stituent assembly, of which he was a member. It was in this capacity that in Aug. 1918 he took office as head of the provisional White administration in northern Russia, at Archangel. His socialist tendencies earned him the distrust of the military. upon whose support his regime rested, and of the British and French representatives, who urged the paramount importance of prosecuting the war; meanwhile, material hardships were causing growing popular dissatisfaction. Unable to maintain the precarious balance between rival pressures, Chaikovski left for Paris (Jan. 1919), where he represented his government at the peace talks, and then for Ekaterinodar (Krasnodar), where, despite opposition from his fellow socialists, he accepted office under Gen. A. I. Denikin. He died in England, at Marrow, on April 30, 1926.

CHAIN, ERNST BORIS (1906–), biochemist of Russian origin, was awarded the Nobel prize for physiology and medicine in 1945, jointly with Sir Alexander Fleming and H. W. (later Sir Howard) Florey, for his prominent part in researches on penicillin. His contributions to biochemical science include studies on the mode of action of snake venoms, spreading factor and insulin; and researches on antibiotics and various submerged mold fermentations. Born in Berlin on June 19, 1906, he studied chemistry and physiology at the Friedrich-Wilhelm university there and after researches in the chemical department of the Institute of Pathology at the Charité hospital, Berlin, during 1930–33, he went to England where at first he worked under Sir Frederick Gowland Hopkins in the school of biochemistry at Cambridge. In 1935 he became university demonstrator and lecturer in chemical pathology at Oxford university and in 1948 was appointed scientific director of the International Research Centre for Chemical Microbiology, at the Istituto Superiore di Sanità, Rome. As well as being a Nobel prize winner, he was made a commander of the Legion of Honour and in 1954 received the Paul Ehrlich centenary prize. He was elected a fellow of the Royal society in 1949.

(R. A. P.; X.)

CHAIN, a series of links, usually of metal, joined together to form a flexible connector. The chain may be formed by interlocking welded or knotted loops or cast links, or by pinning together formed links. In general, chains may be considered in two classes: (1) those used for binding, hoisting, holding, supporting or retaining; and (2) those used in transmitting power or conveying materials.

Thousands of miles of chain are in daily use throughout the world—from tiny fancy jewelry chain to massive anchor chains for ocean liners. from miniature drive chains in delicate control mechanisms to huge "silent" chains weighing more than 50 lb. per foot and transmitting thousands of horsepower.

General Chain Types.—Crane *Chain.*—Without any restrictive term, chain usually refers to the first class, *i.e.*, coil chain (fig. 1[A]). For applications where failure might be dangerous to life or property chains known as crane chains, made from a high-grade wrought iron, are used. This type is intended for slings, cranes. power shovels and marine uses: as in anchor chain. The wrought iron has high ductility, weldability and rust resistance, properties desirable for high-grade chain. The ductility allows the links to deform, making it possible to detect an overload before complete failure of the chain. In operation such a chain may gradually stretch without failure, but a work-hardening effect occurs. When the stretch reaches a certain percentage of the total length. the chain either must be annealed to restore its ductility and usefulness or must be replaced.

For practically all uses. handmade chain of the smaller sizes—made of materials $\frac{3}{8}$ in. or less in diameter—has been replaced by machine-made chain; ior this type, the links are formed, interlocked and welded automatically.

FIG. 2.—TYPES OF CHAINS: (A) EWART LINK WITH BUSHING. (B) BLOCK CHAINS. (C) ROLLER CHAINS. (D) SILENT CHAIN

Proof-Coil Chain.—For general construction, railroad and forestry work, proof-coil chain is employed. The links are formed from steel, generally of the open-hearth type, with a low phosphorus and sulfur content.

Anchor Chain.—Also known as cable or stud-link chain this is made from links having a bar or stud across the inside width of each link. This bar keeps the chain from fouling or kinking, adds weight to the link and prevents the link from deforming under a relatively light load. It does not increase the breaking strength of the chain. (See CABLE.)

Weldless Chain.—This type includes a wide range of styles such as knotted chain, stamped link chain, bead chain and jewelry chain. Knotted chain is usually made on automatic machines which cut, thread and tie the wire to form the completed strands. Made only in the small sizes, it has replaced welded chain to a large extent due to its lower cost. Bead chain finds use in electric fixtures, key chains and other small articles, as well as in light-load drive units where motion in any direction may be desired; it consists of hollow balls connected by solid bars, the bars having upset or balled ends. Stamped link chain, such as sash chain, is a low-cost, moderate strength chain made automatically from links stamped and formed from metal strip.

Testing **of** Chain.—Proof-coil and crane chains are generally given a proof test by the manufacturer. Large purchasers of chain have established specifications giving definite loads under which

the chains must be tested before acceptance. The American Society for Testing Materials has established proof test, break test and safe working loads for chain made from bar stock of $\frac{1}{4}$ in. to 2 in. in diameter.

Care of Chain.—Chain can be damaged easily by improper use. For industrial use chain should be wound on sheaves or winding drums grooved to receive the links smoothly without twisting. The sheaves should be large enough to prevent bending in the links, and kinks or knots should be straightened out. Twisting and dragging over metallic objects, as well as any action which nicks the links, damages the chain. Even in normal use a peening or hammering action occurs between the links, tending to make them brittle. Annealing at intervals under careiully controlled conditions may be necessary to reduce this brittleness and work-hardening. Good practice also includes lubrication of chain passing over sheaves or drums.

Transmission Chain.— For the transmission of power or for conveying purposes where the shafts are separated at distances greater than that for which gears are practical, chain drives are widely used. Here sprockets take the place of the gears but, being widely separated, drive one another through the chain passing over the sprocket teeth. These drives are positive in that there is no slip, yet are adaptable to greatly varying centre distances and, to a limited extent, will absorb shocks from a rapidly changing load. Chain drives have been in use about 2,000 years, but most progress in design and manuiacture has been made since 1900. Leonardo da Vinci designed chain drives used in Europe in Shakespeare's time. The invention of the safety bicycle, the horseless carriage and iarm machinery and the introduction of assembly lines in factories provided an impetus for the development of the high-quality drive chain now manufactured. From the early crude chains to the highly improved, precision-made products of the mid-20th century efficiencies have steadily improved until figures of 98% to 99% are commonly achieved under good operating conditions.

Although many varieties are in service, the types most generally used for power transmission fall into one of four groups: Ewart, block, roller and silent (fig. 2).

Ewart Chain.— Principally used for conveying and elevating equipment, Ewart chain is also employed to transmit light loads at speeds under 400 ft. per minute. The open-link type uses a one-piece cast link. unmachined, which can be assembled or disassembled at will. Use of a pin to iorm a closed-link, or pintle, chain improves the life and periormance.

Block *Chain.*—On 101%-speed,light-load drives the block chain is an improvement over the Ewart type. Maximum speeds may run up to 900 ft. per minute. This chain consists of solid or laminated blocks connected by side plates and pins, the sprocket teeth engaging the blocks and the pitch being the centre-to-centre distance between alternate pins.

Roller Chain.— More accurate timing and higher speeds require the use of roller chain or silent chain. Roller chain is basically a development of the block chain wherein the block is replaced by two side plates, a pair of bushings and rollers. This type of chain is adaptable to widely varying needs, from small-strand drives ior microfilm projectors to large multiple-strand chain for heavy-duty service in oil field equipment.

In order to run at speeds up to 4,000 ft. per minute it is necessary for all parts of the chain to be made with extreme accuracy. The bushings, pins and rollers are ground to close tolerances and the chain is run over balanced cast-iron or steel sprockets having careiully machined teeth. The use of high-quality steels creates chains with ultimate tensile strengths ranging to more than 100,000 lb. for the 3-in. pitch chain. Where increased power requirements must be met without increasing the pitch, a wide chain using multiple strands can be employed. Because the shorter pitch permits a greater number of teeth ior a given sprocket diameter and a reduction in drive weight, quieter and smoother operation is attained.

The sprocket is a wheel with teeth shaped to mesh with the chain (fig. 3). Accurately made sprockets are as essential to good operation and long life as good chain. Four types, depending on the hub arrangement, are in general use, with webbed or ,solid disks available. Sprockets with more than 17 teeth are normally required for best operation, while the nominal maximum is around 125. A small amount of wear in the chain will cause improper tooth action when using excessive numbers of teeth. It is also universal practice to use sprockets with uneven numbers of teeth and chain with an even number of links where possible in order to distribute the wear uniformly. Another feature contributing to difficulty in operation is the chordal action which is especially disturbing in large-pitch, small-sprocket installations. This occurs because the links behave as chords of circles upon entering and leaving the sprocket rather than bending smoothly around the circular surface. Idler sprockets and flat guides may be used to control chain whip.

Silent *Chain.*—The term silent chain is used to describe a type oi chain which, while not exactly silent, is much quieter in operation than other transmission chains. Also known as inverted tooth chain, it consists of a series of inverted tooth links or laminations which mesh into place and seat between the sprocket teeth. In contrast to roller chain the tooth engagement is a gradual sliding action. The links are joined by bushed round pins or combinations of seat and rocker pins. These constructions have been developed to minimize the wear which occurs in the joints. Most silent chain is designed so that straight-sided jaws of the links mate with straight-sided teeth of the sprockets; however, curved (involute) profiles on the teeth engaging straight-sided links also are employed. Such profile changes reduce the chordal action and make possible increased operating speeds. The most economical speeds for silent-chain operation are from 1,200 to 1,500 ft. per minute, but enclosed, well-lubricated drives may be operated up to 5,000 ft. per minute. At speeds below 1,200 ft. per minute it is normally more economical to use standard roller chain.

One feature of silent chain is its variable width. The laminated construction of the links permits the chain to be built up to any desired width to transmit the required power. Thus, installations up to 2,000 h.p. are readily designed on the basis of the manufacturer's ratings of permissible Ioad per inch width of chain.

Roller-chain drive components have been highly standardized; however, silent chain and sprockets have involved greater differences of construction and each manufacturer has carried out his

CHAINAT, the name of both a province (changwat) and its capital in the western part of central Thailand. The area of the province is 1.018 sq.mi. and its population in 1960 was 241,025. Chainat, along with other provinces on the Bangkok delta plain, is noted for the production of rice. corn, oil seeds and hogs. Agriculture is limited because much of the surface is covered with loams that do not hold water as well as does the Bangkok dark heavy clay. The town of Chainat is on the left bank of the Chao Phraya river, 155 mi. north of Bangkok. It had a population of 24,213 in 1947. In 1957 a concrete dam was built across the river a few miles downstream from the town. (T. F. B.)

CHAIN STORE. The chain store is a type of retail operation that links together a central unit with warehouse units and retail stores (selling units). The central unit contains the administrative offices. Physical handling of inbound shipments and outbound orders to stores, along with some buying, are functions of the warehouse units. The actual selling and related operations are performed in the separate retail units.

The retail units may be highly uniform as to physical size, arrangement and inventories, or they may combine several diverse forms. They may consist of department store units or they may be a series of stores selling only food or drugs. But all have one basic principle in common: enough units to permit the physical separation of central office from warehouse and from retail selling units. In sales volume, chains may vary from a few million dollars per year to the multibillion-dollar giants such as Sears, Roebuck and company and the Great Atlantic & Pacific Tea company.

Chain stores may be classified as corporate or co-operative. The term co-operative chains refers to those arrangements whereby either wholesale middlemen or independent retailers or combinations thereof act as the sponsors. This article deals mainly with the corporate chain.

The corporate chain store as a type of retailing institution has been called one of the revolutionary developments in marketing. However, the chain actually evolved from other marketing developments. But even if it is not truly a revolutionary development it is at least one of the most significant in the whole marketing field. Together with the department store and the mail-order company, the corporate chain store represents the first successful application of large-scale integrated methods to a form of retailing.

UNITED STATES

Operating Characteristics.— The success of the corporate chain form of marketing operation is due to the following factors: (1) low selling prices; (2) reduced operating costs; (3) improved retailing practices; (4) extensive use of advertising; (5) distribution of risks; and (6) experimentation with new marketing methods.

The chain's greatest advantage resides in reduced selling prices for comparable quantities and qualities of merchandise. (This does not mean, of course, that corporate chains have lower prices than other retailers for everything they sell.) These lower selling prices may result from lower operating costs, better buying based on financial strength, the ability to use specialists and better knowledge of consumers' demands. By emphasizing larger volume per store, chains usually have worked on lower operating profit margins than other retailers.

The corporate chain placed emphasis on reduced operating costs in relation to sales in fields of retailing where high costs were common. Its achievement of lowered costs resulted from larger sales volume and from other factors. The corporate chain successfully persuaded customers to trade in stores offering fewer free services. It also emphasized fast turnover of goods and utilized division of labour advantageously. The corporate chain made excellent use of integration by owning or leasing motor trucks and by setting up wholly owned subsidiaries either to buy or to manufacture goods. By operating many unit stores, chains made use of widespread advertisements at low costs. Of special significance was the flexibility of the corporate chain in being able to transfer goods, operating methods and personnel among stores at different geographical locations.

Some of the corporate chain's most significant innovations were in the area of improved retailing practices. From its inception, one of these was the clean, modern-appearing, well-planned store utilizing excellent layout and arrangement, bright colours inside and out, modern interior illumination and good physical equipment. The average investment per store of the National Tea company (a food chain) in 1920 amounted to $5,000, compared with more than $100,000 by the mid-1950s, indicating the continued emphasis on store improvement. The corporate chain developed techniques for selecting and training both clerical and managerial personnel. Successful operation involved also careful study, analysis and experimentation in selection of store locations. The corporate chains used government grades in selling goods and greatly expanded the varieties of merchandise carried.

The corporate chain, with its large total sales volume. large volume per store and wide geographical coverage. is in a position to use advertising extensively and effectively. These advertisements are then related to promotion and display within the store. The chains use advanced research methods in evaluating the effectiveness of such advertisements.

The corporate chain may secure good distribution of market risks by diversifying locations and by market research. In addition, the chain often can reduce insurance burdens by combining unlike risks.

One of the most important contributions of the chain is the knowledge gained through experimentation with new marketing methods. Experiments can be carried on in pilot stores and the problems can be reduced or eliminated with little or no effect on the chain's overall operation. Then the new experiment can be extended, if successful, to the entire corporate chain.

Influence on Economy.— In its effect on direct competition the corporate chain started some significant marketing trends. The success of the corporate chain stimulated independent retailers and wholesalers to evolve a similar form of organization— the voluntary co-operative chain— which permitted the independent retailer in effect to apply the principle of the corporate chain to his own needs while maintaining his independent identity. Independent retailers who did not join voluntary chains responded directly to trends introduced by the corporate chain.' Thus, independents modernized store appearance and layout to match or exceed corporate chain standards. In addition, many independents adopted similar price policies. The success of the corporate chain was such a shock to its competitors that it caused a revitalization of the competitors' management operations and marketing outlook. This revitalization was one of the most progressive aspects of retailing history in the second quarter of the 20th century.

Corporate chains affected wholesalers in the following ways: (1) by causing them to form wholesaler-sponsored voluntary chains; (2) by causing them to use other forms of integration, such as private branding; and (3) by forcing them to eliminate or change services in order to build up sales volume and to reduce costs.

Several effects were felt by producers and manufacturers. Farmers were faced with buyers who could and often did dominate particular markets. But, on the other hand, the chains helped farmers by stimulating sales, especially of surplus crops. By use of their own private brands they affected manufacturers. Their ability to enter into production exerted significant influence over their competitors regardless of whether they used it to secure benefits of integration, to exert undue pressure on suppliers or to serve as a threat to induce price concessions. The corporate chains' influence extended also to various service industries—transportation, storage, finance, etc. Through direct ownership of facilities or direct pressure of its accumulated demand for services, the corporate chain upset existing relationships and caused new relationships to be formed.

Finally, the corporate chain gave the consumer better stores in

terms of appearance, modernization, etc. It gave the consumer an opportunity to choose stores providing fewer free services with lower selling prices. The competition so created improved the quality of the entire retailing structure. On the other hand, corporate chains sometimes used their weight to exact unethical advantages while their competitors, in attempts to curb the chains, frequently supported uneconomic legislation which, in turn, worked against the best interests of the consumer. The net total social costs have yet to be measured.

Important Trends.—The corporate chain has played a large part in furthering the following developments:

Use of Chain-Controlled Brands.—These may be carried under direct identification or under subsidiaries' names. Under either form, competition has been stimulated, chains' reputations have been enhanced and consumers' range of choice has been widened.

Support of Government Grades and Grade Labeling.—As used and publicized, these have been useful in giving consumers more objective information on which to base price comparisons. In addition, they have made possible much more effective packaging and thus more effective use of self-service principles.

Experiments in Widening *of* Merchandise *Lines.*—The corporate chain, together with other retailing units, has been among the leaders in experimenting in the sale of products not usually associated with their basic line of business. **A** greater variety of goods adds to profit margins, attracts customers, increases average sales per customer and creates competition among types of stores not normally competitive.

Experiments *in Physical* Arrangements.—As the size of store and average sale per customer increased, the corporate chain has had to experiment continually with new physical arrangements. Examples are special shelving, store directories, check-out stands, mechanized movements of goods within stores and windowless stores.

Innovations in Unit and Method of *Sale.*—It is claimed that corporate chains have been leaders in changing sale of fresh fruits and vegetables from a unit to a pound basis. The influence of self-service on prepackaging of many items has also been considerable. These changes affect sales, change consumption habits and create a demand for new packaging materials and methods. See also MARKETING. (D. A. R.)

GREAT BRITAIN

There are two main types of chain store in Great Britain, the multiple shop and the variety chain store, both of which developed in the second half of the 19th century. By 1900 there were important multiple tea dealers, grocers and provision merchants, chemists, news agents and tobacconists.

Examples of the variety chain stores were the Penny Bazaars which flourished at the end of the 19th century; Marks and Spencer, first opened in 1887; and Woolworth, which spread from the U.S. to England in 1910.

In 1950, according to the first census of distribution, retail firms (other than co-operative societies) with ten or more establishments (branches) handled retail sales to the value of £1,156,000,000; that is, 23% of a total of £5,923,000,000 handled by all retail shops. More than 80% of the trade of the multiples was handled by firms with 25 or more branches. Though no further census had been taken, other official statistics suggest that the chain stores had gained ground relatively to other retailers by the 1960s.

Most multiple organizations developed from small retailing beginnings. In a few trades (*e.g.*, in footwear) some manufacturers set up their own chains of retail shops. In others some multiples extended their operations by going into manufacturing. The "tied house" system of the brewing industry is a form of retailing which has some but not all of the characteristics of multiple store control and management.

The growth of multiple trading in the 20th century became an important competitive force in retailing, affecting small independent shopkeepers, department stores and co-operative societies. In Great Britain, unlike some other European countries and the United States, no government measures have been introduced to control the growth or to handicap the operation of multiple firms. (B. S. Y.)

CHAIR AND **SOFA.** Most of the sitting postures of human beings require no accessories, but cushions or more rigid supports may be used. A support that lifts the sitter above ground or floor level is called a stool, chair, bench or sofa. A stool, meant for one person only, is a horizontal surface lifted up by legs, solid sides or a central stem. Legs, the commonest support for the horizontal surface, are used in threes or more often fours, occasionally more. Back legs may be prolonged upward and cross braced to support the sitter's spine, shoulders or even head; a seat so made is called a chair, or, if support is provided also for elbows and forearms, an armchair. **A** chair widened to seat two or more people side by side is a bench (or settle) if hard-surfaced, and a sofa (settee, couch) if upholstered.

The Chinese, in touch with the west, made beautiful chairs from Han times onward, but in general oriental and primitive cultures favoured sitting without such adjuncts, though cushions and back or armrests were sometimes used. In the far east was developed the cross-legged sitting posture familiar to the west from statues of the Buddha. In the ancient near east men reclined with legs more or less stretched out, and for this utilized day beds or couches.

The occident, sometimes influenced by eastern usages, developed a rich variety of seating furniture over a period of 5.000 years.

Elements **of** Seating Design.—The characteristic design of seating furniture was concentrated, to begin with, usually in the supporting framework rather than in the surface that was covered when the seat was used. Seat legs often were modeled on animal legs, and details of animal anatomy were used on backs and arms as well; paws and claws often were carved on furniture feet. **A** symbolic custom of ancient rulers, sitting on slaves or conquered enemies, was echoed occasionally in seat design. Architectural forms often were reproduced, sometimes to create harmony between a room and its furnishings. Twentieth-century taste tends to prefer another approach that has recurred throughout the history of furniture: parts and joints accented to express the principal forces of support and elasticity.

Ancient Egypt.—Furniture is clearly depicted in Egyptian bas-reliefs and wall paintings, many of which have survived, as has some actual furniture and miniature furniture originally deposited in tombs. The earliest seats represented, shown in use by gods, kings or prominent persons, were animal-legged stools or simple rectangular constructions with flat cushions and low backs; special honour was indicated by a high canopy or, more often, by a footrest. Such chairs were sometimes lifted on platforms borne by subordinates. Higher backs and armrests appear next, and litters (portable couches) for noble ladies. Later, open structure prevailed, the seat was curved for comfort and a sloping back was added, allowing more relaxed posture and stiffening the chair. Egyptian furniture was lightly but strongly built of wood with pegged joints, sometimes bound with leather thongs. The usual rectangular four-legged seat frames often were stiffened by crossbars and small struts; central stems were used only for tables and headrests. Egyptian officials traveled a great deal, and folding furniture, including X-framed stools and chairs, was familiar. Seats accommodated only one person; couches were used only rarely at gatherings, benches apparently not at all. Seats sometimes were richly inlaid and overlaid with precious materials. The principal forms were either abstract or derived from the animal world; details derived from architecture hardly occurred. Egyptian skill and elegance were seldom matched in later chairs.

Ancient Mesopotamia.—Ancient near-eastern empires left bas-reliefs that show stools, chairs, armchairs and couches more massive than the Egyptian and enriched, though less subtly, by inlays and bronze fittings, some of which have survived. The reliefs show the ruler reclining on a thickly cushioned couch, a small table at hand, quaffing wine; his queen attended, seated in a high armchair with footstool. Related Hittite reliefs show a chair with a back that sloped backward beyond vertical rear legs. The set of couch, table, chair and footstool, like the recumbent posture while drinking, remained features of western life for

thousands of years, disappearing only in the early middle ages. Mesopotamian furniture design echoed the ornaments of architecture; animal forms were mere details.

Ancient Greece.—Ancient Greek arts and artifacts show seats and seating arrangements that reflect the influence of older cultures. Men often reclined while eating or drinking; respectable women sat in chairs. The refinement of Egyptian form was equaled and surpassed in the best Greek chairs and couches. Some new elements in seating perhaps were due to the influence of Aegean cultures about whose furniture little is known. In the Greek dining room couches were ranged along the sides of the room, around a drained area into which the food was carried on tables. Greek gods are shown assembled. seated on stools of diverse design, with Zeus in an armchair (Egyptian gods were shown seated on uniform sets of chairs); similar variations in seating are shown in pictures of daily life. Simple scoop-shaped chairs occur in small early Greek terra-cottas.

Most Greek seats were four-legged, while tables and stands were frequently tripod. Folding stools were known. Greek wooden couches, chairs and stools were both tenon- and peg-joined. Cushion covers were strikingly patterned. Chair forms were abstract or referred to animal anatomy; architectural influence is limited to ornaments. The grace of Greek furniture has often been emulated and only very rarely equaled.

Ancient Rome and **Etruria.**—Etruscan ladies were shown sharing their lords' couches decorously in public, but Roman custom was closer to the Greek. Couches used at feasts usually accommodated three reclining persons. Romans translated Greek furniture forms from wood to bronze, which was either structural as well as decorative or was slipped over a wood core. Pieces of this furniture were excavated at Herculaneum and Pompeii; Hellenistic Greece probably led the way in this metallic development. Seats with mattresses, draped to conceal the frame. had draperies behind them and raised ends; seemingly used in women's quarters only, these resemble modern sofas. Both Greeks and Romans built theatres with carved stone seats for prominent persons, and other ceremonial seats of marble or other stone have survived. These sometimes appear as round-based chairs with round. flaring backs and sides. The Romans had similar chairs with high, hooded backs, all woven of rush, straw or wicker; a late Roman relief shows teacher and pupils using equally a set of barrel chairs (but the teacher has a footstool). Roman generals and officials were equipped with folding furniture of wood and metal; the use of folding X-frames survived the middle ages, joining the re-use of classical forms in the Renaissance. Rome's influence was extended by trade to India, where echoes of classical seat forms linger.

Early Middle Ages.—Surviving furniture of this era is largely ecclesiastical. Bishops' chairs of stone, metal or wood. richly ornamented, were often enveloping and monumental; on them and on benches, which were much used, architectural detailing was common, particularly arcading. Seats with storage space built in were often constructed like cabinets. with frames and filler panels. the panels carrying the chief burden of ornament. This taste for massiveness and elaboration led to the neglect of open-frame construction; the independent art of chair design languished for the next thousand years. Illuminated manuscripts showed boxlike high-backed seats mounted on platforms in cubistic massing. Many seats were portrayed with heavy spool-turned frames. Regal chairs often mere metallic. open and folding since they were meant to recall the traditions of Roman officialdom.

Later Middle Ages.—The closed forms and architectural detailing of seats continued, with motifs varying to match those on buildings. Oak was a favourite wood. Some chairs, benches and cabinets had canopies cantilevered from high backs; a few elaborate folding stools with X-frames survive from this period. Drawings and pictures show textiles draped over seats; a formal gradation of seating according to rank evolved, evident in pictures of court life. Built-in masonry benches, already known to the classical world, became commoner; *e.g.*, in window embrasures. A common piece of furniture before a fireplace was a wood bench with a hinged back rail, allowing the sitter to warm alternately front or rear. Late in the middle ages two typical peasant chairs appeared, one with a rush or straw seat. like those still made, and another, all wood, with a solid slab seat into which two upright slabs or three or four splayed legs were wedged; a wider splat driven in from above formed the back.

RENAISSANCE AND AFTER

Renaissance.—The folding chairs of antiquity became prominent again; benches and slab-seat chairs were improved with lighter forms; new rectangular open-framed chairs were devised. their elements sometimes scaled donn from architecture. Oak and walnut were commonly used. accompanied by velvet and leather. Sets of chairs, hardly known since the end of the Roman imperium, reappeared. In time, padded seats and backs became known, softening the rectangularity that prevailed in all save X-framed chairs of metal or wood. One chair with a tilted back, common in Spain, was uncommonly like the Hittite chair. In Spain metal was combined with wood to allow knockdown construction and adjustable backs. Adjustable furniture was regarded as a luxury in other lands: upholstered sofas and chairs with hinged ends or backs appeared in England; similar pieces were considered scandalous when introduced into the palaces of Henry III of France. A growing interest in mathematics and mechanics was expressed in chair frames by the widespread use of spiral wood turning; caning was introduced from the orient. and a few chair frames showed Chinese influence.

Baroque.—At the height of Egyptian and Greek civilizations chairs had been beautiful objects, clearly incomplete without occupants; now, with new means, chairs again were designed more for sitters than as things in themselves. High-backed armchairs acquired side pieces forming wingchairs that sheltered the occupants and localized warmth ("sleeping chairs"). Chair frames. still basically rectangular and now often gilded. were constructed with uprights pivoted to the diagonal. expressing the dominance of the centre where weight was borne. Oblique angles next were introduced in chair backs and legs, particularly back legs to balance the slope above, and in arm elements. These many deviations from strict rectangularity were accompanied by more sensitive carving of the framing members. and by the use of curves and double curves throughout the silhouette of the chair (*e.g.*, cabriole legs) and in horizontal members. Joints were reinforced with glue. Chair frames, liberated from the expression of rigid structure, looked inviting. Cushions, which previously had been added to chairs as ameliorations, now were designed with the frames; upholstery had begun. Upholstered surfaces became more important than the frames that held them; upholstery textiles and leathers were ornamented accordingly. Animal ornament dwindled; the vegetable kingdom supplied a variety of motifs paralleling architectural details. Miniature architectural elements were less favoured in chairs of this era. Stools. benches and sofas all went through these developments; day beds were relegated to private quarters. Baroque etiquette provided a strict hierarchy of seating. but this was often relaxed in private life. Some vagaries of clothing design affected chairs; hoopskirts, for example. required that chair arms retreat from the front corners of seats to accommodate the new width of skirt. Other usages, such as private prayers or gambling also evoked special chair forms.

Rococo.—The vigorous tendencies of baroque chair design were subjected to graceful and capricious detailing by rococo taste. Painted as well as gilt frames were upholstered in tapestry woven like pictures; floral and c-scroll details were common. The highest achievements of antique chair makers were equaled and surpassed at least in sumptuous variety and originality. Signed furniture indicated that contemporary French society appreciated the accomplishment; in England, however. not even the chief cabinetmakers marked their %-orks. Invalids' chairs became elaborately mechanized; rockers were transferred from cradles to chairs, perhaps first in the United States, where Benjamin Franklin was reported to have had a rocking chair in the 1780s. In England rural craft produced Windsor chairs, a lighter form of slab seat with various back designs made of spindles. Seats, legs, spindles and their frames were made of appropriate woods, often by separate makers, and the chair "maker" only assembled them from

ready-made parts. In one Windsor the wheelwright's craft was called on to frame the spindles in a bent inverted U. American Windsor chairs were often more elegant than the English. Naturalistic gardens were one of the chief accomplishments of the English rococo. and rustic effects, recorded many centuries earlier in China. were encouraged in furniture used outdoors or in terrace rooms. For these uses iron furniture gained favour, at first forged and welded and then cast and bolted.

Neoclassicism. — The turn toward a more classical style in furniture seems to have occurred first in England, and chair design changed. Straight lines gained over curved; joints that had been fluid transitions became accented junctions; natural woods, including mahogany, replaced gilt or painted surfaces; inlay became as common as carving; and striped or watered silks prevailed over tapestry. Vegetable ornament in time was replaced by symbolic figures or portions thereof. Generally forms became stable and restful, while constructional skill was expressed in the phenomenal slenderness of many pieces, and in the avoidance of bracing between legs. Beechwood was much used for chair frames. "Gondola" chairs, their backs curved smoothly into the seat frames, and other types were skilfully produced from classical images. The chaise longue or day bed reappeared in public rooms, for ladies' reclining, while men began to enjoy restful club chairs. In Germanic lands Biedermeier furniture arose, least decorated and most inventive extension of neoclassic design; blocky forms were preferred even in upholstery, and for veneers, bright fruitwood. In France contemporaneous taste favoured maple with dark linear inlaid or painted details. In the United States an independent furniture craft flourished among the Shakers, who produced simple, light wooden chairs and benches of extraordinary elegance, refined from German peasant furniture. It was the English. however, with the exemplary designs of Sheraton and Hepplewhite, who lifted this era to its heights. The daring skill and reticent taste of the best English chairs and sofas. frequently ascribed to these makers, challenged the more comfortable masterpieces of the rococo.

Romanticism. — Increased interest in Gothic and oriental effects now swept through design. Chairs and sofas were tufted and fringed to excess, except side chairs (often naïvely "Gothic") and featherweight occasional chairs that supplemented the massive upholstered pieces. Terrace furniture was brought into the house; bamboo became acceptable, as did the folding wood chairs now called deck chairs. Rosewood, dark and richly marked, predominated in elegant furniture. Scoop-shaped chairs were made in *papier maché*, lacquered black and decorated with colour, gilt and inlaid shell. The variety of forms for stools, chairs and sofas was unprecedented; day beds once more retired from public view.

Technological Innovations; Revival Styles. — Toward the middle of the 19th century, wood and metal both contributed to chair design in new ways. Veneers were curved more boldly than ever. as in Belter's carved chair backs made in New York city, and in Michael Thonet's contemporaneous efforts in the Rhineland and Vienna. In 1856, when Thonet perfected the bending of solid wood rods that kept their shape throughout long ocean shipments, he initiated the industrialization of furniture manufacture. Metal coil springs became the basis of tufted upholstery. Whole chair and sofa frames were built up, including arms, above a wood seat ring. in flexible metal wire or rods, buried in upholstery ("Turkish frames"). Chairs also were mounted on small carriage springs (Thomas E. Warren's U.S. patent, 1849). Most ingenious of all was the invention of the cantilevered rocker, produced in tubular iron (1851) by R. G. Winfield of Birmingham, Eng. Iron tubes had served for earlier chairs, some with welded joints; Winfield's was the first chair, so far as is known, to achieve comfort directly through the structure of its frame regardless of upholstery. No subsequent innovation has changed chair design more fundamentally: when the cantilevered chair was again launched in the 1920s it became mass produced as the most popular of all metal porch chairs, especially in the United States.

Adjustable chairs of many varieties were produced for invalids, for barbers, for comfort in the home or in the garden. Few, if any, involved new concepts, and the most popular, the "Morris chair," first made by Morris, Marshall, Faulkner and company of London around 1865, was inspired by an antique; its mechanism resembled that of the Renaissance adjustable seating described above. Chairs were evolved for factory and office uses with appropriate support and adjustability; all but the most utilitarian were designed in one of the many prevalent revival styles. Except for some expert copies of Louis XV and Louis XVI furniture, 19th-century revival styles betrayed their century by an accumulation of minor deviations from the originals.

Aestheticism; the Arts and Crafts Movement; Art Nouveau.—Certain designers of the mid-19th century, particularly in England, believed in returning to handicraft, hoping to recapture its lost excellences. In opposition to them were others who were ready to design for industry and convinced that the needs and means of the times, plus an appreciative understanding of the past and of oriental examples, would lead to suitable furnishings for their day. Both these groups — the aesthetic designers that supplied English industry from the 1870s, and the arts and crafts designers, scornful of industry, that followed them in the 1880s, produced chairs and sofas of good quality and of interesting, if rather forced, style. Arts and crafts furniture was widely accepted in the United States, where it became heavier and plainer than in England. At the turn of the century Belgium, France and Germany led Europe in a movement toward original design, *art nouveau*. Fondness for sinuous outlines and for novelty led to the design of chairs and sofas of great visual interest. More than any previous style, *art nouveau* used vegetal forms and abstractions therefrom, but some of the best designs were wholly abstract. (*See* also ARTS AND CRAFTS MOVEMENT; ART NOUVEAU; DESIGN, 19TH-CENTURY.)

Machine Style. — After World War I European modern designers turned in new directions. The French launched a cubistic style at the 1925 exposition of *Arts Dkcoratifs*. At the Bauhaus school in Germany and through publications such as *l'Esprit Nouveau* in Paris and *de Stijl* in the Netherlands other Europeans were searching more rigorously for a new style: chromium-plated, tubular-steel frames, often spanned by canvas slings, were developed. Chaises longues and cantilevered chair frames were revived. Severe geometry governed the forms, slick finishes and contrasting colours characterized the surfaces of this furniture that was intended to appeal to and satisfy the needs of a mass public. Yet originally and in several later revivals, the style remained a specialty, like the *art nouveau* it replaced. The philosophy of the machine style was more influential than its furniture; but one of its chairs, designed in 1930 by Ludwig Mies van der Rohe, has remained a favourite throughout the years despite its high cost.

Scandinavian and Italian Modern. — Plywood, bent in forms not unlike those of machine-style designers, formed the furniture of Alvar Aalto in Finland; subsequent Scandinavian modern furniture has had freer shapes. By the 1940s, the Danes took the lead. Smoothly carved, curved frames and slight padding mark the pieces by Finn Juhl, Hans Wegner and others. Italian designers were particularly preoccupied with upholstered furniture.

United States and Others. — While Europe assayed the machine style the profession of industrial design (*q.v.*) arose in the United States, whence it spread widely. In seating design its principal contribution has been the improvement of adjustable chairs for transportation industries. These industries pioneered a new upholstery material in England, in the later 1930s, foamed latex. Two American designers, Edward J. Wormley and T. H. Robsjohn-Gibbings (originally English), successfully adapted foamed upholstery for more decorative uses. Machine-style philosophy was upheld in the face of gross early industrial design by a group of Americans who produced remarkable, original and widely influential seating: Charles and Ray Eames, Eero Saarinen and Florence Knoll, all trained at Cranbrook Academy of Art in Bloomfield, Mich. Their work copied neither the machine style nor any other: it was marked by use of industrial materials and processes; its forms were often molded (in reinforced plastics), its joints flexible, its frames light and linear, its upholstery not

notably luxurious. A widely popular chair with a slung seat was evolved in Argentina; English, German, Dutch, French and Japanese designers were also active in the field of seating. Throughout the world, modern designers retained the values recaptured in the baroque era; chairs were designed for users, not as independent works of art or of craft. The old devices of animal, vegetable and architectural ornament seem to have disappeared. See DESIGN. 20TH-CENTURY; see also references under "Chair and Sofa" in the Index volume. (ER. K.)

CHAISE LONGUE: see CHAIR AND SOFA.

CHAITANYA (CAITANYA; also known as GUARANGA), (1486–1533), Indian mystic, though not the founder of Vishnuism in Bengal, left an indelible mark of his personality on that religious movement. Born at Nabadwip in 1486, he grew up in an atmosphere of piety and affection at home and of scholarship and academic pursuits outside. There was in his early career hardly anything that showed promise of his future greatness. But a visit to the holy village of Buddh Gaya (*q.v.*), at the age of 22, resulted in an almost unbelievable transformation in his outlook and personality. Chaitanya returned to Nabadwip a God-intoxicated man, entirely indifferent to all worldly concerns.

A group of Vaishnava devotees soon gathered round him. Not satisfied with the current ritualism and intellectualism, Chaitanya initiated a new mode of congregational worship, called *kirtana,* which consisted in the choral singing of the name and deeds of God, accompanied by peculiar drums and cymbals and synchronized with rhythmic bodily movements, all this culminating in a veritable ecstasy. He thereby propagated bhakti (self-surrendering personal devotion) as the most efficacious way of God-realization.

In 1510 Chaitanya became a regular ascetic. He never interested himself in organizing any cult or sect, nor did he produce any authoritative work on theology, philosophy or ethics. But his simple life of intense religious emotion itself proved at once the source and impetus of a great religious movement. Chaitanya died in 1533, but even in his lifetime he was deified and was regarded as incarnating Krishna and Radha in a single personality.

See *D. C.* Sen, *Chaitanya and His Age* (1922); S. K. De, *Early History of the Vaisnava Faith and Movement in Bengal* (1942). (R. N. D.)

CHAIYAPHUM, the name of a province (*changwat*) and its capital in the western part of northeast Thailand. The province, with an area of 4,165 sq.mi., had a population of 474,751 in 1960. The hills and mountains extend in a north-south direction and are divided by the Pa Sak river, which flows through the province from north to south. Most of the area is covered with fine sandy loams, which are droughty, and with shallow soils on steep, stony slopes. This is one of the country's poorest *changwats.* Chaiyaphum, the capital, is isolated and inaccessible. (T. F. B.)

CHALATENANGO, a department in northern El Salvador, bordered on the south and west by the deep Lempa valley and north by the Sumpul river. Area 817 sq.mi., pop. (1958 est.) 137,257. Although mostly rough country, the department produces 84% of the nation's wheat. Other products include vegetables, cattle, pigs, cheese. henequen, pineapples, corn, beans, sesame and poultry. Near the Honduras border the department is sparsely populated, because of the rugged relief. Its capital Chalatenango (pop. [1958 est.] 15,127), is an old colonial settlement, 38 mi. by highway from San Salvador. (C. F. J.)

CHALCEDON (CALCHEDON; mod. KADIKOY), an ancient maritime town of Bithynia, opposite Istanbul (formerly Byzantium and Constantinople), in the Istanbul *il* of Turkey. It was originally a Megarian colony founded in the early 7th century B.C. on a site so obviously inferior to that of Byzantium on the opposite shore that it was accorded the name of "The City of the Blind." In its early history it shared the fortunes of Byzantium, vacillated long between the Lacedaemonian and Athenian interests and was bequeathed to the Romans by Attalus III of Pergamum (133 B.C.). It was partly destroyed by Mithradates VI (*q.v.*), but recovered under the Roman empire despite the frequent ravages of barbarian raiders. In A.D. 451 it was the seat of the Council of Chalcedon (see COUNCIL). The city was captured by Khosrau II of Persia in A.D. 616. The Turks used it as a quarry for building materials for Constantinople.

CHALCEDON, COUNCIL OF, the fourth ecumenical council, was held in AD. 451 at Chalcedon, near Byzantium. It was occasioned by the need to deal with the Eutychian heresy, and its chief conclusions were concerned with affirming the two natures — divine and human — of Christ. See COUNCIL.

See also references under "Chalcedon, Council of" in the Index volume.

CHALCEDONY (CALCEDONY), a smooth or fine-grained variety of native silica occurring in concretionary, mammillated or stalactitic forms of waxy lustre and a great variety of colours—usually bluish white, gray, yellow or brown. It has a compact fibrous structure and a fine splintery fracture. For composition, mode of occurrence, varieties, etc., see SILICA; CHERT AND FLINT.

Chalcedonic pseudomorphs after other minerals often give rise to very interesting specimens. Hollow nodules of chalcedony containing water and an air bubble which is visible through the semi-transparent wall have been found. In all ages chalcedony has been the stone most used by the gem engraver, and many coloured varieties, described under special headings, are still cut and polished as ornamental stones. See AGATE; BLOODSTONE; CARNELIAN; MOCHA STONE; ONYX; see also references under "Chalcedony" in the Index volume.

CHALCIDICE (mod. Gr. KHALKIDHIKI) is a *nomos* (prefecture) in northern Greece, and consists of a peninsula which terminates in the promontories of Kassandra, Sithonia and Akti. All three were formerly islands, and the isthmuses at their bases are composed of loose sediments. The Kassandra isthmus is crossed by a canal cut in 1937. Xerxes had a passage made through that of Akti. The northwest-southeast trend of the promontories is the result of geologically recent rifting; in consequence the coasts are still steep and difficult to traverse, and the whole area is liable to severe earthquakes. The axis of the main peninsula is formed by the granite mass of Kholomon. Sithonia, too, is composed of ancient igneous rocks, while Akti rises at its seaward extremity to the great white marble pyramid of Mt. Athos (*q.v.*), 6,667 ft. high. The most accessible and fertile parts of the nomos of Khalkidhiki are the low plateaus of the Kassandra promontory and the west coast, where lies Nea Moudhania. Most of the rest is remote wooded mountain country, with some mining villages and many monastic refuges. Area 1,158 sq.mi.; pop. (1961) 79,838. (WM. C. B.)

