ritual vessels in animal form almost indistinguishable from the Shang models that they copied. It was not until the late 10th and 9th centuries that a definite Chou style evolved. Characterized by a powerful and often harsh formality coupled with the use of heavy surface patterns, these animals, despite a decline in technical skill, produced a definite feeling of barbaric splendour. The new style is well illustrated by a bronze tiger (Plate 11), one of a pair, designed evidently not as vessels, but as bases or supports. The smooth, well-integrated modeling of the earlier animals was replaced by a stiff formality in which the component parts of the beast were represented as almost independent elements united largely by the powerful low-relief patterns covering the surface.

Late *Chou.*—By the 7th century B.C. the Chou dynasty, while it continued to lend its name to the era, had sunk to the position of a small feudal state. It was a period of expansion and constant warfare, yet one of great intellectual activity as witnessed by the evolution of the Confucian and Taoist philosophies.

Sculpture, still restricted largely to bronze, returned to the high technical standards of earlier times. The gradual weakening of the old religious beliefs freed this art from its dependence on traditional forms and the wealth of new designs and new techniques bore witness to the strength of contemporary imagination.

Human figures, rarely found after Shang, reappeared. At first crude and ill proportioned, they were soon to be treated with imaginative freedom and marked realism. The use of these small bronzes has not been determined. Some with rigidly extended arms holding short tubes are labeled torch bearers although it is uncertain whether they were intended primarily for the living or the dead. Ming ch'i (artificial tomb figures) for the service of the deceased had begun to replace the sacrifice of living victims in Chou times but if these small bronze statuettes were so employed is open to question.

One of the best of these early figures, cast between the 6th and 4th centuries B.c., stands stiffly erect clasping open cylinders in grotesquely enlarged hands. The treatment of the body and garment was severely simple, only the belt and edge of the robe being indicated. In marked contrast, the head was modeled in considerable detail with careful attention to facial structure and the intricacy of the elaborate coiffure. Despite its obvious rigidity, the over-all effect is one of surprising monumentality in a figure under eight inches in height (Plate II).

Handled with more plastic freedom and unexpected realism, is a delightful bronze statuette of a Mongolian maiden bearing on twin staffs a pair of jade birds (Plate II). It came from Chin-t'sun in Honan province together with some of the finest of Late Chou jades and metal works and, on stylistic grounds, is tentatively placed in the 5th or 4th century B.C. Suggestive almost of actual portraiture are the distinctive modeling of the features and the care taken in the styling of the hair and details of dress.

Possibly earlier, but equally successful as an example of sculptural art, is a bronze dragon which once may have adorned the edge of a massive vessel. It shows a skilful combination of imaginative realism and linear formality, the modeling of the head and body in smoothly flowing planes being emphasized by the tense outline of the mane and wings. Unlike the often harsh designs on Early Chou animals, the delicate surface patterns are restrained and provide a textural quality that adds much to the striking reality of this benign creature (Plate IV).

Far to the south at Ch'ang-sha, capital of the state of Ch'u in Hunan province, excavations brought to light a remarkable series of wood tomb sculptures believed to have been made between the 6th and 3rd centuries. Carved as substitutes for human and animal victims, they illustrate a provincial style little influenced by the cultural centres to the north. Standing figures show characteristically large, flat faces, narrow shoulders and elongated bodies. Features and patterns of the robes are painted. Despite the basic simplicity, these carvings show originality and great technical competence (Plate IV).

Ch'in Dynasty (221–206 **B.C.).**—The era of turmoil following the collapse of Chou hegemony was brought to a close in 221 B.C. when the state of Ch'in, by force of arms, united China for the first time. From this short period were handed down the first important literary references to works of sculpture—the mention of 12 colossal bronze statues of "giant barbarians" placed before the imperial palace at Hsien-yang in Shensi province by command of the first Ch'in emperor. By the 4th century A.D. all these figures had been destroyed and it can be inferred only that metal sculpture on this scale was sufficiently rare to warrant notice. Bronze and hard-stone sculpture on a small scale continued to carry on the stylistic trends of Late Chou.

Han Dynasty (206 **B.C.–A.D. 221).**—The unification of the empire survived the fall of Ch'in and the subsequent four centuries of Han rule witnessed extraordinary physical and cultural expansion. Contact with the fringes of the western world introduced new ideas and influences while Confucianism, by then the state philosophy, and Taoist folklore began to exert their influence on the arts.

Stone sculpture on a large scale reappeared. Timid and awkward at first, by the second half of the period it became more assured; but not until the 5th and 6th centuries A.D. did it come into its own as the chief artistic medium of the Buddhist religion. While the concept of monumental stone sculpture may have come from the middle east, the character and style of Han stone art were definitely Chinese. The few examples that survive are funerary figures connected with events in the life of the deceased or used to guard the "spirit road" to his underground tomb chamber. The most famous of these is a series of stone animals and fantastic monsters from a tomb site in Shensi province associated with the noted general Ho Ch'ü Ping who died in 117 B.C. A large horse (Plate IV) trampling a fallen barbarian symbolizes, it is thought, the defeat of the Huns in central Asia. Despite the monumental character of the animal, only hesitant use is made of the plastic possibilities of the stone, the feeling being more that of a double relief than a free-standing figure. Here is none of the realization of plastic form so beautifully expressed in the small bronzes of Late Chou.

Of greater sculptural quality were the large stone lions and chimeras that appeared first in the second half of the dynasty and reached their culmination in the 5th and 6th centuries A.D. A chimera from Late Han or even slightly later retains the essen-

tially relief character of the earlier horses by emphasizing the animal's profile. However, the modeling of the head and body is treated with far more assurance, and the rigidity of the early monument is relieved by a strong sense of forward motion and by the splendid linear rhythms in the wings (Plate IV).

The character and vitality of Han culture is seen at its best in a series of stone reliefs from the offering shrines of the Wu family in Shantung province dated between A.D. 147 and 168. Contemporary frescoes may have inspired these low reliefs, which are actually more akin to painting than to the plastic arts. The scene illustrated depicts the unsuccessful attempts of the Ch'in emperor to recover the ritual vessels of the Chou dynasty. The figures are represented for the most part in profile with little attempt to indicate spatial depth. Nevertheless, the crowded composition is skilfully handled, the action replete with humour and animation (Plate V).

In spite of the monumental character of Han stone carving, the most truly sculptural art is found in small objects, in which the Chinese were able to bring out the possibility of plastic form far better than they could when working on a larger scale. This generalization seems to hold true throughout the history of Chinese sculpture except during periods strongly under foreign influence.

One of the best of the small Early Han sculptures is a bronze incense burner supported by a lively figure on the back of a mythical beast. The gnome, leaning on one arm while he turns to stare upward, has broken away from earlier conventions of frontality and can be viewed equally well from all sides. The head is strangely large, but the proportions and articulation of the body are handled convincingly and with subtlety (Plate V).

Equally successful in sculptural terms is a pair of bronze bears, thought to have been cast during the second half of the dynasty. Although a popular subject in Han art, their symbolism and purpose are not fully understood. Possibly they were guardians or objects of cult worship. In any case, the creator of this pair with freedom and understanding caught their essential traits—ungainly stance and shaggy power (Plate V).

BUDDHIST SCULPTURE

First Phase (4th to Late 6th Centuries)

Five centuries before Christ, the Buddhist religion was founded in India. But not until the 1st century B.C. did it reach China via the trade routes of central Asia. On Chinese soil Buddhism made slow headway against the established native philosophies of Confucianism and Taoism until its espousal by nomad invaders, chief among them the T'o-pa (Toba) Tatars who founded the Northern Wei dynasty and held sway over a large area of north China.

Northern Wei Sculpture (386–535).—No examples of Buddhist sculpture can be definitely proved to antedate the 4th century. The earliest dated examples are a group of small bronze seated Buddhas of the 4th and 5th centuries made in both north and south China but very similar in style. Typical of these diminutive Buddhas is one dated 451 (Plate V). Stylistically it was little influenced by earlier Chinese traditions but received its inspiration almost wholly from the Buddhist art of central Asia. The trade route sculptors were not themselves the originators of this style, for they in turn combined and modified to suit local taste and materials the artistic concepts of two schools of Indian sculpture. The first was the purely Indian school of Muttra (Mathura) in north India; the second, centred in Gandhara in the northwest, was strongly influenced by provincial Roman classicism. (See INDIAN ART.)

The large head with its prominent *usnisa* (cranial protuberance of wisdom which is one of the sacred marks of a Buddha) is characteristic of these early figures under central Asian influence, as is the simple and compact modeling of the body. Only in the formal and entirely unrealistic arrangement of the folds of the garment can be sensed a possible Chinese desire for linear patterns.

Central Asia appears to have supplied the earliest and the most important models for Chinese Buddhist sculpture. It is quite possible, however, that central and south China may have received other artistic influences from India by sea or by the southern overland route. Unfortunately, so little has survived that it is impossible to create any definite idea of the Southern school.

Of greater importance were the cave chapels of northern and western China carved out of the living rock in imitation of the Indian and central Asian practice. The earliest, dating back to the 4th century, are thought to have been destroyed by a particularly harsh Buddhist persecution between 444 and 452. In 460 work was commenced on a series of caves at Yiin Kang near the T'o-pa capital in Shensi and largely completed by 494 when the capital was moved south to Loyang in Honan province.

The 45-ft. colossal Buddha of cave 20 is typical of the early Yiin Kang style. The fullness of the body, the large head and prominent features are reminiscent of central Asian clay images. More difficult to explain is the curious manner of representing the drapery—one in which the folds were treated as flat, bisected bands which fork into points as they curve over the upper arm. This convention appeared on many contemporary clay and bronze figures and its strong linear feeling suggests the dependence of the sculptors on imported drawings of famous Buddhist images. Despite the stiff and rather heavy proportions, there is a feeling of monumentality and sincerity that gives it marked sculptural and religious significance (Plate VI).

The interior of cave 7 at Yiin Kang, hollowed out between 465 and 470, illustrates the elaborate complexity of these early Chinese cave chapels. Every inch of the walls and ceiling was covered with carved and painted figures reflecting a strange mixture of central Asian. Indian, Persian and classical elements (Plate VI). There is little here that is purely Chinese since the T'o-pas, having assimilated Chinese sculpture. were still trying to master the foreign religion and its polyglot art forms and were not yet in a position to express their own interpretation. But the moment was not far off, for even before the capital was moved to Loyang a native style of sculpture began to evolve at Yiin Kang.

Characteristics of the Native Style.—The first definitely Chinese style of Buddhist sculpture can be seen at its best at the caves of Lung Men, 10 mi. S. of the new capital. A standing Buddha and attendant Bodhisattvas in cave 3 illustrate this new style during the early years of the 6th century. The proportions of the head became longer and show the typical almond-shaped eyes, arched eyebrows and tight mouth. The bodies still retain some of the roundness of the earlier figures, but more and more attention is paid to the linear patterns of the scarves and drapery folds. Once again is seen the Chinese preference for line rather than plastic form when working on a large scale (Plate VI).

The direction taken by this new Chinese interpretation during the first quarter of the 6th century is illustrated by a small relief carving from Lung Men of Prince Siddhartha in meditation—the historical Buddha before he attained enlightenment. The plasticity and articulation of the body found in the art of central Asia has given way to a much flatter, less realistic portrayal. The skirt is arranged in a beautifully varied series of spade-shaped folds that allowed the sculptor full play for his love of linear design and serve as well to emphasize by contrast the charming simplicity of the seated figure (Plate VI).

The Chinese preference for line rather than plastic form is clearly shown in a small bronze shrine dated 518 portraying the Buddhas Sakyamuni and Prabhutaratna discoursing on the Law. This was a popular subject during the 5th and 6th centuries and was drawn from the *Lotus Sutra*, a text which provided the subject matter for much of the contemporary art. The attenuated deities are almost completely dematerialized, only the heads and hands having any real sense of plastic form. It is the linear harmony and movement in the drapery and the soaring flames of the mandola that express the spirituality of these deities far removed from the human world of flesh and blood (Plate VII).

Eighteen years later (536) a splendid gilt-bronze image of a standing Buddha was cast in Hopeh province. The right hand is raised in the *mudra* ("gesture"), signifying "have no fear," the left is extended palm down to indicate "charity." Again, there is no feeling of the physical body, which is lost beneath the voluminous folds of the robe. But in place of the low, tensely linear modeling of the earlier group, the drapery is treated in somewhat more sculpturesque fashion. Strongly contrasted areas of light and

shade, resulting from the greater depth of modeling, produce a dramatic sense of spiritual power augmented by the flaring triangular folds which impart a sense of weightlessness (Plate I).

This truly Chinese sculptural style reached its peak in the first half of the 6th century and continued with local modifications for another 30 years.

Northern Ch'i (550–577).—The states of eastern and western Wei were supplanted by Northern Ch'i and Northern Chou respectively. The former was ardently Buddhist and produced some of the greatest examples of Chinese religious art. The intense feeling of spiritual conviction, so well expressed by the tense linear style, became somewhat more relaxed by mid-century. A stone stele from Shansi province carved in 554 illustrates the softer, more rounded treatment of form with the drapery assuming somewhat gentler curves. The figures remained in low relief and there was still little attempt to endow them with human attributes of weight and articulation (Plate VII).

Shortly after 560, work was started on a new series of Buddhist caves at T'ien Lung Shan in Shansi province. The style of the earliest caves, for the most part a continuation of earlier Chinese traditions, shows in the high reliefs a growing interest in the problems of three-dimensional form. The seated Buddha of cave 2 is treated almost as a free-standing figure with the marked attenuation of earlier times giving way to greater solidarity and more normal proportions (Plate VII).

Although these craftsmen sought greater plasticity in the main figures, they reverted to an almost completely linear style in the low reliefs on the walls and ceiling as witnessed by the standing figure of a holy man from cave 2. The carving is sensitive and sure and the craftsman reveled in the contrast of flowing curves and jagged outline. A more successful example of this first phase of Chinese sculpture would be difficult to find (Plate VII).

Second Phase (Late 6th to Early 7th Centuries)

While T'ien Lung Shan was vacillating between the linear and plastic, other sculptors, most notably those in the area of Ting Chou and the caves of Hsiao T'ang Shan in Hopeh, were concentrating more directly on the problems of plastic representation.

The result of their efforts was a new style of sculpture, which can best perhaps be called the "second phase." The term "transitional style" is sometimes used to indicate the continuity between the first phase and the developed sculpture of the T'ang dynasty (618–906). However, this is apt to be misleading since this new style as it evolved in Northern Ch'i and the succeeding period of Sui had a definite character of its own.

A standing figure of the Buddha Amitabha, made in the Ting Chou region in 577, clearly illustrates the new tendency. The figure, stiffly frontal, is nevertheless free standing with a definite feeling of weight resulting from the three-dimensional treatment of the body. The thin drapery was handled with great restraint and the face became more human in its proportions (Plate VIII).

This new concept of sculpture was due in part to closer contact with India and in part to the growing popularity of a new Buddhist "Pure Land" sect, whose supreme deity was the Buddha Amitabha. The members of this group were not primarily concerned with the attainment of Nirvana (release from desire and sufiering) but with rebirth among the splendours of the Western Paradise which could be achieved merely by evoking the name of Amitabha. The ease of attainment and the immediacy of the gods had a strong appeal which was reflected in sculptural terms by a more realistic portrayal of the Buddhist deities.

Northern Chou (557–581).—This state ruled in northwest China. In 577 it conquered Northern Ch'i only to be overthrown itself four years later by the Sui dynasty. Although the rulers were anti-Buddhist some sacred sculpture was produced, the best in the vicinity of Sian (Sian Fu) in Shensi province. An imposing stone image of Kuanyin (Bodhisattva of Compassion) indicates that the Shensi sculptures even more than those of Hopeh were succumbing to Indian influence. The sensual modeling of the face, the marked S curve of the body in profile and the ornate array of scarves and jewelry were foreign to China. Vivid traces of paint added to the sumptuous, if not very spiritual, quality of the figure. Comparison with dated examples suggests that it was made between 570 and 580 (Plate VIII).

Sui Dynasty (589–618).—The unification of China in 589 was the chief contribution of the Sui dynasty. Although its emperors were ardent Buddhists, neither the quantity nor quality of the sculpture made under their rule was outstanding. The severely simple style of the second phase continued, at times combined with the more florid taste handed down from Northern Chou. There were a number of fine Sui stone carvings, but the most successful examples were the small gilt-bronze figures once part of household shrines.

One of the few to remain intact is a beautiful shrine representing the Western Paradise of the Pure Land sect cast in 593. In the centre Amitabha sits enthroned, flanked by attendant Bodhisattvas, disciples and acolytes. Above rise the jeweled trees that adorn this heavenly paradise and on the lowest level, protecting its approaches. stand guardians and lions. The style of these little figures is direct and simple and there still remains in the formality of the pose and in the facial expression the charm and spiritual conviction found in so many images of the early 6th century (Plate VIII).

T'ang Dynasty (618–906).—A popular revolt ended the oppression of Sui and founded one of the most brilliant eras in Chinese history. At its height, the T'ang empire stretched from Korea to the borders of India, from Indochina deep into Manchuria. Considering the varied influences encompassed by this vast area. it is not surprising that sculpture reached its peak at the same time. Strongly influenced by Indian concepts, the Chinese strove to translate into their own terms the sensuous warmth, freedom and mastery of plastic form achieved by the Gupta and early medieval craftsmen. Figures no longer stiff and strictly frontal but fully articulated, bend and pose in graceful imitation of foreign models. Sculptural art of T'ang is relaxed, worldly, at times self-conscious. entirely confident of its mastery of the faith and ability to express it in visual form.

Unfortunately the materials best suited to the vitality and realism of T'ang (wood, lacquer, clay and bronze) have, with a few notable exceptions, been destroyed by fire, persecution or warfare. Happily in Japan one can still see in images of the 7th and 8th centuries the reflected splendour of these great sculptures. (See Japanese Sculpture.) In China the most important relics which survived were small bronzes and stone figures carved for temples and cave chapels.

Third Phase (Mid-7th to Mid-8th Centuries)

Little sculpture appears to have been made during the first half of the 7th century but the latter half was highly productive. It was at this point that the third phase of Chinese sculpture began. What chiefly distinguished this new style was its dependence on India and the growing interest in the plastic possibilities of the sculptural medium.

The most spectacular monument of the 7th century was undoubtedly the group of stone colossuses at the Lung Men caves in Honan, financed by the empress Wu and completed in 675. The main figure, about 35 ft. high, portrayed Vairocana, the Cosmic Buddha. Badly damaged by erosion, the strength and vitality of the group is best illustrated by one of the attendants, a Vajrapani (thunderbolt-bearing guardian) who shows the growing realism of T'ang in its purposely exaggerated anatomy (Plate VIII).

It was during the last quarter of the 7th century and the early decades of the 8th century that the greatest works of T'ang sculpture were created. Craftsmen were active at many of the important cave sites, not only at Lung Men and T'ien Lung Shan in central China but also far to the west in Kansu at Tun Huang and Ping Ling Ssu.

Dating probably from the late 7th century is a stone carving of an 11-headed Kuanyin from the vicinity of Sian in Shensi. The introduction of Tantric Buddhism from India brought new iconographical features. among them many-headed deities such as this. The figure is more formally treated than the colossal guardian. as befits its high station in the pantheon. The stance is restrained, as was much of the Shensi sculpture, with only a slight feeling of

asymmetry. It is in the slender and human proportioning and the round, rather sensual modeling of the face that T'ang realism appears most noticeably (Plate IX).

On the western border of Kansu province at the caves of Tun Huang equally great sculpture was being produced in a different medium. The walls of the caves were eminently suited for painting but too soft for sculpture. However, a substitute nas found in the local mud which became highly durable when exposed to the sun. Ever since the 4th century, this site had been a flourishing centre for Buddhist art and during the T'ang dynasty it was a hive of activity.

One of the few Tun Huang pieces to have left China is the beautiful kneeling Bodhisattva from cave 143. Fashioned most probably in the early years of the 8th century, the full face and high headdress were typical of T'ang, but the marked slenderness of the figure suggests a style which, because of its distance from the cultural centres. clung to older traditions. The sensitive modeling of the body is emphasized by the elaborately painted designs on the skirt and scarves (Plate IX).

The high point of T'ang stone carving was reached in a series of standing figures (first half of the 8th century). The realization of plastic form and technical competence is shown by the magnificent torso of a Bodhisattva. The tropic sensuality of India appears in the twist of the body and the feeling of resilient flesh, in fine contrast to the metallic quality of the jewelry (Plate IX).

No monumental bronze images have survived, but their undoubted splendour is reflected on a small scale in such figures as the standing Kuanyin cast about 800. The gentle S curve of the body, the aloof countenance and the fluttering scarves create a sense of elegance and refinement rarely surpassed (Plate IX).

Fourth Phase (8th Century and After)

The fourth and last important phase of Chinese sculpture began around the middle of the 8th century and came to an inglorious end in the Ming dynasty. After 750 the quality of Buddhist sculpture began a slow decline and only rarely did it achieve the vitality and breadth of concept of the third phase.

The tendency of the deities to become heavier in proportion and their garments more elaborate and restless is apparent in a small gilt-bronze Kuanyin of the 9th or early 10th century. In much of late T'ang sculpture may be felt a desire on the part of the craftsmen to seek pictorial effects quite unsuited to the medium. Present also is a sense of gentleness. at times almost of sentimentality, which robs these images of their former strength and spiritual conviction (Plate X).

T'ang Tomb Figures.—The popularity of *ming ch'i* for the service of the dead became so great at this time that sumptuary laws were evoked to limit their size and number according to the status of the deceased. Pottery was the favoured material probably because molds could be used to produce quickly the various parts of the figures and animals. The best examples were assembled and finished with skilful care before being glazed or painted. A prancing horse at the Fogg Art museum, Cambridge, Mass., beautifully illustrates the ability of the T'ang craftsman to catch the vigour and tension of an animal in motion (Plate I). This po er to recognize and portray only essential features was present in the earliest sculpture of China, but only in this period did it achieve the freedom and vitality found in the tomb figurines. (See Pottery and Porcelain.)

Sung Dynasty (960–1279).—During most of the Sung era, north China was in the hands of non-Chinese invaders who swept in after the collapse of the T'ang empire and established the dynasties of Liao and Chin. The Sung rulers maintained an uneasy peace with the north until all of China fell before the Mongols.

Very little actual Sung sculpture has survived, but numerous examples made under the Liao and Chin remain. Wood and dried lacquer were the popular mediums and it is probable that most of the work was done either by Chinese or Chinese-trained artisans, for the style was a continuation of the complex, pictorial tendencies of Late T'ang. An exception to this general trend appears in a delightful guardian of dried lacquer. By wrapping lacquer-soaked cloths around a wood armature, the craftsman was able to achieve remarkable freedom of pose and gesture. Whether actually produced in Late T'ang or the Sung period, this figure retains much of the dramatic power and vitality of the 8th century. Motion in the twisting body is restrained and there is humour and great imagination in the exaggerated grimace (Plate X).

Many of the life-size wood figures produced in the north were fine examples of sculpture, as is witnessed by a seated Kuanyin of the 12th or early 13th century (Plate III). Generally portrayed in an elaborate and lavishly painted rocky setting, these images, despite their often self-conscious gentleness and femininity, had a definite sense of grandeur. Almost all were carved with great technical skill and attained a degree of realism that was characteristic of this era.

At this same time an archaistic revival was taking place in an attempt to recreate the manner of Northern Wei, Sui and Early T'ang. The results artistically were not satisfactory for the carving was generally dry and hard, failing in most cases to recapture the earlier spirit.

Yüan Dynasty (1280–1368).—The conquest of China by the Mongols had little immediate effect on the history of sculpture. With no art traditions of their own, the conquerors were better suited by temperament to destroy than to create. In general the sculptural taste of the 13th century with all its complexity and realism continued with little new being added.

A relief at the Chü Yung Kuan gate north of Peking in Hopeh province representing one of the four *Lokapalas* (guardian kings) was carved in 1345. The concept is dynamic and technically skilful, but at the same time rather overtheatrical. The violent emotion and wealth of minute detail covering the surface appear much better suited to the art of painting (Plate X).

Ming Dynasty (1368–1644).—Sculptural inspiration failed at this point. Vast numbers of religious figures were produced but because of internal weakness in the Buddhist faith the creative spirit was lacking and, with a few notable exceptions, the images were repetitive and without conviction. In a seated Kuanyin dated 1385 some of the spark of earlier Chin wood carving still lingered. But there was added a sense of oppressive power in the heavy roundness of the body and the brooding features. The impression is given that deities such as this were carved with the intent to impress rather than inspire (Plate X).

Rarely after the Ming dynasty was there found any significant Buddhist sculpture in China. Popular taste shifted to works on a smaller scale—jade, ivory or porcelain. The age of monumental carving was dead. (U. P. C.)

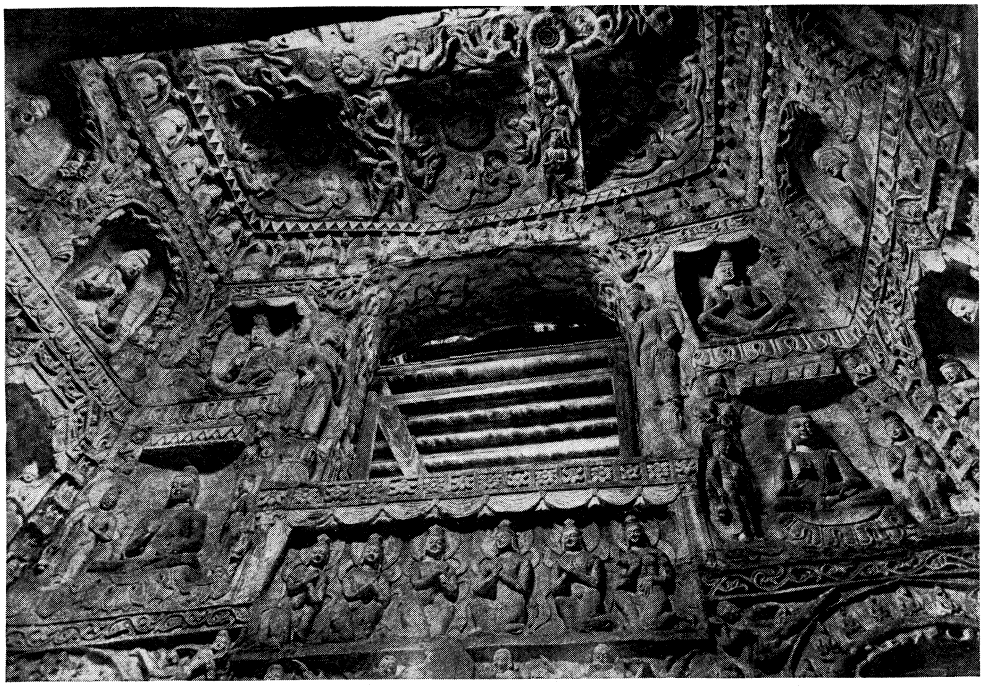
CHIhTESE SCULPTURE

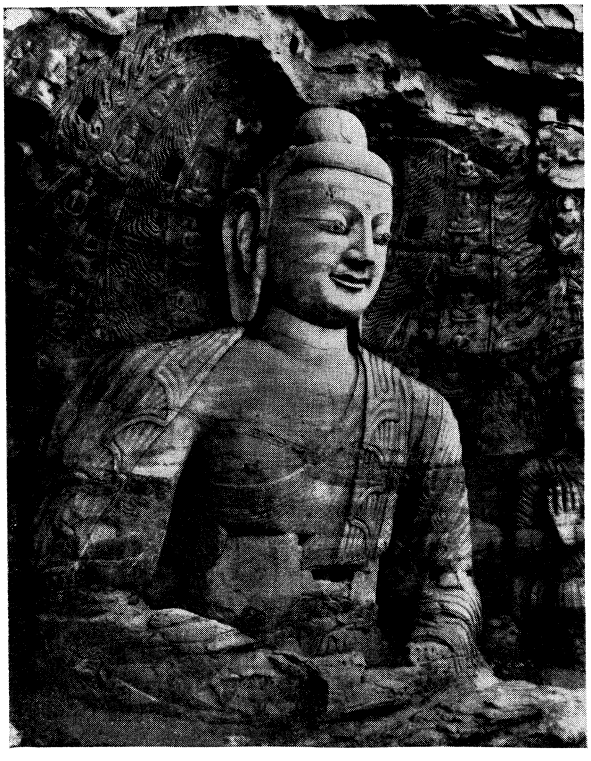


Interior of Cave 7, Yün Kang, Shensi province, late 5th century A.D. (Northern Wei Dynasty)

Stone relief of Prince Siddhartha in meditation, Lung Men caves, Honan province, early 6th century A.D. (Northern Wei Dynasty)

Interior of Cave 3, Lung Men, Honan province, early 6th century A.D. (Northern Wei Dynasty)

Colossal Buddha, Cave 20, Yun Kang, late 5th century A.D. (Northern Wei Dynasty)



BY COURTESY OF (TOP RIGHT, BOTTOM LEFT) JIMBUNKAGAKU KENKYUSHO; FROM 'YUN KANG" BY MIZUNO AND NAGAHIRO, (TOP LEFT) FOGG ART MUSEUM. HARVARD UNIVERSITY, WINTHROP BEQUEST, (BOTTOM RIGHT) FROM BUDDHIST MONUMENTS IN CHINA BY TOKIWA AND SEKINO

Stone Buddha and attendant Bodhisattvas, Cave 2, T'ien Lung Shan, Shansi province, 2nd half of the 6th century A.D. (Northern Ch'i Dynasty, A.D. 550–577)

Stone relief of a Buddhist disciple, Cave 2, T'ien Lung Shan, Shansi, 2nd half of the 6th century A.D. (Northern Ch'i Dynasty)

Bronze shrine of Sakyamuni and Prabhutaratna, dated A.D. 518. (Northern Wei Dynasty)

Stone Buddhist stele dated A.D. 554, Shansi province. (Northern Ch'i Dynasty)

CHINESE SCULPTURE

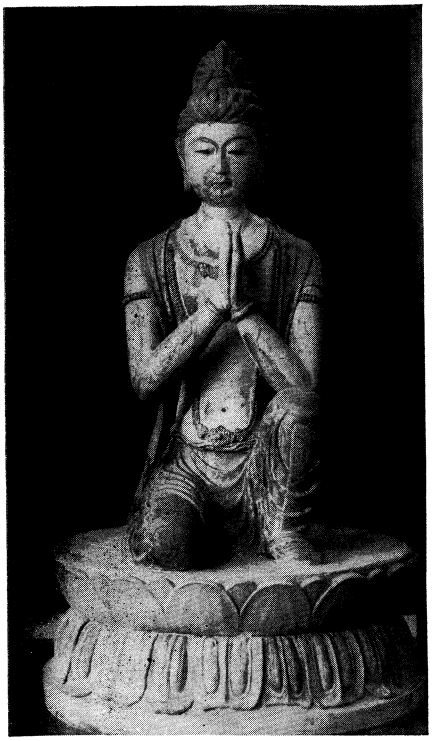
Left: Stone Kuanyin Bodhisattva, Shensi province, c. A.D. 570–580. (Northern Chou Dynasty, A.D. 557–581)

Right: Gilt bronze Amitabha shrine dated A.D. 593. (Sui Dynasty, A.D. 589–618)

Colossal stone guardian from the caves of Lung Men, A.D. 672–675. (T'ang Dynasty, 618–906)

Stone Buddha Amitabha dated A.D. 577. (Northern Ch'i Dynasty, A.D. 550–577)

BY COURTESY OF (TOP LEFT, TOP RIGHT) MUSEUM OF FINE ARTS, BOSTON (BOTTOM LEFT) FROM 'A STUDY OF THE BUDDHIST CAVE TEMPLES AT LUNG MÊN HONAN' BY N ZUNG AND NAGAHIRO. (BOTTOM RIGHT) ROYAL ONTARIO MUSEUM CANADA



Sun-baked mud Bodhisattva, Cave 143, Tun Huang, Kansu province, early 8th century A.D. (T'ang Dynasty, A.D. 618–906)

Gilt-bronze Kuanyin, 7th century A.D. (T'ang Dynasty)

Stone torso of a Bodhisattva, 8th century A.D. (T'ang Dynasty)

Stone relief of 11-headed Kuanyin, Sian, Shensi province, late 7th or early 8th century A.D. (T'ang Dynasty)

BY COURTESY OF (TOP LEFT. CENTS-) FOGG ART MUSEUM HARVARD UNIVERSITY. CENTRE WINTHROP BEQUEST, (RIGHT) MUSEUM OF FINE ARTS. BOSTON, (BOTTOM LEFT) THE SMITHSONIAN INSTITUTION. FREER GALLERY OF ART

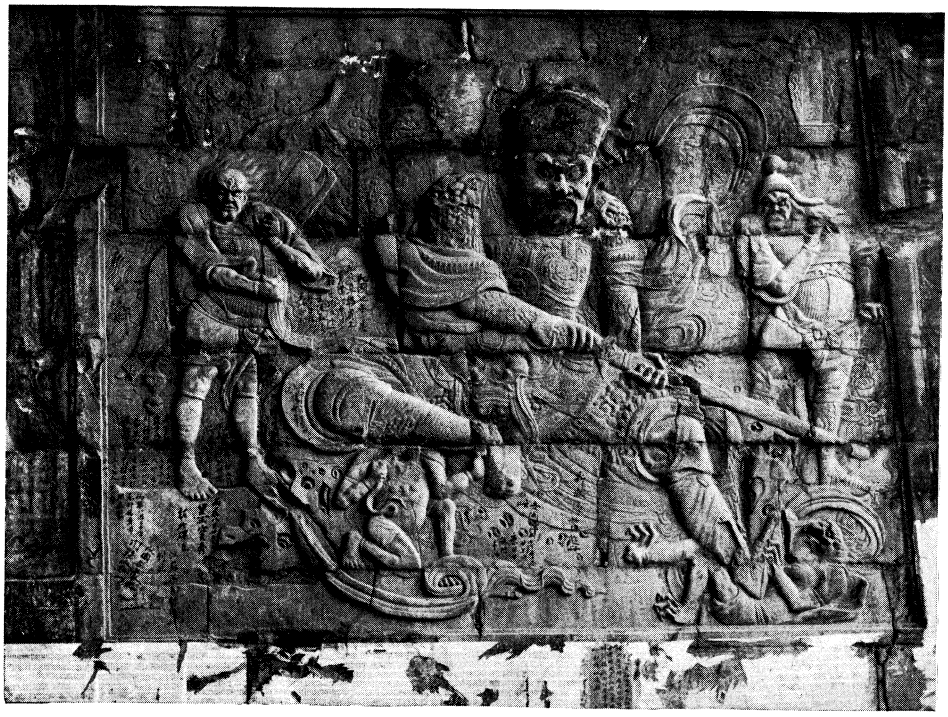
CHINESE SCULPTURE

Wooden seated figure of Kuanyin dated A.D. 1385. (Ming Dynasty)

Gilt-bronze Kuanyin, 9th–10th century A.D. (T'ang Dynasty)

Lacquer Buddhist temple-gate guardian, 9th–10th century A.D. (?)

Stone relief of a guardian king on the Chü Yung Kuan gate, Hopeh province, dated A.D. 1345. (Yüan Dynasty, A.D. 1280–1368)



CH'ING (TA CH'ING), last of the monarchical dynasties of China, was originally the name adopted in 1636 by the Manchus to designate their own regime in Manchuria. Under that name the Manchus rose to rule from 1644 to 1912 over what is generally known as the Chinese empire. Politically the Ch'ing, or Manchu, dynasty went through two phases, a long period of growing power and continued expansion lasting almost two centuries and then a century of decline. defeats and compromise. The whole period was marked by Chinese nationalistic movements that at times flared up into bitter rebellions and that finally in 1912 brought an end to Manchu rule.

The dynasty encompassed the reigns of ten emperors, listed below under their reign titles:

1. Shun-chih (1644–61) (given name Fu-lin; posthumous name Chang Huang-ti; temple name Shih-tsu).
2. K'ang-hsi (1661–1722) (Hsuan-yeh; Jen Huang-ti; Sheng-tsu).
3. Yung-cheng (1723–35) (Yin-chen; Hsien Huang-ti; Shih-tsung).
4. Ch'ien-lung (1736–96) (Hung-li; Ch'un Huang-ti; Kao-tsung).
5. Chia-ch'ing (1796–1820) (Yung-yen; Jui Huang-ti; Jen-tsung).
6. Tao-kuang (1821–51) (Min-ning; Ch'eng Huang-ti; Hsüan-tsung).
7. Hsien-feng (1851–62) (I-chu; Hsien Huang-ti; Wen-tsung).
8. T'ung-chih (1862–75) (Tsai-ch'un; I Huang-ti; Mu-tsung).
9. Kuang-hsu (1875–1908) (Tsai-t'ien; Ching Huang-ti; Te-tsung).
10. Hsuan-t'ung (1909–12) (P'u-i).

The rise of Manchu power began with the Japanese invasion of Korea in 1592. The emperor Wan-li of the Ming dynasty, who was suzerain and protector of Korea, sent an army in response to the appeal of the Korean king for assistance. Nurhachi, at the time a minor Jurchen chieftain in the vicinity of Mukden (Shen-yang), by provisioning the Chinese commissariat in Korea acquired a fortune in silver. an armament industry and a corps of followers. He organized his Jurchen tribesmen, a hunting people skilled in the tactics of encirclement and swift annihilating attack, into combat groups of archers on horseback and spent the years from 1599 to 1613 in subduing and organizing his neighbouring tribesmen. In 1616 Nurhachi assumed his first Chinese imperial title, after which he defeated a large Chinese army and took several border cities. Under his successor, Abahai, the Manchus continued their expansion, reaching the Amur river in the north, reducing Korea to a tributary kingdom and conquering the Mongols of Inner Mongolia. With increased food supplies available from Korea and with additional manpower and horses from the Mongols, the Manchus formed a military machine known as the Eight Banners. There were in fact 24 banners, or divisions, eight each of Manchus, Mongols and Chinese, the first two providing cavalrymen and the third technical artillery and firearms troops.

First Emperors. — Meanwhile in China a half-century of misrule, military defeats and rebellions culminated in 1644 in the capture of Peking by a Chinese rebel leader, Li Tzu-ch'eng. When the Ming emperor committed suicide. the Manchus, whose army was in readiness, seized the opportunity to chase the rebels out of Peking and take over the government. By adopting the Ming form of government and continuing to employ Ming officials, the Manchus pacified the Chinese populace. Chinese military leaders who surrendered were given ranks of nobility, and their troops were organized into the Lu-ying. or Army of the Green Standard, as distinguished from the Manchu Ch'i-ping, or Banner troops. Chinese armed resistance, however, lasted almost 40 years, until 1683, mhen an all-Chinese naval force serving the Manchu emperor forced the surrender of the loyalists on Formosa.

The emperor, K'ang-hsi, then turned his attention to the northern frontiers. For decades the Russians had been exploring along the Amur river and conducting raids into Manchuria. An expedition of Manchu archers, Chinese artillerymen and sailors dispatched from Peking in 1684 forced the Russians two years later to abandon their fort at Albazin. In 1689 a treaty was concluded with Russia at Nerchinsk to demarcate the boundary of Manchuria at the north from the Argun river to the northern tip of Sakhalin Island. In 1688, when the then independent Mongol princes were defeated by the Dzungars from the west and sought help from K'ang-hsi, the emperor gave them shelter, defeated the Dzungars in three expeditions and restored the Mongol princes to their realms as vassals. Thus the empire was extended to include Outer Mongolia. In 1720, by forcing out of Tibet the Dzungars who had conquered the country in 1717, the Manchus added Tibet to their domains. Finally Dzungaria itself and Turkestan were conquered (1755–59), adding to the Ch'ing empire an area roughly three times the size of France. In 1792 an expedition was sent to Tibet to fight Nepalese invaders, and Nepal as a result became the last state to accept tributary status under the Ch'ing. By this time the Manchus had wrought an empire that stretched, east and west, from Sakhalin Island to the Ili river and south to the mountain rampart that guards India. In 1912, even after 70 years of foreign encroachment, the territory inherited by the Chinese republic from the Manchus was still three times as large as that governed by the Ming dynasty.

The long period of Manchu expansion was also one of comparative peace and prosperity in China. Under three distinguished emperors who reigned during the more than 13 decades of the K'ang-hsi (1661–1722), Yung-cheng (1723–35) and Ch'ien-lung (*q.v.*; 1736–96) periods, China's population more than doubled. Commerce thrived and handicraft industry prospered. A vigorous trade in tea, silk and porcelain for the European market was conducted by land with Russia and by sea with the European maritime nations, whose traders flocked to Canton. Roman Catholic missionaries were tolerated, and some were even employed as astronomers and artists. The arts of painting, porcelain manufacture and printing flourished in metropolitan centres, particularly Yangchow, Chingtechen, Soochow and Hangchow. In the intellectual realm, scientific methods of philology were independently developed and applied to the criticism of classical texts.

Decline and Fall. — By the 19th century, however, the Manchu army, whose training had been neglected, had lost its earlier fighting quality. The emperors who ruled after Ch'ien-lung, though still conscientious in the performance of their duties, were weak. Internally, population pressure and concentration of land ownership caused increasing unemployment and the growth of agrarian tenancy. Unrest among the people became commoner and more protracted. Banner troops were sent out only as bodyguards at field headquarters of Manchu commanders, and the Chinese army of the Green Standard and, later, gentry-led volunteers came to form the main body of combat troops.

The decline in Manchu power took place at a period when Europe was going through the French Revolution and the Napoleonic Wars, epochal changes from which England emerged as the world's dominant maritime and industrial power. The western nations were making rapid progress not only in economy and technology but also in economic, political and social theory. The 19th century, the great period of Protestant Christian evangelism, saw the development of other evangelical movements as well. Nationalism, capitalism, imperialism, colonialism and socialism were carried around the world along the routes of European traders. The Ch'ing government could meet them with nothing but an uncompromisingly traditionalist chauvinism. Each foreign war fought by the Manchus in the 19th century — the Opium War (1839–42), the Anglo-French War (1856–60), the French War (1884), the Japanese War (1894–95) and the Boxer uprising (1900) — resulted in humiliating defeat for China, and was followed by a short-lived effort at reform and then a relapse into lethargy. The cumulative effect of these defeats was such that the Manchus lost confidence in themselves and the loyalty or consent of the Chinese they governed. In 1912, faced with a rising tide of Chinese nationalism, they gave up, and the long history of imperial China came to an end.

Causes of the Fall. — The course of military conquest and decline, however, is only a partial explanation, symptomatic of more deep-seated causes, of the rise and fall of the Ch'ing. First of all, it mas only through the support of the Chinese gentry bureaucracy that the Manchus, never more than a small fraction of 1% of the Chinese in numbers, were able to rule over China at all. As a result, there was throughout the period a finely balanced interdependence between Manchu military rulers and Chinese administrators.

For 2,000 years the primary function of the Chinese bureaucracy had been to collect taxes for the support of the emperor

and his army and public works. The additional duties of administering justice and conducting civil service examinations worked toward the same end, for the first principle of the law was the protection of the emperor from treason or disrespect, and one important purpose of the examination system was the elimination of potential nonconformists and rebels. In addition. the selection of officials by examination produced, as a by-product, a political and social stratum of degree holders who did not hold office but who. since they were on terms of social equality with their officeholding peers, served as spokesmen for local interests in normal dealings with the imperial administration. The emperor acted as final arbiter of the system in the settlement of disputes between the civil and the military and between the bureaucrats and the common people; he was also the final point of appeal in cases of injustice or oppression of any kind. During the Ming, few of the emperors gave the bureaucrats complete trust. Most of the time an emperor would select eunuchs to draft orders, conduct intelligence work and act as imperial agents in supervising a provincial administration or even an army in the field. The conflict between bureaucrats and eunuchs led to intrigues and several times to bloodshed, as in the 1620s.

The Manchus, on the other hand, had no use for eunuchs except for menial duties, for the emperor owned several thousand families of bond servants from which able persons could be selected to occupy the essential offices that the Ming eunuchs had held. This mas one reason why the bureaucrats, who had been harassed by the eunuchs, found it to their advantage to serve under the Manchus.

A more important reason, however, is to be found in bureapcratic control of taxation. An official serving without interruption in a series of offices involving the collection of taxes could expect in the natural course of events to amass a fortune. A district magistrate, after he had remitted his quota to the provincial treasury and had shared the surtax with his superiors, was permitted to retain the remainder as his share. His superiors, in their turn, had to satisfy their own superiors, and so on, up to the highest ministers and the emperor himself. The system was one under which the bureaucrats came to regard officeholding as an opportunity to amass as much wealth as possible without being caught.

Under scrupulous emperors corruption could be kept under control, but during two periods of the Ch'ing dynasty, avarice at or near the top resulted in notoriously widespread corruption throughout officialdom. The first period came between 1780 and 1798, when the Ch'ien-lung emperor's favourite, Ho-shen, was in power. The burden of excessive bribes demanded from high provincial officials was passed, step by step, to the people; the result was a demoralized government and discontent among the populace. Even after Ho-shen was removed in 1799, a general rebellion of religious sects in the northern provinces and piracy on the southeast coast necessitated more than ten years of continuous warfare at tremendous cost not only to the treasury but to the vitality of the Manchu regime itself.

The second period of extreme corruption came during the time of the empress dowager Tz'u-hsi, who virtually ruled the country during the reigns of T'ung-chih and Kuang-hsii. During her ascendancy, because of the peculiar difficulties of feminine rule in China, the eunuchs regained some small portion of political influence. Tz'u-hsi's personal demands, in comparison with those of Ho-shen, were not excessive, but the cumulative effect of four decades of venality under her rule proved disastrous to China at the very time that efforts to westernize required an honest administration. Since an "able" bureaucrat of the later part of the Ch'ing period was one who could satisfy his superiors' demands, hold office for a term without causing loud complaint from the people, and yet manage to make a profit, all the modern enterprises under direct or indirect control of the officials failed to develop as they should have; capital and profits were drained off through the manipulations of the men assigned to their management. In sharp contrast, the efficient management of imperial offices by foreigners who had been employed in accordance with treaty provisions—offices such as the maritime customs and the postal service—should have made the officials realize the need for change in the administration; yet venal practices continued unmodified to the last day of the dynasty. The conclusion has been drawn by some that by suppressing the T'ai P'ing, Nien. Muslim and other rebellions in the middle of the 19th century, Chinese officialdom maintained the tottering Manchu regime beyond its natural span and exacted as its reward a larger share in both the management and the profits of the empire.

It must be noted that from the very beginning of the Ch'ing period some Chinese officials refused to compromise their national principles. Some committed suicide when the Manchus triumphed; others joined the Buddhist priesthood. A large number took up arms and fought the Manchus, and in 1683, when the last armed Chinese resistance on Formosa ended, many escaped to the South Seas. Through secret organizations they managed to transmit the old Chinese nationalism to future generations. Known collectively in English as the "Triads," the secret societies flourished in Singapore, Java and other areas, as well as in south China, and were partially responsible for the T'ai P'ing rebellion, which lasted from 1850 to 1864, and for many local uprisings in Formosa and in several mainland areas between 1721 and 1912. The Manchu emperors were aware of this situation, and in the 18th century conducted a bloody inquisition. The secret societies in foreign lands and in the concessions of Shanghai and other treaty ports, however, were out of their reach. When Sun Yat-sen began preaching nationalism in the 1890s and plotting local rebellions, financial and organizational aid came largely from the overseas members of these old anti-Manchu secret societies.

Protestant missionaries of the 19th century unwittingly contributed to the downfall of the Manchus by their translation of the Bible into colloquial Chinese, by publications giving views on social, economic and political reforms, and by giving free education to the poor. The reformers of 1898 based their program partly on knowledge of the west gained through missionary books and periodicals. After 1900 missionary schools became the models for the government's new educational system and provided an impetus for sending students abroad to study. However, the freedom of thought and discussion in foreign lands, especially in Japan, gave some of the students, most of whom came from the gentry-official class, a chance to develop ideas of nationalism, constitutional government and democracy. Significantly, it was a missionary-educated thinker, Sun Yat-sen, who provided leadership for this group of awakened Chinese youth as well as for the members of the secret societies, and who became the nemesis of the Manchu dynasty.

While Sun Yat-sen advocated nationalism and democracy, the officials. even the more progressive, were willing to try at most a constitutional monarchy. Yet after the revolution of 1911–12 forced the Manchus to abdicate, the bureaucrats, like their predecessors in 1644, changed loyalties without hesitation, trimmed off their pigtails and became avowed republicans. The Manchus were gone, but new masters with military power needed tax collectors and apologists, too. See also CHINA: History; MANCHUS.