CHALCIS (mod. Gr. KHALKIS), the chief town of the island of Euboea, Greece, lies at the narrowest point of the Euripus (Evripos or Evripou Porthmos), the strait separating the island from the mainland. Pop. (1951) 23,786. The modern town has a considerable export trade, and rail connections with Athens. It grew rapidly after World War II and became a popular weekend resort for Athenians. The old walled castro by the Euripus was traditionally occupied by Jewish and Turkish families, while the new Greek suburb grew up to the north and east. The Turkish fort of Meli-baba replaced an earlier Boeotian and Chalcidian one of 411 B.C. The site of the ancient acropolis and town lies to the south near the remains of a Venetian aqueduct. The 50-yd. strait, spanned by a swing bridge, is remarkable for its tidal currents, which are irregular and sometimes attain a speed of 12 knots. For the probable derivation of the medieval name Negroponte from Euripus see ECBOEA.

Important Early and Late Bronze Age tombs have been found near the town. In classical times Chalcis was occupied by Abantes and Ionians and its artists won particular fame for their metalwork. With Eretria (*q.v.*), Chalcis took a leading part in founding overseas trading posts and colonies, in north Syria (Al Mina) about 800 B.C. and in Italy (Pithecusae, Cumae) about 750. It founded other colonies in the west and in northern Greece (Chalcidice), but about 700 was severely handled in a war with Eretria (the Lelantine War). It sided unsuccessfully with the Boeotians against Athens in 506 and its land was divided among 4,000 Athenian settlers. It sent 20 ships to join the Greek fleet in 480 B.C. and fought against the Persians at Plataea in 479 (see GREECE:

Ancient History; GRAECO-PERSIAN WARS). Later it joined the Delian league (*q.v.*), but led a Euboean revolt against Athens in 446. In the 4th century it joined the second Athenian confederacy. Philip II of Macedonia installed a garrison in 338 to protect his interests in Greece. Aristotle died at Chalcis in 322. During the medieval period, the town was successively under Venetian and Ottoman control. (J. BO.)

CHALCOCITE, a mineral consisting of cuprous sulfide is known also as copper glance. redruthite and vitreous copper. Next to chalcopyrite, chalcocite is the most important ore of copper, and is perhaps the most characteristic mineral of the zone of secondary enrichment. It seems probable however that at some localities, *e.g.*, Butte, Mont., it is of primary origin. The best crystals are from St. Just. St. Ives and Redruth in Cornwall, and from Bristol in Connecticut.

Chalcocite (Cu_2S) crystallizes in the orthorhombic system. The crystals have the form of six-sided tables or prisms which are usually twinned, with the result that they simulate hexagonal symmetry. The mineral more often occurs as compact masses, which are sometimes of considerable extent. The colour is dark lead gray with a metallic lustre. but this is never very bright, since the material is readily altered. becoming black and dull on exposure to light. The mineral is 'soft (the hardness is 2.5 on Mohs' scale [*q.v.*]) and sectile; that is, pieces can be shaved off with a knife. Specific gravity is 5.7. It has a hexagonal polymorph not known to occur in nature. (CL. F.)

CHALCONDYLES, LAONICUS (CHALCOCONDYLAS LAONICUS) (*c.* 1423–1490?). Byzantine historian, was the author of the valuable work *Historiarum demonstrationes.* He came of a distinguished Athenian family and was educated under Gemisthus Plethon at the Palaeologan court at Mistra in the Peloponnese. His history is prefaced by an admirable survey of the Greek role in world affairs and a discussion of the relationship between Greeks and Romans. It treats the years 1298–1463 in more detail, describing the decline of the Byzantine empire and its conquest by the Ottomans. Its information on Manuel II includes his experiences when traveling in western European countries in search of aid against the Turks. Chalcondyles tried to model his style on that of Thucydides. but he was a great admirer of Herodotus and roused the interest of contemporary Italian humanists in him. He aimed at an objective analysis and in spite of some inaccuracies and the interpolation of farfetched anecdotes, he is one of the most valuable of the later Greek historians.

BIBLIOGRAPHY.—E Darko (crit. ed.), *Historiarum demonstrationes,* 2 vol. (1922–27); I. Bekker (ed.), *Corpus scriptorum Byz. hist.* (1843); J. P. Migne, *Patrologia Graeca,* clix (1866); K. Krumbacher, *Geschichte der Byzantinischen Littrratur,* 2nd ed., pp. 302–305 (1897); G. Moravcsik, *Bysantinofurcica,* vol. i, 2nd ed., pp. 391–397 (1958); G. Ostrogorsky, *History of the Byzantine State,* p. 416 (1956).

His brother, DEMETRIUS CHALCONDYLES (1424–1511), was born in Athens. In 1447 he went to Italy, where Cardinal Bessarion became his patron. He became famous as a teacher of Greek and the Platonic philosophy; in 1463 he was made professor at Padua, and in 1479 was summoned by Lorenzo de' Medici to Florence. In 1492 he moved to Milan, where he died in 1511. He was associated with Marsilio Ficino, Politian and Teodoro Gaza, in the revival of letters in the western world. One of his pupils at Florence was the famous German scholar. Johann Reuchlin. Demetrius Chalcondyles published the *editio princeps* of Homer (1488); *Isocrates* (1493); the Suda lexicon (1499); and a Greek grammar (*Erotemata*) in the form of question and answer.

(J. M. HY.)

CHALCOPYRITE (COPPER PYRITES), a copper iron sulfide, is of wide distribution and is the commonest of the ores of copper. Extensive deposits are mined in the United States, particularly at Butte. Mont., and in Namaqualand, South Africa. Well-crystallized specimens are met with at many localities; far example, formerly at Wheal Towan in the St. Agnes district of Cornwall, Eng., at Freiberg in Saxony. Ger.. and Joplin, Mo.

The colour of chalcopyrite is brass-yellow, and the lustre metallic; the streak, or colour of the ponder, is greenish-black. The rnineral is especially liable to surface alteration, tarnishing with beautiful iridescent colours; a blue colour usually predominates, probably due to the alteration of the chalcopyrite to cupric sulfide or covellite (*q.v.*). It is commonly found massive, granular to compact.

Chalcopyrite may be readily distinguished from pyrite (or iron pyrites). which it somewhat resembles in appearance. by its deeper colour and lower degree of hardness: the former is easily scratched by a knife, while the latter can only be scratched with difficulty or not at all.

Chalcopyrite is decomposed by nitric acid with separation of sulfur and formation of a green solution; ammonia added in excess to this solution changes the green colour to deep blue and precipitates red ferric hydroxide.

Chalcopyrite crystallizes in the scalenohedral class of the tetragonal system, but the form is so nearly cubic that it was not recognized as tetragonal until accurate measurements were made in 1822. Crystals are usuaily tetrahedral in aspect but frequently twinned, and they are often complex and difficult to decipher. The fracture is conchoidal, and the material is brittle. Hardness 4; specific gravity 4.2.

The chemical formula $CuFeS_2$ corresponds with the percentage composition: copper, 34.5%, iron, 30.5% and sulfur 35.0%. However, analyses usually show the presence of more iron. due to the intimate admixture of pyrite. Traces of gold. silver. selenium or thallium are sometimes present, 'and the mineral is sometimes worked as an ore of gold or silver, which may be present in solid solution. (L. J. S.: CL. F.)

CHALDEA (CHALDAEA), a land in southern Babylonia (mod., southern Iraq) frequently mentioned in the Old Testament, sometimes as the equivalent of Babylonia as a nhole. Strictly the name should be applied to the land bordering the head of the Persian gulf. between the Arabian desert and the delta of the Euphrates. This area was called by the Assyrians *Kaldu,* by the Babylonians *Kasdu* and by the Hebrews *Kasdim.* Little is known of the early history when the territory seems to have been settled by seminomads from Arabia, who occupied Ur "of the Chaldeans" (Gen. xi. 28) and adjacent areas.

The first reference to the name is found in the annals of Ashurnasirpal II. king of Assyria from 884 to 859 B C.. though earlier documents commonly designated the same area as the "sez-lands." The Assyrians carefully distinguished the Chaldeans from their northern Babylonian neighbours and from the Aramaeans, Arabs and other tribes in the vicinity. In 850 B C. Shalmaneser III raided Chaldea and reached the Persian gulf or "Bitter sea" which he called the "Sea of Kaldu." The effect of his incursion was short-lived, however. for his successor. Shamshi-Adad V had to intervene again to defeat the Chaldeans supporting the Babylonian rebel Marduk-balatsu-iqbi at the Daban river. Although Adad-nirari III (c. 810 B.C.) claimed several Chaldean chiefs among the vassals of Assyria, the link could not have been strong, for Tiglath-pileser III (745–727 B.C) met strong opposition from rebel sheikhs during his Babylonian campaigns.

On the accession of Sargon II, the Chaldean Marduk-apla-iddina IT, ruler of Bit-Yakin (the biblical Merodach-baladan), seized the Babylonian throne and, despite Assyrian opposition, held it for ten years (721–710 B.C.). His efforts to rouse the western states against Assyria are known from Isaiah's account of his embassy to Hezekiah. king of Judah (Isa. xxxix). After a further brief reign (703–702 B.C.) Merodach-baladan fled and Bit-Yakin was placed under an Assyrian nominee.

With the decline of Assyrian power, a native governor. Nabopolassar, was able to extend Chaldean influence northward. In 626 B C., he became king of Babylon by popular consent and inaugurated there a Chaldean dynasty that held sway until the Persian invasion of 539 B.C. The prestige of his successors, Nabu-Kurri-usur (Kebuchadrezzar; *q.v.*) II (605–562 B.C.) and Nabonidus (556–539 B.C.), was such that "Chaldean" was henceforth synonymous with "Babylonian" (Dan. iii, 8; ix, 1). "Chaldean" also was used more specifically, in the works of Herodotus, Diodorus and Strabo and in the Book of Daniel, to denote the priests and other persons educated in the classical Babylonian literature and

especially in traditions of astronomy and astrology. Through a misunderstanding, the "language of the Chaldaeans" (Dan. i, 4) or "Chaldee" was, until the early 20th century, sometimes used to mean the Aramaic language rather than the Babylonian dialect to which it rightly applies. Xenophon's "Chaldaeans" *(Anabasis,* vii, 25) were the Haldeans or Urartians of Armenia. *See* also BABYLONIA AND ASSYRIA.

BIBLIOGRAPHY.—D. J. Wiseman (ed. and trans.) *Chronicles of Chaldaean Kings* (626–556 B.C.) (1956). (D. J. WI.)

CHALET, a term applied to the timber houses of Switzerland. the Bavarian Alps. Tirol and the French Alps. The chalet is distinguished above all by the frank and interesting manner in which it makes use of its material. wood. The timber used is generally in heavy planks. from 3 to 6 in. thick, and carefully framed together somewhat in the manner of a log house. Side walls, generally low. often project beyond the ends. forming porches or loggias, closed at the ends. Upper floors almost universally project over the stories below, with all sorts of fantastic and interesting bracket treatments. Balconies across the front are common and

TIM GIDAL FROM MONKMEYER

AUSTRIAN CHALET, 17TH CENTURY

are frequently enriched with carved railings. Windows are small and hung as casements In general, roofs are of low pitch and project enormously. both at the eaves and at the gable ends. which are occasionally snubbed with a small triangle of sloping roof at the top. The roof surfaces are covered nith large wood shingles. slabs of slate or stone; in the wilder districts planks are often laid over the roof covering and weighted nith boulders to prevent damage from heavy gales. In plan, the chalet tends toward the square; frequently, not only the house proper but also stables and storage barns are included under one roof. Many local peculiarities of detail exist.

CHALFONT ST. GILES, a village and parish of Buckinghamshire. Eng., about 20 mi. N.W. of London. Pop. (1951) 4.381. Despite urbanization in the vicinity, the village green with its pond and neighbouring 13th-century church retains its charm. The cottage in which the poet John Milton spent some months during 1665–66 in order to escape the Great Plague then raging in London is now a museum. Thomas Ellwood, the Quaker. had found this "pretty box . . . in Giles-Chalfont" for his friend Milton. to whom he had read on occasions in the past. *Paradise Regained* was written in consequence of a suggestion made by Elluood during a visit he paid Milton at Chalfont when he received from him the completed manuscript of *Paradise Lost.*

Quakerism has long been associated with this parish, where Friends in the 17th century met for a number of years in what is today the old Jordans hostel, whose barn is reputed to be constructed of timbers from the vessel "Mayflower" that took the Pilgrim Fathers to America. The Friends meeting house at Jordans (built 1688), and more particularly its burial ground. attract visitors from all parts of the world, who come to see the graves of William Penn, Isaac Penington, and other renowned Quakers. (E. J. DA.)

CHALIAPIN (Rus. SHALYAPIN), **FEODOR IVANOVICH** (1873–1938), Russian bass singer whose dynamic impersonations had enormous influence on style in operatic acting in the first decades of the 20th century. He was born at Kazan, Feb. 13 (New Style; 1, Old Style), 1873, in a poor home and made his early living in numerous humble occupations. He sang in a church choir but first seriously studied singing with Dmitri Ussatov in 1892. He established a reputation as a member of Mamontov's private opera company in Moscow and mastered the roles upon which his international fame later rested: those of Boris in Mussorgsky's *Boris Godunov,* Ivan the Terrible in Rimski-Korsakov's *Maid of Pskov,* Mephistopheles in Gounod's *Faust* and Boito's *Mefistofele,* and Philip II in Verdi's *Don Carlos* as well as the *buffo* roles of Leporello in Mozart's *Don Giovanni* and Don Basilio in Rossini's *Il Barbiere di Siviglia.* He made appearances in Milan (1901), New York (1907), Paris (1908) and London 11913). Although sympathetic to the Bolshevik revolution, Chaliapin felt ill at ease-inSoviet Russia and in 1921 he left the country. He made highly successful visits to the United States and to London and in his later years was much admired as a recitalist. He died in Paris on April 12, 1938.

Chaliapin's powers resided not so much in beauty of vocal line, which seems to have interested him little, as in vivid declamation, the cavernous resonance of his voice and his dynamic acting. He published two volumes of autobiography, *Pages of My Life* (1927) and *Man and Mask* (1932). (WI S M.)

CHALICE, the cup used in the celebration of the Christian Eucharist (*q.v.*). Both the statement of Paul in I Cor. x, 16 about "the cup of blessing which we bless" and the accounts of the institution of the Eucharist in the first three Gospels indicate that special rites of consecration attended the use of the chalice from the beginning. It was not until the recognition of Christianity by the Roman empire in the 4th century that silver and gold became the usual materials for the chalice. In the middle ages the legend of the Holy Grail surrounded the origins of the eucharistic chalice with a magical aura (*see* GRAIL. THE HOLY). The precious stones and elaborate carvings employed for the embellishment of chalices have made them an important part of the history of ecclesiastical art. (J. J. PN.)

CHALK is a white to grayish, loosely coherent limestone composed of the calcareous remains of minute marine organisms—foraminifera (*q.v.*), coccoliths, rhabdoliths, etc.—fine-grained carbonate of uncertain origin and subordinate amounts of shell fragments. The purest kinds of chalk contain up to 99% calcium carbonate in the forms of the mineral calcite (q v.). Sponge spicules, diatom and radiolarian tests, detrital grains of quartz, and chert nodules (flint) contribute small amounts of silica. Also encountered are variable amounts of clayey material, glauconite pellets and calcium phosphate present as pellets and as invertebrate skeletal remains. (*See* also LIMESTOSE.)

Extensive chalk deposits occur in the United States from South Dakota through Texas to Alabama. European deposits are found in western Europe south of Sweden and in England; major production has been in England, France, Belgium and Denmark.

Chalk, just as any other high-purity limestone, is used for making lime and portland cement and as a fertilizer. Whiting may be prepared from chalk either by grinding in water and collecting the finer-sized particles from the suspension; or by dry grinding and pneumatic size-separation. Whiting is used in ceramics and putty; as a filler and extender in a wide variety of materials including cosmetics, crayons, phonograph records. plastics, rubber, paper and linoleum; as a mild abrasive in toothpaste. Large amounts are used in oil paints and as the solid ingredient in casein and other calcimine coatings. Whitings composed of ground marble, limestone, shells or chemically precipitated calcium carbonate compete with those made from chalk. The chief use for true chalk whiting is in making putty, for which its plasticity, oil absorption and aging qualities are well fitted.

See also references under "Chalk" in the Index volume.

(D. L. G.)

CHALKHILL, JOHN (fl. 1600), English poet, author of *Thealma and Clearchus. A Pastoral History in smooth and easie Verse. Written long since by John Chalkhill, Esq., an Acquaintant and Friend of Edmund Spencer* (1683). It appeared with a preface by Izaak Walton dated 1678. Two songs attributed to Chalkhill are included in Walton's *Compleat Angler* (1653). Nothing further is known of Chalkhill, and many critics have doubted his existence, assigning all his works to Walton himself. It may be noticed that Walton's second wife's stepmother's father was called John Chalkhill. "Thealma and Clearchus" is in vol. ii of George Saintsbury's *Minor Poets of the Caroline Period* (1905–21).

(P. Dw.)

CHALK RIVER, a village in Renfrew county, southeastern Ontario, on the Chalk river, about 95 mi. W.N.W. of Ottawa. A small frontier settlement before World War II, its name was given after the war to the Chalk river project which became the focus of atomic energy research in Canada, occupying 10,000 ac. on the Ontario bank of the Ottawa river. The village was incorporated in 1954. Pop. (1961) 1,115. The town of Deep River, 6 mi. up the Ottawa river, dating from 1944, was developed as a residential community for project personnel. Pop. (1961) 5,347.

Facilities of the project include five reactors and about 100 well-equipped laboratories and auxiliary buildings. The staff is engaged in fundamental and applied research in the various peaceful uses of atomic energy, with special emphasis on the generation of economic electric power by using natural uranium oxide as a fuel, with heavy water as moderator and coolant. to produce steam for operating turbines. A wide variety of fundamental research is performed in physics, chemistry, biology and metallurgy, as well as in electronics, engineering, health physics and medicine. The results of research are published in approximately 100 papers and 200 reports per year. The most notable of the isotopes produced at Chalk river is cobalt 60, used for radiography in industry and in theratron units for the treatment of malignant diseases.

"CHALLENGER" EXPEDITION, a prolonged cruise (Dec. 7. 1872–May 26. 1876) for oceanic exploration. carried out through the co-operation of the British admiralty and the Royal society. H.M.S. "Challenger," a wooden corvette of 2,306 tons, was commanded by Capt. (afterward Sir) George Nares (*q.v.*); the scientific staff was under (Sir) C. Wyville Thomson (*q.v.*). The Atlantic was crossed several times. From Cape Town southeast and east the ship visited the various islands between 45° and 50° S., reached Kerguelen Island in Tan. 1874, and proceeded south about the meridian of 80° E. The "Challenger" was the first steamship to cross the Antarctic circle. Early in March she made for Melbourne; from there the route led by New Zealand, the Fiji Islands, Torres strait, the Banda sea, and the China sea to Hongkong. The western Pacific was then explored northward to Yokohama, after which the "Challenger" struck across the ocean by Honolulu and Tahiti to Valparaiso. She then steamed southward. penetrated the Strait of Magellan. touched at Montevideo, recrossed the Atlantic by Ascension and the Azores, and then returned to England. Among the results of the expedition were the determinations of oceanic temperature, ocean currents and the depths and main contours of the great ocean basins: various areas of the world were charted and surveyed, and extensive biological investigation was carried on. Later explorations supplemented these findings but did not materially alter them; the scope and thoroughness of the expedition made it a landmark in the history of exploration. The *"Challenger" Report* was issued in 50 volumes (1880–95), mainly under Sir John Murray, a biologist on the expedition, who succeeded Wyville Thomson in 1882. *See* also references under "Challenger Expedition" in the Index volume.

CHALLIS, JAMES (1803–1882), English clergyman and astronomer who came near to discovering the planet Neptune, was born at Braintree, Essex, on Dec. 12. 1803. Educated at Trinity college. Cambridge. where he was appointed fellow in 1826. he was ordained in 1830, and succeeded G. B. Airy as Plumian professor of astronomy and director of the Cambridge observatory in 1836. He contributed over 200 mathematical. physical and astronomical papers to scientific journals and published 12 volumes of *Astronomical Observations made at the Observatory of Cambridge* (1832–64). containing the chief results of his 2j years' work at the observatory. He also wrote many theological works. Challis is always mentioned in connection with the discovery of Neptune because of his failure to act upon the prediction, given him by J. C. Xdams in 1845, which later proved to have given within 2° the true position of the planet. He was searching for the planet in Aug. 1536. but the pressure of routine observatory work prevented him from reducing the observations that would have revealed it; Neptune was discovered at the Berlin observatory in Sept. 1846. Challis died at Cambridge on Dec. 3. 1882. (O. J. E.)

CHALLIS, a light, all-wool or part-wool fabric of almost gossamer texture used for women's dressing gowns and children's suits and dresses. Challis once was distinguished from all the other muslin-delaine weaves, of which class it is a member, by the tiny romantic designs in which it is printed but it is now available in solid colours. These designs are mostly of 18th and 19th century inspiration and show conventionalized versions of dots, rosebuds, violets and other flowers.

CHALLONER, RICHARD (1691–1781), English Roman Catholic bishop, who revised the Reims-Douai translation of the Bible, was born at Lewes, Sussex, on Sept. 29, 1691. He was educated at the English college at Douai, where he was ordained (1716) and appointed vice-president and professor of theology (1720). In 1730 he was sent to London, where the Catholic community remained small and harassed, and in 1741 was consecrated titular bishop of Debra and nominated coadjutor to Bishop Benjamin Petre, vicar apostolic of the London district, whom he succeeded in 1758. He died in London on Jan. 12, 1781.

Challoner was the author of numerous controversial and devotional books, including his *Catholic Christian Instructed* (1737). a witty reply to Conyers Middleton's *Letters From Rome, Showing an Exact Conformity Between Popery and Paganism* (1729); a popular manual of prayer, *The Garden of the Soul* (1740); and *Meditations for Every Day of the Year* (1753), frequently reprinted and used by many outside his own church. His historical works, always carefully documented, include *Memoirs of Missionary Priests* (1741–42) and *Britannia Sancta* (1745), lives of traditional British saints. In his revision of the Reims-Douai version (1749–50) his purpose was to make the Bible more readable by modernizing the language and to correct earlier errors. As the translators of the Authorized version had made use of the Reims-Douai Bible, so Challoner adopted some of their phrases. His third edition (1752) became the authorized translation for English Catholics.

See E. H. Burton, *Life and Times of Bishop Challoner,* 2 vol. (1909); commemorative essays, Richard *Challoner* 1691–1781 (1946).

(E. E. Re.)

CHALMERS, ALEXANDER (1759–1834), Scottish writer and editor. best-known for his *General Biographical Dictionary* (1812–17), was born in Aberdeen on March 29. 1759. His *Glossary to Shakespeare* (1797) was followed by *English Poets from Chaucer to Cowper* (1810), which revised and expanded Dr. Johnson's *Lives of the Poets.* He edited the *British Essayists: with Prefaces Historical and Biographical* in 45 vol. (1817), as well as publishing the works of James Beattie, Henry Fielding. Edward Gibbon and others. His 32-volume *Dictionary* was a revised and greatly enlarged edition of work first published in 1761. He died in London on Dec. 10, 1834.

CHALMERS, GEORGE (1742–1825), Scottish antiquary, historian and political writer, known principally for his *Caledonia: or an Account, Historical and Topographical, of North Britain,* 3 vol. (1807–24), a comprehensively planned work of antiquarianism, unfinished at his death. Chalmers was born at Fochabers, Moray, educated at Aberdeen and Edinburgh and in 1763 emigrated to Maryland where he practised as a lawyer. After returning to England on the outbreak of the war of American Independence, he published the *Political Annals of the Present United Colonies* (1780), of which only one volume (ending in 1688) appeared, and *An Estimate of the Comparative Strength of Great Britain During the Present and Four preceding Reigns*

(1782), the intellectual ancestry of which is shown by his reprint with a biographical note of Gregory King's *Observations upon the State of England, 1696* (1804). He held the office of chief clerk of the committee of the privy council for trade from 1786 until his death, in London, May 31, 1825. Besides many political works, he wrote lives of Defoe (1785), Allan Ramsay (1800), Sir David Lyndsay (1806) and Mary, Queen of Scots (1818).

See Grace A. Cockroft, *The Public Life of George Chalmers* (1939).

CHALMERS, JAMES (1841–1901), Scottish missionary to New Guinea, was born at Ardrishaig, Argyll, on Aug. 4, 1841. Ordained in 1865, he was sent by the London Missionary society to Rarotonga in the South Pacific (1866). In 1877 he joined W. G. Lawes in southeast New Guinea and on the savage island of Suau. The courage and energy of both Chalmers ("the Livingstone of New Guinea") and his wife brought many new converts to Christianity. At Dopima on Goaribari Island, on April 8, 1901, Chalmers and his fellow missionary Oliver Tomkins were killed by cannibals.

See his *Autobiography (1902).*

CHALMERS, THOMAS (1780–1847), Scottish preacher and theologian, first moderator of the Free Church of Scotland (*q.v.*), was born at Anstruther, Fife on March 17, 1780. In 1803 he was ordained as minister of Kilmany, Fife, while continuing his successful classes in mathematics at St. Andrews and devoting most of his time to scientific study; but after conversion to a firm belief in the necessity of faith for salvation, effected partly by a reading of William Wilberforce's *Practical View of the Prevailing Religious System* (1797), he took up the evangelical position and contributed an article on Christianity as well as the one on trigonometry, which he had already undertaken, to the *Edinburgh Encyclopaedia* (1813). In 1815 he became minister of the Tron church, Glasgow, where he became so famous as a preacher that, when he visited London in 1817, Wilberforce wrote, "all the world is wild about Dr. Chalmers." In July 1819 he was made minister of the new parish of St. John's, Glasgow, and undertook to deal with the problem of its poor, who were then costing the city £1,400 per annum. By 1823, when he accepted the chair of moral philosophy at St. Andrew's, Chalmers had reduced this figure to £280. In Nov. 1828 he was appointed professor of divinity in Edinburgh and became recognized as the leader of that section of the Scottish Church which was claiming independence from civil interference for the church and a vote for parishioners in the choice of their minister. This opposition to the prevailing policy directed an attack against the exercise of patronage, an attack which culminated in the Disruption of 1843, when, on May 18, 203 commissioners marched out of the general assembly because of the government's refusal to admit the church's spiritual independence *(see* SCOTLAND, CHURCH OF). Chalmers, who had already prepared a scheme for the support of those who wished to make what he called "a Christian outgoing . . . a withdrawal from the intolerable position forced upon us," was made moderator of the Free Church of Scotland. He also became principal of their New college in Edinburgh, where he died on May 30, 1847.

A preacher whose sermons were powerful on account of their rugged eloquence rather than their polish, and a theologian more concerned with the solution of man's problems than with the more difficult questions of the nature and existence of God, Chalmers insisted above all in bringing the ethics of the Christian faith to his study of economics and his practice of philanthropy. In 1808 he published *An Enquiry Into the Extent and Stability of National Resources* in which he maintained an optimistic attitude in face of Bonaparte's hostile commercial policy, and in a series of sermons (published in 1817) he claimed that modern astronomical studies only increased the glory of the Christian revelation. The results of his work among the paupers of Glasgow nere fair indication of the efficacy of his ideas, which he later set out in detail in *Christian and Civic Economy of Large Towns,* three volumes (1821–26), and *Political Economy* (1832), works very different in emphasis from those of his contemporaries, William Godmin (*q.v.*) and Thomas Malthus (*q.v.*). His most important theological study was written in 1833 under the title *On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man* and later incorporated in his *Institutes* of *Theology,* published posthumously (1849). His obituary notices testify to the esteem in which Chalmers was held, both as "the veteran hero of the Disruption," and as a minister particularly aware of and attentive to the social and economic needs of those in his care.

See H. Watt, *Thomas Chalmers and the Disruption* (1943).

(H. WA.)

CHALNA (PORT JINNAH), an anchorage established in East Pakistan in Dec. 1950 on the Pussur river as an experimental measure to relieve congestion at Chittagong (*q.v.*) and to handle the traffic of the Cis-Brahmputra area of East Pakistan. As it proved to be a self-supporting project it was made permanent in 1952. Some of the moorings were soon found to be dangerous, because of the proximity of eddies, and the anchorage was shifted a few miles downstream to Mongla. This anchorage is 72 mi. from the sea, extends over a distance of 3 mi., has a depth of 21–45 ft.. and has nine moorings. The navigable channel is well marked with buoys and shore marks. It can accommodate ships of 23-ft. draft throughout the year and ships of 26-ft. draft during the spring tides. Chalna has emerged as an important seaport served by inland water transport with connections to most of the river ports in the province and with the railhead at Khulna. The chief export of Chalna is jute; chief imports are machinery, bagged food grains, salt, coal and general cargo in bulk. Pop. (1961) 3,944.

(K. S. AD.)

CHÂLONS-SUR-MARNE, a city of northeastern France, capital of Marne *département,* is on the Marne in the heart of the rolling Champagne country, 42 km. (26 mi.) by road S.E. of Reims. Pop. (1954) 31,645. The centre of the town is bordered on the west by the Marne, and other branches pass through the town. The cathedral of St. Étienne (13th century) has a 17th-century west façade, fine 13th-century stained-glass windows and a remarkable main altar. The collegiate church of Notre Dame en Vaux (12th century) is a mixture of Gothic and Romanesque styles, having stained-glass windows dating from 1525 and 1526, a Gothic choir and a carillon of 56 bells. Stained-glass windows are a feature of the church of St. Alpin (12th and 16th centuries); St. Jean is another old church. Near the *hôtel de ville* (1772–76) is a 13th-century house containing the library, which includes manuscripts from the 12th to the 15th centuries and carefully preserved incunabula. The college, once a Jesuit establishment, and the former Augustinian abbey (16th and 17th centuries), now a training college, are other notable buildings. Two important railway routes cross at Chklons, from Paris to Strasbourg and from Calais to Basel. The chief industries are beer and champagne production and wallpaper making. Sugar, automobile parts, electrodes, detergents, boots, agricultural machinery, brushes, wire goods and cereals also are produced.

Known to the Romans as Durocatalaunum, Châlons was the chief town of the Catalauni. On the open country between it and Troyes Attila was defeated by the Romans in A.D. 451 *(see* CATALAUNIAN PLAINS, BATTLE OF THE). In the 10th and following centuries it attained great prosperity under its bishops, who were ecclesiastical peers of France. In 1214 the militia of Chklons served at the battle of Bouvines; and in the 15th century the citizens twice repelled the English from their walls. In the 16th-century wars of religion the town sided with Henry IV of France, who in 1589 transferred thither the *parlement* of Paris. The camp of Châlons, about 26 km. (16 mi.) N. of the town, was established in 1856 by Napoleon III, and is a training centre for troops. In World War I Chklons was occupied by the Germans in Aug. 1914 but was retaken by Foch in September. In World War II Châlons was in German hands from June 13, 1940, until Aug. 29, 1944. It was severely bombed in April and July 1344, the cathedral suffering some damage.

(P. SI.)

CHALON-SUR-SAÔNE, an industrial town of east central France, capital of an *arrondissement, département* of Saône-et-Loire, is 81 mi. N. of Lyons by rail. Pop. (1954) 34,187. Chalon is a well-built town, with fine quays, situated on the right bank of the Saône at its junction with the Canal du Centre. The church of St. Vincent, once the cathedral (mainly 12th–15th centuries),

has a choir in the 13th-century Burgundian style. The old bishop's palace dates from the 15th century. The church of St. Peter, with two lofty steeples, is late 17th century. There are remains of the ancient ramparts and a number of old houses. The museum of fine arts and archaeology, recently enlarged, is one of the finest in Burgundy.

Chalon is the seat of a subprefect and a court of assizes, and has a court of first instance, a tribunal of commerce and a chamber of commerce. It ranks next to Le Creusot among the manufacturing towns of Burgundy. With its position as a river port, a railway centre and a crossroad on two highways connecting Paris to Lyons and Switzerland to the west of France, Chalon ranks as the chief commercial centre of the Saône valley. Mechanical and iron and steel works are the principal industries. There are two shipbuilding yards and a works that turns out bridges, tugboats, etc. Chemical and glass works, outfitting workshops and food industries also are important to the town, It is a market for cereals, wines, timber and furs.

Known to the Romans as Cabillonum, it was an important town of the Gallic tribe called the Aedui. It was chosen in the 6th century by Gontram, king of Burgundy, as his capital. The bishopric, founded in the 4th century, was suppressed at the Revolution. In feudal times Chalon was the capital of a countship. In 1237 it was given in exchange for other fiefs in the Jura by Jean le Sage, whose descendants nevertheless retained the title. Hugh IV, duke of Burgundy, the other party to the exchange, gave the citizens a communal charter in 1256. The town resisted a division of the Austrian army in 1814. In World War II the Germans occupied Chalon-sur-Saône from Nov. 1942 until Aug. 1944.

CHALUKYA, the name of two ancient Indian dynasties. The Western Chalukyas ruled as emperors in the Deccan from A.D 543 to 757 and again from about 975 to about 1189. The Eastern Chalukyas ruled in Vengi (in eastern Andhra Pradesh) from about 624 to about 1070.

Pulakesin I, a petty chieftain of Pattadkal in the Bijapur district (*q* v.), whose reign began in A.D. 543, took and fortified the hill-fort of Vatapi (mod. Badami) and obtained from the Kadambas of Hangal rule over the triangle between the Krishna and Tungabhadra rivers and the Western Ghats. After military successes further north his son Kirtivarman secured the valuable Konkan coast. The family then turned their attention to the fertile coastal regions in the northwest and east of the peninsula. Pulakesin II, who succeeded about 610, acquired parts of Gujarat and Malwa and defied the north Indian ruler Harsha of Kanauj, the boundary between them being fixed on the Narmada (Narbada) river. He took Vengi about 624 from the Vishnukundins and gave it to his brother Kubja Vishnuvardhana, the first "Eastern Chalukya." During 641–647 the Pallavas ravaged the Deccan and captured Vatapi but the Chalukya family had recovered by 655 and had extended their power in Gujarat. By 660 they had acquired land in Nellore district (*q.v.*). Vikramaditya I took Kanchi (Kancheepuram; *q.v.*), then the Pallava capital, about 670 and, the Pallavas' submission proving unprofitable Vikramaditya II again captured, but spared the city in 742. Kirtivarman II was superseded by the Rashtrakuta dynasty in 757.

When the last Rashtrakuta fell about 975 Taila founded the second Chalukya dynasty named after the more central capital, Kalyana (mod. Kalyan). His great achievement was to subdue the Paramaras of Malwa. The Chola king, Rajaraja I, invaded the south Deccan about 993, and repeated Chola invasions of the plateau occurred until about 1021. After many vicissitudes the dynasty were supplanted by the Kalachuri family under Bijjala, who usurped the throne about 1156–84. Somesvara IV was restored only to lose the empire in 1189 to the Yadavas (or Sevunas) of Devagiri, the Hoysalas of Dorasamudra, and the Kakatiyas of Warangal, the rulers of the Telugu-speaking parts of the Deccan.

The descendants of Kubja Vishnuvardhana had constantly to fight for the riches of Vengi, and were pawns in the struggle between the Deccan emperors and the Chola kings (*q.v.*). The Cholas eventually adopted the family, and the two countries were united under Rajendra II (Kulottunga I) whose reign began in 1070.

CHALYBITE: *see* SIDERITE.

CHAM, a people who, in central Vietnam, are the surviving inhabitants of Champa (*q.v.*) and who, in Cambodia, are a mixture of Chams and Malays. In Cambodia they number about 100,000 and preserve some original traits, *e.g.*, the predominance of the maternal uncle, but otherwise they are entirely integrated as prosperous Cambodian-speaking weavers and traders. From the Malays they adopted Islam, which they practise faithfully. The Chams of Vietnam (about 16,000) are rapidly being assimilated by the surrounding Vietnamese, but some speak Cham, the link between the Thai-Kadai languages of southern China and Indonesian. They are of medium build and predominantly dolichocephalic, with brown complexions. Self-supporting rice cultivators, they also carry on a small bartering trade (salt, rare woods) between the hill tribes and the Vietnamese. The family is matrilocal and matrilineal. The cult of nature spirits is all important, since ancestors' souls are supposed to settle in the earth when the tomb—near the rice fields—is abandoned after seven years of worship. The Indian culture of ancient Champa left some influences; *e.g.*, in ancient Cham temples, "brahmanes," with female mediums, perform degenerated rites in honour of Po Rome, Po Nagar and Po Klaung Garai, deified heroes of the past.

CHAMBA, a municipality and district in Himachal Pradesh, northern India. Chamba town (pop. [1951] 6,858), district headquarters, is on the right bank of the Ravi on two terraces; the lower, called Chaugan, has public offices and Bhuri Singh museum, and the upper has the residential area. A coeducational government degree college there is connected with Punjab (Panjab) university. Many temples, dating from the 10th century, are notable for their architecture. There are two cloth weaving factories.

CHAMBA DISTRICT (area 3,135 sq.mi.) was formed from the princely state of that name after it merged with Himachal Pradesh in 1948. It forms the isolated northwestern tract of the province and is bordered north and west by Kashmir. The mountainous terrain of the whole district reaches elevations of over 17,000 ft. in the eastern, northern and central parts. The drainage is controlled by the upper waters of the two rivers, the Ravi in the south and the Chenab (there called Chandrabhaga) in the north. Forests abound in Himalayan silver fir, pine and deodar.

The population of the district was 210,177 in 1961. The economy depends entirely upon agriculture; maize (corn). wheat, barley; some upland rice and oilseeds are grown.

The former Chamba state was founded in the 6th century and was sometimes subject to Kashmir and later to the Mogul empire. It came under British influence in 1846 and remained under British paramountcy until its merger with Himachal Pradesh.

(S. S. BH.)

CHAMBER, KING'S, or *camera regis,* was, in England, the earliest royal financial office, part of the royal household. In varying measure at different periods it retained financial and administrative importance until far into the Tudor period. In origin it was literally the bedchamber of the early Anglo-Saxon kings. The bedchamber, together with its adjacent wardrobe *(see* WARDROBES, THE), was naturally the safest place in the household, inaccessible to all but trusted servants, for the custody and storage of valuables, jewels and cash as well as clothes, equipment and eventually records and documents. It could readily become the place for receipt and payment, and its primarily domestic staff, *bedthegns, cubicularii, camerarii* or chamberlains, became engaged also in financial administration. With the growth of the

king's resources, other depositories or treasuries for the storage of cash and valuables had to be found, the most important of which, from the time of King Canute at the latest, was located at Winchester.

During the Anglo-Norman period, the increase in royal financial resources necessitated an elaboration of the machinery. By the time of Henry I the *camera* or bedchamber proper, under the supervision of the master chamberlain, remained as a private apartment; but the *camera curiae* under several chamberlains continued to be the king's privy purse and the financial office of the household, receiving payments and making disbursements and always following the king. The treasury at Winchester, under a treasurer, continued as the principal depository. By the very early 12th or possibly the late 11th century, a third finance office had come into existence, destined to be the great tribunal of account, the exchequer.

The king inevitably continued to need a private treasury close to his person at all times, into which immediate payments could be made in the course of his travels, in response to writs which diverted portions of the sheriff's debts from the normal course at the exchequer, the farms of castles in the king's hands, rents, fines and casual revenues. Possibly as early as the reign of Henry I certain "chamber manors" paid their profits directly into the chamber. Rolls of the chamber were kept from 1164 but they have been lost, and the evidence for chamber finance comes either from quittances recorded on the pipe rolls of the exchequer or from indirect sources. In any event, all revenue was the king's revenue, and he could dispose of it through any available channel, according to convenience or whim.

In the time of Henry II, perhaps earlier, the chamber developed in addition administrative and secretarial functions. This development turned largely upon the acquisition by the department of a seal of its own, which it may have achieved before the reign of John, when a small or privy seal, additional to the king's seal (which by contrast soon became known as the great seal), certainly existed and was used for chamber business. With a recognized seal in its custody, the chamber sent writs to chancery to authorize the issue of documents under the great seal and so became a second secretariat readily adaptable to any administrative need. At about the same time the wardrobe became more prominent as a financial and administrative organ, especially for military and diplomatic purposes, in which it tended to specialize. The chamber itself, with the king present, continued to be the place in or through which all the royal power and discretion could be exercised; the knights and clerks of the chamber could be the king's most intimate and confidential agents for every sort of business.

The circumstances of the long minority of Henry III brought changes in the administrative machinery, for no household office could function until a king became of sufficient age to possess a normal royal household and to move seals at his will. Henry III did not obtain a privy seal of his own until Dec. 1230, and within two years, for reasons which remain mostly conjectural, this seal came to be in the custody, not of the chamber, but of the wardrobe. This change induced a magnification of the financial and administrative importance of the wardrobe and a recession of the chamber, even though the latter remained essential as the organ of household finance and the place where the king's discretion was immediately exercised. This recession remained marked until well into the reign of Edward II.

A revival in the importance of the chamber occurred with the diversion to it of large funds accruing from loans and the profits from forfeited lands, including those of the Templars before 1310 and, for a time, of the "contrariants" or opponents of the king after 1322. These arrangements brought substantial financial resources into the chamber, while the emergence of another small seal, the "secret" seal, in its custody, gave the king an effective secretariat close to himself to compensate for the increasing remoteness and formalism of the privy seal in the custody of the wardrobe. The king's personal will could be implemented in any direction by use of the secret seal. The circumstances of the deposition of Edward II and the minority of Edward III brought about another recession of the chamber, to be followed once again by revival for about 20 years from 1333. Edward III reintroduced the reservation of lands to the chamber, so that the management of estates became a major part of its work, a task facilitated by the creation of a second chamber seal, the griffin seal. With these resources at its disposal, supplemented by substantial subventions from the exchequer, the chamber played a major role in financing the wars with France. This phase in chamber history was terminated by Edward III's decision, promulgated on Jan. 20, 1356, to transfer to the exchequer almost all the reserved lands. The griffin seal thereupon disappeared. The secret seal also became obsolete before Edward III's death, and was destined to be superseded as the king's personal seal by the signet *(see* SEALS). In consequence the chamber rapidly lost most of its importance in administration. It continued to receive the *certum* or regular subvention from the exchequer for household expenses; its staff of knights and chamberlains remained close to the king and available for every kind of confidential business, but there was to be no notable revival of its administrative importance until late in the 15th century.