CHINGFORD, a municipal borough (1938) and residential area in the Epping parliamentary division of Essex, Eng., 16 mi. N.E. of London by road. Pop. (1961) 45,777. It lies between the river Lea and the western outskirts of Epping forest. To the east flows the river Ching.

It is mentioned in Domesday Book as Cinghefort. The church of All Saints has Early English and Perpendicular remains. Queen Elizabeth I's half-timbered hunting lodge at Dannet's Hill is an Epping forest natural history museum.

CHINGLEPUT, a town and district of Madras state, India. The town is 37 mi. S.S.W. of Madras city. Pop. (1951) 22,667, (1959 est.) 27,000. Its name means "town of red lotuses." The most prominent building is the fort, used since 1887 as a trades school for juvenile offenders. It was built by the king of Vijayanagar (*q.v.*) in the late 16th century after the decline of that empire, but about 1640 it fell to the Muslim sultanate of Golconda. It was captured in 1751 with French support by Chanda Sahib, son-in-law of the nawab of Carnatic (*q.v.*), but was taken by Robert Clive (*q.v.*) a year later. The town is on the main road and Southern railway line from Madras to Tiruchirapalli. A branch runs northwest to join the Madras-Bangalore line at Arakonam.

CHINGLEPUT DISTRICT surrounds, but excludes, the city of Madras. Pop. (1961) 2,193,721. Area 3,065 sq.mi. District headquarters are at Saidapet, a southern suburb of Madras. The district has mainly loamy soils, with red sandy ground in the northwest and gray sands along the coastal strip. In the south is the Palar river, dry part of the year; irrigation depends largely on tanks fed by the three months' cold-weather rain. The main crop is paddy, followed by millets and some peanuts. Chromepet, 16 mi. S.W. of central Madras, owes its existence to the chrome tanning industry and is the seat of the Madras Institute of Technology.

The district's historic sites include Kancheepuram (*q.v.*), Mamallapuram (Mahabalipuram) and St. Thomas's Mount (see MADRAS). Mamallapuram (or "Seven Pagodas") on the coast south of Madras was founded by the Hindu Pallava king Narasimha-varman (d. A.D. 674). Surviving monuments include the famous raths or monolithic shrines and the huge sculptured relief "The Descent of the Ganges from the Himalaya," with life-size figures of men and animals (including elephants). The *raths* (*rath,* "car" or "chariot") are a group of eight Shaivite shrines, each cut from a huge boulder. The largest is about 40 ft. high.

Later monuments at Mamallapuram include three masonry temples built in the early 8th century by Narasimha's successor Rajasimha, of which the most notable is the Shore temple.

(G. KN.)

CHINGOLA, the civil and government township associated with the Nchanga copper mine, Western province, Northern Rhodesia. Federation of Rhodesia and Nyasaland. The mine maintains its own purely residential tonnship, while Chingola provides government, educational. industrial and trading services for both townships; recreational facilities are abundantly provided by the mine township. Pop. (1956) 4,640 non-Africans and employed Africans. Begun in 1943, Chingola, 5,000 ft. above sea level in densely wooded country, became a municipality in 1957. It is linked by a branch line to Rhodesia railways and by macadamized roads to all towns of the copper belt.

CHINGPAW, a Tibeto-Burman people and language in eastern Assam (India), northern Burma and southwestern Yünnan (China). The closest affinities of the language are to Burmese, Bodo-Naga and Kuki-Chin. The major dialects in Burma lie largely within the Kachin state, as follows: Tsasen (Hukawng valley westward into Assam, where it is known as Singpho). Duleng (vicinity of Putao), Hkahku (Sumprabum and the Triangle), Htingnai (west of Mogaung) and Gauri (Bhamo and the northern portion of the former Shan state). Chingpaw speakers, originally hill folk, have now borne the language into the towns and cities of northern Burma, and it may be the medium of instruction in schools up to the third standard (grade). In recent times it has become common practice to equate Chingpaw with the Burmese appellation Kachin (*q.v.*), although the latter subsumes not only Chingpaw speakers but those whose languages are the more distantly cognate Maru (Maru, Hpon, Atsi, Lashi, Maingtha), Nung and Lisu.

Hill-dwelling Chingpaw practise rotational cultivation, with double cropping of rice, millet, corn (maize), yams, beans and pumpkins. Under Chinese and Shan influence some have taken up wet-rice agriculture. Skilful weavers, the women retain colourful local costumes, while the men tend to adopt the dress of the lo—land. A Chingpaw village may comprise between 10 and 20 houses, several such villages, each under a headman, forming a larger polity under a chief. In autocratic villages the chief is the youngest son within the founding patrilineage; in democratic communities he may be a self-made leader. In offerings to the spirits, it is only in the former that the major religious festival can be performed, but all villages may have priests and mediums.

CHIN HILLS, a constituent hill group of the mountain arc stretching from the Arakan Yoma northward to the Patkai hills, between Burma and India. This mountain arc, compressed at either end, has advanced farthest toward the west in the centre where the long parallel folds are most numerous and the arc broadest. The Chin hills form the highest part of this central stretch. They consist simply of a succession of long narrow troughs and ridges, from 5,000 to 9,000 ft. high, with little flat land either in the valley bottoms or on the ridge tops. There is a marked contrast beta-een the humid tropical conditions of the deeply cut valleys and the cooler temperatures of the ridges. This contrast is reflected in the vegetation. Above 3,000 ft. the tropical forest gives way to oak and pine woods which in turn give way above 7.000 ft. to the rhododendron. **A** migratory form of agriculture, the *taungya* system, is practised in these hillside moods where the greater part of the population is centred. Clearings are made and the wood burned for fertilizer. Such clearings are cultivated for two or three years and then abandoned. Bamboo, bracken and elephant grass then spring up with such vigour that natural reafforestation is impossible. The main crop cultivated by this method is jowar millet, contrasting with rice in the plains of Lower Burma. Some rice is grown in the Chin hills on the lower slopes on terraces constructed with the help of felled timber.

The north-south trend lines of Indochina as a whole have permitted the populating of the region with Mongoloid peoples coming donn from the north and have hindered east-west movement of both peoples and culture so that the valleys are peculiarly isolated. The Arakan Yoma-Patkai mountain arc exemplifies these features. It constitutes a frontier zone between Indian and Burmese cultures and its hill tribes remained independent of British administration until the close of the 19th century. The Chin hills. lying on the Irrawaddy side of the watershed, were eventually occupied to prevent raids by the hill folk on the plains of Burma. They were then administered primarily with the object of preserving the peace and of building up a sound government on the basis of the tribal system. The substitution of peaceful agriculture for raiding produced changes in the distribution of population; the defensive hill sites were deserted and population became concentrated on the more easily cultivable land. The whole of the southern part of the Arakan Yoma-Patkai mountain arc from the Chin hills southward into the Arakan Yoma is occupied by the Chin peoples who belong to the southern Mongoloid race group and are linguistically a branch of the Tibeto-Burmans. This was recognized by the creation of the Chin Hills special division when Burma became independent in 1948. The division comprises the old Chin hills proper (10,377 sq.mi.; pop., 1941, 186,405) and also the former Arakan hill tracts.

(P. M. R.; L. D. S.)

CHIN HILLS SPECIAL DIVISION. Under the constitution for the Union of Burma drawn up in 1947 provision was made for the recognition of the special interest of the Chin peoples (*see* CHIN) living in the tangle of forested hills between India and Burma. Lacking the cohesion of the Shans, Kachins and Karens, now forming autonomous states within the Union of Burma, the Chins do not form a state, but their territory has been constituted a special division and their interests are the concern of the minister for Chin affairs in the cabinet. The division comprises broadly the Chin hills (*q.v.*) proper, now known as the Northern Chin Hills district, and the former Arakan hill tracts. previously part of Arakan and now known as the Southern Chin Hills district, together with the former Pakokku Hill tracts. Total area 13.903 sq.mi. Some parts of the division, including Mt. Victoria (10,018 ft.), rise to more than 8,000 ft. The main cen-

tres are Falam and Tiddim in the north and Paletwa in the south. Efforts are being made to bring the division into closer touch with Burma proper by the construction of roads and there are all-weather airstrips at Kalemyo and Kyauktu. The total population in 1956 was estimated at 230,115 living in 11,314 villages, but only 265 of these villages had over 50 houses so that the provision of 275 schools was a creditable performance. (L. D. S.)

CH'IN-HUANG-TAO (CHINWANGTAO), former treaty port on the shores of the Gulf of Liaotung in Hopeh province, northeast China. was opened to foreign trade in 1901. Pop. (1953 census) 186.800. The port has an artificial harbour that was developed by the Kailan mining administration for the export of coal from the Kailan mines, 60–100 mi. W. of the port. Export trade originated almost entirely from the coal field and comprised not only coal but also coke, firebrick and cement manufactured at T'angshan, the industrial town built on the coal field. Ch'in-huang-tao had the largest glass factory in China. As the only ice-free port of north China, it developed an important transit trade by rail for Tientsin and south Manchuria, since the town is on the main rail line between Manchuria and north China. After 1931 the port became an important centre of Japanese smuggling into north China. Guarded by the U.S. marines in 1945–46, the port was undamaged at the end of World War II.

Under the Chinese Communists the city developed considerable light and handicraft industry after 1952. The Kailan mines were confiscated and their production notably increased, so that by 1958 they were the largest coal producer in the Chinese Communist industrial program, with further production increase planned. Coal mining in 1958 was carried on at other points nearer the port, notably at Shih-men-chai, to the north, since the region produces very good bituminous coal. (J. E. SR.)

CHINNAMP'O is the chief port of northwestern Korea, 34 mi. W. of P'yongyang, on the estuary of the Taedong river Floating docks overcome the handicap of the high tides of the shallow Yellow sea. Heavy industries, notably a copper and gold refinery, and light industries. such as rice milling, were developed during the days of Japanese control (1910–45). North of the city along the coast are some solar-evaporation salt pans. Eight miles east of the city on the Taegon estuary is Kyomipo, an iron and steel centre. The population of Chinnamp'o was estimated at 75,000 in 1958. (S. MCC.)

CHINON, a town of western France, in the *département* of Indre-et-Loire (*q.v.*), is situated on the banks. of the Vienne, 46 km. (28.6 mi.) S.S.W. of Tours by road. Pop. (1954) 4,602. It lies under a rocky height crowned by ruins of the famous castle, its narrow, winding streets containing many turreted houses of the 15th and 16th centuries. Of its oldest church, the Romanesque St. Mexme, only the façade and nave are left. The church of St. Stephen dates from the 15th century, that of St. Maurice from the 12th, 15th and 16th centuries.

The castle, which has undergone considerable modern restoration, consists of three separate strongholds. That to the east, the Chbteau de St. Georges, built by Henry II of England, has almost vanished, only the foundation of the outer wall remaining. The Chbteau du Milieu (11th to 15th centuries) includes the keep, the Pavillon de l'Horloge and the Grand Logis, where the first meeting between Joan of Arc and Charles VII took place. Of the Chbteau du Coudray, which is separated by a moat from the Chbteau du Milieu, the chief remains are the Tour du Moulin (10th century) and two later towers. A statue of Rabelais, who was born in the vicinity of the town, stands on the river quay.

Chinon is on a secondary railway from Tours to La Roche-sur-Yon. Cooperage is the chief industry, but there is a nuclear power reactor nearby.

Chinon (Caïno) existed before the Roman occupation of Gaul, and was from early times an important fortress. It was occupied by the Visigoths, and subsequently, after forming part of the royal domain, came to the counts of Touraine, the counts of Anjou, and then to Henry II of England. It was won back to France by Philip Augustus in 1204, after a year's siege. In World War II Chinon was occupied by the Germans from June 1940 until Aug. 1944.

CHINOOK, an important American Indian people who held the Columbia river and adjacent territory from the mouth to The Dalles. Their culture was a localized form of the Northwest Coast type, with plank houses, good canoes, trade, slavery and potlatch distributions of property, but without secret societies or totemic art. The language is distinctive, and a selection of words from it, much simplified phonetically and with the grammar obliterated, forms the basis of the Chinook jargon. This trade language contains also French, English, Nootka and other Indian ingredients and prevails from California to Alaska. The Chinook were organized by settlements rather than tribes; some of their divisions are known as Clatsop, Wasco and Wishram. Estimated at 16,000 in 1805, they decreased (from disease) to a twentieth in the next 50 years and in the early 1960s numbered perhaps 200–300, known under different names on several reservations containing ethnic mixtures.

CHINOOK, the name given to a warm dry wind on the east side of the Rocky mountains in North America blowing from a westerly direction, primarily in winter. Winds of the same type occur in other parts of the world, and are known generally as foehn winds. The word chinook was first used at Astoria, Ore., to represent a warm moist wind blowing off the Pacific ocean, because it came from the direction of the Chinook camp near the mouth of the Columbia river. The modern chinook is presumably the same Pacific air after some of its moisture has condensed over the west slopes of the mountains. This makes the air warmer and drier as it descends the east slope of the Rockies, where it undergoes compressive heating and drying. When the chinook reaches the western Great Plains of the United States or Canada in winter, it often replaces the cold, dry continental air normally prevailing there. It is called "the snow eater" because it causes a rapid disappearance of snow on the ground by melting and evaporation. A chinook is likely to occur when a strong low-pressure area farther north is moving eastward. Sometimes the frontal boundary betueen chinook and continental air masses oscillates due to minor disturbances traveling along the front. An example of remarkably rapid temperature changes from this cause occurred on Jan. 22, 1943, at Rapid City. S.D., on the east side of the Black hills Morning temperatures shifted back and forth between 10° to 15° F. and 55° F. several times. the most rapid change being a 44° temperature rise in only 15 min. *See* also WIND.

(E. M. Bs.)

CHINQUAPIN, the name given to several North American shrubs or small trees belonging to the genus Castanea of the Fagaceae (*q.v.;* beech family). The most important of these is C. pumila, a shrub or small tree found chiefly in dry soils from New Jersey to northern Florida and westward to southwestern Missouri and eastern Texas. In Arkansas and Texas, where it attains its best development, it occasionally reaches a height of 45 ft. and a diameter of 30 in. It is closely related to the chestnut, C. *dentata,* from which it differs in its much smaller leaves, which are white-woolly beneath, and its usually solitary nut, which like that of the chestnut is very sweet and edible.

On the Pacific slope the name chinquapin is given to two species of Castanopsis, a genus closely allied to Castanea. Golden chinquapin (Castanopsis *chrysophylla*), found from southern Washington to southern California, is a magnificent tree which occasionally attains a height of 150 ft. and a trunk diameter of 8 ft. The lance-shaped evergreen leaves, three to five inches long, are clothed beneath with minute golden-yellow persistent scales. The fruit is similar to that of the chestnut and contains one or two hard-shelled nuts with a sweet kernel. The wood is reddish-brown, straight grained, easily worked and takes an excellent finish, yet it is not extensively utilized. The bark, although devoid of tannin, is sometimes used to adulterate that of the tanoak (*Lithocarpus* densiflorus), with which it is often associated in the forest. Bush chinquapin (C. *sempervirens*) is a small spreading shrub of dry mountain slopes in California. Some authorities re-

gard it as a variety of the golden chinquapin. (E. S. HR.)

CHINTZ, a word derived from the Hindu chint, "spotted or variegated." This name was given to a kind of stained or painted calico produced in India. It is now applied to a highly glazed printed calico, commonly made in several colours on a light ground and used for hangings, covering furniture, etc.

CHIOGGIA, a town in the Veneto region of Italy, in the province of Venezia, is situated 24.1 km. (15 mi.) S. of Venice, of which it is a suffragan diocese. Pop. (1957 est., comm.) 48,902. The town rises on a lagoon on one of the islands along the coast of the Veneto and is crossed by three parallel canals. It is joined to the mainland by a bridge and by a railway from the Polesine which ends at Rovigo, 37 km. (23 mi.) away, and is connected to Venice by water and by road.

The 11th-century cathedral, rebuilt in the pseudoclassical style to the design of Baldassare Longhena, contains paintings of the Venetian school. S. Martino has a valuable polyptych by Paolo Veneziano (1349) and S. Domenico (13th century, renovated in the 18th century) contains the "St. Paul" of Vittore Carpaccio. Also of note are the column of the charming Piazzetta Vigo with its Byzantine capital and the episcopal square with its 18th-century statues. The town is the birthplace of the painter Ambrogio Marinetti (1710–96), called Il Chioggiotto.

The main commercial activity is fishing and the fishing port is one of the largest in Italy. Through the port, also, Istrian stone is imported and products of the kilns of the Polesine and herbs cultivated in the vicinity are exported. There is a naval construction yard.

The town is perhaps the Fossa Clodia mentioned by Pliny. Destroyed by the invading barbarians, it became part of the duchy of Venice and reproduced in the commune the duchy's methods of administration. In 1797 invading French troops made Chioggia a free port in competition with Venice.

The Naval War **of Chioggia.**—This war (1378–81), so called from the decisive action at Chioggia, marked the last phase of the economic rivalry between the two great maritime republics of Genoa and Venice (*qq.v.*). Genoa, backed by the king of Hungary and Francesco da Carrara, lord of Padua, had defeated the Venetian army under Vettor (Vittorio) Pisani at the battle of Pula. The Genoese then sent into the Adriatic 50 galleys and other ships under Adm. Pietro Doria. They took Chioggia and began to harass Venice from there, while Carrara did the same from the mainland. Barriers were thrown across the Venetian canals and Pisani, made commander of the Venetian fleet, manned every vessel in the arsenal with pressed men. After several encounters at the entrance of the port of Chioggia, the Genoese made the mistake of setting fire to a Venetian sailing ship which sank at the mouth of a canal, trapping the Genoese galleys. The Venetians themselves then sank a number of other ships loaded with stones in the canal, making the blockade more thorough. Carlo Zeno, recalled from his mission of harassing Genoa's colonies in the east, then arrived with a substantial reinforcement of 15 galleys. The Genoese, tormented by hunger, drove the inhabitants of Chioggia from the town in order to conserve supplies. But even so, food was insufficient. Doria had died in battle, and his successor treated with the Venetians, who demanded unconditional surrender. On June 24, 1380, 4,000 men, reduced to skeletons by hunger and hardship, the miserable remnant of what had been the most powerful marine force in the Mediterranean, gave themselves up. The war dragged on through 1380 and ended on May 20, 1381, with the peace of Turin, brought about by the mediation of Amadeo VI of Savoy.

See I. Tiozzo, *Chioggia* (1926); *V.* Lazzarini, ***Due** documenti della guerra di Chioggia* (1864). (M. T. A. N.)

CHIOS (Gr. KHIOS; Ital. SCIO), an island of Greece on the west coast of Asia Minor, about 30 mi. long from north to south and from 8 to 15 mi. broad. Pop. (1951) 64,672. The north and west are mountainous with steep coasts; south and east there is fertile, open country. The capital, Chios, on the east coast. has a small, safe harbour. Pop. (1951) 24,361. The climate is healthy. Oranges, olives and even palms grow freely and the figs were famous in antiquity, but wine and gum mastic have always been the principal products. The latter, collected from a wild shrub, gives flavour and name to a popular Greek liqueur (mastikha). Antimony, calamine and marble are worked; there is a tanning industry and considerable coasting trade. The island, which is of volcanic origin, has no real water course, and its irrigation is entirely artificial. Severe earthquakes have occurred, particularly in 17 B.C. and 1881.

The ancient city lies beneath the modern and little is known about it. Six miles to the north is Dascalopetra, or "Homer's Seat," a rock-cut shrine of Cybele. At Ayion Gala in the northwest the British excavated an Early Bronze Age cave. In the south both British and Greek archaeologists have explored the important temple of Apollo Phanaios (at Fana), and at Emporio British excavations (1951–55) uncovered an Early Iron Age fortified town, an archaic town and sanctuary and a late Roman basilica and fortress. At the centre of the island is the monastery of Nea Moni, founded 1042–56, with fine 11th-century Byzantine mosaics. In the town there is an impressive medieval castro.

Homer was reputed to have lived in Chios, and it was the home of the school of bards, the Homeridae. Glaucus of Chios was supposed to have invented iron welding in the 6th century B.C. and Dexamenos of Chios was a noted gem engraver of the late 5th century. The island's coins are characterized by the sphinx and wine jar. Of the antiquities which have left the island the most famous are the head in the style of Praxiteles now in the Boston Museum of Fine Arts and the Hellenistic bronze horses now surmounting the façade of St. Mark's, Venice, which were removed in the 5th century A.D. from Chios to Constantinople and thence to Venice in 1204.

Mycenaean settlement on Chios may be referred to the Greek legends about Oinopion. It was resettled by Abantes from Euboea, and in the 8th century B.C. was admitted to the Panionic league.

The Chian colony at Maronea on the coast of Thrace reinforced the wine trade of the mother city. Like Miletus, Chios in 546 submitted to Cyrus I of Persia as eagerly as Phocaea resisted him. When Miletus revolted, 100 Chian ships joined in offering desperate opposition at Lade (495). Persian reprisals were severe and temporarily successful, for Chian ships, under the tyrant Strattis, served in the Persian fleet at Salamis. However, Chios joined the Delian league (formed 478–477) and long remained a firm ally of the Athenians, retaining political independence and a navy of its own. In 412 the island left the league. In 384 it entered a second alliance with Athens, but in 357 again seceded. It was reputed one of the best-governed states in Greece for, although it was governed alternately by oligarchs and democrats, neither party persecuted the other severely. Late in the 4th century, however, civil dissension left it a prey to Idrieus, the dynast of Caria (346), and to the Persian admiral Memnon (333). During the Hellenistic age Chios retained its independence, supported the Romans in their eastern wars and was made a "free and allied state." Under Roman and Byzantine rule the island's industry and commerce were undisturbed, its chief export at this time being the Ariusian wine of the northwest coast (Ariusia).

After temporary occupations by the Seljuk Turks (1089–92) and by the Venetians (1124–25, 1172, 1204–25), Chios was given in fief to the Genoese family of Zaccaria. In 1346 it passed definitely into the hands of a Genoese maona or trading company, which was organized in 1362 under the name of the Giustiniani and alone exploited the mastic trade. The Greeks, however, were allowed to retain their rights of self-government. In 1415 the Genoese became a tributary to the Ottomans and, in spite of occasional secessions which brought severe punishment (1453, 1479), the rule of the Giustiniani was not abolished until 1566. Capture by and reconquest from the Florentines (1595) and the Venetians (1694–95) temporarily injured the island's prosperity. In 1822, during the Greek War of Independence, a large number of the Christian inhabitants were massacred or sold into slavery by the Turks. Many of the survivors fled to Syros and founded its prosperous carrying trade. But Chios' natural resources made its recovery certain. The island passed quietly from Turkish to Greek rule during the Balkan War of 1912. It was occupied by Germany between 1941 and 1944. (J. Bo.)

CHIPMUNK, a small, active, terrestrial squirrel. Two genera are known; *Tamias,* with one species, *striatus,* occurs over eastern United States and Canada, and *Eutamias,* with many species, occurs in western North America east to the Great Lakes region and south to northern Mexico and also in central and eastern Asia. The body is four to six inches long and bears longitudinal dark stripes on the back and usually a dark stripe crosses the eye. In the eastern chipmunk the central stripe is bordered by brownish lines and the two outermost stripes are separated by wider whitish lines. The hip region is coloured reddish-brown, and the four-inch tail is bushy. The den is in a burrow excavated by the chipmunk. Chipmunks live in loose colonies; sometimes several share a burrow but only rarely the same grass-lined nesting chamber. They relish seeds, berries and tender vegetation but sometimes eat animal food. Seeds are commonly stored underground for use in winter and are carried in the capacious cheeks. Because of their food habits chipmunks occasionally become a nuisance in gardens but can easily be controlled by trapping, poisoning or fumigation. Two to eight young are born in spring or summer; a second litter, usually smaller, is often produced in areas having long summers. The gestation period is about a month. Chipmunks climb and swim well. The call is a shrill chirring or chipping sound. (K. R. KN.)

ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

CHIPMUNK (TAMIAS STRIATUS) OF EASTERN NORTH AMERICA

CHIPPENDALE, THOMAS (1718–1779), celebrated English cabinetmaker, was the son of John Chippendale, a joiner of Otley, Yorkshire, and was baptized there on June 5, 1718. Nothing is known of Chippendale's early life until his marriage to Catherine Redshaw in London in 1748. In 1753 he moved to St. Martin's lane, a fashionable cabinetmaking district. There remained his showrooms, workshops and home for the rest of his life. Chippendale was elected to the Society of Arts in 1759, but declined re-election in the following year. In 1766 his first partner, James Rannie, died and Chippendale continued the business alone until he took Thomas Haig into partnership in 1771. The activities of both his partners appear to have been limited to the business affairs of the firm. His first wife died in 1772 and he married Elizabeth Davis in 1777. In 1779 Chippendale died of tuberculosis and was buried on Nov. 13 at St. Martin-in-the-Fields, London.

Chippendale, though head of an important firm, was not the leading cabinetmaker of his day and his exaggerated posthumous reputation is attributed largely to his work *The Gentleman and Cabinet Maker's Director,* first published from St. Martin's lane in 1754. This folio, the most important collection of furniture designs published in England up to that time: illustrated almost every type of mid-18th-century domestic furniture. The first and second (1755) editions contained 160 plates; the third edition, published in weekly parts from 1759 to 1762, had 200. The designs represent the fashionable furniture of the period. The rococo style, adapted from the French *rocaille,* predominates, characteristically employed in the many designs for mahogany chairs with intricately pierced splats and elaborately carved case furniture. Other designs show essays in the Chinese and Gothic taste, some to be carved in softwood and japanned or gilded. Though the plates in the *Director* are signed by Chippendale, it is now accepted that many were the work of employed designers, notably H. Copland, who had previously published designs in the rococo style. M. Lock, who had published rococo designs with Copland, was employed to provide special designs for clients. Original drawings for plates in the *Director* are preserved in the Victoria and Albert museum, London, and in the Metropolitan museum, New York.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, N.Y., ROGERS FUND, 1908

CHIPPENDALE SIDE CHAIR (C. 1740–50)

Chippendale's name is given indiscriminately to great quantities of mid-18th-century furniture, but, in fact, only comparatively few pieces can be assigned with certainty to his workshop: it should be realized that Chippendale, once established as head of a large firm, did not make furniture himself. Even pieces that resemble designs in the *Director* cannot be attributed to his firm without further evidence, for the designs were available to contemporary cabinetmakers, some of whose names appear in the original list of subscribers. In certain cases, where a piece corresponds to a *Director* plate and where the original owner was a subscriber to the *Director,* or is known to have employed Chippendale, a tentative attribution may be made, as with a fine mahogany chair at Arundel castle, West Sussex, an unusual bookcase at Wilton house, Wiltshire, and the furniture from the Chinese bedroom at Badminton, Gloucestershire, now in the Victoria and Albert museum.

From the 1760s onward, influenced by Robert Adam, Chippendale adopted the new neoclassic style. Existing bills for work carried out by his firm at Nostell priory and Harewood house, Yorkshire, during this last phase of his career, not only identify the fine mahogany and marquetried satinwood furniture in the neoclassic taste which he supplied to these houses, but also show that as "cabinet-makers and upholsterers," his firm undertook all branches of interior decoration. The superb satinwood and inlaid commodes and other furniture at Harewood house, Yorkshire, are masterpieces of the cabinetmaker's craft and on them Chippendale's reputation may safely stand.

THOMAS CHIPPENDALE (*c.* 1749–1822), eldest son of the above, succeeded his father and until the retirement of Thomas Haig in 1796 the firm traded under the title of "Chippendale and Haig." Though declared bankrupt in 1804, the younger Chippendale continued the business at St. Martin's lane and opened an additional shop in the Haymarket in 1814, which was removed to Jermyn street in 1821. The firm continued to make high-quality furniture as well as undertaking such work as upholstery and paper hanging. Fine Regency-style furniture supplied by the firm to Harewood and to Stourhead house, Wiltshire, can be identified from existing bills. Like his father, the younger Chippendale was a member of the Society of Arts and is known to have exhibited five pictures at the Royal Academy between 1784 and 1801. He died in 1822.

CHIPPENHAM, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, Eng., on the Wiltshire Avon, 20 mi. S.W. of Swindon by road. Pop. (1961) 17,525. Chippenham (Cippanhamm, Chipeham) was the site of a royal residence where, in 853, Aethelwulf celebrated the marriage of his daughter Aethelswith with Burgred, king of Mercia. The town was occupied by the Danes during their invasion of 878, and in 933 was the meeting place of the witan. In Domesday Book Chippenham appears as a crown manor. The town was governed by a bailiff in the reign of Edward I; it was incorporated in 1354 and sent two members to parliament until 1867 and one until 1885. The London-Bath road crosses the Avon at Chippenham by a stone bridge of 20 arches. St. Andrew's parish church, originally 12th-century Norman, has been enlarged in different styles. The grasslands of the neighbouring Cotswold hills reared the sheep which gave Chippenham its fame as a woolen centre from the 16th century. This trade has declined and the town is a centre for milk distribution and processing. Other industries are bacon curing, food processing, tanning, furniture making and electrical and railway engineering. A weekly cattle market is held.

CHIPPEWA, the name often used to refer to the Ojibwa, one of the important Algonkian Indian tribes of Canada and the United States. See OJIBWA.

CHIPPING CAMPDEN, a market town of Gloucestershire, Eng., lies near the northern edge of the Cotswold hills, 29 mi. N.E. of Gloucester by road. Pop. (1951) 2,619. It is noted for the beauty of its buildings of Cotswold stone erected by medieval wool staplers; outstanding structures include the 15th-century market hall, the house of a great wool merchant, William Grevel (d. 1401), a range of almshouses and the Perpendicular "wool" church of St. James.

In 1173 the manor passed to Hugh de Gondeville, and about 1204 to Ralph, earl of Chester, both of whom granted charters to the town. Throughout the 12th–14th centuries Campden (Chipping, "market") was an important centre of the wool trade, many sheep being raised on the Cotswolds, but its importance dwindled when the staple was taken to Calais, France. John Ruskin and William Morris reintroduced weaving by bringing their guild of handicrafts there from London. Campden was incorporated in 1605, but was never represented in parliament. The corporation was abolished in 1885. In the Restoration period the "Campden Wonder" took place, when the Perrys (a woman and her two sons) were hanged for the presumed murder of William Harrison, who later returned with a curious story of kidnapping that has never been substantiated.

CHIPPING NORTON, a municipal borough of Oxfordshire, Eng., is 20 mi. N.W. of Oxford by road. Pop. (1961) 4,241. It stands 650 ft. above sea level on the slope of a northern spur of the Cotswolds. The wide main street is flanked by 18th-century houses in Cotswold stone. The church of St. Mary the Virgin, rebuilt in the 15th century in the Perpendicular style, is one of the beautiful Cotswold "wool" churches. The almshouses, erected in 1640 and internally modernized, are also examples of local architecture. The guildhall is a fine example of Cotswold medieval building. A castle existed in the middle ages, but only grass-covered mounds remain. From 1302 to 1366 Chipping Norton returned two representatives to parliament. In 1606, when James I granted its charter of incorporation, it was one of the five most important towns in the county. Local occupations are mainly agricultural. although there are a tweed mill, a provender mill and an ironworks.

CHIQUIMULA, a department in eastern Guatemala, bordering Honduras and El Salvador. Its area is 917 sq.mi., and its population (1957 est.) 143,843. Its capital is Chiquimula. The predominantly Indian population raises maize, beans and wheat, and pastures beef cattle. There are also some plantations that grow coffee, sugar cane and rice. Access is by highway to Zacapa in the Motagua valley and by rail to Zacapa or southward to San Salvador. Trails, impassable in wet weather, connect it with Copán in Honduras. (P. E. J.)

CHIQUITOAN, an independent linguistic stock of South American Indians, so called from the Chiquito, who are the best knoun of its tribes. The stock occupies a considerable area in eastern Bolivia, in the forested hilly country on the northern border of the Chaco. In recent times they have held the area between the headwaters of the Guaporé on the north and the hills on the northern bank of the Otuquis river on the south, and between the San Miguel river in the west and the Paraguay in the east. It is probable that they formerly extended farther west to the foothills of the Andes and may have been forced eastward as a result of the displacement of peoples caused by the invasion and settlement of the Chiriguano in the early 16th century. The Chiquito were a rather warlike and mainly nomadic hunting and fishing folk of simple culture. Their name, meaning "little ones" in Spanish, was given them on account of the very small doorways of their tiny thatched huts, through mhich one had to crawl on hands and knees. They seem to have had some palisaded strongholds and to have used poisoned arrows. Some of the tribes made good pottery and simple textiles. They had no canoes. Monogamy was the rule except for the chiefs, who were not hereditary but chosen for valour and ability. The youth before marriage lived apart in a special house. The shamans appear to have used snakes a good deal in connection with their religious ceremonies.

See Alfred Métraux, "Tribes of Eastern Bolivia and the Madeira Headwaters" in *Handbook of South American Indians,* ed. *by* Julian H. Steward, Bureau of American Ethnology Bulletin 143, vol. 3, pp. 381–395.

CHIRCHIK, a town in the Uzbek Soviet Socialist Republic, U.S.S.R., lies on the Chirchik river 20 mi. N.E. of Tashkent. Pop. (1959) 65,000. It is an important industrial centre producing nitrogen fertilizer and related chemicals, agricultural machinery and chemical industry equipment. It also possesses a large hydroelectric station and there are shoe and clothing factories. The town, mhich has several technical colleges, was developed industrially in the 19'30s on the site of Kirgiz-Kulak village in Tashkent *oblast.* (G. E. WR.)

CHIRICO, GIORGIO DE (1888–), Italian painter, whose remarkably imaginative paintings suggested the mood of early 20th-century Italy and had a marked effect on the Surrealist movement. Born of Italian parents in Volos, Greece, on July 10. 1888, Chirico entered the Munich Academy of Fine Arts at 18. His early style was influenced by the painting of Arnold Bocklin and the philosophy of Nietzsche. Moving to Paris in 1911, he created his famous style of boldly painted enigmatic objects and simplified architecture set in strongly accentuated perspectives. By 1915 he was in the Italian army, but ill-health freed him from most military duty. With Carlo Carrà at Ferrara he practised a modification of his earlier manner called the *scuola* metafisica, marked by a generally denser and more arbitrary arrangement of his unusual forms. After World War I he adopted a more realistic and romantic style that was less widely admired.

See J. T. Soby, *Giorgio* de *Chirico* (1955). (J. C. SE.)

CHIRIQUÍ, a province in western PanamL bordering the Pacific ocean. Pop. (1960) 186.801; area 3,460 sq.mi. David, the provincial capital (pop. 22,694), is in the centre of agricultural areas. North of David in highland valleys are coffee and orange growing districts; south and east are the most important cattle grazing areas of PanamL. West of David, banana plantations developed by the United Fruit company produce most of the bananas exported from PanamL. Agricultural districts are connected by railways with Pedregal, important in coastwise shipping, and Puerto Armuelles, from which bananas are exported. (C. F. J.)

CHIROMANCY, the art of telling character or fortune by studying the lines of the hands. See PALMISTRY.

CHIRON, in Greek mythology, one of the centaurs (see CENTAUR), the son of Cronus and Philyra, a sea nymph. He dwelt at the foot of Mt. Pelion, and was famous for his wisdom and knowledge of the healing art. He offers a remarkable contrast to the other centaurs in manners and character. Many of the most celebrated heroes of Greece were brought up and instructed by him. Accidentally pierced by a poisoned arrow shot by Hercules, he renounced his immortality in favour of Prometheus, and was placed among the stars as the constellation Sagittarius.

CHIROPODY, the diagnosis and treatment of conditions affecting the feet. See PODIATRY.

CHIROPRACTIC is a system of treatment of human diseases and injuries based on the premise that the nerve system controls all other systems and all physiological functions in the body; that interference with the nerve control of these systems impairs their function and induces disease by rendering the body less resistant to infection or other exciting causes. The chiropractor treats by adjustments and manipulation of the structures of the body, especially the spinal column, to restore normal nerve function. D. D. Palmer began the practice of chiropractic in 1895.

CHIROPTERA, the order of mammals containing the bats. The forelimbs on these animals are modified into a wing so that they can truly fly. The name of the order is derived from Greek and means "hand wings." See BAT; see also references under "Chiroptera" in the Index volume.

CHIRU (*Pantholops* hodgsoni), an antelope of Tibet and extreme northern India; it lives at elevations of about 12.000 to 18,000 ft., which are above the usual agricultural areas. They are grayish fawn colour with white undersides. The males have a

blackish face and a somewhat swollen muzzle, showing affinity with the saiga (*q.v.*) in adjacent territory. The sharp horns-of the males reach a length of 28 in., and the height of the animal at the shoulder sometimes may be slightly over 30 in. Although it may weigh as much as 120 lb., the chiru can normally outrun dogs or wolves. The only call recorded is a bleat. In mating habits the chirus resemble some other herd animals, such as the wapiti, in that the male gathers a harem of 10 to 20, becomes thin with lack of feeding and wages serious battles with rivals. The females seem indifferent and require much herding by the male to keep the group together. Mating takes place in the autumn and fawns are born in May.

This animal has been held sacred by some Tibetans and the meat is not eaten by lamas (though it is very tasty to others who hunt it); the blood is supposed to have medicinal properties, and the future is said to be foretold by the knobs on the horns. A side view of the chiru, with a single horn aspect, has caused some people to strengthen their belief in the unicorn.

(O. J. M.)

CHISHOLM, HUGH (1866–1924), whose intellectual and organizing abilities were shown in his editorship of the *Encyclopedia Britannica*, particularly in the 11th edition, was born in London on Feb. 22, 1866. Graduating from Oxford in 1888, he became assistant editor of the *St. James's Gazette* in 1892, and editor in 1897.

In 1900 he joined the *Times* as co-editor of the new supplementary volumes constituting the 10th edition of the *Encyclopædia* (1902), and as editor in chief (1903) he was responsible for the new (11th) edition (1910–11), and for the *Britannica Year-Book 1913*. He was city editor of the *Times* from 1913 to 1920, when he reassumed the editorship of *Britannica* for the new supplementary volumes of the 12th edition (1921–22). He died in London on Sept. 29, 1924.

See also ENCYCLOPAEDIA.

See Herman Kogan, ***The*** *Great EB (1958).*

CHISLEHURST AND SIDCUP, an urban district in the Chislehurst parliamentary division of Kent, Eng., 11 mi. S.E. of London by road. Pop. (1961) 86,907. Chislehurst is 300 ft. above sea level, almost surrounded by commons and woods, Petts wood being National trust property. The church contains tombs of the Walsinghams. Bettensons and Sydneys (after whom Sydney, N.S.W., was named). Napoleon III and the empress Eugénie lived at Camden house (now a golf club), built in 1609 by William Camden, the antiquary. The mortuary chapel attached to St. Mary's Roman Catholic church for several years contained the body of the emperor, for whom it was built. In 1934 Chislehurst, Sidcup, Mottingham, North Cray and St. Paul's Cray were joined.

CHISWICK: *see* BRENTFORD AND CHISWICK.

CHITA, an *oblast* of the Russian Soviet Federated Socialist Republic. is in the Transbaikalia region of the U.S.S.R., bordering on the Mongolian People's Republic and northern China. Pop. (1959) 1,036,387. Area 166.602 sq.mi. The whole *oblast* displays marked relief, consisting of a complex series of mountain ranges, plateaus, valleys and depressions, with a general southwest-northeast orientation. The area has been affected by uplift, rifting and fracturing in every major geological folding period.

The major range is the Yablonovy in the west and north centre of the *oblast.* The greater part of Chita *oblast* is drained by the rivers which unite to form the Amur, notably the Argun and the Shilka. The latter is formed by the confluence of two sizable rivers, the Ingoda and the Onon. The north is drained by the tributaries of the Lena (*q.v.*), the largest of which is the Vitim. Most of the *oblast* is covered by coniferous forest, dominated by Dahurian larch, with podsol soils often underlain by permafrost. In the more extensive depressions of the south and southeast, there is forest steppe and steppe vegetation, developed on black earth and chestnut soils. The climate, although varying locally with relief. is severely continental. with an annual range of about 80° F. and extremely cold winters. The *oblast* has a January average of −14" F. Rainfall is low, from 16 in. on the higher areas to 10–12 in. in the lowlands, with a marked late summer maximum. Winter snow cover is very thin, which, together with low spring rainfall, often affects crops adversely.

In 1559 there were 49.109 inhabitants in the Agin-Buryat National Okrug, which lies within the *oblast.* Apart from the Buryats there are some Yevenki or Evenki (Tungus) living in the north. The bulk of the population are Russians. Cossacks first entered the area about 1650 and in 1653 founded Irgenski Fort near the modern town of Chita and in 1658 founded Kerchinsk, which became a major trading centre with China. The 1689 treaty of Kerchinsk with China halted the Russian advance into the Amur basin and the Chita region remained a frontier zone until the mid-19th century, when the Amur area was occupied. Russian settlement was slight until the discovery of gold in 1830 and reached large proportions only after the coming of the Trans-Siberian railway in 1897. This railway, which traverses the *oblast,* is still the main axis of communication The *oblast* was formed in 1937 after dissolution of the East Siberian Territory. In 1948 its eastern part was added to Amur *oblast.*

In 1959 there were 9 towns and 40 urban areas, with 575,781 inhabitants, or 55.6% of the total population. Apart from Chita (*q.v.*), the administrative centre. the main towns are Petrovsk-Zabaykalski in the west, and Nerchinsk and Sretensk in the Shilka valley.

The *oblast* is rich in mineral resources and the most important sector of the economy is mining, particularly of gold (chiefly at Balei), silver, tin, zinc and lead. By the 1960s iron and copper reserves were being exploited. Coal and lignite are mined and production in the early 1960s amounted to more than 3,000.000 tons, about half coming from the Chernovskoye field. Metallurgy is concentrated in Petrovsk-Zabaykalski. Other industries include machine-building at Chita, shipbuilding at Kokui, near Sretensk, and timber mills and metal works along the Trans-Siberian railway. Timber working is important and widespread. Because of the relief and climate, agriculture is not well developed. despite considerable plowing in 1954–56 under the virgin lands scheme, and livestock rearing. especially of sheep, is dominant. Fox and squirrel furs are exported from the *oblast.*

(R. A. F.)

CHITA, a town and *oblast* centre in the Russian Soviet Federated Socialist Republic of the U.S.S.R., stands on the Chita river, near its confluence uith the Ingoda. Pop. (1959) 171.000. Founded in 1653 as the Cossack Irgenski fort, Chita derived its early importance from trade with China. The improvements in draining and leveling carried out by the Dekabrists (*q.v.*), exiled to Chita after the plot of Dec. 1825, developed it into a prosperous settlement, but it displayed marked development only after the coming of the Trans-Siberian railway in 1897. Chita has locomotive and rolling stock repair works, sawmills, a meat-packing and a flourishing sheepskin and leather industry. Its educational facilities include medical and pedagogical institutes. Near the tonn the former Chinese Eastern railway branches off to Harbin and Mukden, thus making the town a most important junction.

(R. A. F.)

CHITAL (AXIS DEER), a medium-sized deer *(Axis axis)* of India and Ceylon. Among the most beautifully marked deer, it has a reddish-fawn coat heavily spotted nith white. Antlers, three-tined, distinguish the males.

Chitals live in herds in the jungle and seldom venture far from water.

See also DEER. (L. H. M.)

CHITALDRUG (CHITRADURGA), a municipality and district in Mysore, India. The town of Chitaldrug, the district headquarters (pop. [1951] 25,081; [1959 est.] 37,000), is 118 mi. N W. of Bangalore and has a considerable trade in cotton. It possesses massive fortifications erected under Haidar Ali and Tipu Sahib toward the close of the 18th century; and to the west are remains of a city of the 2nd century A.D.

Chitaldrug is the terminus of a railway from Chikjajur on the Hubli-Bangalore line of the Southern railway.

CHITALDRUG DISTRICT has an area of 4,185 sq.mi. and a popu-

lation (1961) of 1,094,128. The rainfall is low, and the Vedavati or Hagari river, in whose valley the town lies, is mostly dry in the hot season. Vanivilasa Sagara dam has been constructed on the river and a considerable area brought under irrigation. Rice and sugar cane are the chief irrigated crops, and cotton is the dry crop. Minerals found in the district include copper, lead, gold and iron ore.

Several parallel chains of hills, reaching an extreme height of 3,800 ft., cross the district; otherwise it is a plain. The largest town in the district is Davangere (56,018) with cotton factories and trade in cotton and grain. Educational facilities include a degree-granting college and an engineering college affiliated to Mysore university.

CHITARRONE: see LUTE.

CHITIMACHA, a tribe of American Indians living on the shores of Grand lake and the banks of Grand river in Louisiana at the time the French settled that region. The Chitimachan linguistic group included three tribes: the Chitimacha, Washa and Chawasha. The name comes from the Choctaw *chuti,* "cooking pot," and *masha,* "they possess" ("they have cooking vessels").

They called themselves *Pantchpinunukansh,* "men altogether red," a designation apparently made after the coming of the whites. War with the French over the murder of the missionary St. Cosme in 1706 was concluded by presentation of the head of the murderer. They were monogamists, and women had authority in their government. In 1950 there were an estimated 120 Chitimacha on reservations in southern Louisiana.

See also MUSKOGEAN INDIANS.

CHITON, common name for. and a genus of, a small mollusk of the order Polyplacophora and the class Amphineura (*q.v.*). See MOLLUSCA.

CHITRAL, a princely state comprising the most northerly portion of the Malakand agency in the tribal areas (after 1947 called "frontier regions") of West Pakistan. It is bounded north and west by Afghanistan, the Wakhan valley dividing it by 12 mi. from the U.S.S.R., and is therefore of strategic importance; to the east it is bounded by Gilgit agency, to the south and southeast by Dir state and Kalam in the Swat Kohistan. Area 5,727 sq.mi. Pop. (1961) 113,057. Chitral is a scenic region of deep valleys and lofty ranges, with snow-covered mountains and rich pine forests. It includes the Tirich, Turikho and Mulikho valleys in the west and Yarkhun valley in the northeast. The valleys are extremely fertile, and wheat. barley, maize (corn) and rice are grown. Chitral also produces excellent walnuts and fruit, including grapes, apricots and mulberries; these form an important element of diet. There are some minerals, including iron ore. lead, copper, manganese and antimony. The chief exports are daggers, sword belts and embroidered cloth.

The capital town, Chitral (Chitrar or Kashkar), is 128 mi. N. of Peshawar on the Chitral river, in a valley which is barely 2 mi. wide. It can be reached by road from Nowshera. via Mardan, Malakand, Dir and the Lowarai pass (10,230 ft.), which is open for motor vehicles during the summer. It is connected with Gilgit by the Shandur pass (12,250 ft.) and is linked with Peshawar by air service.

The dominant tribe inhabiting the main valley are the Khos, whose language Khowar (known as Chitrali) is the lingua franca of the state. They are believed to have migrated from the Oxus region. The aboriginal Kafirs occupy only some remote valleys. Many of them have become Muslims and are called sheikh. The Chitralis are born horsemen; polo is the national game and is played throughout the state.

The valley is said to have been subdued by the Chinese in the 1st century B.C. and was ruled by them for several centuries. Muslims from Afghanistan first entered Chitral early in the 11th century A.D. and converted the population to Islam, the people of upper Chitral being members of the Isma'ili sect.

The present ruling family claim descent from Baba Ayub, said to be a grandson of the Mogul emperor Babur (*q.v.*). Baba Ayub settled in Chitral early in the 17th century and entered the service of the chief, who was of the same family as the rulers of Gilgit. When this line became extinct the great grandson of Baba Ayub, Mohtram Shah (also known as Shah Kator I) became chief and was the first to adopt the title of Mehtar ("prince").

Pursuing their policy of asserting control over the northwest passes between India and Russia, the British established an agency in Gilgit in 1889, with a subsidiary at Mastuj for Chitral. A British garrison was maintained until the state acceded to Pakistan following the partition of the subcontinent in 1947. His Highness Mehtar Saifur Rehman took over the government in 1953. He died in an air crash in 1954 and was succeeded by his son Saiful-Mulk Nasir, then a minor.

The CHITRAL RIVER rises in the Hindu Kush in the north of the state and, flowing southwestward into Afghanistan (where it is called the Kunar), joins the Kabul river 5 mi. E. of Jalalabad after a 300-mi. course.

BIBLIOGRAPHY.—G. Robertson, *Chitral* (1898); R. C. F. Schomberg, *Kafirs and Glaciers: Travels in Chitral* (1938); ***Yearbook*** of the North-West Frontier Province Government Press (1954). (K. S. **AD.**)

CHITTAGONG, the chief port of East Pakistan, and the name of a district and division of that province. The port was known to the civilized world from the earlier centuries of the Christian era and to Arab sailors by the 10th century A.D. It was the Porto Grande of the Portuguese and Venetian voyagers and was described by João de Barros in 1552 as "the most famous and wealthy city of the Kingdom of Bengal." It has been generally identified with the city of Bengala described by Portuguese and other writers.

Conquered by the Muslims in the 14th century, Chittagong passed to the Arakanese in the next century. The piratical raids of the Arakanese and their Portuguese mercenaries led to the dispatch of a strong force by Shaista Khan. the Mogul governor (nawab) of Bengal, who in 1666 occupied the district. Chittagong was ceded to the East India company by Nawab Mir Kasim Ali in 1760

The port is on the right bank of the Karnaphuli river, about 12 mi. from its mouth. and is picturesquely situated with varied scenery of river and sea, green hills and plains. Many houses are built upon little hillocks. It has a healthful climate, the temperature rarely rising above 85° F. between February and June, and the heat is mitigated by sea breezes. The town is the terminus of the Pakistan Eastern railway, connecting it with Dacca via Comilla. It is linked by air mith Dacca, Cox's Bazar, Rangoon and Calcutta. Pop. (1961) 364,205. It has a splendid natural harbour. Tea, jute and jute manufactures constitute the principal exports. After the creation of Pakistan in 1947 much trade mas diverted there from Calcutta, and the port was considerably improved. In the early 1960s it was capable of handling approximately 2,000,000 tons of cargo annually and could provide berthing facilities for 20 ships at a time—four times the capacity prior to independence.

Life centres around the harbour. The chief buildings include the court buildings on the Fairy hills, on the site of the former Portuguese fort: the Juma Masjid. built on a low hill by Ummed Khan (son of Shaista Khan); and the Circuit house, facing the Niaz stadium. The following colleges are affiliated with Dacca university: Chittagong college, the Government College of Commerce, the Women's college, the Law college, Night college and three other colleges, together with the Islamic Intermediate college, which is housed in a building erected by the Portuguese about 1650. There is a cadet college at Faujdarhat (about 5 mi. distant). Batali hill is a favourite evening resort. The shrine of Ba Yazid (8 mi. from the city) is visited by thousands of devotees. Principal industries include cotton and jute mills, tea and match factories, and engineering works. The industrial area extends for about 10 mi. to the north and northeast. Being the gate of East Pakistan for foreign trade, the town has offices of many foreign firms and banks. It is the headquarters of Pakistan Eastern railway and the railway workshop is located in the nearby town of Pahartali.

CHITTAGONG DIVISION is one of four divisions of East Pakistan. It comprises the five eastern districts of Chittagong, Chittagong Hill Tracts, Noakhali, Comilla and Sylhet. It includes 14 sub-

divisions of thanas (police units of local administration) and about 17,000 villages. Area 17,017 sq.mi. Pop. (1961) 13,629,650.

CHITTAGONG DISTRICT consists of a narrow strip of coast with valleys and low ranges of parallel hills, running in a southeasterly direction along the northeast of the Bay of Bengal. The hills are generally formed of strata of sand, clay, shale and a hard gray sandstone of the Tertiary period. The seaboard is composed of hard clay, deposited originally by the tide; where the tide still has access to it the soil is salty. The higher parts of the Chittagong hills are densely forested, while the lower portions are to a great extent covered with brushwood. The forest-clad hills abound in wild animals, including elephants, bisons, tigers, leopards, deer and wildcats. Between the hills lie cultivated valleys, filled by alluvial deposits of sand and clay washed down from the hills. The climate is moist, warm and equable with heavy rainfall (over 100 in. annually), mainly during the summer monsoons. Vegetation is luxuriant and the country is green throughout the year.

Rice, mainly of the winter or *aman* type, is the most important crop; tea is grown on low hills which are unfit for rice cultivation; deep-sea fishing is practised in the bay and every river, lake and ditch swarms with fish. Area 2,703 sq.mi. Pop. (1961) 2,982,931.

CHITTAGONG HILL TRACTS DISTRICT of East Pakistan occupies the hill country between Chittagong district and the Lushai hills in Assam, India. The highest point is 4,034 ft. above sea level. Under the Karnaphuli project a dam was constructed at Kaptai. A paper mill is also located on the bank of the Karnaphuli river at Chandraghona. Most of the hills are covered with forests containing valuable timber, bamboos, canes and a kind of grass known as sun.

The climate is hot, humid and unhealthful. The hills are unsuitable for cultivation, and the terracing of slopes is rendered difficult by the lack of stones for revetment. The district produces almost all the cotton grown in East Pakistan. Other important crops are rice and oilseeds. Waterways are the chief means of communication. Cotton-weaving and the making of bamboo nets and baskets are the chief cottage industries. Area 5,096 sq.mi. Pop. (1961) 385,079. About 75% are Buddhists, half of whom belong to the Chakma tribe. The headquarters are at Rangamati.

(K. S. AD.)

CHITTOOR (CHITTUR), a commercial town and headquarters of Chittoor district, Andhra Pradesh, India, lies 80 mi. W. of Madras. Pop. (1951) 38,894. Area 7.75 sq.mi. It has a college affiliated to Sri Venkateswara university, Tirupathi, several high schools, a training school, a hospital and sanatorium. It is a market centre for gur (molasses), mangoes and peanuts, and is noted for the manufacture of biscuits and confectionery. The Indian Express, a well-known daily newspaper, is printed and published there. The town has rail and road connections with Madras and Bangalore.

CHITTOOR DISTRICT (area 5,908 sq.mi.) was formed from the northern part of North Arcot district. Pop. (1961) 1,913,169. It is in great part hilly, being traversed by spurs of the Eastern Ghats radiating east and south. The surface in the hill country is rocky except for patches of stunted jungle, but the narrow valleys between the hills are fertile and the hills themselves are highly mineralized, showing copper and iron especially. The chief crops are rice, millet and oilseeds.

The temple of Sri Venkateswara on the Tirumalai hills in Chandragiri taluk is the most famous in the district and attracts pilgrims from all parts of India. The temple of Siva in Kalahasti town is also famous. (B. S. R.)

CHITTORGARH, a district in the Udaipur division of Rajasthan, India, lies in the southeast of the state. Pop. (1961) 710,880. Area 4,033 sq.mi. Its headquarters is the fortress town of Chitor or Chitorgarh, 65 mi. E.N.E. of Udaipur, famous as the ancient stronghold of the Sesodia Rajputs. The fort, 500 ft. above the surrounding plain and the Gambheri river, existed in the 8th century A.D. It was thrice besieged by Muslim attackers, its defenders preferring death for themselves and *jauhar* (collective self-immolation) for their womenfolk to surrender. The first such siege (1303). when Sultan Alauddin Khalji of Delhi sought the beautiful Padmavati, wife of the rana Bhimsingh, is celebrated through the poems of Chand Bardai and Mohammed Jayasi (see HINDI LITERATURE). In the second siege (1534–35), by Sultan Bahadur Shah of Gujarat, 32,000 Rajputs died in battle and 13,000 women by jauhar. At the third siege (1567) by the Mogul emperor Akbar the story was similar; the great heroism of the chiefs Jaimal and Patta, celebrated in numerous Rajput ballads, was commemorated by Akbar himself. After the loss of Chitor the Sesodia capital was transferred to Udaipur.

The zigzag ascent to the fort is guarded by seven magnificent gateways with guardrooms, largely of trabeated construction. Within the high walls remain the palaces of Jaimal and Patta and of Bhimsingh; of many Jain and Hindu temples that of Vriji, built about 1450 by Rana Khumba, has a large sikhara tower. Most prominent, however, are two exquisitely sculptured Jain towers of the 12th and 15th centuries known as the towers of Fame and Victory. (J. B.-P.)

CHIU-CHIANG (KIUKIANG), a former treaty port of Kiangsi province, China, on the Yangtze river midway in its course between the central (Hupeh) basin and the delta. It was a municipality in 1956, though its population, by the 1953 census, was only 64,600. Lying just above the P'o-yang lake debouchment into the Yangtze, Chiu-chiang has been the traditional port of export for the varied products of Kiangsi. The newer occidental port lies just west of the old Chinese city. A rail terminal and passenger transit port, Chiu-chiang has never been a centre of manufacturing. Kiangsi rice, tobacco, cotton and ramie (grass cloth) pass through the port and much Kingtehchen porcelain has traditionally been shipped from there. After 1952 the Chinese Communists used the port as an iron ore collecting and shipping port.

Behind the port rise the ranges of the Chiu-kung Shan, the chief tea-growing district of Kiangsi, for whose black teas Chiu-chiang is the traditional collecting centre. Ku-ling, an important summer resort near the top of Lu Shan, lies 15 mi. S. of the city.

(J. E. SR.)

CHIUSI: see CLUSIUM.

CHIVALRY, the knightly class of feudal times. The primary sense in the middle ages is "knights" or "fully armed and mounted fighting men." (See also CAVALIER; CHEVALIER.) Thence the term came to mean that gallantry and honour expected of knights. Lastly, the word came to be used in its general sense of "courtesy." (See also KNIGHTHOOD AND CHIVALRY.)

In English law chivalry meant the tenure of land by knights' service. The court of chivalry instituted by Edward III, with the lord high constable and earl marshal of England as joint judges, had summary jurisdiction in all cases of offenses of knights and generally as to military matters. When the earl marshal alone presided it was a court of honour deciding as to precedence. coats of arms, etc. From 1737 until 1954 no case was brought before this court. Then, in 1954, the court met with the earl marshal presiding to hear a petition from the Manchester city corporation alleging the improper use of the city's coat of arms by the Manchester Palace of Varieties.

CHIVES (Allium schoenoprasum), a small, hardy perennial plant related to the onion, of the family Liliaceae. Its small white, elongated bulbs and narrow, cylindrical, hollow leaves (six to eight inches long) develop in dense clumps. Flower stalks arise, bearing dense, attractive, spherical umbels of bluish flowers above the foliage; they often produce but few seeds. Chives may be propagated by seeds, but is more commonly propagated by planting the tiny bulbs obtained by dividing the clumps. A flowerpot of chives, if judiciously trimmed, can be kept in a sunny window for a continuous small supply of leaves, which are used as a food flavouring. (V. R. B.)

CHKHEIDZE. NIKOLAI SEMENOVICH (1864–1926), Georgian Social Democratic leader, prominent also in Russian politics in the decade preceding the revolution of Nov. 1917, was born at Kutaisi in the Caucasus. In the early 1890s he helped N. Zhordania and others to introduce Marxist ideas into Georgia.

Thanks to nationalist feeling, these ideas soon struck deep root, and Georgia became a stronghold of the Menshevik wing of Russian social democracy. In 1907 Chkheidze was elected to the Russian state duma, where for nearly ten years he led the Social Democratic group, earning a nation-wide reputation as spokesman for the extreme left. In 1917, on the outbreak of the March revolution, he became chairman of the Petrograd soviet of workers' and soldiers' deputies, in which he vainly sought to conciliate both the moderate and extremist elements. His vacillations helped to discredit the original leadership of the soviet, which was soon swept away by the rising tide of Bolshevism. After the November Revolution Chkheidze returned to Transcaucasia, becoming president of the national council (subsequently the constituent assembly) of the independent republic of Georgia, which he represented at the Paris peace conference. When Georgia was occupied by the Bolsheviks (1921) he emigrated to France. On June 13, 1926. at Leuville, near Paris. distressed at the situation in his homeland, he died after attempting to commit suicide.

(J. L. H. K.)

CHLOPICKI, (GRZEGORZ) JOZEF (1771–1854), Polish general, was born at Kapustyn in Volhynia in March 1771. He enlisted in the Polish army in 1785 and fought in the campaigns of 1792–94 before and after the second partition of Poland. He then took service under the French, in their new Polish-Italian legion, and distinguished himself in the Italian campaign of 1797–1805 at the storming of Peschiera and at Mantua. On Polish soil again with the Napoleonic armies, he commanded the first Vistula regiment in 1807. In the Peninsular War he obtained the Legion of Honour for his heroism at Epila and in the storming of Saragossa. He accompanied Napoleon's Grande Armée into Russia in 1812. On the reconstruction of the Polish army in 1814 he was made a general of a division, but four years later. having quarreled with the Russian grand duke Constantine, he resigned.

Chlopicki held aloof at first from the Polish national rising of 1830, but at the request of his countrymen he accepted the dictatorship on Dec. 5, 1830. Lacking faith in the success of the war. he clung to the hope of negotiation with Russia and acted purely on the defensive. On Jan. 17, 1831, he resigned and became nominally a private soldier. Actually, however, he continued his command until, seriously wounded at the battle of Grochow, on Feb 25, 1831, he was forced to retire from public life. He died in Cracow on Sept. 30, 1854.

See J. C. H. Harbut, *Jozef Chlopicki* (1930) ; *W.* Tokarz, *Wojna polsko-rosyjska* 1830–31 (1930). (ST. HE.)

CHLORAL (TRICHLOROACETALDEHYDE; CCl_3CHO) is a heavy, oily, colourless liquid, with a pungent odour and taste, the hydrate of which—$CCl_3CH(OH)_2$—is used medicinally. Chloral was first prepared by J. von Liebig in 1832. Chloral hydrate was introduced into medicine in 1869 (at the time when cannabis, alcohol and opium were the main central nervous system depressants) by O. Liebreich on the erroneous assumption that it would be changed to chloroform in the body and thus act as an anesthetic. However, even though. it does not change in the body, it does have a depressant action on the central nervous system; the erroneous assumption upon which its use was originally based resulted in the contribution of a valuable therapeutic agent (one of the many instances illustrating the value of serendipity in science).

Chemistry of Chloral and Chloral Hydrate.—Chloral—14 times heavier than water and with a boiling point of 208° F. (97.8° C.)—is prepared by passing dry chlorine into cooled absolute alcohol. In the presence of an alkali, chloral is changed to chloroform (*q.v.*); in the presence of water, chloral becomes chloral hydrate, a transparent crystalline compound with a melting point of 134.6° F. (57° C.). By condensation with chlorobenzene in the presence of sulfuric acid, chloral is converted into the important insecticide DDT, or dichloro-diphenyl-trichloro-ethane (see ENTOMOLOGY: Principles of Insect Control).

Pharmacological Actions and Toxicity.—Chloral and its hydrate, the form commonly used, have the ability to produce general anesthesia, but the dose required for this effect is too close to the lethal dose to have practical usefulness. The sedative action of chloral hydrate, which is achieved by giving doses in the range of one or two grams, is the most important action of the drug. After doses in this range sedation occurs in 10 to 15 minutes, and a sleep lasting from five to eight hours ensues within an hour; there is no aftereffect or "hang-over." Since the drug does not usually depress reflexes, it is not very serviceable as an anticonvulsant.

The fatal dose of chloral hydrate for adults by mouth is about 10 g., but care should be exercised in giving even more than 2 g. in a single dose. The usual symptoms of poisoning by chloral hydrate are deep stupor, dilation of blood vessels, fall in blood pressure, fall in body temperature and slowed respiration. Death results from respiratory depression usually within 5 to 10 hours. Acute poisoning can also occur from the combination of liquid chloral and alcohol, which constitutes the so-called "knockout" drops or "Mickey Finn." This mixture has a rapid and potent depressant effect.

The treatment for poisoning by chloral is accomplished by washing out the stomach, maintaining body temperature and administering stimulants to increase respiration and to elevate the blood pressure; artificial respiration is also used.

Medicinal Uses.—The sedative effects of chloral hydrate are similar to those produced by barbiturates (*q.v.*). The drug is frequently administered to patients undergoing withdrawal from morphine, alcohol or barbiturates and to those with delirium tremens (see DELIRIUM). Chloral hydrate is one of the least expensive and most effective hypnotics, but its value is frequently neglected in present-day medicine mainly because of the prominence given to the easier-to-take pill barbiturates in medical literature.

(K. P. Du.)

CHLORAMPHENICOL (CHLOROMYCETIN) is an antibiotic substance originally obtained from cultures of the funguslike actinomycete Streptomyces venezuelae and used in the treatment of many infectious diseases. It was the first of the broad-spectrum antibiotics (*q.v.*) to be reported, being characterized and identified by Paul R. Burkholder in 1947. Chemical synthesis of the substance was reported in 1950, at which time the chemical name chloramphenicol was applied to the compound.

Chloromycetin, the'registered trade-mark name adopted for the compound by the original manufacturer, has been found to be effective against a wide variety of infectious agents, including both gram-negative and gram-positive bacteria. certain rickettsiae, spirochetes and viruses. It acts to inhibit the growth and multiplication of the microorganisms sensitive to it. Chloramphenicol usually is given orally and is rapidly absorbed from the gastrointestinal tract, diffusing readily into the body tissues and fluids.

Gastrointestinal disturbances and diarrhea are not commonly seen following the administration of chloramphenicol, and, because of the rapid inactivation of the antibiotic in the digestive tract, little inhibition of the normal bacterial flora of the large bowel is observed. In rare instances, the administration of chloramphenicol has been complicated by the development of an aplastic anemia due to depression of the bone marrow by the drug

(T. W. L.)

CHLORATES: see CHLORINE.

CHLORINE, a chemical element of the halogen family, is a strong-smelling, greenish-yellow gas. It was prepared first in 1774 by K. W. Scheele from hydrochloric acid and manganese dioxide. Because he was unable to decompose the gas, H. Davy (1810) contended that it was an element and showed further that hydrochloric acid itself contains only hydrogen and the new element, which he called chlorine. Hence in its reaction with manganese dioxide, hydrochloric acid loses hydrogen rather than gains oxygen, as had been believed. Davy's views eventually prevailed, chlorine was accepted as an element, and Antoine Lavoisier's theory that all acids contain oxygen was discarded. The name "chlorine" is taken from the greenish-yellow (Greek *chloros*) colour of the gas. The chemical symbol for chlorine is Cl; its atomic number is 17; and its atomic weight is 35.453.

Chlorine is never found uncombined in nature. Estimated to account for 0.15% of the earth's crust, it occurs most abundantly in soluble chlorides, such as sodium chloride in salt water and rock salt, and in smaller quantities in such insoluble materials

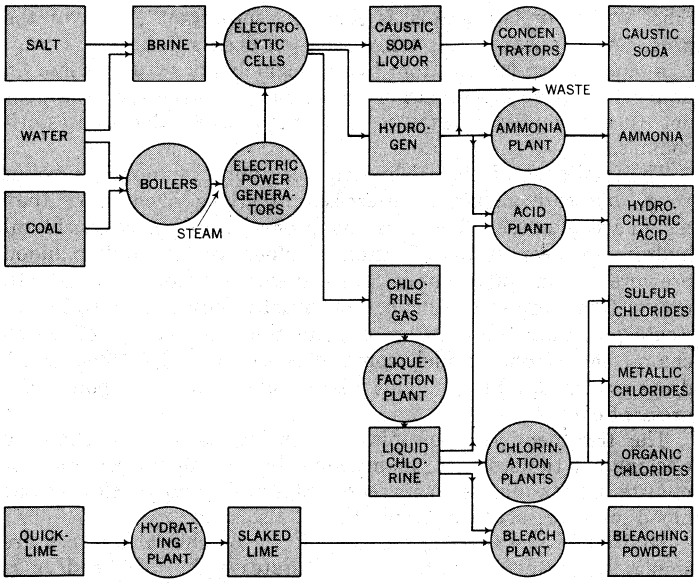

FIG. 1.—THE MANUFACTURE OF CHLORINE AND ITS DERIVATIVES
From left to right: the manufacture of chlorine from salt and water; the principal industrial compounds formed; and the commercial utilization of by-products

as horn silver ($AgCl$). Chlorine as chloride is an essential constituent of animal life.

Chlorine is an active poison and was the first gas used in chemical warfare in World War I. It causes suffocation, constriction in the chest, tightness in the throat and edema of the lungs after severe exposure. As little as 2.5 mg. per litre in the atmosphere causes death in a few minutes, but less than 0.0001% by volume may be tolerated for several hours. Its strong odour, however, gives warning of its presence at much lower concentrations than are dangerous.

Uses.—Originally the only large consumers of chlorine were the paper and textile industries, and most of the chlorine produced was consumed in the manufacture of bleaching powder for their uses. (See BLEACHING; BLEACHING POWDER.) Early in the 20th century began the shipment and use of liquid chlorine, which could be used directly in bleaching, and the proportion used in the manufacture of bleaching powder declined. Chlorine is an effective germicide, and chlorination of municipal water supplies has become general. In some instances chlorine is used to disinfect sewage. The rise of the rayon industry, which employs chlorine for the bleaching of pulp, provided a major outlet for industrial chlorine.

Although the amount of chlorine employed for bleaching and disinfecting was undoubtedly increasing, the fraction of the total chlorine production going into this field was declining because of the tremendous increase in the amount of chlorine consumed by the chemical industry.

Chlorine has become widely used in the production of both organic and inorganic chemicals (fig. 1). Chlorine reacts with carbon disulfide (*q.v.*) to form carbon tetrachloride and sulfur chloride,

$$CS_2+3Cl_2=CCl_4+S_2Cl_2$$

The main uses of carbon tetrachloride are as a solvent, in fire extinguishers and in dry cleaning. Sulfur chloride, also made by combining sulfur and chlorine, is used in the vulcanization of rubber and as a chlorinating agent in organic syntheses. Sulfur chloride was used in the preparation of mustard gas, an important chemical warfare agent in World War I. Another important chlorinating agent, thionyl chloride ($SOCl_2$), is made by the reaction of chlorine, sulfuric acid and sulfur chloride. Thionyl chloride is used to form the acid chlorides of organic acids, which are valuable intermediates in organic syntheses. Chloride combines with phosphorus to form phosphorus trichloride (PCl_3), which may be oxidized by potassium chlorate to phosphorus oxychloride ($POCl_3$), which is another useful chlorinating agent in forming acid chlorides from organic acids. Chlorine and carbon monoxide form carbonyl chloride, or phosgene ($COCl_2$), which has been employed in chemical warfare and is also used in metallurgy to transform certain oxides to chlorides.

A number of metallic chlorides are prepared with the use of chlorine. Anhydrous aluminum chloride is made by the reaction of chlorine with scrap aluminum or with aluminum oxide and carbon. It is used in the petroleum industry and as a catalyst for many organic syntheses. Anhydrous ferric chloride, made similarly, is employed in water clarification. Chlorine is used in the preparation of silicon chloride, from which the silicon synthetics are prepared. Silicon chloride and titanium tetrachloride are used in forming smoke screens. Magnesium chloride ($MgCl_2$) is fused and electrolyzed for the production of metallic magnesium; zinc chloride ($ZnCl_2$) is an essential constituent of dry batteries. Stannic chloride ($SnCl_4$) is used in the textile trade. Its volatility is the basis for a method of recovery of tin from used tin plate.

Chlorine enters directly or as an intermediate into many organic syntheses of industrial importance. Chlorination of organic materials may be done at low temperatures with liquids or in the vapour phase at higher temperatures; the reactions may or may not require a catalyst. Since most organic materials may be chlorinated at different points on the molecule, or to different degrees, the conditions of chlorination must be carefully controlled. For example, the chlorination of a compound containing a benzene nucleus with an aliphatic side chain occurs in the benzene nucleus when the temperature is low in the presence of certain catalysts, but in the side chain at elevated temperatures or in the presence of sunlight.

Of the chlorinated derivatives of methane (CH_4), carbon tetrachloride (CCl_4) has been mentioned Chloroform ($CHCl_3$) is used as a solvent and in medicine. Methyl chloride (CH_3Cl) is used as a refrigerant. Dichlorodifluoromethane (CCl_2F_2), known as Freon, is used as a household refrigerant. Ethyl chloride (C_2H_5Cl), a derivative of ethane (C_2H_6), is used in the production of lead tetraethyl. Unsaturated hydrocarbons, such as acetylene, combine directly with chlorine to form liquids such as acetylene tetrachloride ($CHCl_2\,CHCl_2$) which are largely used as solvents and in dry cleaning.

Chlorinated aromatics serve as intermediates in the dye industry. Chlorobenzene (C_6H_5Cl) is hydrolyzed to produce phenol (C_6H_5OH). The insecticide DDT is dichloro-diphenyl-trichloroethane $(ClC_6H_4)_2CHCCl_3$. Paradichlorobenzene ($C_6H_4Cl_2$) is used as a moth repellent. Chlorine is an essential raw material in manufacture of many plastics, nylon and synthetic rubber.

For other uses of chlorine compounds, see Chlorine Compounds, below.

Laboratory Preparation.— The element may be prepared on a laboratory scale by treatment of hydrochloric acid, or any soluble chloride in acid solution, with strong oxidizing agents such as manganese dioxide, potassium permanganate or potassium dichromate. Concentrated sulfuric acid, however, will not liberate chlorine. The essential change in the preparation of the element from chloride is the removal of an electron from the chloride ion, $2Cl^- = Cl_2 + 2e$. Chlorine may also be prepared by the reaction of a hypochlorite with an acid. Since chlorine is readily available in cylinders of various sizes, preparation in the laboratory is of little practical importance.

For the preparation of chlorine on a large scale, see Commercial Preparation, below.

Chemical Properties.— Chlorine is a member of Group VII of the periodic system. While it is essentially an electronegative element, tending to go to the chloride ion of oxidation state -1, chlorine is also known in the $+1$, $+3$, $+4$. $+5$ and $+7$ states of oxidation. Chlorine combines directly with all but a few elements; oxygen. fluorine, nitrogen, carbon and the inert gases being exceptions. The binary compounds thus formed are called chlorides (see HYDROCHLORIC ACID AND HYDROGEN CHLORIDE). Many of these reactions occur at room temperature; *e.g.*; with pondered antimony $2Sb+3Cl_2=2SbCl_3$. If free from moisture, chlorine is much less reactive, and higher temperatures are required for reaction, thus permitting the storage of dry liquid chlorine in steel

cylinders. Chlorine reacts at high temperatures with certain oxides in the presence of carbon to form chlorides; *e.g.*,

$$Al_2O_3+3Cl_2+3C=2AlCl_3+3CO$$

With water at 0° C., chlorine forms a crystalline hydrate, $Cl_2.8H_2O$, which decomposes on warming. This compound is of historical interest for. while experimenting with the hydrate, Michael Faraday in 1823 discovered that chlorine became liquid under pressure at low temperatures and later succeeded in liquefying a number of other substances which were previously known only in the gaseous state. A solution of chlorine in water contains a small amount of hydrochloric and hypochlorous acid because of the reversible reaction,

$$Cl_2+H_2O=H^+ + Cl^- + HOCl$$

The equilibrium constant is 4.8×10^{-4} at 25° C. Since the hypochlorous acid slowly loses its oxygen, the solution of chlorine in water is unstable, the chlorine eventually being all transformed to hydrochloric acid. Chlorine is readily absorbed in basic solutions. for the neutralization of the hydrochloric and hypochlorous acids prevents equilibrium being established. The reaction at room temperatures may be represented by

$$Cl_2+2OH^-=Cl^-+OCl^-+H_2O$$

thus producing a mixture of chloride and hypochlorite (see BLEACHING POWDER). In hot concentrated alkali, chlorine forms chloride and chlorate,

$$3Cl_2 + 6OH^- = 5Cl^- + ClO_3^- + 3H_2O$$

Chlorine is a strong oxidizing agent. In aqueous solution the electrode potential

$$\tfrac{1}{2}Cl_2(g)+e=Cl^-$$

is 1.358 v. at 25° C. Hence chlorine displaces bromine and iodine, which have lower potentials, from bromides and iodides. In aqueous solution chlorine oxidizes and is itself reduced to chloride by such ions as sulfide, thiosulfate, sulfite. ferrous and stannous. Chlorine combines with carbon monoxide to form carbonyl chloride (phosgene), $COCl_2$; with sulfur dioxide to form sulfuryl chloride, SO_2Cl_2; and with nitric oxide to form nitrosyl chloride. NOCl. Many organic compounds are chlorinated by chlorine.

Hydrocarbons react with chlorine by addition of chlorine to double bonds, or substitution of hydrogen by chlorine. In some cases, as with turpentine, the reaction is violent, all the hydrogen is removed as hydrogen chloride, and a residue of carbon is left.

Physical Properties.— Some of the more important physical properties of chlorine are listed below:

Stable isotopes	35, 37
Radioactive iiotopes	32–34, 36, 38–40
Electron configuration	$1s^2, 2s^2, 2p^6, 3s^2, 3p^5$
Affinity for additional electron	3.75 ev
Crystal radius of chloride ion	1.81 Å.
Molecular weight	70.91
Density at 0" C. and 1 atm.	3.214 g./l.
Roiling point at 1 atm.	−34.05° C.
Freezing point	−101° C.
Critical temperature	144° C.
Critical pressure	76.1 atm.
Critical density	0.573 g./ml
Vapour pressure of liquid in atmosphere at T° kelvin	Log P = −1,499.5/T−4.022 log T+15.844
Heat of fusion	22.9 cal./g.
Heat of vaporization	65.8 cal./g.
Heat capacity of gas at constant pressure and a t room temperature	0.226 cal./g.
Heat capacity at T° K.	$8.28+0.56\times10^{-3}$ T cal./mol.
Heat capacity of liquid	16 cal./mol.
Entropy at 298.1° K.	53.31 cal./mol./degree
Solubility in water at 20° C.	0.09 mol./l. at 1 atm.

CHLORINE COMPOUNDS

Oxides of Chlorine.— Four oxides, chlorine monoxide (Cl_2O), chlorine dioxide (ClO_2), chlorine hexoxide (Cl_2O_6) and chlorine heptoxide (Cl_2O_7), are known. ClO_4 or Cl_2O_8 has been made in solution by the reaction of iodine with silver perchlorate dissolved in benzene. All the oxides are unstable and reactive and cannot be produced by direct synthesis. Chlorine monoxide is made by the reaction of chlorine with mercuric oxide,

$$HgO+2Cl_2=HgCl_2+Cl_2O$$

In an industrial process chlorine monoxide is formed by the reaction of chlorine on solid sodium bicarbonate,

$$2Cl_2+2NaHCO_3=Cl_2O+2NaCl+2CO_2+H_2O$$

It is slightly darker yellow than chlorine, condensing to a liquid at 2° C. and solidifying at −116° C. Chlorine monoxide is the anhydride of hypochlorous acid, readily dissolving in water to form the acid.

$$Cl_2O+H_2O=2HOCl$$

Chlorine dioxide is formed by the action of strong acids on chlorates. best with oxalic acid.

$$2KClO_3+3H_2C_2O_4=2ClO_2+2H_2O+2CO_2+2KHC_2O_4$$

In the industrial preparation of sodium chlorite, chlorine dioxide is first formed by the reaction of hydrochloric acid on calcium chlorate,

$$Ca(ClO_3)_2 + 4HCl = CaCl_2 + 2ClO_2^- + Cl_2 + 2H_2O$$

the accompanying chlorine being removed by absorption on lime. Chlorine dioxide decomposes explosively to Cl_2+O_2. It is a gas with a much stronger yellow colour than chlorine, liquefying at 10° C. and solidifying at −76° C. It is not an acid anhydride, hardly reacting with water and but slowly with alkalies to give a mixture of chlorite and chlorate. Chlorine hexoxide, formed by the action of light or ozone on chlorine dioxide, is a red oil, freezing at −1° C., decomposing slowly at higher temperatures. Chlorine heptoxide, the anhydride of perchloric acid, is formed by removal of water from that acid by phosphorus pentoxide. It is a rolourless liquid boiling at 80° C. and freezing at −91.5° C. It explodes with shock.

Hypochlorous Acid and **Hypochlorites.**—In these compounds chlorine exists in the +1 state of oxidation. Hypochlorous acid, HOCl, is quite weak, the dissociation constant being 4×10^{-8} at 25° C., and unstable, decomposing to hydrochloric acid and oxygen. The hypochlorite ion is stable in alkaline solution. Hypochlorites are formed in solution by the neutralization of hypochlorous acid or by the absorption of chlorine monoxide or chlorine by alkaline solutions. If chlorine is employed an equivalent amount of chloride is formed along with the hypochlorite.

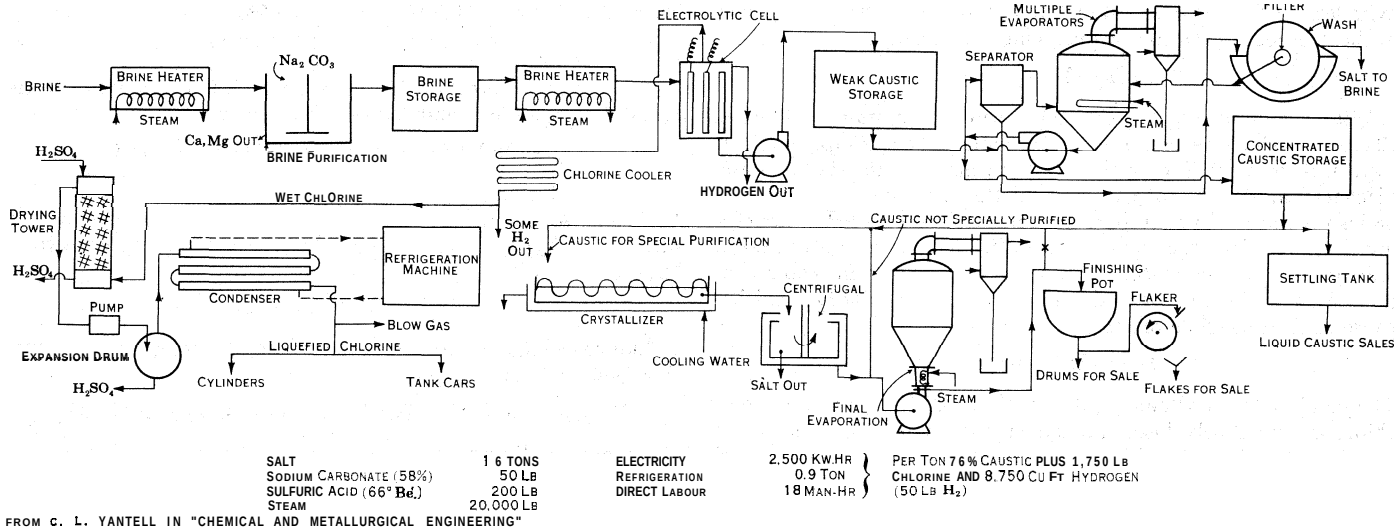
Because of the weakness of hypochlorous acid, hypochlorites are considerably hydrolyzed and preparation of the pure salts is difficult. Only a hydrated calcium hypochlorite, $Ca(OCl)_2.2H_2O$, is available in solid form, although solid sodium hypochlorite has been prepared. Sodium and calcium hypochlorite are widely used in bleaching and disinfecting, their effectiveness being attributed to their oxidizing powers. They are also effective oxidizing agents in preparative chemistry, lead dioxide for example being formed from lead acetate by the action of sodium or calcium hypochlorite in basic solution.

Chlorous Acid and **Chlorites.**—Salts of chlorous acid, $HClO_2$, are called chlorites and contain the ion ClO_2^-, in which chlorine is in the +3 oxidation state. Sodium chlorite is made by passing chlorine dioxide into alkaline solution containing carboniferous material,

$$4ClO_2+4NaOH+Ca(OH)_2+C=4NaClO_2+CaCO_3+3H_2O$$

Chlorites are generally soluble and stable in alkaline solution. Chlorous acid, although somewhat stronger than hypochlorous acid, is mdch less stable, and on acidifying a solution containing a chlorite, decomposition to ClO_2 occurs rapidly. Sodium chlorite is employed in bleaching.

Chlorates and Chloric Acid.— Chlorine in the +5 oxidation state occurs in chloric acid and its salts the chlorates. Chlorates are formed in solution by the reaction of chlorine with hot alkalies, or on mixing, at the proper temperature, the anode and cathode solutions resulting from electrolysis of sodium chloride solution. The chlorate is generally separated from the accompanying chloride by crystallization of the potassium salt which is only



FROM C. L. YANTELL IN "CHEMICAL AND METALLURGICAL ENGINEERING"

FIG. 2.— ELECTROLYTIC CAUSTIC SODA AND CHLORINE

Flow sheet showing the several stages from brine, the raw material, to caustic soda and chlorine, the products

moderately soluble, but other chlorates may be made by either of these methods. A solution of chloric acid ($HClO_3$) may be prepared by adding sulfuric acid to a solution of barium chlorate and filtering to remove the precipitated barium sulfate. By evacuating at room temperature the solution may be concentrated to about 50% $HClO_3$, but in more concentrated solution decomposition is rapid. Chloric acid is a strong acid, hence chlorates are not hydrolyzed in solution. Chlorate ion is stable in neutral or basic solution, but in acid solution chlorates are readily reduced to chloride by such reagents as sulfur dioxide. Potassium chlorate, a white crystalline material melting at 350° C., is unstable with respect to the decomposition $2KClO_3 = 2KCl + 3O_2$, and other chlorates decompose similarly. This reaction is highly exothermic and irreversible, but the decomposition is relatively slow below 400° C. It is markedly susceptible to catalysts; a mixture of potassium chlorate and manganese dioxide decomposessmoothly at moderate temperatures and serves as a source of small amounts of oxygen in the laboratory. A mixture of potassium chlorate and a reducing material such as charcoal or sulfur is dangerously explosive. Because they serve as a concentrated source of oxygen, chlorates are employed in fireworks, matches, etc. Potassium chlorate is claimed to be an effective antiseptic in the treatment of ulcers of the mouth, but in quantity is poisonous. Sodium chlorate is sold commercially for use as a weed killer.

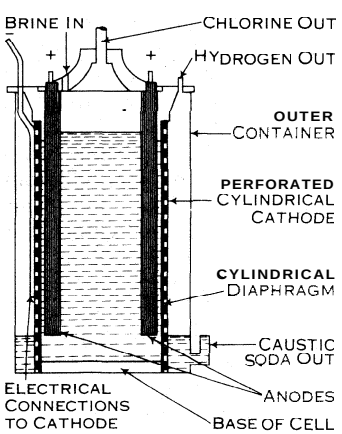


FIG. 3.— CYLINDRICAL DIAPHRAGM CELL

Hydrogen is set free at the perforated cathode as the brine percolates through it, leaving caustic soda in solution. The chlorine is set free at the carbon anodes

Perchlorates **and** Perchloric Acid.—In these compounds chlorine is in its highest oxidation state, +7. Potassium perchlorate may be made by carefully heating the chlorate,

$$4KClO_3 = 3KClO_4 + KCl$$

and separating the perchlorate, which is less soluble than either the chloride or chlorate, by crystallization. Commercially, however, it is made by electrolysis of chlorate solutions at high current density. The perchlorates in general are soluble, their solutions are stable, and even in strongly acid solution are reduced with difficulty. A perchlorate may be distinguished from a chlorate by treating in acid solution with sulfur dioxide, which reduces the latter readily but does not affect the perchlorate. Barium and magnesium perchlorates form stable hydrates and are employed as drying agents to remove moisture from gases. Perchloric acid is made by treatment of potassium perchlorate with sulfuric acid and separation of the perchloric acid by vacuum distillation. While perchloric acid is much more stable than chloric acid, the pure acid decomposes slowly at 92° C. At ordinary temperatures perchloric acid is a liquid with a strong affinity for water. It forms a stable hydrate, $HClO_4.H_2O$, which is a solid below 50° C. although the anhydrous acid only freezes at −112° C. It is commonly sold in 60% solution and finds application in analytical chemistry. It is one of the strongest acids. The concentrated acid is a powerful oxidizing agent and in contact with reducing materials violently explosive, as are the solid perchlorates at higher temperatures. Solid perchlorates lose oxygen on heating as do the chlorates but are somewhat more stable. They may be used in place of chlorates in explosives and fireworks, as they are considered safer to handle.

COMMERCIAL PREPARATION

Almost since its discovery chlorine has been produced on a large scale for use in industry. The long-obsolete Weldon process was first employed, making use of the reaction of hydrochloric acid with manganese dioxide,

$$MnO_2 + 4HCl = Cl_2 + MnCl_2 + 2H_2O$$

by which K. W. Scheele first discovered chlorine. At best, only about one-third of the hydrochloric acid is transformed to chlorine in the process, and the lack of materials in which these corrosive substances could be handled made the Weldon process difficult and expensive.

About 1868 Henry Deacon developed a process by which chlorine was made by the reaction of hydrogen chloride gas and atmospheric oxygen. The reaction employed,

$$4HCl + O_2 = 2Cl_2 + 2H_2O$$

is reversible and incomplete. The rate of reaction was found to be satisfactory when the gases were passed over pumice in contact with cupric chloride, a catalyst, at about 430° C. Under these conditions about 70% of the hydrogen chloride could be converted to chlorine. The hydrogen chloride required in the Deacon process was largely a by-product of the LeBlanc soda process (see ALKALI MANUFACTURE). With the decline of the latter, the Deacon process mas abandoned, and electrolytic methods became widely used.

Electrolytic Process.—In the early 1960s the electrolysis of brine was the major source of industrial chlorine. A minor source was the electrolysis of fused sodium chloride, in which metallic sodium is the primary product and chlorine a by-product.

Electrolytic chlorine was first produced successfully on a com-

mercial scale about 1890. The following half century saw an enormous increase in the amount of chlorine produced. Technical improvements greatly increased the efficiency of production, but the process remained basically unchanged. The raw materials are salt (NaCl) and water; the products chlorine, sodium hydroxide (alkali or caustic soda) and hydrogen. The change which is brought about by electrical energy may be represented by

$$\underset{\text{salt}}{2NaCl} + \underset{\text{water}}{2H_2O} = \underset{\text{chlorine}}{Cl_2} + \underset{\text{sodium hydroxide}}{2NaOH} + \underset{\text{hydrogen}}{H_2}$$

Although the electrolysis of salt (fig. 2) produces equivalent amounts of both chlorine and caustic soda, the chlorine is regarded as the primary product and the caustic soda a by-product because, without a market for chlorine, the caustic soda so produced cannot compete economically with caustic from the ammonia-soda process.

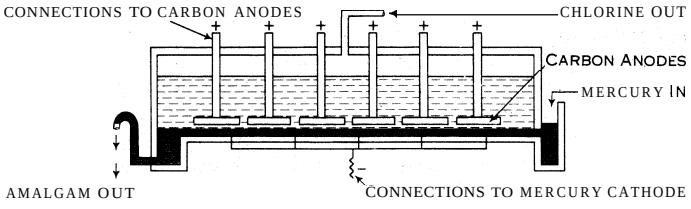

FIG. 4.—PRINCIPLES OF A MERCURY CELL

Mercury, which acts as a cathode, enters the cell at one end, propelled by a mechanical device. Brine flows through the cell in the same direction as the mercury (entrance and exit not shown). The mercury-sodium amalgam formed by the electrolysis leaves the cell and travels to a separate chamber in which it is made the anode, the sodium going into solution as sodium hydroxide. After extraction of the sodium, the mercury returns to the cell and repeats the cycle

Two distinct types of cells are employed, the diaphragm cell (fig. 3) and the mercury cell (fig. 4). In both, the electrolyte is a strong solution of salt (brine). Calcium and magnesium ions are precipitated from the brine before it enters the cell by addition of sodium carbonate, since these ions would otherwise precipitate in the cell and interfere with its operation. Both types employ graphite anodes but differ in the cathode material. Iron cathodes are generally used with the diaphragm-type cell, while a mercury cathode is the distinctive feature of the mercury-type cell. The reaction at a graphite anode is the liberation of chlorine gas,

$$2Cl^- = Cl_2 + 2e$$

Small amounts of oxygen ucually accompany the chlorine, thus reducing the efficiency of operation (see ELECTROCHEMISTRY).

Diaphragm Cell.—In a diaphragm cell, hydrogen is discharged from the iron cathode. Discharge of sodium does not occur in the presence of water, for the potential required to discharge sodium is much greater than that at which hydrogen is set free. The hydrogen comes from the water, leaving hydroxyl ion in solution,

$$H_2O + 2e = H_2 + 2OH^-$$

The cathode and anode solutions must be kept separate for, with chlorine formed at the anode and sodium hydroxide at the cathode, mixing of the solutions would result in the formation of hypochlorite instead of evolution of chlorine. The diaphragm, commonly made of asbestos paper, serves this purpose. The diaphragm is adjacent to, and supported by. the cathode. Later practice favoured the nonsubmerged diaphragm, where the brine seeps through the diaphragm and is electrolyzed, and the alkaline solution trickles to the bottom of the cell. The cathode liquors average 110 to 120 g. NaOH per litre and 140 to 170 g. NaCl per litre. An outlet above the cathode allows the hydrogen to escape or to he collected. The anode section generally has a concrete cover with an opening for collection of the chlorine.

Some of the diaphragm-type cells in common use in the early 1960s were the rectangular Allen-Moore and Hooker type S (U.S.), the Hargreaves-Bird (British). Krebs (French), Billiter (German) and the cylindrical Vorce (U.S.). The bell jar cell. without diaphragm and with a slowly streaming electrolyte, has been employed in Europe.

Factors influencing the design of cells are the initial cost, life period, purity of product and efficiency with which electrical energy is utilized. Theoretically, the decomposition of aqueous sodium chloride solution requires about 2.2 v., but in operation the voltage drop per cell is found to be from 3.3 to 4.5 v. Hence, although the current efficiency in the modern cell is more than 90%, the energy efficiency is only 50%–60%. The excess voltage required results from energy lost as heat because of the resistance of the electrolyte, which may be minimized by having large electrodes close together, and to overvoltage effects at the electrodes. The overvoltage is largely a property of the electrode material, in the choice of which resistance to chemical action and cost must be considered.

The commoner types of cell operate at 1,000–5,000 amp., but the current density in amperes per square inch of electrode surface is only 0.12–0.50. An average yield per kilowatt hour is about two-thirds pound of chlorine and the same weight of sodium hydroxide. The different types of cell vary considerably in size, from the cylindrical Vorce cell, only 26 in. in diameter, to the Billiter cell, 18 ft. long, 10 in. wide and 2 ft. deep.

The operation of the diaphragm-type cell is accompanied by decreased efficiency because of the clogging of the diaphragm, which must be renewed at intervals of from one month to a year, varying with the different types of cell. In the Hargreaves-Bird cell, steam and carbon dioxide enter the cathode compartment, changing the sodium hydroxide to sodium carbonate. The diaphragm in this cell has a long life which is attributed to the action of the steam.

Mercury Cell.—In the mercury-type cell sodium is discharged into the mercury cathode at the bottom of the cell, and no hydrogen is evolved. Mechanical agitation moves the amalgamated mercury to a separate compartment of the cell where it is made the anode, causing the sodium to go back into solution as sodium hydroxide, while hydrogen is discharged from an ion cathode above. The over-all reaction is the same as with the iron cathode-type cell. The advantage of the mercury-type cell is that the caustic soda solution is free from chloride and may be produced at as high as 50% concentrate in the cell, while in the other cells the caustic soda is more dilute and considerable chloride must be separated to prepare the sodium hydroxide for sale. The disadvantage of the mercury-type cell is the high cost of mercury. The efficiencies reported are about the same as for the diaphragm-type cell. The cells are operated with much greater currents, however, up to 15,000 amp. The original mercury-type cells were developed by H. Y. Kastner (U.S.) and C. Kellner (Austria). Modern versions are the Krebs, Mathieson, I. G. Farbenindustrie and Imperial Chemical industries cells.

A 1945 report from Germany stated that all new installations since 1936 had been of mercury-type cells, presumably because of lower power costs and a plentiful supply of mercury from Spain. The new-type cells are steel tanks from 20 to 40 ft. long, 25 in. wide and 8 in. deep. The sides are coated with rubber, and a thin layer of mercury on the bare steel bottom serves as cathode. The tank slopes to give a mercury flow such that 0.2% of sodium is accumulated at 15,000 amp. The sodium is stripped from the mercury, without electrolysis, in an adjoining compartment. Brine, entering with 310 g. of NaCl per litre, is electrolyzed at from 70° to 90° C. and leaves the cell with 220–270 g. of salt per litre. The loss of mercury is reported to be from 1% to 7% per year.