The need to rehabilitate finances after the civil wars of Henry VI's reign induced Edward IV and his successors to revive the chamber as the most effective instrument for the exercise of royal initiative. Most of the royal lands, other than the duchy of Lancaster, were made accountable to the chamber by Edward IV, so that the funds at its disposal once again became very substantial. This revival was continued by Richard III and the Yorkist scheme was ready to hand and carried still further by Henry VII. From about 1487 the treasurer of the chamber was the most important financial officer of the crown. Not only the profits from crown lands but many other items of revenue were diverted away from the exchequer into the chamber, including the profits of wardship and other feudal dues, the proceeds of the hanaper and the law courts, the pension from France and sometimes parliamentary grants. The exchequer was now left with little but the ancient revenue; *i.e.,* the farms of the counties and towns and the customs. The treasurer of the chamber was not accountable at the exchequer, but his accounts were closely supervised by Henry VII himself and periodically audited by councilors designated for the purpose. The system was continued far into Henry VIII's reign, and completed by the statutory recognition of boards of surveyors and auditors to supervise it. The establishment of a variety of other financial organs in the 1530s greatly reduced the chamber's resources and financial preeminence, however, while the radical reform and revival of the exchequer in the 1550s brought the chamber to an end as anything more than a household department dependent upon other sources for its only funds.

The use of a chamber for financial purposes was universal in most of Europe in the medieval period and later. Every king and reigning prince, bishops, abbots, secular magnates, most towns, the empire and the papacy all developed a *camera* for some financial purpose, and each possessed a history of its own, which differed materially from that of the kings of England.

CHAMBERLAIN, SIR (JOSEPH) AUSTEN (1863–1937), British statesman whose long and distinguished career reached its climax in the foreign secretaryship from 1924 to 1929, was the eldest son of Joseph Chamberlain by his first wife, Harriet Kenrick. He was born at Birmingham on Oct. 16, 1863. After leaving Rugby school he went to Trinity college, Camb idge, and afterward studied in Paris and Berlin. He served first as his father's private secretary, entered parliament in 1892 and remained an M.P. until his death. He was civil lord of the admiralty (1895–1900), financial secretary to the treasury (1900–02) and postmaster general (1902) in the governments of Lord Salisbury and A. J. Balfour, while his father was colonial secretary.

When his father resigned as colonial secretary in 1903 in order to advocate a policy of tariffs which did not commend itself to

most of his colleagues, Austen (a lifelong supporter of a protective tariff) remained in the government, with his father's blessing. and was made chancellor of the exchequer (1903–05). During the term of the Liberal government he was active in opposition. and on Balfour's resignation from the leadership of the Conservative party in 1911 he was a strong candidate for the succession. He and his rival, Walter (afterward Viscount) Long! being equally matched, however, both withdrew in favour of Andrew Bonar Law.

When H. H. Asquith formed the first coalition government in May 1915, Chamberlain joined it as secretary of state for India and remained in that post under David Lloyd George's prime ministership. He resigned in July 1917 as a result of criticism of his department for the deficiencies in medical and other supplies for the disastrous Mesopotamia campaign. though no blame attached to him personally. He re-entered the government in April 1918 as a member of the war cabinet, and in Lloyd George's peacetime coalition he became chancellor of the exchequer (Jan. 1919). In March 1921, on Bonar Law's retirement because of poor health, he was elected leader of the Conservative party and became lord privy seal and leader of the house of commons. He was a loyal supporter of Lloyd George and the coalition government, particularly over the Anglo-Irish treaty of Dec. 1921, in the negotiations for which he took a leading part. Discontent grew, however, among the Conservatives, and led to the Carlton club meeting of Oct. 19, 1922, at which the Conservatives decided to withdraw from the coalition and thus brought it to an end. Chamberlain opposed this decision and resigned the leadership, being succeeded by Bonar Law. He remained outside the government during the ministries of Bonar Law and Stanley Baldwin (1922–24). but returned to office as foreign secretary in Baldwin's second government (Nov. 1924–June 1929).

As foreign secretary, Chamberlain's greatest achievement was the Locarno pact (Oct. 1925) by which Germany's western frontiers were mutually guaranteed by Great Britain, France, Italy, Belgium and Germany, and Germany's entry into the League of Nations was assured. The "Locarno spirit," supplemented by frequent meetings of Chamberlain and the French and German foreign ministers, Aristide Briand and Gustav Stresemann, at sessions of the League of Nations, seemed to promise an era of peace. Chamberlain was rewarded with the knighthood of the Garter on Nov. 30, 1925. He was co-winner (with Charles Dawes) of the 1925 Nobel peace prize and Briand and Stresemann shared the award a year later. Later events clouded his popularity, among them the breaking-off of diplomatic relations with U.S.S.R. after a police raid in the building occupied by Arcos, the Russian state trading agency (May 1927), the failure of the Geneva conference on naval disarmament (Aug. 1927), the abortive and unnecessarily secret Anglo-French negotiations for disarmament in July 1928 and his dealings with China (1927) and Egypt.

When the national government of Ramsay MacDonald was formed in Aug. 1931 Chamberlain became first lord of the admiralty. His brief tenure of the office coincided with the naval mutiny at Invergordon against the scale of the economy cuts in pay (Sept. 15), for which he was not to blame. He held no office after the general election of Oct. 1931, but remained in parliament as a respected and influential elder statesman. He died in London on March 16, 1937. In appearance rather stiff (like his father, he always wore a monocle), Chamberlain was the most loyal of colleagues, hard working, shrewd and formidable in debate. He published two volumes of memoirs, *Down the Years* (1935) and *Politics From Inside* (1936).

See Charles Petrie, ***Life and Letters*** of . . . *Sir Austen Chamberlain*, 2 vol. (1939–40). (C. L. M.)

CHAMBERLAIN, CHARLES JOSEPH (1863–1943), U.S. plant morphologist and cytologist, was born near Sullivan; O., on Feb. 23, 1863, and educated at Oberlin college, graduating in 1888. Most of his life he was connected with The University of Chicago, from which he obtained the degree of Ph.D. in 1897 and Sci.D. in 1923. He became instructor there in 1901, after which he spent one year in Bonn, Ger., working in the laboratory of Eduard Strasburger. After his return to Chicago he was appointed assistant professor in 1907 and associate professor in 1911; he was professor of plant morphology and cytology from 1915 until his retirement in 1931. Chamberlain's work in organizing the university's botanical laboratories was fundamental. and he was in charge of them from the beginning. His interest in the morphology and life history of cycads caused him to make many exploring trips. which resulted in the assembling of a complete collection of living cycads in the greenhouses of the university. He visited Mexico in 1904, 1906, 1908 and 1910 and made a long journey in 1911–12 to New Zealand and Australia. returning through South Africa. In 1914 and 1922 he collected specimens in Cuba. He died on Feb. 5, 1943.

Chamberlain's publications include *Morphology of Spermatophytes* (1901), *Morphology of Angiosperms* (1903) and *Morphology of Gymnosperms* (1910; 2nd ed.. 1917), all in collaboration with J. M. Coulter; among his other works are *Methods in* Plant *Histology* (1901; 5th ed., 1932) and *Gymnosperms, Structure and Evolution* (1935).

CHAMBERLAIN, HOUSTON STEWART (1855–1927), British-born political philosopher, whose theories on the racial superiority of the so-called Aryan element in European culture influenced the development of National Socialism (*q.v.*), was born in Southsea. Eng.. on Sept. 9, 1855, the son of an admiral and nephew of Sir Neville Bowles Chamberlain. Prevented by ill-health from entering the army, after going to school at Cheltenham and in Paris. he studied natural science at Geneva (1879–84) and in Vienna. He became an ardent admirer of Richard Wagner and his first book. published in France in 1892. was *Notes sur Lohengrin;* other books on Wagner included *Das Drama Richard Wagners* and a biography emphasizing the Teutonic element in Wagner's thought. In 1908 he settled in Bayreuth, and married, as his second wife, Wagner's daughter. Eva.

Chamberlain's most important work, *Die Grundlagen des neunzehnten Jahrhunderts,* a brilliant though biased historical resumé of the whole range of European thought and culture, was published in 1899; an English translation, *The Foundations of the 19th Century,* with an introduction by Lord Redesdale. appeared in 1911. In it Chamberlain expounded what he meant by the quality "Germanism." which he regarded as being the source of all that is best in the European tradition. The Germans. for him, included all those belonging to the western Aryan group of peoples, and were; he felt, the nation best suited to establish a new European order. His anti-Semitism, which was developed and exploited by later thinkers, was based on the idea that the Jews introduced an alien note into European history and tended to debase the culture of those with whom they became assimilated. His theories. which owed much to the writings of the comte de Gobineau (*q.v.*), gained force because they provided a rational basis for the prevalent emotional pan-Germanism and nationalism.

Chamberlain became increasingly German in feeling and supported Germany in World War I, becoming naturalized in 1916. He died in Bayreuth on Jan. 9, 1927. His other works include studies of Kant (1905) and Goethe (1912); and *Lebenswege meines Denkens* (1919).

CHAMBERLAIN, JOSEPH (1836–1914), British statesman, famous as the champion of imperial unity and tariff reform, was born in London on July 8, 1836. His father, Joseph Chamberlain. master of the Cordwainers' company, carried on a family business of boot and shoe manufacture, was a Unitarian in religion and a Liberal in politics. Young Joseph entered the family business in 1852, spent two years in his father's London office and was then sent to Birmingham to represent his father's interest in the firm of Nettlefold, screw manufacturers. He proved an exceptionally successful businessman and was able to retire in 1874 with a fortune of £100,000.

Local Politics. — Chamberlain entered the municipal and political life of Birmingham in 1868 when the local Liberal association was reorganized. He held advanced radical opinions and was in favour of a program of "free church, free land, free schools, free labour." He was elected to the town council in 1869 and from then till 1873 worked for the realization of various projects of municipal reform. In 1873 the Liberals gained control of the

council and Chamberlain was chosen mayor, an office he retained by re-election until June 1876.

Chamberlain's work as mayor of Birmingham set an example which revolutionized English municipal life. The conference of local sanitary authorities summoned by him and held in Jan. 1875 was the beginning of the modern movement for better and healthier organization of town life. In Birmingham he carried through the municipalization of the gas and water supply and the improvement scheme by which slums were cleared away and 40 ac. laid out in new streets and open spaces. New municipal buildings were erected, Highgate park was opened for recreation and the free library and art gallery were developed. By his share in these reforms Chamberlain became not only one of Birmingham's most popular citizens but also a man of mark outside. He was a cool and hard-hitting orator. and his spare figure, incisive features and single eyeglass soon made him a favourite subject for the caricaturist. In private life he showed loyalty to his friends and what John Morley described as "a genius for friendship." His aggressiveness. however, made his actions and speeches the object of more controversy than was the lot of any other politician of his time. It may be added that his interest in Birmingham remained undiminished during his life. He was the founder and first chancellor of Birmingham university (1900). At his express wish, his family declined an offer for his burial in Westminster abbey so that he might be buried at Birmingham.

Parliamentary Beginnings. — At the general election of 1874 Chamberlain had stood unsuccessfully as parliamentary candidate for Sheffield. In 1876 he was returned to the house of commons, unopposed, as a member of parliament for Birmingham — John Bright's colleague. He had already shown much interest in education (having become chairman of the executive council of the new National Education league in 1870) and his maiden speech in the commons (Aug. 4, 1876) was on Lord Sandon's education bill. At this period, too, he paid considerable attention to the question of licensing reform.

After the general election of 1880 the prime minister, W. E. Gladstone, was compelled to recognize the services of the radicals in the election by the inclusion of Sir Charles Dilke and Chamberlain, who were sworn allies, in the new ministry. They had resolved together that one of them must be in the cabinet. Chamberlain. willing to give the preference to Dilke, was himself chosen as president of the board of trade. Dilke became undersecretary for foreign affairs but, at the end of 1882, he too entered the cabinet as president of the Local Government board, and the alliance between the two rising ministers was more powerful than ever. Gladstone, however, turned rather to his old friends, Lord Granville and Lord Spencer, and had little personal sympathy with the new men. Dilke and Chamberlain stood for more far-reaching social reforms at home than their elder colleagues, and they also differed on foreign affairs, demanding more vigorous measures in Egypt after the massacre at Alexandria (1882).

Irish Policy. — The deepest fissure, however, was on Irish policy. Chamberlain hated coercion, and in 1882 he was authorized to negotiate with the Irish Nationalist leader Charles Stewart Parnell The result was the "Kilmainham treaty." Parnell, on May 2, 1882, was released from Kilmainham jail, having agreed to advise the cessation of outrages and the payment of rent, while Gladstone's ministry was to relax its coercive administration. Thereupon, W. E. Forster, the Irish secretary, resigned. His successor, Lord Frederick Cavendish, was immediately murdered in Phoenix park, Dublin. Chamberlain, conspicuously marked out for the post of danger, was prepared to face the risk but was not appointed. Eventually, in 1885, after indirect negotiation with Parnell through Capt. William O'Shea, he placed before the cabinet a plan which would have devolved extensive autonomous powers on the Irish government without weakening the imperial connection. When his proposals came before the cabinet (May 9) all the members of the house of lords except Granville voted against them; of the members of the house of commons only the marquess of Hartington (afterward duke of Devonshire) opposed them. Proposals for a Coercion bill and a Land Purchase bill were then put forward. Dilke and Chamberlain resigned, but the resignations did not take effect before the government was defeated on the budget (June 8, 1885). Both before and after the defeat Chamberlain associated himself with what was known as the "unauthorized program"; *i.e.*, free education, small holdings for agricultural labourers, graduated taxation and local government.

At the general election of Nov. 1885 Chamberlain was returned for West Birmingham. The Liberal strength in the nation generally was, however. reduced so that the Irish vote became necessary to Gladstone if he was to command a majority. Chamberlain had an open mind on the Irish question. He foresaw that between Home Rule and separation there was but a step, and in a letter written on Dec. 26 he went so far as to discuss a federalist scheme for the British Isles with five separate parliaments. In December it was stated that Gladstone intended to propose Home Rule for Ireland, and when the new parliament met in Jan. 1886 Lord Salisbury's ministry was defeated. Lord Hartington and some other Liberals declined to join Gladstone in view of the altered attitude he mas adopting toward Ireland, but Chamberlain—stipulating for liberty of judgment on the prime minister's Irish policy when embodied in definite legislative shape--entered the cabinet as president of the Local Government board. On March 15, 1886, he resigned, explaining in the house of commons (April 8) that while he had always been in favour of the largest extension of local government to Ireland consistent with the integrity of the empire and the supremacy of the imperial parliament, he was unable to recognize that the scheme communicated by Gladstone to his colleagues maintained those conditions. In May the followers of Bright and Chamberlain, and those of Lord Hartington, decided to vote against the second reading of the Home Rule bill instead of pressing for modifications in committee, and on June 7 the bill was defeated, 93 Liberal Unionists — as they were generally called — voting against the government. Chamberlain was the object of bitter attacks from the Gladstonians for his share in this result. The ensuing general election, however, returned to parliament 316 Conservatives, 78 Liberal Unionists and only 276 Gladstonians and Nationalists. When the house met in Aug. 1886 it was decided by the Liberal Unionists, under Hartington's leadership. that their policy henceforth was essentially to keep Gladstone out. However, the old Liberal feeling still pi-evailing among them was too strong to permit their leaders to take office in a coalition ministry. Instead, Chamberlain determined to impose a progressive social policy on the Conservatives as the price of his indispensable support on the Irish question.

Chamberlain's view on domestic legislation transformed the Conservative party. Before 1892 he had the satisfaction of seeing Lord Salisbury's ministry pass such measures of social reform as those dealing with coal mines regulation, allotments, county councils, housing of the working classes, free education and agricultural holdings, besides Irish legislation like the Ashbourne act, the Land act of 1891 and the Light Railways and Congested District acts. In Oct. 1887 Chamberlain was selected by the government as one of the British plenipotentiaries to discuss the Canadian fisheries dispute with the United States, and a treaty was signed at Washington, D.C., on Feb. 15, 1888, which proved to be a real settlement.

At the general election of 1892 Chamberlain was re-elected for West Birmingham with an increased majority, but the Unionist party as a whole was narrowly defeated. The Irish Nationalist vote again held the balance in the house of commons and, with a small and precarious majority, Gladstone, on Feb. 13, 1893, introduced his second Home Rule bill. During the 82 days' discussion in the house of commons Chamberlain was its most unsparing critic.

Colonial Secretary. — In 1895, at his own request, Chamberlain became secretary of state for the colonies in Lord Salisbury's ministry. His influence in the Unionist cabinet was soon visible in the Workmen's Compensation act. However, after the Jameson raid (Dec. 1895) South Africa demanded the chief attention of the colonial secretary (see SOUTH AFRICA, UNION OF; TRANSVAAL). In his negotiations with Pres. Paul Kruger one masterful temperament was pitted against another. Chamberlain had a very difficult part to play in a situation dominated by suspicion on both sides.

The report of a commons committee (July 1897) definitely acquitted both Chamberlain and the colonial office of any privity in the Jameson raid, but Chamberlain's detractors continued to assert the contrary. Opposition hostility reached such a pitch that in 1899 there was hardly an act of the cabinet during the negotiations with President Kruger which was not attributed to the personal malignity and unscrupulousness of the colonial secretary. The Bloemfontein conference of 1899 was a serious attempt to secure amicable agreement, but its failure did not deter Chamberlain irom making repeated efforts to ensure peace. Once the South African War had begun, however, Chamberlain was the mainstay of British public opinion when nearly all the world was hostile. The "khaki" election, held at a moment of victory in 1900, was fought in effect under Chamberlain's leadership and on his policies.

Chamberlain's tenure of the office of colonial secretary between 1895 and 1900 must always be regarded as a turning point in the history of the relations between the British colonies and the mother country. In spirit he was an imperial federationist even before his separation from Gladstone. From 1887 onward he worked for the establishment of friendly relations between the different parts of the empire for purposes of defense and commerce. One of his successful achievements was the Australian Commonwealth act of 1900.

The support Great Britain received from the self-governing colonies during the South African War intensified Chamberlain's imperialism, and he became increasingly absorbed by the ideal of a united empire. The settlement after the war was full of difficulties, financial and other, in South Africa. In Nov. 1902 Chamberlain, bent upon a conciliatory settlement with the Boers, went to South Africa. He arranged with the leading Transvaal financiers that in return for support from the British government in raising a Transvaal loan they would guarantee a contribution of £30,000,000 which, by so much, should repay the British treasury the cost of the war.

Tariff Reform. — At the imperial conference of 1902 the attitude of the overseas premiers had shown that the only way toward a closer political union of the whole empire was on lines of mutually preferential commerce, deviating irom the strict traditional doctrines of free trade. Chamberlain therefore decided to introduce a measure of imperial preference. As a first step he proposed that the shilling registration duty on imported grain, a-hich had been reintroduced in the budget of 1902, should be remitted in favour of the colonies. C. T. (after ard Lord) Ritchie, the chancellor of the exchequer. demurred, but Chamberlain believed that he had convinced the rest of the cabinet and particularly the new prime minister, A. J. Balfour. While Chamberlain was in South Africa, however, Ritchie persuaded the cabinet members to change their minds, and Chamberlain returned, shortly before the introduction of the budget, to find that his proposal had been dropped. For the moment he remained in the cabinet, but the seed of dissension was sown. The first public expression of his views was given in an epoch-making speech to his constituents at Birmingham (May 15, 1903), when he outlined a plan for raising more money by a rearranged tariff, partly to obtain a preferential system for the empire and partly to produce funds for social reform at home. The fact that Chamberlain's policy involved the taxation of food gave his opponents a welcome opportunity to work up an extensive agitation against "the dear loaf." Chamberlain argued that since 1870 certain other countries (Germany and the United States) with protective tariffs had increased their trade in much larger proportion, while English trade had been chiefly maintained by the increased business done with British colonies. A scientific inquiry into the facts was needed. Balfour managed to hold his colleagues and party together by taking the line that particular opinions on economic subjects should not be made a test of party loyalty. However, the activities of the Tariff Reform league, founded to further Chamberlain's policy, aroused Chamberlain's free-trade colleagues inside the cabinet, and in Sept. 1903 the crisis came to a head. The public had its first intimation of impending events with the appearance on Sept. 16 of Balfour's *Economic Notes* on *Insular Free Trade*. The next day appeared the board of trade fiscal blue book, and on the 18th conflicting resignations were announced — not only of the more rigid free traders in the cabinet. Ritchie. Lord Balfour of Burleigh and Lord George Hamilton, but also of Chamberlain himself for the opposite reason.

A cordial exchange of letters between Chamberlain and Balfour was published. Chamberlain pointed out that he was committed to a preferential scheme involving new duties on food and could not remain in the government without prejudice while it was excluded from the party program. Remaining loyal to Balfour and his general objects, he could best promote this course irom outside. Balfour, while reluctantly admitting the necessity of Chamberlain's taking a freer hand, expressed his agreement in the desirability of a closer fiscal union with the colonies, but questioned the immediate practicability of any specific plan. He was willing to adopt fiscal reform so far as it covered retaliatory duties, but thought that the exclusion of taxation of food from the party program was in existing circumstances necessary, so long as public opinion was not ripe. The fact that Chamberlain's son, Austen. remained in the cabinet and was promoted chancellor of the exchequer suggested that there was an underlying agreement between Chamberlain and Balfour and that the two would join forces again once Chamberlain had won over public opinion to his policy.

The tariff reform movement itself was now outside the purely official program, and Chamberlain (backed by a majority of the Unionist members) threw himself with impetuous ardour into a crusade on its behalf. On Oct. 6, 1903, he opened his campaign with a speech at Glasgow. His positive proposals were: (1) no tax on raw materials; (2) a small tax on food other than colonial, *e.g.*, two shillings a quarter (eight bushels) on foreign grain other than maize and 5% on meat and dairy produce excluding bacon; (3) a 10% general tariff on imported manufactured goods. To meet any increased cost of living. he proposed to reduce the duties on tea, sugar and other articles of general consumption. This speech was the type of others that followed quickly during the year. At Greenock he emphasized the necessity of retaliating against foreign tariffs:"Agriculture has been practically destroyed, sugar has gone, silk has gone, iron is threatened, wool is threatened. cotton will go! How long are you going to stand it?" On Jan. 18, 1904, Chamberlain ended his series of speeches by a meeting at the Guildhall. in the City of London, the keynote being his exhortation to his audience to "think imperially." In the session of 1904 he tried to persuade Balfour to go to the country in the autumn on a policy of tariff reform. He failed in this and, instead, launched a second public campaign.

In Jan. 1905 correspondence was published between Chamberlain and the duke of Devonshire relating to difficulties arising from the central Liberal Unionist organization's subsidizing local associations which had adopted the program of tariff reform. The duke objected to this departure from neutrality. Chamberlain retorted that this was a matter for a general meeting of delegates to decide. If the duke was outvoted he might resign his presidency. For his own part he mas prepared to allow the local associations to be subsidized impartially, so long as they supported the government, but he was not prepared for the violent disruption, which the duke apparently contemplated, of an association so necessary to the success of the Unionist cause. The duke replied that the differences between them were vital, and he would not be responsible for dividing the association into sections, but mould rather resign. Chamberlain then called a general meeting in February, when a new constitution was proposed. In May, at the annual meeting of the Liberal Unionist council, the "free food" Unionists, being in a minority, retired, and the association was reorganized under Chamberlain's auspices, Lord Lansdowne and Lord Selborne (both cabinet ministers) becoming vice-presidents. Meanwhile Chamberlain's supporters in the Conservative party succeeded at three successive party conferences (1903, 1904 and 1905) in carrying, by overwhelming majorities, resolutions in favour of tariff reform.

In reply to Balfour's appeal for the sinking of differences (Newcastle, Nov. 14, 1905), Chamberlain insisted at Bristol (Nov. 21) on the adoption of his fiscal policy; and Balfour resigned on

Dec. 4 on the ground that he no longer retained the confidence of the party. At the crushing Unionist defeat in the general election in Jan. 1906, Chamberlain was triumphantly returned for West Birmingham and all the other divisions of Birmingham returned Chamberlainite members. This, by contrast with the national disaster to the Unionist party as a whole, was one of the most astonishing events in British electoral history.

In the first weeks of the session of 1906 Chamberlain acted as leader of the opposition, but he had no desire to set himself up as leader in Balfour's place and a common platform was arranged between them on which Balfour should continue to lead the remnant of the party. A letter from Balfour of Feb. 14 admitted the necessity of making fiscal reform the first plank in the Unionist platform and accepted a general tariff on manufactured goods and a small duty on foreign grain.

Chamberlain's own political activity was cut short in the middle of the session of 1906. His 70th birthday was celebrated in Birmingham with immense enthusiasm, but the effort of this celebration on top of years of overwork proved too much. Immediately afterward he had a stroke of paralysis. For some time his adherents hoped that he might return to the house of commons, but he was never able to speak in public again and although he was returned unopposed at the general elections of 1910, he appeared in the commons on only two occasions.

He died at his house in London on July 2, 1914. In his last speech (July 9, 1906) he had uttered words which may fairly be given as his political testament: "The union of the Empire," he said, "must be preceded and accompanied by a better understanding, by a better sympathy. To secure that is the highest object of statesmanship now at the beginning of the 20th century; and if these were the last words that I were permitted to utter to you, I would rejoice to utter them in your presence, and with your approval. I know that the fruition of our hopes is certain."

In municipal, national and imperial politics alike, Chamberlain showed himself essentially a constructive radical, more concerned with getting things done than with theoretical considerations or party loyalties. His progress from the extreme left wing of Liberalism to the leadership of the imperialist movement epitomizes the rise of the industrial middle classes of Britain in the period between the first Reform bill and World War I. However, his championship of social reform, foreign alliances, imperialism and protection was, in each case, a direct challenge to the prevailing doctrines of *laissez faire,* "splendid isolation" and free trade. He was thus a forerunner and inspirer of the themes that were to dominate British politics in the generation following his death.

Chamberlain married three times: in 1861, Harriet Kenrick (d. 1863); in 1868, Florence Kenrick (d. 1875), a cousin of his first wife; and in 1888 Mary Endicott, daughter of the U.S. secretary of war in Pres. Grover Cleveland's first administration. His two sons, Austen (by his first wife) and Neville (by his second), both rose to political prominence and are separately noted.

Biographies: The official biography is *The Life of Joseph Chamberlain* 5 vol. (1932 *et seq.*), vol. i–iii by J. L. Garvin (1932–34) and vol. iv by H. J. Amery (1951). There are also lives by N. M. Marris (1900); S. H Jeyes (1903); Louis Creswicke, 4 vol. (1904); A. Mackintosh (1906); Lord Milner, J. Spender, Sir H. W. Lucy *et al.* (1912); Sir Charles Petrie (1940). (H. C.; H. J. Ay.)

CHAMBERLAIN, (ARTHUR) NEVILLE (1869–1940), British statesman whose name is closely associated with the policy of "appeasement" toward Germany in the years immediately preceding World War II, was prime minister from 1937 to 1940. He was born at Edgbaston, Birmingham, on March 18, 1869, the son of Joseph Chamberlain (*q.v.*) by his second wife, Florence Kenrick. Intended for a business career, he was educated at Rugby and at Mason college, Birmingham (later Birmingham university), and then went to Andros Island in the Bahamas, where for seven lonely years he struggled unsuccessfully to bring a sisal plantation of his father's to prosperity. On his return in 1897 he entered business in Birmingham. He was chairman and manager of two small but successful metalworking firms, active in the chamber of commerce and chairman of the general hospital. He entered the city council in 1911 and was lord mayor in 1915; Birmingham's unique municipal savings bank, started in 1916. mas his creation. He was brought to London by David Lloyd George. then prime minister, as director-general of national service in Dec. 1916, but was given insufficient powers and resigned after seven months. His consequent dislike for Lloyd George was never forgotten, and was an important factor in the later careers of both men, spurring Chamberlain to vindicate himself in a political career.

Chamberlain entered parliament in his 50th year, being elected, as a Conservative, for the Ladywood division of Birmingham in the general election of Dec. 1918. When Lloyd George's coalition government fell in Oct. 1922, Chamberlain temporarily parted company with his half-brother Austen and joined the Conservative government of Andrew Bonar Law as postmaster general. In Feb. 1923 he entered the cabinet as minister of health, and in August he became chancellor of the exchequer in Stanley Baldwin's government (which fell in the following January). On the return of the Conservatives to power in Nov. 1924, he again became minister of health. As such, he was responsible for a notable program of legislation, particularly widows', orphans' and old-age contributory pensions (1925) and the Local Government act, 1929. His position as potential leader of the party in succession to Baldwin was now assured, and was strengthened by his reorganization of the Conservative central office as chairman of the party in 1930.

Chamberlain played a large part, as Baldwin's deputy, in the formation of the national government of Ramsay MacDonald in Aug. 1931, and was minister of health in it. After the return of the national government at the general election of Oct. 1931 he became chancellor of the exchequer. His main achievements during his five and a half years' tenure of this office were the maintenance of a balanced budget, the ending of the "economy cuts" in 1934–35, the conversion of £2,000,000,000 of 5% war loan to 3½% in 1932, the beginning of rearmament in 1934 and the introduction of a general tariff—his father's old ambition—in the Import Duties act of 1932. He supported the policy of sanctions against Italy at the start of the Abyssinian war in 1935, but was the first member of the cabinet to advocate publicly their abandonment in 1936.

Chamberlain succeeded Baldwin as prime minister on May 28, 1937. His term of office was dominated by the aggressions of Hitler's Germany in Europe, which Chamberlain attempted to limit by diplomatic negotiations in which he took, for a prime minister, an unusually large and personal part. His policy of appeasement, generally popular at the time, aimed first to detach Italy from Germany (the Anglo-Italian agreement of April 16, 1938). It culminated in his three visits, by air, to Hitler in Sept. 1938 in order to prevent Germany's demands for the cession of the Sudeten territories by Czechoslovakia from leading to a general European war. The Munich agreement (Sept. 30) conceded to Hitler virtually all his demands and left Czechoslovakia defenseless. Chamberlain returned a popular hero, but the precariousness of the peace was shown by the great acceleration of rearmament which he immediately instituted. When Hitler seized the rest of Czechoslovakia on March 15, 1939, Chamberlain abandoned appeasement, and on March 31 announced that Great Britain would guarantee to Poland its assistance against a similar attack. Military conscription (for the first time during peace) was introduced in April. Chamberlain's efforts were now directed toward preparing for war while attempting to discourage Hitler from making it, both by warning him that Great Britain would fight and by attempting to negotiate a pact of mutual assistance between Great Britain, France and the U.S.S.R. in the event of war. The conclusion of the Soviet-German treaty on Aug. 23 frustrated this policy. When the Germans attacked Poland on Sept. 1, Chamberlain countered with Great Britain's declaration of war on Germany on Sept. 3.

Chamberlain remained prime minister during the period of the "phony war," reforming his cabinet to include Winston Churchill; Liberals and Labour refused to join it. After the failure of the

British expedition to Norway in April *1940,* Chamberlain's policies were debated in the house of commons, and the defection of his Conservative critics so reduced his majority that he resigned on May *10* (the day of the German invasion of the Low Countries). He remained in Churchill's coalition government as lord president of the council until ill-health compelled him to resign this office and the leadership of the Conservative party on Sept. *30.* He died at Heckfield, near Reading, on Nov. 9, *1940.*

In appearance, Chamberlain was somewhat harsh and gloomy. He was an able executive, very clearheaded. rather autocratic in manner (particularly as prime minister) and intolerant of minds weaker than his own. He was perhaps too ready to believe Hitler's fair words and to sacrifice Czechoslovakia at Munich, but he strove hard and bravely to preserve peace, convinced that his policy was the only possible one, and he brought the British peoples into the war, when it came, united. His supporters claim that by the Munich agreement Britain gained valuable time for rearmament; his critics argue that the loss of possible allies in *1938* offset this advantage. His support of Churchill as his successor in *1940* was magnanimous and invaluable.

CHAMBERLAIN, OWEN *(1920–*), U.S. physicist and Nobel prize winner, who with Emilio Segrb confirmed the existence of the antiproton, was born in San Francisco, Calif., on July *10. 1920.* After he was graduated from Dartmouth college (1941), he served from *1942* to *1946* as a physicist with the Manhattan Engineering District, the project which developed the atomic bomb. He later worked at the Argonne National laboratory near Chicago. Ill., while completing studies for his Ph.D. in physics at The University of Chicago. In *1948* he joined the faculty of the University of California, where his research dealt with alpha-particle decay, neutron diffraction in liquids and high-energy nucleon scattering. He and Segrè, using the proton beam from the powerful bevatron at the University of California's radiation laboratory in Livermore, produced antiprotons *(1955).* A negatively-charged elementary particle, the antiproton had been long thought to exist, but its existence had not previously been proven. For their discovery, Chamberlain and Segrb were awarded the *1959* Nobel prize in physics.

CHAMBERLAIN, originally an officer of a sovereign's court, charged with the superintendence of certain domestic affairs. The functions of chamberlains, however, differed according to the two meanings acquired in the early middle ages by the Latin word *camera,* which might denote (1) the royal treasury or *(2)* the king's bedchamber. Whereas the *camerarius* of the Carolingian sovereigns of western Europe was their treasurer, the terms *camberlanus* and *cambellanus* came to be used in medieval Latin as synonyms for *cubicularius,* the proper designation of an official whose function was to attend on the king's person, as the *praefectus sacri cubiculi* ("prefect of the sacred bedchamber") had attended on the Roman emperors.

England. — The *hordere* (Lat. *thesaurarius*) under the Anglo-Saxon kings was the equivalent of the Carolingian *camerarius,* namely the royal treasurer. With the marshal, he was the principal officer of the king's court. After the Norman conquest the chamberlain's functions became manifold. As he had charge of the administration of the royal household. his office was of financial importance, for a portion of the royal revenue was paid, not into the exchequer, but into the *camera regis.* In time the office became hereditary and titular, but the complexity of the duties necessitated a division of the work, and the office was split up into three: the hereditary and sinecure office of *magister camerarius* or lord great chamberlain *(q.v.);* the more important domestic office of *camerarius regis,* king's chamberlain or lord chamberlain *(q.v.);* and the chamberlains (*camerarii*) of the exchequer, who were originally representatives of the chamberlain at the exchequer and afterward in conjunction with the treasurer presided over that department. In *1826* the last of these officials died, when by an act passed *44* years earlier they disappeared.

The modern English representatives of royal chamberlains in the sense of *cubicularii* are the gentlemen and grooms of the bedchamber.

France. — The successor of the Carolingian *camerarius* in the French kingdom was the *grand chambrier de France,* whose *chamberie* came to be held as a fief of the crown. Held by great nobles seldom at court, this office became more and more honorary until it disappeared with Henry II's accession to the crown (Henry himself had previously held it). Meanwhile its functions had long been overshadowed by the growing power of the *chamberlains* (Lat. *cubicularii, cambellani,* but sometimes even *camerarii* also), who had originally been men of low birth in attendance on the king's person. As the office of the *grand chambrier* declined, so the *chamberlains* advanced in numbers and in rank until, in the 13th century, one of them emerges as a great officer of state, the *chambellan de France* or *grand chambellan,* who at times shares with the *grand chambrier* the revenues derived from certain trades in the city of Paris. The office of *grand chambellan,* which in its turn soon became purely honorary, survived till the Revolution. Among the prerogatives of the *grand chambellan* was the right to hand the king his shirt at the ceremonial levee. The offices of *grand chambellan, premier chambellan* and *chambellan* were revived by Napoleon. continued under the Restoration, abolished by Louis Philippe and restored by Napoleon III.

Germany. — The *Erzkammerer (archicamerarizis,* "archchamberlain") of the Holy Roman empire represented the Carolingian *camerarius* in later times. This office was a hereditary perquisite of the electors of Brandenburg from *1415.* The term equivalent to *cubicularius* was *Kämmerer* in Austria and in Bavaria, *Kammerherr* or *Kammerjunker* elsewhere in Germany. These personal chamberlains used to carry a golden key attached to the back of their coats as insignia of their office.

The Vatican. — In the Roman curia the apostolic chamberlain (*camerarius;* It. *camerlengo*) is at the head of the treasury of the Holy Roman Church and, in the days of the temporal power, not only administered the papal finances but possessed an extensive civil and criminal jurisdiction. During a vacancy of the Holy See he is at the head of the administration of the Roman Catholic Church. The office dates from the 11th century, when it superseded that of archdeacon of the church. The various privy chamberlains of the papal *famiglia,* on the other hand, are *cubicularii* (It. *camerieri; see* VATICAN, THE).

Other Uses of the Term. — Monasteries and cathedrals used also to have chamberlains, in imitation of the courts of secular princes. These chamberlains had charge of the finances, gave notice of chapter meetings and provided the materials necessary for religious services. Likewise, corporations appoint a chamberlain. The chamberlain of the corporation of the City of London, for instance, is the treasurer of the corporation, admits persons to the freedom of the City and, in the chamberlain's court, of which he and the vice-chamberlain are judges, exercises concurrent jurisdiction with the police court in determining disputes between masters and apprentices. Formerly nominated by the crown, after *1688* he was elected annually by the liverymen.

CHAMBERLAYNE, WILLIAM *(1619–1689),* English poet whose heroic verse romance *Pharonnida (1659)* offers to those who brave its complexities and length some treasures of poetic invention and imagery. Born in *1619* at Shaftesbury, Dorset. he practised there as a physician. fought on the royalist side in the Civil War, being present at the second battle of Newbury, and died at Shaftesbury in Jan. *1689.* His royalist feeling is shown in his tragicomedy, *Love's Victory* (1658), which has fine lines hidden among its bombast, and in *England's Jubile* (1660), a poem in honour of the Restoration. The poet Robert Southey and the critic George Saintsbury both praised Chamberlayne, and the latter reprinted *Pharonnida* in his *Minor Poets of the Caroline Period,* vol. i *(1905).* S. W. Singer also reprinted *Pharonnida* and *Love's Victory* in *1820.*

CHAMBERLEN, the name of a family of English medical

men, whose claim to remembrance is the parts they played in the introduction of the midwifery (obstetrical) forceps.

WILLIAM CHAMBERLEN, the founder of the family, went to England as a Huguenot refugee in 1569. His son PETER CHAMBERLEN the elder (d. 1631) was a surgeon at Southampton and later in London. where he was admitted to the Barber Surgeons' company. He enjoyed a great reputation as an accoucheur and attended the queens of James I and Charles I. In spite of his connection with the court, he was in constant conflict with the College of Physicians because of his alleged irregular practice. PETER CHAMBERLEN the younger (1572–1626), his younger brother, practised as surgeon and man midwife in London and was also often in conflict with the licensing authorities. In 1616 he put forward an unsuccessful scheme for the incorporation of the midwives in London. PETER CHAMBERLEN (1601–83), son of Peter Chamberlen the younger, one of the physicians to Charles II, attempted to revive his father's scheme for a company of midwives and was also known as an advocate of public baths. HUGH CHAMBERLEN the elder (1630–?), his eldest son, is best known as the originator of various projects relating to land banks: state medical services and the prevention of plague. His eldest son, also HUGH CHAMBERLEN (1664–1728), was a fashionable physician who numbered among his patients Dean Swift and Bishop Atterbury. There is a monument to him in Westminster abbey. PAUL CHAMBERLEN (1635–1717), the second son of Peter, practised as an accoucheur in London and invented a quack remedy known as the "anodyne necklace" to facilitate the cutting of babies' teeth.

It is probable that the first Peter Chamberlen was the inventor of the midwifery forceps, but Hugh Chamberlen the elder was the chief exploiter of the iamily secret and by his position as accoucheur at the court and his contacts abroad did most to spread the use of the forceps. The forceps themselves were lost to the world for more than 100 years until in 1813 four sets were discovered in a box hidden under a floor board at Woodham Mortimer hall. near Maldon. Essex. a house occupied by Peter Chamberlen in the time of Charles II. The secrecy which the Chamberlens maintained in regard to the nature of their invention has been strongly condemned.

See W. Radcliffe, *The Secret Instrument: the Story of the Chamberlen Forceps* (1947). (W. J. BR.)

CHAMBERLIN, THOMAS CHROWDER (1843–1928), U.S. educator and geologist. is noted as the author of the planetesimal hypothesis of the origin of the planets. Born at Mattoon, Ill., on Sept. 2j, 1843, he graduated from Beloit college, Beloit, Wis., in 1866 (A.B.) and returned to the college in 1873 as professor of geology. He served also as assistant state geologist of Wisconsin until 1876, when he was made chief geologist of the Wisconsin geological survey (1876–82). From 1882 to 1887 he served as U.S. geologist in charge of the glacial division; from 188; to 1892, as president of the University of Wisconsin, Madison; from 1892 to 1919, as head of the geological department of The University of Chicago, retiring as professor emeritus in 1919. He studied glaciers in Switzerland in 1878 and in Greenland in 1894, as geologist to the Peary relief expedition. His principal scientific work in later years was the study of fundamental problems of geology, particularly as related to the origin and growth of the earth. His planetesimal hypothesis was that a passing star might have caused eruptions from the sun: solid particles mould gravitate and. falling like snow, produce the earth without melting. Others argued that there must be melting or dispersion.

His chief publications are *Geology of Wisconsin,* 4 vol. (1873–82); *Reports of the Glacial Division U.S. Geological Survey* (1882–87): a three-volume treatise on geology (with R. D. Salisbury, 1906); reports on researches on certain fundamental problems in geology to the Carnegie Institution of Washington, *Year Books* 2 to 27; *The Tidal and Other Problems* (1909); "Diastrophism and the Formative Processes," numerous articles in the *Journal of Geology,* vol. xxi (1913–21); *The Origin of the Earth* (1916); *The Two Solar Families: the Sun's Children* (1928).

CHAMBER MUSIC, a term usually applied to music written for from two to nine or ten solo instruments, each playing an independent part equal in importance with the rest, and generally though by no means invariably planned on the lines of the four-movement sonata (*q.v.*). The "classical" age of chamber music began in the late 18th century with the string quartets of Franz Joseph Haydn, and the string quartet (two violins. viola and 'cello) has been the favourite and most important combination ever since, but intimate music for small instrumental ensembles had flourished for centuries before Haydn.

Pre-Classical Chamber Music.—The phrase *musica da camera* seems to have appeared first in Italy in the latter part of the 16th century to indicate any kind of music not intended for use in church or for a dramatic or festive purpose; it was not limited to instrumental music and the first publication to which the English term was applied—Martin Peerson's *Mottects or Grave Chamber Musique* (1630)—consisted of "Songs of five parts . . . fit for Voyces and Vials, with an Organ Part." There was at this period still no sharp differentiation between vocal and instrumental music (other than that written for lutes or keyboard instruments) and vocal ensemble music was commonly performed partly or wholly on instruments, yet even the middle ages had been acquainted with purely instrumental compositions other than those written for dancing; a 13th-century manuscript at Bamberg contains three-part instrumental motets ("In seculum viellatoris") and the 15th-century Trent codices have preserved at least one indisputably instrumental trio. In the collections printed from the 1530s onward by continental and (later) English publishers as "suitable to sing and play on any sort of instrument" or "apt for the Viols and voices," unmistakably instrumental pieces appear; the style of these *ricercari, canzoni* and *fantasie* (in English, "fancies") is based on vocal motets or polyphonic chansons but was modified more and more by considerations of instrumental technique. Such are the two "Fantazias," one for four (no. 15), the other for six viols (no. 26), of the *Psalmes, Songs, and Sonnets* published in 1611 by William Byrd.

The favourite combination was the homogeneous "consort" of viols, though mixed ensembles (broken consorts) were also common, but no particular instruments were specified by composers until the last years of the 16th century: by Giovanni Gabrieli in some of the *canzoni da sonar* of his *Sacrae symphoniae* (book i) (Venice, 1597) and Thomas Morley in his *First Booke of Consort Lessons, Made by Diuers Exquisite Authors for Six Instruments* (1599).

Although the viols were gradually superseded by the violin family and the polyphonic style was succeeded by one in which one or two melodic lines were accompanied by a bass *(basso continuo)* over which a keyboard player or lutenist filled out the harmony in accordance with a shorthand of figures, the "sonatasn" of the early 17th century were still modeled to some extent on vocal prototypes. However, the development of violin technique brought complete emancipation. Just as the vocal monody was paralleled by the solo sonata, the then-favourite form of the vocal duet with continuo suggested a type of instrumental canzone or "sonata" in which two instruments duetted in the same way; indeed the duet sonata appeared (in Salomone Rossi's *Varie sonate,* 1613) before the solo (in Biagio Marini's *Affetti musicali,* 1617). The duet sonata has become universally known as the "trio sonata" from the circumstances that it was conceived in three "real" parts and that in the course of time the bass exchanged its merely supporting function for a more active role in the thematic interplay; it became the most important type of baroque chamber music. But while the instrumental combination remained constant, the structure underwent various changes. The connected sections of the *canzone,* with their contrasts of pace and rhythm, had become by the 1660s four or five separate, self-contained "movements"—as in the *Sonate,* op. 2 (1667), of the Bolognese violinist-composer, G. B. Vitali (*q.v.*). Generally consisting of two slow movements alternating with two quick ones and commonly used in Italy, like the earlier *canzoni* for preludes and interludes in church services, such sonatas were known as *sonate da chiesa* ("church sonatas"). At the same time another type of sonata derived from the dance suite was known as *sonata da camera* ("chamber sonata"). The two types reached classical perfection in the *sonate da chiesa* (1681 and 1689) and *da camera* (1685 and 1694) of Arcangelo Corelli

(*q.v.*), the last and greatest of the Bolognese school. But there had always been some interchange between the two types; even Vitali's *sonate* da ckiesa sometimes have gigue-like last movements; and after Corelli they became so assimilated that the distinction disappeared. The trio sonatas of Handel and his generation represent the final maturity of the form.

The trio sonata was originally and essentially an Italian form. Henry Purcell's two sets of sonatas (1683; 1697) were confessedly written in "imitation of the most fam'd Italian Masters" (in particular, Vitali); and although trio sonatas had been published in Germany (*e.g.* by Johann Pachelbel and Dietrich Buxtehude in the 1690s) the classic form seems to have been introduced there by the Veronese E. F. dall'Abaco, whose op. 3 (Paris. c. 1712) is outstandingly fine. The much earlier (1667) *Sonate* da camera of Johann Rosenmiiller were five-part works, published in Venice. In France even Couperin fell victim to the fashionable "fureur de composer des sonates à la manière italienne" and, despite characteristic picturesque, even programmatic elements (as in Le *Parnasse,* ou *L'Apothéose* de Corelli, 1725), his chamber works are the most Italianate of all his compositions.

Trio sonatas and other instrumental compositions of the baroque period were normally performed by one player to each part other than the bass, which would be both played on a stringed instrument (or bassoon) and filled out by organist or harpsichordist But there was no distinction between "chamber" music in the modern sense and orchestral music. A number of movements in Handel's trio sonatas figure, with or without additional viola parts, in his overtures and concertos, and as late as the middle of the 18th century passages in trio sonatas were sometimes marked tutti, indicating that trios could be converted into concertos by employing additional players for the passages so marked. Nor was there any differentiation between chamber and orchestral in the instrumental works—divertimenti, *quadri,* quartetti and the rest—in the new style that was replacing the baroque and was to lead to Viennese classicism. Johann Stamitz's op. 1 (Paris, c. 1755) consisted of *Sonates . . .* ou a *trois* ou avec *toutes* [sic] *l'orchestre.* Haydn's earliest "string quartets," op. 1 and 2 (composed in the 1750s), were not originally so called; they certainly need a double bass in addition to the 'cello; parts for oboes and horns exist for op. 1, no. 5. and horn parts for op. 2, nos. 3 and 5.

Classical Chamber Music.—It was principally in Haydn's hands that the quartet for solo strings established itself as a favourite form of instrumental music during the latter part of the 18th century, among the innumerable combinations of strings and wind (with or without *continuo*) that flourished during the age of rococo. In his op. 17 set (composed in 1771) the virtuoso first-violin parts are unmistakably for a solo player; henceforth there was a real chamber style, distinct from an orchestral one. In op. 20 (1772) the other instruments in the quartet began to assert their individual voices, if not yet to claim equality with the leader, and in op. 33 (1781), "written" (as he himself pointed out) "in an entirely new manner," Haydn employed that fragmentation of thematic material and distribution of it among all four instruments that was to give the classical string-quartet style its character of a conversation between equals.

The keyboard continuo disappeared from the string quartet but lingered on in other combinations long after it was redundant; characteristically, Johann Christian Bach's Quintets, op. 11, for flute, oboe, violin, viola and bass, were originally published about 1777 with the bass figured while another contemporary edition omitted the figuring. On the other hand, fully written-out keyboard parts now became more common. Johann Christian's father, Johann Sebastian, had written six sonatas for violin and cembalo concertante: that is, true duets for violin and harpsichord, not accompanied violin solos. Very typical of the midcentury are Franz Xaver Richter's *Sonate* da camera for flute (or violin), 'cello and harpsichord obbligato. But such works are not the true ancestors of the Viennese classical "violin sonata" (piano and violin duet) and "piano trio" (piano, violin and 'cello). These sprang from the keyboard sonatas, popular from the 1760s onward, which were provided with ad libitum parts for violin or violin and 'cello. Even Haydn seldom liberated the strings from this unaccustomed subordinate role; the process of gradual emancipation can be traced in Mozart but was really completed only with Beethoven.

Mozart took over the developed form of string quartet from Haydn, imbued it with his own personal qualities, above all in the sets dedicated to Haydn (1785) and to Frederick William II of Prussia (1791), and in turn influenced the last and greatest of Haydn's quartets, most of which (from op. 71 onward) were written after the younger composer's death. Beethoven's first six quartets, op. 18 (published 1801), already showed a strongly marked creative personality without adding anything remarkable to the medium as such, but in the three quartets, op. 59 (published 1808), dedicated to Count Razumovsky, the dimensions are enormously extended; in architecture, though not in texture, the "Razumovsky" quartets are really symphonic. Two quartets, op. 74 and 95, written in 1809 and 1810, return to more normal dimensions, though they are adventurous in style, and in the last five—six if the Grosse Fuge originally composed as the finale of op. 130 is included—the so-called "posthumous quartets" op. 127, 130, 131, 132 and 135 (composed 1824–26) Beethoven advanced into a world of sound that even he had never entered before and where the most sympathetic of his contemporaries were unable to follow him. Ellipsis, deliberate sketchiness of texture and disregard of euphony combined to puzzle the musicians of the next generation as well; it was not until 1853 that the C sharp minor Quartet, op. 131, was "made clear" to Wagner "for the first time."

While the string quartet was Beethoven's favourite chamber-music medium, he also embodied some of his finest music in duet sonatas for violin or 'cello with piano and in the piano trio. On the other hand, his only string quintet, though fine, is an early work whereas Mozart's string quintets are among the finest of his mature chamber compositions. They are scored with two violas whereas Schubert, in his great C major Quintet, op. 163, followed Luigi Boccherini (*q.v.*) in using two 'cellos. Schubert's chamber music is mostly for quartet or piano trio, but he also wrote a superb string and wind Octet, op. 166, deliberately as a companion piece to Beethoven's early Septet, op. 20, and the popular "Trout" Quintet, op. 114, for an ad *hoc* combination of violin, viola, 'cello, bass and piano.

The piano quartet (piano, violin, viola and 'cello) was taken over by Mozart from Johann Christian Bach and other composers of that generation but it never seriously attracted Beethoven; despite the popular Schumann specimen, op. 47, it was really left to Brahms, Dvofhk and Fauré in the late 19th century to exploit its possibilities. As for the combination of piano with string quartet (piano quintet), which one might have expected to be popular. this was long left to minor masters such as Prince Louis Ferdinand of Prussia; the earliest example by a well-known composer is that (op. 44) by Schumann (1842), by whose time the piano had developed more power; next came op. 34 of Brahms (1864) and after that a small but distinguished series of successors by Franck, Fauré, Dvořák, Reger, Florent Schmitt and others. As for the "clarinet quintet" (clarinet and string quartet), the challenge of Mozart's great exemplar was never seriously taken up until Brahms ventured at the very end of his life (op. 115). Chamber-music composers tend to be conservative in their choice of media—in which they are wise since it is more difficult to find ensembles to play unusual combinations—and some innovations, such as Ludwig Spohr's double quartets (employing two string quartets antiphonally), have completely failed to establish themselves.

Post-Classical Chamber Music.—The chamber music of the middle and later 19th century has certain marked characteristics, notably domination by the piano even in the nature of the string-writing. This is very marked in Schumann and Mendelssohn, and is also perceptible in Brahms. Shorter and lighter forms were introduced, from Schumann's *Phantasiestücke,* op. 88, for piano trio to Glazunov's Novelletten for string quartet, op. 15. The true nature of chamber music was sometimes lost sight of as composers became conscious that their quartets and trios would be performed not only in intimate circles but also in fairly large concert halls; the fine workmanship of the classical quartet texture was too often forgotten and quasi-orchestral effects introduced,

as in Tchaikovsky's Piano Trio. op. 50. composed in 1882 in memory of Nicholas Rubinstein. The Tchaikovsky Trio has as its second and last movement a gigantic set of variations. each of which is associated with an (unspecified) episode of Rubinstein's life; it is therefore program music with an enigmatic program. But. on the whole. the 19th-century vogue for program music left chamber composition untouched: the only really successful example is Smetana's autobiographical String Quartet in E minor. *From my Life* (1876), which is also marred by passages of quasi-orchestral writing. The true tradition of classical chamber music was preserved during the latter part of the century by Brahms and Dvořák in central Europe. Borodin and Taneev in Russia. and Franck, d'Indy and Fauré in France.

Chamber music. by its nature. is not in itself an experimental medium. The 20th century has seen the employment of unusual combinations such as Debussy's Sonata for flute. viola and harp (1916) and Webern's Quartet for violin, clarinet. saxophone and piano (1930), the co-option of the human voice to the string quartet as in Schonberg's op. 10 (1908) (as distinct from the use of chamber-music combinations to accompany the human voice. as in Vaughan Williams's song cycle *On Wenlock Edge,* 1909), and the introduction of new technical devices of string-writing in the quartet itself by Bartok, Stravinsky and others. It has seen a vogue—perhaps suggested by Wagner's *Siegfried Idyll* (1870)—for the chamber orchestra (an orchestra of solo instruments), which has been used not only in "chamber symphonies" such as Schonberg's two (1906 and 1939) but also in opera (*e.g.* Britten's *The Rope of Lucretia* [1946] and *Albert Herring* [1947]). Yet such innovations have proved no more than sidetracks leading to no very important consequences. Most of the important chamber music of the 20th century has been conceived for the established "classical" combinations, above all for the string quartet. which has proved the most adaptable of media and as suited to impressionism. neoclassicism. polytonality and 12-note serialism as to the idioms of the Viennese classics or those of 19th-century romanticism. Such profoundly different 20th-century masters as Bartok. Milhaud and Shostakovich have put much of the best of themselves into their series of quartets, and hardly any instrumental composer of any significance has failed to contribute at least one work to the literature. The duet sonata for piano and some other instrument (usually the violin) has remained almost equally popular—the various examples by Debussy. Hindemith. Janáček, Bartók and Copland (to take names almost at random) are among the established masterpieces of 20th-century music—and the other conventional combinations hardly less so: the piano quintet, piano trio and string trio have inspired outstanding works by musicians as diverse as Florent Schmitt and Shostakovich, Ravel. Roussel and Webern.

CHAMBER OF COMMERCE: *see* TRADE ORGANIZATION.

CHAMBERS, EPHRAIM (c. 1680–1740), English encyclopaedist whose work inspired the 18th-century French encyclopaedists. He was born at Kendal, Westmorland, and apprenticed to a globe maker in London. The first edition of his *Cyclopaedia, or Universal Dictionary of Arts and Sciences* appeared in 1728, and its success led to Chambers' election to the Royal society. The *Encyclopédie* of Diderot owed its inception to a French translation of Chambers' work. Chambers also wrote for the *Literary Magazine* (1735–37) and translated the *Practice of Perspective* from the French of Jean Dubreuil and. with John Martyn, the hotanist, the *History and Memoirs of the Royal Academy* of *Sciences at Paris* (1742). He died on May 1j, 1740.

For a detailed description of the plan of his *Cyclopaedia, see* the article ENCYCLOPAEDIA.

CHAMBERS, ROBERT (1802–1871), Scottish author, publisher and, with his brother William, founder of the firm of W. and R. Chambers and of *Chambers's Encyclopaedia,* was horn at Peebles on July 10, 1802. In 1818 Robert began business as a bookstall keeper in Edinburgh, and became the friend of many literary figures. including Sir Walter Scott. who greatly admired his *Traditions of Edinburgh* (1825). Numerous other historical, literary and geological works followed. many based on his personal research. *Vestiges of the Natural History of Creation* (1844) caused great controversy. but was praised by Charles Darwin as having "done excellent service . . . in removing prejudice, and in thus preparing the ground for the reception of analogous views." In 1832 Robert and William together started *Chambers's Edinburgh Journal,* and this led to the establishment of the publishing firm of W. and R. Chambers, *Chambers's Encyclopaedia* was edited by Andrew Findlater but personally supervised by the brothers (*see* ENCYCLOPAEDIA).

Robert died at St. Andrews, Fifeshire. on March 17, 1871. William continued as head of the firm until his death in 1883, when he was succeeded by Robert's son, Robert (1832–88). The management remained in the family.

CHAMBERS, SIR WILLIAM (1723–1796), British architect. was born at Goteborg. Swed.. son of a merchant of Scottish descent. At 16. after education in England, he entered the service of the Swedish East India company; a voyage to Canton. China, supplied the materials for his *Designs of Chinese Buildings* (1757). In 1749 he left the sea to study architecture. first in Paris and then in Rome. Returning to England in 1755 he became architectural tutor to the prince of Wales. the future George III. This appointment led to an extremely successful career as an official architect, during which he became successively one of the two architects of the works (the other being his great rival Robert Adam; *q.v.*), comptroller of the works and surveyor general. In 1768 he helped found the Royal Academy, of which institution he was a pillar for the rest of his life; in 1770. upon receiving the knighthood of the polar star from the king of Sweden, he was allowed by George III to assume the rank and title of an English knight.

His best-known works are Somerset house, London; the casino at Marino, near Dublin; and the ornamental buildings (including the pagoda) at Kew palace, Surrey. In the last he went as far in the direction of romantic eclecticism as any architect of his time. But in general he was an architectural conservative who used a profound knowledge of European (especially French) architecture to give a new look to the accepted motifs of Palladianism. His books, notably *A Treatise on Civil Architecture* (first published 1759), had an influence which extended beyond the shores of England in space and after their author's death in time. He died on March 8, 1796, and was buried in Westminster abbey.

See H. XI. Colvin, *A Biographical Dictionary of English Architects, 1660–1840* (1954); John Summerson, *Architecture in Britain, 1530–1830* (1954). (*Ms.* W.)

CHAMBERS, in law, the rooms of judges or judicial officers who deal with questions of practice and other matters not of sufficient importance to be dealt with in court. It is doubtful at what period the practice of exercising jurisdiction in chambers commenced in England; there is no statutory sanction before 1821, though the custom can he traced back to the 17th century. An act of 1821 provided for sittings in chambers in vacation (*i.e.*, between terms of the court). and an act of 1822 empowered the sovereign to call upon the judges by warrant to sit in chambers on as many days in vacation as should seem fit. while the Law Terms act, 1830, defined the jurisdiction to be exercised at chambers. The Judges' Chambers act. 1867, was the first act, however. to lay down proper regulations for chamber work, and the Judicature act. 1873. preserved that jurisdiction and gave power to increase it as might be directed or authorized by later rules of court. The term "chambers" is, in ordinary professional speech, applied to the rooms or offices where counsel practise. *See* PRACTICE AND PROCEDURE.

CHAMBERSBURG, a borough of Pennsylvania, U.S., and the seat of Franklin county, is on a 615-ft. elevation in the broad, fertile Cumberland valley, 52 mi. S.W. of Harrisburg and 142 mi. W. of Philadelphia. Orchards, grain fields and dairies surround the borough, which has grain elevators, food-processing plants,.

other industries and one of the largest ordnance depots in the U.S.

Chambersburg was founded in 1730 by Benjamin Chambers. It became a borough in 1803. John Brown made it his headquarters while planning the Harpers Ferry raid in 1859 and Gen. Robert E. Lee massed Confederate troops there for the attack at Gettysburg in July 1863. Wilson college, a Presbyterian college for women chartered in 1869, and Penn Hall, a junior college for women established in 1906, are in Chambersburg. Caledonia State forest, Buchanan State park, Cowan's Gap State park and Pres. James Buchanan's birthplace are nearby. For comparative population figures *see* table in PENNSYLVANIA: *Population.* (A. J. Fo.)

CHAMBÉRY, a city of southeastern France, the old capital of the duchy of Savoy and now capital of the *département* of Savoie (*q.v.*), located between the massifs of Beauges and La Grande Chartreuse in the valley of the Leysse river, 112 km: (69.5 mi.) by road E.S.E. of Lyons. Pop. (1954) 28.872. The northwest part of the city was badly bombed in 1944 and has been rebuilt with wide streets; the southeastern section retains its 17th-century aspect and has many reminders of the 15th and 16th centuries. The cathedral of St. Francis of Sales dates from the 14th and 15th centuries; the church of Lémenc has a 9th-century crypt. The château of the dukes of Savoy was founded in 1232 and rebuilt in the 15th century; after a fire the building housing the prefecture was built adjoining it. The Sainte-Chapelle of the château contained the Holy Shroud from 1502 to 1578. Les Charmettes, the country house near Chambkry where J. J. Rousseau lived with Mme de Warens, retains its 18th-century atmosphere. The most characteristic street is the rue de Boigne. running from the château to the elephant monument (1838) of Gen. Benoît de Boigne, a benefactor of the city. There are a number of schools and technical colleges in Chambéry as well as many learned societies. The city is on the main railway line from Paris and Dijon to Modane and Italy. Chief industries are manufacture of aluminum, cement, shoes, skins and glass fibre.

The Roman station of Lemincum gave its name to the rock of Lémenc, which overlooks the town on the north. In the 14th century the counts of Savoy installed themselves in the chbteau on the other slope of the valley and Chambéry became their capital. It was made capital of the *département* of Mont Blanc after the entry of revolutionary forces in 1792, but was returned to the house of Savoy by the treaties of Vienna and Paris. Savoy was finally joined to France after the plebiscite of 1860. In World War II Chambéry was occupied by the Germans from Nov. 1942 to Aug. 1944. (P. BA.)

CHAMBORD, HENRI CHARLES FERDINAND MARIE DIEUDONNÉ D'ARTOIS, COMTE DE (1820-1883), French pretender to the crown, the "Henry V" of the Legitimists, was born in Paris on Sept. 29, 1820, the son of Charles Ferdinand. duc de Berry (*q.v.*). Born seven months after his father's assassination, he was hailed as "l'enfant du miracle." He was created duc de Bordeaux and, in 1821, as the result of a subscription organized by the communes of France, received the chbteau of Chambord, though he did not use the title until May 1839. His education was influenced by hatred of the French Revolution. After the revolution of July 1830, his grandfather Charles X abdicated in his favour and proclaimed him king as Henry V (Aug. 2, 1830), but the crown went instead to Louis Philippe, head of the house of Bourbon-Orléans. The young prince accompanied Charles X into exile and resided successively at Holyrood, at Prague, at Gorz and, from 1844, at Frohsdorf in Austria. The death of Charles X in 1836 and that of his uncle, the duc d'Angoulême, in 1844 left him the last male representative of the elder branch of the Bourbons. On Nov. 7, 1846, he married Thérèse, eldest daughter of Francis IV of Modena, but the marriage was childless.

The comte de Chambord allowed the revolution of 1848 and the *coup d'état* of 1851 to pass without any assertion of his claims. The Italian war of 1859, with its menace to the pope's independence, roused him to activity. On Dec. 9, 1566, he issued a manifesto against Napoleon III's policy, declaring the cause of the pope to be that of society and liberty and holding out promises of civil and religious liberty "and above all honesty." On Oct. 9, 1870. after the fall of Napoleon III, he invited Frenchmen to accept a government "whose basis was right and whose principle was honesty." The ensuing elections placed the republican parties in a minority in the national assembly, and the abrogation of the law of exile against the Bourbons enabled the comte to return to France. where he spent three days at Chambord. It was thence that, on July 5, 1871, he issued a proclamation in which he publicly posed as king, but in which he refused to accept the tricolour of the Revolution. Such obstinacy made further negotiation pointless, and the comte left France.

The fall of Adolphe Thiers in May 1873 presented the royalists with an opportunity which they were quick to seize. The prime minister, the duc de Broglie, was an avowed adherent, and the president, Marshal MacMahon, was a benevolent neutral. Moreover, Louis Philippe's grandson, Louis Philippe Albert, comte de Paris, journeyed to Frohsdorf for a formal reconciliation of the two branches of the house of Bourbon (Aug. 5). After this, Lucien Brun and Pierre Charles Chesnelong were sent from Paris to interview the comte de Chambord at Salzburg and obtained satisfactory assurances. On his return to France, however, Chesnelong received a letter (dated Salzburg, Oct. 27) in which the prince declared that he had been misunderstood and that he would give no guarantees: he refused to inaugurate his reign by an act of weakness and become "the legitimate king of the Revolution." A last effort was made in the national assembly, in June 1874, when the restoration of the monarchy was formally moved. The motion was rejected by 272 votes to 79, and on Jan. 30, 1875, the republic was formally consecrated by Henri Wallon's amendment, which obtained a majority of one vote only. The comte de Chambord died at Frohsdorf on Aug. 24, 1883.

The comte de Chambord's publications include: *Mes ide'es* (1872). *Manzfesfes et programmes politiques, 1848–73* (1873) and *De l'institution d'une régence* (1874). The comte de Paris succeeded to his pretensions.

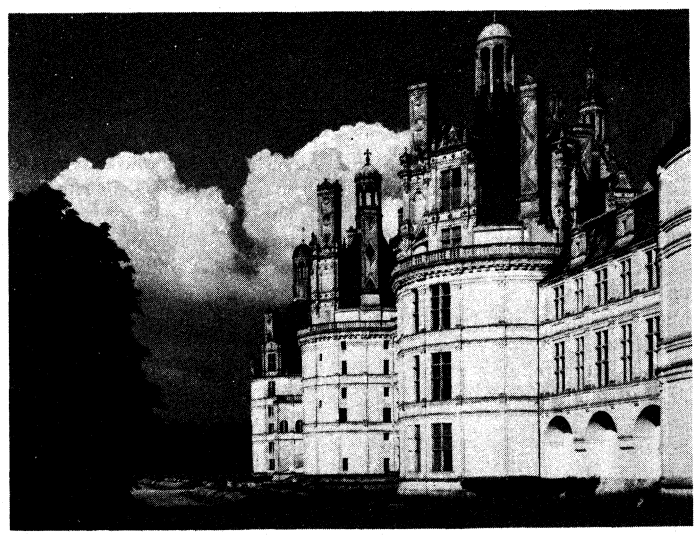
CHAMBORD, a village of central France, the only commune in France owned entirely by the state, in the *département* of Loir-et-Cher, is situated on the left bank of the Cosson river, 18 km. (11 mi.) E. of Blois by road. Pop. (1954) 170. The village lies in a park surrounded by walls 32 km. (20 mi.) in circumference. The great château of Chambord, one of the marvels of Renaissance architecture and originally a hunting lodge of the counts of Blois, was completely rebuilt by Francis I and Henry II, beginning in 1519 (see RENAISSANCE ARCHITECTURE: *France).* Stanislaw I Leszczynski lived at Chambord from 1725 to 1733, and the chbteau was bestowed by his son-in-law, Louis XV, upon Marshal Maurice



ARCHIVES PHOTOGRAPHIQUES

CHAMBORD CHÂTEAU; 16TH CENTURY

Saxe. Napoleon gave it to Marshal L. Berthier. from whose widow it was purchased by subscription in 1821 and presented to the duc de Bordeaux, who took the title of comte de Chambord. On his death it came by bequest to the house of Parma, from whom it was sequestrated in 1914. It was purchased by the state in 1932.

Chambord is not on a railway, the nearest convenient station being at Blois. The main industry is catering for tourists, for whom spectacles of *"son et lumière"* are presented. Occupied by the Germans for a few months in 1870–71, during the Franco-German War, Chambord was occupied by them again from June 1940 to Aug. 1944.

CHAMBRE ARDENTE, an extraordinary court of justice in France, mainly held for the trials of heretics (Fr. "burning chamber"). These courts were originated by John, cardinal of Lorraine, the first of them meeting under Francis I. The *chambre ardente* co-operated with an inquisitorial tribunal also established by Francis I, the duty of which was to discover cases of heresy and hand them over for final judgment to the *chambre ardente.* The court was abolished in 1682.

See N. Weiss, *La Chambre Ardente* (1889).

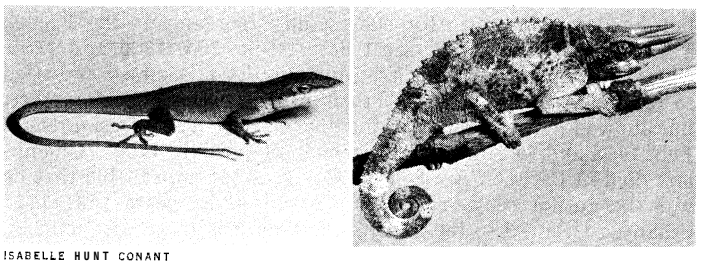
CHAMELEON, the common name for members of the remarkable lizard family Chamaeleontidae. Because of similar abilities to change colour, the name is misapplied to American lizards of the genus *Anolis,* particularly *A. carolinensis* of the eastern U.S. *(see* IGUANA), and to southeastern Asiatic lizards of the genus *Calotes,* especially the "bloodsucker," *C. versicolor (see* LIZARD. *Agamidae).* Of the 80 species of chameleons, which belong preponderantly to the genus *Chamaeleo,* half live in Madagascar and most of the rest in Africa south of the Sahara. The others include one species along the southern Mediterranean from Spain to Syria (the common chameleon, C. *chamaeleon),* two on the Arabian peninsula and one in Ceylon and southern India (C. *zeylanicus*)

Chameleons range in length from 1½ in. to 2 ft. The body is compressed laterally; the head is short and often ornamented with occipital crests or dermal flaps and frontal horns or scaly processes. The limbs of these predominantly arboreal lizards are modified for climbing in having the digits fused into opposed bundles of two and three. The tail also is a grasping organ in *Chamaeleo,* but not in the other genera of the family *(Brookesia, Leandria* and *Evoluticauda).* The bizarre appearance of chameleons stems not so much from the foregoing specializations as from the large eye. which is enclosed by fused eyelids except for a small central opening. The eyes are independently movable, but when prey is noticed by one the other swivels into position to give binocular perception for accurate judgment of distances. Without this perception the chameleon's extraordinary use of its tongue for feeding would not be very efficient. The tongue has a large sticky tip and a tubular, elastic basal part. When at rest the latter is telescoped over an elongated projection of the hyoid. Ring muscles of the tubular section contract about this slippery spike of bone to propel the tongue outward, sometimes to a distance exceeding the body length. Prey is deliberately stalked until within range; the tongue is shot out and then rapidly retracted, usually with the intended victim adhering to the sticky tip. Most chameleons feed on insects but very large species are known to secure birds.

The renowned colour-changing of chameleons is not, as popularly supposed, maneuver for camouflage. It is actually dependent on several factors, including light, temperature and emotional stimuli. The mechanism involves dispersion or concentration of pigment in melanophore cells, which are under control of the autonomic nervous system (in contrast to hormonal control in *Anolis).*

The species differ in their ranges of colours and patterns, but many can assume green, yellow or cream, or dark brown, frequently with darker or lighter spots on the ground colour. Although not necessarily matching the background, the disruptive patterns, in combination with the compressed body shape, probably do provide concealment among forest shadows and leaves from snake and bird enemies.

Most chameleons are oviparous and are obliged to descend to bury their 2 to 40 eggs in the earth or rotting logs. Incubation



ISABELLE HUNT CONANT

(LEFT) AMERICAN "CHAMELEON" OR ANOLE (ANOLIS CAROLINENSIS), (RIGHT) AFRICAN THREE-HORNED CHAMELEON (CHAMAELEO OWENI)

lasts about three months. A few South African species bear young alive.

The head ornaments are either better or exclusively developed in males. At least some are related to territorial defense: a dominant male of *C. dilepis* responds to an invading male by expanding the body, puffing out the throat and elevating or waving his occipital flaps. If this fails to bluff the intruder, the defender charges and snaps and usually drives him away.

See K. P. Schmidt and R. F. Inger, *Living Reptiles of the World* (1957). (G. B. R.)

CHAMFORT, SEBASTIEN ROCH NICOLAS (1740?–1794), French writer, famous for his wit and conversation. An illegitimate child, his parentage and date of birth are uncertain, but he was probably born during 1740. He was brought up in a small village near Clermont-Ferrand by the wife of a grocer, François Nicolas, and educated as a free scholar at the Collège des Grassins. After leaving school he made his way to Paris, where, supported by the hospitality of a worldly and sophisticated society which appreciated his conversational genius, he led a precarious existence until two comedies, *La Jeune Indienne* (1764) and *Le Marchand de Smyrne* (1770), established his reputation. Later he secured an introduction at court and when his *Mustapha et Zéangir* was performed beiore Louis XVI in 1776 he obtained a pension from the king. In 1781 he was elected to the Academy.

Aiter 1789 he devoted himself wholeheartedly to the cause of the Revolution. Author of republican articles for the *Mercure de France,* he was a member of the *Club de 1789* and secretary of the Jacobin club. At first his Jacobinism was uncompromising, but later, under the excesses of Marat and Robespierre, his enthusiasm decreased and he became critical of the Convention. In July 1793 he was arrested and imprisoned for a few days. The threat of further imprisonment, two months later, was sufficient to make him attempt suicide. In this endeavour he was unsuccessful, but he never really recovered from the self-inflicted wounds and he died at Paris on April 13, 1794.

Chamfort is now known only by his *Maximes et Penskes* and *Caractbres et Anecdotes,* published posthumously in 1795, of which there have been many editions. The best was published under the collective title *Produits de la Civilisation perfectione'e* in 1953. His many other works possess no great literary value.

CHAMILLART, MICHEL (1652–1721), the French statesman who was responsible for the financing and provisioning of the French army during the first half of the War of the Spanish Succession, was born in Paris on Jan. 10, 1652. After serving as intendant at Rouen, he was in 1690 summoned to Paris and made intendant of the finances of the kingdom. He was appointed *contrôleur-général* of finance on Sept. 5, 1699, minister of state on Nov. 29, 1700, and secretary of state for war on Jan. 7, 1701.

Chamillart was a sound economist and a competent administrator, whose favour with Louis XIV was variously attributed to honesty and to skill at billiards. He was forced by the exigencies of war to resort to unpopular and unsound financial expedients and so was unjustly blamed for the country's economic predicament. As minister of war he was also criticized for the loss of Catalonia in 1706 and for the mishandling of the siege of Turin,

but he deserves praise for successfully reorganizing the French armies after each of the great defeats of 1704, 1706 and 1708. Chamillart soon recognized the impossibility of his task and tried to resign in 1706. Louis XIV then insisted on his retaining office, but allowed him to hand over the finances to Nicolas Desmarets in Feb. 1708 and to relinquish his remaining posts in 1709. Chamillart died in Paris on April 14, 1721. It is not improbable that he was the author of the *Mémoires* covering the years 1681–1712 usually attributed to the marquis de Sourches (L. F. de Bouchet, 1645–1716). (B. J. R.)

CHAMINADE, CÉCILE LOUISE STÉPHANIE (1857–1944), French composer and pianist known for her piano pieces in a light style, of which the well-known *Scarf* Dance is typical. Born in Paris, Aug. 8, 1857, she was a pupil of Benjamin Godard and became popular throughout Europe and the U.S. as a pianist in her own compositions. Charm and grace mark the style of her numerous piano pieces and songs. Her larger works include the symphony. *Les Amazones,* the ballet Callirhoe (both 1888), piano and flute concertos, chamber works and an unpublished *opéra-comique,* La *Sévillane.* She died at Monte Carlo, April 17, 1944.

CHAMISE (*Adenostoma fasciculatum*), a North American shrub of the rose family (Rosaceae), called also chamiso. found in the chaparral belt on foothills and mountain slopes in California. ranging up to 5,000 it. altitude. It grows from two to ten feet high. with shreddy brown bark. slender twiggy branches, resinous, narrow leaves in bundles or fascicles and small white flowers in panicled clusters. Chamise is the most abundant and characteristic small shrub of the higher foothills west of the Sierra Nevada, where, between the lower foothills and the yellow pine belt. it often forms a distinct zone called chamisal. See also CHAPARRAL.

CHAMISSO, ADELBERT VON (LOUIS CHARLES ADÉLAIDE CHAMISSO DE BONCOURT) (1781–1838), German writer and botanist, a leading member of the north German group of romantic poets. was born Jan. 30, 1781, at the château Boncourt in Champagne. During the French Revolution the family fled to Würzburg and then to Berlin. where Chamisso became page to Queen Louise, went to the iamous Franzosische *Gymnasium* and in 1798 entered a Prussian infantry regiment. He remained in active service when his family returned to France. studied philology and philosophy and fell in love u-ith a governess. Cérès Duvernay, and, although his love was unrequited. it awakened his poetic talent. Together with Baron de la Motte Fouque. J. E. Hitzig and Varnhagen von Ense, he edited, during 1804–06, the Berliner *Musenalmanach,* in which his first poems appeared. In 1804 he founded the Nordsternbund, a society of Berlin romanticists.

Chamisso took part in the war of 1806, left the army after the capitulation of Hameln. stayed in France from 1807 to 1808. where he fell in love with the writer Helmina von Chézy, and was a member of the circle of Mme de Staël. there and in Switzerland. He then returned to his studies at Berlin and in 1813 wrote his Peter *Schlemihls wundersame Geschichte,* the story of the man who sold his shadow to the devil. which allegorized his own situation as a man without a country and his inner disunion during the German war of independence against France. The most iamous of his works; it has been translated into most European languages. During 1815-18 Chamisso was botanist to the Russian ship "Rurik," which Otto von Kotzebue commanded on a scientific voyage round the world: his diary,. *Reise um* die *Welt mit* der *Romanzoffischen Entdeckungs-Expedition* (1821), is a classic of its kind. In 1818 he became custodian of the botanical gardens at Berlin and in 1819 married Antonie Piaste. During 1828–32 he wrote his most important poems—song cycles, ballads. narrative verses and *terza rimas*—published mainly in the *Deutscher Musenalmanach,* of which he became editor in 1832. He died at Berlin on Xug. 21, 1838.

The model for Chamisso's poetry is to be found in the lyrics of Goethe and Ludwig Uhland; it aims at freshness and popularity and is at its best in expressing simple human feelings as in the lyrical cycle "Frauenliebe und -leben," which has become world famous set to music by Robert Schumann. His ballads deal with national legends ("Das Riesenspielzeug") and with ethical and social problems ("Die Sonne bringt es an den Tag." · Die alte Waschfrau'). and show his romantic fondness for mournful subjects ("Vergeltung," "Salaz y Gomez"). His social and political poems are on subjects similar to those treated by Béranger, whose poems he translated in 1838. His later lyrics were more realistic. and were praised by Heine. As a scientist he is connected with the discovery of the metagenesis of certain mollusks. He also wrote *Bemerkungen und Ansichten* and *Übersicht* der *nutzbarsten und schädlichsten Gewächse* in *Norddeutschland* (1829). As a philologist he is known for his studies of Australasian languages.

BIBLIOGRAPHY.—The first collected edition of Chamisso's works was ed. by J. E. Hitzig, with biography and letters, 6 vol. (1836–39); also editions by M. Koch (1883), O. F. Walzel (1892). M. Sydow (1907) and H. Eulenberg (1929). See also K. Fulda, Chanzisso und seine Zeit (1881); G. Hofmeister, *Adelbert von Chamisso* (1883); K. Leutzner, *Chamisso,* Life and Works (1893); R. CHAMOIS, the Franco-Swiss name of a hollow-horned ruminant *Rupicapra rupicapra.* It is the only species in the genus, though every European range possesses a local race. It is the type of the tribe *Rupicaprini,* which includes several goatlike genera (see BOVIDAE). About the size of a roebuck (*q.v.*), with a short tail. it is distinguished by the vertical. backwardly directed horns in both sexes, though these are larger in the male. Though differing in the shade of their hair. all the various races have black and white face markings and a black tail and dorsal stripe. The alpine race is chestnut brown in summer. lighter and grayer in winter. A thick underfur is developed in the cold weather.

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

CHAMOIS (RUPICAPRA RUPICAPRA)

Chamois live in small herds, but the old males join these only during the rutting season (October). when they engage in fierce contests with each other. The period of gestation is 20 weeks, and the usual number of offspring is one. In summer the sure-footed chamois ascend to the snow line, being exceeded in the loftiness of their haunts only by the ibex (*q.v.*); in winter they descend to wooded regions. Chamois hunting is a favourite sport of the Swiss and Tirolese and of amateurs from all countries. As a result of this, the chamois has become rare in many of its old haunts, but it is now preserved in the Swiss National park in the Engadine. Exceedingly wary and astonishingly agile, the animal is very difficult of approach. It feeds in summer on mountain herbs and flowers, in winter on the young shoots of the pine.

The soft, pliant skin is made into the original "shammy" leather, though this is also made from the skins of other animals (especially sheep and goats). The flesh is prized as venison. During the 20th century the chamois was successfully introduced from Austria into New Zealand. The German name for the chamois is Gemze or Gemsbock; however, the latter name as gemsbok is applied to an antelope of southern Africa.

CHAMONIX, a town of southeastern France, *département* of Haute-Savoie (*q.v.*), is a well-known Alpine tourist resort situated on the Arve river 96 km. (60 mi.) W. of Annecy at an elevation of 3,416 ft. Pop. (1954) 2,630. The valley of Chamonix, running from northeast to southwest, is watered by the Arve. which rises in the Mer de Glace, largest of the Mont Blanc glaciers. On the southeast towers the snowclad chain of Mont Blanc, and on the northwest the rugged chain of Brévent and Aiguilles Rouges. Chamonix is the best starting point for the exploration of the glaciers of the Mont Blanc chain, as well as for the ascent of Mont Blanc itself. It is connected with Geneva by a railway.

The valley is first mentioned about 1091, when it was granted by the count of the Genevois to the great Benedictine house of St. Michel de la Cluse, near Turin, which by the early 13th cen-

tury had established a priory there. In 1786 the inhabitants bought their freedom from the canons of Sallanches, to whom the priory had been transferred in 1519. The first party to publish (1744) an account of its visit was that of R. Pococke. W. Windham and other Englishmen who visited the Mer de Glace in 1741. The development of tourism is modern. In World War II Chamonix was occupied by the Gernians from Nov. 1942 to Aug. 1944. See also MONT BLANC.

CHAMPA, an ancient kingdom of Indochina extending over the southeastern coastal region of modern Vietnam from Tourane in the north to Cape Varella in the south. It was occupied by the Chams, a people of Indonesian stock and Indianized culture; for their modern descendants see CHAM. Probably autochthonous, the Chams belonged originally to the Dong-son Neolithic culture. Later they came in contact with the higher civilizations of the Chinese then ruling Tongking and of Indian merchants from overseas. This latter influence prevailed and Champa became a powerful state, second only to Cambodia.

Appearing during the 2nd century A.D. under the name of Lin-yi in Chinese histories, Champa first comprised four small states named after Indian regions: Amaravati (Quang-nam); Vijaya (Binh-dinh); Kauthara (Nha-trang); and Panduranga (Phan-rang). Unified later under strong dynasties, they disappeared one by one in the same order (from north to south) in the course of 14 centuries during which the Chams retreated under the pressure of the Vietnamese. Eventually the race was almost completely annihilated.