Distribution.—Chlorine from the cells is freed from moisture by the action of concentrated sulfuric acid, cooled and liquefied by compression. The liquefied chlorine is sold in steel cylinders and tank cars. The large chlorine-caustic soda plants are generally located at points where both salt and electrical power are cheapest. However, some paper mills and rayon manufacturers, which are large users of both chlorine and caustic soda, run their own electrolytic plants. In this case the chlorine need not be liquefied and may be piped directly to the point of use.

CHLORITE, a group of green, micaceous hydrous aluminum silicates, usually of magnesium and ferrous iron.

Chlorites generally occur as alteration products of other minerals. They are common rock-forming minerals in clastic sediments (composed of pre-existing rocks) and in hydrothermally altered igneous rocks, and are important constituents in metamorphosed rocks, such as green or chlorite schists (see SCHIST). The cleavage of the chlorites is prominent but less perfect than that of the micas; and lamellae are softer (hardness = 2 to 3), and are pliable but not elastic. Chlorites are chemically distinguished from the true micas by greater water content (12% or 13%) and the essential absence of alkalis.

The fundamental crystallization scheme of the chlorites accommodates compositions whose empirical formulas may be expressed as $(Si_{4-x}Al_x)\ (Me^{2+}_{6-x}Me^{3+}_{x})O_{10}(OH)_8$, where Me^{2+} are divalent metals, Me^{3+} are-trivalent, and x may be as great as 2. Co-ordination of the fourfold ions is tetrahedral and of the sixfold, octahedral. Small contents of several divalent metals are frequently present, and in some compositions ferric iron or chromium partially replaces the essential tetrahedral aluminum. Group fundamentals and ranges of specific compositions were reviewed by M. H. Hey (1954).

Chlorites whose compositions conform strictly to the ideal formula are called orthochlorites. Hexagonal outlines are more or less distinct. Many other chlorite compositions, especially those containing ferric iron, are called leptochlorites, and are presumed to have been derived from orthochlorites by oxidation in the solid state with compensating loss of hydrogen. The physical properties of leptochlorites are less regular, and they more frequently include associated impurities. Experimental conversions of ferrous orthochlorites to leptochlorites have been accomplished, probably first by A. N. Winchell (1926).

Orthochlorite species names most frequently used are penninite, clinochlore and corundophyllite for predominately magnesian compositions; and daphnite for the abundantly ferrous iron-bearing.

Chamosite and thuringite are frequently used leptochlorite names, and unusual chemical compositions are often referred to by varietal names, as kammererite and kotschubeite for chromium-bearing members.

A rich polymorphism, based on extension of the principles set forth by S. B. Hendricks and M. E. Jefferson for true micas, exists within the chlorite crystallizations, and even within a given crystal some areas may be uniaxial, others biaxial.

CHLORITOID: see UTTRELITE.

CHLOROFORM (TRICHLOROMETHANE) is a noninflammable, clear, colourless, mobile, heavy liquid with sweet, pleasant, ethereal odour, used primarily as an anesthetic and fat solvent. It was made in 1831 simultaneously by Samuel Guthrie in the United States, E. Soubeiran in France and Justus von Liebig in Germany, but Sir James Simpson of Edinburgh was the first to use it as an anesthetic, in 1847. Chloroform anesthesia, however, was attacked on religious grounds (based on Gen. iii, 16, "In pain you shall bring forth children"), and controversy over it continued until 1853 when John Snow gave it to Queen Victoria during the birth of Prince Leopold, her seventh child.

Chloroform is one of the most potent inhalation anesthetics, a few millilitres being enough usually to produce surgical anesthesia. Chloroform is commonly inhaled from an open mask and can produce deep anesthesia in a few minutes. It is mainly excreted with the exhaled air, and the patient wakes up in 10–15 minutes, usually groggy but with very little nausea or vomiting.

The margin of safety in chloroform use is relatively narrow, and this is probably the reason for the high mortality in inexperienced hands. It has a depressing and undesirable effect on most organs, especially the heart, blood vessels, liver, pancreas and kidneys. The fatalities occurring during induction of anesthesia, termed primary collapse, are most often due to overdosage. Delayed chloroform poisoning is seen when chloroform is given in high concentration with too little oxygen, and occurs most often in patients in poor nutritional condition. When overdosage, high concentration and inadequate oxygenation are avoided, then, and only then, can chloroform be regarded as a useful agent. It does not deserve to be abandoned as a surgical anesthetic, however. It is often the preferred anesthetic in very hot climates because of its high boiling point, in very cold climates because of its high potency, and in the presence of flames, high-voltage electricity and under other conditions where explosive anesthetics would be too dangerous to use.

Chloroform is sometimes used internally as an anodyne, a carminative and in cough medicines. Externally it is used in solutions, ointments or liniments as a local irritant or counterirritant for treatment of such conditions as rheumatism, headache and neuralgia. It is an effective anti-itching agent for insect bites, and in industry has a limited use as a fat solvent.

The chemical formula of chloroform is $CHCl_3$. Specific gravity of the liquid is 1.476 at 20° C. The vapour is about four times as heavy as air. It solidifies at −62° C, and boils at 61° C. (142° F.); critical temperature is 260° C. It dissolves poorly in water (1 ml. in 140 ml. at 20° C.) but easily in animal and vegetable lipoids, alcohol, ether, acetone, gasoline and most other organic solvents.

Chloroform can be prepared from many hydrocarbons (most often from alcohol or acetone), but during the process numerous toxic products may be formed; *e.g.,* phosgene, chlorine, hydrochloric acid and ethyl chloride. Although it is not inflammable, when exposed to flame, heat, light or oxygen it may be decomposed to the same toxic compounds. See also ANESTHESIA AND ANESTHETICS.

CHLOROMYCETIN: see CHLORAMPHENICOL.

CHLOROPHYLL, CHEMISTRY OF. The green pigment which is present in leaves and algae is known as chlorophyll. Attempts to prepare the colouring matter of leaves in a pure form have shown that it is not homogeneous. R. Willstatter was able to separate it into four components: two green ones, chlorophylls *a* and b ($C_{55}H_{72}O_5N_4Mg$ and $C_{55}H_{70}O_6N_4Mg$); and two yellow ones, carotene ($C_{40}H_{56}$) and xanthophyll ($C_{40}H_{56}O_2$). At the same time, he found that the ratio of the blue-green chlorophyll a to the yellow-green chlorophyll b is 3:1, while that of xanthophyll to carotene is 2:1. The proportion of chlorophyll a + b to xanthophyll + carotene is about 3:1.

Later work (V. Lubimenko, 1921; A. Stoll and E. Wiedemann, 1938) showed that these pigments are not present in the leaf in the free state but are combined with a protein in the form of chloroplastin. Consequently, they pass into ether from an aqueous solution of the leaf pigment only after splitting the organic complex (called "symplex" by Willstatter, 1934). Chloroplastin is decomposed not only by high concentrations of salt but also by the presence of alcohol or acetone, so that the normal extraction process using these solvents liberates the individual pigments.

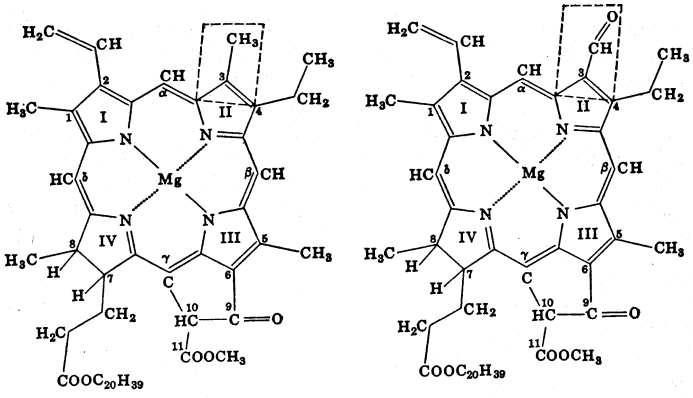
The separation of the carotenoids and the chlorophylls is achieved by distribution between suitable solvents, according to the method of Willstatter and Stoll (1913). Later, the technique of chromatographic analysis was employed to prepare the components in a pure state and to test their homogeneity. This led to preparations which careful spectrographic analyses proved to be of uniform composition (A. Winterstein and G. Stein, 1934; G. Mackinney, 1940–42; F. P. Zscheile, 1934–43). The pure chlorophylls are usually obtained as dark-green waxes. Progress in purification has enabled both chloropbylls to be characterized more

precisely by their absorption spectra and, finally, to be crystallized, component a being obtained in green hexagonal plates and component b in dark-green needles (A. Stoll and E. Wiedemann. 1955–59). Crystallized derivatives of both components can be easily obtained after elimination of the phytol and the central magnesium atom (R. Willstatter and A. Stoll, 1913). The methods employed for the identification of the chlorophylls and for their quantitative determination are based upon characteristic absorption and fluorescence spectra (C. Dhéré and O. Biermacher, 1914–36; A. Hagenbach, F. Auerbacher and E. Wiedemann. 1936; A. Stern and co-workers, 1936–38; F. P. Zscheile and D. G. Harris, 1943). In ether solution the absorption maxima correspond to the following wave lengths (A. Winterstein and G. Stein, 1933):

chlorophyll a: **663** **623** 607 577 **534** 507 494 **432** mμ
chlorophyll b: **644** **614** **594** 567 **542** 503 456

The connection between fluorescence and the part played by chlorophyll in photosynthesis has been thoroughly investigated (J. Franck. 1935–42; A. Kautsky, 1932–39; E. W. McAlister, 1937–41; E. C. Wassink, 1937–46). The essential chemical properties of the chlorophylls and their most important derivatives will be discussed in relation to the formula depicted for chlorophyll a. The characteristic features of the structure of chlorophyll are the porphin system, the magnesium atom with its complex linkage and the phytyl radical (R. Willstatter and A. Stoll, 1913).

The components of the porphin system were ascertained by

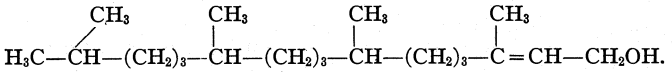


CHLOROPHYLL a AND CHLOROPHYLL *b*. THE DIFFERENCE IN THE TWO STRUCTURES IS INDICATED BY THE AREAS WITHIN THE DOTTED LINES

Willstatter (1904–12) when he carried out his first work on the degradation of the chlorophylls. The nature of the 16-membered ring system, composed of four pyrrole rings linked by methine bridges (α-δ), was then elucidated by H. Fischer (1915–30), who confirmed the formula suggested by W. Kuester in 1912 for hemin. The stage of hydrogenation of the chlorophyll nucleus is that of the phorbins: *i.e.*, dihydroporphyrins. The chlorophylls. therefore, contain two hydrogen atoms more than the porphyrins. which possess the maximum possible number of double bonds in the ring system. The structure of the porphin system and of the individual substituents was established by H. Fischer by degradation reactions and by the syntheses of numerous porphyrins, including most of those obtained by degradation of chlorophylls.

The discovery that magnesium, bound in the form of a metallic complex, forms an essential component of the molecules of the natural chlorophylls caused great surprise at the time (R. Willstatter. 1904), and this type of magnesium linkage remained unique. It may be that the magnesium has a share in the part played by chlorophyll in the assimilation process. The magnesium atom also constitutes a characteristic difference between the chlorophyll and the blood pigment hemin. which is an iron complex but otherwise possesses a similar structure, including a porphyrin system whose substituents agree closely with those of the chlorophyll porphyrins. When the chlorophylls are treated with acids. the magnesium atom is easily split off. the colour then changing from pure green to brownish green. The magnesium can be replaced by copper, zinc or other metals. The corresponding copper complexes are stable and are used as industrial pigments; *e.g.*, in the soap and cosmetic industries.

The structure of the simple unsaturated alcohol phytol. $C_{20}H_{39}OH$, was elucidated by F. G. Fischer (1928) by total synthesis, which showed it to be an isoprene derivative. It was later shown that phytol, as a structural component of vitamins E and K_1, is connected with special physiological functions.



phytol

Before discussing the individual reactions by which derivatives of chlorophyll may be formed, it should be mentioned that chlorophyll b differs from chlorophyll a only in having an aldehyde group in position 3 in ring II in place of a methyl group; *i.e.*, it has an oxygen atom in place of two hydrogen atoms. Most reactions follow the same course with both components, so that they can be discussed as one. Simple reactions which leave the phorbin system intact and do not alter the relative positions of the substituents include the action of the specific enzyme (chlorophyllase) and the reactions with dilute acids and alkalies (*see* table).

In green leaves. chlorophyll is accompanied by the enzyme chlorophyllase. the quantity of which varies according to the variety of plant. Its specific action is the removal of the phytyl group, which is replaced by water, methyl or ethyl alcohol according to the nature of the medium present (R. Willstätter and A. Stoll, 1910; C. Weast and G. Mackinney, 1940). In this way, chlorophyllides are produced, which still contain magnesium. The reaction is reversible. since chlorophyllase can also be used to introduce phytol (R. Willstatter and A. Stoll, 1910), as well as other higher alcohols (H. Fischer, 1938), into the chlorophyll molecule.

Dilute acids split off the magnesium from chlorophyll and chlorophyllides with the formation of phaeophytin and the corresponding phaeophorbides. respectively. This reaction is also reversible, since it is possible by means of the Grignard reagent (R. Willstätter and L. Forsén, 1911) or magnesium alcoholatc (A. Stoll and E. Wiedemann, 1933; H. Fischer, 1934) to reintroduce the magnesium.

By the action of hot alkalies. both the chlorophylls and the phaeophytins and phaeophorbides are converted into tricarboxylic acids by saponification of the phytyl and methyl ester groups and the cleavage of the carbocyclic side ring (C, – C,). Thus, the chlorophylls yield the isochlorophyllins. which are converted by acidification into chlorin e_6 in the case of chlorophyll a, and into rhodin g_7 in the case of chlorophyll *b;* these end products being also obtained from the phaeophorbides and their esters.

The determination of the structure of the chlorophylls and their primary derivatives was carried out by way of the related porphyrins. These are obtained by degradation of the phorbins with alkali. or by treatment with hydrogen iodide. This reagent reduces only the double bonds. During the subsequent working up. aerial oxidation takes place until the ring system is completely dehydrogenated. As will be described later. at the same time a vinyl group is converted to an ethyl group during the reduction. It therefore follows that the most important phaeoporphyrins formed in this way (phaeoporphyrin a, in the a series and phaeoporphyrin b_6 in the b series) are isomers of the phaeophorbides a and *b*. The numerals added as subscripts indicate the number of oxygen atoms present. F'haeoporphyrin a_5 still contains the carbocyclic side ring from C_6 to C_γ which, as an acetoacetic ester group, is responsible for the ready transformation into the tricarboxylic acids chlorin e_6 and chloroporphyrin e_6, respectively.

To confirm this acetoacetic ester grouping. it was essential to demonstrate the presence of an enolizable keto group. which was achieved by the preparation of oxime and benzoyl derivatives of phaeophorbide a. By oximation of phaeophorbide b it was possible to prove the presence of a further carbonyl group in addition to the keto group, so that a dioxime and two monoximes were obtained in this case (A. Stoll and E. Wiedemann, 1934).

Enolization in the carbocyclic side ring is also proved by the so-called phase test, which is characteristic of the intact chloro-

phyll molecule. When an ethereal chlorophyll solution is shaken with concentrated alcoholic alkali, the green colour changes suddenly to brown, followed, after several minutes, by a return of the green colour owing to hydrolysis of the carbocyclic ring. Oxidized chlorophyll derivatives, which form even on standing in alcoholic solution. especially on the alkaline side, no longer give the phase test and are known as allomerized chlorophyll derivatives and purpurins (J. B. Conant, 1931–34; A. Stoll and E. Wiedemann, 1932–3j; H Fischer and co-workers, 1933).

The presence of the vinyl group in position *2* of the chlorophyll molecule was proved by hydrogenation and by a specific oxidation reaction (oxoreaction). Its position was confirmed by elimination of the acetyl group thus produced and identification of the resulting porphyrin (H. Fischer and co-workers, 1935).

The green compounds. the phorbins, to which the chlorophylls and their primary derivatives belong, arise from the red porphyrins by the reduction of one of the double bonds in the nucleus. The natural phorbins are further characterized by the above-mentioned vinyl group in place of the ethyl group in position 2. The fact that the phorbins are dihydroporphyrins was proved by oxidation of their copper complexes (H. Fischer and K. Herrle, 1937; H Wenderoth. 1939; H. Gibian, 1942). The placing of the two hydrogen atoms in positions 7 and 8 in the pyrrole ring IV followed from the optical activity of chlorophyll derivatives in which other asymmetric centres had been eliminated (H. Fischer and H. Wenderoth, 1940). The optical rotation in acetone is $[\alpha]_{720}^{25} = -262°$ for chlorophyll *a;* and $[\alpha]_{720}^{25} = -267°$ for chlorophyll b (A. Stoll and E. Wiedemann, 1933).

In principle, the conversion of porphyrins into green compounds can be achieved by hydrogenation. The main obstacles which have so far prevented a total synthesis of the chlorophylls are the severity of the conditions which have to be employed and the simultaneous reduction of the 2-vinyl group if previously introduced. In the case of simple porphyrins, it has been possible to effect the introduction of hydrogen in the required 7:8 position (A. Treibs and E. Wiedemann, 1928; H. Fischer and H. Helberger, 1929; H. Fischer and H. Wenderoth, 1940). The introduction of magnesium, of the phytyl and vinyl radicals and of the carbocyclic side ring has been carried out successfully.

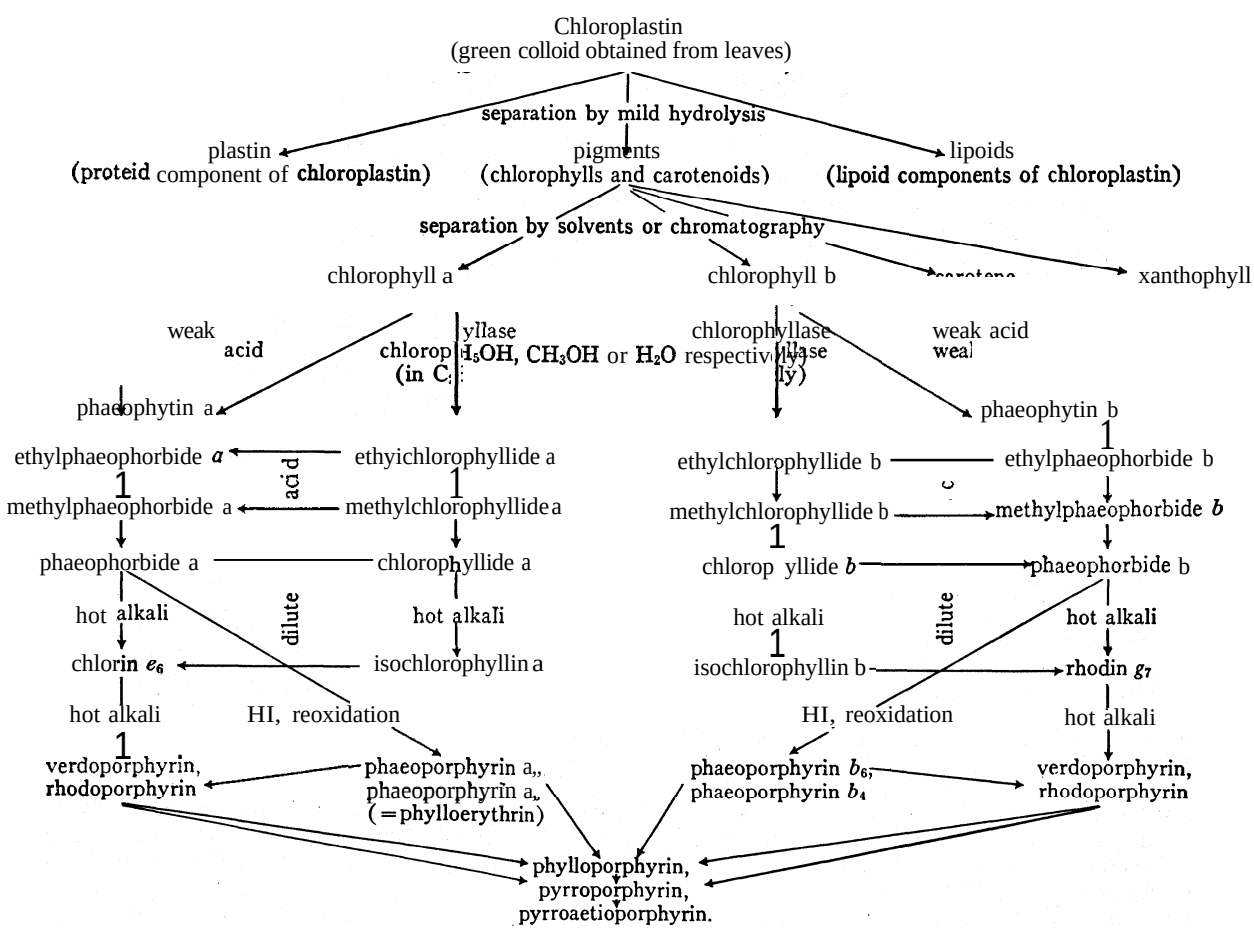
As precursors of the chlorophylls in plants, protochlorophylls were found which are converted into chlorophylls on exposure to light (N. A. Monteverde and V. Lubimenko, 1894–1912). It is probable that these protochlorophylls belong to the porphyrins but otherwise possess the same structure as the chlorophylls (K. Noack, 1928–31; A. Seybold, 1937).

A chlorophyll derivative has been found in photosynthetic bacteria and has been named bacteriochlorophyll (C. B. van Niel, 1932–36). Its structure can be derived from that of chlorophyll a by the addition of two H atoms to the double bond in ring II and by replacing the vinyl group in position 2 by an acetyl group (H. Fischer and co-workers, 1937–38). Compared with the spectra of the chlorophylls, the absorption bands of bacteriochlorophyll are shifted into the infrared (C. B van Niel, 1938).

Only brief reference can be made to the part played by the leaf pigments in the assimilation of carbon dioxide without discussing the many theories relating to this phenomenon. An important result is the confirmation that the assimilatory quotient of the expired oxygen to the assimilated carbon dioxide is always equal to 1 (R. Willstatter and A. Stoll, 1917).

The function of chlorophyll in photosynthesis (*q.v.*) has been defined as that of an energy transformer or of an assimilatory ferment (R. Emerson, 1936; A. Stoll, 1936). The path of the assimilated carbon, from carbon dioxide to the final products, especially in the case of sucrose, was elucidated by M. Calvin and co-workers (1947–52) using radioactive carbon. The intermediates were identified by means of radioautographs and chemical analysis.

The combination of chlorophyll with protein in chloroplastin is of special significance for this function, since only as a result of this combination is chlorophyll able to remain resistant to light (Lubimenko, 1921). Chloroplastins from different plants are not identical. A characteristic of chloroplastin is its great tendency



toward agglomeration; and even the smallest molecular weights measured by the ultracentrifuge on electrophoretically homogeneous chloroplastin preparations run into several millions (A. Stoll and E. Wiedemann, 1938–47).

See also references under "Chlorophyll, Chemistry of" in the Index volume. (A. STL)

CHLOROPICRIN, product of the distillation of bleaching powder with many nitro compounds (*e.g.*, picric acid, nitromethane), may be prepared also by the action of concentrated nitric acid on chloral or chloroform, or by the action of aqua regia (*q.v.*) upon almost any organic substance. The commonest method of preparation (A. W. von Hofmann. 1866) consists of adding a solution (saturated at 30° C.) of one part of picric acid to a paste of ten parts of bleaching powder and water. A violent reaction occurs, and chloropicrin (nitrochloroform, trichloronitromethane), CCl_3NO_2, distills over, generally without external heating. It is a colourless liquid of boiling point 112° C. and of specific gravity 1.692. It is almost insoluble in water but is readily soluble in alcohol; it has a sharp smell, and its vapour powerfully affects the eyes. Chloropicrin has been employed in chemical warfare as a lachrymatory, irritant and lethal agent. High concentrations of this chemical cause fatal lung injuries, and death may ensue from exposure to its action even at low concentrations.

CHLORTETRACYCLINE (AUREOMYCIN) is an antibiotic substance obtained from cultures of the actinomycete *Streptomyces aureofaciens* and used in the treatment of many infectious diseases. Chlortetracycline is the chemical name of the substance; Aureomycin the registered trade-mark.

It was isolated and described by Benjamin M. Duggar in 1948 and was found to be effective against a wide variety of infectious agents including both gram-negative and gram-positive bacteria, certain large viruses, rickettsiae and some protozoal parasites. Chlortetracycline inhibits the growth and multiplication of those infectious agents sensitive to the drug, but only in very high concentration is it capable of directly killing the disease-producing microorganisms. It usually is given orally and is rapidly absorbed from the gastrointestinal tract, diffusing readily into the body tissues and fluids. Chlortetracycline also is available in preparations suitable for parenteral and topical administration.

The systemic administration of chlortetracycline causes gastrointestinal disturbances in some patients; diarrhea due to inhibition of the normal bacterial flora of the large bowel is not uncommon.

The rates of growth of chickens, poults and hogs have been found to increase markedly by the addition of minute quantities of chlortetracycline to their feed. (T. W. L.)

CHMIELNICKI, BOHDAN (*c.* 1595–1657), hetman of the Zaporozhian Cossacks, celebrated for his rebellion against Polish rule in the Ukraine. Educated in Poland, he served in his youth with the Polish and Cossack forces against the Turks. Eventually, however, a quarrel with Daniel Czaplinski, the Polish governor of Czehryn, led to his fleeing, in Dec. 1647, to the Cossack Zaporozhian host, a stronghold of runaway serfs and bandits on the Dnieper river (*see* COSSACKS). From there he struck an alliance with the Crimean khan, and in April 1648 the Cossack-Tatar force moved against the Poles. Polish defeats in May at Zheltye Vody and at Korsun were followed by a mass rising of the Orthodox peasantry and clergy in the Dnieper region, dissatisfied with Polish rule and religious policies. The rebel forces then moved into Poland proper, won another victory at Pilawce (Sept. 23) and took Lvov (Lwow), massacring Catholics and Jews and looting on their way. Chmielnicki was at this point still willing to recognize Polish sovereignty, and Poland, to appease him, bestowed on him the title of hetman. In spring 1649, however, armed conflict was renewed. This time the disloyalty of the Tatars compelled Chmielnicki to come to terms. The compact of Zborow signed between the Poles and Tatars (Aug. 8, 1649) secured for Chmielnicki a virtually independent Cossack principality. Even so. the restless Cossacks would not live in peace. War was resumed, and in June 1651 the Poles defeated the Cossacks at Berestechko. Chmielnicki now had to seek help from Moscow. On Jan. 18, 1654, at Pereyaslavl, he put his people under the Russian tsar's authority in return for extensive self-rule. When in 1654 the Russians invaded Poland. Chmielnicki did not offer them military assistance and entered instead into secret negotiations with the Swedes. He was about to betray Moscow by putting the Cossacks under Swedish rule when he died, at Subotov, on Aug. 6. 1657.

A skilful diplomat and military leader, Chmielnicki was also intemperate, anarchistic, incapable of sustained industry and sometimes indecisive at critical moments. His rebellion ruined the once flourishing Dnieper lands, and the Pereyaslavl treaty was the beginning of the end of Cossack liberties, which Moscow gradually restricted and finally abolished.

CHOATE, JOSEPH HODGES (1832–1917), U.S. lawyer, diplomat, and public speaker, one of the great trial lawyers in U.S. history, was born at Salem, Mass., on Jan. 24, 1832. He was a distant relative of the noted lawyer Rufus Choate (*q.v.*). After graduating from Harvard college in 1852 and from the Harvard law school in 1854 he was admitted to the Massachusetts bar in 1855, and to the New York State bar the following year. He allied himself with the newly formed Republican party and gained early recognition for his strong support of John C. Frémont for president in the election of 1856.

He was associated with many of the most famous lawsuits, including that over the will of Samuel J Tilden, the Kansas prohibition cases, the Chinese exclusion cases, the income tax cases and the case of Gen. Fitz-John Porter (*q.v.*). In 1871 he became a member of the Committee of Seventy in New York city. which was instrumental in breaking up the Tweed ring. Choate's legal career was remarkable for its length, covering a period of more than 55 years. He never held elective office but was ambassador to Great Britain from 1899 to 1905 and head of the U.S. delegation to the second Hague conference in 1907. As ambassador to Great Britain Choate brought about the abrogation of the Clayton-Bulwer treaty (*q.v.*) of 1850, thus paving the may for the unilateral construction of the Panama canal by the United States. For years Choate mas one of the most popular after-dinner speakers in the United States, sharing honours with Chauncey Depew. He died in New York city on May 14, 1917.

BIBLIOGRAPHY.—T. G. Strong, *Joseph H. Choate, New Englander, New Yorker, Lawyer, Ambassador* (1917); *Joseph Choate, a Great Ambassador* (1918); Edward Sandford Martin. *The Life of Joseph H. Choate* (1920); Frederick C. Hicks (ed.), *Argunzents and Addresses of Joseph Hodges Choate* (1926). (F. M.)

CHOATE, RUFUS (1799–1859), U.S. senator and leader of the Massachusetts bar during the 1850s, was born at Essex, Mass., on Oct. 1, 1799. He graduated from Dartmouth college in 1819. He then spent a year in the law school at Harvard university, followed by study in the law office of William Wirt in Washington. D.C. He was admitted to the Massachusetts bar in 1822 and practised for five years, during which time he also served in the Massachusetts legislature. In 1830 he was elected to the U.S. house of representatives as a Whig from the Salem district. He was re-elected in 1832 but soon resigned to return to his law practice in Boston. In 1841, when Daniel Webster resigned his senate seat to become secretary of state, Choate was chosen to complete the term. In the U.S. senate he made a series of brilliant speeches on the tariff. the Oregon boundary, the Fiscal Bank act and the annexation of Texas. At the close of his term in 1845 he resumed the practice of lam in Boston. After Webster's death in 1852 Chnate was generally conceded to be the leader of the Massachusetts bar. During the rest of his life no amount of urging could persuade him to abandon the legal profession for public office, except for a short term as attorney general of Massachusetts in 1853–54. He died July 13, 1859 at Halifax. N.S., while en route to Europe. *See* his *Works* (edited with a memoir by S. G. Brown) published in 2 vols. in 1862. The *Memoir* was afterward published separately (1870).

See also *E. G.* Parker, *Reminiscences of Rufus Choate* (1860); E. P. Whipple, *Some Recollections of Rufus Choate* (1879); Claude M. Fuess, *Rufus Choate* (1928). (F. M.)

CHOBE: *see* KWANDO.

CHOCÓ, a department on the Pacific coast of the republic of Colombia, northwest South America, bounded by Panama on the north. Almost the entire area (18,327 sq.mi.) of the department is covered with dense tropical rain forest, and the average rainfall probably exceeds that of any other equatorial area on earth; at Quibdó, the capital, it is above 420 in. There is no dry season. The scant population of the Chocó (147,380 in 1961) is for the most part Negroid, descendants of escaped colonial slaves who were employed in placer mining on the Atrato (*q.v.*) and San Juan rivers, which are still Colombia's primary sources for platinum. A few Indian groups survive in the more isolated hill areas. White settlers from Antioquia have begun to populate the eastern mountain margins. The vast swamplands of the Atrato are the most formidable barrier blocking completion of the Pan-American highway between Central and South America. (Js. J. P.)

CHOCOLATE: see COCOA.

CHOCTAW, a prominent Indian tribe in southern Mississippi, of Muskogee stock. Their name is apparently a corruption of the Spanish chato, "flattened," which referred to their practice of flattening the heads of male infants. They farmed intensively. The Choctaw were allies of the French and enemies of the British and of most of the Muskogeans. In the later 18th century they began drifting west of the Mississippi, and about 1832 the majority moved to what is now eastern Oklahoma, where they remained self-governing and semicivilized until their absorption into American citizenship in 1906. At mid-20th century they numbered about 17.500 exclusive of Negro freedmen included in the "nation," but include many of mixed blood; the original population seems to have been only slightly larger.

See also MUSKOGEAN INDIANS; OKLAHOMA: History.

CHODKIEWICZ, JAN KAROL (1560–1621), Polish general prominent in the wars against Sweden and Muscovy, was born (probably) at Bykhov on the Dnieper and educated by the Jesuits at Wilno (Vilna) and in Germany at Ingolstadt. He was appointed *starosta* ("governor") of Samogitia in 1599 and acting commander in chief of Lithuania in 1601. In the war against Sweden for possession of Livonia he drove the duke of Sodermanland (later Charles IX of Sweden) from Riga, took Dorpat (Tartu) in 1603 and destroyed a Swedish army three times larger than his own at Kirkholm (Salaspils) in Sept. 1605. The Polish diet, however, never sent him adequate supplies. After helping to defeat the civil war of 1606–07 in Poland and to relieve Riga when the Swedes were threatening it again in 1609, he was sent to attack Moscow (1612). but his army mutinied for lack of pay and he had to retreat to Smolensk. Reinforced, however, by Prince Wladyslaw (King Sigismund III's son), he took the fortress of Dorohobuz in 1617. After the truce of Deulino between Poland and Muscovy (1619) he was sent to defend the southern frontier against the Turks. He died on Sept. 24, 1621, just after forcing the Turks to raise the siege of Khotin (Chocim). (ST. HE.)

CHODOWIECKI, DANIEL NICOLAS (1726–1801), German genre painter and engraver of Polish descent, who developed a particular talent for recording the life and manners of the German middle class, was born at Danzig on Oct. 13, 1726. Largely self-taught, he began engraving in 1758. His first popular success was the sentimental painting "Jean Calas and His Family." After designing and engraving several subjects from the story of the Seven Years' War, Chodowiecki produced the famous "History of the Life of Jesus Christ." Few books were published in Prussia for some years without plate or vignette by Chodowiecki. His 2,000 etchings were a record of 18th-century life in comfortable interiors, observed with a kindly humour that lacked the bite of William Hogarth, with whom he was often compared, despite his own disclaimers. He became director of the Berlin academy in 1797. He died in Berlin on Feb. 7, 1801.

CHOERILUS (1) (fl. c. 510 B.C.), Athenian tragic poet, with his first performance c. 522 B.C., is one of the earliest recorded tragedians, but now little more than a name. One contest (c. 498) between Choerilus, Pratinas and Aeschylus was remembered as the occasion when the spectators' wooden seats collapsed. The Suda lexicon gives him the monstrous number of 160 plays, and, more reliably, 13 victories; he was also credited with some innovations in masks and costumes. All that survives is a title, *Alope,* and an elaborate metaphor (unless this is to be attributed to the epic poet Choerilus).

See A. Nauck (ed.), *Trag. Gr. Frag. (1926).*

(2) Epic poet of Samos, of the 5th century B.C. Little that is trustworthy is known of his life. It must have been in his last years that the Spartan general Lysander, according to Plutarch, began taking him around in his retinue, hoping to be immortalized in a poem. The legend that he was originally a runaway Samian slave who attached himself to Herodotus seems to be a reflection of his indebtedness to the historian for the material of his chief work, the Persika or *Perseis,* a verse-chronicle of (probably) the rise of Persia and its wars on the mainland and with Greece. The scanty extant fragments include the opening lines in which he regrets the ancient days when all subjects for poetry were new and unused; clearly he felt himself to be in the Homeric tradition in composing an epic on recent history.

See G. Kinkel (ed.), *Ep. Gr. Frag.,* i (1877). (A. M. DE.)

CHOIR, a body of singers with more than one voice to a part, formed for the purpose of singing either sacred or secular music, or both, and consisting of boys, women and men either in single groups or combining boys and men in a cathedral choir or women and men in a mixed choir of the kind used in performances of opera and oratorio. The term "boy choir," much used in the United States, refers not to a choir consisting exclusively of boys but to a choir in which the treble parts are sung by boys instead of women. A "mixed choir" is normally composed of women (sopranos and contraltos) and men (tenors and basses) and finds its place in predominantly secular functions, whereas a "male voice choir" is made up either of boys (trebles) and men (countertenors [altos], tenors and basses), heard in cathedrals and collegiate churches, or entirely of men.

The growth of the secular choir coincided to a large extent with the beginnings of opera, in which choruses have always taken some part, even though their contribution may not equal that of the soloists and orchestra in length or importance. In most operas crowd scenes involving peasants, soldiers, apprentices or whatever is most suitable to the subject of the opera provide the opportunity for the composition of parts for a choir, the actual size of which must depend on the size of the theatre and its budget. It has usually been the custom to employ professional singers in opera house choirs, or choruses (as they are more generally called). An oratorio choir, on the other hand, is part of an entirely different tradition, which stems from the augmented church choirs used to provide the choral portions of a given work, whether sung in or out of church. The oratorio choir is the home of the amateur singer, and although there have been, and still are, notable exceptions to this rule, its almost universal application is made a virtual necessity by the sheer weight of numbers customarily employed.

Handel was in the habit of presenting his oratorios and operas with a choir of medium size, but the Handel commemoration of 1784 which took place in Westminster abbey and in the Pantheon in London called for as large a body of singers as could be conveniently found. Of the 525 performers, the choir numbered 274: 59 trebles, 48 countertenors, 83 tenors and 84 basses. This choir was, however, dwarfed by the 2,000 singers who took part in the first Handel festival at the Crystal palace, London, in 1857, while subsequent years of this same festival saw the number creep up to well over 3,000. Even the concerts *monstres* of Berlioz rarely made use of a choir numbering more than 500, although he claims that he once heard, in St. Paul's cathedral in London, a choir of 6,500 at the anniversary meeting of the Charity Children in 1851. It was from such meetings as these, beginning with the meetings of the Three Choirs of Gloucester, Worcester and Hereford (1724 or perhaps earlier), that local choral festivals, widely popular in the 20th century, sprang.

Choirs have taken part in church services from the earliest times, but for many centuries their role was confined to singing plainsong in unison. This kind of choir varied considerably in size and style. In a monastery or nunnery all were expected to take their part in the singing of services, even though (in a small

community) there might be no more than 10 or 12 members. In a well-endowed abbey, cathedral, collegiate church or royal chapel, the choir might consist of as many as 50 or 60 trained voices. In England, the medieval system whereby a canon could appoint a substitute (*vicarius*) led to the formation of self-governing colleges of vicars choral, who were usually in deacon's or subdeacon's orders. Below them in rank were clerks of the choir (clerici *chori*), also in minor orders, who were sometimes referred to as "altarists" or "secondaries."

Boys are found in choirs of secular cathedrals where they were trained by the precentor to take part not only in the singing but also in the liturgy. Boys with intelligence and a good voice could progress via thurifer, subdeacon and deacon to vicar choral; and as time went on they enjoyed lodgings and privileges of their own as well as tuition in subjects other than music. At St. Paul's cathedral in the early 16th century there mere 12 minor canons. 16 chantry priests (who also sang in the choir), six vicars and ten choristers. Cardinal Wolsey's private chapel consisted of a dean, gospeler and epistler, 10 chaplains, 12 clerks and 10 choristers. At the funeral of King James I the choir of the Chapel Royal was made up of 19 gentlemen of the chapel and 12 children, and with them was the choir of Westminster abbey, an additional 17 men and 10 children.

Apart from plainsong, there was no choral singing in the early church, for when harmony first came into use its relative complexity demanded soloists as interpreters. Italian manuscripts begin, however, to hint about 1430 at the use of a choir for straightforward polyphony, with the direction that sections of the liturgy in three-part harmony are to be sung by the chorus (*i.e.*, by all voices) in contrast to the sections in two-part harmony, marked either unus (to indicate one voice to a part) or duo (to describe such sections as duets for solo voices). This alternation of soloists and chorus eventually led to the use of two choirs, one on each side of the church, or placed (as at St. Mark's, Venice) in galleries so that psalms, canticles and even masses could be sung antiphonally. Music for divided choirs (*cori spezzati*) was developed in the early 16th century and brought to a splendid peak of excellence in the early 17th by Giovanni Gabrieli. See also CHURCH MUSIC; OPERA. (D. W. ST.)

CHOISEUL, CÉSAR, DUC DE (1598–1675), French marshal and diplomatist, notable for his loyal services to the crown under Louis XIII and Louis XIV, was a member of the old family of Choiseul, which had its seat in the valley of the Upper Marne. Known at first as the comte du Plessis–Praslin, he served with the army in the siege of La Rochelle and in the defense of the island of RC against the duke of Buckingham in 1627 and accompanied the French forces to Italy in 1629. He was appointed ambassador at the court of the duke of Savoy in 1630 and was engaged in diplomatic and administrative work in Italy until 1633, when war was declared between France and Spain. He then distinguished himself in the ensuing Italian campaign (he was made lieutenant general of the army in Italy in 1641) and in Catalonia. He was made marshal of France in 1645. During the Fronde (*q.v.*) he remained constantly loyal to the regent Anne of Austria and to Cardinal Mazarin, assisting the prince de Condé in the siege of Paris (Jan.–March 1649) and winning the important victory over Turenne and the Spaniards at Rethel (Dec. 1650). He became minister of state in 1652 and was created duc de Choiseul in Nov. 1665. He was concerned in some of the negotiations which led to the Anglo-French treaty of Dover (1670). He died in Paris on Dec. 23, 1675.

CHOISEUL, ÉTIENNE FRANÇOIS DE CHOISEUL, DUC DE (1719–1785), French diplomat and statesman. the leading and most consistent advocate of France's alliance with Austria and the creator of the Bourbon "Family compact" of 1761 with Spain, was born in Lorraine on June 28, 1719. He was the eldest son of the marquis de Stainville, François Joseph de Choiseul, who was grand chamberlain of Francis, duke of Lorraine. He entered the army and served with distinction in Bohemia, Italy and the Netherlands during the War of the Austrian Succession. attaining the rank of lieutenant general in 1748. His rise to political eminence was facilitated by his marriage, in 1750, to Louise Honorine Crozat (granddaughter of the rich financier and war contractor Antoine Crozat. marquis de Châtel) and by the favour of Madame de Pompadour, whom he had saved from being expelled from the court by a possible rival mistress, the wife of his own cousin, in 1752.

Madame de Pompadour secured for Choiseul his first diplomatic appointment as ambassador to the Vatican in 1753. His main task was to secure from Pope Benedict XIV a modification of the bull *Unigenitus* of 1713, which had made French Jesuits and Jansenists irreconcilable. His success in this mission led to his nomination in March 1757 as ambassador to the court of Vienna with instructions to foster and develop the newly formed alliance with Austria. Together with the cardinal de Bernis (*q.v.*) he was responsible for the conclusion of the second treaty of Versailles (May 1, 1757) which brought France and Austria together in an offensive alliance to recover Silesia for Austria.

On Dec. 3, 1758. Choiseul, having become a duke and peer of France, succeeded Bernis as minister of foreign affairs at a most critical juncture of the Seven Years' War. For the next 12 years he maintained himself as a pluralist in ministerial office. A firm advocate of the Austrian alliance, he yet wished to limit France's financial and continental commitments under the second treaty of Versailles and to pave the way for separate peace negotiations between France and Great Britain. This was the purpose of the third treaty of Versailles (March 1759). Choiseul's conclusion of an offensive and defensive treaty with Spain on Aug. 15, 1761 (the "Family compact"), though it deferred the immediate prospects of peace, provided France with much-needed naval support in the period after 1763.

Choiseul showed skill and resource in the final negotiations leading to the peace of Paris in 1763 and remarkable tenacity in rebuilding France's military and naval strength in the postwar period. During his period of office at the admiralty (Oct. 1761–April 1766) he increased French ships of the line from 40 to 64 and the frigates from 10 to 45, thus providing France with the effective means of intervening decisively against Great Britain during the War of American Independence. As minister of war (Jan. 1766–Dec. 1770) he began a fruitful period of army reform which continued down to the Revolution: he moved recruitment from captains, provided a core of noncommissioned officers and improved the training of professional officers. He also gave his attention to recreating the sources of French commercial strength in the West Indies; to France's strategical interests in the Mediterranean, which he secured by the acquisition of Corsica in 1768; and to plans for the invasion of England. In domestic affairs he used his influence to ensure the resumption of the *Encyclopédie* after its suppression in 1759 and was responsible for the expulsion of the Jesuits from France in 1762.

Between 1763 and 1770 Choiseul encountered increasing opposition from the friends of the Jesuits, from critics of his military reforms and, after 1768, from the chancellor René Nicolas Maupeou (*q.v.*). Madame de Pompadour's death in 1764 removed one of his most powerful supporters, and his enemies won her successor Madame du Barry to their cause. Support from Marie Antoinette, who married the future Louis XVI in 1770, could not offset Madame du Barry's hostility. The final cause of Choiseul's fall from power was criticism of his plans for war with England in 1770 over the Falkland Islands at a time when France was passing through one of its periodical financial crises. He was dismissed from office on Dec. 24, 1770, and exiled to his estates at Chanteloup in Touraine. Allowed to return to Paris in 1774, he never recovered political power. He died in Paris on May 8, 1785. He left some important *Mémoires*, ed. by F. Calmettes (1904).

CHOISYA, a genus of four to five species of evergreen shrubs native from Arizona to southern Mexico, belonging to the rue, or citrus, family (Rutaceae; *q.v.*), and distinguished by palmately compound leaves of 3 to 13 leathery leaflets, the white

flowers bisexual with five petals and ten stamens, and the fruit a five-valved, usually ten-seeded, capsule. One species (C. ternata), called Mexican orange, is widely grown in tropical and warm-temperate regions as an ornamental. (G. H. M. L.)

CHOKEDAMP: see COAL AND COAL MINING: Hazards *of* Mining.

CHOKWE (BAJOKWE), a Bantu people estimated to number about 600,000, inhabit the southern part of the Republic of the Congo (former Belgian Congo) from the Kwango river to Lualaba, northeastern Angola, and, since 1920, the northwestern corner of Northern Rhodesia. They live in woodland savanna intersected with strips of rain forest along the rivers. snamps and marshlands. They are a mixture of many aboriginal peoples and conquering groups of Lunda origin.

For centuries Chokwe chiefdoms have been tributaries of the Lunda paramount chief Mwata Yamvwa in the Congo. During the latter half of the 19th century they revolted several times and on one occasion gained temporary ascendance. Among the northern Chokwe hunting is very important, and there are privileged corporations of hunters. Hoe cultivation overrides hunting among the southern Chokwe, the staple crops being manioc, peanuts, yams, millet, beans and maize; the southern Chokwe of Angola keep some cattle. The political structure seems to range from tributary chiefdoms with courts modeled on that of the Mwata Yamvwa to autonomous village groups. Villages are compact and arranged into compounds; square huts or circular grasshouses are grouped in circles around the central meetinghouse.

Descent is matrilineal, marriage is virilocal and residence is avunculocal (see KINSHIP). Marriage payments are low; polygyny is restricted to the chiefly and wealthy classes; cross-cousin marriages are permitted. Circumcision of boys, the use of initiation masks and elaborate girls' initiations occur throughout the area. The Chokwe are exceptional craftsmen; the carving of masks, statues and stools, plaiting, pottery, basketry and ironwork are much developed. The rites of the mungongi association with dances by stilt-walkers have great significance. See also AFRICA: Ethnography (*Anthropology*): West Central Africa.

CHOLA, the name of a south Indian Tamil dynasty, of unknown antiquity antedating the early Sangam poems (probably c. AD. 200). The dynasty originated in the rich Cauvery valley, Uraiyur (now Tiruchirapalli) being their oldest capital.

The legendary king Karikala was the common ancestor through whom small Deccan and Xndhra families called Chola or Choda claimed a connection with the Uraiyur family. The Chola country (Coromandel) stretched from the Vaigai river in the south to Tondai-mandalam, the capital of which was Kanchi (Kancheepuram; *q.v.*), in the north. Much of Tamil classical literature and the greater Tamil architectural monuments belong to this period. which also saw the revival of Shivaism (Saivism) and the development of southern Vishnuism (Vaishnavism). Revenue administration, village self-government, and irrigation were highly organized under the Cholas.