After obscure struggles against the Chinese colonies in Tongking, Bhadravarman emerged about A.D. 400 as the first great king of an already completely Indianized country, and the founder of Mison, for centuries to come the national shrine. The Chinese, in revenge for incessant Cham raids. destroyed their capital in 446. but under a new dynasty in the 6th century Champa threw off its allegiance to China and enjoyed peaceful prosperity. In the 8th century the centre of power shifted to the southern provinces where Cham culture made great progress despite renewed Chinese pressure, Javanese raids and the growing power of Cambodia. In 875 the Indrapura dynasty won back the crown of the unified country for Amaravati where they built magnificent temples, but their kings could not compete with the ambitious kingdom of Annam to which they were forced to relinquish Amaravati in A.D. 1000, ruling thereafter for a time in Vijaya. The Annamese, however, increased their pressure and between 1044 and 1069 annexed Vijaya also. For a short space only, between 1074 and 1081, Harivarman IV, the founder of a new dynasty, was able to resist them. In 1145. Champa was conquered by the kingdom of Cambodia but soon afterward was freed by Jaya Harivarman I (1147–66). His successor was even able, in 1177, to sack Angkor. Again between 1190 and 1220 the Chams were subject to Cambodia under its great king, Jayavarman VII, and were not freed until after his death. Then they were attacked by their worst enemies, the Tran kings of Annam, and in 1283 the Mongols raided the country.

During the 14th century the Cham kings became mere vassals of Annam despite the courage of their last heroic king, Che Bong Nga (1360–90). One by one their provinces were colonized until finally Champa was entirely absorbed. Nevertheless Cham culture played an important part, though this may have been unrecognized or minimized, in the formation of Vietnam.

The Chams were primarily a sea-going people — fishermen and, above all, pirates, who were dreaded by all ships sailing the seas between China and Indonesia. Ashore they grew rice, for the cultivation of which they created an ingenious irrigation system. They cremated their dead. They spoke Cham, an Indonesian language. which was written in Indian characters. The literary medium was Sanskrit. The élite enjoyed a brilliant syncretic culture the basis of which was largely Indian. Sivaism was predominant and Buddhism of both Vehicles played its part. Among the people, however, the worship of nature spirits was never superseded until the introduction of Islam from the 15th century onward.

Cham art is known only from the temples which were usually built by kings for their favourite gods. Architecture was confined to tiered brick towers. Sculpture was devoted to statues of the gods. the pedestals of which were adorned with figures in relief. From the subtle and smiling harmony of the Indian Gupta period Cham artists evolved a more personal style of sculpture. They created fantastic forms springing with wild energy as though the Indonesian spirit were gradually breaking free from foreign and enforced aesthetic standards. (See also INDIAN ARCHITECTURE: *Champa.*)

Practically unknown and often underrated, Cham culture is one of the most important human phenomena of ancient Indochina. It is the only culture of mainland Asia with Oceanic features. See also INDONESIAN ART and INDONESIAN ARCHAEOLOGY.

CHAMPAGNE, an old province of France, corresponding to the modern *département* of Marne (*q.v.*) together with most of Ardennes, Aube and Haute-Marne and parts also of Aisne, Seine-et-Marne, Yonne and Meuse (*qq.v.*). It was bounded on the north by the bishopric of Liège and by Luxembourg, on the east by Lorraine, on the south by Burgundy and on the west by fle-de-France and by Picardy. Its westernmost extension was part of the region of Brie (*q.v.*). The name Champagne is derived from the great plains (Lat. *campi*) near Reims, Châlons-sur-Marne and Troyes.

Reims.—In the last century of the Roman empire the battle of the Catalaunian Plains against the Huns was fought in Champagne. From the beginning of the Merovingian period the diocese of Reims (*q.v.*) assumed a great significance in French national history, as it was the bishop of Reims, St. Remi, who baptized Clovis, and the archiepiscopal domain was always to remain independent of the counts of Champagne (see below). The custom whereby the French kings went to Reims for their coronation was established in early Capetian times. The college founded by the archbishops in the 10th century was made famous by Gerbert, the future Pope Silvester II.

Countship. — Counts of Troyes (*q.v.*) are recorded from the middle decades of the 9th century. From 877 they seem to have been hereditary vassals of Burgundy. About 940, however, Troyes came into the hands of Herbert of Vermandois (d. 942), and in 966 it passed to his younger son, Herbert the Old, who was already count of Meaux in Brie. These two countships became the nucleus of what was later called the countship of Champagne. The house of Vermandois, meanwhile, not only reduced to vassalage a number of adjacent territories but also was linked by marriage with the counts of Blois and Chartres (see BLOIS. COUNTSHIP OF), so that, when its male line died out (1019 or 1020, or perhaps c. 1023), Eudes II of Blois became count of Troyes and Meaux (he is reckoned as Eudes I of Champagne, though in fact the title "count of Champagne," which first appears in 1077, did not supersede "count of Troyes" as the principal designation for the Champagne inheritance until the beginning of the 13th century). For the next 100 years the Champagne inheritance was regarded as dependent on the Blois-Chartres countships, and Troyes and Meaux were even separated from one another in partitions of the combined Blois-Champagne inheritance from 1089 onward. In 1125, however, Thibaut IV of Blois became Thibaut II of Champagne, reuniting the family possessions, and on his death (1152), when another partition took place, Blois and Chartres went to the younger son, whose descendants thenceforth, until their male line died out, were regarded as depending on the counts of Champagne.

Thibaut and his successors in the 12th and 13th centuries raised the countship of Champagne to the apogee of feudal power. Henry I the Liberal, count from 1152 to 1181, married Mary, daughter of Louis VII of France and Eleanor of Aquitaine, and won renown as a crusader. His son and successor Henry II (d. 1197) went also on crusade and married Isabella, heiress of the kingdom of Jerusalem, in 1192, thus becoming recognized as the actual leader of the crusaders, though he never secured the royal title. Henry II's nephew Thibaut IV (*q.v.*), count from 1201 to 1253, was the most famous of these counts and a poet as well; he succeeded his maternal uncle Sancho VII as king of Navarre (Theobald or Teobaldo I) in 1234. His sons Thibaut V (d. 1270) and Henry III (d. 1274) succeeded as counts and as kings, but

Henry III left only a daughter, Joan. Joan in 1284 married Philip the Fair. who became king of France as Philip IV next year. On Joan's death (1305) Champagne passed to her son Louis. who united it to the crown on becoming king as Louis X (1314).

Fairs.—Apart, however, from the prowess of its counts, the great celebrity of Champagne, in the middle ages, lay in its fairs, particularly in the 12th and 13th centuries. At the crossing of the roads from Flanders. Germany, Italy and Provence, Champagne was indeed a convenient meeting place. Drapers from the north, wool merchants from England, importers of alum, dyes and spices from the Mediterranean ports, dealers in linen and in furs from Germany and leather sellers from Spain and Africa could easily meet there and bargain together. The great fairs lasted 49 days each and were six in number: one at Lagny, one at Bar-sur-Aube, two at Provins and two at Troyes. Each fair opened with a week devoted to the receiving of merchandise, four weeks then were spent in selling and the last fortnight in the settling of accounts. For this purpose, clearances and transfers of funds came more and more to be used between customers; and thus the fairs became regular banking centres, where people not connected with the trade itself might also transact business.

These fairs had special legislation, and special magistrates called "masters of the fairs" had control of the police. Because of the fairs. Champagne, rather a poor region at first because of the nature of its soil, became rich; and this accounts both for the opulence of its towns (particularly under Henry the Liberal and Thihaut IV) and for the emancipation of the cities, as well as for more violent movements.

From the end of the 13th century Champagne began to lose its pre-eminence, first commercially, then financially. Commerce was diverted to Paris, to Flanders and to Italy, and new trade routes were developed over the Alps and along the Rhine valley as well as by sea.

French Province.—Champagne suffered as a battlefield in the Hundred Years' War, and the treaty whereby Isabella of Bavaria surrendered France to Henry V of England was signed at Troyes (1420). Charles VII, however, was crowned at Reims after Joan of Arc's victories (1429). In the 16th century Meaux became the first great centre of the Reformation in France. Under Francis I of France, the territories of the countship were merged with the extensive domains that had formerly belonged to the bishops of Reims, of Chdlons and of Langres to form the military *gouvernement* of Champagne. From the point of view of financial organization, the greater part of the province was included in 1542 in a *généralité* under an intendant whose seat was first at Reims, later at Châlons (hence the name *généralité* of Châlons); the western areas, however, were included in the *généralité* of Paris, and smaller areas in other *généralités*. As a frontier province, Champagne was exposed to invasion in the wars between the French and the Habsburgs. and it was in Champagne that the civil wars of religion between Catholics and Huguenots broke out (massacre of Vassy, 1562). The principality of Sedan was incorporated in Champagne on its annexation to France in 1642.

Economically Champagne prospered because of the textile industries of Reims and Troyes, the metallurgy of St. Dizier and its vicinity and the great vineyards *(see* WINE).

Dissolved into *départements* during the French Revolution, the country has been invaded whenever France has been attacked from the east—from the time of the battle of Valmy (1792) to the engagements of World Wars I and II.

(MI. M.)

CHAMPAGNY, JEAN BAPTISTE NOMPERE DE, DUC DE CADORE (1756–1834), French statesman and diplomat, foreign minister under Napoleon, was born at Roanne on Aug. 4, 1756, of a noble family. Educated at La Flkche and at the École Militaire in Paris, he entered the navy and served as an officer during the American Revolution, being severely wounded in 1782. He resigned his commission in 1787. Elected deputy to the estates-general by the *noblesse* of Forez in 1789, he went over to the third estate on June 21. A member of the constituent assembly's committee for the navy, he occupied himself with the reorganization of the fleet. In 1793 he was imprisoned for some months as a former nobleman. Having been elected to the directory of the Loire *département* in 1795, he was nominated a member of the council of state by Kapoleon Bonaparte in 1799 and appointed French ambassador to Vienna in 1801. In 1804, however, he was recalled to become minister of the interior. As such, he proved himself an excellent administrator.

In 1807 Champagny succeeded Talleyrand as foreign minister. In this capacity he was responsible for the annexation of the papal states, for the abdication of Charles IV of Spain, for the Franco-Russian negotiations at the congress of Erfurt (all in 1808) and for the peace of Schonbrunn between France and Austria (1809), for which he was made duc de Cadore. He also negotiated Napoleon's marriage to Marie Louise (1810).

In 1811 a disagreement with Napoleon led to Champagny's resignation as foreign minister, but he remained a minister of state and intendant general of the crown. A senator in 1813, he was made secretary general of the regency in that year and again in 1814. When the allies were invading France he accompanied Marie Louise to Blois and undertook a mission to the Austrian emperor.

Champagny went over to the Bourbons on the first Restoration and was made a peer of France, but rejoined Napoleon during the Hundred Days. Consequently he was excluded from the peerage at the second Restoration but he was readmitted in 1819. He supported Louis Philippe's cause in 1830 and died in Paris on July 3, 1834. His *Souvenirs* appeared posthumously in 1846.

One of his sons, FRANÇOIS DE CHAMPAGNY (1804–1882), wrote numerous books on Roman history. Another, NAPOLÉON JOSEPH DE CHAMPAGNY (1809–1872). published a *Notice biographique* of his father (1836) and a *Traité de la police municipale,* four volumes (1844–62).

See L. Mercier, *Nompère de Champagny* (1889); J. Valynseele, *Les Princes et Ducs du premier Empire* (1959).

(J. Go.)

CHAMPAIGN, a city of east-central Illinois, U.S.. located across a city street from the city of Urbana (*q.v.*), owes its origin to the building by the Illinois Central railroad of a branch line (which later became the main line). Surveyors laid out the railroad addition to Urbana in July 1853, 2 mi. W. of the older town where the unbroken prairie made laying of the tracks simple and inexpensive. Many citizens of the older town immediately built new homes in the vicinity of the depot and tried unsuccessfully to persuade others to abandon the Urbana site. In 1855 a bill incorporating the city of Urbana and including the depot within its limits was defeated in the legislature at the insistence of residents of the depot area. Two years later, separate incorporation was given to West Urbana and in 1860 West Urbana became the city of Champaign. The names Urbana and Champaign are memorials to early citizens who came from Urbana, Champaign county, O.

As in the case of Urbana, the University of Illinois provides the chief income for the city, but Champaign in the second half of the 20th century became increasingly industrial, manufacturing alloy castings, soybean oil, gloves, refrigeration and air-conditioning equipment, academic apparel and vegetable oil products. A council-manager form of government went into effect in 1958. For comparative population figures *see* table in ILLINOIS. *Population.*

(N. M. BE.)

CHAMPAIGNE, PHILIPPE DE (1602–1674), Belgian painter of the French baroque, whose work is characterized by a grave reality, depicted in harmonious sombre tones and severe design, was horn at Brussels of a poor family. He was a pupil of J. Fouquikres; and, going to Paris in 1621, was employed by N. du Chesne to paint with Nicolas Poussin in the palace of the Luxembourg. His best works are to be found at Vincennes and in the church of the Carmelites at Paris, where his celebrated Crucifix, a signal perspective success, is on one of the vaultings. Aiter the

death of Du Chesne, Philippe became first painter to the queen of France, and ultimately rector of the Academy of Paris. As his age advanced and his health failed, he retired to the religious community of Port-Royal, where he had a daughter cloistered as a nun, of whom (along with Catherine Agnès Arnauld) he painted a picture highly remarkable for its solid, unaffected truth. This, indeed. is the general character of his work. He produced an immense number of paintings. His portraits of Cardinal Richelieu are among his best-known works. He died on Aug. 12, 1674.

CHAMPARAN is a district in the northwest corner of Bihar state, India, between the Gandak and Baghmati rivers and Nepal. Area 3,553 sq.mi. Pop. (1961) 3,009,841. This roughly parallelogram-shaped district has in its northwest corner two Siwalik ranges, the Dun and Sumeswar hills. These hills of uncompacted and highly dissected sedimentary rocks are largely forested with sal (Shorea robusta). They cover 364 sq.mi. and are on the average 1,500 ft. above sea level. South of the hills is a narrow gravelly belt called the Bhabar, and below this is a marshy and grassy belt known as terai. The remainder of the district is a cultivated alluvial plain diversified by mango groves. The principal rivers are the Gandak, navigable all the year round, the Burhi Gandak, Lelbagi, Dhanauti and Baghmati. A chain of lakes occupying 139 sq.mi. and marking an old bed of the Gandak runs through the centre of Champaran. Three canals, the Teur, Dhaka and Tribeni, irrigate about 135,000 ac. in the north of the district. The Tribeni canal, from the Gandak, is the longest of these. The principal crops of Champaran are rice, maize (corn), wheat, barley. oilseed and sugar cane. Sugar cane has replaced the indigo plantations of the 19th century. Champaran has saltpetre refineries and leads other districts of Bihar in the number of sugar and rice mills.

The administrative headquarters are at Motihari (pop. [1951] 24,489), which is associated with the Champaran Satyagraha of Mahatma Gandhi in 1919 against indigo planters. There are nine other towns, the largest being Bettiah (pop. [1951] 35,634). The Nepalese treaty of 1815 was signed at the small town of Sagauli. The district contains three of the sandstone pillars engraved with edicts which Asoka the emperor (*q.v.; c.* 250 B.C.) erected to promote Buddhism. These are at Lauriya Nandangarh, Lauriya Araraj and Rampurva. (E. AH.)

CHAMPION. In the judicial combats of the middle ages in western Europe, women, minors and persons disabled by age or infirmity were allowed to nominate champions. Hence the word has come to be applied to anyone who champions, or contends on behalf of, any person or cause. The clergy, as individuals or corporations, were represented by champions; and in France and the empire that function was part of the duties of the advocatus who acted for bishops and abbots. Trial by battle was a recognized institution in Anglo-Norman law.

The office of king's champion (*campio regis*) is peculiar to England. His function was to ride, clad in complete armour, with the high constable on his right and the earl marshal on his left, into Westminster hall during the coronation banquet and challenge to single combat anyone who should dispute the king's right to reign. The challenge was repeated three times—at the entrance to the hall, in the centre and at the foot of the dais. On picking up his gauntlet for the third time, the champion was pledged by the king in a covered gilt cup, which was then presented to him as his fee. If he had had occasion to fight and had been victorious, his fee would have been the armour he wore and the horse he rode, the second best in the royal stables, but no such occasion ever arose. This ceremonial was not performed after George IV's coronation (1821), when the last coronation banquet took place.

Scrivelsby manor in Lincolnshire is held in grand sergeanty by the service of acting as the king's champion. The first recorded claim to the office was put forward by Henry Hillary in 1327. at the time of Edward III's coronation, and it is not known if he was successful. Hillary based his claim on tenure of Scrivelsby manor, which he had acquired by marrying Joan, daughter of Sir Philip Marmion. There is no evidence that the office of king's champion existed before 1327, or that any member of the Marmion family ever laid claim to it. Moreover there is no mention of grand sergeanty in the post-mortem inquisitions taken on the death of Sir Philip Marmion in 1291, and Scrivelsby manor was found to be held by barony. Nonetheless the court of claims allowed Sir John Dymoke (who had married Joan Marmion's granddaughter and heiress) to act as king's champion at Richard II's coronation (1377), and Dymoke's descendants, as lords of Scrivelsby manor, exercised the office at subsequent coronations down to 1821. After 1902 they carried the standard of England.

CHAMPLAIN, SAMUEL DE (c. 1567–1635), French explorer, colonizer and first governor of French Canada, known as the "father of New France," was born about 1567 at Brouage on the Bay of Biscay, the son of a sea captain. As a youth he fought under Henry of Navarre (Henry IV) in the religious wars, but in 1598 he took service under the king of Spain and, having been brought up to the sea, enlisted in an expedition to the West Indies and Central America. He was gone for more than two years, and visited all the principal American ports, pushing inland from Veracruz to Mexico City. The manuscript account of his adventures was not published until the latter part of the 19th century, when an English translation was printed by the Hakluyt society in 1859. The French text was included in the edition of Champlain's works by the Abbé Laverdière in 1870. It has often been pointed out that in his narrative Champlain suggested the construction of a Panama canal, "by which the voyage to the South Sea (Pacific ocean) would be shortened by more than 1,500 leagues"; but it should be noted that he was not the first to make this suggestion.

The statement has been made that when Champlain returned to France in 1601 he was appointed royal geographer; but there seems to be no evidence for this. He was, however, appointed geographer to the expedition sent out to America in 1603 by Aymar de Chatte, on whom the king had bestowed a patent as lieutenant general of New France; *i.e.,* all the land in North America claimed by France. This was Champlain's first visit to the Gulf of St. Lawrence, and he explored the St. Lawrence river as far as the island of Montreal. Aymar de Chatte died in 1603; but the patent held by him was conferred by the king on the sieur de Monts (*c.* 1561–c. 1630) with whom Champlain revisited the new world in 1604. On this occasion he explored the coast of North America as far south as Cape Cod, seeking a site for a new settlement and making surveys and charts. His was no doubt the most accurate attempt to map the coast of Maine and New England made up to that date. Champlain's party first attempted a settlement on an island near the mouth of the St. Croix river, where they spent a disastrous winter; but eventually they settled at Port Royal (later Annapolis Royal, Nova Scotia) on the Bay of Fundy. The colony at Port Royal took root but in 1613 it was destroyed by the Virginians under Sir Samuel Argall. In 1607, however, Champlain had returned to France, and there he persuaded the sieur de Monts to found a colony on the St. Lawrence. He was given command of one of two vessels sent out and on July 3, 1608, he established at Quebec the first permanent white settlement in North America, north of Florida.

Champlain devoted the rest of his life to making this settlement a success. In 1609, in order to insure the fur trade with the Algonkins and the Hurons to the west, he took part in an expedition of these Indians against the Iroquois to the south of the St. Lawrence. He discovered the lake that bears his name, and near the southern end of the lake he secured for his Indian allies a victory over the Iroquois—a victory which ushered in a century of warfare between the French and Hurons on the one hand. and the Iroquois and English on the other. In 1611 Champlain established a trading post at Mount Royal (now Montreal), as an outpost against the Iroquois and in 1612 he was appointed commandant of New France. In 1613, lured by the false report of one of his men that the Ottawa river led to "the sea of the North" (presumably Hudson bay), he ascended the Ottawa as far as Allumette Island, but finding the story false, he turned back. It was on his ascent of the Ottawa that he lost his astrolabe, which was

found two and a half centuries later by a farmer who turned it up while plowing at the site of the ancient portage. (*See* A. J. Russell. *On Champlain's Astrolabe,* pamphlet. 1879.)

In 1615 Champlain again ascended the Ottawa and, crossing over by the French river. reached Georgian bay. He spent the winter in the Huron country to the south of the bay, and in the spring was persuaded to accompany a war party of the Hurons across the eastern end of Lake Ontario, into the Iroquois country to the south of the lake. A few miles south of Lake Oneida, he had a second encounter with the Iroquois and was slightly wounded. He then returned to Quebec by way of the Huron country. This iourney marked the end of his explorations, The rest of his life he devoted to the colony at Quebec. He became, in 1628. one of the "One Hundred Associates" of the Company of New France, appointed by Cardinal Richelieu to supervise the colony, and became, in effect, the deputy of the company in Canada. In 1629, Champlain was compelled to surrender Quebec to an English expedition under the Kirke brothers, and was taken a prisoner to England. In 1632 the colony was restored to the French by the treaty of St. Germain-en-Laye, and in 1633 Champlain returned to Quebec. There he died on Christmas day, 1635. In 1610 he had married Hélène, 12-year-old daughter of Nicholas Boullé, secretary of the King's chamber. After his death she became a nun.

Champlain wrote and published a number of books, including *Les Sauvages* (1604), *Les voyages du Sieur de Champlain* (1613). *Voyages et dkcouvertes faites en la Nouvelle-France* (1619). *Les voyages du Sr. de Champlain* (1620), and *Les voyages de la Nouvelle France occidentale* (1632).

BIBLIOGRAPHY.—Champlain's works were edited by the Abbe C. H. Larerdiere, under the auspices of the University of Laval, 6 vol., (1870). and re-edited by H. P. Biggar for the Champlain society, 6 vol. (1922–1936), with a translation into English, and with a portfolio of Champlain's maps and charts. There is also a translation of Champlain's voyages in English by A. N. and E. G. Bourne, 2 vol. (1906), in the "Trailmakers Series." Fuller bibliographical information will be found in H. Harrisse. *Notes pour servir à l'Histoire de la Nouvelle France* (1872) and in P Gagnon, *Notes bibliographiques sur les écrits de Champlain,* Bulletin de la Société de Géographie de Quebec (1908).

There are several biographies of Champlain but by far the best has been Morris Bishop, *Champlain: The Life of Fortitude* (1948). There is no contemporary portrait of Champlain known to be in existence; the portrait of him which has been repeatedly reproduced is a portrait of an entirely different person copied by an obscure artist in 1854, and palmed off as the portrait of Champlain. See also H. P. Biggar, "The Portrait of Champlain," *Can. Hist. Review.,* vol. 1 (1920).

(W. S. WA.)

CHAMPLAIN, **LAKE,** with a total length of 125 mi. from north to south, forms the boundary between Vermont and New York for most of its length. It extends from Missisquoi bay and the Richelieu river in Canada southward to South bay near Whitehall, N.Y. It has a maximum width of 13 mi. and a total area of 490 sq.mi., consisting of 435 sq.mi. of water surface and 55 sq.mi. of islands. The lake empties into the St. Lawrence river through the Richelieu river.

Lake Champlain is extensively utilized for commercial and pleasure boat navigation. Most of the lake is 100 to 335 ft. deep and there are few shoals. The navigation season is limited to eight months, however, by ice conditions. The lake is a link in the international waterway between New York harbour and the lower St. Lawrence. It is connected with the harbour by the narrows of Lake Champlain (a national, improved waterway at the southern end of the lake), Champlain canal and the Hudson river, with a controlling depth of 12 ft. The St. Lawrence may be reached from Lake Champlain by way of the Richelieu river and Chambly canal, with a controlling depth of 63 ft. Commerce along the lake consists largely of petroleum, newsprint and fertilizer. The most important ports are Burlington, Vt., and Rouses Point. Plattsburgh and Port Henry, N.Y. Plattsburgh air force base occupies the site of a former (1815–1946) army post.

Lake Champlain fishing is popular; the catch includes trout, salmon, bass and walleye (pike perch). The tributaries and their branches—Otter creek and the Mettawee, Poultney, Winooski, Lamoille, Missisquoi, Bouquet, Xusable, Saranac and Great Chazy —are fished for trout.

The Champlain lowland, the widest in Vermont, spreads across 25 mi. in the north. It slopes from an average elevation of 300 ft. in the south to 120 ft. in the north. and is underlaid by limestones, dolomite, shale and sandstone. and largely covered by postglacial lake deposits and glacial till. The lowland's flat or rolling topography and dairy and fruit farms contrast with the abrupt, sharp rise of the fronts of the Green and Adirondack mountains with their high peaks and forested slopes. The Champlain valley is the major dairy region in Vermont and the most-traveled route from southern New York to Canada. Its highways lead summer vacationers and skiers to famous resorts at its mountainous border.

History.—Lake Champlain was discovered in 1609 by the French explorer and soldier Samuel de Champlain, from whom the lake takes its name. During the early period of settlement, Lake Champlain was the gateway between French Canada and the English colonies. It played an important part in all the wars during which hostile peoples faced each other across the lake. The first engagement ended when Champlain, with an expedition of about 80 friendly Algonquin and Huron Indians, defeated the Iroquois on its shores in 1609. Thus began the long struggle between the French and the Five (later Six) Nations. (*See* also IROQUOIS.)

In 1731 the French built a fort at Crown Point, N.Y., and in 1; jj another at Ticonderoga; both were important strategic points during the French and Indian War and the American Revolutionary War. They controlled the easiest and most natural route between Canada and New Tork. During the French and Indian War (*q.v.*), English and colonial expeditions twice failed to capture Crown Point. Ft. Ticonderoga was the scene of the severe repulse administered to Gen. James Abercrombie by General Montcalm in 1758 Both forts were finally occupied by Gen. Jeffrey Amherst. During the American Revolution Ethan Allen's Green Mountain Boys captured both points early in the war. Allen took Ticonderoga in a surprise attack. When asked by the British commander by what authority the surrender of the fort was demanded, Allen made his historic reply, "In the name of the great Jehovah and the Continental Congress." During the subsequent years of the war the fort changed hands several times. On Oct. 11, 1776, the first battle between an American and a British fleet, the battle of Valcour Island, was fought on the lake. Benedict Arnold, the American commander, with a decidedly inferior force, inflicted severe damage on the enemy and then escaped during the night. Although overtaken two days later he again, after a fight of a few hours, made a successful retreat, saving all his men.

At the beginning of the War of 1812 the U.S. naval force on the lake, though very small, was superior to that of the British, but on June 3, 1813, the British captured two U.S. sloops in the narrow channel at the northern end and gained supremacy. Both sides then began to build and equip vessels for a decisive contest. By May 1814 the Americans had regained supremacy. Four months later a British land force under Sir George Prevost and a naval force under Capt. George Downie confronted a U.S. land force under Brig. Gen. Alexander Macomb, strongly entrenched at Plattsburgh and a U.S. naval force in Plattsburgh bay under Commodore Thomas Macdonough. The British opposed about 11,000 men to the Americans' 1,500, and 16 vessels of about 2,400 tons with 937 men and 92 guns to 14 American vessels of about 2,240 tons with 882 men and 86 guns. The naval battle occurred on the morning of Sept. 11, 1814. Although the weight of the metal thrown by the guns of Macdonough's fleet was greater than that of the British fleet, the latter had more guns of long range. Knowing that in a battle in the open lake he would be at a disadvantage, Macdonough anchored his fleet in a manner that forced Downie to pass between him and the land and prevented Downie from anchoring his fleet out of range of the U.S. guns. Downie was killed early in the fight, and the British fleet was soon driven out of action. As the lake was entirely in the control of the Americans. Prevost was forced to retreat during the night of Sept. 12–13, leaving his sick and wounded behind. The British gave up further efforts to invade New York. *See* also WAR OF 1812.

CHAMPMESLÉ, MARIE (née DESMARES) (1642–1698), French actress. creator on the stage of a number of Racine's heroines, was born in Rouen. In 1666 she married the actor Charles Chevillet de Champmeslé (1642–1701), and by 1669 both were members of the Marais theatre in Paris. In the following year they joined the Hôtel de Bourgogne, where Mlle Champmeslé had her first success when she was allowed to play Hermione in Racine's *Andromaque*. Only with difficulty could Racine be persuaded by his friends to see the newcomer's debut, but after the performance he snore to write more roles for her. Thereafter Mlle Champmeslé celebrated her greatest triumphs in creating such Racinian parts as the title role of *Bérénice*, Roxane in *Bajazet*, Monime in *Mithridate* and the heroines of *Iphigénie* and *Phèdre*. Racine. who was also her lover, coached her and imparted to her the system of musical declamation he had developed. Mlle Champmeslé indeed is credited with having founded the French tradition of the "touching voice." The art with which she employed her voice elicited applause from many playgoers, most of whom came, according to Mme de Sévigné, to admire the actress, not the play. In 1679 she left the Hôtel for the amalgamated Molière-Marais company, which was to form the nucleus of the Comédie Française (1680). At the height of her fame she taught acting to her niece Christine Antoinette Charlotte Desmares and to Mlle Duclos. who, after 1693. served as her understudy and who inherited Mlle Champmeslé's roles when the latter died in Auteuil on May 15, 1698. *See* also RACINE, JEAN. (A. M. N)

CHAMPOLLION, JEAN FRANÇOIS (1790–1832), French Egyptologist and founder of scientific Egyptology, called LE JEUNE to distinguish him from J. J. Champollion-Figeac *(q v.)*, his elder brother, was born at Figeac, in the *ddpartement* of Lot, on Dec. 23, 1790. At the age of 16 he read before the academy of Grenoble a paper in which he maintained that Coptic was the ancient language of Egypt. He soon after moved to Paris. In 1809 he was made professor of history in the Lyceum of Grenoble. His first decipherment of hieroglyphics dates from 1821. In 1824 he nas sent by Charles X to visit the Egyptian antiquities in the museums of Italy, and on his return was appointed director of the Egyptian museum at the Louvre. In 1828 he was commissioned to conduct a scientific expedition to Egypt in company with I. Rosellini. In March 1831 he received the chair of Egyptian antiquities. which had been created specially for him. in the Collège de France. He was engaged with Rosellini in publishing the results of their Egyptian researches when he died at Paris on March 4. 1832. Champollion's brilliant discoveries met with great opposition. much of it acrimonious and personal, chiefly from scholars reared in the classical tradition who resented the prominence given by these discoveries to an ancient "barbarian" nation. The rival claims of the contemporary Englishman, Thomas Young. really amount to very little and have since been dismissed by those who are competent to judge.

Champollion's writings included: *L'Égypte sous les Pharaons*, two volumes (1814); *De l'écriture hiératique* (1821); *Précis du système hiéroglyphique, etc.* (1824); *Panthéon e'gyptien, ou collection des personnages mythologiques de l'ancienne Égypte* (incomplete, 1823–25); *Grammaire égyptienne* (1836–41), and *Dictionnaire e'gyptien* (1842–43), edited by his brother; *Lettres écrites d'Égypte et de Nubie* (1833). Champollion also wrote several letters on Egyptian subjects. *See* also ROSETTA STONE.

See H. Hartleben, *Champollion, sein Leben und sein Werk*, 2 vol. (1906); *Lettres de Chanzpollion le Jeune*, 2 vol. (1909).

CHAMPOLLION-FIGEAC, JACQUES JOSEPH (1778–1867), French archaeologist, elder brother of the Egyptologist Jean François Champollion, was born at Figeac in the *département* of Lot, on Oct. 5, 1778. He became keeper of manuscripts at the Bibliothèque Nationale in Paris and professor of paleography at the École des Chartes. In 1819 he became librarian of the palace of Fontainebleau. where he died on May 9. 1867. His works include: *Nouvelles recherches sur les patois ou idiomes vulgaires de la France* (1809). *Annales de Lagides* (1819) and *Chartes latines sur papyrus du VI^e siècle de l'ère chrétienne*.

His son AIMÉ (1812–1894) became his assistant at the Bibliothèque Nationale and, in addition to a number of historical works, wrote a biographical and bibliographicnl study of his family in *Les Deux Champollion* (1887). (J. WH.)

CHANCEL, strictly, that part of a church close to the altar and separated from the nave *(q.v.)* by cancelli or screens. This space, originally known as the space *inter cancellos,* or *locus altaris cancellis septus,* came itself to be called the chancel. Later the word came to include the whole of that part of the church occupied by altars, communion tables and all the officiating clergy and singers, *i.e.*, the presbytery *(q.v.)*, the chancel proper and the choir. The term "choir" is also sometimes applied to this part of the church; otherwise, it pertains to only the space designated for the singers.

In basilican churches, the chancel is set apart only by a low railing; *e.g.*, S. Clemente. Rome. Such divisions correspond more to the altar, communion or sanctuary rail of a modern church than to the developed medieval chancel screen. In the highly organized medieval church, the chancel is clearly differentiated from the nave by the raising of the floor level, and by the chancel or rood screen *(see* JUBE). This screen is frequently continued on each side, behind the choir stalls, and around the east end of the cathedrals of sanctuary, as in Paris. Bourges and Amiens. At the side, such screens form the back of the choir stalls. The chancel screen in front of the altar is sometimes only a low parapet, sometimes a light, openwork structure of wood or metal. but often, especially in the large cathedrals and abbeys of England. a massive and solid stone structure. frequently carrying the organ. In collegiate and monastic churches, these screens thus completely separated the spaces reserved for services for the members of the clerical community from the spaces for popular services, for which a second altar was usually set up to the west of the screen. as formerly in Westminster abbey.

Chancel sizes vary enormously. On the European continent they usually extend from the east end to the crossing, as in many modern churches, but in abbey churches, and generally in English medieval churches, they comprise also several bays of the nave. In the churches of Paris the chancel is relatively small. The chancel screen becomes more open and its main function is to support a crucifixion group; it is, therefore, primarily a rood screen. In small churches the chancel is sometimes lower and narrower than the nave. The size of the chancel is determined by ecclesiastical

EARLY ENGLISH CHANCEL OF ST. MARGARET'S CHURCH. LEICESTER, ENG.

developments as well as architectural styles, particularly by the amount of emphasis placed upon the sacrament of the Eucharist.

CHANCELLOR, RICHARD (d. 1556), English seaman whose famous visit to Russia Iaid the foundations of English trade there, is said to have been brought up by the father of Sir Philip Sidney. When in 1553 Sir Hugh Willoughby fitted out an expedition in search of the northeast passage to China, Chancellor was appointed pilot general. It was arranged that the expedition should meet at Vardö. but because of unfavourable weather Chancellor's was the only one of the seven ships that arrived. He therefore went on alone into the White sea and thence overland to Moscow, where the tsar sho ed him great hospitality and gave him a letter for the sovereign of England granting very favourable conditions for English trade. Chancellor rejoined his ship in the summer of 1554 and went back to England. His successful negotiations with the emperor resulted in the foundation of the Muscovy company in 1555. Chancellor left England again for Moscow in 1555, arriving in November of that year. He lost his life in a wreck on the return voyage, on Nov. 10, 1556, off Pitsligo on the coast of Aberdeenshire.

CHANCELLOR. The title of chancellor is given to a group of widely assorted offices held by persons of most diverse ranks. These varieties of office and rank are easily accounted for by the diversity of the functions exercised from the Roman period by those who bore this title and by the development of these functions according to country or institutions.

Origins. — The word chancellor, cancellarius, was first applied to the minor officials of the Roman law courts who used to stand near the balustrade or bar. cancellus, erected in the courts to separate the tribunal from the public. They were responsible for ensuring order during the hearings and were also the intermediaries between magistrates and those to be tried and so, like the notarii or clerks, were entrusted with official functions. In palace business the Roman emperors employed officials of the same kind who worked in the offices (*scrinia*) that constituted what is now called the imperial chancellery, although that expression was not used at the time. The barbarian kingdoms that emerged from the dismemberment of the Roman empire took up this form of administration in their turn. In the Frankish kingdom during the Merovingian period continuity of administration was secured by the appointment of a *summus referendarius* ("chief clerk"), always a layman, who mas confirmed in his office by the committal to him of the king's seal. Several of these clerks could hold office at the same time. They disappeared at the accession of the Carolingians whose chancellery was directed by a single head, always an ecclesiastic, and who, during the 9th and 10th centuries, bore the title of *summus sacri palatii* cancellarius or archicancellarius. This archchancellor was first recruited from among the subordinate officials but became in time one of the most important officials of the palace. The office was held, from the reign (814–840) of Louis the Pious, by the archbishop of Reims, the abbot of St. Denis, members of the imperial family or men of great learning.

Ecclesiastical Chancellors. — The popes, from the earliest centuries of the church, used departments modeled on the imperial chancellery. But, although the office existed, the title of *cancellarius* was not retained; business was dispatched by the bibliothecarius ("librarian"). The title of chancellor reappeared in 1027, but only for one century, and from the end of the 12th century the cardinal head of the chancellery was always called the vice-chancellor. Since the decree Sapienti Consilio of June 29, 1908, the chancellery, one of the three offices of the Roman curia, has as president a cardinal who once again bears the title of chancellor and has power to issue litterae sub *plumbo* ("letters under seal").

As did the pope and the great lay lords, the bishops also provided themselves with administrative staffs, and each diocesan curia required a cancellarius to maintain the records of the curia, register them, keep the bishop's seal and sign official documents. The signature of the chancellor or vice-chancellor began to appear from the 10th century onward.

The Chancellor as a Great Officer **of** State. — The chancellorship in England developed on different lines from the chancellorships on the continent of Europe. For the history of the English officeof chancellor see LORD HIGH CHANCELLOR; EQUITY. (See also CHANCELLOR OF THE DUCHY OF LANCASTER; CHANCELLOR OF THE EXCHEQUER.)

France. — The title of chancellor, which was found among the institutions of the French monarchy until its final suppression in 1848, was borne by people performing widely differing functions. Under the early Capetians and up to the reign (1180–1223) of Philip Augustus, it is possible to distinguish between two officials: on the one hand, the archchancellor or archchaplain, nearly always the archbishop of Reims, himself head of the chapel royal; and on the other the chancellor proper, the head of the chancellery offices whose staff, notarii, was recruited from among the clerks of the chapel. As such, the chancellor, always an ecclesiastic, was at the head of the administration at the royal palace and responsible for the issue of royal documents and charters; but he was also invested with judicial powers, charged with the control of the ecclesiastical affairs of the kingdom and even with foreign affairs. Fearing the excessive power of the holder of this office (who, under Louis VI, exercised simultaneously with it the offices of seneschal and steward) the kings from 1127 onward often left the position unfilled, and Philip Augustus did not appoint a holder after 1185. It was re-established in 1223 by Louis VIII for the benefit of Brother Guérin, bishop of Senlis, who held it until his death in 1227 but had no successor. The office of chancellor was held from that time until 1314 by a "warden of the seal." *custos sigilli* or vice-cancellarius, always of the lower clergy. Philip the Fair was the first to confer the office upon laymen (Pierre Flote from 1298 to 1302, Guillaume de Nogaret from 1307 to 1313) but when, even during his reign, it reverted to ecclesiastics, these were once more bishops. It seems also that in current usage the warden of the seal was once again called chancellor. Thenceforth, and until the suppression of his office in 1790, the chancellor of France, the last great crown officer to survive, saw his functions grow in importance until they made him the second personage of the kingdom. The chancellors were chosen by the king (with the assent of the council of state from the reign of Charles V). In the 16th and 17th centuries they were eminent jurists, and in the 18th century great personages, although the king did not hesitate to relieve them of their duties on occasion. Louis XV tiendra les *sceaux* en sa *personne* ("will himself hold the seals") from 1757–61.

The office, suppressed at the Revolution, was re-established in 1804 by Napoleon, but in imitation of its form under the Germanic Holy Roman empire, with the title of imperial archchancellor bestowed on J. J. R. Cambacérès. The office of chancellor was re-established in May 1814, its duties now making of its holder a real minister of justice. It remained vacant from 1830–37. Until suppression of the office in 1848, the chancellor assumed the functions of president of the house of peers.

The orders of chivalry (St. Michael, the Holy Spirit) had likewise at their head a chancellor who assisted the king in the creation ceremony by delivering their insignia to the new knights. The existing orders of the Legion of Honour and of the Liberation both have at their head a grand chancellor.

The title of chancelier continues also to be used in France for the large class of officials who discharge notarial duties in some public offices, in embassies and consulates. They draw up diplomas and prepare all formal documents, which they issue on payment of a fee (*droits* de *chancellerie*), and superintend the registration and preservation of the archives.

Spain. — The office of chancellor emerged in the reign of Alfonso VII of Castile (1126–57) who, in imitation of the French kings, entrusted to one of his secretaries, thenceforth called the chancellor, the custody of the royal seal and the charge of legalizing with it all official documents and letters. Alfonso XI, who reigned from 1312 to 1350, conferred the titles of canciller de Cnstilla and of Maestro del Real *Archivo* on the archbishop of Toledo. The king's private seal was kept by the Canciller del sello de la *puridad;* this office was suppressed in 1496. Laymen also were entrusted with the office, which the minister of pardons and justice exercised for a time between 1873 and 1875. The Gran *Canciller* de *Indias*

headed the council in the governor's absence and issued all decrees concerning the American possessions. This office was abolished in 1873.