Chola kings and emperors bore the titles Parakesarivarman and Rajakesarivarman alternately: their chronology is difficult being based mainly on regnal years. Vijayalaya (c. 850–870) began the occupation of the territory of the Pallavas which was extended under Aditya I. Parantaka I (907–*c.* 947), "the destroyer of Madura" (the capital city of the Pandyas [*q.v.*]), defeated Sinhalese invaders and united the lands of the Cholas and the Pandyas between 926 and 942. Coming to terms with the Rashtrakutas (*q.v.*) he took Nellore from them about 940, but the Rashtrakuta king, Krishna III, seized Tondai-mandalam. Rajaraja I (985–1014). an able administrator, protected Vengi (the Godavari districts), and occupied the Gangavadi territory (Mysore state), annihilating the western Gangas. By 996 he had conquered Kerala (the Chera country), and acquired the north of Ceylon, With the booty he built the great Brihadisvara temple at Tanjore. By 1014 he had acquired the Laccadive and Maldive islands, Rajendracola Deva I outdid his father's achievements: he placed a son on the throne at Madura, completed the conquest of Ceylon, overran the Deccan (c. 1021), and sent (1023) an expedition to the north which penetrated to the Ganges river and brought back Ganges water to the new capital Gangaikondacholapuram. He conquered kings of Srivijaya and other portions of the Malay peninsula and archipelago.

Rajadhiraja fought the Pandyas and Cheras, and defeated the Chalukya Somesvara I in 1046, but was killed at the battle of Koppam against the same foe in 1054. Virarajendra, who succeeded in 1063, attempted to render the Chalukya empire in the Deccan harmless, but his death enabled Vikramaditya Chalukya to dabble in Chola family quarrels. Kulottunga I, who succeeded in 1070, wisely abandoned the Deccan and concentrated on uniting the whole eastern coast. Intrigues concerning the right to the Pandya throne embroiled Cholas. Pandyas and Ceylon from about 1166. From 1216 the Hoysala kings obtained valuable lands in the Chola country; former Chola feudatories threw off their allegiance; northern powers intervened; and the upheaval facilitated the Pandya conquest of 1257. The dynasty ended in 1279.

CHOLERA is a term that has been applied to a wide variety of acute diarrheal diseases of short duration. Cholera nostras, simple cholera, European cholera. British cholera and cholera infantum or summer diarrhea of infants are relatively mild enteric diseases characterized by sudden onset, acute diarrhea sometimes accompanied by vomiting, low fatality and recovery in one to five days. These diseases are of diverse, and in many instances uncertain, etiology. Known etiologic agents include the paratyphoid bacilli (*Salmonella*), certain of the dysentery bacilli, especially the Sonne and Newcastle types, and some members of the genus *Proteus.* It is probable that certain of the lesser known enteric bacilli, such as the paracolon bacilli, are causally associated with this kind of disease in man. In many instances these infectious agents are transmitted by food, and differentiation of food-borne infections and food poisoning is not sharp; it is not unlikely that in the past food poisoning such as that produced by ingestion of staphylococcal enterotoxin was classed as simple cholera. These diseases are, however, to be distinguished from the acute, specific and highly fatal infection with Vibrio cholerae known as true cholera, Indian cholera or, most commonly, Asiatic cholera. In modern medical literature the generic use of the term cholera fell into disrepute, and came to refer almost invariably to Asiatic cholera. These enteric diseases of man are unrelated to fowl cholera, an epidemic hemorrhagic septicemia of chickens caused by the bacillus *Pasteurella aviseptica,* or to hog cholera, which is of virus etiology; man is not susceptible to infection with either of these agents.

Historical Background.—References to acute, epidemic diarrheal disease are not uncommon in historical literature. As early as the 5th century B.C. Thucydides described the occurrence of such a disease in Athens, and the earliest report in the Indian literature of what may have been cholera is that of Susruta in the 7th century A.D. The earlier descriptions are equally applicable to bacillary dysentery, and it was not until the 15th century that the acute, epidemic diarrheal disease which was probably cholera was described; such, for example, was the epidemic disease that brought about the destruction of Ahmed Shad's army in 1438, and that described by Jacobus Bontius in the Netherlands Indies in 1629. According to the Chinese writers, cholera reached China from India in 1669.

Cholera, however, mas probably endemic in India, in the delta of the Ganges river and in lower Bengal, in remotest antiquity. With increasing facilities for travel, the disease spread from India overland through Persia into Russia, and by sea routes to China and the far east on the one hand. and on the other through Arabia into Asia Minor and Egypt and from there into Europe proper. Later it became apparent that there may be an endemic focus of infection in central China. in the valley of the Yüan river which flows into the Yangtze river through Tung-T'ing lake, and from which the disease spread down the valley of the Yangtze

and into the coastal areas. Whether this endemic centre was a recent development or only recently discovered is problematical, but it was not associated with the great pandemics of the 19th century and early part of the 20th century.

The first of the great pandemics began in India in 1817, and spread by land to China in 1818, to Ceylon in 1819 and by sea to Mauritius and East Africa in 1820, to the Philippines, China and Japan in 1822 and by land to Persia and Arabia in the same year and from there to Russia through Astrakhan in 1823, but this pandemic did not reach Europe proper. Another pandemic wave began in India in 1826 and folloned a similar course, but spread farther, reaching European Russia, via China. Manchuria and Mongolia, and through Astrakhan. It reached Moscow in 1830 and spread from Moscow to St. Petersburg, into Germany and across the North sea to Great Britain, reaching Edinburgh in 1832. The infection was carried from Europe to North America, entering Canada in 1832 and spreading south to Ft. Dearborn (Chicago) and down the Mississippi valley. It appeared concurrently in New York city and Boston and spread south and west, so that by 1836 cholera was present in most of the U.S. and did not disappear until 1838. The pandemic wave occurring between 1840 and 1849 and that of 1863–66 reached Europe by overland routes via Mecca and Egypt and spread to North America, giving rise to the outbreaks of 1867 and 1873. Another pandemic began in India in 1879 and the disease reached Europe through Egypt by 1883, affecting especially the Mediterranean ports of France. Spain and Italy. It was during this epidemic that Robert Koch carried out his studies on the etiology of the disease *(see* below). Another serious outbreak spread from India in 1891 and was carried to Europe by pilgrims returning from Mecca, reaching that continent the following year and primarily affecting European Russia. It was in this outbreak that the Russian composer Petr Ilich Tchaikovsky died of cholera. Still another great pandemic began in 1902, spreading from India to China and the Philippines, and to Europe by 1908 and 1910. With the development of knowledge of the etiology of the disease and efficacious methods of control, no pandemic spread occurred after 1910.

Cholera recurs annually in India in epidemic form and with great loss of life, usually not less than 200,000 deaths per year. The disease has spread into eastern Europe on occasion, for example, during the Balkan War in 1913; there were only a few cases in central Europe during World War I and several small outbreaks in Russia and Poland in the 1920s; an epidemic also occurred in Egypt during the late summer and early autumn of 1947. Epidemic cholera occurs with some frequency in the far east, especially in Burma, Indochina, the China coast and Manchuria, and sporadic cases occur in the Philippines and Indonesia. While the epidemic disease is readily controlled by sanitary measures, these are not available under primitive conditions, and should such preventive measures break down on any large scale, the rapidity of travel customary in the 20th century would make possible the spread of cholera in pandemic proportions in a matter of a few weeks or months.

The Cholera **Vibrio.**—Although Félix Pouchet reported finding vibrios in the stools of cholera patients as early as 1849, it was not until 1883 that the causal agent of the disease was isolated and studied by the German bacteriologist Robert Koch. From the excrements of cholera patients, first in Cairo and the following year in India, he cultured a small, slightly curved bacillus now known as *Vibrio cholerae*. Its etiologic relation to the disease was suggested by its occurrence in enormous numbers in the stools of infected persons, substantiated by fatal infection of the guinea pig on intragastric inoculation and proved beyond reasonable doubt by accidental laboratory infections of man with pure cultures of the microorganism.

The cholera vibrio is a member of a large group of gram-negative, comma-shaped bacteria that are morphologically indistinguishable from one another. This group is ordinarily divided into two parts, the one made up of the noncholera vibrios and the other of the cholera and choleralike or paracholera vibrios. The former includes a variety of saprophytic forms found in water and soil, together with some species that are pathogenic for lower animals, such as those producing a fatal septicemia in birds, contagious abortion of sheep and the like. The members of the latter group are parasites of man, and the paracholera vibrios have been found with some frequency in association with mild diarrheal disease.

The best known of the choleralike vibrios are the El Tor vibrios, which were first isolated at the quarantine station at Tor, Egypt (see map), in 1906 from pilgrims suffering from diarrhea, and afterward were found repeatedly under similar circumstances. The question of the pathogenicity of these vibrios was raised again in the Celebes epidemic of 1938. The disease was identical with true cholera on clinical grounds, but was apparently caused by an El Tor vibrio; the development of the far-eastern phase of World War II prevented detailed study. Epidemic disease of El Tor vibrio etiology appeared in Hong Kong in 1960, and in Manila in 1961, spreading through the Philippines. Although, unlike the cholera vibrio. these bacteria are found in the absence of disease they mould appear to be an occasional cause of cholera.

The cholera vibrio is characterized physiologically by its rapid growth, requirement for free access to oxygen, tolerance of alkali and marked susceptibility to deleterious factors in the environment. It may be isolated from contaminated specimens by culture on a medium of high alkalinity. An enriched medium containing defibrinated blood or hemoglobin and adjusted to pH 9.5 is used; the best known of these media are Adolf Dieudonné's medium and that of Col. Edward Bright, G. A. Vedder and W. van Dam. Because of its relatively slight resistance the vibrio dies out in a few days on contaminated leafy vegetables and similar foods and does not persist in water so long as does the typhoid bacillus.

The differentiation of the cholera vibrio from closely related vibrios is of considerable importance. While these vibrios commonly give the cholera-red or nitrosoindole reaction in nitrate-peptone water culture, and usually ferment sucrose and mannose but not arabinose, strains are biochemically heterogeneous and cannot be identified on the basis of cultural reactions alone. They are, however, closely related immunologically in that they contain a common heat stable somatic O antigen and fall into a serologic group designated O subgroup I; provisional identification may be made by agglutination with monospecific antiserum. Certain of the El Tor vibrios are members of this group also, but the El Tor vibrios form a soluble hemolysin acting on goat red blood cells while the cholera vibrios do not. The two may be differentiated by the Greig test in which equal volumes of peptone water culture of the vibrio and a 5% suspension of goat erythrocytes are mixed, incubated and read for hemolysis. The cholera vibrio is, therefore, defined as a nonhemolytic vibrio of O subgroup I. Serologic types of the cholera vibrio, arising from minor differences in the O antigen and demonstrable by the use of absorbed antiserums, were described by Japanese workers in 1913 and 1921. These were designated the Inaba or original type, the Ogawa or variant type, and the Hikojima or middle type. The first two are distinct from one another and the last is related to both end types. These serologic types do not differ in pathogenicity.

Cholera in Man.—Under natural conditions cholera is exclusively a disease of man. Susceptibility of individuals varies widely and is markedly influenced by predisposing factors such as low gastric acidity and gastrointestinal disturbance arising from purging, alcoholism, infection with other enteric bacteria and the like. The vibrio enters the body via the mouth, usually in contaminated water or food, and sets up an infection in the small intestine, seldom penetrating the tissues beyond the superficial layers of the mucosa. The incubation period is short, probably never longer than five days and sometimes less than one. The vibrio does not form an extracellular toxin, but the cell substance is toxic, and with proliferation and disintegration of the vibrios within the lumen of the bowel, the endotoxin is liberated and symptoms appear.

The disease usually develops in three relatively well-defined stages: the stage of evacuation, the stage of collapse or algid stage and the stage of reaction.

The onset is usually abrupt and characterized by a purging diarrhea followed by copious vomiting. The lower bowel is

emptied of fecal matter early in the disease, and the stool takes on a typical rice-water appearance, a nonoffensive, whitish, opaque, albuminous fluid containing flakes of mucus and having a slight albuminous odour. The diarrhea is both profuse and frequent, is painless without colic or tenesmus and is sometimes described as a literal pouring away of pints of pale fluid. The stomach is emptied at the onset of vomiting, the vomitus soon assumes the same appearance as the stools and may contain cholera vibrios, and there is exhaustive retching and hiccup. With the cumulative dehydration and loss of fixed base, agonizing cramps occur in the muscles, especially of the legs and feet, and sometimes of the arms, abdomen and back, and the sense of prostration is extreme. This stage lasts from 2 to 12 hours, and its duration is inversely related to the severity of the symptoms.

It passes insensibly into the algid stage characterized by almost continuous purging and vomiting and extreme collapse. The appearance of the patient changes rapidly, the skin becomes lax, wrinkled and cold and clammy to the touch, and the classic cholera facies appears, with eyes sunken, cheeks hollow and cyanosis about the eyes and lips; the voice becomes husky and the expression anxious and apathetic. The blood pressure falls, the pulse cannot be felt at the wrist and the urine is suppressed. Death may occur from circulatory failure or from asthenia.

With cessation of vomiting and diarrhea, the patient enters the third stage of reaction, in which, if the duration of the algid stage has been only a few hours, recovery should occur with restoration of blood pressure, disappearance of cyanosis, and flow of urine.

If the impairment of renal function has been serious with damage to the kidney parenchyma, flow of urine is not resumed, and death may result in four to five days.

The pathology of the disease, sometimes attributed to the action of absorbed toxin, is equally well accounted for on the basis of extreme dehydration, hypochloremia (lowered chloride content of the blood), acidosis and impairment of renal function. The severe dehydration results in a similarity between the patient with cholera and one in shock, but it is not complete because plasma elements other than fluid and electrolytes are not lost in cholera. The specific gravity of the blood rises to as high as 1.064 with polycythemia and disproportionate leucocytosis. The outstanding post-mortem changes are the marked rigidity, with almost immediate stiffening of the limbs after death, and the pronounced dehydration of the tissues, though the body is usually well nourished because of the relatively short duration of the disease. Convalescence is commonly uneventful, with disappearance of vibrios from the stools in ten days to two weeks, but cardiac failure may result from slight exertion. The case fatality rate is usually 40% to 60% in untreated cases, but may be reduced to 10% to 20% by adequate treatment.

Treatment. — Treatment is both symptomatic and specific. The former is directed toward the replacement of fluid, the maintenance of blood and tissue chloride and the counteraction of acidosis. This may be achieved through the intravenous administration of hypertonic alkaline salt solution. Sterile stock solutions of hypertonic saline, alkaline saline, alkaline hypotonic saline and bicarbonate are mixed in proportions indicated by the state of the patient, and the amount administered is determined by the degree of dehydration as shown by the specific gravity and pressure of the blood. Collapse is favourably affected by atropine and beta-hypophamine, and the pain of muscular cramps may be relieved by whiffs of chloroform. Use of morphine and alcohol in any form is avoided. Specific treatment, such as the therapeutic use of anticholera serum and the administration of potassium permanganate or kaolin for neutralization of the toxin, has been disappointing, although cholera bacteriophage by mouth seems to have some small favourable effect. Certain drugs of the sulfonamide group, especially sulfaguanidine, and several of the broad spectrum antibiotics such as the tetracyclines were given extensive trial in Indian clinics without apparent effect on the clinical disease, although the period of vibrio excretion seemed to be shortened; chemotherapy of the disease was of questionable value.

A majority of cases of cholera, especially during an epidemic, can be diagnosed on clinical grounds alone, and during an epidemic all suspected cases should be treated as cholera, and all contacts as potential cases. Diagnosis of the isolated case is more difficult but is more important from the public health point of view. The disease may be confused with fulminating bacillary dysentery, with the algid and choleraic forms of malaria, trichinosis, food poisoning of staphylococcal or streptococcal etiology, mushroom poisoning or poisoning with antimony or arsenic. The bacteriological diagnosis of cholera is dependent upon the isolation and identification of the vibrio. The demonstration of typical vibrios in a gram-stained smear from a flake of mucus is suggestive, and the vibrio may be isolated by culture on a selective medium and identified by agglutination with specific O antiserum and a negative reaction to the Greig test.

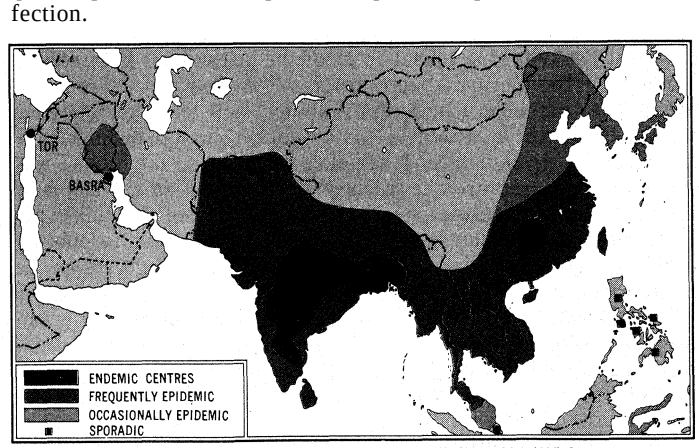
Immunity. — Infection with the cholera vibrio provokes an immune response as indicated by the appearance of bacteriolysins, agglutinins and other antibodies in the blood serum. Immunity to subsequent infection is not of a high order, however, nor does it persist for more than one to two years at the most. Prophylactic immunization was practised almost from the time of the discovery of the cholera vibrio, beginning with the work of Jaime Ferran in Spain and that of Waldemar Haffkine in India. A variety of immunizing preparations was used, including living vibrios, bacteriophage lysate and bilivaccine (vaccine prepared from a liver extract) by mouth as well as the usual type of vaccine.

Modern vaccines consist of suspensions of cholera vibrios killed by heat or phenol in isotonic saline in a concentration of 8,000,000,000 per millilitre and are administered in two parenteral inoculations of 0.5 and 1.0 ml. one week apart. The vaccines used in India contained the Inaba type only, but bivalent vaccines containing equal proportions of the Inaba and Ogawa types are widely used. Immunity appears as early as the third to fifth day after inoculation but is effective for less than a year, and reinoculation should be practised every six months.

The results of prophylactic inoculation have been to some degree conflicting. For example, an extensive immunization program carried out in Indochina in the 1930s apparently produced no immunity to the disease, but field studies in India consistently gave encouraging results. In such a study carried out in Madras during the severe epidemic of 1941–42 the incidence of the disease was reduced more than 90% by prophylactic immunization.

Epidemiology and Control. — The dissemination of cholera is dependent upon connecting links between infected fecal material and the mouths of susceptible persons. The vehicle is most often water, but the disease is also transmitted by foods consumed in the raw state and by direct or indirect personal contact.

The explosive character of the epidemic is attributable to the simultaneous infection of large numbers of persons, as by a common water supply, coupled with the short incubation period, and its dramatic aspect is accentuated by the high case fatality rate. When the epidetnic has run its course in a nonendemic area, the disease dies out completely because of the fragility of the vibrio and the absence of the chronic carrier state in cholera, and subsequent epidemics are dependent upon reimportation of the infection.



FROM W. BURROWS, "TEXTBOOK OF MICROBIOLOGY," W. B. SAUNDERS CO. (1954)

APPROXIMATE DISTRIBUTION OF ASIATIC CHOLERA, 1930–40

In endemic areas, however, the infection persists in a smoldering form and, while the mechanism of its maintenance is not altogether clear, it is highly probable that it depends on the occurrence of mild cases of the disease transmitted from person to person under the relatively primitive conditions prevailing. For example, in some parts of India water is stored in tanks that serve for the disposal of fecal material and as a source of water for washing and drinking purposes; such water supplies are seldom protected by the usual sanitary measures such as chlorination, filtration or other means of purification. Habitual defecation in open fields about inhabited areas and the use of fresh night soil as fertilizer in truck gardens makes possible the dissemination of the disease by flies and by leafy vegetables and the like.

Under ordinary circumstances spread of the disease into Europe is prevented by inspection at the quarantine stations at Tor and at Basra, Iraq *(see* map), and it is readily controlled by the usual sanitary practices, especially water purification and sewage disposal. This was strikingly illustrated in the Balkan War in 1913 in which infection was widespread in the Bulgarian army about Sofia, but cases in the capital were largely imported and the disease showed little tendency to spread; Sofia was efficiently sewered and had an excellent water supply.

Ultimate control of the disease depends upon the development of a higher standard of living in the primitive parts of the far east, and under ideal conditions cholera could probably be stamped out entirely.

T.* Mackie *et al, A Manual oj Tropical Medicine,* 2nd ed (1954); J. E. Ash and S. Spitz, *Pathology of Tropical Diseases* (1945); W. Burrows, *Textbook of Microbiology,* 17th ed. (1959). (W. Bu.)

CHOLESTEROL, a waxlike solid alcohol, is closely related, chemically, to vitamin D, the steroid hormones, and bile acids. *(See* also HORMONES.) Although cholesterol ($C_{27}H_{45}OH$) is present in all animal cells, it is particularly abundant in the adrenal glands. the brain and the spinal cord, and it is produced by the liver and several other organs of the body. Cholesterol appears to be essential to life. although its physiological function is not clearly defined.

Abnormal accumulations of cholesterol are associated with certain pathological conditions. *e.g.*, atherosclerosis *(see* below) and gallstones *(see* GALL BLADDER, BILIARY TRACT AND LIVER, DISEASES OF). Atherosclerosis. the major form of "hardening of the arteries," is a disease in which a progressive deposition of cholesterol-containing fatty materials occurs just below the inner surface of the arterial walls The amount of cholesterol in the diet is not a significant factor in the development of atherosclerosis. since the human liver ordinarily synthesizes approximately twice as much cholesterol as is obtained from foods. Cholesterol is present only in animal fats and not in fats obtained from plant sources A compensatory system regulates the synthesis of cholesterol in the liver. with increasing dietary intake of cholesterol accompanied by decreasing hepatic synthesis, and vice versa.

Man is uniquely susceptible to atherosclerosis. Blood plasma levels of cholesterol appear to be related to the development of atherosclerosis, and the amount of cholesterol present in human plasma is normally much greater than the amounts observed in other mammals and experimental animals. In humans with very low plasma cholesterol levels, the incidence and severity of atherosclerosis observed is very low. In several species of laboratory animals it is possible to induce the development of atherosclerosis under conditions which result in artificially elevated levels of plasma cholesterol. Higher plasma cholesterol levels have not been established as the cause of atherosclerosis, however, in spite of the frequency with which the two conditions are associated in human patients Several factors are involved, including nutrition, age and sex, hormone balance and emotional stress.

Several research scientists have demonstrated that a diet low in fat and total calories is more effective in helping to reduce the plasma cholesterol level than is a low-cholesterol diet. The type of dietary fat and the quality and amount of protein in the diet may also be related to the development of atherosclerosis.

Atherosclerosis is a very complex disease. and its development is affected by several factors, including nutrition. Much more research is needed in order to solve the problems of its prevention, early diagnosis and successful therapeutic treatment. See also ARTERIES, DISEASES OF.

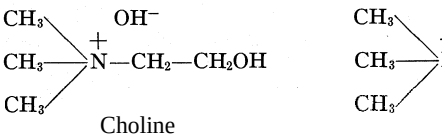
Najjar (ed.), *Fat Metabolism* (1954); L. N. Katz and J. Stamler, *Experimental Atherosclerosis* (1953). *(C. H.* LH.)

CHOLINE is a constituent of all living cells. It plays a significant role in animal nutrition *(see* VITAMINS) and is a constituent of two very different and physiologically important substances, acetylcholine and lecithin.

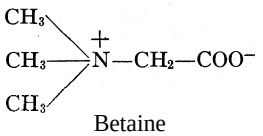
Acetylcholine, a key compound in nerve function, is alleged to be connected with the transmission of impulses along nerves and, furthermore, is specifically released at the endings of a group of nerves called cholinergic. which include primarily the so-called parasympathetic nerves. On stimulation of the nerve acetylcholine is released from an inactive, bound form and is then rapidly converted to the very much less active free choline and acetate by the enzyme cholinesterase. In the subsequent recovery period the choline is recombined with acetate and once more incorporated into the structure of the nerve. which is then ready for the passage of another impulse. Inhibitors of cholinesterase such as physostigmine (eserine) and neostigmine (prostigmin) prolong the lifetime of free acetylcholine and cause symptoms similar to those brought about by administration of acetylcholine itself. The so-called nerve gases act in the same way. These poisons are synthetic derivatives of phosphoric acid, and related nonvolatile materials have been used as insecticides.

Lecithin is a member of a group of substances known as phospholipids, which derive their name from the fact that they contain phosphate in the form of a fatty substance. The phospholipids have both water-soluble and fat-soluble groups. They are consequently good emulsifying agents and important structural components of the cell. Chemically, lecithin is called phosphatidyl choline. Phosphatidic acid contains two molecules of fatty acid and one molecule of phosphoric acid esterified with one molecule of glycerol. In lecithin, the choline is bound to the phosphoric acid end of phosphatidic acid.

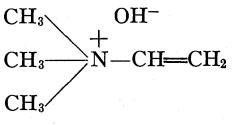
Choline may be regarded as a derivative of betaine, which occurs in plants. Betaine exists as an internal salt, with the positive charge on the nitrogen atom neutralized by the negative charge on the oxygen of the carboxyl group. In choline, since there is no carboxyl group, the positively charged nitrogen atom holds a negatively charged ion, which may be Cl^- or any other anion rather than OH^-. A slight change in the chemical structure of choline may produce highly toxic substances. Thus, removal of the elements of water produces the extremely poisonous trimethylvinylammonium hydroxide or neurine.



Choline



Betaine



Neurine

Muscarine, a very toxic substance isolated from some poisonous mushrooms. is also chemically related to choline.

(B. V.; H. C. F.)

CHOLON, in the Republic of Vietnam, now part of the prefecture of Saigon (*q.v.*), was formerly a separate municipality and the capital of Cholon province. It lies to the west of the city of Saigon, from which it is separated only by the Arroyo Chinois, a small water channel; the urbanized area was linked commercially and physically by streetcars, roads, canals and rail-

way and in 1932 became one political unit, first called Saigon-Cholon and later Saigon prefecture. Cholon itself has an oriental appearance; from its foundation late in the 18th century it has been dominated by immigrants, at first Chinese from Fukien and Canton, then by Annamites and Tongkingese from territories now in the Democratic Republic of Vietnam. While long settlement has blurred racial distinctions, about half the townspeople are of Chinese parentage.

The flimsy, tightly compacted lanes are as much a reflection of immigrant origin as is the typical wood-and-plaster, one-storied house design. The brilliant neon signs of the bazaarlike main street show the old and the modern east side by side. The town is threaded by water channels congested with many kinds of river craft which ply through the maze of distributaries on the Mekong delta and bring to Cholon, whose name significantly means "great market," rice and dried fish products from as far inland as Sisophon and Battambang and forest products from the Oaotian Mekong. Cholon collects, bulks and grades the Asian staples, rice and fish, which are later exported from the international port at Saigon. For several months a year there congregates at Cholon a large floating population living on its junks, used at other times to carry trade goods to the interior. Timber mills, junk-building yards, tanneries and crude dye works (for fish nets) have grown up in the town, as have brick and pottery works using local clays and supplying the huge Indochinese demand for earthenware pots and jars. (E. H. G. D.)

CHOLULA (CHOLCLA DE RIVADAHIA), an ancient town of Mexico, in the state of Puebla (*q.v.*), 8 mi. W. by N. of Puebla, the state capital. Altitude 6,912 ft. Pop. (1950) 11,616. Famed for its many domed churches, Cholula, by legend, has a church for each day of the year. The Royal chapel in the plaza has 48 domes. True to custom, the Spaniards built a church on top of each native temple in this important pre-conquest town dedicated to the god Quetzalcoatl. An imposing pyramid of sun-dried bricks topped by the Chapel of Los Remedios stands 177 ft. high, covering nearly 45 ac. Archaeologists tunnelling through this pyramid built a small railway to aid their excavations which is used also to carry tourists inside. Any historical data in the temple of Quetzalcoatl which once crowned this pyramid was doubtless destroyed in 1519 by Hernán Cortés during his march inland to conquer Montezuma's capital. Tenochtitlán. Cortes estimated that Cholula then had 20.000 inhabitants with as many again in surrounding suburbs. The Cholulans, a textile and pottery trading people, were Nahuatl speakers with a nominal allegiance to Montezuma. The pyramid is believed to have been built by a people inhabiting Cholula before those conquered by the Spaniards. (H. R. HY.)

CHOLUTECA, a department in southern Honduras, bordering the Gulf of Fonseca and Nicaragua. Its population (149,205 [1961]) is 80% rural. Coastal plain savannas, broad Rio Choluteca lowlands and mountains are important agriculturally. Chief products are cotton, sesame with 90% of national output, harvested forage grasses, cattle and swine. Of the department's total area of 1,626 sq.mi. 60% is farmland, of which 48% is pasture and 10% cultivated. A highway traverses the central part of the department, connecting Choluteca city (pop. [1950] 7,075), the departmental capital, with Tegucigalpa by way of the Inter-American highway from near Nacaome. (C. F. J.)

CHOMUTOV (Ger. KOMOTAU), a city of North Bohemia region, Czech.. at the foot of the Ore mountains, lies 52 mi. N.W. of Prague on the western tip of a lignite-mining area. Pop. (1957 est.) 32,583. It is thought to have been a Czech settlement in origin, steadily Germanized in the middle ages and remaining German in character until the end of World War II. In the 14th century it was a commandery of the Teutonic knights, and evidence of Chomutov's age and standing are in the arcaded market place, the town hall (originally a castle) and St. Catherine's church. Lignite mining is the major economy of the region, but iron and steel manufacture and paper and glass industries are long established. (H. G. S.)

CHONBURI, a province of Thailand situated on the eastern shore of the upper Gulf of Siam. Area 1,732 sq.mi.; pop (1960) 337,058. It produces a surplus of rice and leads the country in the production of sugar cane and cassava. With nearly 100 miles of coast line, fishing and salt extraction are important occupations. Major industries include fish freezing and processing, sugar refining and liquor distilling. Chonburi, the provincial capital (pop. [1957 est.] 29,734), is known locally as Bangplasoi. South of the capital is a popular seaside resort area centring on Siracha, and at the southern tip of the province is the Sattahip naval base (G. W. SK.)

CHONDRICHTHYES, the cartilaginous fishes, includes the sharks, rays (including skates) and chimaeras. They rank as a class, also called Selachii, differing fundamentally from true or bony fishes (Osteichthyes) in having the following characteristics: a cartilaginous skeleton, well-developed jaws, numerous teeth in series, two pairs of appendages supported by pectoral and pelvic girdles and males with external sexual organs or "claspers" attached to the pelvic fin. The skin is armed with placoid scales. toothlike in structure. Five to seven pairs of gill clefts are evident; the spiracle (a vestige of a former pair of gill clefts) is present or absent. The posterior end of the vertebral column is either straight or heterocercal. None of the cartilaginous fishes has an air or swim bladder. Elasmobranch, a term sometimes generally applied to all cartilaginous fishes, refers more precisely to those of the subclass Elasmobranchii (Euselachii), the sharks and rays.

Geographical **Distribution.**—Whereas sharks are for the most part marine, at least two species of the genus *Carcharhinus* enter the fresh naters of the Ganges, Tigris and Zambezi rivers. The species *C. leucas* is landlocked in Lake Nicaragua; it is also present in other Central American lakes having access to the sea. In addition to the sharks, the sawfishes (family Pristidae) and sting rays (Trygonidae or Dasyatidae) ascend rivers for considerable distances. Sharks are associated with the tropics and they are more numerous both in species and in numbers in the warmer oceans. However, the majority of sharks live and breed in comparatively shallow waters off the continents; other species are pelagic and keep to the open seas.

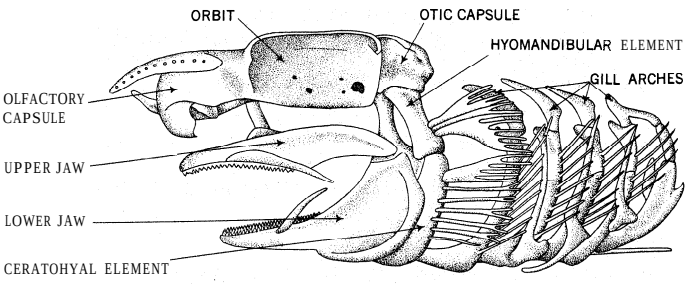
The families Scylliorhinidae (cat sharks, European dogfishes or roussettesj, Squalidae (spiny dogfishes, bramble sharks and the Greenland shark), Squatinidae (angelfishes) and Rajidae and related families (the true skates and rays) are bottom-living sharks found in temperate waters.

FORM AND FUNCTION

Body Form. — Sharks and rays are a natural, primitive group, with much divergence in body form. The prevalent conception of a shark is of a cylindrical fish with a transverse crescentic mouth, paired gill slits and prominent lunate dorsal fin. The fantastically flattened and expanded heads of the hammerhead sharks (*Sphyrna*), the excessive length of the upper caudal lobe of the thresher shark (*Alopias*) and the whalelike dimensions of *Rhineodon* and *Cetorhinus* are notably body variations among sharks. Sharks move with a sculling motion of the tail; swift pelagic sharks exhibit a marked development of the upper caudal lobe and a corresponding streamlining of the body and fins. Slower moving forms have more rounded fins, and the caudal lobes are more nearly equal.

The sawfishes, skates. guitarfishes, sting rays, eagle rays and the giant devilfish are much fattened sharks, with more or less disc-shaped bodies and ventral gill openings. The pectoral fins, enlarged and winglike, function as effective swimming organs. Within this group there is considerable variation in the shape of the head, and the tail is sometimes reduced to a filament. A group of chimaeras, the ratfishes, are curious sharklike inhabitants of deep aaters or cool seas. Their bodies. covered with smooth skin, end with a long, tapering tail; the males have a forward-projecting organ on the forehead (tenaculum) as well as before the pelvic fins. From the correspondence between habits and form of the fins in living Chondrichthyes, it is certain that *Cladoselache,* a primitive shark of the upper Devonian strata, with broad-based, pointed fins and strongly heterocercal tail, was a pelagic shark and a strong swimmer.

Gill Arches and **Jaws.**—Chondrichthyes are in many respects the most primitive of the vertebrates, and a study of their struc-



BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON

FIG. 1.—SCYLIORHINUS SKULL SHOWING JAWS AND GILL ARCHES

ture and development throws light on the origin of jaws, teeth and limbs. They differ from the cyclostomes (lampreys, etc.) in their method of breathing, water being taken into the pharynx and expelled through gill clefts by the expansion and contraction of the pharynx. The gill clefts are comparatively narrow slits on the head between the eye and the pectoral fin, except in the basking shark (*Cetorhinus*), where they extend from the upper to the lower surface of the body. The usual number is five, but in the frilled shark (*Chlamydoselachus*), the cow shark (Hexanchidae) and one of the saw sharks (*Pliotrema*) there may be six or seven gill clefts. Each successive gill cleft is partitioned by thick interbranchial septa, forming a series of gill pouches, that interconnect the pharynx and gill clefts.

The gill arches, lying in the form of a half loop on the inner edge of the septa between openings leading from the pharynx, are closed or opened by special muscles. All, except the anterior gill pouch, contain paired gill filaments that act as respiratory membranes. These appear as thin red straps from which the name "elasmobranch" (straplike gills) originated. Forward of the gill slits is a vestigial gill cleft, called the spiracle, that is often absent in sharks. This is enlarged in rays through modification in the method of breathing. The rays, in adapting to life on the sea floor, inhale water through the spiracles, expelling it through the gill clefts, thus avoiding the intake of silt or sand, which might clog up the delicate respiratory membranes.

The jaws of Chondrichthyes represent modification of the first two branchial arches into biting jaws; they consist of the upper jaw or palatoquadrate cartilage and the lower jaw or Meckel's cartilage. The upper jaw may be firmly attached but is not fused to the cranium; the lower jaw articulates with the upper jaw and is partly suspended to the hyomandibular arch. In the chimaeras the upper jaw or palatoquadrate is completely fused with the cranium and the supporting element of the hyoid arch is vestigial.

Teeth. — In having the body covered with denticles formed of dentine, the Chondrichthyes resemble the most primitive Agnatha (jawless fishes), the Silurian and Devonian Coelolepidae (*see* CYCLOSTOME). Similar but smaller denticles may occur in the mouth and pharynx, and the true teeth are to be regarded as homologous structures. The teeth are attached to the membrane covering the jaws; this membrane continually moves outward so that, upon injury or loss, the outermost teeth are replaced by others that migrate outward over the jaw.

FIG. 2.—PTERICHTYS, AN ANCIENT PLACODERM, AN OFFSHOOT OF THE CHONDRICHTHYES

Fins. — In the Chondrichthyes both median and paired fins are keellike outgrowths of the body strengthened by horny fin rays; their skeleton consists primarily of a series of cartilaginous rods segmented into two principal pieces, basals within the body and radials in the fin; each of the rods has a muscle on each side. A study of the development shows that all the fins begin as longitudinal folds of the epidermis, at the base of which a mesenchyme plate develops; next a double series of buds from the body muscles migrates into the fins, and later the cartilaginous skeleton differentiates out of the mesenchyme plate. From their similar structure and development the conclusion is drawn that the median and paired fins have a similar origin and that they originated as outgrowths of the body. The limb girdles, pectoral arch and pelvis are formed by fusion of the anterior basals, and sharks in which there is no pelvis (*Cladoselache*) are the most primitive.

Vertebral Column. — In Chondrichthyes the vertebral column consists of the notochord and its cartilaginous sheath and of dorsal and ventral series of paired cartilaginous plates; the dorsal plates may meet above the spinal cord, or the arch may be completed by a median series of cartilages, but the whole is below the longitudinal elastic ligament. There are no paired elements meeting above the ligament and carrying a series of spines, as in the true fishes, and their ventral counterparts, the pleural ribs and hemal spines, are also absent. The cartilaginous sheath of the notochord may be calcified and segmented into centra. Each vertebra has a neutral plate, or basidorsal cartilage, perforated or notched behind for the exit of the ventral root of a spinal nerve, and another, interdorsal, perforated or notched for a dorsal root. In the caudal region of the Euselachii the vertebrae are twice as numerous as the muscle segments, so that every other pair of basidorsals and interdorsals has no nerve exits; this condition, known as diplospondyly, may be due to the need for greater flexibility of the tail. The tail of the chimaeras is polyspondylic; *i.e.*, the vertebrae are more than twice as numerous as the myotomes. In musculature, visceral anatomy, etc., the Chondrichthyes have a general resemblance to the more primitive bony fishes; thus the intestine has a spiral valve and the heart has a conus with several series of valves. The brain is characterized by the large divergent olfactory lobes.

Development. — In all living Chondrichthyes fertilization is internal, the males being provided with paired intromittent organs, mixopterygia, which are appendages of the pelvic fins, with a cartilaginous internal skeleton and with a groove or canal along the whole length of each, which is the duct of a glandular sac at its base. The eggs are large, heavily yolked and enclosed in horny cases; in many sharks and rays the eggs are not laid, the cases are absorbed and development proceeds within the body of the mother. Some of these viviparous forms (*e.g.*, Mustelus) have a yolk-sac placenta, and in certain rays (*e.g.*, *Pteroplatea*) long uterine villi pass into the spiracles of the young and furnish a nutritive secretion.

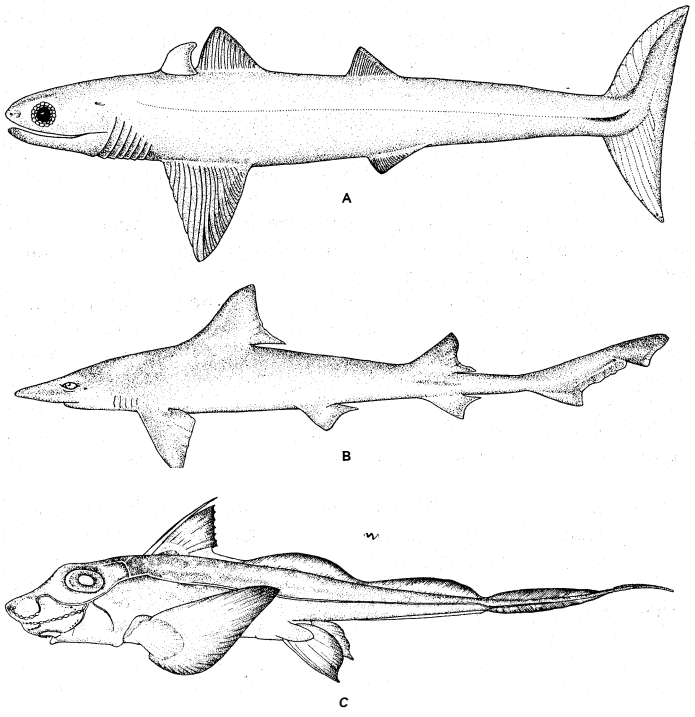
FIG. 3.— DIAGRAMMATIC DISSECTION OF A FEMALE SHARK

GEOLOGICAL HISTORY

Paleontology. — Many living genera of Euselachii are of considerable antiquity; all the recent families except the Carchariidae and Trygonidae have genera living today that are found fossil in Cretaceous strata, and such specialized forms as Squatina and *Rhinobatus* occur in the Jurassic, together. with Heterodontus, *Pristiurus* and Hexanchus. The curious *Scapanorhynchus*, with



FROM A S ROMER. "THE VERTEBRATE STORY"; REPRODUCED BY PERMISSION OF W B. SAUNDERS CO (1959). (A) AFTER DEAN AND HARRIS: (B) AFTER GARMAN; (C) AFTER DEAN

FIG. 4.—CARTILAGINOUS FISHES: (A) PRIMITIVE DEVONIAN SHARK (CLADOSELACHE): (B) MODERN SHARK (MUSTELUS): (C) CHIMAERA

long shovellike snout, was discovered in 1898 living in deep water off Japan, but had long been known from Cretaceous rocks. *Protospinax,* a recently described Jurassic shark. appears to stand in the same relationship to *Pristiophorus* that *Rhinobatus* does to *Pristis.* The saw shark *(Pristiophorus)* has the snout produced into a long blade with a series of teeth on each side, and in this resembles the saw ray *(Pritis)*; but *Pristis* is evidently a modified *Rhinobatus. Protospinax,* a shark with the snout produced and flattened as in *Rhinobatus* but except for the more primitive median fins otherwise similar to *Pristiophorus,* is of some interest.

The Euselachii are not certainly known before the Trias, for the Carboniferous and Permian Orodontidae, Cochiliodontidae, Petalodontidae and Psammodontidae, generally assigned to this subclass. are mainly known from teeth. The Holocephali also date back to the Trias Of the Paleozoic subclasses only the Pleuropterygii can be regarded as ancestral. the Devonian *Cladoselache* being the most primitive shark known.

The **Placodermi.**—The researches of Stensio (1925) have revealed the relationship to the Chondrichthyes of the Arthrodira, a group of Paleozoic fishlike vertebrates in which the head is covered by a shield of bony plates, movably articulated with a bony carapace that protects the anterior part of the body. Below the head shield Stensiö found a cartilaginous cranium wholly or partly invested inside and out by a thin layer of bone. This cranium is of typical Chondrichthyes form, with prominent olfactory capsules; there are no dermal bones (parasphenoid. vomers) below it. It is clear that the Arthrodira are not true fish but an independent offshoot of the Chondrichthyes. It is. perhaps. best to place them in a separate class. Placodermi. which will include also the similarly armoured Paleozoic Asterolepida *(see* PLACODERM).

FIG 5.—A STING RAY (DASYATIDAE) SHOWING EXPANDED PECTORAL FINS AND STING ATOP THE TAIL

CLASSIFICATION

Although later taxonomic outlines of the Chondrichthyes or Selachii are available, none surpasses the following modified scheme of C. T. Regan (1906) in comprehension and basic worth.

SUBCLASS PLEUROPTERYGII.

Paleozoic sharks with broad-based, paired fins, the pelvics without any fusion of the basalia, the pectorals scarcely more advanced in structure. Cladoselache, Cladodus, *Symmorium,* Cratoselache.

SUBCLASS ACANTHODII.

Paleozoic sharks with a strong spine at the anterior edge of each fin. As in the Pleuropterygii, the paired fins were broad-based, and mixopterygia appear not to have been developed. Acanthodes, etc.

SUBCLASS ICHTHYOTOMI.

Paleozoic sharks in which the pectoral hasalia form the segmented axis of a biserial fin like that of Ceratodus (lungfish); males with mixopterygia. Pleuracanthus.

SUBCLASS EUSELACHII (ELASMOBRANCHII).

These are the modern sharks and rays Pectoral fin with metapterygium (fused basalia), and with propterygium and mesopterygium, formed by union of proximal segments of anterior radials; pelvic fins with pelvis and basipterygium; males with mixopterygia. Pterygoquadrate free from skull. Hyomandibular articulating with skull and supporting jaws. Gill clefts with separate external openings

Order Pleurotremi (Sharks).——Pectoral fins free from head; gill openings lateral. Hyomandibular with cartilaginous rays supporting the first half gill. Two halves of pectoral arch well separated above.

Suborder Notidanoidea. Six or seven gill openings. A single dorsal fin above the anal Rostrum simple.

Family Chlamydoselachidae (Chlanzydoselachus).
Family Hexanchidae (*Hexanchus,* Heptanchus).

Suborder Galeoidea. Five gill openings. Two dorsal fins and an anal; no fin spines. Rostrum triradiate.

Family Odontaspididae (Odontaspis, *Scapanorhynchus*).
Family Lamnidae (Lamna, Carcharodon, Alopias, Cetorhinus).
Family Orectolobidae (Orectolobus, *Chiloscyllium, Stegostonea, Ginglymostoma,* Rhinodon).
Family Scylliorhinidae (*Scylliorhinus,* Pseudotriakis).
Family Carchariidae (Carcharias, Sphyma, *Galeus, Mustelus*).

Suborder Squaloidea. Five or six gill openings. Two dorsal fins, each typically preceded by a spine, but if these are wanting the anal fin is also absent. Rostrum simple.

Family Hybodontidae (Mesozoic).
Family Heterodontidae (Heterodontus, Gyropleurodus).
Family Protospinacidae (Jurassic).
Family Pristiophoridae (Pristiophorus, Pliotrema)
Family Squalidae (*Squalus, Spinax, Centrophorus, Somniosus*).
Family Squatinidae (*Squatina*).

Order Hypotremi or Batoidei (Rays).—Pectoral fins produced forward and joined to head; gill openings ventral. Hyomandibular purely suspensory.

Suborder Narcobatoidea. Large electric organs between pectoral fins and head. Suprascapulae united above vertebral column.

Family Torpedinidae (Torpedo, Narcine, etc.).

Suborder Batoidae. No large electric organs. Suprascapulae united to vertebral column.

Family Rhinobatidae (Rhinobatur, Discobatus).
Family Pristidae (*Sclerorhynchus,* Pristis).
Family Rajidae (Raja, Psanzmobatis, etc.).
Family Trygonidae (Trygon, Myliobatis, Rhinoptera, etc.).

SUBCLASS HOLOCEPHALI

Males with mixopterygia. Pterygoquadrate fused with skull. Lower jaw with one pair of tooth plates, upper with two pairs. Hyoid arch complete, with pharyngohyal. Gill clefts opening into a chamber with one external opening.

Family Squaloraiidae (Mesozoic).
Family Myriacanthidae (Mesozoic).
Family Chimaeridae (Chimaera, *Callorhynchus, Rhinochimaera*).

The three subclasses distinguished by the presence of mixopterygia are evidently derived from a common ancestor, which was not hyostylic, for the presence of a complete hyoid arch in the Holocephali, with a pharyngohyal above the epihyal or hyomandibular, shows that they are not derived from a form in which the hyomandibular articulated with the skull and supported the jaws. In the Paleozoic subclasses the palatoquadrate appears to have articulated with the otic region of the skull; such an articulation occurs in the Hexanchidae and Hybodontidae of the Euselachii, but whether it is primitive or secondary in these is uncertain. Some authors consider the Holocephali to be related to the squaloid sharks, but their tooth plates appear to be formed by fusion, not enlargement, and are therefore not comparable with

the enlarged lateral teeth of Heterodontus, and the dorsal fin spine is not an enlarged denticle as in the squaloids, but is formed by concrescence of horny rays; moreover, the structure of the hyoid arch, and the separate pelves, preclude the derivation of the Holocephali from the Euselachii.

See RAY and SHARK; see also references under "Chrondrichthyes" in the Index volume.

CH'ONGJIN, a leading industrial centre and port of the province of North Hamgyong. northeastern Korea. The coastal rail line goes inland from Ch'ongjin to tap the Tumen river valley and make connections with Manchurian railroad lines. The iron ore mined at Musan, inland along the Tumen river, was the base for Ch'ongjin's iron and steel industry developed in the 1930s by the Japanese who called the city Seishin. Extensive dredging improved the harbour, and the blasting of rocks and earth provided materials for development of the expanded industrial and residential site of the city. Lanam city and part of Pulyung Kun were incorporated into Ch'ongjin in 1960. The population in 1953 was estimated at 200.000. (S. McC.)

CHONIATES, MICHAEL (c. 1138–*c.* 1222). often incorrectly called MICHAEL ACOMINATUS, Byzantine writer and ecclesiastic whose homilies. speeches. poems and correspondence throw considerable light on conditions in Attica and in Athens, and on the events of his day. Born at Chonae (Colossae) in Phrygia, he studied at Constantinople and in about 1175 was appointed archbishop of Athens, where he remained for nearly 30 years. After the capture of Constantinople by the Latins and the establishment of the Latin empire (1204), he retired to the island of Ceos, where he died (c. 1222). His most notable writings are his memorial to Alexius III Angelus on the abuses of Byzantine administration, the poetical lament over the decline of Athens, the monodies on his brother Nicetas and on Eustathius, archbishop of Thessalonica, and his panegyric on Isaac II Angelus.

BIBLIOGRAPHY.—There are editions of his works by S. Lampros *(1879–80)* and in *J.* P. Migne, *Patrologia Graeca,* vol. cxl *(1865)*. *See* also *A.* Ellissen, *Michael Akominatos (1846)*, with several pieces in Ger. trans.; G. Stadtmueller, "Michael Choniates, Metropolit von Athen (ca *1138–ca 1222)*" in *Orientalia Christiana Analecta,* vol xxxiii, part 2 *(1934)*; bibliography in G. CHONIATES, NICETAS (d. 1213), sometimes erroneously called ACOMINATUS, Byzantine author and scholar, who wrote a history covering the years 1118–1206, was born at Chonae (Colossae) in Phrygia. Having been imperial secretary under the emperor Isaac II Angelus, he was governor of the theme of Philippopolis from 1189 and then grand logothete. At the capture of Constantinople by the Latins (1204) he fled to Nicaea and established himself at the court of Theodore I Lascaris. The history (Chronike diegesis), in 21 books, was probably revised after the years 1204–06, and there are signs that its author had not finally completed it. It would appear that he had access to John Cinnamus' history and to Eustathius' description of the Norman capture of Thessalonica. Nicetas' history is an important source, particularly for the years 1143–1206, and it contains an additional note on the statues in Constantinople at the time of the Latin capture and looting of the city. He also left speeches, theological works and poems which provide valuable information on the years 1180–1210, particularly on the rise of the Bulgarian empire and the effects of the Latin conquest. His Thesaurus orthodoxies is a revision of Zigabenus' *Panoplia dogmatica.*

CHONJU, city in southwestern Korea in the province of North Cholla, 30 mi. inland from Kunsan. Through widespread irrigation and reclamation, the large plain between Chonju and Kunsan was developed for commercial rice production. Chonju has many rice warehouses and cleaning mills. Modern paper, cotton and silk mills have replaced the once famous handicraft industries. For centuries the city was a provincial and regional capital and the presence of famous classical scholars and poets invigorated the cultural life. On hills to the south are grave sites, temples and pavilions. Pop. (1960) 188,726. (S. McC.)

CHONOS ARCHIPELAGO (ARCHIPIELAGO DE LOS CHONOS), a cluster of islands just west of the Chilean mainland approximately in latitudes 43° 45′ to 45° 45′ S. They are separated from the mainland by the Moraleda channel, a drowned extension of Chile's longitudinal valley. Geologically the Chonos are related to the coastal range of Chile and Chiloé. However, the terrain is lower than to the north, and Quaternary glaciers once traversed the group, scouring land surfaces and channels. The Guaitecas and other islands of the archipelago north of King channel (Level, Rojas and Chaffers) are within Chiloé province (*q.v.*). South of King channel the islands (as Benjamin, James, Melchor and Rivero) are in Aysén province (*q.v.*). The Chonos were discovered in 1553 and explored and charted several times thereafter by the Spanish, and by 19th century British, Chilean and Italian hydrographers. Seal hunters and lumbermen from ChiloC have visited the islands since the early 1800s; no significant settlements have resulted. (J. T.)

CHONTALES, a department, mostly in the Central Highlands of Nicaragua. Area 2,050 sq.mi. Its population (1959 est., 67,539) is widely scattered in mountain valleys. The departmental capital and largest town, Juigalpa (pop. 3,242); lies at 1,600 ft. elevation. The department produces livestock, corn, vegetables, fruits, and in the eastern part, lumber. At Jabalí about 78 mi. E. of Managua is the oldest and one of the more important gold and silver mining areas in Nicaragua. A modern highway from San Benito, on the Inter-American highway. goes through Juigalpa eastward to Ciudad Rama on the Escondido river. (C. F. J.)

CHOPIN, FRÉDÉRIC FRANÇOIS (FRYDERYK FRANCISZEK) (1810–1849), Polish composer and pianist, was born at Zelazowa Wola, near Warsaw, on March 1, 1810. On his paternal side Chopin was of pure French origin, his father Nicholas Chopin having been born (1771) of French peasant stock at Marainville in the Vosges. At the age of 16 Nicholas traveled to Warsaw in the suite of a certain Weydlich, the steward of important Polish estates, and never saw his native France again. He identified himself with his new country and on June 2, 1806. married Tekla Justyna Krzyzanowska, a relation of the Skarbek family of Zelazowa Wola, with whom he had found employment as a tutor.

Education and Training.—Frédéric was the second of four children. He was brought up in a refined and cultivated, if modest, home and the characteristics of elegance and aristocratic distinction that soon marked his personality and later gave a unique stamp to his compositions derived from this home atmosphere and from the high social circles of Warsaw to which the young prodigy was admitted from his earliest years. The boy's remarkable musical gifts were directed in the first instance by Adalbert Zywny, a Czech established in Warsaw; but his simple instruction in piano playing was soon left behind by his pupil, who discovered for himself an original approach to the piano and was allowed to develop unhindered by academic rules and formal discipline. Chopin's parents were wise enough to insist on their son's receiving a thorough general education, and it was only on the completion of his high school studies that he was placed in 1826 under the able guidance of Joseph Elsner, director of the Warsaw conservatory. Even before he came under Elsner's eye Chopin had shown a deep interest in the folk music of the Polish countryside and had received those ineffaceable impressions that later gave an unmistakable national colouring to his work. At the conservatory he was put through a solid course of instruction in harmony and

composition; it was only in piano playing itself that he was practically self-taught.

His Career.—After a preliminary expedition to Berlin in *1828* Chopin made his first real contact mith the outside world when he visited Vienna and made his debut there on Aug. *11, 1829.* A second concert confirmed his success and on his return home he prepared himself for further achievements abroad by writing his two piano concertos in F minor *(1829)* and E minor *(1830)* and other works for piano and orchestra designed to exploit his brilliantly original piano style. His first études (studies) were also written at this time *(1829–32)* in order to enable both himself and others to master the technical difficulties that were inseparable from his new conception of piano playing. In March and Oct. *1830* he presented his new works to the Warsaw public and then left Poland on Nov. *2,* with the intention of visiting Germany and Italy for further study. He had gone no farther than Vienna when news reached him of the Polish revolt against the Russians, and this together with the disturbed state of Europe caused him to remain profitlessly in Vienna until the following July when he finally decided to make his way to Paris. Soon after his arrival in what was then the centre of European culture and a focal point of the romantic movement Chopin realized that he had found the exact milieu in which his genius could flourish. The circles to which his talents and distinction admitted him quickly acknowledged that they had found the artist whom the moment called for, and after a brief period of uncertainty Chopin settled down to the main business of his life—teaching and composing. His high income from these sources set him free from the strain of concert giving to uhich he had an innate repugnance. Nevertheless his reputation as a pianist did not suffer from this quasi-retirement and a legend grew around his name even during his lifetime, thanks to the rapturous accounts of the few who heard him privately and to the steady flow of new compositions that began with the publication of his early mazurkas in *1832* and continued without interruption until *1847.*

Chopin's youthful love affairs with Constantia Gladkowska in Warsaw *(1830)* and Maria Wodzinska in Dresden *(1835–36)* came to nothing, although he actually became engaged to the latter. In *1836* he met for the first time Aurore Dudevant, better known as George Sand (*q.v.*), and their liaison began in the summer of *1838.* In the autumn of that year the pair made their celebrated excursion to Majorca during which Chopin completed his Preludes, Opus *28,* but in most other respects the trip was disastrous, and the privations that Chopin endured brought on the slow decline in his health which ended with his death from tuberculosis ten years later. However the period following the return from Majorca was the happiest and most productive of his life. and the long summers spent at Nohant, George Sand's country estate, bore fruit in a succession of masterpieces. Family dissensions caused by the marriage of George Sand's daughter Solange brought the liaison to an end in *1847* and thereafter Chopin seems to have given up his struggle with ill-health. The revolution of Feb. *1848* produced a temporary dissolution of the society upon which he depended for his living and he sought escape in a visit to England and Scotland during the summer of 1848. His reception was enthusiastic but he did not have the strength to profit by it. His last public appearance on a concert platform was made at the Guildhall, London, on Nov. *16, 1848,* when, in a final patriotic gesture, he played for the benefit of Polish refugees. He returned to Paris on Nov. *23* and died at *12,* Place Vendôme on Oct. *17, 1849.* He was buried at the cemetery of Père Lachaise.

Evaluation as Pianist.—As a pianist Chopin was unique in acquiring a reputation of the highest order on the basis of an extreme minimum of public appearances—few more than *30* in the course of his lifetime. His original and uninhibited approach to the keyboard allowed him to exploit all the resources of the modern piano. He was inexhaustible in discovering colourful new passage work and technical figures; he understood as no one before him, and few since, the true nature of the piano as an expressive instrument, and he had the secret of writing music whose very existence is bound up with the instrument for which it was conceived and which cannot be imagined apart from it. His innovations in fingering, his use of the pedals and general treatment of the keyboard are a milestone in the history of the piano. and his works set a standard that is recognized as unsurpassable.

Evaluation as Composer.—Chopin as a composer has acquired increased stature after a period (the later years of the 19th century) during which his work was judged by academic standards that were in fact inapplicable to its forward-looking character. It is now seen that his harmonic and formal procedures often anticipate Wagner, Richard Strauss and even the Impressionists. Music like the finale of the "Funeral March" Sonata (Sonata in B flat minor, Opus *35)* or the second Prelude is well in advance of its time in its abandonment of the classical diatonic system used contemporaneously by Mendelssohn and others. Chopin's sonatas are remarkable for the boldness with which he threw overboard the accepted rules of his time and wrote first movements whose form is dictated by the nature of their musical material rather than by adherence to a standardized scheme. He had the rare gift of a very personal melody, expressive of heartfelt emotion but never merely sentimental; and his music is penetrated by a poetical feeling whose appeal has been almost universal, so that people of the most varied races and cultures have come under its spell. His rhythm, melody and harmony can be recognized at once yet may not be successfully imitated, since each of his works is the reflection of a mysterious, withdrawn and exquisitely sensitive musical nature. Although "romantic" in its essence, Chopin's music has none of the expected trappings of romanticism—there is a classic purity and discretion in everything he wrote, and not a sign of romantic exhibitionism. He found within himself and in the tragic story of Poland the chief sources of his inspiration. The theme of Poland's glories and sufferings was constantly before him and in his polonaises and numerous mazurkas he transmuted the primitive rhythms and melodies of his youth into enduring art forms. From the great Italian singers of the age he learned the art of "singing" on the piano and his nocturnes reveal the perfection of his cantabile style and delicate charm of his ornamentation, while his ballades and scherzos have a dramatic turbulence and passion such as to dispel the notion that Chopin was merely a drawing-room composer. His total output was small and practically limited to solo pianoforte, yet within its limited framework its range is seen to be vast, comprehending every variety of intensely experienced emotion.

Works.—Chopin's works are available in many collected editions, the best of which are the Polish National editions published in Warsaw from *1949* onward and based on original manuscripts. His work consists of *2* piano concertos; *21* nocturnes; *27* studies; nearly *60* mazurkas, of which *42* were published by Chopin himself; 21 waltzes; 4 scherzos: 4 ballades; *26* preludes; *4* impromptus; *16* polonaises; 3 piano sonatas: and many individual pieces such as Barcarolle Opus *60,* Fantasia Opus *49,* Berceuse Opus *57* and 19 Polish songs.

BIBLIOGRAPHY.—*Chopin,* published in 1851 by Liszt (actually written by the princess Sayn-Wittgenstein), and the *Life* by F. Niecks (1888) contain interesting details from contemporary sources. *See* also W. Murdoch, *Chopin: His Life* (1934); *H.* Weinstock, *Chopin* (1949); *A.* Hedley, *Chopin* (1947) and *Selected Correspondence of Chopin* (1962); M. CHOPSTICKS (Chinese *k'uai-tze;* Japanese *hashi*), a pair of wood, bone or ivory sticks, often tapered, used primarily in China, Japan and Korea as eating and cooking utensils. Chopsticks for eating, sometimes ornately carved and metal tipped, are about $\frac{1}{4}$ in. in diameter and *7–10* in. long; kitchen chopsticks are somewhat longer. Japanese restaurants provide patrons with disposable chopsticks in sealed sanitary envelopes. In use, one chopstick is held rigidly between the base of the thumb and forefinger and braced against the tip of the third finger; the other is held lightly between the tips of the thumb and first two fingers and is moved up and down, the two tips forming a pincers to pick up pieces of pre-cut bite-sized food. During a meal chopsticks, when not in use, are laid on the table with the tips that touch the food resting on a small stand. Etiquette requires that they not he laid across the bowl until the meal is finished.

CHORALE (Ger. Choral), a metrical hymn tune associated in common English usage with the Lutheran Church in Germany. In the unreformed church, the word had been used to distinguish, in the liturgical plainsong, that which was to be sung by many voices in unison from that which was to be sung by one voice. The term *cantus choralis* was used in this sense; and in German Catholic circles before the Reformation the choral plainsong was knoun as *cantus* concentus, as distinguished from the (solo) *cantus accentus* As late as 1872, H. Mendel's *Musiklexicon* devoted the whole of its article on "Chorale" to a study of plainsong. But in 20th-century speech the word always carries the Reformed sense. Martin Luther himself composed, or caused to be composed, many hymn tunes that were known at once as "chorales" (Chorale) because they were designed for congregational singing. That they were called "chorales" does not imply that they were designed for singing in harmony; unison singing was the rule of the Reformed churches, both in Germany and in other countries. It was only gradually, however, that the melody shifted from the tenor to the treble line and that the organ was established as the harmonic base for congregational singing.

The earliest large collection of such melodies was the *Encheiridion* (1524), edited by Luther and J. Walther (1496–1570). From that time the technique of chorale writing expanded, and many collections nere published. Luther himself is credited with the composition of several, including Ein' *feste* Burg and *Vom Himmel hoch,* of uhich he certainly wrote the words and almost certainly wrote or adapted the music.

Landmarks in the history of chorale development are the names of Michael Weisse (c 1484–15343, N Herman (c. 1485–1561), N Selnecker (1528–92), P Nicolai (1556–1608), composer of the celebrated *Wachet Auf,* M. Vulpius (*c* 1560–1616), J Schein (1586–1630) and, greatest of all, J. Criiger (1598–1662). Cruger edited the first editions of Praxis *pietatis* melica, a collection of tunes first published in 1644 and continuing in successive editions.

More complex chorales come from J. Eccard (1553–1611), M. Praetorius (1571–1621) and H Schütz (1585–1672). Eccard's chorales are virtually brief motets: Praetorius was one of the first systematic arrangers in polyphonic style of tunes from earlier sources (*Musae* Zionae, 1609); Schutz's contributions are in his *Psalmen Davids* (1628), in many of which is foreshadowed the more sophisticated and lyrical style adopted by the later pietist composers. For these. and for later German hymnody, *see* HYMN.

In the passions and cantatas of J S. Bach, the chorale appears as a richly harmonized hymn tune in which the audience is expected to join with the choir. Bach's "chorales" (some of which are sung as English hymn tunes) are strictly chorale arrangements. It was Bach's practice to take a well-known hymn tune, remove (as the convention of his day required) its irregular rhythm and adorn it with elaborate harmony. Bach's own compositions in this field were devotional songs; it is fair to say that he never composed a "chorale." But in later works that imitate the passions of Bach, a congregational hymn is not infrequently inserted, and sometimes this is, by analogy. known as a chorale.

The chorale-prelude is a musical form most closely associated with organ music, in which a chorale is made the basis of a (usually) short piece that decorates or varies the chorale. The organist in Lutheran churches traditionally introduced congregational hymns not by playing a phrase over but by extemporizing briefly on the tune; hence "prelude." These extemporizations become chorale-preludes; the form was invented well before Bach's time, and since his death most organ composers have attempted it; and even when the *cantus firmus* is not a German tune, the piece is often still called chorale-prelude. The most eminent exponents of the form for organ were (before Bach) D. Buxtehude and (after him) S. Karg-Elert and C. H. H. Parry.

(E. R. Ro.)

CHORDATE is the common name given to one of the major groups, or phyla, into which the animal kingdom is subdivided. The chordate phylum (Chordata) is dominated by the vertebrate subphylum, but contains in addition three other subphyla, the members of which share some basic chordate characteristics in common with the vertebrates: (1) an elongate rod, or notochord, which stiffens the body; (2) a single, hollow nerve cord located on the dorsal (back) side; (3) an enlarged chamber, or pharynx, the sides of which are perforated by gill slits, just posterior to the mouth; (4) blood contained within vessels and propelled by a heart located on the ventral (belly) side; (5) a tail extending beyond the anus. Although these features are not present in all adult chordates, they appear at some stage in the life cycle of every chordate. The possession of these common characteristics indicates that all members of the chordate group are descended from a common ancestor. (See also VERTEBRATE.)

The three nonvertebrate subphyla (often called protochordates) are small marine forms. The cephalochordates, of which *Amphioxus* (*q.v.*) is best known, are small fishlike animals which as adults display all the general features of the phylum. The urochordates, or tunicates (*q.v.*), are almost devoid of chordate features in the sessile, adult state; but they produce a free-swimming larva having a dorsal hollow nerve cord, notochord, and other chordate features. The wormlike hemichordates never have a well-developed notochord but only a tiny rod in the head region; their affinity to the other chordates is doubted by some authorities.

See J. Z. Young, *The Life of* Vertebrates (1952).

(F. MG.)

CHOREA: *see* ST. VITUS' DANCE.

CHOREOGRAPHY. (1) The art of creating and arranging dances for theatrical performance, as for a ballet, opera or musical comedy. (2) The complete sequence of dance patterns in a theatrical production. (3) Choreography originally signified the notation of dances in script (as devised by Raoul Ager Feuillet in 1699); the phrase "dance notation" has generally superseded this usage.

Although dance patterns often appear to the spectator to be the result of spontaneous improvisation, any ballet or formal dance composition is planned as carefully as a complicated orchestral score. A choreographer decides the number of dancers to be used in each section of his projected work; he is responsible for the floor pattern, or movement of the dancers around the stage, as well as for the sequence of steps executed by each individual dancer. If he is staging a dramatic ballet, he must devise a method of expressing his theme or story through pantomime or dance movement. If it is a pure dance work, he must invent new patterns of movement or arrange existing onks with such skill and ingenuity that they alone will hold the attention of an audience.

The statement of the theme of a ballet, its development, climax and denouement are all planned by the choreographer and translated by him into terms of movement. He not only selects or invents the dance steps and patterns to be used but teaches them to the dancers. The choreography of a work is learned by the performers through direct imitation and not, as is the case with music, through the reading of a score.

The creation of a ballet usually begins with the writing of a libretto. This can be based on an existing literary work, as was customary in the 18th and 19th centuries, but in the 20th century it has been most frequently the original work of the choreographer. If a new musical score is commissioned, the choreographer collaborates closely with the composer, often going so far as to indicate not only the character and style of the music required but the actual rhythmic patterns and the number of measures needed in each. The great ballets of Petr Tchaikovsky, for example. were composed in intimate collaboration with the ballet master Marius Petipa, who outlined the dances of The Sleeping Beauty and The Nutcracker in meticulous detail before Tchaikovsky set them to music.

If the choreographer works from an existing score, the rhythms and general atmosphere of the work are predetermined by the composer. This is the case in such ballets as Scheherazade, staged by Michel Fokine to music by Nicolai Rimski-Korsakov, Pillar of Fire, choreographed by Antony Tudor to music by Arnold Schönberg, and Symphony in C, arranged by George Balanchine to music by Georges Bizet. For Scheherazade and Pillar of Fire, the choreographers superimposed new plots, entirely unrelated to the origi-

nal intentions of the composers, on musical works which they found appropriate in style and feeling. In Symphony in C an abstract symphonic work was chosen to accompany a plotless ballet in which dance steps reflected the changing moods of the music.

Choreographers are almost invariably skilled, experienced professional dancers, for no others are fully qualified to understand the capabilities and limitations of the human body in dance movement. The successful practice of choreography demands not only an expert practical knowledge of dancing, preferably in several different techniques (such as ballet, modern dance, folk and ethnic forms and tap dancing), but a basic knowledge of music and an active imagination. Because taste and style are reflected in the choreographer's choice of movements, poses and patterns, as well as in his use of costume and scenery, his work gains in authority if he is also thoroughly grounded in painting, sculpture, poetry and the other arts.

Choreography in its most elementary form is seen in the circles and straight lines of simple folk dances. Geometric forms such as straight and diagonal lines, squares, rectangles, circles. semicircles and spirals continue to be found in the most advanced manifestations of the art. The geometrical element was predominant in the court ballets of the 17th century, where design was formal and symmetrical. As drama entered the ballet through the work of Franz Hilverding. Gasparo Angiolini and the distinguished theoretician Jean Georges Noverre, greater freedom of movement and pattern were introduced, and choreographers explored new ways of making dancing expressive. During the 19th century Filippo Taglioni. Jean Coralli, Jules Perrot and Arthur Saint-Leon became adept at suggesting place and period through the incorporation of folk dance materials in ballet, while the increased use of dancing on the points of the toes lent a suggestion of flight and an atmosphere of mystery to conventional ballet steps. Choreographers of the later 19th century often exploited tours de force such as spinning turns and tricks of balance, calling attention to the acrobatic accomplishments of their dancers, with a corresponding neglect of poetry and elegance. Fokine, in the early years of the 20th century, returned to dramatic ballet in such-important works as Petrouchka, *Scheherazade* and The Firebird.

The emergence of modern dance as an independent dance form, in Germany and the United States, between 1915 and 1935, brought with it a strong impetus toward experimentation and a challenge which stirred choreographers in all dance forms to more inventive, imaginative and original work. Dancing in opera. musical comedy, films and television all underwent fundamental changes and were vastly enriched by new and broader concepts of dance design. Isadora Duncan, Ruth St. Denis, Ted Shawn, Mary Wigman, Martha Graham and Doris Humphrey were among the pioneers of modern dance choreography; their work was extended and carried into the field of popular entertainment by Agnes de Mille, Jerome Robbins and Michael Kidd.

In ballet choreography, Balanchine and Frederick Ashton perhaps went furthest in extending and developing classic dance design, while Tudor and Robbins discovered new means of expressing subtleties of emotion through the dance.

Choreography, throughout its history, has suffered from the fact that no universally satisfactory system of dance notation has been devised, so that the discoveries of one period must be passed on from one dancer to another through direct example and imitation. Many things have been lost in this process. After 1950, dances by Petipa and complete choreographic works by Balanchine, Hanya Holm and a few others were recorded in the most successful system of dance writing, Labanotation (see DANCE NOTATION).

Perhaps because so few written examples are available, and study of them is complicated by the fact that very few individuals are adequately prepared to read those scores that have been notated, there has been little systematic teaching of choreography. Dance composition, the teaching of which was pioneered by Louis Horst, was included in the curriculum of the Neighborhood Playhouse, New York city, in 1928, and was later introduced at Bennington college, Bennington, Vt., Connecticut college, New London, the Juilliard School of Music, the High School of Performing Arts, New York city, and other schools and universities.

Nevertheless, professional theatre choreographers continue to learn chiefly through observation and practical experience. Such experience is usually difficult to obtain, for a choreographer is not able to practice his art in solitude, like a writer, composer, painter or sculptor. He must experiment with living dancers. Under the conditions prevalent in the modern commercial theatre, mistakes are prohibitively expensive, and consequently managers tend to engage proved choreographers who are known to be competent craftsmen. Experimentation was carried on. nevertheless. by such co-operative groups as Choreographers' Workshop, active in New York city from 1946 to 1954, and Ballet Workshop, active in London after 1951. See also BALLET. (LN. ME.)

CHORIAMBIC VERSE. The choriamb is a metron of the form $-\cup\cup-$ used in Greek and Latin verse. Unmixed sequences of choriambic metra are sometimes found in Greek lyric (*e.g.*, Sophocles, Oedipus *Tyrannus,* 483–486. and antistrophe), but the choriamb most commonly appears as a constituent of aeolochoriambic verses (see PROSODY, CLASSICAL). Thus the verse called "lesser asclepiad" is composed of aeolic base (⏑⏑), choriamb and $-\cup\cup-\cup-$; *e.g.*,

Maecenas atavis edite regibus (Horace, *Odes* I, i)

The greater asclepiad contains two choriambs; *e.g.*,

aetas carpe diem, quam minimum credula postero.

Horace (Odes I. xi, xviii; IV, x) and Catullus (xxx) use sequences of greater asclepiads unmixed. In his lyric stanzas Horace often combines lesser asclepiads with glyconics and pherecrateans (see GLYCONIC) in such patterns as three lesser asclepiads and glyconic (*e.g.,* Odes I, vi, xv) or two lesser asclepiads. pherecratean, glyconic (*e.g.,* Odes I, v, xiv, xxi, xxiii). In Horace the aeolic base usually takes the form $--$, as in the lines quoted above.

Choriambic verses have occasionally been composed in English in imitation of classical poetry; *e.g.,*

/ ⏑ / ⏑ ⏑ / / ⏑ ⏑ / / "

Here the flame that was ash, shrine that was void, lost in the haunted wobd (Rupert Brooke). (L. P. E. P.)

CHORICIUS OF GAZA (fl. first half of the 6th century A.D.). Greek sophist and rhetorician whose orations were accepted as models by medieval writers. A pupil of Procopius of Gaza (d. c. 538), he wrote his master's funeral oration and continued his work. A number of his orations have survived, including panegyrics and wedding and funeral speeches. Some of his speeches on historical personages are valuable sources of information.

The *Ekphrasis* eikonos or description of a cycle of paintings in Gaza, formerly attributed to him, is now considered to belong to Procopius of Gaza.

BIBLIOGRAPHY.—J. F. Boissonade, *Choricii Gazaei orationes, declamationes, fragmenta* (1846), supplemented by C. Graux in *Revue de philologie,* vol. i (1877), rev. ed. *by* E. Richtsteig, "Teubner Series" (1929); W. Schmid in Pauly-Wissowa, *Real-Encyclopadie,* vol. iii, pt. 2 (1899); W. Christ, W. Schmid and O. Stahlin, *Geschichte d. griech Litt.,* ii, pt. 2 (1913). (J. M. HY.)

CHORLEY, a municipal borough (1881) in the Chorley parliamentary division of Lancashire, Eng., 22 mi. N.W. of Manchester by road, on the Leeds and Liverpool canal. Pop. (1961) 31.262. The town is on the fall line between a westward projection of the Pennines and the north Lancashire plain. The church of St. Lawrence is mainly Perpendicular and contains fine woodwork. The beautiful Elizabethan mansion of Astley hall, with its park. mas presented to Chorley as a World War I memorial. and the corporation bought Duxbury park estate (541 ac.) in 1932. Duxbury hall is associated with Myles Standish (*q.v.*), the early New England colonist. Since 1779 cotton has been the chief industry and machinery for the mills has been made there since 1866. A foundry, laundry and cleaning works, the making of rubber, cosmetics, footwear and rope, employ most of the inhabitants. There is a large reservoir owned by Liverpool corporation waterworks.

CHOROTEGA, the most powerful Indian tribe of northwest Costa Rica at the time of the Spanish conquest, and a linguistic family ahich includes besides the Chorotega proper, Chiapaneco, spoken by a small group in Chiapas, Mex., and the two extinct languages Choluteca, located on the Gulf of Fonseca in Honduras,

and Mangue, centred on the Pacific coast of Nicaragua. The Chorotegan family is affiliated with the larger Oto-Manguean stock of Mexico and Central America. According to early Spanish chroniclers, the Chorotega claimed to have migrated from a homeland in Chiapas many generations prior to the Conquest driving the aboriginal inhabitants out of their new territory. The Chorotega were maize farmers, had markets and a quasi-democratic social structure in which chiefs were elected, and carried on frequent warfare nith neighbouring peoples. They wore padded cotton armour and fought with bow and arrow and a wooden sword set with small flint knives, a typically Mexican weapon Religious festivals featured the South American custom of the ritual drinking bout; however, Mexican traits such as human sacrifice and self-mutilation of the ears, tongue and genitals were also present. A pantheon of gods was worshiped in specially constructed temples Chorotegan culture and language disappeared during the colonial period

For the Chorotegan languages, see INDIAN, LATIN-AMERICAN. (M. D. Co)

CHOROTÍ (CHOROTES), a South American Indian tribe belonging to the Matacoan linguistic family (see MATACO) About 3,000 in number, they live in the region of the upper Pilcomayo river in the Gran Chaco (near the juncture of the frontiers of Bolivia. Paraguay and Argentina), where they subsist by means of agriculture and fishing. supplemented by wild-food gathering and hunting.

The bon is the aboriginal weapon, and in former times the Choroti wore thick shirts of string "mail" in battle to ward off arrows. Woolen wrap-around skirts with ornamented borders constitute the typical dress for both sexes. Nets, netted bags and simple pottery are made

Choroti society basically consists of land-owning bands of 50–200 persons. Monogamy is the characteristic form of marriage, with girls selecting their future husbands.

See Alfred Métraux, "Ethnography of the Chaco," Bureau of American Ethnology Bulletin 143, vol 1, pp. 197–370 (1946) (M J H)

CHORUS, a term used in music and drama to designate those who perform in a group as opposed to those who perform singly (see DRAMA: Greek Drama; CHOIR). In England some Elizabethan dramatists wrote the chorus part for a single player who introduced and commented on the action of the play.

In music the word has several applications to the organized body of singers in opera, oratorio, cantata and church music; to compositions sung by such bodies; to the refrain of a song. sung by a group of singers, betneen verses for solo voice; and. as a medieval Latin term to the crwth (q v.) or to the bagpipe.

CHORZOW, a town in southwest Poland in the Katowice *wojewodztwo* (district), is on the Cracow-Wroclaw railway line Pop. (1960) 146.700.

Chorzow was at one time the country seat of the bishops of Wroclaw near Bytom, and as such shared the political fate of the Bytom principality (see BYTOM). It became Polish by the division of Upper Silesia in 1921. Classified as a town in 1934, it nas formed of several industrial settlements, the largest being Königshiitte, later renamed Krolewska Huta, which became a town in 1569 In 1919 half the population of Krolenska Huta was German speaking. but by 1939 the number of Germans had been reduced to 15%. A new attempt to Germanize the town took place during World War II, but after the war Chorzow became purely Polish. Chorzow is an important centre of heavy industry and mining. One of the first coal mines in the Upper Silesian basin was started in 1790 at Swietochlowice, a little to the southwest The iron foundry known as the Konigshiitte began operation in 1802, thereby laying the foundations for the future town of that name During World War I a second coal mine was started at Chorzon. The town has several coal mines, two foundries and a steel works, much enlarged after 1947. a streetcar and steel factory, a nitrogen and other chemical products factory, a zinc foundry and electrical industry. (K. M Wi.)

CHOSEN: see KOREA

CHOSROES: see KHOSRAU.

CHOTA NAGPUR, a plateau in eastern India, approximately conterminous with Chota Nagpur division of Bihar state; a considerable portion of India's heavy industry is located there. The division, occupying the hilly southern part of Bihar, consists of Palamau, Hazaribagh, Dhanbad, Ranchi and Singhbhum districts (*qq.v.*), with a total area of 27,419 sq.mi. and pop. (1951) 8,544,259. The Chota Nagpur uplands lie between the basins of the Ganges, Son and Mahanadi rivers, at an altitude of 1,000–2,000 ft. It is a comparatively cool, forest-clad, much dissected and overdrained region. The plateau, which is mainly formed of crystalline rocks, is traversed in the centre by the faulted sedimentary coal-bearing trough of the Damodar basin. There are a number of beautiful waterfalls, particularly in Ranchi district. Chota Nagpur has one chief crop, unirrigated rice; subsidiary crops are maize. oilseeds, pulses and potatoes. The principal forest products are timber, particularly sal; lac (of which Chota Nagpur is the world's leading producer); tussah silk; and mahua flowers, which are used as food and as a source of country liquor.

Chota Nagpur contains the Jharia, Giridih, Bokaro, Karanpura and Daltonganj coal fields and produces about half the coal of India. The mica belt, occurring mainly in Hazaribagh district. is one of the main sources of mica in the world. Other important mineral products of the region are iron, copper, manganese, chromite, china clay, limestone: apatite. kyanite, fire clay and bauxite. Notable manufactures are iron and steel, aluminum, railway engines and coaches, fertilizer, copper and cement. Industrialization expanded upon completion of four dams (Tilayia, Konar, Maithon and Panchet) and a huge thermal plant at Bokaro as part of the Damodar valley project (see DAMODAR). The plateau is connected by road and rail with Calcutta to the east, Patna to the north, and with cities in the south and west via Cuttack and Bilaspur. (E. AH.)

CHOUANS, the name given to the bands of peasants. mainly smugglers and dealers in contraband salt, who rose in revolt in the west of France in 1793 and joined the Vendéan royalists (see VENDÉE, WARS OF THE). The Breton word *chouan,* meaning "screech-owl," is supposed to have been applied originally as a nickname to Jean Cottereau (1767–94), the leader of the revolt, and afterward extended to his followers. In any case, it was appropriate. for they were night birds and used the hoot of an owl as a signal. The motive for revolt was less devotion to the monarchy than resentment at interference by the new republican government with their old habits; the ruin of their contraband trade by the abolition of the gabelle (*q.v.*); the attacks by the Convention on the priesthood; and, above all, the enforcement of conscription. Their methods of warfare were barbarous and were met by barbarous reprisals. A vivid picture of these wild people is given by Honor6 de Balzac in his novel Les *Chouans.*

CHOU EN-LA1 (1896–), one of the leaders of the Chinese Communist party (C.C.P.): was born in 1898. His ancestral home was in Shao-hsing. about 200 mi. S. of Shanghai. Having been exposed to western ideas in his early youth in Chinese and Japanese schools, he took part in the 1919 student demonstrations in Peking, which gave him his first jail experience. As a student in France (1920–24) he founded the first Chinese Communist youth unit. His second arrest occurred in 1926 when he was political commissar of the Whampoa Military academy founded by the Kuomintang, and he barely escaped death in 1927 in Shanghai when the Kuomintang broke with the C.C.P. (see CHINA: *History: Nationalism and Communism*). As head of the C.C.P. military committee and a leading member of the political bureau in the late 1920s. he represented the C.C.P. at Comintern meetings in Moscow and had a hand in the numerous uprisings in China.

In 1931 he joined Mao Tse-tung in southern Kiangsi where they directed the defense of their soviet base against repeated Kuomintang attacks. After they were driven out by the Kuomintang, and executed the Long March in 1934–35 from Kiangsi to Yenan in north China. Chou emerged as spokesman for the embryonic Chinese Communist regime. He negotiated with the Kuomintang during and after World War II. His acquaintance with the western world and his diplomatic talent. which won many friends for the C.C.P. and impressed many visitors during this

period, were again in full display at the Asian-African conference at Bandung, Indon., in April 1955. Upon the establishment of the Chinese Communist regime in 1949, Chou became premier and foreign secretary, relinquishing the latter post in 1959.

Dedicated to the party but showing no Napoleonic thirst for personal power, eloquent in defending the party's position but offering no personal interpretation of communist theories, Chou was able to survive the C.C.P. power struggle. His wife, Teng Ying-ch'ao, his comrade in revolution since their high-school days. also was an important C.C.P. leader. (KA. H.)

CHOUGH *(Coracia pyrrhocorax),* a bird of the crow family. It inhabits mountains and rocky coasts in Europe and north Africa. The combined effects of persecution by man and competition with the jackdaw (*q.v.*) have reduced its numbers and it is now rare. Recognized by its black plumage and bright red legs and red, curved beak, the chough is more slenderly built than the crows. It is less common in Great Britain and Ireland, though a breeding resident. The alpine chough *(C. graculus)*, slightly smaller and with a yellow bill, is a gregarious inhabitant of inland mountains and valleys of south Europe.

CHOU-SHAN CH'ÜN-TAO (CHUSHAN, CHUSAN), an island archipelago off the north coast of Chekiang province, China. It represents the submerged terminus of the Tayü Ling, the dominant range of Chekiang. The outermost islands, which lie across the entrance to Hangchow bay, have periods of heavy fog and are swept by the beginning currents of the tidal bore that runs up the bay. The southern islands are becoming choked with silt from the Yangtze estuary, to the north, and may eventually become tied to the mainland.

Chou Shan Island, largest of the group, was during the 15th and 16th centuries an entrepôt for trade with Japan, as Hong Kong today serves China for trade with Great Britain. Great Britain failed to establish a trade centre there in the early 19th century. The Chinese Nationalists maintained a military base on Chou Shan from 1949 to 1953. P'u-t'o Island, east of Chou Shan, also is of importance in the fishing industry, but its chief interest long has been its many monasteries and temples, for it is historically famous as a Buddhist pilgrimage centre. The islands carry on agriculture and salt-making from sea water, but the prime product is fish, chiefly marketed through Ningpo on the Chekiang mainland. (J. E. SR.)

CHRESTIEN, FLORENT (1541–1596), French poet, satirist and a noted Hellenist. was born at Orléans on Jan. 26, 1541. A pupil of Henri Estienne, he was appointed at an early age as tutor to Henry of Navarre, later Henry IV, who subsequently made him his librarian. He was a contributor to the *Satzre Ménippée,* the famous pasquinade written in the interest of his former royal pupil, and his norks include a Latin version of *Hero and Leander* and French versions of George Buchanan's *Jephthes* and Oppian's *De venatione.* Though brought up a Calvinist, he was converted to Catholicism before his death at Vendôme in Oct. 1596.

CHRÉTIEN DE TROYES (fl. 1170), French medieval poet who was the author of the earliest surviving Arthurian romances. Knowledge about his life is very slight and most of the information available is derived from his references to himself in his works. Of these, those extant are, in probable chronological order, *Erec, Cligès, Le Chevalier à la Charette (Lancelot), Le Chevalier au lion (Yvain), Guillaume d'Angleterre* and *Le Conte del Graal (Perceval),* all of which, except the next to the last. deal with Arthurian legend. Since the poet refers to himself as "Chrestiiens de Troies," he was presumably a native of Troyes in Champagne. He was familiar with the writings of Ovid, may have taken holy orders and was patronized by two of the most prominent figures of his time: Marie, the daughter of Louis VII of France and Eleanor of Aquitaine, who became countess of Champagne by her marriage in 1164, and Philip of Alsace, cousin of Henry II of England, who was count of Flanders after 1168 and, as guardian of the young Philip Augustus. virtual regent of France from 1180 until 1182. For the first of these patrons he composed *Le Chevalier à la Charette;* for the second, *Le Conte del Graal.* It is not known whether Chrétien ever visited Philip's court. but the knowledge of geography displayed in *Cligès* suggests that he may have been to England. *Erec* was written after the appearance of Wace's *Roman de Brut* in 1155. *Le Chevalier à la Charette* was written after 1164 when Marie became countess of Champagne. *Le Conte del Graal* was begun before Philip went on crusade, from which he never returned, in 1190. Most probably, therefore, all the more important works of Chrétien were completed between 1160 and 1180.

The romances, which are no more than accounts of chivalrous adventures built around the framework of a love story, enjoyed great popularity. Chrétien handles the themes of courtly love and Arthurian legend with a detachment at once humorous and sympathetic and his work represents the most sophisticated product of the 12th-century courtly movement. Although his characters possess little depth and the situations with which they are faced are often extravagantly unreal, many such faults, hitherto attributed to the author, are the result of the complicated mythological ancestry of the persons and events he described. In any case, such defects would not have been regarded as serious in works which were intended merely as an intellectual pastime for courtly society, particularly when their author possessed such a brilliant narrative technique as Chrétien.

BIBLIOGRAPHY.—The best editions of *Erec, Cligès, Le Chevalier à la Charette* and *Le Chevalier au lion* are still those prepared by W. Foerster between 1884 and 1899. An English translation of these works, under the collective title *Arthurian Romances,* was reprinted in 1955. The best edition of *Le Conte del Graal* was published in 1956. For general criticism of Chrétien's work *see* R. R. Bezzola, *Le Sens de l'aventure et de l'amour* (1947); R. S Loomis, *Arthurian Tradition and Chrétien de Troyes* (1949); W. A. Nitze, *Perceval and the Holy Grail* (1949); J. Frappier, *Le Roman breton: Chrétien de Troyes, Perceval ou le conte du Graal* (1953); S. Hofer, *Chrétien de Troyes: Leben und Werke des altfranzösischen Epikers* (1954). Many of the classic critical works on Chrétien are not easily obtainable; those given here contain bibliographies of earlier studies.

CHRISM, a mixture of olive oil and balsam used in the ritual of Eastern and Latin churches. The anointing of priests, kings and prophets in the Old Testament was interpreted by the early church as having been fulfilled in the triple role of Christ, whose name signifies "the Anointed One"—*i.e.,* by the Holy Spirit. Consequently, from at least the 2nd century, the church ritually anointed all newly baptized as a sign of their sharing in the royal priesthood of Christ (*cf.* I Pet. ii, 9). In the West the word chrism (from Gr. *chrio,* "to anoint") was retained for the oil; in the Greek church, beginning with the 4th century, the term *myron* ("perfumed oil") was substituted (appropriately, because in the complicated Greek rite of blessing the oil as many as 50 aromatic substances are added; in the west, sweet-smelling balsam has been added to the olive oil since the 6th century).

In the Latin Church, chrism is consecrated by the bishop in a special chrism mass on the morning of Maundy Thursday. The ceremonial is highly solemn, characterized by processions with the oil and requiring the assistance of 12 priests, 7 deacons and 7 subdeacons. The consecratory preface states that the sacred oil elevates those anointed with it to a sharing in the dignity of priests, kings, prophets and martyrs. In Eastern churches the consecration of the *myron* is a privilege normally reserved to patriarchs.

Chrism is used in the Latin Church for the postbaptismal annointing and for confirmation, for the consecration of bishops, churches, altars, chalices and patens, and for the blessing of bells and of baptismal water. In the rite of ordination of priests, chrism was used for the anointing of hands from the 7th to the 12th century, when the oil of catechumens came to be substituted through an unfortunate misunderstanding. Since the 6th century chrism also has been used in the ritual of coronation of kings and emperors: these, as a consequence, were no longer regarded as laymen but as belonging somehow to the ranks of the clergy, with special obligations and liturgical rights. The claim of emperors and kings to a voice in the election of bishops was often based on this fact. (G. L. D.)

CHRIST, the "Anointed One," the Greek (*Christos*) translation of the Hebrew "Messiah"; the title given in the New Testament to Jesus of Nazareth. See JESUS CHRIST: *The Picture of Christ in the Early Church;* MESSIAH.

CHRIST, CHURCHES OF, a group of churches, found chiefly in the United States. with a membership of approximately 2,000,000 (about 62,000 outside the U S.) in about 18.800 local churches. They are strongest in Michigan, the Ohio valley and in the southern and southwestern sections of the U.S., including Florida and California. Each church is known locally as a Church of Christ, its members as Christians, and is autonomous in government, with elders as overseers, deacons and a minister or ministers. There is no organization beyond the local church.

The Churches of Christ claim to have originated on Pentecost in Jerusalem, AD. 30, and to be identified with New Testament churches in origin, doctrine and practice. They believe that in the early centuries there were departures from New Testament teachings to the extent that the identity of churches as they were in New Testament times became lost. Efforts were made to restore the doctrine and practice of these churches, but it was not until the early part of the 19th century that they culminated in Great Britain and then the United States in what became known as the "restoration movement." Leaders of this movement—a number of whom were originally Presbyterians—deplored existing religious divisions, certain doctrines they considered erroneous, and the making and demands of creeds. They pleaded for the Bible alone. nithout creedal human additions, and for the unity of the people of God by the restoration of New Testament Christianity. Refusing affiliation with any sect, they called themselves simply "Christians." Foremost leaders were Barton W. Stone. Thomas Campbell and his son Alexander, and Walter Scott (see also CAMPBELL. ALEXANDER; DISCIPLES OF CHRIST).

About the middle of the 19th century controversies arose among the Christians, principally over the scriptural authorization for organized missionary societies to do the work of the church and the use of instrumental music in Christian worship. These led to an open division, with those favouring the societies and instrumental music being listed in 1906 by the federal census of religion as Disciples of Christ and those opposed as Churches of Christ. The latter hold that organized societies and instrumental music are unauthorized by the New Testament, that the New Testament church had neither and hence both are innovations.

After the division the Churches of Christ continued to gron substantially and rapidly in the United States and abroad. Though the church is opposed to organized mission societies. missionary work is nonetheless carried on in 80 foreign fields. Convinced of the importance of Christian education, members of the Churches of Christ operate 20 liberal arts colleges and many high schools in which the Bible is taught. Three of the colleges offer graduate work in religion and other fields. There is a weekly cooperative nation-aide radio and television program known as the "Herald of Truth." Members of the church also publish newspapers and operate orphanages and homes for the aged.

Sunday worship in the Churches of Christ consists of unaccompanied congregational singing, prayer, teaching. preaching. giving and the Lord's Supper. There are other worship and teaching services on appointed days during the week, with periodic special and evangelistic meetings.

The Churches of Christ have no creed in the sense of a humanly formulated statement containing official articles of faith. They believe in the manifestation of God in Christ, in the all-sufficiency of the Bible, with the primacy of the New Testament, as the revelation of the will of God and the only rule of faith and practice. They continue to advocate the restoration of New Testament Christianity. They believe that the word of God is the seed of the church (Luke viii. 11). When received it produces faith in Christ, repentance from sin, confession of faith in Christ, burial with Christ in baptism for the remission of sins. and thus leads to Christian worship, Christian living and the hope of eternal life as it did in Yew Testament times.

CHRISTADELPHIANS (Greek for "Brothers of Christ"), sometimes also called THOMASITES, a religious body founded about 1848 by John Thomas (1805–71), who, after studying medicine in London, migrated in 1844 to Brooklyn. N.Y. There he at first joined the followers of Thomas and Alexander Campbell (q *v.*), but afternard struck out independently, preaching largely upon the application of Hebrew prophecy and of the book of Revelation to current and future events. Both in the United States and Great Britain he gathered a number of adherents. The name Christadelphians was adopted during the Civil War when the denomination had to organize formally in order to justify its objection to military service.

The local organization, called an ecclesia. is congregational in polity, with no distinction of clergy and laity. Ruling or serving brethren are elected. who minister without compensation. Annual fraternal gatherings are held for fellowship and Bible study. The Christadelphians number around 4,000 in 115 ecclesias in the United States. They publish four magazines. chief of which are the Faith (Waterloo, Ia.) and the *Christadelphian* (Birmingham. Eng).

The Bible is the only authoritative creed, and membership in the society requires a profession of faith and baptism by immersion. The group rejects orthodox views of the Trinity, and its theology is strongly millenarian, centring in the hope of a world-wide theocracy with its seat at Jerusalem and involving belief in a conditional immortality of the body.

CHRISTCHURCH, a municipal borough of Hampshire Eng., stands at the confluence of the Avon and Stour rivers, adjoining Bournemouth on the coast. 21 mi S.W. of Southampton by road. Pop. (1961) 26,198. It includes the villages of Mudeford and Highcliffe. The neighbourhood was of great importance in later prehistoric times and much of the Late Bronze and Early Iron Age intercourse of Britain aith the continent seems to have focused on Hengistbury head and Christchurch. In 901 it was seized by Aethelwald. but was recaptured by Edward the Elder. The town's Saxon name long survived in the form Christchurch Twynham, but in Domesday Book it appears as Thuinam when it mas a borough belonging to the king. Henry I granted Christchurch (about 1100) to Richard de Redvers, who erected the castle, of which only fragments remain. The Norman Constable's house on Castle Mound has been restored. The town's first charter was granted by Baldwin of Redvers, 1st earl of Devon. about 1150; Baldwin, the 7th earl, granted to the burgesses the tolls of the fair at St. Faith about 1257. Holy Trinity fair is mentioned in 1226.