The Holy Roman Empire, Germany **and** Austria. — The archbishop of Mainz, chancellor of the kingdom of Germany exercised from 965 the functions of archchancellor of the empire, *Erz-Kanzler,* until the suppression of this office in 1806. His jurisdiction never extended to Italy which, during the 12th century. depended for this purpose on the archbishop of Cologne, while the archbishop of Besançon became in 1045 archchancellor of the kingdom of Burgundy. At the beginning of the 14th century the archbishop of Trier bore the title of archchancellor of the kingdom of Arles. These last titles however became purely honorary and only the archbishop of Mainz preserved effective authority. Nevertheless, the direction of the chancellery of the Reich was held not by the archchancellor but by the chancellor, *cancellarius aulae imperialis (regalis),* who was always an ecclesiastic and often a bishop. As immediate collaborator of the sovereign he was present everywhere, at councils and tribunals, in the internal administration of the Reich as on the occasion of diplomatic missions. Karl von Dalberg, archbishop of Mainz and last archchancellor of the empire, became chancellor of the confederation of the Rhine. The confederation of North Germany had a *Bundeskanzler*, the title which Bismarck bore when the empire was reestablished in 1871. Thereafter Bismarck called himself the *Reichsknnzler,* acting at the same time as president of the council to the Prussian government, and concentrating in his own hands the direction of all branches of the administration. The constitution of Weimar (Aug. 1919) made the *Reichskanzler* head of the government; nominated by the president of the Reich. he appointed ministers and was responsible to the Reichstag for the government, Hindenburg nominated Hitler to this office on Jan. 30, 1933. After 1949 the constitution of the German Federal Republic established a *Bundeskanzler* appointed by the federal diet on the proposal of the federal president.

In the German states as in France the title of chancellor was also given to government and diplomatic officials who performed notarial duties and had charge of archives. The title of chancellor has naturally been widely used in the German and Scandinavian states. and in Russia since the reign of Peter the Great. It has there. as elsewhere, wavered between being a political and a judicial office. Frederick the Great of Prussia created a *Gross-Kanzler* for judicial duties in 1746. But there was in Prussia a state chancellorship on the Austrian model. It was allowed to lapse on the death of Karl August von Hardenberg in 1822. The Prussian chancellor after his time was one of the four court ministers *(Hofamter)* of the Prussian monarchy.

The Habsburg house of Austria in their hereditary dominions, and in those of their possessions which they treated as hereditary, even where the sovereignty was in theory elective, made a large and peculiar use of the title of chancellor. In the family slates the administration was based upon a group of councils. Until the March revolution of 1848 it was conducted through boards presided over by a chancellor. There were three aulic (*i.e.,* court) chancellorships for the internal affairs of their dominions, "a united aulic chancellorship for all parts of the empire (*i.e.,* of Austria. not the Holy Roman) not belonging to Hungary or Transylvania, and a separate chancellorship for each of those last-mentioned provinces." There were also a house, a court and a state chancellor each for the business of the imperial household and of foreign affairs, who were not, however, the presidents of a board. These officers were in fact secretaries of the sovereign, and administrative or political rather than judicial in character, although the boards over which they presided controlled judicial as well as administrative affairs. In fact. the Austrian chancellors controlled all state policy from the time when the direction of the various chancelleries or departments was united in one person such as W. A, von Kaunitz or C. von Metternich.

Chancellor of a University. — From the time of the foundation of the principal European universities during the 12th and 13th centuries, their heads were called chancellors; even before the foundation of the Sorbonne this title had been borne at Paris by the head of the chapter school of Notre Dame. In the bishop's name, the chancellor had general charge of the teaching, conferred degrees and exercised jurisdiction over all members of the university. But from the end of the 13th century his powers were so limited that the title had become a mere form; authority and the conferment of degrees had devolved upon the rector. In the Italian universities, which were of private origin, the chancellor was appointed by the popes or the emperors. Likewise Oxford and Cambridge, where the office still exists, had no chancellor before the mid-13th century. From the 16th century every university would have besides its rector a chancellor who, in the cathedral towns, was the bishop. The functions of the chancellor in the Catholic universities were made uniform by the decree *Deus scientiarum* of May 24, 1931.

In England the chancellorship of the universities is conferred on noblemen or statesmen of distinction, whose principal function is to look after the general interests of the university, especially in its relations with the government. The chancellor is represented in the university by a vice-chancellor, who performs the administrative and judicial functions of the office. In the United States the heads of certain educational establishments have the title of chancellor.

Miscellaneous.—The judicial institutions of some countries still include a chancellor who may be only a minor legal official concerned with the drafting and conservation of acts, such as the *canciller registrador* in Spain, or the clerk of a court elsewhere, or an official whose functions may on the other hand permit him to intervene in the pronouncement of judgment, as in Great Britain and Italy.

In Scotland the foreman of a jury is called its chancellor. In the United States the chancellors are judges of the chancery courts of the states *(e g.,* Delaware and New Jersey) where these courts are still maintained as distinct from the courts of common law. In other states (*e.g.,* New York since 1847) the title has been abolished. There is no federal chancellor in the United States.

In diplomacy generally the chancellor of an embassy or legation is an official attached to the suite of an ambassador or minister. He carries out the duties of a secretary, archivist, notary and the like. and is at the head of the chancery, or chancellery, of the mission. The functions of this office are the transcribing and registering of official dispatches and other documents and, in general, the transaction of all minor business, *e.g.*, marriages, passports and the like, connected with the duties of a diplomatic agent toward his nationals in a foreign country.

CHANCELLOR OF THE DUCHY OF LANCASTER, the representative of the crown in the management of its lands and the control of its courts in the duchy of Lancaster. These lands and privileges have always been kept distinct from the hereditary revenues of the sovereign, whose palatine rights as duke of Lancaster were distinct from his rights as king. The Judicature act of 1873 left only the chancery court of the duchy, but the chancellor can appoint and dismiss the county court judges within the limits of the duchy. He is responsible also for the land revenues of the duchy and keeps the seal of the duchy. As the judicial and estate work is done by subordinate officials, the office is usually given to a minister whose assistance is necessary to a government, but who is not burdened with the duties of an important department.

CHANCELLOR OF THE EXCHEQUER, the minister in charge of the British treasury. His principal duty is to prepare

and present in the house of commons the budget for each financial year. The speech in which the chancellor presents his budget summarizes the government expenditure estimated for the coming financial year and outlines his proposals for raising the revenue necessary to meet it. It is also, in modern practice, an analysis of the general economic situation. Since the Victorian era the treasury has exercised a large measure of administrative control over the claims and expenditures of other departments, in relation to which the chancellor is thus in a particularly powerful position.

Historically the name of this office derives from the separation of the chancery from the exchequer in the reign of Henry III. The office has grown to its present importance since the board of the treasury ceased to sit as such and the first lord of the treasury came to be, by invariable practice, the prime minister who is ordinarily divorced from day-to-day responsibility for the treasury. See also EXCHEQUER. (W. T. Ws.)

CHANCELLORSVILLE, a village in Spottsylvania county, Va.. situated almost midway between Washington, D.C., and Richmond, Va. It was the central point of one of the greatest battles of the American Civil War, fought from May 1 to 4, 1863, between the Union army of the Potomac under Gen. Joseph Hooker, and the Confederate army of Northern Virginia under Gen. Robert E. Lee. (See AMERICAN CIVIL WAR; WILDERNESS.) Gen. "Stonenall" Jackson was mortally wounded in this battle.

CHANCERY, in English law, refers to the court presided over by the lord high chancellor and hence, in a broader sense, to the practices and principles of this court. commonly known as equity. In 1873 the court of chancery, along with the other superior courts, was consolidated in the supreme court of judicature. where it comprises the chancery division of the high court of justice (*q.v.*). For the history of the court and its jurisdiction see EQUITY: *England;* LORD HIGH CHANCELLOR; ENGLISH LAW.

In the United States, chancery is generally used as a synonym of equity, and chancery courts are equity courts in the few jurisdictions where such tribunals are separately maintained (see EQUITY: *United* States).

For the diplomatic sense of chancery (chancellery), *i.e.,* as the office of a chancellor or as a place for issuing and recording official documents, see CHANCELLOR; DIPLOMATIC.

CHAN CHAN, a great ruined and deserted pre-Inca city on the north coast of Peru, once (about A.D. 1420) the capital of a populous, powerful and relatively advanced civilization known as the Chimú.

The City. — Chan Chan lies in the Moche valley, about 300 mi. N. of Lima, between the Pacific ocean and the modern city of Trujillo. The ruins cover six to ten square miles, thick with the remains of buildings of adobe mud bricks, with mud surfacing often decorated with relief arabesques in repetitive textile designs. Because of the almost entire absence of rain, the ruins are remarkably well preserved; some of the walls which formerly surrounded the city as well as its component parts still reach a height of about 30 ft. It is divided into about ten well-planned quadrangular "wards," relatively similar, each with straight parallel streets, rows of gable-roofed houses, pyramidal temples, stone-lined reservoirs, gardens and cemeteries. The population was certainly very great. In its prime the city must have been verdant, but today, the irrigation ditches neglected, not a leaf is to be seen.

In spite of the size and importance of Chan Chan as one of the major archaeological sites of Peru, no full scientific description and no plan had been published by the early 1960s.

The People. — Before the explosive establishment of the Inca "empire" the Chimú had what was probably the largest and most important "kingdom" in Peru; they were the principal rivals of the Inca. They were the descendants — culturally at least — of the earlier population, the Moche or Mochica. formerly known as the "Proto-Chimu." The Chimú domain had been extended by conquest from Piura to Paramonga and Casma in the south. Two Spanish chroniclers recorded their historical and partly mythological traditions; the Chimú, like all the aboriginal Peruvians, had no system of writing. They were overcome in A.D. 1465–70 by the great Inca conqueror Pachacfitec and his son Topa Yupanqui, who assembled a great army to subdue them. Accounts of the war differ. but that most generally accepted is that the Chimú ruler's councillors convinced him of the futility of resisting Inca might.

Chimú culture was based on agriculture, aided by immense and admirable works of irrigation engineering. They were skilled craftsmen and did excellent work in textiles and in gold, silver and copper. Pottery types tended to be standardized, with quantity production, made in molds, and generally of a plain black ware. The language, known as Yunca (Yunga) or Mochica. now extinct, was very different and probably entirely distinct from that of the Inca.

BY COURTESY OF THE UNIVERSITY MUSEUM, UNIVERSITY OF PENNSYLVANIA

SILVER AND GOLD VESSELS OF THE CHIMÚ CULTURE. PERU

The Chimú culture flourished in what is sometimes described as the Urbanist or City-builder phase of Peruvian cultural development, variously estimated as lasting two to four centuries preceding A.D. 1450. There seems to have been considerable social stratification from peasant to nobility, and probably all the basic elements of the contemporary Inca civilization were present on a slightly smaller scale. See also ANDEAN CIVILIZATION.

CHAN-CHIANG (Cantonese TSAM-KONG), a port city on the east coast head of the Luichow peninsula, on Kuang-chou wan (Kmangchow bay), Kwangtung province. south coast of China. Pop. (1953 census) 166,000. Communist China began to enlarge the port in 1954, to create a major south-coast seaport, and in July 1955 completed a 200-mi. branch railway from Li-t'ang in Kwangsi to Chan-chiang. Highways link the port with the peninsula and the hinterland. Its landlocked harbour with water depths of more than 30 ft. lies behind a group of offshore islands.

In the 19th century Kuang-chou wan was a pirate base. To protect its possessions in Indochina and eliminate piracy France in 1898 exacted from China a 99-year lease on an approximately 300-sq.mi. area, including a strip of mainland, the deepwater mouth of the small Ma-ch'ih river, the bay and the offshore islands. which became internationally known as Kwangchowwan. France returned the area to China in 1946. The French base, Fort Bayard, grew into a French colonial city with a population of about 25.000. Nearby was the Chinese-built trade centre of Tche-kam, a settlement of about 50,000. The leased area had a population of about 300.000 in 1946. The French had developed an airport, hospitals and naval and port facilities for medium-sized ships, which served as the basis for further port enlargement. See also KUANG-CHOU WAN. (J. E. SR.)

CHANCRE is a term formerly used loosely to designate any sore or ulcer. especially one of a corroding nature or venereal origin. It is now applied almost exclusively to the primary lesion of syphilis. which used to be called a hard, indurated or Hunterian chancre. It appears at the site of inoculation in from one to seven weeks after exposure, and is most commonly found on the external genitals, but sometimes on the lip, tongue and other parts. A small, hard, translucent swelling appears at the infected spot, becomes gradually larger (up to one inchj, and often breaks in the centre, leaving a shallow ulcer. This lesion is the chancre and represents the first reaction of body tissues to the causative agent, *Treponema pallidum.* Diagnosis is established by finding the organism in scrapings from the ulcer. See VENEREAL DISEASES.

CHANCROID, an acute, localized infection, usually of the genital area, acquired in most instances through sexual contact.

The causative agent is a microorganism called the Streptobacillus of Ducrey. The sulfonamide drugs are effective in its treatment. *See* VENEREAL DISEASES.

CHANDA (ancient CHANDRAPUR, "city of the moon"). a town in Maharashtra state, India, headquarters of Chanda district. is near the confluence of the Wardha (*q.v.*) and Erai rivers, 85 mi. S. of Nagpur. It was the capital of a Gond tribal dynasty from the 12th to 18th century, and must once have had a much larger population than it had at mid-20th century, as shown by the 5½-mi. circuit of its old city walls. Pop. (1951) 40,744. Chanda is on the Central railway, connected southward with Hyderabad and Vijayavada, and north ard with Wardha on the Nagpur-Bombay line **A** narrow-gauge line of the Southeastern railway runs northeast via Nagbhir to Nagpur. Chanda is noted for silk fabrics, ornamental slippers and similar minor manufactures. **A** large annual fair is held. Bhandak, a village near Chanda, was the capital of the Hindu Vakataka dynasty from the early 4th to the early 6th century A.D. The Vakataka kings controlled Madhya Pradesh and much of the central and western Deccan, and were the patrons of several of the cave-temples at Ajanta (*q.v.*).

CHANDA DISTRICT has an area of 9.200 sq.mi., but this includes 4,000 sq.mi. of wild and thinly populated country, and 2,700 sq.mi. covered by government forest reserves, including the Tairoba game and national park in the north. The forests yield valuable teak and other timber and contain large bamboo jungles. Coal of poor quality is found in the west at Ballarpur, Warora and Ghugus, and high-grade iron ore is found in the east near Alewahi on the Chanda-Nagbhiv railway line. Rice is the main crop, followed by large areas of jowar (sorghum) and small millets, and some sugar-cane and garden crops. On the northwest border cotton and wheat are grown. Irrigation is effected by numerous tanks and large storage reservoirs.

Chanda is a picturesque part of the country, with varied scenery, wooded hills and interesting archaeological remains, old temples and forts, notably at Bhandak, Markandi and Wairagarh. But the climate is unpleasantly hot and the forests malarial.

The Marathi language spoken in the northwest of the district gives way to Telugu in the south and to Hindi (Chhattisgarhi dialect) in the northeast. In all the wilder tracts aboriginal tribespeople predominate, and Gondi and other tribal dialects are common. The total population of the district in 1961 was 1,238,701. (D. G. NA)

CHANDELIER is a frame of metal, wood, crystal or glass suspended from the roof or ceiling for the purpose of holding lights—lamps, candles, electric lamps, etc. *See* CANDLESTICK; LAMP.

CHANDERNAGORE (CHANDARNAGAR), a former French settiement in India, situated on the right bank of the Hooghly, 21 mi. above Calcutta with which it is connected by rail. Pop. (1961) 67,534 (including the southern suburb of Gourhati). Chandernagore became a French settlement in 1674 and, though captured twice by the British, remained under the French until 1950 when it was incorporated into India following a plebiscite. It was then included in Hooghly district, West Bengal, and made a municipal corporation in 1954. Its magnificent buildings, including the former Government house (now a museum and art gallery), stretch along Quai Dupleix, overlooking the river. There is a large, fine Roman Catholic church, built by the French in 1880, and a college. Cotton weaving and furniture making are the principal industries One of the largest jute mills of West Bengal is located there. (S. P. C.)

CHANDIGARH, the capital of the Punjab, India, is situated a few miles south of the Siwalik range in the plain between the Sukhna and Patiala streams, 151 mi. N.N.W. of Delhi by rail. Pop. (1951) 5,294. The city with a projected population of 150,000 was planned by Le Corbusier (*q.v*) in collaboration with Indian architects. to replace the former capital city lost to Pakistan when India achieved its independence. The site was selected in 1948. Construction started in 1950, and the broad layout of the city was completed by the early 1960s. Chandigarh is divided into 30 rectangular sectors, 24 of which are residential. Each sector has an area of 250 ac. and a housing capacity of 15,000 and is self-contained in civic amenities. The grid of the roads is so planned that the fast moving traffic is segregated from the internal traffic of the sectors. The high court, nine-storied secretariat, the legislative assembly chamber, and Raj Bhavan (governor's house) are all situated in the northern portion of the city. To the northeast is a large artificial lake. In the southeast is the sector allotted for industrial establishments, separated from the city by a 400-ft. green belt. The city is also the seat of Panjab university, which occupies another sector, together with all the post-graduate departments which include natural and social sciences, languages and humanities.

Chandigarh is connected by rail with Ambala and Delhi on the one hand and Kalka and Simla on the other. It is also connected with all the important towns of the Punjab by direct bus routes. (O. P. B.)

CHANDLER, ZACHARIAH (1813–1879), U.S. politician, was born at Bedford, N H., on Dec. 10, 1813. In 1833 he moved to Detroit nhere he became a prominent dry-goods merchant and amassed a fortune. After serving as Whig mayor of the city (1851–1852) he ran unsuccessfully for governor of Michigan in 1852. Two years later he took part in the founding of the Republican party at Jackson, Mich.

Chandler was elected to the U.S senate in 1857 and during the American Civil War played an important role on the joint committee on the conduct of the war. Because of his extremism, he clashed frequently with President Lincoln during the war and with President Johnson during the Reconstruction period. His advocacy of firm measures in dealing with the south was coupled with a consistent belief in sound money, protective tariffs and internal improvements. After being defeated for re-election in 1875 he was appointed secretary of the interior by President Grant (1875–1877). During the disputed presidential election of 1876 he served as chairman of the Republican national committee and vigorously upheld the claims of Rutherford B. Hayes. He was re-elected to the senate in Feb. 1879, but died on Nov. 1 of that year in Chicago. Chandler was an effective champion of emancipation and radical reconstruction whose methods were often ruthless, but whose skill was unquestioned.

See Wilmer C. Harris, *The Public Life of Zachariah Chandler, 1851–*1875 (1917); T. Harry Williams, *Lincoln and the Radicals (1941)*; "Zachariah Chandler: an Outline Sketch of His Life and Public Services," *Detroit* Post *and Tribune (1880).* (H. L. T.)

CHANDOS, BARONS AND DUKES OF. The English title of Chandos began as a barony in 1554, and was continued in the family of Brydges (becoming a dukedom in 1719) until 1789. In 1822 the dukedom was revived in connection with that of Buckingham, becoming extinct in 1880. However Oliver Lyttelton, a descendant of the Buckinghams, took the title on becoming a viscount in 1954.

JOHN BRYDGES (c. 1490–1557), the son of Sir Giles Brydges (the name was variously spelled), served with Henry VIII in France and was knighted there in 1513. He was a prominent figure at the courts of Henry and his successors Edward VI and Mary I. In Mary's reign he took part in suppressing Sir Thomas Wyat's rebellion, and as lieutenant of the Tower of London (1553–54) he was the jailer of Lady Jane Grey and, for a while, of the princess Elizabeth. He mas made Baron Chandos in 1554 and died at Sudeley castle, his home in Gloucestershire, on April 12, 1557.

John's three successors were all members of parliament. The 5th baron, GREY (*c.* 1580–1621), was lord lieutenant of Gloucestershire and was known as "king of the Cotswolds." His son GEORGE (1620–55). 6th baron, supported King Charles I against the parliamentarians. WILLIAM (d. 1676), 7th baron, was succeeded by a kinsman, SIR JAMES BRYDGES (1642–1714), 8th baron, who was English ambassador to Constantinople from 1680 to 1686.

The best-known member of the Brydges family was JAMES (1673–1744), 1st duke of Chandos, who was born on Jan. 1, 1673, son of the 8th baron. He was paymaster general of the forces from 1705 to 1713 and, profiting from this lucrative office, he amassed a huge fortune. He was made Viscount Wilton and earl of Carnarvon in 1714 and marquess of Carnarvon and duke of Chandos in 1719. He is chiefly remembered for his connection

with Handel, whom he employed for two years and who composed the Chandos anthems and the oratorio Esther in the duke's service. Chandos was also famous for Canons, the great house he built in Middlesex. Alexander Pope satirized its monotonous magnificence in the lines on "Timon's villa" in his Epistle to Lord *Burlington* (1731). Jonathan Swift called Chandos "a great complier with every court." After his death on Aug. 9, 1744. Canons was pulled down and on the death of his grandson, JAMES BRYDGES (1731–89), 3rd duke, the title became extinct.

It was revived for RICHARD GRENVILLE (1776–1839). marquess of Buckingham, husband of the 3rd duke's daughter Anna, when he was made duke of Buckingham and Chandos in 1822 (see BUCKINGHAM, EARLS, MARQUESSES AND DUKES OF). Christian, the daughter of the 3rd duke of Buckingham and Chandos, married Sir Thomas Lyttelton, and their descendant, OLIVER LYTTELTON (1893–), a member of Winston Churchill's war cabinet from 1941 to 1945 and colonial secretary from 1951 to 1954, was created Viscount Chandos in 1954.

See C. H. Baker and M. Baker, *Life and Circumstances of James Brydges, First Duke of Chandos* (1949).

CHANDOS, SIR JOHN (d. 1370), English military captain, soldier of fortune and a founder member of the Order of the Garter (1349), was a lifelong follower and companion of the Black Prince. fighting under him at Crécy (1346), Poitiers (1356) and Nájera (1367). Given the lands of the viscount of Saint Sauveur in the Cotentin, Chandos was made constable of Guienne in 1362 and seneschal of Poitou in 1369. He had administrative talent, and was esteemed by friend and foe as an honourable negotiator. His great rival, the French captain Bertrand du Guesclin, mas among his admirers. Wounded in a skirmish at Lussac-les-Châteaux near Poitiers, Chandos, who was unmarried, died at Mortemer on Jan. 1, 1370. His herald wrote a life of the Black Prince, a valuable source of contemporary information. (I. P. S.)

CHANDRAGUPTA (CHANDRAGUPTA MAURYA) (reigned *c.* 321?–*c.* 296 B.C.), Indian emperor, founder of the Maurya dynasty. He seized the throne of the important Indian kingdom of Magadha (in modern Bihar) from the last of the Nanda dynasty, and by conquest extended his dominions to include a great part of northern India. He thus laid the foundations of the first great empire in the history of India. The process of conquest and consolidation was carried further by his son Bindusara and his grandson Asoka (*q.v.*), under whom the empire attained its greatest extent.

The Puranas and the Pali chronicles of Ceylon agree in attributing a reign of 24 years to Chandragupta. The Greek accounts of the campaigns of Alexander the Great tell of a meeting between Alexander and an Indian called Sandrocottus, who at first supported Alexander and afterward quarreled with him. The identification of this Sandrocottus with Chandragupta of the Indian sources was of fundamental importance in establishing a chronology for early Indian history, for which it provided the first certain date. At the time of Alexander's invasion, Chandragupta had not yet won the kingdom of Magadha, and the exact date of his accession has been disputed. It is probable however that this event took place within a year or two of Alexander's death in 323 B.C.

During 305–304 B.C. Chandragupta defeated an attempt by Seleucus Nicator to win back some of Alexander's Indian conquests, and concluded a treaty with him by which Seleucus relinquished claim to satrapies covering a considerable part of what is now Afghanistan and Baluchistan.

According to tradition Chandragupta won his way to power with the aid of a Brahman politician Chanakya, also called Kautilya, to whom is attributed the Arthasastra, a treatise on statecraft. It is generally accepted that this text, though probably interpolated, contains a genuine nucleus of information about the organization of Maurya government. This information is supplemented by the account written by the Greek Megasthenes who was sent by Seleucus as ambassador to Chandragupta's capital Pataliputra (Patna, known to the Greeks as Palibothra). Unfortunately only portions of Megasthenes' work have survived in the form of quotations by later classical writers. See also INDIA: History.

CHANDRA GUPTA I (reigned C. A.D. 320–*c.* 335), Indian emperor, the son of Ghatotkacha and grandson of Sri Gupta, the earliest known ruler of the Gupta line. Chandra Gupta appears to have greatly strengthened the power of his dynasty, partly by conquest, but largely through his marriage with the princess Kumaradevi of the important tribe of the Licchavis of north Bihar. To commemorate this event special gold coins were minted, depicting both king and queen and mentioning the Licchavis on the reverse. Chandra Gupta was the first Gupta ruler to assume the title of emperor (maharajadhiraja), and his territory included most of the Gangetic plain from Allahabad to northern Bengal. He apparently abdicated in favour of his son Samudra Gupta. The chronology of the Gupta era, dating from A.D. 320, which was widely used in India for several centuries, is generally believed to be based either on Chandra Gupta's accession or on his marriage with Kumaradevi.

See R. C. Majumdar and A. D. Pusalker (eds.), *History and Culture of the Indian People,* vol. iii, *The Classical Age* (1954). (A. L. BA.)

CHANDRA GUPTA II (VIKRAMADITYA) (*c.* A.D. 376–C. 414), emperor of northern India, the son of Samudra Gupta and grandson of Chandra Gupta I. According to a later tradition he came to the throne after assassinating a weak elder brother. Rama Gupta, and married the latter's widow. Inheriting what was already a very large empire Chandra Gupta continued his father's policy of expansion by conquering the Saka rulers of Ujjain. The date of this conquest cannot be ascertained with precision, but on the evidence of dated coins it must have occurred bet een the years 388 and 409. To strengthen his southern flank Chandra Gupta concluded a matrimonial alliance with the powerful Vakataka kingdom of central India, his daughter Prabhavati Gupta marrying the Vakataka king Rudrasena II. Rudrasena died young, and for several years Prabhavati acted as regent for her sons, thus increasing Gupta influence in the south. Chandra Gupta also appears to have made a matrimonial alliance with the Kadamba dynasty of Mysore. He is almost certainly the king Chandra referred to in the inscription on the famous iron pillar at Mehrauli, near Delhi, but this appears to be a conventional panegyric, and is not sufficient to prove that he fought successfully in Sind and Bactria.

Among Chandra Gupta's numerous titles is *Vikramaditya* ("Sun of Valour"), which appears on some of his silver coins. This fact would suggest that he is the prototype of the king Vikramaditya of later Hindu tradition, who is said to have conquered Ujjain from the Sakas and established the Vikrama era in 57 B.C. Vikramaditya is further said to have been a most benevolent ruler, under whom India enjoyed peace and great prosperity, and also a great patron of art and literature, maintaining at his court the "nine jewels" (*navaratna*), chief of whom was the poet Kalidasa. Except for the date all these details are consistent with the identification of Vikramaditya with Chandra Gupta II. for the mildness of Chandra Gupta's government and the prosperity of his subjects are attested by the Chinese Buddhist pilgrim Fa-hsien, who traveled in India from about 400 to 411, while the internal evidence of Kalidasa's works suggests that he lived at about this time. The discrepancy in the dates may be explained as due to the erroneous association in medieval times of the Krita or Malava era, long current in the region of Ujjain, with the name of Vikramaditya.

See R. C. Majumdar and A. D. Pusalker (eds.), *History and Culture of the Indian People,* vol. iii, *The Classical Age* (1954). (A. L. BA.)

CH'ANG-AN, an alternate name for Hsi-an (Sian) city, China, and for a district in which the city at times has been situated. Another name for Ch'ang-an Hsien (district) seat, a few miles south of Hsi-an, is Wei-ch'ii (sometimes erroneously Wang-ch'ü or Wangkü). China's capital during many dynasties from the Han to the T'ang was located in Ch'ang-an Hsien. See SIAN. (H. J. Ws.)

CHANG CH'IEN (d. 114 B.C.), Chinese explorer, was the first man to bring hack a reliable account of the lands of central Asia to the court of China. Dispatched by the emperor Wu Ti of

the Han in 138 B.C. to establish relations with the Yiieh-chi people, he was captured by the Hsiung-nu, enemies of China, and detained for ten years. He finally managed to reach his destination and returned to China after 13 years absence. In his travels he visited Fergana, Bactria and Sogdiana and gathered information on Parthia, India and other states in the area. His mission brought the Chinese into contact with the outposts of Mediterranean culture, opened the way for exchanges of envoys between these states and the Han, and ied to the introduction into China of a superior breed of horses and new plants such as grapes and alfalfa.

See Friedrich Hirth, "The Story of Chang Kien," J. *Amer. Orient. Soc.*, 37:106 (1917). (B. D. W.)

CHANG CHIH-TUNG (1837–1909), Chinese official and reformer, mas one of a triumvirate of provincial officials who played pivotal roles in the affairs of the Chinese government in the late 19th century, the others being Li Hung-chang (*q.v.*) and Liu K'un-i. Born on Sept. 2, 1837, into an official family, and recipient of the highest civil-service examination degree. Chang served successively as governor-general of Kwangtung-Kwangsi (1884–89) and Hupeh-Hunan (1889–1907). In these posts he advocated a policy of synthesizing Confucianism with western technology and methods which he expressed in a famous slogan, "Chinese learning for fundamental principles, western learning for practical application." He founded China's first iron and steel mill, cotton mills, and promoted the construction of the Peking-Hankow railroad. Chang was respected as a scholar, and in an age of increasing official corruption died, on Oct. 4, 1909, a, poor man.

See A. *W*. Hummel (ed.), *Eminent Chinese* of *the Ch'ing Period* (1943–44). (AL. F.)

CHANGCHOW (CH'ANG-CHOU), an old city about 60 mi. S.E. of Nanking, in Kiangsu province, China, on the Shanghai-Nanking railway. Pop. (1953 census) 296,500. Until 1949 both the names Changchow and Wutsin were used, but the Communist government officially returned to the 7th-century name. The city has a long history as an inland port, connecting local canals with the Grand canal. In the modern period divisional railroad shops have been located in a suburb to the south of the old city. Changchow has become an important modern centre of light industry, and is a regional trade centre. (J. E. SR.)

CHANG CHUN (1148–1227), also known under his monastic name of CHIU CHU-CHI, Chinese Taoist adept and alchemist, is famous principally for the journey which he made from China at the invitation of the great Mongol conqueror Genghis Khan to visit the latter in his camp in central Asia to the north of the Hindu Kush mountains. A record of the journey was kept by his disciple Li Chih-chang, who accompanied him. Chang Chun was born in 1148 at Chihsia in the province of Shantung. He became a Taoist monk and was a pupil of Wang Che. the founder of a sect distinguished by extreme asceticism and a special doctrine of the *hsingming* or "natural state" of man which had been lost but could be recovered by prescribed practices. In 1188 Chang Chun was invited to instruct the Kin dynasty emperor Shih Tsung then reigning over northern China. In 1215 Peking was captured by the Mongols and in 1219 Genghis Khan, who had heard of his reputation, sent a minister named Liu Wen to bring him to his court. Chang Chun went first to Peking, and thence, having received an invitation also from Tamuga, the younger brother of Genghis, who resided in northeastern Mongolia, crossed the Gobi desert northward and visited Tamuga's camp near Buir-nor. He arrived in Sarnarkand in the middle of winter (1221–22). In the following spring he went on to the camp of Genghis on the slopes of the Hindu Kush. He reached Peking on his return journey at the beginning of 1224 and remained there until his death in 1227.

See Li Chih-chang's account of the journey, the *Hsi Yu Chi*, translated with an introduction and notes by Arthur Waley under the title *The Travels of an Alchemist* (1931). For the geographical significance of Chang Chun's travels *see* C. R. Beazley, *Dawn oj Modern Geography*, vol. iii (1906). (G. F. HN.)

CH'ANG-CH'UN, a Manchurian city in western Kirin province, 175 mi. N.E. of Mukden, 145 mi. S.W. of Harbin. on the main north-south Manchurian railway line, and on the bank of the I-t'ung river: a minor tributary of the Sungari. Pop. (1953) 855,200. The city began as a local trading centre for north Chinese settlers at the end of the 18th century. It expanded rapidly and from 1905 to 1935 was a major junction and transshipment point between the Kussian-owned broad-gauge Chinese Eastern railway and the Japanese-owned standard-gauge South Manchurian railway. Ch'ang-ch'un was equipped with sizable railroad shops and also became the junction for railways extending westward into Inner Mongolia and eastward into northern Korea. The city became a regional capital for the Manchurian soybean industry.

In 1932 it was designated the new capital of Manchukuo by the Japanese and renamed Hsinking (Japanese Shinkyō). A large, well-planned, new city was constructed and the population increased from 90,000 (1930) to nearly 500,000 in 1945. Water was supplied from artesian and shallow wells and from a reservoir 22 mi. distant on the I-t'ung. Power supply came chiefly from the Hsiao-feng-man dam on the Sungari near Kirin city. In addition to administrative. commercial and transportation functions. the city was a centre for light industries (soybean and grain processing) and higher educational facilities. Severely damaged during the Chinese civil war, it declined in importance after 1945. Renamed Ch'ang-ch'un once more, it gradually regained its importance as the regional economic capital of central Manchuria.

It was designated by the Peking government as the automotive centre of China, and the first major truck factory began producing in 1956. (N. S. G)

CHANGE OF LIFE: see MENOPAUSE.

CHANG HSÜEH-LIANG (1898–), Chinese war lord, was the son and successor of Chang Tso-lin (*q.v.*). He became the ruler of Manchuria in 1928 on the death of his father, but was expelled by the Japanese in 1931 because he acknowledged the authority of the Chinese government at Nanking. He withdrew into northwestern China. where he fought the Chinese Communists until 1937 when he detained Chiang Kai-shek at Sian until the Nationalist leader agreed to form a united front with the Chinese Communists against the Japanese. Chang Hsüeh-liang became a prisoner and was taken to Formosa when Chiang's government fled there in 1938. (D. G. G.)

CH'ANG-SHA, a city and capital of Hunan province, China, on the east hank of the middle Hsiang river at 28° 12′ N. lat., 112° 59′ E. long., has long been important as a gateway into the middle Yangtze valley and, in modern times, as the upstream limit of steam shipping. It was for many years a treaty port, westerners being attracted by the great tea production and the assumed buying power of the population in China's "rice bowl." Traditionally, Ch'ang-sha is famous for several handicrafts: coloured silk embroidery pictures, oiled paper umbrellas, grasscloth linen, brush pens and bamboo carvings, while the main basic industries were rice hulling, saw milling, boatbuilding and the smelting of antimony, manganese, lead and zinc—all for out-shipment. After World War II. factories were erected to make machine tools, mining and farm equipment, pharmaceuticals, fertilizers and rubber products.

Ch'ang-sha is well connected to the rest of China by water. by rail (the Peking-Canton, Chekiang-Hunan, and Hunan-Kweichou railways) and by a highway to Szechwan that bends south of the Yangtze gorges. In the second half of the 20th century, the city was again a busy river port with many wide, paved streets and modern buildings. Pop. (1953) 650,600. (TE. H.)

CHANG THANG, meaning "northern plain" in Tibetan: is a vast tract of flat highlsnd forming the northern part of Tibet. It stretches 700 mi. from the Pamirs in the west to the Tsaidam marshland in the east and 300 mi, from the Kunlun range on the north to the Thanglha range on the south. It is an inhospitable waste of frozen desert dotted with innumerable lakes. The average altitude is 15,000 ft., and the climate is generally rigorous; its severity is aggravated by the winds which blow with gale force during the greater part of the year.

The Tibet tableland probably was once the bottom of the ancient Tethys sea; the numerous lakes are its remnants. Because of the absence of rain. the lakes over the centuries have shrunk greatly in size and their waters have become exceedingly saline Salt crusts cover flats and ancient beaches on the hillsides

hundreds of feet higher than the present level of the lakes. Rich deposits of borax and soda are found in the region. The exacting environment is unsuitable for permanent human habitation, and only a handful of hardy nomads with roving tents and cattle live on the grassland. (T.-L. S.)

CHANG TSO-LIN (1873–1928), was a Chinese war lord who dominated Manchuria and parts of north China during the period 1913 to 1928. He rose to power as the protégé of the Japanese and in return granted them vast concessions in Manchuria. This enabled them to undertake a program of investment and economic development that ultimately transformed Manchuria into one of the most heavily industrialized areas in Asia.

In the hope of becoming something more than the viceroy of Japan in Manchuria, Chang interested himself in north Chinese politics. In 1920 he helped the so-called Chihli clique of militarists expel their rivals from Peking. Upon finding that his allies were unwilling to share their new power with him he tried to seize the capital, but was defeated and driven back into Manchuria by the Chihli armies under Wu P'ei-fu (*q.v.*). In 1924 he renewed the war and this time he was victorious, largely because Wu was deserted by his principal lieutenant, Feng Yii-hsiang. After defeating an attempt by Feng to bring about his overthrow, Chang enlisted the support of Wu and with his assistance routed Feng's army. By 1928 he was established in Peking, where he assumed the powers of a military dictator, perhaps with the intention of founding another imperial dynasty.

Chang's plans were thwarted by the armies of the Kuomintang, which in 1927 invaded north China under the leadership of Chiang Kai-shek. Disheartened by military reverses and frightened lest the Japanese desert him in order to protect their position in Manchuria, he ordered his troops to abandon Peking to the advancing Nationalists. He died on June 3, 1928, when his train was destroyed by a bomb planted by Japanese extremists, who hoped that his death would provoke the Japanese army into occupying Manchuria. His son Chang Hsueh-liang (*q.v.*) succeeded in command of his forces. (D. G. G.)

CHANNEL FERRY: *see* FERRY.

CHANNEL ISLANDS (French ÎLES NORMANDES), an archipelago in the English channel, lies west of the Cotentin peninsula of France at the entrance to the Gulf of St. Malo, and 50–100 mi. S. of Weymouth, Eng. Except for the Roches Douvres and the îles Chausey, the Channel Islands are British (crown dependencies), having been attached to the English crown since the Norman conquest; they do not form part of the United Kingdom. The four main islands, Jersey, Guernsey, Alderney and Sark (*qq.v.*), total nearly 75 sq.mi.

There are several lesser islands and a labyrinth of rocks and reefs. In the north, the Casquets, a group of jagged rocks 7 mi. W. of Alderney, formed a menace to shipping until a lighthouse was established on the highest rock in 1877. Burhou and Ortac are uninhabited rocky islets between Alderney and the Casquets. Lihou (38 ac.), close to the west coast of Guernsey, was the site of the church of Notre Dame de Lihou regarded as sacred by fishermen who, even 100 years after the Reformation, still lowered their sails in salute when passing. Herm (320 ac.), between Guernsey and Sark, was the site of a religious house founded in the 12th century from St. Helier abbey, Jersey. It had a Franciscan friary in 1440 and became for a while the last refuge of Roman Catholics when the Reformation overtook the islands. Later, governors of Guernsey used it as a game preserve. In the 19th and early 20th centuries the island was let to private tenants, one of whom raised wallabies there. In 1946 the states (legislature) of Guernsey bought Herm for use as a resort. A tidal eddy at the north end has thrown up a beach half a mile long formed wholly of sea shells of about 40 genera with 200 varieties. Just south of Herm is Jethou (44 ac.), a circular island privately owned; it is botanically interesting as the home of a white pimpernel and a yellow forget-me-not said to be peculiar to the island. Brecqhou (74 ac.) is separated from the west coast of Sark by the dangerous 70-yd. channel of Le Gouliot. It has a mansion and cottages and is privately owned. The Ecréhou rocks are 5 mi. N.E. of Jersey. The Minquiers, about 15 mi. S. of Jersey, is a large rocky reef of which one peak (Maitresse île) is large enough for habitation. The Roches Douvres, 28 mi. W.S.E. of Jersey, are under French jurisdiction, as are the îles Chausey which lie 10 mi. W.N.W. of the port of Granville, France.

Physical Characteristics.— The Channel Islands were detached from the Armorican massif by erosion and by postglacial submergence. The isobath of 150 ft. encloses the whole group, which submarine hollows subdivide into five parts. Alderney is linked to the Casquets by Burhou, Ortac, and various banks; additional shallows occur in the Race of Alderney between the island and Cap de la Hague. Guernsey, with Lihou and off-lying rocks to the west, is separated by the Little Russel strait from Herm and Jethou, and these from Sark and Brecqhou by the Great Russel. La Déroute strait intervenes between the Guernsey group and the Ecréhou rocks, Paternosters (Pierres de Lecq), and Jersey itself, from which shoals run east-southeast toward the mainland. The Minquiers and the îles Chausey form the fourth group, the Roches Douvres the fifth. Tidal ranges are everywhere great and tidal streams strong.

The islands have strong geological affinities with nearby parts of northwest France. They are composed largely of schistose. gneissose and coarsely crystalline rocks (granitic and syenitic types). Lavas and intrusives outcrop widely in east Jersey. All these rocks are regarded as Pre-Cambrian. The coarse, massive conglomerate of northeast Jersey may be Permian, while the sandstone of east and southeast Alderney is Lower Cambrian.

Indurated and slightly metamorphosed graywackes, equated with the Phyllades de St. Lô of the mainland. outcrop in Jersey between St. Ouen's and St. Aubin's bays; similar rocks protrude in the extreme southeast and southwest of Guernsey. In southwest Jersey, the metasediments end against the granite and granulite which enclose St. Brelade's bay, while granite borders them on the north. To the east they are overlain by bulky lavas, andesitic below and rhyolitic above; well-developed spherulitic texture distinguishes the rhyolites. A complex array of intrusive and metamorphic rocks projects into southeast Jersey. Most of south Guernsey is based on dioritic and granitic gneisses; the crystalline rocks of the north, ranging from hornblende-gabbro through diorites to granite, display the effects of progressive granitization. which is perhaps also identifiable in the rocks of the south. Alderney is composed of granitic and allied rocks in the southwest, syenite in the centre and sandstone in the east, the outcrops being complicated in detail by faulting. Sark and Brecqhou are cut in hornblende-schist, gneiss and granite, while Herm, Jethou, and the îles Chausey are entirely granitic. The remaining groups of shoals are formed of granite or of diorite gneiss. Intrusive dikes of dolerite abound throughout the archipelago; dikes of mica-lamprophyre are found in Guernsey, and dikes of granite-porphyry in west Alderney and southeast Jersey Vein minerals in Sark include amethyst.

The Channel Islands were incorporated in the Armorican folds. There is some evidence for folding along northeast to southwest axes, but fold structures are much obscured by faults. The main islands may themselves be fault blocks, Guernsey being tilted northward and Jersey southward. Frequent minor earth tremors indicate continuing activity along some fault lines.