The Augustinian priory church, dedicated to the Holy Trinity, and dating from the 12th century is cruciform, lacking a central tower but having a Perpendicular tower at the west end and a Perpendicular choir. The nave and transepts are principally Norman and very fine. Early English additions appear elsewhere, and the rood screen is of ornate Decorated workmanship. The priory. dissolved in 1539, became so famous that its name. Christchurch, finally replaced the town's older name. The town was re-incorporated by royal charter in 1886.

Largely residential, Christchurch is also a seaside resort with a small harbour for sailing yachts and small craft. A regatta takes place every August; the sailing club was established in 1884. The Red house is a museum and art gallery. Besides its salmon fisheries, Christchurch has light industries, the chief of which is the building of aircraft. The Bailey bridge, invented by Sir Donald Bailey, was built there during World War II.

CHRISTCHURCH, capital city of the provincial district of Canterbury, New Zealand, lies on the east coast of South Island, to the north of Banks peninsula. The population (1961) of 151.-333 (including suburbs 220,322) makes it the second largest city in New Zealand after Auckland. Situated on the alluvial Canterbury plains close by Banks peninsula. which mas once a volcanic island. the city, unlike others in New Zealand, is laid out in a rectangular pattern and is sometimes known as the "Garden City" or the "City of the Plains." The small but attractive river Avon winds through Christchurch and there are beautiful parks and gardens uhich, with reserves and recreation grounds, account for

one in every eight acres of the city. The focal point of the city is Cathedral square, which is dominated by the 240-ft. spire of the Anglican cathedral built in the Gothic style from designs by Sir Giles Gilbert Scott. There is also a Roman Catholic pro-cathedral attached to a convent of the Sacred Heart. Christchurch has always been regarded as one of New Zealand's leading centres of education. Some of its oldest and finest buildings are schools, such as Christ's college and the University of Canterbury, founded in 1873. The Robert McDougall Art gallery and the Canterbury museum, which has a fine collection of native birds (including remains of the extinct moa), a replica of an early Christchurch street and a planetarium, are situated by the Botanical gardens and Hagley park. The latter divide the residential districts in the north and west of the city from the commercial area. Other buildings include the government offices and the Princess Margaret hospital.

The main port is Lyttelton, a natural deep anchorage, 7 mi. S.E. Two roads over the Port hills and road and rail tunnels connect the port and city. The port handles more than 1,500,000 tons of goods annually, the chief exports being wool, meat, dairy products and wheat and the chief imports motor spirits (gasoline), oil, fertilizers, iron and steel. Six miles to the northwest of the city centre is Christchurch international airport. Situated on a shingle formation of more than 1,000 ac., it is one of the country's main airports, with direct services to Melbourne and Sydney in Australia and to other cities in New Zealand. A four-lane highway connects the airport with the city, which has thus become a major freight-handling centre as well as an important centre for industry connected with aviation. Christchurch also has good road and rail connections with Blenheim to the north, Dunedin and Invercargill to the south and Greymouth to the west through the Southern Alps.

With its good transport facilities, bountiful supply of water from artesian wells and unlimited quantities of inexpensive hydro-electric power, Christchurch has become the second most important industrial centre of New Zealand. Before World War II the city was chiefly dependent on the rich agricultural district surrounding it, the plains being mainly devoted to cereals and grazing. However, there were a number of important industries. including meat freezing and woolen and implement manufacturing, and after 1945 industrial expansion was phenomenal. By 1960 there were more than 2,200 factories producing such goods as clothing. carpets, wood and cork products, furniture and transport equipment. In 1960 it was estimated that the annual value of goods produced in Christchurch was more than £100,000,000. of which more than one-third represented the value added to the raw materials used. Industrial expansion has been helped by the ready availability of fully serviced land zoned for industrial purposes.

Christchurch mas the last and most successful colonizing project inspired by Edward Gibbon Wakefield and his New Zealand company. It mas founded by the Canterbury association, formed in 1848 largely through the efforts of John Robert Godley, which planned to establish a model Church of England settlement. The first settlers under the scheme reached Lyttelton on Dec. 16, 1850. (C. P. G.)

CHRISTIAN I (1426–1481), king of Denmark, Norway and Sweden, founder of the royal house of Oldenburg, was born on May 21, 1426, the son of Count Dietrich the Happy of Oldenburg and Hedvig of Holstein. When, in Jan. 1448, Christopher III died childless, Christian's uncle Adolf, duke of Schleswig and count of Holstein, was next in succession, but he recommended his nephew to the Danish *rigsraad*. Christian became king in the same year and in 1449 married his predecessor's widow, Queen Dorothea of Hohenzollern (1430–95).

Sweden now chose the former regent Karl Knutsson (Charles VIII) as king, while Norway hesitated. Christian's foremost political aim was to restore the northern union. At a meeting of the Danish and Swedish councils at Halmstad in 1450 he was recognized as king of Norway and heir in Sweden. Yet he supported a Swedish faction which, in 1457, deposed Charles. In March 1460, the nobles of Schleswig and Holstein chose Christian as formal successor to his uncle, though a declaration of 1448 had decided that Denmark and Schleswig should never be ruled by the same regent. Christian's Swedish plans were ruined in 1471, when the recalled Charles VIII defeated him at Brunkeberg near Stockholm. In Denmark, the nobles were restive, but this danger was met with the help of the commons in 1468, the year in which the Danish estates were first called together.

Always lacking funds, Christian could not enforce his trade laws favouring the burghers. Generous grants of privilege were the price of friendship with the Hanseatic league, whose claims to sole trading rights in Iceland entangled Denmark in a war with England (1469–74). In 1469 Christian married his daughter Margaret to James III of Scotland. As a pledge for a dowry the Norwegian Orkneys and Shetlands with the almost forgotten sovereignty over the Hebrides and Man were ceded to James—a grant never redeemed. Christian's concordat with the pope made it easier for him to deal with the Danish Church. After his visit to Rome in 1474 he obtained (1475) a papal bull for a university, which he founded in Copenhagen in 1479.

Christian combined Renaissance drive with medieval chivalry. He had courage and ambition and loved splendour and extravagance. But though he was daring and farsighted in his designs, he lacked resolve in realizing them. He died in 1481. (A. E. Cn.)

CHRISTIAN II (1481–1559), king of Denmark, Norway and Sweden, son of King Hans (John) and Christina of Saxony, was born at Nyborg castle on July 1, 1481, and succeeded his father on the Dano-Norwegian throne in 1513. In 1502 and 1506–12 he had been an able viceroy in Norway, favouring the burghers; the *rigsraad* and nobles were therefore loath to accept him. To compromise, he had to grant a charter at a Dano-Norwegian *rigsdag*, nhereby the *rigsraad* was assured control of the government and the nobility acquired sole right to office under the crown, in addition to securing extensive powers in their enfeoffed estates. As the Swedish delegates present had no mandate to elect a king, the question of the union remained open and Sten Sture the younger continued as Swedish regent.

In Norway Christian had taken up two Dutch women of bourgeois origin, Dyveke as his mistress and her mother, Sigbrit Villoms (or Villomsdotther), as counselor. This association continued even after his marriage in 1515 to Elizabeth (Isabella) of Habsburg, sister of the future emperor Charles V. If the *rigsraad* disapproved of Dyveke, it also resented Sigbrit's influence. This clever woman became controller of the sound tolls and soon took charge of the financial business of the state. At first Christian tried not to breach the charter openly, though he bypassed the *rigsraad* and used the chancellery to bring in some reforms in favour of the burghers, especially the merchants, who gained sole trading rights in disregard of privileges claimed by the nobles and the Hanseatic league.

The storm broke in 1517. Christian accused Torben Oxe, governor of Copenhagen castle, of having poisoned Dyveke, and had him beheaded. Thereafter he ignored the *rigsraad* and the charter. The chancellery took on direct supervision of the provinces and for governors chose burghers loyal to the king. Christian appointed bishops at will. Hans Mikkelsen, burgomaster of Malmö, became his special counselor. The government assumed a mainly bourgeois character.

Christian stopped negotiating with the Swedes and, without the *rigsraad's* consent, resolved to fight. Both through diplomacy and help from the Swedish unionist party under Archbishop Gustav Trolle, Christian had prepared well for this war. Yet twice the Danes mere beaten outside Stockholm (1517–18). Sten Sture imprisoned the archbishop, for which Pope Leo X excommunicated him. Christian now rebuilt his forces round an elite core of mercenaries and in 1520 attacked again. This time he prevailed. On Jan. 20 Sten Sture was defeated and mortally wounded at Bogesund. The victors quickly advanced to Stockholm and Uppland. On March 6, Swedish councilors assembled at Uppsala recognized Christian as king, and he in return granted an amnesty and undertook to rule according to the constitution of the former union. The nationalist party held out in Stockholm till September.

Christian was crowned king of Sweden on Nov. 4. Celebrations went on for three days, but on Nov. 8 occurred the "Stockholm

blood bath," which cost the lives of about 80 Swedes—bishops, nobles and burghers. The previous day Gustav Trolle had laid dubious charges of heresy on inconvenient opponents; an ecclesiastical committee hastily pronounced them heretics, and they were turned over to the secular authorities for execution. Whether the king or the archbishop had instigated this massacre, the effect was not as intended. Rallying round Gustavus Vasa, a young noble. the Swedes in Jan. 1521 began a war of liberation. In June 1523 Gustavus Vasa was proclaimed king of Sweden. The northern union ceased to exist.

At Stockholm, in 1520, Christian had drawn up plans for a northern trading association which was to work with the south German merchant house of the Fuggers to crush the Hanseatic league and take over all Baltic trade. Meanwhile Denmark saw sweeping legal reforms. producing in 1521–22 the two new codes of the *bylov* (borough law) and *landlov* (land law). Influenced by Dutch and German institutions. these codes emphasized the power of the king and greatly altered Denmark's social structure. Class differences were limited by extension of the burghers' commercial privileges and guarantee of the peasants' freedom. The church was organized on a national basis under the supremacy of the king, and numerous humanitarian and cultural reforms were introduced.

The king's setback in Sweden, the break with the Hanseatic league, the provocative administration of the provinces, the new laws and fear of a hereditary monarchy stiffened opposition from the Danish nobles. Christian was now prepared to compromise. but too late. The Jutlanders of the *rigsraad*, having decided to depose him and appoint his uncle Frederick, duke of Schleswig-Holstein, renounced their allegiance on Jan. 20. 1523. As opposition from the nobles grew, Christian lost heart and with his counselors left Copenhagen on April 13 to seek help abroad.

Christian settled in the Netherlands. His power was broken. It was not until 1531 that, with the help of his brother-in-law the emperor Charles V, he was able to raise an army and sail to Norway, where he was once again welcomed as king. He abandoned the struggle, however, and sought to negotiate with Frederick I. In spite of a safe conduct, he was arrested at once and imprisoned at Sonderborg castle and later (1549) at Kalundborg castle. where he died on Jan. 25, 1559.

Christian's character was as changeable as his portraits are contradictory. Sometimes an energetic man of action. at others a spineless and hesitant doubter, he was usually frank and sociable but on occasion completely governed by suspicion and cruelty. But against the charge of vacillation it may be argued that he stood by his bourgeois principles. (A. E. Cn)

CHRISTIAN III (1503–1559), king of Denmark and Norway. who established the state Lutheran Church in Denmark, was the eldest son of Frederick I of Denmark and his first wife, Anne of Brandenburg. and was born at Gottorp on Aug. 12. 1503. Early in life Christian became a convinced Lutheran. His tutor between 1518 and 1520 was Wolfgang von Utenhof from Wittenberg university, and in 1521 Christian was himself present at the diet of Worms. When. in 1523. his father was elected Danish king in succession to Christian II, Christian at once clashed with the Catholic majority in the *rigsrnnd.* Because of his Protestant zeal when *statholder* in Schleswig-Holstein (1526) and during his visit to Norway (1529), he was not elected heir while his father still lived. When Frederick died in 1533. the Catholic councilors preferred Christian's younger brother Hans; with the Protestant councilors' approval. the election was put off for one year. Meanwhile the burgomasters of Copenhagen and Malmö conspired with the Lutheran burgomaster of Lubeck to restore the imprisoned Christian II (*q.v.*) to the throne, and Lubeck's forces invaded Holstein. But in Aug 1534 an assembly of Jutlandish nobles and bishops at Rye in Jutland proclaimed Christian king. In summer 1536 Copenhagen surrendered to his forces. He began consultations on a religious settlement with the Catholic bishops. but they were so obstinate that he arrested them during the night of Aug. 11–12. Next day, the lay members of the *rigsraad* swore not to oppose further changes in the church. On Oct. 30 a national assembly made over all episcopal property to the crown and established the Lutheran Church in Denmark with the king as its head! while Christian confirmed the privileges and constitutional rights of the *rigsraad* which proclaimed his son Frederick heir to the throne.

In 1537 the Danish Church was reorganized under the guidance of advisers, particularly Johann Bugenhagen from Wittenberg university. Christian himself maintained close personal contact with Wittenberg. But despite his German origins and sympathies he established good relations with the *rigsraad*, thanks mainly to the chancellor Johan Friis, and became completely reconciled with the Danish nobility. His Holstein councilors wanted him to live at Gottorp, as his father had done, but he refused and, from 1539, resided permanently in Denmark.

Christian's foreign policy rested on his alliance with the German Protestant rulers. This counterbalanced the persistent hostility of the Holy Roman emperor Charles V, who supported the claims of his nieces, the daughters of Christian II, to the Scandinavian kingdoms. In 1542 the Danish nobility voted Christian a 20th part of their property, which enabled him to clear his debt with Holstein. Thenceforth Christian and his Danish councilors took the lead in foreign policy. The conciliatory policy of Christian's German advisers was abandoned, and in 1542 war was declared against the emperor. The closing of the sound to shipping from the Habsburg Netherlands was very effective. At the diet of Speyer in May 1544 Charles V concluded peace with Denmark. From then on, Christian avoided all foreign complications, refusing to take part in the war of the League of Schmalkalden (1546) and acting as a mediator between the Albertine and Ernestine Wettin of Saxony (1554). When Christian died on Jan. 1, 1559. Denmark was rich and peaceful. His reign saw measures fitted to a country In transition, the administration had been modernized. and Denmark had become a full member of the European system. Though not perhaps a great ruler: Christian was a good one, with a strong sense of duty and genuine piety.

See K. Fabricius (ed.), *Danmarks Konger (1944).* (As. F.)

CHRISTIAN IV (1577–1648), king of Denmark and Norway, the son of Frederick II of Denmark and Sophia of Mecklenburg, was born at Frederiksborg castle on April 12, 1577, and succeeded to the throne on the death of his father (April 4, 1588); during his minority, which lasted till Aug. 17, 1596, the government was carried on by a regency of four members of the *rigsraad*, who supervised his education. Soon after his coronation in 1596 Christian won the initiative in politics. The *rigsraad*, however, succeeded in restraining his hostile policy against Sweden until Christian threatened to declare war as duke of Schleswig-Holstein (1611). The Kalmar War (1611–13) against Gustavus Adolphus of Sweden was successful, but inconclusive.

At home Christian encouraged the formation of trading companies and fostered manufactures, which, however, did not thrive. By contrast, his new silver mines at Kongsberg in Norway were a success, and Copenhagen received many fine new buildings. He founded important new towns which furthered commerce and strengthened Denmark's defenses. He employed Dutch architects and engineers and himself took part in the planning and execution of his projects. Gliickstadt in Holstein and Christianshavn were among the new ports, and Christiansstad in Scania and Christianopel in Blekinge were strategically placed near the Swedish frontier. Christian followed the brilliant career of Gustavus Xdolphus with envy. He had no army to match the Swedish, but spared no expense to maintain the superiority of the Danish navy and built a protecting harbour and an arsenal in Copenhagen.

By 1624 the Thirty Years' War had reached a critical phase for the Protestants: the Catholic forces were dangerously near the Baltic, and Christian agreed to intervene. He had aspirations in northern Germany and even dreamed of diverting the commerce of Hamburg to Gluckstadt. He had gained the election of his second son, Frederick. as coadjutor of the secularized bishopric of Bremen in 1621 and as bishop of the adjoining Verden in 1623. Besides these German ambitions, family ties may well have led him to help the Protestants. for Elizabeth, his niece, was wife of the elector Palatine. In 1625 Christian started operations against the Catholic league, but his defeat by Tilly at Lutter-am-

Barenberge (Aug. *1626)* made retreat imperative. Tilly and Wallenstein invaded and plundered Jutland, and in Jan. *1628* Christian was compelled to form an alliance with Gustavus Adolphus. After a Swedish-Danish army and fleet had compelled Wallenstein to raise the siege of Stralsund (Aug. 1628), however, Christian declined a further alliance with the Swedes and concluded a separate peace with the Holy Roman emperor at Lubeck (May *12, 1629).* Unfortunately Christian would neither conciliate Sweden nor protect himself by a system of counteralliances, while his special rights in the Baltic and his privileges as king of Norway alienated him in the long run from both the United Provinces and England. Raising the sound tolls, he obstructed trade while at the same time obtaining an increased income independent of the *rigsuaad.* By mediating in favour of the emperor, after the death of Gustavus Adolphus in *1632,* he tried to minimize the influence of Sweden in Germany. In May *1643* the Swedes declared war on Denmark and by the end of Jan. *1644* Jutland was in their possession. Christian then showed something of his earlier drive and, since the Swedish offensive flagged, the Danes were able to save the important fortress of Malmö. At first the Swedish army could not cross from Jutland to Fünen for want of a fleet and later attempts to transport it to the Danish islands were repulsed under Christian's personal direction (July *1, 1644).* Though the Danish fleet blockaded the Swedish ships in Kiel bay they escaped, and the annihilation of the Danish fleet by the combined navies of Sweden and Holland at the end of September forced Christian to come to terms. Peace was finally signed at Bromsebro in *1645. (See* DENMARK: *History.)*

The king's last years were further embittered by the antagonism of the nobility. Throughout his reign the *rigsraad* and the nobility had opposed his warlike policies. But in the *1630s* and early '40s Christian's position was strengthened by the marriages of his daughters with members of the aristocracy. However, the strain on the finances caused by the war gave the *rigsraad* and the nobility their opportunity, and finally Christian's sons-in-law also quareled with him. He died in Copenhagen on Feb. *28, 1648.*

CHRISTIAN V (1646–1699), king of Denmark and Norway, the son of Frederick III of Denmark and Sophia Amalia of Brunswick-Luneburg, was born on April *15, 1646,* at Flensburg, and succeeded to the throne on Feb. *9, 1670.* Christian was well liked and easily made contacts with the common people. Nevertheless he was conscious of his dignity and absolute power. He disliked the old Danish nobility and therefore opened the highest offices of state to Holstein nobles and well-placed burghers, who were admitted to the two new orders of nobility, counts and barons, set up in *1671.* Peder Schumacher, a commoner: became first his leading counselor and in *1674* was made *rigskansler* (chancellor), having been created Count Peder Griffenfeld (*q.v.*) in *1673.* As chancellor he reorganized the central administration and tried to conduct a peaceful foreign policy based on alliances. When he failed, the envy of his enemies led to his downfall in *1676.* Thereafter Christian, though neither gifted nor well educated, tried to govern alone. The Scanian War *(1675–79)* impoverished Denmark and Norway without gain. More significant was the appearance of a new code of lam in *1683 (Christian V's Danske Lou).* for which he is mainly remembered. A "will." dedicated to his son and successor Frederick IV, contains his reflections on government and absolute power. He died in a hunting accident on Aug. *25, 1699.*

See K. Fabricius (ed.), *Dannzarks Konger* (1944). (As. F.)

CHRISTIAN VI *(1699–1746),* king of Denmark and Norway, the son of Frederick IV of Denmark and Louise of Mecklenburg-Güstrow, was born on Nov. *30, 1699.* He ascended the throne after his father's death on Oct. *12, 1730.* Tolerably gifted, he became a diligent and conscientious ruler choosing able ministers, but he was insignificant in appearance, shy and reserved. Like his consort, Sophie Magdalene of Brandenburg-Kulmbach (1700–1770), he was imbued with German pietism. Frivolous amusements were banned at court; but the royal couple's love of splendour did find expression in costly buildings, such as Christiansborg castle (built 1733–45). In *1733* he re-established the national militia but acceded to the landowners' demand that peasants liable to conscription should remain on the estates where they were born. His foreign policy was pacific. In *1734* he formed a 15-year alliance with Sweden; from Protestant sympathies he allied himself with England *(1734–42);* and in *1742* a Danish-French treaty was concluded. In *1743* he unsuccessfully urged the election of his son, Crown Prince Frederick, as successor to Frederick I of Sweden. Christian interested himself in commerce, education and the care of the poor, and with sincere devoutness he encouraged a pietistic national church. He died on Aug. *6, 1746.*

See H. Schultz, *Danmarks Historie,* vol. iii, new ed. (1942). (F. SK.)

CHRISTIAN VII (1749–1808), king of Denmark and Norway from *1766,* was born on Jan. *29,* 1749, the son of Frederick V, king of Denmark, and his first consort Louise, daughter of George II of Great Britain. He became king on his father's death on Jan. *14, 1766.* Poorly educated, systematically terrorized by a brutal governor and hopelessly debauched by corrupt pages, he grew up virtually a mental incompetent. After his marriage, in Oct. *1766,* with Caroline Matilda (1751–75), daughter of Frederick, prince of Wales, he abandoned himself to the worst excesses. In *1768* he undertook a European tour, visiting Holland, France, Germany and England. Shortly after his return in Jan. *1769* his mental instability became complete. He became completely subservient to Count Struensee (*q.v.*) who, after the dismissal of J. H. E. Bernstorff in *1770,* controlled all affairs of state. In *1772,* however, Struensee was executed for adultery with the queen. Christian, who had signed the warrant for Struensee's arrest with indifference, remained king only nominally, the government being conducted by his advisers and, from *1784,* by the crown prince Frederick. The divorced queen, retaining her title, went to Celle in Hanover, where she died on May *10, 1775.* Christian died on March *13, 1808.*

BIBLIOGRAPHY.—E. S. F. Reverdil, *Struensee et la cour de Copenhague, 1760–1772* (1838); *P.* Nors, *The Court of Christian VII of Denmark* (1928); *H.* Schultz, *Danmarks Historie,* vol. iii, new ed. (1942). (F. SK.)

CHRISTIAN VIII (1786–1848), king of Denmark from *1839* to *1848* who had also been king-elect of Norway in *1814,* the elder son of Frederick (d. 1805), the youngest son of King Frederick V, was born at Christiansborg castle on Sept. *18,* 1786. His first marriage (June 1806), with his cousin Charlotte Frederica of Mecklenburg-Schwerin, was dissolved in *1810.* In May *1813* Christian became *statholder* in Norway. In Jan. *1814* Frederick VI had been compelled to cede Norway to Sweden by the treaty of Kiel, but Christian, despite opposition from a small pro-Swedish party was elected regent of Norway on Feb. *16. 1814,* by an assembly of notables. This was confirmed by the constituent assembly convened at Eidsvold in April and on May *17,* Christian was elected king of Xorway. On June *30* representatives of Austria. Russia, England and Prussia arrived in Christiania to compel Christian to observe the treaty of Kiel, but he rejected the ultimatum and prepared for armed resistance to the Swedish forces The Swedish crown prince Charles John (Bernadotte) easily defeated the Norwegians and the brief war ended with the treaty of Moss on Aug. *14, 1814.* Christian returned to Denmark and in *1815* married his second wife, Caroline Amelia of Augustenburg Because the government suspected him of democratic views, he nithdrew from public affairs; only in *1831* did he become a member of the council of state. On Dec. 3, *1839,* Christian succeeded Frederick VI as king. He disappointed the Liberals because he opposed constitutional reform; but he reduced the national debt, reformed the prisons and authorized the opening of the restored Icelandic *althing* in *1843.* Yet Christian shunned precipitate social reform.

In Schlesnig-Holstein Christian's vacillating policy was unpopular nith Danes and Germans alike. On July *8, 1846.* he promulgated an open letter whereby the Danish law of succession was declared valid in Schleswig *(see* SCHLESWIG-HOLSTEIN QUESTION)

and Lauenburg. This was a main cause of the Schleswig insurrection of March 1848. Christian died at Plon on Jan. 20. 1848.

BIBLIOGRAPHY.—A. Linvald (ed.), *Kong Christian VIII's Dagbpger og Optegnelser,* vol i, *1799–1814* (1943), *Den unge Prins (1943)* and *Kong Christian VIII Norges Statholder (1952);* Y. Nielsen, *Norge i 1814* (1904). (F. SK.)

CHRISTIAN IX (1818–1906), king of Denmark, was a younger son of William, duke of Schleswig-Holstein-Sonderburg-Beck (duke of Gliicksburg from 1825; d. 1831), and Louise of Hesse-Kassel (d. 1836). granddaughter of Frederick V of Denmark. Born at Gottorp on April 8, 1818, Christian entered the army in 1835 and served against the Schleswig insurgents of 1848. In 1842 he had married Louise of Hesse-Kassel (d. 1898), the cousin of the reigning king, Frederick VII. Frederick VII. however, and his uncle and heir-presumptive Prince Ferdinand (1792–1863) were both childless; and thus the succession to the duchies of Schleswig and Holstein as well as to Denmark was precarious *(see* SCHLESWIG-HOLSTEIN QUESTION). The result was that, despite the possible rights of other claimants, the representatives of the great European powers meeting in London in May 1852 signed a protocol establishing Christian as heir to the kingdom and the duchies. In March 1863 Frederick VII issued a charter (approved the following September) treating Schleswig as an integral part of his kingdom. He died, however, on Nov. 15, and Christian then became king. To ratify the constitution would be a breach of the London protocol, to withhold his consent would provoke bitter opposition in Denmark. By ratifying the constitution on Nov. 18 Christian brought Denmark into conflict with the German confederation. and the war which followed ended with the separation of the duchies from Denmark on Oct. 30, 1864. In Denmark itself a struggle between the parties of the right (supported by the *landsting)* and the Ieft (supported by the *folketing*) occupied much of the reign. For many years Christian successfully excluded the radicals from office, but in 1901 he was forced to assent to the formation of a cabinet of the left. Christian was a simple and upright man, but had no real contact with his people. He died at Copenhagen on Jan. 29, 1906.

His daughter Alexandra married Edward VII of Great Britain and by his many connections he became something of a patriarch among the ruling houses of Europe. His second son, George, had been king of the Hellenes from 1863 and his grandson Charles became king of Norway in 1905 as Haakon VII.

See H. P B Barfod, *Hans Majestet Kong Christian IX,* 2 vol. (1888–*1906);* A. Thorsøe, *Kong Christian den Niende (1906).*

CHRISTIAN X (1870–1947), king of Denmark (1912–47) and of Iceland (1918–44), was born on Sept. 26. 1870, at Charlottenlund near Copenhagen, the eldest son of the future King Frederick VIII and Louise of Sweden-Norway. Entering the army in 1889, Christian became chief of the royal guard in 1898 and a major general in 1908. Crown prince from 1906, he became king on his father's death on May 15, 1912.

In Dec. 1914 Christian attended at Malmo the first of a series of meetings held by the Scandinavian kings during World War I. On June 5, 1915, he signed an amendment to the Danish constitution which altered the electoral laws and extended the franchise to women. On Nov. 30, 1918, he signed the federal act whereby Iceland became an independent kingdom, and "king of Iceland" was incorporated into the royal title. When the act came up for review in 1944, Iceland severed all ties with Denmark and became a republic. In July 1920 Christian received an enthusiastic reception when he visited Slesvig Nord. that part of Schleswig-Holstein ceded to Denmark by the treaty of Versailles.

During World War II Christian, who remained at the head of affairs even after the German occupation of Denmark in 1940, gained much respect by his resistance to Nazi pressure. During these years he was frequently to be seen riding in the streets of Copenhagen; the royal horseman became a national symbol. However in May 1943 he was forced to make a speech against the increasing sabotage of munitions and railways. After a rebellion against the occupation forces in August, Christian was held a virtual prisoner at Sorgenfri castle and later at the palace of Amalienborg in Copenhagen until the German surrender. On May 9, 1945, he opened the free Danish parliament. He died at Amalienborg on April 20, 1947. Christian had married Alexandra of Mecklenburg-Schwerin in 1898, and their eldest son Frederick (b. 1899) succeeded him as Frederick IX.

See J. Byskov, *Christian den X's Denmark,* 2 vol. (1947–48)

CHRISTIAN OF BRUNSWICK (1599–1626), Protestant military commander, the prototype of the ruthless, ambitious and ineffectual younger son of the German dynasties in the period of the Thirty Years' War, was born on Sept. 20, 1599. at Groningen, the residence of the bishops of Halberstadt, his father, Duke Henry Julius (d. 1613). being the Protestant administrator of the bishopric. In 1616 Christian was elected administrator in succession to his father, but his incessant quarrels with the chapter and his unruly disposition, which earned him the nickname of "Mad Christian," made him seek his fortune in military enterprises He fought under Maurice of Orange in the Netherlands against the Spaniards and in 1621 raised an army in aid of Frederick V of the Palatinate. former king of Bohemia. He was defeated by Tilly at Hochst in Hesse on June 20, 1622, and at Stadtlohn in Westphalia on Aug. 6, 1623, but continued guerrilla warfare in Loner Saxony and the lower Rhineland. maintained by English. Dutch and French subsidies after he had renounced his bishopric. He was included in the anti-Habsburg alliance of 1625 under the leadership of Christian IV of Denmark, but died at his brother's capital, Wolfenbuttel, on June 16, 1626, without having achieved any major success in the field.

See H. von Xylander, *Herzog Christian von Braunschweig (1926).* (S. H. S.)

CHRISTIAN, WILLIAM (1608–1663), Manx politician, famous in Manx history as Illiam Dhone ("Brown William"), the patriot martyr of a well-known ballad, was born on April 14, 1608, a son of Ewan Christian. one of the Manx deemsters. In 1648 he was appointed receiver-general by the 7th earl of Derby, lord of the Isle of Man. In 1651 Derby crossed to England to fight for Charles II, leaving Christian to command the island militia. The countess still resided in Man, and after the earl's capture at the battle of Worcester she negotiated ior his release in return for the surrender of the island to the parliamentarians. Thereupon Christian headed a revolt, but he also negotiated with the parliamentarians. Soon the island was in the power of Col. Robert Duckenfield who in Oct. 1651 had brought over a parliamentary fleet. The countess had to surrender her two fortresses, Castle Rushen and Peel castle. Christian was appointed governor of the island in 1656. Two years later, accused of misappropriating money, he fled to England, but in 1660 he was arrested in London for debt and imprisoned for 12 months. On his release, hoping to benefit under the Act of Indemnity of 1661, he returned to Man. In spite of the act, Charles, the new earl of Derby. ordered his seizure. The deemsters were induced to pass sentence upon him, and Christian was shot at Hango hill on Jan. 2, 1663. This arbitrary act angered Charles II; the deemsters were punished, and some reparation was made to Christian's family. Christian is chiefly celebrated through the ballad *Boase Illiam Dhone,* which was translated into English by George Borrow, and through the reference to him in Sir Walter Scott's *Peveril of the Peak.*

CHRISTIAN BROTHERS: *see* CHRISTIAN BROTHERS OF IRELAND; CHRISTIAN SCHOOLS, BROTHERS OF THE.

CHRISTIAN BROTHERS OF IRELAND (in full, BROTHERS OF THE CHRISTIAN SCHOOLS OF IRELAND; FRATRES SCHOLARUM CHRISTIANARUM DE HIBERNIA; F.S.C.H.), a Roman Catholic teaching congregation founded in 1802 in Waterford, Ire., by Edmund Ignatius Rice, a merchant. Rice was inspired to establish his order to serve the needs of poor Catholic boys, the English laws of the period prohibiting the establishment of Catholic schools. Between 1802 and 1820 Rice succeeded in opening a number of primary schools in the Iarger cities of Ireland, and in the latter year the Holy See by apostolic brief constituted his little band of workers into a religious institute; the Christian Brothers were the first Irish order of men formally approved by a charter from Rome.

There are about 3,700 brothers in 14 countries teaching 150,000 boys and young men in academic, commercial and industrial schools and colleges; the brothers also conduct orphanages and institutions for the deaf and blind. The government of the order is vested in a superior-general who is assisted by four brothers constituting a general council. Each province is governed by a brother provincial who is assisted by four brothers forming a provincial council. The brothers were established in the United States in 1906 in New Yorkocity. The home of the congregation is in Dublin. (D. T. R.)

CHRISTIAN CATHOLIC CHURCH, the name assumed by a religious organization founded at Zion City near Chicago, Ill., in 1896, by John Alexander Dowie. See DOWIE, JOHN ALEXANDER.

CHRISTIAN CHURCH, EARLY: *see* EARLY CHRISTIAN CHURCH.

CHRISTIAN DEMOCRATIC PARTIES. The first modern Christian political parties arose out of conflicts over church and state. They appeared in the 19th century among Protestants in the Netherlands and among Catholics in Germany, Belgium. Switzerland and the Netherlands. Their chief aim was to defend the freedom of the church and the rights of Christian parents in the schools against attacks by Liberals, Nationalists and, later! Socialists. Without this direct challenge to religious interests, parties on a specifically Christian basis would probably not have arisen. From about 1880 the accent in European politics shifted toward social reform. Socialist movements provided much of the initial drive, but in most. European countries they adopted doctrines of materialism to which Christians could not subscribe. Where this happened the Christians set up their own social movements — trade unions, farmers', youth and women's movements — which soon reinforced the Christian political parties.

After World War I parties began to base their appeal less exclusively on church issues and more on the common interest of citizens in politics and social welfare. Parties founded in this period, such as the Parti Démocrate Populaire in France (1924; forerunner of the Mouvement Républicain Populaire [M.R.P.] founded in 1944) or the Partito Popolare in Italy (1919; dissolved by the Fascists in 1926; restored in 1944 as Partito Democratico Cristiano), had this new orientation from the start, and the older parties were converted to it. This evolution was completed by the end of World War II. The predominantly Catholic German party. founded in 1870 and known as Zentrum, dissolved itself "voluntarily" in 1933. The Christlich-Demokratische Union, formed in western Germany in 1946, grouped Catholics and Protestants alike.

On their revival after World War II several parties took the opportunity to revise their constitutions to fit the new aims: some also changed their names. At the same time they became more aware of problems such as European unity or aid to less-developed areas, and co-operated more with one another. Their programs, though varying in detail, start from agreed general principles. Christian Democracy is:

(1) Personalist. Policy should "lead to the fullest development of the greatest possible number of personalities" (from the program of the Parti Chretien Social of Belgium), through both individual and collective action: personalism is not individualism.

(2) Pluralist, in two senses. First, policy should respect the existence of different "spiritual families": Catholic, Protestant, Jewish, Muslim, humanist. These can and should enjoy equal political and social rights, being free to develop in their own way so long as they respect the similar rights of others. Secondly, to offer the best chance ior the growth of human personality, the social structure should be federal. The Christian Democrats support the idea of a welfare state, but understood as an educational state, which helps and trains its citizens to provide for their own needs, rather than an executive state which provides for them directly itself. Individuals and small groups are to be given all the responsibility they can take, but must also act as members of larger groups: the family as a member of the local community and, ultimately, the state as a member of an international community. The Christian Democrats support federation or confederation in Europe and Latin America.

(3) Conservative though not traditionalist. The Christian Democrats call for large changes and are not specially attached to the past. But they stress growth and continuity and oppose revolutionary change.

(4) Christian Democrats also support an open society based on competition and political and social democracy, where policy is based on a "common estimate" arrived at after full discussion. But they insist that direction and economic planning are needed to build the framework for such a society.

(5) Though agreeing that economic policy is basic, the Christian Democrats insist that it should not be stressed at the expense of political and especially cultural policy.

Many of the antagonisms that once separated Christian Democrats from Liberals and Socialists have died down. The Christian Democratic parties often co-operate with these groups, and with them resist antidemocratic forces of the right and left.

After World War II Christian Democratic parties held a majority or close to a majority in the parliaments of the German Federal Republic. Italy. the Netherlands, Belgium and Austria. They were influential in the parliaments of France, Switzerland and Luxembourg. In Latin America Christian Democratic parties, though mostly small, grew in strength after 1945. Christian Democratic political movements existed also in Poland, Hungary, Czechoslovakia and the Baltic states until the Communist dictatorship, and in Spain until Gen. Francisco Franco's victory in the civil war, and were carried on by citizens of these countries in exile. The western European parties and the eastern European exile movements were represented in the so-called Nouvelles Equipes Internationales (founded 1947; headquarters Paris). The Latin-American parties set up in 1949 a Christian Democratic Organization of America. An International Union of Young Christian Democrats was founded in 1948. A first world convention of Christian Democratic movements was held in 1956 and a second in 1958, and an Inter-Continental Committee of Christian Democracy was established.

Most Christian Democratic parties used "Christian" in their titles. A few, especially the Catholic People's party in the Netherlands. still used denominational titles. One, the French M.R.P., did not refer to Christianity in either its title or its statutes. Support came mainly from practising Catholics and Protestants. Protestant support was strongest in the Netherlands and the German Federal Republic, while the Christian Democratic party in Norway was almost entirely Protestant. In the Netherlands, Protestants voted for their own two parties, in Germany for the same party as Catholics. Party constitutions were drawn so as to open membership not only to practising Catholics and Protestants but to members of other religions and to humanists or nominal Christians. Support from sources other than practising Catholics and Protestants was small but not negligible.

Support was drawn more evenly than in other parties from different social classes, thanks partly to the religious factor and partly to the wide influence of the Christian Democratic social movements. There was generally no formal link between these movements and the political parties, but there was informal consultation and mutual aid. The parties were all independent of church authorities, but here too there was often informal co-operation. Until after World War I the division of spheres between churches and parties mas not clear. In several countries this gave rise to disputes. Such disputes became rarer after 1945 but they did occur, especially in Italy and the Ketherlands.

See M. P Fogarty, *Christian Democracy in Western Europe, 1820–1953* (1957), with a full bibliography; Mario Einaudi and François Goguel-Nyegaard, *Christian Democracy in Italy and France (1952).*
(M. P. F.)

CHRISTIAN FLAG. There is no one official flag of all Christian churches. By common usage, however, a so-called Christian flag came to be recognized by a number af churches. It consists of a white rectangular field with a blue rectangle in the upper corner at the mast side which contains a red Latin cross. C. C. Overton, a New York Sunday school superintendent. has been credited with designing this flag in 1897. Overton selected white to signify purity; blue, courage; and the red cross, sacrifice. Other designs incorporating the cross have been officially adopted by various churches.

CHRISTIAN INSTRUCTIQN, BROTHERS OF (LA MENNAIS BROTHERS; INSTITUTUM FRATRUM INSTRUCTIONIS CHRISTIANAE; F.I.C.), a Roman Catholic lay congregation of religious founded in Brittany in 1817 by J. M. R. de Lamennais

(brother of H. F. R. de Lamennais) and Gabriel Deshayes. They number about 2,200 members, whose main work is teaching. They operate colleges, high schools and elementary schools in Europe. North and South America, Africa and Asia. The administrative centre cf the community, originally in Ploermel. France, was transferred in 1903 to the Island of Jersey; U.S. headquarters are in Alfred. Me. (Ro.)

CHRISTIANITY, the religion that traces its origins to Jesus of Nazareth, whom it affirms to be the chosen one (Christ) of God.

Christianity is the religion of one-third of the population of the earth. Nearly 1,000,000,000 human beings are identified in some way or other with the Christian movement, half of them in Europe and most of the rest in North and South America. Despite its representation and support in many lands, therefore. Christianity is principally a western phenomenon. Yet the influence of Christianity extends beyond the borders of Christendom. It has affected other religions, as it has been affected by them, and its ethos continues to shape the characters of individuals and nations that no longer live by its creed. Even Communism, its bitterest enemy and most formidable rival in the 20th century, has been called "a Christian heresy," which, even while it rejects the fundamental tenets of the Christian faith, rejects them in a manner and with a passion that owe much to Christian sources.

As one of the chief forces in the history of mankind, Christianity needs to be examined historically, for only thus is it possible to grasp the extent of its influence or become aware of its pervasive power. One section of this article will therefore be a brief survey of the history of Christianity. In the contemporary world, moreover, Christianity continues to form the lives of men and of entire cultures by its precepts. Hence a survey of its history must be followed by an examination of its present state—its major divisions, their relative size, their distinctive features and their peculiar doctrines and practices. That examination mill constitute a second section of this article. Still Christianity is more than a force in human history or a powerful contemporary movement. It claims to be an interpretation of the world and of human life that makes sense of them in the light of divine revelation. Hazardous though such an undertaking must be in a divided Christendom and in a secularized culture, a description of this Christian claim belongs in such an article as this. The third chief part of this article will give an account of Christianity as a way of belief, as a way of worship and as a way of life; thus it will attempt to state the meaning of Christianity as this meaning is shared and debated by its various proponents.

No proponent — whether of a religion or of a political, social or aesthetic system of values — can attain complete objectivity in his portrayal of something in which he believes passionately and with conviction. But the "objectivity" of the outside observer frequently fails to grasp or to explain the power by which a religion is able to elicit loyalty and trust from its adherents. The scholarly interpretation of Christianity, if it is to be both sensitive to that power and reasonably objective in its method, must proceed from within the circle of the Christian movement and still pay serious attention to the criticisms and insights of those "outsiders" whose rejection of Christianity is based not upon trivial objections but upon an understanding of its ultimate claims. Such has been the method at work in the comaosition of this article.

HISTORY OF CHRISTIANITY

Christianity begins with Jesus Christ. The effects of his life, the response to his teachings and the experience of his death and resurrection were the beginnings of the Christian community; for a more detailed account of these beginnings the reader is referred to the article JESUS CHRIST and to the problems discussed there. When the apostle Peter is represented in the New Testament as confessing that Jesus is "the Christ, the Son of the living God," he speaks for the Christianity of all ages. And it is in response to this confession that Jesus is described as announcing the foundation of the Christian church: "You are Peter, and on this rock I will build my church, and the powers of death shall not prevail against it."

EARLY CHRISTIANITY

Jesus was a Jew, as were all the apostles. Thus the earliest Christianity is in fact a movement within Judaism; the very acknowledgment of Jesus as "the Christ" means the confession that he is the fulfillment of the promises originally made to Abraham, Isaac and Jacob. But the Christian gospel encountered opposition within Judaism, just as Jesus had, and soon it turned toward the gentile world. Ideologically, this required Christian thought to define the gospel as both the correction and the fulfillment of Greek and Roman philosophy. This definition was the assignment of the Christian apologists of the first three centuries (*see* APOLOGISTS, EARLY CHRISTIAN). Politically, the Christian expansion into the world of Greco-Roman paganism and its rejection of such religious practices as the worship of Caesar brought upon the early Christians the suspicion of their fellow citizens and even persecution by the Roman authorities. Nevertheless, Christian churches continued to arise in many portions of the Roman empire, attracting Romans of every social class.

The inward growth of the Christian community matched this outward growth in numbers and prestige. Christians celebrated and shared the grace and power given in Christ by participating in the rites he had instituted, especially baptism and the Eucharist. They recited the events of his life, exhorting, teaching and urging one another to prepare for his coming again, which they apparently hoped to see very soon. In this hope they set themselves consciously apart from the way of life that characterized "the world" in its terminal stages. As the company of those who were chosen by God in the last days of the world, the early Christians were bound together by ties of mutual love and concern. "See how they love one another!" is said to have been the reaction of pagans to the evidence of this mutual concern.

Neither the Christian remembrance of the acts of God in Christ nor the Christian practice of mutual love, however, took place in a vacuum. From the very outset the Christian community was a community of structure. Its remembrance and celebration followed a pattern that was indeed fluid in some of its details but was nonetheless fixed in its basic outline. Similarly, the office of the apostles, traced by the primitive church to the ordinance of the risen Christ himself, was the basis for the earliest structures of administrative and pastoral organization. And the collections of the sayings and deeds of Jesus were combined with the writings of the apostles to form a body of Christian sacred writings. From these primitive structures emerged the threefold system of apostolic authority in bishop, creed and biblical canon, with which the early church met the challenge of preserving its continuity despite the death of the apostles and the postponement of the Lord's return.

Even in these early centuries the Christian movement was plagued by heresy and torn by strife. The New Testament itself bears marks of the strife provoked by early exponents of a Christian Gnosticism (*q.v.*), who bent the gospel into conformity with their theories of sin and salvation. But the flowering of the Gnostic heresy within Christianity occurred during the 2nd century, when Basilides and Valentinus (*qq.v.*) arose to claim that true apostolic Christianity had been transmitted secretly to them and their followers rather than to the church, with its bishops and scriptures. Though differing from these Gnostics in significant ways, Marcion (*q.v.*) also purported to be the restorer of apostolic, especially Pauline, 'doctrine 'and practice. Claiming that the church had forsaken the pristine holiness of the apostles and had become too worldly, Montanism (*q.v.*) asserted that the promise of the "counselor" given in the last discourses of Jesus in St. John had been fulfilled in the life and teachings of the prophet Montanus.

The crystallization of bishop, creed and canon as the triple norm of apostolic Christianity was accentuated, if not actually hastened, by the need for a definition of orthodoxy against these heresies and schisms. As it resisted both a syncretism that would have absorbed it into a universal world-religion (Gnosticism) and a particularism that would have restricted it to the select few (Montanism), Christianity asserted that it was catholic, or universal, in its message and appeal. It was, of course, catholic in

principle long before it became catholic in fact. The gospel of a Saviour who had died for the entire world; a message communicated in the Koine or common Greek that had become the universal literary language of the empire; a polity that co-ordinated local responsibility with ecumenical concern, especially through the growing prestige of the bishop in the capital city of the Roman *oikoumene;* a participation in the spirit of Greco-Roman classicism that nevertheless remained open to both the ancient oriental and the new Germanic cultures—these features characterized the Christianity of the first three centuries as "catholic"—*i.e.,* as possessing identity plus universality.

Little is recorded about the Christians of these centuries; both their number and their names remain largely unknown. Those whose names have become part of the historical record are the bishops, heretics and saints—these categories are not mutually exclusive—who attracted more than the usual attention in their own time and thus became the spokesmen to later times for the silent in the land. Thus Tertullian (*q.v.*), who died about 220, has come to epitomize the radical No spoken by the church to the world and its culture, as Clement of Alexandria (q *v.*), who died in almost the same year, and Origen (*q.v.*), who died about 254, are the recurring symbols of the Christian conviction that Christ is "the desire of all nations" and the answer to the quest of the philosophers. In the thought of Irenaeus (*q.v.;* d. c. 200) the Christianity of the 2nd century produced a system that summarized many of its fundamental beliefs about the renewal and redemption accomplished in Christ. From the history of the use of these names it is clear how easily they can all become clichés, but behind the clichés is the struggle of Christianity during the first three centuries of its history to be faithful to the deposit of its faith and relevant to its world, and to be both at the same time. See also EARLY CHRISTIAN CHURCH.

ESTABLISHED CHRISTIANITY

How long that struggle might have continued is a matter of conjecture, for in the first decades of the 4th century Christianity received a boon that altered its history: toleration, recognition and eventually establishment. by the state. The emperor Constantine I the Great, for what appears to have been a mixture of personal and political motives, identified himself with the Christian movement (see CONSTANTINE). Except for a brief revival of paganism under Julian (*q.v.*), who died in 363, a Christianity of some sort. whether orthodox or heretical, was the religion of the Roman emperors thereafter. as it was of the Germanic tribes who eventually displaced the empire. So it was that after Rome had "fallen" Christianity preserved many of the values of Rome and thus provided later centuries with a link to classical culture.

Christian Dogma, Theology, Institutions.— Acceptance of Christianity by the Roman emperors helped to make possible the establishment of a general council as a means for adjudicating controver es in the areas of doctrine and discipline (see COUNCIL). Out of the decisions of the councils in the 4th, 5th and 6th centuries came the classical Christian dogmas of the Trinity and the Person of Christ, which have been the criterion of Christian orthodoxy ever since. (For the history of these dogmas see JESUS CHRIST; TRINITY.) Christianity thus acquired an intellectual formulation that befitted its new status as the dominant religious force in the Mediterranean world. It acquired theological spokesmen also, whose speculations and systematizations. based upon Scripture and dogma, created the vocabulary and set the style for a Christian culture. Most prominent among these theologians in the west was Augustine, whose ***City*** of God summarized the case for Christianity against a moribund paganism, and whose treatise On the ***Trinity*** combined fidelity to authority with philosophical reflection into a new synthesis (see AUGUSTINE, SAINT, of Hippo). The Greek-speaking portions of the church were more richly endowed with theological leaders than was the Christian west. Athanasius (*q.v.*) defended the full deity of Christ against the Arians. Basil, Gregory of Nyssa and Gregory of Naziansus (*qq.v.*), "the Cappadocian Fathers," refined and expanded the teachings of Athanasius into a more complete doctrine of the Trinity. (See also FATHERS OF THE CHURCH.) During the 5th and 6th centuries the theological parties at Antioch and Alexandria, building on the foundation of the doctrine of the Trinity, contributed to the development of the doctrine of the two natures in the person of Christ.

As Christianity in both east and west was coming to terms with the empire, monasticism (*q.v.*) arose as a way to express the continuing separation of the church from the world. The figure of Anthony the hermit, dramatically described by Athanasius. represented the Christianization of an asceticism that had been at work in Egypt even before the coming of the gospel. A second stage in the development of monasticism was the rise of the communal or cenobitic form of the monastic life and the establishment of monasteries and convents, first in the eastern section of the church through the work of Pachomius and then much later (6th century) in the western portion through the work of Benedict of Nursia. Instituted as a means of denying the world, monasticism became, through its role in the missionary enterprise and through its educational work, one of the principal means by which Christianity conquered the world. Another factor in that conquest of classical culture by the mission and expansion of Christianity was the growth in the prestige and power of the bishop of Rome. (For a detailed account of this development see PAPACY.) Pope Leo I the Great (d. 461) made the primacy of the Roman bishop explicit both in theory and in practice and must be counted as one of the most important figures in the history of the centralization of authority in the church (see LEO). The next such figure was Gregory I the Great (*see* GREGORY), pope from 590 to 604, whose work shaped the worship, the thought and the structure of the church as well as its temporal wealth and poner.

Byzantine Christianity.— Still a part of the universal church but increasingly isolated from the west by differences of language, culture, politics and religion, Byzantine Christianity folloned its own course in the shaping of the heritage of the primitive church. The eastern churches never became as centralized in their polity as did the church in the west, but developed the principle of the relative independence or "autocephaly" of each national church. During the centuries when western culture was striving to domesticate the German tribes. Constantinople, probably the most civilized city in Christendom, blended classical and Christian elements with a refinement that expressed itself in philosophy, the arts. statecraft, jurisprudence and scholarship. A thinker such as Michael Psellus in the 11th century, who worked in several of these fields, epitomizes this synthesis. It was from Byzantine rather than from Roman missionaries that most of the Slavic tribes received Christianity; Byzantium was also the victim of Muslim aggressions throughout the period known in the west as the middle ages. Following the pattern established by the emperors Constantine and Justinian, the relation between church and state in the Byzantine empire co-ordinated the two in such a way as often to subject the life and even the teaching of the church to the decisions of the temporal ruler—the phenomenon often termed "Caesaropapism."

All these differences between the eastern and the western parts of the church, both the religious differences and those that were largely cultural or political, came together to cause the schism between the tno. It is not easy to date this schism, for the alienation between west and east erupted several times: in the 9th century through conflict over the mission to the Slavs; in the 11th century as a contest over rank and authority; in the 13th century with great vehemence in the Christian sack of Constantinople and the establishment of the Latin patriarchate there; in the 15th century after the failure of the union of Florence and after the fall of Constantinople to the Turks (see also BYZANTINE EMPIRE). Whatever the date, the two divisions of the church have been separated, both in spirit and in fact, for about half of Christian history, more than twice as long as Protestantism and Roman Catholicism.

Papacy and Empire.— Conflict with the east was both a cause and an effect of the distinctive development of western Christianity during the middle ages. If Popes Leo I and Gregory I may be styled the architects of the medieval papacy. Popes Gregory VII (d. 1085) and Innocent III (d. 1216) should be called its master builders. Gregory VII reformed both the church and the papacy

from within, establishing the canonical and moral authority of the papal office when it was threatened by corruption and attack; Innocent III made the papal claims to universality an ecclesiastical and political fact, exercising his authority at all levels of the life of the church in the 13th century. Significantly, both these popes were obliged to defend the papacy against the Holy Roman empire and other temporal rulers. The battle between the church and the empire is a persistent theme in the history of medieval Christianity. Both the involvement of the church in feudalism and the participation of temporal rulers in the crusades can be read as variations on this theme. Preoccupied as they often are with the history of the church as an institution and with the life and thought of the leaders of the church, the documentary sources of knowledge about medieval Christianity make it difficult for the historian to descry "the religion of the common man" during this period. Both the "age of faith" depicted by Neo-Gothic romanticism and the "dark ages" depicted by secularist and Protestant polemics are a gross oversimplification of history. Faith there was during the middle ages, and intellectual darkness and superstition too; but only that historical judgment of medieval Christianity is valid that discerns how subtly faith and superstition can be blended in the piety and thought of medieval (and of modern) men.

Medieval Thought. — No product of medieval Christianity has been more influential in the centuries since the middle ages than medieval thought, particularly the philosophy and theology of scholasticism (*q.v.*), whose outstanding exponent was Thomas Aquinas (d. 1274). The theology of scholasticism was an effort to harmonize the doctrinal traditions inherited from the Fathers of the early church and to relate these traditions to the intellectual achievements of classical antiquity. Because many of the early Fathers both in the east and in the west had developed their theologies under the influence of Platonic modes of thought, the reinterpretation of these theologies by scholasticism required that the doctrinal content of the tradition be disengaged from the metaphysical assumptions of Platonism. For this purpose the recovery of Aristotle — first through the influence of Aristotelian philosophers and theologians among the Muslims, eventually, with some help from Byzantium, through translation and study of the authentic texts of Aristotle himself — seemed providential to the scholastic theologians. Because it managed to combine a fidelity to Scripture and tradition with a positive, though critical, attitude toward the "natural" mind, scholasticism is a landmark both in the history of Christianity and in the history of western culture. Very few theological systems have managed to play this dual role, which can be a symbol (depending upon one's own position) either of the Christianization of society and culture or of the betrayal of Christianity to the society and culture of the middle ages. (See also AVERROISM, LATIN.)

Reformation. — The latter interpretation of scholasticism and of the medieval church itself animated the Protestant Reformation (see REFORMATION). Protestantism differed from the various protest movements during the later middle ages by the thoroughness of its polemic against the ecclesiastical, theological and sacramental developments of western Catholicism. Initially the Protestant Reformers maintained the hope that they could accomplish the reformation of the doctrine and life of the church from within, but this proved impossible (again depending upon one's position) either because of the intransigency of the church or because of the extremism of the Protestant movements or because of the political and cultural situation. The several parties of the Reformation may be conveniently classified according to the radicalism of their protest against medieval theology, piety and polity. The Anglican Reformers, as well as Martin Luther (*q.v.*) and his movement, were, in general, the most conservative in their treatment of the Catholic tradition; John Calvin and his followers were less conservative; the Anabaptists and other groups in the left wing of the Reformation were least conservative of all (see CALVINISM; REFORMED CHURCHES; ANABAPTISTS). Despite their deep differences, the various Reformation movements were almost all characterized by an emphasis upon the Bible, as distingished from the church or its tradition, as the authority in religion; by an insistence upon the sovereignty of free grace in the forgiveness of sins; by a stress upon faith alone, without works, as the precondition of acceptance with God; and by the demand that the laity assume a more significant place in both the work and the worship of the church.

The Reformation was launched as a movement within the established Christianity that had prevailed since Constantine. It envisaged neither schism within the church nor the dissolution of the Christian culture that had developed for more than a millennium. But when the Reformation was over, both the church and the culture had been radically transformed. In part this transformation was the consequence of the Reformation, in part it was the accompaniment of the Reformation. The voyages of discovery, the beginnings of a capitalistic economy, the rise of modern nationalism. the dawn of the scientific age, the culture of the Renaissance — all these factors, and others besides. helped to break up the "medieval synthesis." Among these factors, however, the Reformation was one of the most important, and certainly for the history of Christianity the most significant. For the consequences of the Reformation, not in intention but in fact, were a divided Christendom and a secularized west. Roman Catholicism, no less than Protestantism, has developed historically in the modern world as an effort to adapt historic forms to the implications of these consequences. Established Christianity, as it had been known in the west since the 4th century, ended after the Reformation, though not all at once.

MODERN CHRISTIANITY

Paradoxically, the end of "established Christianity" in the old sense resulted in the most rapid and most widespread expansion in the history of the church. The Christianization of the Americas and the evangelization of Asia, Africa and Australasia have given geographical substance to the Christian title "ecumenical." Growth in areas and in numbers, however, need not be equivalent to growth in influence. Despite its continuing strength throughout the modern period, Christianity has retreated on many fronts and has lost much of its prestige and authority.

During the formative period of modern western history, roughly from the beginning of the 16th to the middle of the 18th century, Christianity participated in many of the movements of cultural and political expansion. The explorers of the new world were followed closely by missionaries — that is, when the two were not in fact identical. Protestant and Roman Catholic clergymen were prominent in politics, letters and science. Although the rationalism of the Enlightenment (*q.v.*) alienated many people from the Christian faith, especially among the intellectuals of the 17th and 18th centuries, those who were alienated often kept a loyalty to the figure of Jesus or to the teachings of the Bible even when they broke with traditional forms of Christian doctrine and life. Citing the theological conflicts of the Reformation and the political conflicts that followed upon these as evidence of the dangers of religious intolerance, representatives of the Enlightenment gradually introduced disestablishment, toleration and religious liberty into most western countries; in this movement they were joined by various Christian individuals and groups that advocated religious freedom not out of indifference to dogmatic truth but out of a concern for the free decision of personal faith.

The state of Christian faith and life within the churches during the 17th and 18th centuries both reflected and resisted the spirit of the time. Even though the Protestant Reformation had absorbed some of the reformatory energy within Roman Catholicism, the theology and morals of the church underwent serious revision in the Catholic Counter-Reformation (see ROMAN CATHOLIC CHURCH: History: Reform and Definition). Fighting off the attempts by various countries to establish national Catholic churches, the papacy sought to learn from the history of the Reformation and to avoid the mistakes that had been made then. Protestantism discovered that separation from Rome did not necessarily inoculate it against many of the trends it had denounced in Roman Catholicism. The confessional orthodoxy of the 17th century both in Lutheranism and in the Reformed Churches displayed many features of medieval scholasticism, despite the attacks of the Reformers upon the latter. Partly as a compensation for the over-

emphasis of orthodoxy upon doctrine at the expense of morals, Pietism (*q.v.*) summoned Protestant believers to greater seriousness of faith and purpose. Valid though its summons was. Pietism unwittingly played into the hands of its enemies. helping to make it possible for the rationalism of the Enlightenment to undermine traditional Christian belief.

In alliance with the spirit of the Enlightenment, the revolutions of the 18th. 19th and 20th century aided this process of undermining. Roman Catholicism in France. Eastern Orthodoxy in Russia and Protestantism in former European colonies in Africa were identified — by their enemies if not also by themselves—as part of the *ancien régime* and were nearly swept away with it. As the discoveries of science proceeded, they clashed with old and cherished notions about the universe and about man, many of which were passionately supported by various leaders of organized Christianity The age of the revolutions — political, economic. technological, intellectual—was an age of crisis for Christianity. It was also an age of opportunity. The critical methods of modern scholarship, despite their frequent attacks upon traditional Christian ideas, helped to produce editions of the chief documents of the Christian faith. the Bible and the writings of the Fathers and Reformers, and to arouse an unprecedented interest in the history of the church. The 19th century has been called the great century in the history of Christian missions, both Roman Catholic and Protestant (*see* MISSIONS). By the very force of their attacks upon Christianity the critics of the church helped to arouse within the church nen apologists for the faith. who creatively reinterpreted it in relation to the new philosophy and science of the modern period. The 20th centurv saw additional challenges to the Christian cause in the form of Communism and of resurgent world religions. Both the relation of church and state and the missionary program of the churches thus demanded reconsideration. But the 20th century also saw renewed efforts to heal the schisms within Christendom. The ecumenical movement began within Protestantism and Anglicanism, eventually included some of the Orthodox Eastern churches. and began to engage the sympathetic attention of Roman Catholicism as well (*see* ECUMENICAL MOVEMENT).

From the history of Christianity both the critics and the adherents of the Christian movement could derive support for their ideas. To the critics of Christianity its history could prove that Christian faith was tied inseparably to world views that had been outmoded by modern discoveries and that therefore the churches were living fossils. doomed to become extinct as the full implications of science dawned upon an increasing number of believers. To the adherents of Christianity its history could prove the almost infinite adaptability of the Christian faith to a great diversity of societies, cultures and philosophies, as well as its ability to convey the grace of God to men of every social station and cultural background. Pet Christianity is not simply an important element of the history of western culture. It continues to claim the faith and the obedience of hundreds of millions. Therefore even so cursory a survey of Christianity as this article must deal also with the present state of the Christian movement.

PRESENT STATE OF CHRISTENDOM

A map of the religions of the world at the middle of the 20th century would have revealed that Christianity was the most widely disseminated faith on earth. Virtually no nation has remained unaffected by Christian missions, although in many countries Christians are only a small fraction of the total population. Most of the countries of Asia and of Africa have Christian minorities, some of these, as in India, numbering several million. Yet such a map would show the concentration of Christians in the domain of European or "western" culture. It would also give visual representation to the divisions within Christendom. Each major denomination is treated in a separate article in this encyclopaedia, where its history, tenets and practices receive a fuller exposition than this article can give them and where a bibliography on the denomination is supplied. The purpose here is to provide an overview of the principal divisions and thus to set the articles about the individual traditions into their proper context.

ROMAN CATHOLICISM

The Roman Catholics in the norld probably outnumber all other Christians combined. They are organized in an intricate system that spans the life of the church from the local parish to the papacy. Under the central authority of the papacy, the church is divided into dioceses. whose bishops act in the name and by the authority of the pope but retain considerable administrative freedom within their individual jurisdictions. Similarly, the parish priest stands as the executor of papal and diocesan directives. Alongside the diocesan organization and interacting with it is a chain of orders, congregations and societies; all of them are of course, subject to the pope. but they are not as directly responsible to the bishop as are the local parishes. It would. however, be a mistake to interpret the polity of the Roman Catholic Church in so purely an organizational a manner as this. For Roman Catholic polity rests upon a mandate that is traced to the action of Jesus Christ himself, when he invested Peter, and through Peter his successors, with the power of the keys in the church Christ is the invisible head of his church, and by his authority the pope is the visible head.

This interpretation of the origin and authority of the church determines both the attitude of Roman Catholicism to the rest of Christendom and its relation to the social order. Believing itself to be the true church of Jesus Christ on earth, it cannot deal with other Christian traditions as equals without betraying its very identity This does not mean, however, that anyone outside the visible fellowship of the Roman Catholic Church cannot be saved; nor does it preclude the presence of "vestiges of the church" in the other Christian bodies. During the 20th century the Roman Catholic Church has increasingly concerned itself with its "separated brethren ' both in Eastern Orthodoxy and in the several Protestant churches. Thus the ecumenical movement has evoked interest not only in the Protestant groups with which it began but in Orthodoxy and Roman Catholicism as well. As the true church of Christ on earth. Roman Catholicism also believes itself responsible for the proclamation of the will of God to organized society and to the state This role has brought the church into conflict with the state throughout church history. Yet the political activities of individual churchmen, of whom Richelieu and Mazarin are good illustrations, must not be confused uith the fundamental obligation of the church. as the divinely ordained society to which the revelation of God has been entrusted. to address the meaning of that revelation and of the moral law to the nations and to work for a social and political order in which both revelation and the moral law can function.

Both in democratic and in totalitarian societies during the 20th century, the relation of the Roman Catholic Church to the state continued to engage the attention of political leaders and of prelates and theologians.

Doctrine. — The understanding that Roman Catholicism has of itself, its interpretation of the proper relation between the church and the state and its attitude to other Christian traditions are all based upon Roman Catholic doctrine. In great measure this doctrine is identical with that confessed by orthodox Christians of every label, and consists of the Bible, the dogmatic heritage of the ancient church as laid down in the historic creeds (*see* CREED) and in the decrees of the ecumenical councils, and the theological work of the great doctors of the faith in east and west. If, therefore, the presentation of the other Christian traditions in this article compares them with Roman Catholicism, this comparison has a descriptive rather than a normative function; for to a considerable degree, Protestantism and Eastern Orthodoxy have defined themselves in relation to Roman Catholicism. In addition, as the final section of this article will attempt to show, most Christians past and present do have a shared body of beliefs about God, Christ and the way of salvation.

Roman Catholic doctrine is more than this shared body of beliefs, as is the doctrine of each of the Christian groups. It is necessary here to mention only the three distinctive doctrines that have achieved definitive formulation during the 19th and 20th centuries: the infallibility of the pope, the immaculate conception and bodily assumption of the Virgin Mary (*see* INFALLIBILITY; IM-

MACULATE CONCEPTION; ASSUMPTION, FEAST OF THE). On most other major issues of Christian doctrine, Roman Catholicism and Eastern Orthodoxy are largely in agreement, while Protestantism differs from both Eastern Orthodoxy and Roman Catholicism on several of these. For example, Roman Catholic theology defines and numbers the sacraments differently from Orthodox theology; but over against Protestantism, Roman Catholic doctrine insists upon the centrality of the seven sacraments — baptism, confirmation, penance. Eucharist, extreme unction (*qq.v.*), matrimony and holy orders — as channels of divine grace.

Liturgy. — The Roman Catholic doctrine of the sacraments is a summary, in liturgical form, of that which is affirmed by Roman Catholic liturgy. The church is not merely an organization, nor is it a school of doctrine. It is the place where God and man meet, as God approaches man through grace and man approaches God through worship. Hence the focus of Roman Catholic piety is the Eucharist, which is both a sacrament and a sacrifice. Other forms of corporate worship and of private devotion radiate from this point of central focus. The obligations of church membership are also derived from the sacramental system. either as preparations for worthy participation in it or as expressions of the obedience sustained by it. Instruction in these obligations and in the implication of the faith for the moral and intellectual life is the responsibility of Roman Catholic educational institutions all over the world, which, despite the low educational level of the church in many cultures. surpass any other system of schools in Christian history both in size and in the academic excellence of their finest products. The missions of the church and its institutions of mercy, like the schools, are largely in the hands of religious orders; orders of men are listed in the article ORDERS AND CONGREGATIONS, RELIGIOUS, and the major orders of men and women are described in individual articles; orders of nuns and sisters are discussed generally in WOMEN'S RELIGIOUS ORDERS. *See* also ROMAN CATHOLIC CHURCH.

CHURCHES OF EASTERN CHRISTENDOM

Roughly 150.000.000 Christians belong to the various Christian traditions of the east. Separated from the west, the Orthodox churches of the east have developed their own way for half of Christian history. Each national church is autonomous. The "ecumenical patriarch" of Constantinople is not the eastern pope but merely the first in honour among equals in jurisdiction. Eastern Orthodoxy interprets the primacy of Peter, and therefore that of the pope, similarly, denying the right of the pope to speak and act for the entire church by himself, without a church council and without his episcopal colleagues. Because of this polity Eastern Orthodoxy has identified itself more intimately with national cultures and with national regimes than has Roman Catholicism. Therefore the history of church-state relations in the east has been very different from the western development, because the church in the east has sometimes tended toward the extreme of becoming a mere instrument of national policy while the church in the west has sometimes tended toward the extreme of attempting to dominate the state. The history of ecumenical relations between Eastern Orthodoxy and Protestantism during the 20th century was also different from the history of Protestant-Roman Catholic relations. While keeping alive their prayer for an eventual healing of the east-west schism, the Orthodox churches have established communion with Anglicanism and with the Old Catholic Church and have participated in the conferences and organizations of the World Council of Churches (*q.v.*).

Doctrinal authority for Eastern Orthodoxy resides in the Scriptures, the ancient creeds, the decrees of the first seven ecumenical councils and the tradition of the church. The scope and content of this tradition are not specified; hence it is not always easy to discover just what the Eastern Orthodox churches teach on a particular doctrinal question. In addition to the two issues mentioned in the discussion of Roman Catholicism above, the chief dogmatic difference between Roman Catholic and Eastern Orthodox thought is on the question of the procession of the Holy Spirit (*q.v.*) from the Father and Son, the so-called *filioque*.

But "orthodoxy," in the eastern use of the term, means primarily not a species of doctrine but a species of worship. The Feast of Orthodoxy on the first Sunday of Lent celebrates the end of the iconoclastic controversies (see ICONOCLASTS) and the restoration to the churches of the icons, which are basic to Orthodox piety. In Orthodox churches (as well as in those eastern churches that have re-established communion with Rome), the most obvious points of divergence from normal western practice are: the use of the vernacular, though an archaic form of the vernacular, in the liturgy; the right of the clergy to marry before ordination, though bishops may not be married; and the administration to the laity of both species in the Eucharist at the same time by the method of intinction. The rediscovery of Eastern Orthodox liturgy and piety by western Christians, both Roman Catholic and Protestant, is an interesting by-product of the ecumenical contacts of the 19th and 20th centuries. *See* also ORTHODOX EASTERN CHURCH.

PROTESTANTISM

Although there is a greater variety of thought and expression within both Roman Catholicism and Eastern Orthodoxy than outsiders usually recognize, both must appear monolithic when compared with Protestantism. Formulating a definition of Protestantism that would include all its varieties has long been the despair of Protestant historians and theologians, for there is greater diversity within Protestantism than there is between some forms of Protestantism and some non-Protestant Christianity. For example, an Anglican or a Lutheran high-churchman has more in common with an Orthodox theologian than he has with a Baptist theologian. Amid all this diversity, however, it is possible to define Protestantism formally as non-Roman western Christianity and to divide most of Protestantism into four major confessions or confessional families — Lutheran, Anglican, Reformed and Free Church.

Lutheranism. — The largest of these non-Roman Catholic denominations in the west is the Lutheran Church, whose membership totals approximately 70,000,000. The Lutheran churches in Germany, in the several Scandinavian countries and in the Americas are distinct from one another in polity, but almost all of them are related through various national and international councils, of which the Lutheran World federation is the most comprehensive. Doctrinally, Lutheranism sets forth its distinctive position in the Book of Concord, especially in the Augsburg Confession (*qq.v.*). A long tradition of theological scholarship has been responsible for the development of this position into many and varied doctrinal systems. Luther, as noted above, moved conservatively in his reformation of the Roman Catholic liturgy, and the Lutheran Church, although it has altered many of his liturgical forms, has remained a liturgically traditional church. Most of the Lutheran churches of the world have participated in the ecumenical movement and are members of the World Council of Churches, but Lutheranism has not moved very often across its denominational boundaries to establish full communion with other bodies. The prominence of Lutheran societies in the history of missions during the 18th and 19th centuries gave an international character to the Lutheran Church; so did the development of strong Lutheran churches in North America, where the traditionally German and Scandinavian membership of the church was gradually replaced by a more cosmopolitan constitutency. (See LUTHERANS.)

Anglicanism. — The Anglican communion. with perhaps 40,000,000 members, is not only the established church of England but the Christian denomination of many believers throughout the world. Like Lutheranism, Anglicanism has striven to retain whatever it could of the Catholic tradition of liturgy and piety, but after the middle of the 19th century the Catholic revival in Anglicanism went much further to restore ancient liturgical usage. Although the Catholic revival also rehabilitated the authority of tradition in Anglican theology, great variety continued to characterize the theologians of the Anglican communion (*see*, for example, MODERNISM). Anglicanism is set off from most other non-Roman churches in the west by its retention of and its insistence upon the apostolic succession of ordaining bishops. The Anglican claim to this apostolic succession, despite its repudiation by Pope Leo XIII in 1896, has largely determined the role of the Church

of England in the discussions among the churches. Anglicanism has often taken the lead in inaugurating such discussions, but it has demanded the presence of the historic episcopate as a prerequisite to the establishment of full communion. During the 19th and 20th centuries many leaders of Anglican thought were engaged in finding new avenues of communication with industrial society and with the modern intellectual. The strength of Anglicanism in the new world and in the younger churches of Asia and Africa has confronted this communion with the problem of deciding its relation to new forms of Christian life in these new cultures. As its centuries-old reliance upon the establishment in England has been compelled to retrench, Anglicanism has discovered new ways of exerting its influence and of expressing its message. (See ANGLICAN COMMUNION and the articles referred to there.)

Presbyterian and Reformed Churches. — Protestant bodies that owe their origins to the reformatory work of John Calvin and his associates in various parts of Europe are often termed "Reformed." particularly in Germany, France and Switzerland. In Britain and in the United States they have usually taken their name from their distinctive polity and have been called Presbyterian. They also number about 40,000,000. They are distinguished from both Lutheranism and Anglicanism by the thoroughness of their separation from Roman Catholic patterns of liturgy, piety and even doctrine. Reformed theology has tended to emphasize the sole authority of the Bible nith more rigour than has characterized the practice of Anglican or Lutheran thought, and it has looked with deeper suspicion upon the symbolic and sacramental traditions of the Catholic centuries. Perhaps because of its stress upon biblical authority, Reformed Protestantism has sometimes tended to produce a separation of churches along the lines of divergent doctrine or polity, by contrast with the inclusive or latitudinarian churchmanship of the more traditionalistic Protestant communions. This understanding of the authority of the Bible has also led Reformed Protestantism to its characteristic interpretation of the relation between church and state, sometimes labeled theocratic, according to which those charged with the proclamation of the revealed will of God in the Scriptures (*i.e.*, the ministers) are to address this will also to civil magistrates. As the church is "reformed according to the word of God." so the lives of the individuals in the church are to conform to the word of God; hence the Reformed tradition has assigned great prominence to the cultivation of moral uprightness among its members. During the 20th century most of the Reformed churches of the world took an active part in the ecumenical movement. (See PRESBYTERIAN; REFORMED CHURCHES.)

Free Churches. — In the 19th century the term "free churches" was applied in Great Britain to those Protestant bodies that did not conform to the establishment. such as Congregationalists, Methodists and Baptists (and Presbyterians in England); but since that time it has come into usage among the counterparts to these churches in the United States, where each of them has grown larger than its British parent body. As the Reformed denominations go beyond both Anglicanism and Lutheranism in their independence of Catholic traditions and usages, so the free churches have tended to reject some of the Catholic remnants also in classical Presbyterian worship and theology. Baptists (*q.v.*) and Congregationalists see the local congregation of gathered believers as the most nearly adequate visible representation of Christ's people on earth. (See CONGREGATIONALISM.) The Baptist requirement of free personal decision as a prerequisite of membership in the congregation leads to the restriction of baptism to believers (*i.e*, those who have made and confessed such a decision of faith) and therefore to the repudiation of infant baptism; this in turn leads to the restriction of communion at the Eucharist to those who have been properly baptized. In Methodism (*q.v.*) the free church emphasis upon personal commitment leads to a deep concern for moral perfection in the individual and for moral purity in the community. The Disciples of Christ (*q.v.*), a free church that originated in the United States, make the New Testament the sole authority of doctrine and practice in the church, requiring no creedal subscription at all; a distinctive feature of their worship is their weekly celebration of Communion. Emphasizing as they do the need for the continuing reformation of the church, the free churches have, in most cases entered into the activities of interchurch co-operation and have provided leadership and support for the ecumenical movement. This co-operation, as well as the course of their own historical development from spontaneous movements to ecclesiastical institutions possessing many of the features that the founders of the free churches had originally found objectionable in the establishment, has made the question of their future role in Christendom a central concern of free churches on both sides of the Atlantic.

Other Churches and Movements. — In addition to these major divisions of Protestantism, there are other churches and movements not so readily classifiable; some of them are quite small, but others number millions of members. These churches and movements would include, for example, the Society of Friends (*q.v*), known both for their cultivation of the "inward light" and for their pacifism: the Unitarian and Universalist bodies, which do not consistently identify themselves as Christian (see UNITARIANISM; UNIVERSALIST CHURCH); Christian Science (*q.v.*), Baha'i (*see* BAHA'I FAITH), Unity and other theosophic movements, which blend elements from the Christian tradition with practices and teachings from other religions; Pentecostal churches and churches of divine healing, which profess to return to primitive Christianity; and many independent churches and groups, most of them characterized by a free liturgy and a fundamentalist theology (see FUNDAMENTALISM). Separately and together, these groups illustrate how persistent has been the tendency of Christianity since its beginnings to proliferate parties, sects, heresies and movements. They illustrate also how elusive is the precise demarcation of Christendom, even for those observers whose definition of normative Christianity is quite exact.

MEANING OF CHRISTIANITY

Christian history and the variety of Christian churches and sects have given some observers the impression that Christians really have nothing in common except the name. That impression is only confirmed when well-meaning reductionists define the essence of Christianity in formulas such as "the fatherhood of God and the brotherhood of man," which mean as little or as much as one may want to make of them. A related formula, but one whose history has rendered it much more precise and more inclusive, is taken from I Cor. xiii, 13: "So faith, hope, love [charity] abide, these three." These three have traditionally formed the basis for Christian catechisms and may be used here to provide the framework for a brief statement of the meaning of Christianity as a way of belief, as a way of worship and as a way of life.

A Way of Belief. — Christian faith is both a conviction about God and a trust in the ways of God. It rests upon divine revelation as a disclosure of these ways in the history of Israel and of the church, but especially in Jesus Christ. With Judaism Christianity confesses that God is one and that he is the Creator of all. God is present and active in his creation but is neither identical with it nor captive within it. As the crown of God's creation, man has been endowed with a special mark of God's presence and activity. "the image of God," which reflects the mind of the Maker. Yet man's life does not in fact conform to the will of his Creator, but is bent away from God to the service of lesser goods. This conflict between man as he is in essence (the creature of God and therefore good) and man as he is in existence (the son of fallen Adam and therefore sinful) cannot be resolved by the moral or intellectual striving of man alone. He has been alienated from the ground of his own being, has violated the law and righteousness of God, and is subject to the power of death (see SIK). TO become again what he was intended to be, man needs the grace of God, which can break the power of death and give man a new birth. In the incarnation of his Son, Jesus Christ, God has granted men this grace.

Christ. the eternal Son of God, was equal with God the Father—at least since the Council of Nicaea this statement has been part of the first classic confession of Christian orthodoxy, that God is one in his "essence" and three in his "persons," Father, Son and Holy Spirit (see TRINITY). But the eternal Son of God, who was truly God, became just as truly man by being born of the Virgin

Mary—this is the second classic confession of Christian orthodoxy. The life of Jesus Christ on earth was human life as God had intended human life to be. But more, it was part of the plan by which God wanted to restore his grace to men and to break the power of death. Therefore the teachings of Jesus described the coming of the reign of God and summoned men to cast off their old ways and to heed the will of God; and the deeds of mercy in the public ministry of Jesus were signs of God's saving care for those who turned to him in acknowledgment of their need and in expectation of his rescue. The specific means of rescue and thus the climax in the earthly life of Christ the Saviour was the cross. His death on the cross satisfied the law and righteousness of God, took away the power of death, and opened to man the possibility of living by the grace of God in the Kingdom of God. And his resurrection from death marked the end of the power of sin and death, the beginning of a newness of life.

The content of Christian faith has been defined in different ways by different theologians; but this conviction that the life, death and resurrection of Jesus Christ are the means by which God has brought about the salvation of the world would be identified by most Christians in most centuries as the absolutely irreducible minimum of Christian belief.

The communication of this salvation and its eventual consummation are the subjects of the Christian confession about the person and work of the Holy Spirit (*q.v.*). The Third in the divine Trinity, the Holy Spirit proceeds eternally from God—whether from both the Father and the Son or only from the Father was a point at issue between the eastern and the western parts of the church. To the Holy Spirit is assigned the inspiration of the men who revealed the will of God from the beginning, for "he spake by the prophets." The continuing life of the church is similarly said to be a special activity of the Holy Spirit, which preserves its unity, creates its holiness, assures its catholicity and guarantees its bond with apostolic Christianity. Sustaining this life in the church and communicating the grace of God to the believer are the means of grace, the sacraments (variously defined and numbered) and the word of the gospel (variously identified). Imperfect though it continues to be, the life of grace is the way toward the perfection that is the content of the life eternal. The consummation of the plan of divine salvation is to come with the end of human history, the appearance of Jesus Christ as the judge of all mankind and the resurrection of the dead. This consummation is both an article of Christian belief and an object of Christian hope.

Every sentence of this summary of Christian belief would probably call forth a challenge from one or another theology; so would its many omissions. Yet following as it does the outline of the most nearly universal Christian confession, the Nicene Creed, it seeks to meet the threefold standard of orthodoxy and catholicity formulated by Vincent of Lérins in the 5th century: "that which has been believed everywhere, always, and by everyone."

A Way of Worship.—The knowledge of God and the service of God are the twin themes of Christianity. The service of God consists of both hope and charity (*q.v.*). In many Christian writers, therefore, the exposition of the meaning of hope has been based upon the Lord's Prayer. The prayer that the name of God, as the Father in heaven, may be hallowed embraces all Christian worship and all the Christian hope. By its corporate worship the church confesses the unholiness of men in the presence of divine holiness, and prays: "Lord, have mercy upon us." In the *Sanctus* of the Mass or in the Protestant hymn "Holy, Holy, Holy," Christian worship is directed not toward man and his achievements, nor even toward man and his need, but toward the glory of the "name" of God; *i.e.,* toward God as he has revealed himself in Christ. Private prayer and devotion may frequently rise from a deep and personal sense of need, but Christianity as a way of worship shifts this focus from man to God and considers man's need in the light of God's grace. Hope is therefore the content of Christian worship, for hope is directed toward the future as God's future and is the anticipation of deeds of God yet to come.

The biblical term for those deeds yet to come is "the Kingdom of God." Christian worship celebrates the reign of God over the world as founded in the creation and as re-established in the coming of Christ, and it looks for the further disclosure of the reign of God in the events of history and in the consummation of history. The accents of past, present and future all appear in the hope and worship of the church. Recognizing the contrast between the world as it is in essence (where the will of God is always obeyed) and the world as it is in existence (where the will of God is often defied), the church prays that "on earth," in the world of men and nations, the will of God may be carried out as perfectly as it is "in heaven," in the world of angels and perfected saints. Only when it has thus prayed for the sanctification of the name of God. the coming of the reign of God and the accomplishment of the will of Gqd, does the petition of the church go on to request the necessities of daily life.

This does not mean, as heretics from within Christianity and opponents from outside it have charged, that Christianity looks upon the body and its needs as unimportant or even sinful; for God is the Creator of the body, who redeemed it together with the soul and who promises to raise it from the dead. But it does mean that God is God, without whose grace man cannot live though he have all he needs of daily bread. Penitence for sin, request for deliverance and adoration of God for his glory recur as the motifs of Christian worship. Each motif is both a petition toward God and an imperative toward man. Therefore the prayer for forgiveness is made contingent upon the readiness to forgive others; the request for deliverance from evil does not sound without the reminder of the reality of temptation; the adoration of the glory of God, together with the opening petition that the name of God be hallowed, encloses every human plea for aid within a doxology that acknowledges the sovereignty of God over all. When Christianity assumes the postures of expectation and worship, it voices this hope, whose ultimate source and final object is the Father, Son and Holy Spirit confessed and described by Christian faith—not only a Deity and a Creator, but a Father and a Saviour who is also a Brother as well as a Master, eternal Love as well as eternal Truth.

A Way of Life.—As a way of life, Christianity is defined as a life of charity or love, love toward God and love toward men. Here the priority of man's relation to God. which is fundamental to the Christian way of belief and to the Christian way of worship, asserts itself once more. The commandment, "You shall love the Lord your God with all your heart, and with all your soul, and with all your mind" is the first and greatest commandment. Upon it is based the second: "You shall love your neighbor as yourself." For where the commandment of love toward God is properly understood, there the commandment to love other men, as well as all other commandments, will proceed from it as corollaries.

The commandment of love toward God has been the subject of extensive theological discussion (see CHARITY). For if love is a desire to possess the object—as, for example, sexual love, *eros,* is—is it not idolatrous to "love" God in the sense of wishing to subject him to one's own will and desire and to use him as a means toward a lesser end? But if, as some theologians argue, love as *agape* is to be defined exclusively as the recognition of another's need and the desire to answer that need, it may be equally idolatrous for man to suppose that God stands in need of his creatures and of their love. The Augustinian way out of this dilemma is the one followed by many Christian interpreters of the meaning of love. The love of God for man is the recognition of man's need, the vision of man's potentiality and the desire to answer the need and to make the potential a reality through the gift of Christ. But the love of man for God necessarily partakes of the nature of love as a desire to be united with its object, for the soul of man yearns for union with God "as a hart longs for flowing streams." Yet it is necessary to classify all of man's loves on the basis of their objects. A soul is healthy if it loves each of these objects according to the particular nature of the object, desiring things as things (and no more), persons as persons (and no less) and God as God (and both things and persons in God). So the soul ascends through desire and yearning to a love for God that elevates him above all temporal objects.

The avoidance of idols, reverence for the "name" of God, and

the observance of the sabbath as a day of worship and rest are practical expressions of man's love for God. The practical expressions of one's love for the neighbour vary according to one's own situation and according to the neighbour's need, but the Decalogue enumerates the principal relationships in which man's love for his fellow men articulates itself. Chronologically and logically first among these relationships are the home and the family. where love takes the form of mutual respect between parents and children. Yet the respect for human life itself is perhaps even more elemental; the commandment "You shall not kill" puts the authority of God around the body and life of another and makes violence against another human being a sin against God.

A violation of the bond of marriage is also interpreted as a desecration of the relation between man and God, not merely as a breach of human morality. Love for another human being implies a due regard for his earthly possessions and for his reputation.

In precise ethical terms most of these requirements of the Ten Commandments are comprehended not so much in love as in justice, for they are a may of rendering to each his due. The charity spoken of in Christian ethics is never less than justice, which is the indispensable condition for wholesome relations in human society. But love transcends justice, goes the second mile and has regard for the total person. Justice without love may become legalistic, love without justice may become sentimental. Hence the Christian ethic of charity takes justice seriously, not only as the least that God demands but often as the most that man can achieve under the conditions of human existence. Justice is an instrument of love and sometimes its most satisfactory expression. Yet the Christian gospel declares that God has gone beyond justice to love, granting grace and forgiveness in Christ not because men have deserved it but out of his mercy. Man's responding love for God and for fellow man also goes beyond justice. Thus it opens one to the possibility of a service to others that does not demand its due, but "bears all things, believes all things, hopes all things, endures all things." Faith, hope and charity: faith is the acknowledgment of God's love for man in Christ; hope is the expectation of further love from God; charity is love in action. Because it comprehends the other two in this may and because it is said to abide even when both faith and hope have attained their goals, "the greatest of these is charity." In it is also the meaning of Christianity.

BIBLIOGRAPHY.—Throughout this encyclopaedia there are hundreds of articles on the institutions, eras, personalities, issues and ideas of Christianity. Most of the articles contain specific bibliographies. In the present article only a few very general works can be cited, from which the reader can proceed to a study of detailed topics. *The Oxford Dictionary of the Christian Church,* ed. by F. L. Cross (1957), is the most useful one-volume work of reference on Christianity and things Christian. Both *The Catholic Encyclopedia (1907 et seq.)* and *Die Religion in Geschichte und Gegenwart (3rd* ed.; *1957 et seq.)* are multivolume encyclopaedias, in which the reader may obtain information about many issues in Christianity, as well as extensive bibliographies.

One-volume collections of Christian sources include: H. S. Bettenson, *Documents of the Christian Church (1943)* and Colman J. Barry, *Readings in Church History (1960 et seq.).* Multivolume collections available to the English and American reader are: *The Ante-Nicene Fathers; The Nicene and Post-Nicene Fathers; Ancient Christian Writers; The Fathers of the Church;* and *The Library of Christian Classics.* In addition, the works of many major figures in Christian history have appeared in various editions and translations, many of which are listed in the bibliographies of biographical articles.

General histories of Christianity include: Philip Hughes, *A History of the Church (1934 et seq.);* Williston Walker, *A History of the Christian Church,* rev. ed. *(1959);* Kenneth Scott Latourette, *A History of the Expansion of Christianity (1937* ff.). Histories of special eras or topics are: Hans Lietzmann, *Geschichte der Alten Kirche,* Eng. trans. *(1937 et seq.);* Philip Carrington, *The Early Christian Church (1957);* J. N. D. Kelly, *Early Christian Doctrines (1958);* Etienne Gilson, *History of Christian Philosophy in the Middle Ages (1955);* T. M. Lindsay, *History of the Reformation (1907);* James Hastings Nichols, *History of Christianity 1650–1950 (1956).* The present state of Christendom is discussed in: Einar Molland, *Christendonz,* Eng. trans. *(1959);* F. E. Mayer, *The Religious Bodies of America (1955); Christianity Divided,* ed. Daniel J. Callahan *et al. (1961);* *A History of the Ecumenical Movement 1517–1948,* ed. Ruth Rouse and Stephen Neill *(1954);* B. J. Kidd, *The Churches of Eastern Christendonz (1927).*

(J. J. PN.)

CHRISTIAN SCHOOLS, BROTHERS OF THE (INSTITUTUM FRATRUM SCHOLARUM CHRISTIANARUM; F.S.C.), often simply CHRISTIAN BROTHERS, the first religious congregation of male nonclerics in the Roman Catholic Church to devote itself exclusively to schools and solely to learning and teaching. Members, numbering more than *17,000,* are found on all continents. The congregation was formally founded at Reims by St. Jean Baptiste de La Salle (*q.v.*) in *1684* for the education of boys, especially of poor families. Benedict XIII raised the congregation to the status of a papal institute in *1725.* Historically the brothers have engaged in popular education through varied types of schools depending upon the requirements of localities and times. Besides teaching in elementary, secondary and teacher-training schools, the brothers administer and staff welfare or corrective schools, and in the United States they also conduct seven colleges. The superior general and administrative officers reside at the motherhouse in Rome. (For the Brothers of the Christian Schools of Ireland, *see* CHRISTIAN BROTHERS OF IRELAND)

See Brother A. Gabriel, *The Christian Brothers in the United States 1848–1948 (1948);* Georges Rigault, *Histoire générale de l'Institut des Frères des écoles chrdtiennes, 9* vol. (1936–53).

(AU. P.)

CHRISTIAN SCIENCE, founded by Mary Baker Eddy (*q.v.*) in the latter half of the 19th century, is simultaneously, as the term is popularly used, a religious faith; an institution, organization or church; a movement; a philosophy; and a way of life. Mrs. Eddy herself seems to have thought of it as representing a recovery of certain lost emphases of primitive Christianity, notably, but not solely, the emphasis on healing. She considered that she had rediscovered Jesus' healing method, and healing has continued as the central emphasis in Christian Science. Repeated testimonies by persons that they have been healed. given in the midweek testimony meetings and in various publications and broadcast by radio and television, are the principal means of attracting new members into the movement. Once healed, many, but by no means all, become members of the organized Church of Christ, Scientist.

Christian Science is more than a healing faith, however. It has a theology as definite as that of any of the Christian churches but differing markedly from orthodox or even liberal Christian theology. While Christian Science uses the theological vocabulary of traditional Christianity, the meaning it assigns to many familiar terms—such as God, Christ, heaven, salvation, Trinity, etc.—is quite different from that ordinarily given them in the orthodox churches. *(See* "Glossary" in *Science and Health,* pp. 579–599.) The fundamental theological teachings are best to be seen in the "Christian Science Platform" (pp. *330–340)* and in the chapter "Recapitulation" (pp. 465–497), which are designated as the basis of Christian Science class instruction, the most important means of perpetuating the basic teachings of the movement.

God is Principle, impersonal or, perhaps better, suprapersonal by definition, though there is a continuous alternation of emphasis on the personal and impersonal nature of God in Mrs Eddy's own writings. In *Science and Health,* p. 465:9–10, she wrote, "God is incorporeal, divine, supreme, infinite Mind, Spirit, Soul, Principle, Life, Truth, Love." Christ is not synonymous with Jesus, though Jesus manifested the Christ in fullest measure. There is no place in Christian Science for a vicarious atonement as taught in traditional orthodoxy, yet it is through Christ Jesus, chiefly as Way-Shower, that salvation is to be won. There is no magic or forensic deliverance from sin. "The way to escape the misery of sin is to cease sinning. There is no other way" *(Science and Health,* p. 327:12–13). The ethical teachings of Jesus are accepted by Christian Science as in the general Christian tradition.

The Bible is basic to Christian Science, and Christian Scientists are encouraged to read and study it as much as or more than most other Christians are, but always in the light of Mrs. Eddy's later revelation. found chiefly in *Science and Health With Key to the Scriptures,* supplemented by her other published writings, including the *Church Manual.* In general, the method of interpretation is that employed by most so-called metaphysical groups, highly subjective and allegorical rather than literal or dependent

on painstaking linguistic and critical study. *(See* "Key to the Scriptures," in *Science and Health,* pp. 501–578.)

Christian Science is part of a widespread movement with roots going back into the general intellectual movements in New England, notably Transcendentalism (*q.v.*), but influenced also in its beginnings by the teachings of Emanuel Swedenborg and by the 19th-century interest in spiritualism and mesmerism (hypnosis). Just how much Mrs. Eddy was influenced in the formulation of her healing doctrine by Phineas Parkhurst Quimby (*q.v.*), considered the father of the New Thought movement. whom she originally credited with healing her in 1862. is a moot question. Mrs. Eddy herself fixed on the year 1866 as the date of discovery of the Christ Science that she named Christian Science *(Science and Health,* p. 107). Though New Thought and Christian Science differed substantially in their final formulation, the points they have in common — metaphysical interest and general point of view, essential conceptions of God and of man, emphasis on healing and ultimately also on general well-being and prosperity (though differing greatly in the method by which these may be attained) — mark them as phases of a single movement.

Christian Science, first an idea, then a teaching and practice, expressed itself eventually in an institution. The First Church of Christ, Scientist, of Boston, which came to be known as The Mother Church, of which other Christian Science churches throughout the world are branches. It was organized and given its constitution and by-laws by Mrs. Eddy personally (these now embodied in the *Church Manual*) several years after the publication in 1875 of *Science and Health.* But she was to revise both of these many times before they reached their present form. recognized by Christian Scientists as the divinely revealed basis of the faith and organized institutional life of Christian Science.

After difficult years of opposition and struggle, the movement spread rapidly until it had become world-wide, with branches in most of the principal countries of the world. No statistics of membership are given, but it is estimated that there are about 300.000 members. more than 3,000 societies or churches and over 9,000 practitioners.

The church is a centralized institution, under the direction of a self-perpetuating board of directors of five persons, originally four, named by Mrs. Eddy, and eventually constituted as her successors, operating according to the *Church Manual.* Under the board's direction are carried on a multitude of activities: the church's work of healing through accredited practitioners; publication and distribution of literature, including the writings of Mrs. Eddy, and periodicals such as the *Christian Science Journal,* the *Sentinel* and the influential daily *Christian Science Monitor;* lectures; promotional activities; religious'education and maintenance of the purity of the church's teachings through supervision of class instruction, primary and normal, through which all those aspiring to leadership in the church ordinarily are expected to pass. The branch churches have their own boards of directors and their own constitutions and by-laws, but these must be consonant with the provisions of the *Church Manual* of The Mother Church. As a church, the Church of Christ, Scientist, has its own form of worship, uniform the world over, the chief feature being the reading by officially elected readers of passages from the Bible chosen by church authorities, followed by the reading of correlative passages from *Science and Health.* There is no sermon beyond this in any Christian Science church.

As a movement, Christian Science spreads far beyond the organized church. Some former members now withdrawn from the church, and others who have never joined it but have been attracted to the study of Christian Science, faithfully study the textbook, revere Mrs. Eddy and even, in some cases, serve as practitioners, though without official listing in the *Christian Science Journal.* Some outside the church teach classes and write books and articles on Christian Science, though without the approval of the church authorities. While there have been occasional rebellions against constituted authority, no dissident group has attained much strength or permanence. Many of the nonchurch members are concerned to present Christian Science as a true science, as effective and invariable as any other science in its results, and not as a revelation that falls within the control of an ecclesiastical institution.

As a philosophy, Christian Science is a pure idealism. theoretically monistic in its outlook but often enough practically dualistic, as indeed is much of Judaism and Christianity. It is in their denial of the reality of the phenomenal or material world, and of the reality of evil, that Christian Scientists differ from some of the other metaphysical groups and from most of western Christianity.