The highest parts of the islands are strikingly flat. Jersey, Guernsey and Herm reveal very clearly the results of marine notching at various levels. Notching has also taken place on Alderney, but Sark rises abruptly from the sea. Old bay floors, backed by curving lines of old cliffs, are conspicuous in the west of Guernsey and along the south coast of Jersey, where intermittent falls of base level of amplitude 20–30 ft. are recorded. The old marine features all belong presumably to the Pleistocene (*sensu lato*); raised beach deposits are known at about 120 ft., 60 ft. and 25 ft. above present sea level, the last two series being important archaeologically through their association with bone-bearing and implementiferous caves. All the streams on Jersey and Guernsey have been intermittently rejuvenated by falls in base level, and those of Jersey have developed bold valley-in-valley forms enclosing incised meanders. The limited catchments on the smaller islands nourish few permanent streams.

Climate.—Climate is maritime throughout the Channel Islands, which are well exposed to influences from the Atlantic ocean. About half the recorded winds are westerly, averaging about 10 m p.h Mean annual range of temperature is low—about 17° F. for Guernsey, and slightly higher for Jersey, which is somewhat more subject in winter to the spread of cold air from the mainland. August is the warmest month and February the coldest; temperatures are strongly affected by sea surface temperatures to the west. Snow is uncommon; killing frosts are rare; and the growing season is very long. The air is unaffected by pollution, sunshine exceeds an average of five hours a day the year around and atmospheric humidity is consistently high. All these circumstances greatly favour cropping.

Rainfall is reliable throughout the islands. July, the driest month, averages little less than two inches of rain. October is the wettest month, with 4½ in. or more; rainfall subsequently declines slowly through November, December and January, and then drops more steeply in February. The considerable spatial range of mean annual rainfall in Jersey and Guernsey has been analyzed in detail. The total exceeds 40 in. in north-central Jersey, falling below 35 in. in the southwest and below 30 in. in the extreme southeast. The west and north fringes of Guernsey have less than 30 in., while parts of the southern plateau record more than 35 in. Local effects of shelter occur in some enclosed valleys.

Heavy demands on water supply are made both by domestic and agricultural consumers, especially on Guernsey where numerous greenhouses demand irrigation. Public supplies from reservoirs impounded in incised valleys and from boreholes trapping deep aquiferous fissures are supplemented by shallow wells on the plateaus. by water contained in abandoned quarries and (in Guernsey) by distillation of seawater. (G. H D.)

Vegetation.—The sunny almost frost-free climate with adequate rainfall enables many more southern and Mediterranean species to thrive despite the general absence of lime in the granitic soil. Fuchsia. japonica, camellia, acacia, mimosa, hydrangea. clematis. tamarisk, gunnera and columbine grow wild in the woods and wayside. About 700 wild flowering plants are recorded, 650 in Jersey. Species rare or absent in the British Isles include blue romulea (*Romulea parviflora*), broad-leaved thrift (Armeria *plantaginea*), loose-floaering orchis (*Orchis* laxiflora), the wall daisies Erigeron *canadensis* and E mucronatus, the garlic *Allium triquetrum,* quillwort Isoetes hystrix and several grasses and sedges, including galingale (Cyperus *longus*), *Scirpus americanus* and *Milium scabrum.* Intensive cultivation of level and south-facing land has reduced woodland largely to north-facing slopes, where native trees. recorded in the analysis of pollen from Jersey peat deposits, still grow: oak, ash, wych-elm, beech, lime, birch, pine. alder, cedar and hazel. Introduced later, sycamore is now a fairly dominant tree. Characteristic of the sheltered lanes and cliff hollons are many species of ferns, mosses and lichens; wild daffodils (known as Lent lilies), foxgloves and gorse are abundant, as well as the shon y purple bugloss *Echium plantagineum,* and on the cliff tops heather, ling, thyme. rockrose, autumnal squill and lady's-tresses (*Spiranthes spiralis*). Bulbs of *Nerine* sarniensis from South Africa were washed ashore from a ship wrecked off the islands in the 17th century; these plants, now known as Guernsey lilies, also flourish in Jersey. At low tide hundreds of acres of sand and rocks are exposed where the luxuriant growth of seaweed (vraic) is harvested as fertilizer for the early potato crops.

Animal Life.—The small size of the islands, their isolation since prehistoric times, and their dense human population have limited the number of terrestrial species. The rabbit is the largest wild animal, and with the hedgehog, mood mouse, house mouse and black and bronn rats, is found on all the main islands. The mole is confined to Jersey and Alderney. Guernsey has an insular species of field vole *Microtus sarnius,* and Jersey a large docile bank vole *Clethrionomys caesarius.* The continental shrew *Crocidura russula* is universal; but in Jersey is confined to the coast. its place being taken inland by a variety of the common shrew *Sorex araneus fretalis.* The red squirrel. probably introduced a few centuries ago, is common in Jersey. where the stoat also survives, having lately disappeared from Guernsey. The fox was formerly hunted in Jersey, where the last one was killed about 1860. Bats are scarce, but the pipistrel and long-eared species are found, especially in Jersey's sheltered valleys. Common and Atlantic seals are rare visitors to the coasts; where porpoises, dolphins and sometimes turtles are recorded. Of reptiles the grass snake is found in Jersey only. The large green lizard Lacerta *viridis* inhabits Jersey and Guernsey, the wall lizard L. *muralis* and the common toad inhabit Jersey only. The Channel Islands frog Rana *dalmatina,* a southern species not found in northern France, the slow worm and the palmated newt, are widespread.

Breeding land birds are few and, like the mammals, continental rather than British in character; cirl bunting, Dartford warbler and Kentish plover are of special interest. Many species common to the British Isles pass through on migration. The cliffs and outer islets of the group support colonies of gannets (Alderney), cormorants, shags, storm petrels, common and Sandwich terns, kittiwake, herring gulls and great and lesser black-backed gulls, razorbills, guillemots, puffins and oystercatchers. Raven and peregrine falcon also nest.

The ormer *Haliotis tuberculata,* a succulent mollusc with a large iridescent shell, reaches its northern limit in the Channel Islands. where it is found at low tide, and is relished as a table delicacy. Lobster, crab and octopus are fished commercially.

(R. M. Lo.)

Population.— Most of the inhabitants of the Channel Islands are of Norman descent, but there is a large admixture of Breton blood and the people of Alderney are of mainly English stock.

The population (1961 census 104,378) is concentrated chiefly in Jersey (57,200) and Guernsey (41,178). Alderney had, in 1951. 1,350 and Sark 437. Herm has been continually occupied for more than a century, while Jethou and Brecqhou are occasionally and Lihou usually unoccupied. Inhabitants in these lesser islands were estimated in 1956: Herm 30, Jethou 2, Lihou none, Brecqhou 6 (all totals exclude visitors). Maîtresse fle is the only one of the Minquiers large enough for habitation, but houses stand on Marmoutier, Blanche fle and Maître Île of the Ecréhou group. The Roches Douvres and the Casquets have lighthouses; on the fles Chausey are a farm, church, hotels and a lighthouse.

Totals for the group were 50,581 in 1821; 90,739 (including a large garrison) in 1851; 95,618 in 1901; 96,772 (estimated from records) in 1939; and 99,609 (excluding visitors) in 1951. Since the mid-19th century natural increases and immigration have been more than offset by emigration, which is a long-standing practice. About 70% of the inhabitants at the 1961 census were born in the Channel Islands; there is little interchange of people between Jersey and Guernsey, which cherish a traditional rivalry.

Settlement in Alderney is nucleated with most inhabitants living in St. Anne's overlooking Braye harbour; Newtown forms an appendage of St. Anne's at a lower level. Nucleation was associated with the holding of arable land in common; relics of a three-field system have been identified, and St. Anne's is still surrounded by the compact block of farmland called the Blaye. Sark is divided into farm holdings with fixed boundaries. In Jersey and Guernsey. centuries of subdivision of farmland among heirs have produced systems of tiny fields and scattered dwellings, which contrast strongly with the port towns. About half the population of Jersey lives in St. Helier (*q.v.*) on the south coast where Fort Regent dominates the harbour at the east end of St. Aubin's bay. St. Helier has spread across a naturally-filled lagoon on to plateau spurs descending between converging valleys; its influence is felt in nearby parts of St. Saviour and St. Clement parishes on the east. The east coast port of Gorey, and St. Aubin, a third port at the west end of St Aubin's bay, each have about 1,500 inhabitants. More than two-fifths of the people of Guernsey live in the parish of St. Peter Port (*q.v.*); the town itself is on the coast, where valleys run down to the sea near the junction between the southern plateau and the northern lowland. Parts of the adjacent St. Martin parish, southwest of St. Peter Port, are rapidly becoming residential. St. Sampson in northeast Guernsey surrounds a harbour constructed in the former tideway which used to traverse the north of the island; serving as Guernsey's second port, it has about 2,225 inhabitants.

AUTHENTICATED NEWS

COBO BAY. ON THE WEST COAST OF THE ISLAND OF GUERNSEY. CHANNEL ISLANDS

History.—The land which was to form the Channel Islands was first inhabited by men of the Middle Paleolithic period whose remains have been found in Jersey. At that time Jersey was still attached to the mainland, though Guernsey, Sark and Alderney may already have been islands. There appears to be a long gap between the men of the Middle Paleolithic and the Neolithic people whose abundant remains, chiefly megalithic tombs, exist in most of the islands. From the 3rd millennium B.C. habitation appears to have been continuous. The Bronze Age is well represented in Jersey and Alderney, less well in Guernsey; toward the end of this period Celtic people first came to the islands. Their most striking memorial is the hoards of Gaulish coins found principally in Jersey. During Caesar's campaigns in Gaul, his legions probably drove many refugees into the islands and overwhelmed them there, but Roman remains are scanty. Fort Nunnery in Alderney was possibly a Roman defense against Saxon invasion and a structure at Le Pinacle in Jersey may be of Roman date.

The history of the islands during the 1st millennium A.D. is obscure. Memories of the Celtic saints Samson and Magloire, the apparently Saxon Marculf and the Frankish Helier suggest that the islands were the meeting place of Breton and Frank in the 6th century. In the 9th century they must certainly have been included in the Breton conquest of what was later western Normandy. Their place names indicate, however, that they were subsequently settled by the Northmen, although at what stage in their raiding and settlement there is no evidence to show. It is most likely that when the Cotentin and the Avranchin were ceded to William "Longsword." the second duke of Normandy, in 933, the islands were included in the transfer; and they may well have been the object of internal colonization by dukes of Normandy early in the 11th century. From the time of William the Conqueror until the early years of the 13th century the islands were as closely integrated into the social and political structure of the duchy of Normandy as if they were part of the mainland. Ecclesiastically they were in the Norman diocese of Coutances. much of their land was held by Norman monasteries or by Norman barons whose chief estates lay on the mainland, and they were included in the financial and judicial administration of the duchy. Since, for most of this time, the duke of Normandy was also the king of England, the islands were thus brought into contact with England.

In 1204, in the time of John, king of England and duke of Normandy, the conquest of continental Normandy by the king of France was completed; but, for some reason never satisfactorily explained, the islands remained in the possession of the king of England. They were, however, not incorporated into the kingdom of England, though annexed to the crown in 1254. When peace was made in 1259, Henry III did liege homage to the king of France for all the lands that he held south of the Channel, and there can be little doubt that the Channel Islands were thereby included, still, in the kingdom of France. The strains to which this situation gave rise led to prolonged although intermittent warfare between the two kingdoms, in which the islands suffered heavily and in the course of which they were detached *de facto* from the kingdom of France. They continued to be ruled by the law of Normandy with their own customs and administered by courts which, though held in the king's name, were staffed by local men and out of which the islanders gradually built up their organs of self-government.

The sufferings of the islanders under repeated French attacks (1294, 1336–40, 1372–77, 1403, 1406, with Guernsey, Alderney and Sark occupied 1338–40 and Jersey 1461–68) resulted eventually in their being accorded the privilege of neutrality, apparently recognized first by local custom and later ordained by papal bull in 1483. The privilege seems to have given the islands some protection during the wars of the 16th century, though it made them an important centre of political intelligence and espionage. This neutrality was not denounced by the English government until 1689. The Reformation was brought to the islands by French refugees in the reign of Edward VI and took Calvinist form. Churches were organized on the Presbyterian model in Jersey and Guernsey and the first interinsular synod met in 1564. Attempts were made to transfer the islands from the diocese of Coutances to Salisbury in 1496 and to Winchester in 1499; but it was not until 1569 that they were effectively detached from Coutances and put under the jurisdiction of Winchester. For the remainder of the century, however, Presbyterianism dominated the islands. Jersey was not brought into the Anglican fold until 1623; Guernsey not until 1663. R'esleyan Methodism made a great impression on the islands, where Anglicanism had no real force until the 19th century.

During the Civil War, Jersey was held for the king and Guernsey (apart from Castle Cornet) for Parliament. Charles II was first proclaimed in Jersey and stayed there on two occasions (April 17 to June 25, 1646, and Sept. 17, 1649 to Feb. 13, 1650). Elizabeth castle in Jersey and Castle Cornet in Guernsey did not surrender to parliamentary forces until Dec. 15, 1651. (New Jersey in the United States, granted in 1664 to Lord Berkeley and Sir George Carteret, was named in honour of the latter's defense of Jersey for Charles TI.) Thereafter, apart from internal disturbances, the islands were left in peace until two French attacks were made on Jersey in 1779 and 1781—the last made famous by the heroic defense led by the young Maj. Francis Pierson. During the French Revolutionary Wars the islands must have seemed desperately insecure, particularly as they were active centres of counter-revolutionary activity and espionage; but the French made no further attacks. Vast sums were spent then and during the 19th century on fortifying the Channel Islands.

In World War I they made a proportionate contribution to the Allied cause, but they were not molested. By 1939 their strategic position as English outposts across the Channel no longer had any significance, and no attempt was made to defend them when German forces overran France. They were under German occupation from July 1940 until May 9, 1945, when the German garrison surrendered to the Royal Navy. (LE. P.)

Administration **and** Social Conditions.—The Channel Islands were part of the former duchy of Normandy, and were united with the English crown at the Norman conquest. Contrary to popular impression, however, ruling monarchs of the United Kingdom do not possess ducal status with respect to the Channel Islands. which are attached directly to the crown. The islands are not affected by acts of the parliament at Westminster unless specifically named therein, in which case the acts are registered by the island legislatures. Government is, in legal theory, effected by the monarch in council; in practice the islands have considerable freedom in the management of their affairs. Legislative and administrative arrangements are greatly complicated by diiferences from island to island. and by the enforcement of laws that derive partly from the ancient customary laws of Normandy.

Apart from one brief interval, the Roches Douvres and the fles Chausey have always been French. The remaining islands are grouped into two distinct bailiwicks of Guernsey and Jersey. That of Guernsey consists of Guernsey itself (with Lihou, which is linked by a causeway to Guernsey at low spring tides), Alderney, Herm, Jethou, Sark (with Little Sark), Brecqhou and numerous tiny islets. The bailiwick of Jersey includes Jersey, the Ecréhous and the Minquiers. Sovereignty over the Ecréhous and the Minquiers was disputed between England and France for more than 300 years; in 1953 the International Court of Justice confirmed British sovereignty.

Lieutenant governors of Jersey and Guernsey are personal representatives of the sovereign; they may sit and speak in the island legislatures but may not vote; however they have the power to veto certain forms of legislation. The legislative bodies are known as the States (in Guernsey, the states of Deliberation), presided over by a bailiff appointed by the crown with rights of dissent and a casting vote. The states of Jersey consist of 12 senators, 12 constables and 28 deputies; the dean is an ex officio member but has no vote. The states of Guernsey consist of 12 counsellors, 33 people's deputies and 10 *douzaine* (parish) representatives. The states of Alderney have 9 popularly elected members. The Chief Pleas of Sark consist of 40 tenants and 12 elected deputies under the presidency of the seneschal; the Seigneur of Sark (in 1960. La Dame) is chief of the island. and can enforce such regulations as the prohibition of automobiles and of female dogs.

Jersey and Guernsey have stipendiary magistrates, but justice is administered on each mainly by a royal court, composed of the presiding bailiff and 12 jurats, who in Jersey are elected by an electoral college and in Guernsey by the states of election. Alderney has its own court.

Until 1949 the royal court of Guernsey had considerable legislative power. Post-World War II reforms of the legislatures and judiciaries of Guernsey, Jersey and Alderney simplified procedure without dislodging all the accretions of past centuries. Full-time paid police are maintained in St. Helier and St. Peter Port, but control in the country parishes is in the hands of parish officers, or elected unpaid constables. Ancient groupings of families are recorded in the status of *centeniers, vingteniers, douzainiers,* and corresponding divisions of land.

Rates of income tax, and of customs and excise, are significantly lower in the Channel Islands than in the United Kingdom; supertax, death duty, estate duty and purchase tax are not exacted. Hence the islands attract persons retiring on income, or who can become domiciled there before retirement. Household tenure is greatly complicated by the residue of customary law, including the intricate law of inheritance. Subdivision of holdings in Jersey and Guernsey has encouraged dense settling of the country districts, and pressure on land is severe; the resulting high prices of houses, combined with the cost of importing, raise the average cost of living.

Social security schemes, including pensions and family allowances, are in operation; family allowances were introduced in the Channel Islands earlier than in the United Kingdom, with a view to mitigating the effects of emigration on the age-structure of the population. The islands (excluding Sark) have reciprocal agreements with the United Kingdom regarding the provision of medical treatment and benefits. Primary and secondary education is provided by the states; there are also private schools, and Jersey and Guernsey each have two secondary boarding schools, one for boys and one for girls (including Elizabeth college for boys founded in Guernsey by Queen Elizabeth I in 1563).

The official language in Jersey is French, but English is commonly used; proceedings of the states and royal court of Guernsey are conducted in English. Official (Parisian) French differs considerably from the Norman-French patois still surviving in the country districts, while the patois itself varies from island to island and even from one part of Guernsey or Jersey to another.

In the 19th century Jersey and Guernsey struck their own copper coins, which circulate alongside English copper. Guernsey issues £1 and 10s. notes, interchangeable with English notes in the islands.

Economy.—The productive economy has long combined agriculture with other activities which have usually been complementary but occasionally competitive. Within agriculture the last two centuries have produced a combination of farming with specialized cropping, and farming itself has increasingly specialized on dairying.

During the middle ages the islands partook in the Gascon wine trade. Fishing was mainly of the inshore kind until the 16th century, when Channel Island craft entered the newly developing cod fishery of Newfoundland, establishing a connection that lasted 300 years. Domestic knitting throve in Tudor and Stuart times, when in addition to the garments named guernseys and jerseys, many stockings were produced. Local sheep farming was encouraged by the demands of knitters, but wool imports were also necessary.

Jersey and Guernsey developed a notable export trade in cider during the 18th century, when a quarter or more of the arable land was put down to orchards. During the Napoleonic wars sheep farming and orchards lost much ground to wheat and barley and to cattle raising. Shipowners engaged in privateering, which had become profitable during the American War of Independence, and in smuggling French wines into England. Orchard cultivation and cider making revived in the first half of the 19th century, especially in Jersey, and potato growing for export was established in Jersey, Guernsey and Alderney. Disastrous attacks of blight in the mid-19th century permanently curtailed production of potatoes in Guernsey and Alderney, but the Jersey trade recovered fully and later increased. Agricultural experiments in the 19th century eventually provided Guernsey with one of the world's greatest concentrations of greenhouses; greenhouse cultivation relied initially upon grapes, which were later replaced by tomatoes because of difficulties of packing and transport. By the 1960s. Guernsey excelled in the growing of tomatoes under glass and

in the production of cut flowers, while Jersey favoured early potatoes and tomatoes grown in the open; the extent of greenhouses in Jersey was, however, increasing. Market garden produce went mainly to Great Britain. Alderney and the smaller islands are little concerned in groaing for export.

Specialized cropping has much reduced the area of farmland, but the practice of double cropping impedes rigid distinction of farmland from market gardens. Cultivation of grains. roots and green crops on the remaining farms is ancillary to dairying; dairy farms in Jersey and Guernsey are located principally on the high ground. The two local breeds of Jersey and Guernsey cattle, renowned for their high grade of milk, had their characteristics fixed in the second half of the 19th century; these popular cattle are still bred for export (*see* CATTLE).

Agriculture and horticulture combined form the main employment of the men in the islands, while women are mainly employed in personal service. Manufacturing is little developed apart from the processing of local produce, but includes the manufacture of tobacco and textiles. Ships were built in Jersey and Guernsey during the 19th century, but the industry was destroyed by the advent of metal ships and by the decline of inshore fishing Attempts to mine silver on Sark and copper on Guernsey proved either unsuccessful or uneconomical. Stone quarrying was extensive during the 19th and early 20th centuries, when large amounts of various crystalline rocks were exported. Although road metal and monumental stone are still quarried. the industry is well below its former peak.

Agriculture and horticulture apart. the present economy depends heavily on tourism, which is highly favoured by climate, customs status. scenery, advertising policies and passenger services by sea and air. Already well in evidence before World War II, the tourist trade greatly increased in the 1950s and 1960s. It leads to no more than slight seasonal unemployment in the winter months.

External freight traffic passes mainly through the ports of St Helier and St. Peter Port; Gorey serves as an alternative port of arrival in Jersey, and St. Aubin has a small port trade. St Sampson deals with heavy seaborne cargoes, including south Wales anthracite used in the furnaces of greenhouses. Alderney, Herm and Sark are served from Guernsey. Mails and increasing quantities of light parcels are carried by air; Jersey, Guernsey and Alderney have airfields.

Shipping services for passengers and cargo link Jersey and Guernsey aith Southampton and Weymouth (Eng) and with St Malo (France). There are additional cargo connections with London and Liverpool. Airlines connect Jersey and Guernsey nith England, Wales. Scotland, Ireland and France. Charter flights are made in addition to scheduled runs, and passenger movement by air exceeds that by sea.

Freight traffic is mainly between the islands and the United Kingdom. Imports consist mainly of foodstuffs, solid and petroleum fuels and building materials. Horticulturists import glass, fertilizers, chemicals, bulbs and packaging materials.

Jersey exports potatoes, tomatoes, vegetables, stone and scrap iron; Guernsey exports tomatoes, flowers, stone, tar and scrap iron.

Internal services are provided by interisland boats and by bus services centred on St. Helier and St. Peter Port. Narrow roads confined by earth banks or stone walls limit the size of vehicles. The islands are linked to the English mainland by telephone.

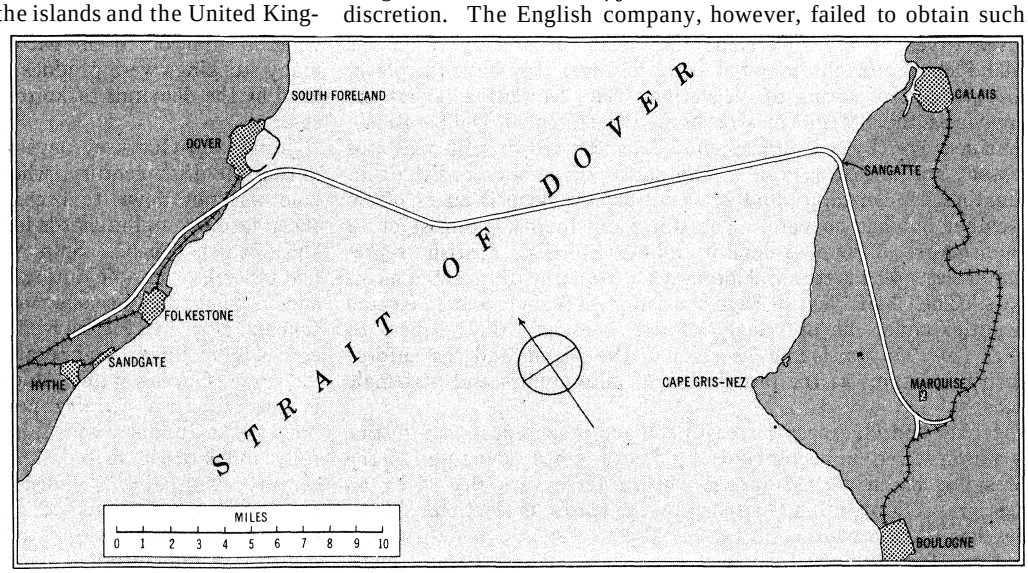
CHANNEL TUNNEL (ENGLISH CHANNEL). A tunnel under the English channel was first proposed by a French engineer, Thomé de Gamond (1807–75), who submitted a scheme for it to Napoleon III in 18j6. He was joined in his work by the British engineers Isambard Brunel, Joseph Locke and Robert Stephenson, and later by Sir John Hawkshaw. The proposal was seriously considered by the railway companies on both sides of the channel, and a convention with the French government to regulate it was signed in 1875. Then the bitter rivalry of the South Eastern and the Chatham and Dover railway companies created difficulties and the scheme became a political question. W. E. Gladstone was a keen supporter, as were John Bright. Lord Lansdowne and Lord Salisbury, while Joseph Chamberlain and the war office opposed. The subject mas referred to a joint select committee of the commons, which considered many reports by generals favouring the scheme and a memorandum by Lord Wolseley strongly resisting it. The committee decided against the proposal by 6 to 4, Lord Lansdowne, the chairman, voting for it. Thereafter succeeding British governments all opposed the scheme.

After Louis Blériot had flown the channel in 1909, a channel tunnel committee was formed in the house of commons, under the chairmanship of Sir Arthur Fell, which ultimately numbered more than 400 members of parliament. The Labour party joined en masse and Herbert Xsquith promised to have inquiries made. World War I broke out and nothing could be done. After the war David Lloyd George promised to make more inquiries. Andrew Bonar Law and Stanley Baldwin did nothing. James Ramsay MacDonald, in July 1924, offered to consult all the living former prime ministers. The five met and rejected the scheme, although a two to one majority of M.P.'s supported it. So the channel tunnel scheme was shelved again but the idea did not die.

The French Channel Tunnel company had held a concession from its government since 1875 and could resume work at its own discretion. The English company, however, failed to obtain such



MAP OF PROPOSED TUNNEL SPANNING THE ENGLISH CHANNEL

powers. In 1957 the channel tunnel project was revived. An agreement setting up a channel tunnel study group was signed in Paris on July 26 by representatives of the following groups: (1) a French group represented by the French state railways and the French Channel Tunnel company: (2) a British group. under the aegis of the Channel Tunnel Co., Ltd.; (3) the Suez Canal company; and (4) an American company, Technical Studies. Inc. The proposal most favourably considered in the past has been for twin railway tunnels following an alignment similar to that shown in the plan which, it was hoped. would allow all underwater tunneling to be carried out in the Lower Chalk which outcrops in the cliffs on each side of the channel.

There are several difficulties involved in providing a road tunnel under the channel. First. the cost of ventilation would be prohibitive; second, there are great difficulties in dealing with accidents or breakdowns in a tunnel of this length; third, many drivers would not be temperamentally capable of driving through such a tunnel.

There have been many developments in overcoming the technical problem in constructing a channel tunnel, since the channel tunnel committee reported to the British parliament in 1930.

(A. F.; W. Hw.; H. D. M.)

CHANNING, EDWARD (1856–1931), U.S. historian, whose claim to eminence rests largely on his monumental work covering the history of American development from discovery through the American Civil War, was born in Dorchester, Mass., on June 15, 1856. He was closely identified with Harvard university, where he took all of his collegiate work, including the Ph.D. degree (1880). As a teacher at Harvard between 1883 and 1929, he helped to train many students who later became prominent scholars and statesmen. He excelled as a historical detective unraveling historical episodes. Social Darwinist thought influenced his outlook and led him to stress the triumph of the forces of union over those of particularism as the dominant theme in American history. In emphasizing the significance of urbanization and of improvements in transportation, he challenged the frontier thesis of his illustrious colleague, Frederick Jackson Turner (*q.v.*). Although Channing was sometimes chided for his provincial New England bias, his six-volume *History of the United States* (1905–1925) ranks as a unique accomplishment in American historical writing because of its combination of chronological sweep, original research in sources, and freedom from slavish commitment to orthodox interpretations. The 6th volume was awarded the Pulitzer prize for history. Channing died Jan. 7, 1931.

(J. A. DEN.)

CHANNING, WALTER (1786–1876). U.S. physician. the first to use ether as an anesthetic in obstetrics. was born in Newport. R.I., on April 15, 1786. He was the brother of William Ellery and Edward Tyrrell Channing. He studied at Harvard university and at the medical school of the University of Pennsylvania, Philadelphia, where he received his M.D. in 1809. He then studied medicine in Europe before returning to Boston, Mass., in 1812 to set up practice as an obstetrician.

Three years later he was appointed first professor of obstetrics at Harvard, where later he was dean of the medical school (1819–47). In 1847 he first used ether in deliveries, and in the next year reported its successful employment in more than 500 obstetric cases.

Channing was one of the founders of the Boston Lying-In hospital in 1832 and was a co-editor of the *Boston Medical and Surgical Journal.* From 1822 to 1825 he was librarian of the bfassachusetts Medical society, and from 1828 to 1840 acted as treasurer of the society. He died on July 27, 1876.

CHANNING, WILLIAM ELLERY (1780–1842), U.S. clergyman. author and leading spokesman for Cnitarianism, spoke his mind on so many issues that, as Ralph Waldo Emerson remarked, his writings are almost a history of his times. Because those times were the incubation period of both Transcendentalism and organized movements to root out slavery, intemperance; poverty and war, Channing remains a figure of considerable interest. His moral earnestness, intense individualism and confidence in the goodness of human nature gave him an enviable reputation as a liberal. .Actually he was more conservative, theologically, than Emerson, and far less certain that society could be improved by collective action than William Lloyd Garrison and Elihu Burritt.

He was born April 7, 1780, at Newport, R.I.. into a prominent family forced to retrench after the father's untimely death in 1793. Sent to Harvard college, from which he graduated in 1798, he proved a good student, outstanding in writing and public speaking. but he was not strongly attracted to any vocation. In the autumn of 1798, distressed, apparently. by his obligations, he deserted a desultory reading of theology to become tutor to a dozen children in Richmond, Va. on the invitation of David Meade Randolph. In the Randolph household, he encountered John Marshall and other notables whose conversation and social grace he much admired. Slavery, viewed at first hand, he found detestable, corrupting both Negroes and whites. Serious, shy and homesick, he read, often far into the night, the available books—works by Voltaire, Rousseau, William Godwin and Mary Wollstonecraft. Deciding that man's most deadly sin is avarice, he momentarily considered joining a community rejecting personal property, but his social speculation gave way to a more typical New England absorption in the Bible. Before returning to Newport in July 1800, he had. as he wrote in his *Memoirs,* experienced a "change of heart" about religion and acquired an "ardent desire to serve mankind." His health, however. was permanently broken, for in his lonely soul searching he had feared that his sensual nature was getting out of control and had taken such steps against it as deliberate fasting and sleeping on the bare floor.

At home, he turned energetically to the study of theology, first in Newport's Redwood library and then at Harvard, where he returned in Jan. 1802. Soon he was supplying pulpits in the vicinity of Cambridge, Mass. Immediately successful as a preacher (he was not the first instance of the appeal of a keen mind in a frail body), he was installed as minister of the Federal Street church. Boston. on June 1, 1803, and remained there until his death. In 1814 he married a wealthy cousin. who helped him conserve his strength for the study and pulpit. After 1817 he had an assistant and was able to take much needed vacations, among them a year's travel in Europe in 1822–23 and a winter in the West Indies in 1830–31. He was 62 when he died of typhoid fever. in Bennington, Vt., on Oct. 2, 1842.

His early ministry was quiet but impressive. his congregation requiring a new and larger church by 1809. Tending to avoid abstruse points of doctrine. he preached morality. charity and Christian duties. He became Boston's most eloquent critic of Napoleon and of the unpopular War of 1812. and thereafter was in demand for the ceremonial occasions of New England Congregationalism—the fast, thanksgiving and election days, the ordinations and dedications, the formal lectures. Many of his discourses on these occasions were promptly published.

Channing reached an even larger audience by writing for the liberal Boston periodicals, first the *Monthly Anthology,* and then the *Christian Disciple,* which in 1824 became the *Christian Examiner.* The tone of these journals mas offensive to such orthodox Calvinists as Jedidiah Morse, who founded the *Panoplist* in 1805 to wage war on liberal heresies. Channing mas plunged into controversy in 1815 by a *Panoplist* denunciation of the Boston clergy as "Unitarians" rather than Christians. His defense, *A Letter to tlze Rev. Samuel C. Thacher* (1815). was followed by *Cnitarian Christianity* (1819). a discourse at the ordination in Baltimore of Jared Sparks. and by two powerful articles in the *Christian Disciple:* "Objections to Unitarian Christianity Considered" (1819) and a review later reprinted as "The Moral Argument Against Calvinism" (1830). Reluctantly, but decisively, Channing ac-

cepted the label of Unitarianism (*q.v.*) and defended his faith as "a rational and amiable system, against which no man's understanding, or conscience, or charity, or piety revolts."

Channing's reputation in his time as a man of letters resulted from several long essay-reviews, among the first of their kind in the United States. One took Milton's *Treatise on Christian Doctrine* as a starting point *(Christian Examiner,* 1826), a second Scott's life of Napoleon (1827–28). and a third a book of selections from Fénelon (1829). All have a perceptibly moralizing tone and are valuable chiefly as evidence of the temper of the times. *Remarks on a National Literature* (1830), less widely read, is an interesting snticipation of Emerson's *The American Scholar.*

The most puzzling aspect of Channing is his attitude toward social reform. He sympathized with the abolitionists, the pacifists, the prohibitionists and with those who would change the system of education or of society, and a large proportion of his writings deals with the problems these reformers expected to solve. Channing could not bring himself, however, to join the organizations springing up all around him. "Remarks on Associations" *(Christian Examiner,* 1829) marshals the arguments for and against the collective approach, among the latter a still pertinent examination of the tendency toward bureaucracy in charitable agencies. "There is," he concluded, "no moral worth in being swept away by a crowd. even towards the best objects."

Brown, and the basic source (most of the Channing manuscripts having been destroyed by fire), W. H. Channing's *Memoir,* 3 vol. *(1848).* R. L. Patterson's *The Philosophy of William Ellery Channing* (1952) is the fullest analysis of Channing's thought. (T. HR.)

CHANSON is the French word for song, but, when used in English, normally refers to the medieval or renaissance art song cultivated in France and using French texts. The Latin theorists of the middle ages called it *carmen* or *cantilena,* while the Provençal writers spoke of the canso.

The troubadours were the first canso poets and composers, and the author of a 13th-century Provencal treatise considers the canso to be a love song that cannot be set to an existing melody but must have a new one. A 14th-century treatise, *Las leys d'amor,* is more precise and points out that the canso has from five to seven strophes. Such details prove mainly that the troubadour definitions referred to the content rather than the form of a song, for the *vers* also had five or more strophes, but its text was concerned with philosophical and intellectual matters.

The heyday of the southern French troubadours was the 12th century, that of the northern French trouvères the 13th. The latter imitated the troubadours to a great extent, but they have left some 1,500 pieces as against the troubadours' 300. The *chansons de geste* (*q.v.*) are, of course, one type of northern French *chanson,* but unfortunately only two melodies exist that can be associated with the long epic poems that flourished in the 11th and 12th centuries. Undoubtedly a single melodic phrase was used in these pieces for every line of the strophe, or *laisse,* except that a variant might be used for a concluding line in the manner of a coda. Johannes de Grocheo, writing in Paris about 1300, includes the rondeau among the *cantilenae, i.e.,* the type of dance song popular in the 13th century, which had the form *A* B *a A a b A* B (the capitals represent refrain lines mith identical text; the music consists throughout of the two phrases *A* and B). The typical 13th-century chanson derives from certain troubadour songs such as "Be m'an perdut" by Bernart de Ventadorn (Ventadour) with the verse form *a* b *a b c d b.* The identity of the two parts of the first half of the composition persisted in northern France, although the length of the strophe might vary, for instance in works by Thibaut IV, king of Navarre. In the 14th century this type developed into the popular ballade form, which was usually polyphonic. In fact this was the most important 14th-century development in the history of song. The music of the troubadours and trouvères had been monodic. and instrumental accompaniments were never written down.

The rondeau continued to be fairly popular, but attained its greatest favour as a polyphonic form in the early 15th century. Most of the other forms of early song disappeared, and the so-called fixed forms, ballade, rondeau and *virelai,* reigned supreme. The *virelai,* which had a basic form *A* b b *a A,* was much less frequently composed than the other two song types. These pieces were solos with an accompaniment of one, two or three instruments. The three-part work was standard till the end of the 15th century. However, four-part writing had become the norm in church music by the middle of the 15th century, so that it was only natural that about 1500 the style of mass and motet began to transfer itself to the chanson. At first the transference was very literal, and such men as Josquin Desprès and his Flemish contemporaries wrote chansons of a serious cast with learned counterpoint in four or five completely vocal parts. Antoine de Févin seems to have been the leader of a school of simpler chanson composition, often with folklike texts and in only three parts. From about 1530, however, it was the Parisian school that triumphed with a light-textured four-part type of chanson that employed two sorts of texts, the first fairly conventional love poems and the second definitely obscene verses. The two leading composers in the first half of the 16th century were Clément Janequin and Claude de Sermisy. Janequin is best known for his so-called program chansons, which can be paralleled by 14th-century *virelais* and works in canon called *chaces.* Such compositions, which imitate the sounds of battles ("La bataille de Marignan") and nature ("L'alouette"), are not typical of either the 14th or the 16th century, but must be taken into account in the history of song.

The second half of the 16th century revealed three new trends. One was the inlitation of the ancients that led to the *chanson mesurée à l'antique.* Modern measures such as duple and triple time mere abandoned and the quantitative prosody of longs and shorts produced music that alternated crotchets and minims mithout the feeling of a barline. The finest composer in this style was Claude Le Jeune, who also wrote in a more contrapuntal style than Janequin or Sermisy, sometimes in five or more parts and on a large scale. Orlando di Lasso was one of the greatest *chanson* composers, though his genius expressed itself in Italian madrigals, German *Lieder* and even Latin secular works as well. The last important *chanson* composer seems to have been Eustache du Caurroy (1549–1609). By the first years of the 17th century polyphonic secular music for unaccompanied voices was outmoded, and the new age demanded solo airs with lute accompaniment.

See G. Reaney, "The Middle Ages" and D. Stevens, "The Renaissance" in **A.** Robertson and D. Stevens (eds.), *A History of Song* (1960). (G. RE.)

CHANSONS DE GESTE (from Med. Lat. *gesta,* "deeds," "chronicles"), the title occasionally given by the authors themselves to about 80 medieval epic poems in Old French, largely anonymous, which form the core of the Charlemagne legends (*q.v.*). The *Chanson de Roland* is the greatest and best known *(see* ROLAND, LEGEND OF). This literature, dominated by feudal and aristocratic preoccupations, narrates the warring deeds of the great barons of Carolingian and sometimes Merovingian times, covering approximately the 8th and 9th centuries. Although contemporary poets (followed by modern scholars) sought to group these poems into three cycles they form. essentially, two groups. The first deals with the struggle between Christian France, with Charlemagne as emperor and champion of Christendom, and a strangely conventionalized, polytheistic and even idolatrous Islam; to this group belong the *Roland* and its related poems and the series relating to Guillaume d'Orange (*q.v.*), the only group that can be said to constitute a homogeneous cycle. Into the second series fall the poems of the barons, such as those concerning Girart de Roussillon, Doon de Mayence, Ogier the Dane. the Loherains or Raoul de Cambrai: ". . . turbulent barons who were not necessarily in rebellion against their sovereign, but transgressed against the moral code of their epoch by their behaviour one to another." (Jessie Crosland, *The Old French Epic,* Basil Blackwell & Mott Ltd.. Oxford, 1951.) But even this division is to some extent arbitrary; the tno themes were far from mutually exclusive and such was the popularity of many of the poems that characters from one were frequently borrowed and exploited by the author of another.

The poems all have in common their essentially heroic themes

and treatment, with a particular predilection for the description of great battles — whether of Christians arrayed against hosts of "Saracens" eclectically recruited from the Moghreb to the Caucasus, or of the army of one great baron against another, father against son, brother against brother — and of single combats between individual champions. Such is the stuff of the earlier poems, those of the 12th century, but those of the 13th century and later have been much influenced by the themes of courtly love (*q.v.*) and by *romans d'aventures* and not infrequently introduce elements and material more appropriate to these genres. just as their authors sought to exploit the popularity of their heroes by composing poems devoted to their *Enfances*, or youthful exploits, and even created for them complete and quite fictitious lists of forebears and descendants.

Though the earlier poems contain a spark of historical truth, the historical background is of the flimsiest and is not infrequently distorted (the famous opening stanza of the *Roland* contains a magistral misstatement in every line); kings are confused (*e.g.*, Charles Martel and Charles II the Bald) and Guillaume d'Orange, whose death preceded that of Charlemagne, is portrayed as the loyal supporter of the emperor's successor, the pusillanimous weakling Louis the Pious. Despite such anachronisms, the principal protagonists are the recognizable contemporaries of the rulers of Carolingian France, engaged in actions which, if at times entirely fictive, at others have at least a vague basis in historical reality as revealed by the Latin chroniclers; but the authors of the *chansons de geste* were not chroniclers and their preoccupation is with the wars, the battles, the feuds, the legal and moral niceties of the feudal allegiances of their heroes, expressed in terms that often have a ring that is more Capetian than Carolingian. The theme of the conflict between personal ambition or passion on the one hand and feudal obligations on the other is too fundamental to be merely coincidental; more than one critic has suggested that the *chansons de geste* were written as propaganda in favour of the royal house of France and perhaps some of its great families, but on a much higher plane they glorify loyalty to national and religious ideals.

Despite their divergent provenance in both time and space, the poems as we possess them largely conform to a single pattern in form and style. This is originally an oral form of literature, the poems (or passages from them) being declaimed or, more accurately, intoned to a melopoeic accompaniment on a lute-type instrument by professional *jongleurs* to such audiences as they could command in baronial castles, at fairs, on the occasion of church festivals or to groups of pilgrims. The earliest were written in the well-characterized epic decasyllable with a caesura after the fourth syllable (more rarely after the sixth), which later gave way to the alexandrine, just as the original organization in assonating stanzas (*laisses*) of unequal and indeterminate length gave way to even longer rhymed stanzas. (Only one of the very early poems, the fragmentary *Gormond et Isembard*, composed in octosyllables, does not conform to this pattern; in both content and form it seems to have some affinity with the ballad.) The audience seems to have shared with the poets a taste for detailed descriptions of battles and single combats with their surrounding events and such descriptions had very early become stylized and conventional.

Although the subject matter is Carolingian and even Merovingian, the poems in their extant versions are very much later and few, if any, appear to have survived in their primitive forms. With rare exceptions. such as the manuscript of the *Roland* now in the Bodleian library. Oxford, the majority of manuscripts are late 13th century, frequently constituting great repertories, and appear to be library or collectors' pieces; such was the vogue, in that period, of cyclic collections, that some manuscripts have received the material addition of pages of interpolated text. Divergences between the various manuscripts of a given poem reveal that copyists allowed themselves some licence in the transcription of their texts, so that groups of manuscripts not infrequently appear as so many "editions," making the reconstitution of an original text conjectural. This instability of the textual tradition has its repercussions on the problem of the dating of the various poems. the manuscripts being in most cases as much as a century more recent than the texts they contain. In the almost total absence of any internal or external criteria linguistic evidence alone is available. and 19th-century editors and critics attempted on this basis to arrive at approximate datings. Some of their more categorical conclusions were later invalidated; it seems improbable that any such method can offer a guarantee of accuracy within a margin of less than several decades and the assertions of these editors, although still quoted, require to be accepted with some reserve. Within these limitations, and relying much on a subjective appreciation of narrative, style and structure, scholars agree that the most fruitful period for the development of the poems as they have survived was about the middle third of the 12th century.

It is against this background of textual instability and uncertainty that has to be debated one of the most complex problems of literary history, that of the origins of the *chansons de geste.*

Critics in the 19th century, deeply influenced by the ideals of German Romanticism, and headed by the great Romance scholars Gaston Paris and Pio Rajna, postulated an unbroken oral and popular tradition of lyric or epic poems composed under the immediate impact of the events which they narrated. In *Les Le'gendes épiques,* four volumes (1908–13), Joseph Bédier contested this "traditionalist" theory. Establishing the relationship between the *chansons de geste* and the sanctuaries on pilgrim routes in France, Spain and Italy and the collaboration between the monks and the *jongleurs,* he saw the poems as aimed at attracting pilgrims to the sanctuaries, but, more important, as being of relatively recent composition, not earlier than the 11th century. To the theories of uninterrupted epic transmission, he opposed that of "universal silence," and to that of spontaneous popular creation, the conscious and professional poet at work. For a quarter of a century alone among leading Romance scholars, Ferdinand Lot upheld the "traditionalist" view. (On this debate, *see* I. Siciliano, *Le Origini delle canzoni di gesta,* 1940; French trans. by P. Antonetti, *Les Origines des chansons de geste,* 1951.) However, in the 1940s and 1950s (Bédier died in 1938) there was some reaction against Bédier's "individualist" theory and a "neotraditionalist" school grew up; in France, René Louis revived the theory of uninterrupted transmission with particular reference to *Girart de Roussillon,* and Jean Frappier restated the traditionalist interpretation of the Guillaume d'Orange legend. In Spain the great medievalist Ramon Menéndez Pidal in his *La Chanson de Roland y el Neotradicionalismo* (1959) produced the manifesto of "neotraditionalism," based on the premise of the identity of transmission between the proto-Roland and the Spanish *romances,* and going so far as to identify individual lines as belonging to the most primitive version and others introduced at various stages.

The problem owes much of its complexity to the uncertain interpretation to be placed on occasional mentions by 11th-century or earlier Latin chroniclers in terms of a *canitur,* a *traditur* or a *cantilena* in the context of a historical event or personage forming the subject of a *chanson de geste,* and to similar Latin texts. including The Hague fragment. To the neotraditionalist, such allusions are proof of the existence of narrations closely akin to the *chansons de geste* which have come down to us. The "individualist" is more inclined to interpret such evidence as suggestive of local and oral traditions relating to the personages concerned, in short the raw material of the poems rather than the poems themselves. The debate has thus come to be centred on the problem of the "latent state" of the legends and it may be that through an attempt to discriminate more clearly between local oral traditions on the one hand and literary creations on the other, the two conflicting schools of thought may be reconciled.

CHANT: see AMBROSIAN CHANT; CHURCH MUSIC; PLAINSONG.

CHANTAL, SAINT JANE FRANCES DE (JEANNE FRANÇOISE FRÉMIOT, BARONNE DE CHANTAL) (1572–1641), French religious founder of the Visitation order, was born Jan. 28. 1572, at Dijon where her father was president of the *parlement* of Burgundy. In 1592 she married Baron de Chantal, who was accidentally killed hunting in 1601, leaving his widow with four young children. In 1604 she heard St. Francis de Sales preach, and placed herself under his direction. In 1610, after her eldest daughter had married and her 14-year-old son was provided for, she took her two remaining daughters to Annecy, where she founded the Visitation order. It counted 86 houses at her death in 1641 and 164 by 1767, when she was canonized. Aug. 21 is her feast day. (A. FE.)

CHANTERELLE (CHANTARELLE), an edible mushroom known botanically as *Cantharellus cibarius* (family Agaricaceae), found in woods in summer. It is golden yellow, somewhat inversely conical in shape and about 2 in. broad and high. The cap is flattened above with a central depression and a thick-lobed irregular margin. Running down into the stem from the cap are a number of shallow thick gills. The substance of the mushroom is dry and opaque with a peculiar smell suggesting ripe apricots or plums. The flesh is whitish tinged with yellow. The chanterelle is common in coniferous woods in northeastern United States and Canada. It is sold in the markets of Europe, where it forms a regular article of food: but it seems little known in Great Britain. Before being cooked it should be allowed to dry, and then thrown into boiling water.

Care should be taken to distinguish the true chanterelle from the false chanterelle (C. *aurantiacus*), a closely related species, which is suspected of having caused poisoning. The latter species is more orange in colour, with thinner, broader and closer gills.

CHANTHABURI, the name of a province (*changwat*) and its capital in southeast Thailand. The province borders the Gulf of Siam on the southwest and Cambodia on the east. With an area of 2.337 sq.mi. and a population of 149,557 in 1960 it had a population density of 64 per square mile. Most of the province is hilly to mountainous and is covered with a rain-forest type of vegetation. The people live in farming villages near patches of alluvial soil on the flood plains and deltas of short rivers, and in fishing villages along the coast. Both the town and its *changwat* are connected to Bangkok. 135 mi. to the northwest, by an all-weather road and by ocean transportation. The town's deep-water port is Laem Sing on the gulf. Both the province and its capital are noted for rubber, rice and fruit. Although the Thais predominate, there are large numbers of Cambodians and Chinese in Chanthaburi. Originally a part of the Khmer empire, this area has belonged to Thailand for about four centuries. (T. F. B.)

CHANTILLY, a town of France, Oise *département*, is situated 41 km. (25 mi.) N. of Paris, by road. Pop. (1954) 6,983. The town, located near the forest of Chantilly, is a favourite holiday resort for Parisians. Formerly well known for its lace and porcelain manufacture and as the residence of the Condés, it is now even more celebrated for its château, park and the annual races of the French Jockey club. The château, on a small rocky island in an artificial lake, was originally built in the 14th century, but very few old parts have survived numerous restorations and rebuildings. The adjoining chatelet (*c*. 1360) was designed by Jean Bullant. Chief annexes are the stables, built (1719–35) to house 240 horses, and the Château d'Enghien, built in 1772 for the duc d'Enghien. The park and chhteau (now an important museum) were bequeathed to the Institut de France by the duc d'Aumale in 1886, along with his library and collections. . The station, Chantilly-Gouvieux, is on the main line from Paris to Calais, Brussels and Amsterdam. Chantilly is mainly residential, and its chief industry is catering for tourists. Film-making and forestry also are important.

In the reign of Charles VI the lordship of Chantilly passed to Pierre d'Orgemont, chancellor of France. In 1484 it passed to the house of Montmorency and in 1661 to the house of Condé. In 1830 the estate passed into the hands of Henri, duc d'Aumale.

Chantilly has been under German occupation several times: in 1870–71, during the Franco-German War; for a few days in Aug. 1914 in World War I; and from June 1940 to Aug. 1944 in World a I French headquarters were at the Hôtel du Grande Condé from Nov. 1914 until March 1917. (R. M. BU.)

CHANTREY, SIR FRANCIS LEGATT (1781–1841). English sculptor and donor of the Chantrey bequest. was born on April 7, 1781. at Norton, near Shefficld. After receiving lessons in wood carving and painting, he went to try his fortune in Dublin and Edinburgh and in 1502 went to London, where he worked as a wood carver. His first commission for sculpture came in 1805 from Sheffield. but it was not until 1811 that he found fame and fortune with his bust of Horne Tooke. exhibited at the Royal Academy. Chantrey was elected associate of the Royal Academy in 1815 and Royal Academician in 1518 and was knighted in 1835. He died suddenly on Nov. 25, 1841. Under the terms of his will his fortune was left to his widow and after her death to the Royal Academy. The income from the bequest was to be spent chiefly on purchasing the most valuable works in sculpture and painting by artists of any nation residing in Great Britain at the time of execution. Chantrey's chief statues are Lord Melville at Edinburgh; George IV in Windsor castle and at Brighton; George Washington in the state house, Boston, Mass.; William Pitt in Hanover square, London; and the equestrian statues of Sir Thomàs Rlunro at Madras. George IV in Trafalgar square. London, and Wellington outside the royal exchange. London. Chantrey's best-known monument is that of the Robinson children in Lichfield cathedral. but he considered that his figure of Lady Frederica Stanhope at Chevening. Kent. was his best work. Chantrey produced a large number of busts of which the finest is undoubtedly that of Sir Walter Scott at Abbotsford.

See R. Gunnis (comp.), *Dictionary of British Sculptors, 1660–1851* (1953). (R. Gs.)

CHANT ROYAL, a fixed form of verse developed by French poets of the 13th to the 15th centuries. It is first mentioned by the late 13th-century poet Rutebeuf, and has all the appearance of an extended ballade (*q.v.*), though it is not possible to determine which of the two appeared first. Its standard form consisted. in the 14th century, of five stanzas of from 8 to 16 lines of equal measure. without refrain, but with identical rhyme pattern in each stanza and with an *envoi* using rhymes from the stanzas. Guillaume de Rlachaut gives the *envoi* three lines, Eustache Deschamps from four to eight. but he occasionally omits it. In the 15th century the chant royal acquired a refrain and the *envoi* was normally about half the length of the stanza. This had usually from 10 to 12 lines. their numher being dictated by the numher of syllables in the refrain, both feminine and masculine decasyllabics allowing, however, stanzas of 11 lines. Jean Molinet, in his *Art et science de rhétorique* (1493), and Étienne Pasquier both stress the difficulties of the genre, and the latter considers it better suited than the ballade to solemn and pompous themes. Pierre Fabri. in his *Grand et vrai art de pleine rhétorique* (1521), gives detailed instructions about length of stanza and rhymes. Like the ballade, the chant royal admitted of variations: as the *serventois*, a poem in honour of the Virgin Mary, it early acquired, then lost. the refrain; similar varieties were the *amoureuse* (love poem), the *sotte amoureuse* (playful love poem) and the *sotte chanson* (comic poem).

Clement Marot was a master of this genre, and his *Chant royal chrétien,* with its refrain *Santé au corps et Paradis à l'âme* ("Health to the body and Paradise to the soul"), was famous. La Fontaine was the last exponent of the chant royal before its eclipse. It was revived in the 19th century but, as Théodore de Banville says, it essentially belonged to the ages of faith when its subjects could be either the exploits of a hero of royal blood or the processional splendours of religion. It was introduced into England only in the late 19th century. the first English chant royal being Edmund Gosse's *The Praise of Dionysus* (1877). It is practically unknown in any other literature.

See L. E. Kastner, *A History of French Versification,* pp. 268–271 (1903); G. Lote, *Histoire du vers français,* vol. ii, pp. 285–290 (1949). (F. J. WE.)

CHANUTE, OCTAVE (1832–1910), U.S. aeronaut. whose work and interests had a profound influence on Orville and

Wilbur Wright and on the invention of the airplane, was born in Paris, France, on Feb. 18, 1832. He went to the United States with his parents at an early age. Chanute established a reputation as a civil engineer and had many years of experience as a builder of railroads and railroad bridges before he turned his attention to aviation. Attracted by the work of Otto Lilienthal (*q.v.*) and others in Europe who were experimenting with gliding flight, Chanute (then in his 60s) established a glider camp on the sand dunes of Lake Michigan near Chicago; there he and his associates made about 2,000 gliding flights without accident in machines of his own design. Chanute was particularly interested in problems of control and equilibrium, and the data he accumulated proved extremely useful to the Wright brothers in evolving their earlier designs. He was in constant correspondence with the Wrights, and on several occasions visited their camp at Kitty Hank during the period (1901–02) of their gliding experiments which preceded their final success. Chanute died in Chicago on Nov. 23, 1910. (S. P. J.)

CHAO K'UANG-YIN (T'AI-TSU) (927–976), first emperor of the Sung dynasty who unified China after a century of internecine warfare and laid the foundation for one of the most brilliant periods of Chinese history. Though he was addicted to liquor and was an unexceptional general without great ambitions, in the year 960 he was acclaimed emperor by his army, which was dissatisfied with a child on the throne. He thwarted any further army uprisings by stripping the military governors of their commands, promising them a quiet, pleasant life in the capital, and replacing them by civil servants. His centralization of military and financial power brought about final unification: one kingdom after the other surrendered or was conquered (central China in 963, the west in 965, the south in 971, the remaining provinces in 975). He died at K'ai-feng, Nov. 14, 976, and the task of unification was carried on by his younger brother and successor T'ai-Tsung. See also SUNG. (ET. BA.)

CHAO PHRAYA (MAE NAM): see MENAM CHAO PHYA.

CHAOS, connected etymologically with the Greek verb *chaskein,* "to yawn," "to gape open," designates in early Greek cosmology either the primeval emptiness of the universe before things came into being or the abyss of Tartarus, the underworld. Both concepts occur in the Theogoay of Hesiod. First there was Chaos, in Hesiod's system. and then Earth and Eros (Desire). Chaos does not generate or beget Earth; the offspring of Chaos are Erebus (Darkness) and Night. Night ,begets Xether, the bright upper air, and Day. Night later begets the dark and dreadful aspects of the universe; *e.g.,* Sleep, Dreams! Death, War, Strife, Famine, Grief. This ties in with the other early notion that saw in Chaos the darkness of the underworld.

In the later cosmologies Chaos generally designates the original state of things, however conceived. Aristophanes' Birds (11, 691 ff.) gives a parody of an Orphic cosmogony in which the birds claim to be descended from winged Eros and murky Chaos. In lyric poetry Chaos indicates the Aether or upper air (*cf.* Bacchylides. v. 27). Aristotle took Chaos in Hesiod as a prephilosophical way of designating space (cf. his Physics, iv, 1). Later philosophers, except for the Stoics, followed Aristotle. The Stoics identified Chaos with water after a false etymology from the verb cheein, "to flow." The later Stoics designated as Chaos the watery state which follows the periodic destruction of the universe by fire and which precedes its reconstruction. From Stoic sources undoubtedly came the picture of Chaos in Ovid's *Metamorphoses* (i. 7 ff.j, the original raw and formless mass in which all is disorder and confusion, from which the maker of the Cosmos, the ordered universe. produces the elements, the forms of determinate being and the order and harmony of the universe. The popularity of Ovid in the Renaissance and modern times has made this the modern meaning of the word. This concept of Chaos also was applied to the interpretation of the Creation story in Gen. i (to which it is not native) by the Latin church fathers (*e.g.,* Lactantius and St. Augustine). (R. R. PR.)

CHAOUÏA, a region of Morocco which comprises three cercles (districtsj Chaouïa-Centre, Chaouïa-Nord and Chaoui'a-Sud in Casablanca province. Chaoui'a ("sheep raisers") is traditionally applied to tribes established between Fedala, Casablanca and Settat, a region originally called Tamesa and occupied by Masmouda Berbers who, after their conversion to Islam, fell into a heresy and are historically known by the name of Berghwata. The country, ravaged by their struggles with the orthodox Muslims. was repeopled by nomadic Arabs from the 12th century onward. In the 20th century there was a considerable influx of Europeans and the country has returned to its original role as farming land, producing principally cereals. (A. AM)

CHAPAIS, SIR (JOSEPH AMABLE) THOMAS (1858–1946), Canadian lawyer, public official and historian, noted for his eight-volume history of Canada under British rule, was born at St. Denis-de-la-Bouteillerie, Que.. on March 23, 1858, the son of Sen. J. C Chapais. one of the ,'fathers of confederation." Chapais was educated at St. Anne's college and Laval university. Quebec. and was called to the Quebec bar in 1879. In March 1892 he was called to the legislative council of Quebec and he thereafter held various public offices until he retired in May 1897. From 1884 to 1901 Chapais edited Le *Courrier du* Canada, published weekly in Quebec. In 1907 he was appointed professor at Laval university. He published several works on history and law, including *Cours d'Histoire* du Canada (8 vol.. 1919–35), a study of British colonial policy with emphasis on constitutional and political problems. On Dec. 31, 1919, he was called to the senate of Canada. He was knighted in 1935. He died at St. Denis on July 15, 1946.

CHAPARRAL, a mixed forest formation of low hard-leaved, stunted trees and shrubs resulting from short, wet. cool winters and long, arid. hot summers. The word is believed to have been derived from *chaparro,* the Spanish name for "live oak." Chaparral grows slowly and shrubs 25 years old will usually average not more than two or three inches in diameter and five or six feet in height. This type of forest growth occurs chiefly in southern California in the United States, along the coast of Chile. in Europe and Asia along the Mediterranean and as far east as Turkistan. in Africa near the Cape of Good Hope and on the southern and southwestern coasts of Australia and Tasmania. Its chief economic value lies in its ability to conserve ground water, which it accomplishes below the surface through its root system and above the surface by breaking the force of hot winds and shading the ground to prevent evaporation.

Of the 150 different species of woody plants believed to exist in the chaparral of southern California 20 dominant types—among them chamise, manzanita, ceanothus, sumac, sagebrush, scrub oak and buckthorn (*qq.v.*)—represent 90% of the growth. In former times the Indians used the nuts, berries and seeds of several of the plants for food. Some species were once in demand as fuel and others are still used for fencing. The bee industry flourishes in the chaparral region, several profusely flowering shrubs, such as the black sage, being excellent honey plants. It is estimated that there are 5.500.000 ac. of chaparral in the United States. Chaparral formations protect the upper watersheds of the coastal streams in California for about 450 mi.

CHAPBOOK, the name first given by early 19th-century book collectors and others to little stitched tracts formerly sold cheaply by itinerant dealers or chapmen in western Europe and North America. Chapbooks were mostly about $5\frac{1}{2} \times 43$ in. in size and four or multiples of four pages long, illustrated with crude but vigorous woodcuts. They contained tales of popular heroes, legend and folklore, jests, notorious murders, ballads, almanacs, nursery rhymes, school lessons, farces, biblical tales, dream lore and other popular matter. The texts were mostly crude and anonymous but some may have been the anonyms of well-known writers; Thomas Bewick's first illustrations were for chapbooks. Though of little literary value, they formed the major part of secular reading and are a guide to the manners and morals of their times. The chapmen were supplied by printers in the larger towns. Most of the earliest English and German chapbooks derived from the French ones which began to appear at the end of the 15th century. In America they were both imported from England and produced locally. When religious and other more serious tracts appeared and cheap magazines developed in the early 19th century,

chapbooks lost popularity and disappeared.

There are good collections in the British museum. London, the Bodleian library. Oxford, and, in the U.S., in the New York public library and Harvard university library.

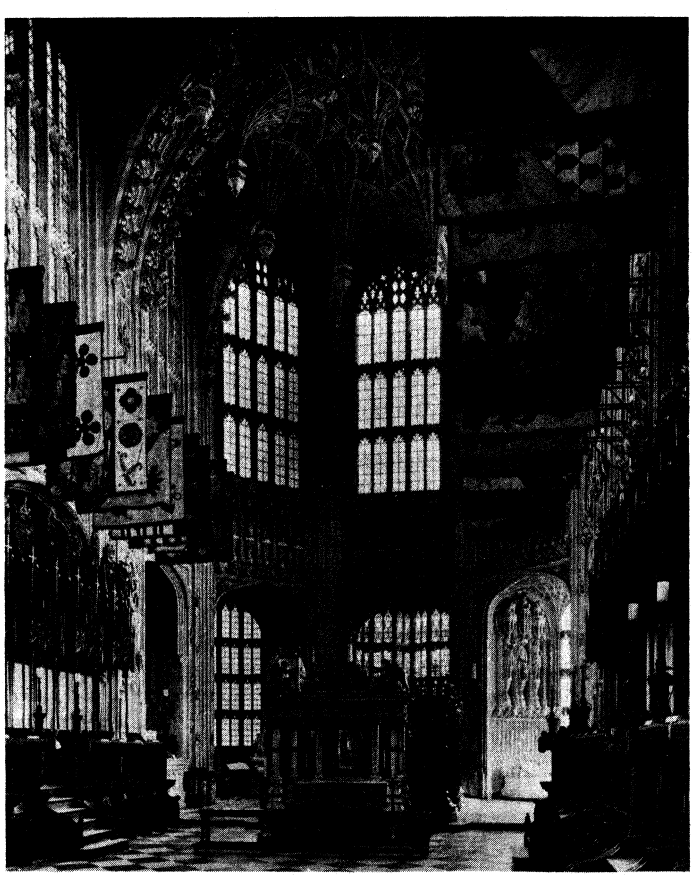
CHAPEL is a term variously employed to designate a Christian house of worship that for one reason or another is not entitled to the name "church."

Capella, the diminutive of *cappa,* "cloak," mas the name given to the shrine in which the cloak of St. Martin was kept and carried about by the Frankish kings on their journeys and military campaigns. This peculiar use was transferred to any sanctuary containing relics, the priest of which was called *capellanus* or chaplain (*q.v.*). By a further extension, the word was identified with all places of worship that were not mother churches *(ecclesiae matrices),* so as to include a large number of miscellaneous foundations. Most nearly akin to the original meaning is the application of the term to the oratories, places of private worship, attached to royal residences. Thus the Sainte Chapelle, the palace chapel at Paris. a masterpiece of Gothic architecture consecrated in 1248, was built by St. Louis to enshrine the relic of the Crown of Thorns, which he had brought from Constantinople. In the next century, other *saintes chapelles* were founded by princes of the French royal house at Bourges, Riom and elsewhere. Such chapels royal were usually founded as collegiate establishments, and other collegiate chapels were founded by prelates and noblemen in connection with their castles and manor houses.

Traditionally, British usage since the Reformation has been reluctant to apply the designation "church" to any house of worship not belonging to the established Anglican church. Therefore Nonconformist meetinghouses, Wesleyan places of worship and even Roman Catholic churches have been called "chapels." In Ireland the term has clung persistently to Roman Catholic places of worship. But. apart from this. the modern tendency is to abandon the employment of the word for special classes of religious building and to give the title "church" to all, regardless of their denominational affiliation. Thus "chapel" has come to mean what it meant before the rise of Nonconformity: a subordinate house of worship that is auxiliary to or parallel with a church. In the United States "chapel" may sometimes mean simply a small church.



A. F. KERSTING

CHAPEL OF HENRY VII, BUILT FROM 1502 TO 1512, A ROYAL MORTUARY CHAPEL IN WESTMINSTER ABBEY, LONDON

Most frequently, however. the word is applied to three types of structure: a building in which religious services are conducted on the campus of a college or university (a usage dating to the 18th century in the United States and to the 17th century or even earlier in Great Britain) or in a hospital; the house of worship at a military base; and the room in an undertaker's establishment set aside for funeral services. *See* also RELIGIOUS ARCHITECTURE

(A. H. T.; J. J. PN.)

CHAPEL, in the printing trade, the name of the fellowship of compositors (and, nowadays, of all crafts) in a printing works. The president is termed the "father of the chapel." In the United States he is called "the chairman." The name chapel is used not only of the fellowship itself but of the meetings it holds. At these meetings, the chapel discusses such things as the general welfare of the body, the conditions of work, relations with employers, and trade union matters.

The accepted version of the origin of the use of the word chapel in this connection is that it is derived from the fact that the famous English printer, William Caxton, first set up his press in or near Westminster Abbey. Writing in 1716, Myles Davies. in his *Athenae Britannicae* said, "William Caxton first practis'd Printing in the Abbey of Westminster, A.D 1471, thence a Printing-Room came to be call'd a Chappell amongst our Printers." Another explanation is offered by Joseph Moxon, who in his *Mechanick Exercises* (1683) wrote, "Every Printing-house is by the Custom of Time out of mind, called a Chappel: and all the Workmen that belong to it are Members of the Chappel: and the oldest Freeman is Father of the Chappel. I suppose this stile was originally conferred upon it by the courtesie of some great Churchman, or men (doubtless when Chappels were in more veneration than of late years they have been here in England), who for the Books of Divinity that proceeded from a Printing-house gave it the Reverend Title of Chappel."

CHAPELAIN, JEAN (1595–1674), French poet and literary critic, who aimed to apply the precepts of empirical philosophy to literature, was born in Paris on Dec. 4, 1595. He first attracted the notice of literary circles in 1619–20, with a translation of *Don Guzman de Alfarache.* This was followed by a remarkable preface to Marino's *Adone.* Chapelain became a pupil of the aged François de Malherbe and a close friend of Claude de Vaugelas and Valentin Conrart, so that he was naturally one of the founders of the Académie Franqaise, in which he came to exercise a major influence, as he caused his friends and followers to be elected members. In 1663, when Colbert decided to grant pensions to deserving writers, it was Chapelain who was entrusted with the naming of candidates. A number of writers, however, opposed his influence: Giles Menage had pamphlets written against him; Gilles Boileau, Franqois Payot de Lignières and Antoine Furetière wrote criticisms and epigrams on him; Olivier Patru and his circle held him up to derision; and Luillier Chapelle, Racine, Furetiere and the Boileau brothers composed a skit entitled *Chapelain décoiffé* (1663). Chapelain died in Paris on Feb. 22, 1674.

Chapelain's poetry and his literary criticism must be considered separately. As a poet, he began writing an epic, *La Pucelle,* in 1630 and published the first 12 cantos in 1656. This was a failure, and he decided not to have the final 12 cantos printed (they were eventually published in 1882). As a critic, however, he had great merits. as can be seen in various short works published by him and in his voluminous correspondence. A friend of Pierre Gassendi and a confirmed opponent of Descartes, he is the principal

representative of the attempt to apply empirical philosophy in the sphere of literary criticism. He does not invoke Aristotle's authority through blind admiration for the Poetics; but 2,000 years of satisfactory results seemed to him to prove that the Aristotelian theory of tragedy was valid. Likewise, he recommends common sense, moderation and wisdom, the characteristic qualities of the empiricist; so that he stands aloof from the excesses of purism and shows a far more catholic taste than the doctrinaire classicists. He could equally enjoy medieval literature, Spanish picaresque novels and La Fontaine's *Contes*.

BIBLIOGRAPHY.—For Chapelain's prose writings, see *Les Lettres de Jean Chapelain* ed. by Tamizey de Larroque (1880–83) and the *Jean Chapelain, opuscules critiques*, ed. by Alfred C. Hunter (1936). There is an excellent thesis on Chapelain by G. Collas, *Un Poète protecteur des lettres au 17e siecle: Jean Chapelain* (1912). (AE. A.)

CHAPELLE ARDENTE, the chapel or room in which the corpse of a sovereign or other exalted personage lies in state pending the funeral service. The name refers to the many candles lighted round the catafalque. This custom is first chronicled as occurring at the obsequies of Dagobert I (d. 639), the Metovingian king of the Franks.

CHAPLAIN in its origin and later usage is closely linked with chapel (*q.v.*). In the 4th century chaplains (Lat. *capellani*) were so called because they kept St. Martin's famous half cloak (Lat. capella). This cloak, preserved as a relic by the kings of France and carried with them when they went to war, gave its name to the tent and later to the simple oratory or chapel where it was preserved. To this precious relic were added other relics that were guarded by chaplains appointed by the king during the Merovingian and Carolingian period, and particularly during the reign of Charlemagne, who appointed clerical ministers (*capellani*) who lived within the royal palace. In addition to their primary duty of guarding the sacred relics they also said mass for the king on feast days, worked in conjunction with the royal notaries and wrote any documents the king required of them. With this extension of the duties of chaplains and the increase in their number their duties gradually became more identified with direct service to the monarch as advisers in both ecclesiastical and secular matters. This was due for the most part to the fact that the clergy were learned and well skilled in writing and in the Latin tongue at a period when few people could either read or write.

The practice of kings' appointing their own chaplains spread throughout western Christendom. Many of the royal chaplains were appointed to bishoprics and the highest offices in the church; and down to the present day the British monarchs have appointed their own royal chaplains. The duties of royal chaplains have varied throughout the centuries; appointment by the British sovereign to the Royai College of Chaplains is now chiefly an honour, carrying with it little more than the duty of preaching occasionally in the chapel royal. In the Church of England diocesan bishops appoint clergy to be domestic, examining or honorary chaplains on their own personal or diocesan staffs.

In modern usage the term chaplain is not confined to any particular church or denomination. Clergy and ministers appointed to a variety of institutions and corporate bodies—such as cemeteries, prisons, hospitals, schools, colleges, universities, embassies, legations and armed forces—usually are called chaplains. In some countries where the church is totally independent of the state, service chaplains are maintained, as for instance in the United States, but in others, as in France since 1905, they are not.

British Armed Forces.—Chaplains serve in each of the three services. They are drawn from the ministries of the major churches in the country: Church of England, Church of Scotland. Roman Catholic, Methodist, Baptist and Congregationalist. The chief chaplain in each service (the chaplain of the fleet in the navy. the chaplain general in the army, the chaplain in chief in the air fcrce) bears the title of archdeacon and discharges his ecclesiastical functions under licence of the archbishop of Canterbury. There is a Roman Catholic bishop in ordinary to the forces, and the principal Roman Catholic chaplain in each service is a vicar general. There is a senior Jewish chaplain to the forces.

(J. W. L.)

United States.—Armed Forces.—The continental congress made the first formal provision for chaplains in the armed forces of the colonies on July 29. 1775. The first army chief of chaplains was appointed (in the grade of colonel) in 1920: in 1944 the chief of chaplains was made a major general. As in the other services. the number of chaplains varies with the personnel strength of the army. The U.S. Army Chaplain school is located at Fort Hamilton, N.Y.

The navy chaplain corps traces its history back to Nov. 28, 1775, when the continental congress adopted navy regulations directing regular performance of divine service aboard ship. The first chief of the navy chaplain corps was appointed in 1917 (although the office of the chief of naval chaplains was not statutorily created until 1944). The U.S. Navy Chaplain school is located at Newport, R.I.

In 1942 an air chaplain was appointed to supervise the chaplains of the U.S. army air forces. The U.S. air force became an independent service in 1947, but the army and air force chaplaincies were not separated until May 10, 1949. The U.S. Air Force Chaplain school is located at Lackland air force base. Texas.

The duties of the chaplain in all three services are parallel. He must furnish or arrange for religious services and ministrations; advise his commander and fellow staff officers on matters pertaining to religion and morality; administer a comprehensive program of religious education; serve as counselor and friend to the personnel of the command; and conduct instruction classes in the moral guidance program of his service. Chaplains at higher command echelons exercise technical supervision over chaplains of subordinate headquarters. All three services supplement the services of active duty chaplains with auxiliary chaplains when necessary. Under international conventions, chaplains are protected personnel. They cannot be required to bear arms. The denominationai distribution of chaplains reflects as far as feasible the size of the religious body concerned in the national population.

Other.—Since June 1945 the chaplaincy service of the Veterans administration has been organized on a national basis. Chaplains serve in the administration's hospitals under the supervision of a director, himself a chaplain, in the department of medicine and surgery. Though a majority are former military chaplains, their status is that of civil service employees. Denominationally they reflect the needs of the hospital to which they are assigned Their ministry is of necessity chiefly to individuals. Chaplains are also appointed for both houses of the congress and for most state legislatures to lead the lawmakers in prayer at the beginning of each session.

(A. C. PN)

CHAPLIN, CHARLES SPENCER (1889–), English motion-picture actor, was born April 16, 1889, and passed his childhood in London. At an early age he appeared on the music hall stage with his father. In 1910 he went to the United States as a leading comedian in a Fred Karno production. Engaged there by Mack Sennett to make films with the Keystone Comedy company in Los Angeles, Chaplin became famous for the blend of comedy and pathos in his habitual portrayal of the little tramp. The tramp character made his first appearance in Chaplin's second film, *Rid* Auto Races at *Venice.*

In 1918 he formed his own company and began production of a series of films that placed him in the front rank of artists. Among them were: *A* Dog's *Life* (1918), *Shoulder Arms* (1918), The Kid (1921), The Gold Rush (1925), The Circus (1926), *City* Lights (1931), *Modern Times* (1936), The Great Dictator (1940), *Monsieur Verdoux* (1947) and Limelight (1952). With Douglas Fairbanks, D. W. Griffith, Mary Pickford and others he was a founder of the United Artists corporation. Notified in 1952 that his U.S. re-entry rights would be questioned by the justice department, Chaplin surrendered his U.S. re-entry permit at Geneva, Switz., in 1953.

CHAPMAN, FRANK MICHLER (1864–1945), U.S. ornithologist who did pioneer work in popularizing bird study, was born at Englewood, N.J., June 12, 1864, and had no formal education beyond academy. He joined the staff of the American Museum of Natural History, New York city, as assistant in 1887, served as assistant curator (1888–1901) and associate curator

(1901-08) of ornithology and mammalogy, and as curator of ornithology (1908-42) until his retirement.

Chapman originated the habitat bird groups and seasonal bird exhibits. Beginning in 1887 he traveled widely, collecting and photographing the birds of temperate and tropical America. He published his widely used *Handbook of Birds of Eastern North America* (1895), *The Warblers of North America* (1907) and a dozen other popular books. His technical papers covered life histories, geographical distribution, and systematic relationships of American birds, after 1911 dealing largely with the origin of Andean bird life and resulting in volumes on *The Distribution of Bird Life in Colombia* (1917), *Birds of the Urubamba Valley, Peru* (1921) and *The Distribution of Bird-Life in Ecuador* (1926). His field adventures are well presented in his *Camps and Cruises of an Ornithologist* (1908) and *Autobiography of a Bird-Lover* (1933'). Chapman was founder and editor (1898–1935) of *Bird-Lore* magazine, president of the American Ornithologists union (1911-14) and vice-president of the Explorers club (1910-18). He was awarded the first Linnean medal (1912), the first Elliot medal (1918) of the National Academy of Sciences, the Roosevelt medal (1928) and the Burroughs medal (1929). Brown university, Providence, R.I., awarded him the Sc.D. degree in 1913. He died in New York city on Nov. 15, 1945. (G. F. Ss.)

CHAPMAN, GEORGE (1559?–1634), English dramatist, poet and translator of Homer and one of the most powerful and important Elizabethan writers, was the second son of Thomas Chapman, yeoman of the hundred of Hitchin. by his wife Joan, daughter of George Nodes of Shephall. His family appears to have been strongly Protestant. and well connected on his mother's side. Anthony à Wood. in his *Athenae Oxonienses,* claims that Chapman went to Oxford, but he took no degree. By 1585, he was in London in the service of "the wealthiest commoner in England," Sir Ralph Sadler, though himself in debt. He appears to have gone to the Low Countries, where he may have seen military service.

On Dec. 31, 1593, his first work, *The Shadow of Night . . . Two Poeticall Hymnes,* was entered in the stationers' register; it was followed in 1595 by the poem *Ovid's Banquet of Sense.* On Feb. 12. 1596, Chapman is mentioned in Henslowe's *Diary* (a mine of information on theatrical history for this period) as the author of *The Blind Beggar of Alexandria,* a successful comedy; other entries occur in 1597 and 1599. Later he wrote plays for performance by the children of the revels, the children of Paul's and the King's men. In 1603 he became server in ordinary to Prince Henry. From the first decade of King James's reign, about a dozen plays survive, of which *Bussy d'Ambois* (1607), *The Conspiracy and Tragedy of Charles Duke oj Byron* (1608) and *The Widow's Tears* (1612) are his masterpieces. His translation of the *Iliad,* of which the first books appeared in 1598, was completed in 1611. It was encouraged by Prince Henry. whose death in 1612 deprived Chapman of his chief support; he sought a new patron in the king's favourite, the earl of Somerset, to whom he dedicated the two volumes of the *Iliad* and the *Odyssey* of 1616, although by this time Somerset was disgraced. In his later years Chapman appears to have written few plays. but completed "the work that I was born to do" by translating the minor Homeric poems. He died in London on May 12, 1634, and was buried in St. Giles-in-the-Fields, where Inigo Jones, who collaborated with him in producing at least one masque, performed in honour of the princess Elizabeth's marriage in 1614, erected a monument.

Chapman's views of the poet's task were lofty, and were early set out in the preface to *Ovid's Banquet of Sense,* addressed to Matthew Roydon, a follower of Sir Walter Raleigh. He wrote in praise of Raleigh a poem De *Guiana Carmen Epicum,* published with Lawrence Keymis' *A Relation of the Second Voyage to Guiana* (1596); he was also a friend of Christopher Marlowe, for whose *Hero* and *Leander* he wrote in 1598 a conclusion which arnounts to a "correction" of its libertine views. Whether he were also the "rival poet" of Shakespeare's *Sonnets,* and whether Shakespeare caricatured Chapman as Holofernes in *Love's Labour's Lost,* is a matter of dispute; certainly the Southampton-Essex faction which Shakespeare appears to have supported was opposed to Raleigh, yet Chapman dedicated to Essex his first installment of the *Iliad.*

Though he clung to the older literary tradition of seeking a patron instead of relying on the public. Chapman n-as singularly unskilful in compliment. In 1605 with his friend Ben Jonson he was imprisoned for his share in *Eastward Ho!*—a play which reflected on the Scots. In 1608 he was in trouble again for his comments on French politics in *The Conspiracy and Tragedy of Charles, Duke of Byrors.* His attempt in *Andromeda Liberata* (1614) to defend the scandalous marriage of Somerset was so maladroit as to bring down his patron's wrath. A lover of arms, yet a visionary and contemplative, who wrote "A Coronet of Love Sonnets for his mistress Philosophy," Chapman seems to have been deeply interested in politics and religion but in so detached a fashion that he defended the massacre of St. Bartholomew on general principles. He mas addicted to paradox; his plays contain lengthy praise of cuckolds and of "the dangerous tobacco."

Living a life of poverty (he was obliged in 1599 to renounce for ready money the claims to his mother's inheritance of Shephall). Chapman yet seems to have achieved some public success, particularly by his comedies, in which Plautine conventions were successfully adapted to current manners. He anticipated Ben Jonson's comedy of humours, and enjoyed a stormy and uncertain friendship with him. Jonson's manuscript notes on Chapman's *Homer,* preserved in the Fitzwilliam museum, Cambridge, are far from complimentary; it is clear that Chapman, like most students of his time. relied heavily on Latin commentaries, books of mythology and other aids to learning. His passionate devotion to the arts had more enthusiasm than clarity. His praise of obscurity in poetry. in the preface to *Ovid's Banquet of Sense,* depends upon the doctrine of inspiration derived from Hermes Trismegistus. It was thought that the ancient poets had embodied in their poetry a divine wisdom, concealed under symbolic or mythological form; Francis Bacon assumes such a view in his *Wisdom of the Ancients,* where lie interprets ancient myths. Elsewhere. Chapman says that Homer appeared to him in a vision upon Hitchin hill, and commanded the translation of his works. In translation, Chapman treated Homer as a writer to be moralized, adding moral glosses within the text to "explain" it.

Initial rapture was succeeded by a struggle for words which left Chapman's poetry. as he himself recognized, in a volcanic and uncertain state, flashes of great power and splendour alternating with turgid and pedantic eccentricities. The complexity of his thought recalls that of John Donne, but he has not Donne's analytic clarity. In his greatest work. the tragedies, the Marlovian stature of the heroes unfits them for ordinary life and its necessary compromises; such unadaptable grandeur also characterizes Chapman as a poet. In the 9th edition of the *Encyclopedia Britannica,* Swinburne said: "In most of his tragedies, the lofty and labouring spirit of Chapman may be said rather to shine fitfully through parts than steadily to pervade the whole; they show nobly altogether as they stand, but even better by help of excerpts and selections." On the other hand, in his edition of Chapman's *Homer,* Allardyce Nicoll has observed that the sustained sweep of the work rather than its detail constitutes its true greatness.

To his contemporaries, Chapman stood uncompromisingly for the worth and divine dignity of poetry. John Webster, John Fletcher, Nathaniel Field paid tribute to him; and in the venerable bearded head of the portrait of 1616, not unfittingly surrounded by clouds, may be seen something of the heroic simplicity of the great Elizabethan, and his fitness to render Homer in English.

Among his last published works, *Pro Vere, autumni lachrymae* (1622), a plea for the succour of the valiant Sir Horatio Vere "beseiged. and distrest in Mannheim," recalls the glory of earlier days, when he had sung the exploits of Raleigh and had perhaps campaigned in the Low Countries. Achilles as the model of soldierly virtue had seemed to him but a pale reflection of Essex, and his tragic heroes had all been warriors. The soldiers' and the scholars' virtues were complementary for Chapman; both were opposed to the aims of the worldling, whether a sensualist or a seeker after political power. If in his works there sometimes sounds a note of contempt for the common pleasures of life, an acerbity and ill-judged moral reproot toward worldly success,

which was a temptation that had not notably come his way, this derived from his Xeoplatonic view of divine poetry as "excitation to virtue and deflection from her contrary.", This view Chapman shared with Sir Philip Sidney and Ben Jonson. On the other hand, in his *Invective Against Mr. Ben Jonson,* which survives'in a manuscript in the Bodleian library, Oxford, Chapman accused his friend of precisely that arrogance to which he himself is prone; and whether or not in writing *Love's Labour's Lost,* Shakespeare set himself in opposition to Chapman by extolling the active life against the contemplative, the pleasures of the senses against those of the study, this difference appears in the general tendency of their works. Chapman had no gift for precise and exact delineation of character; each of his plays is dominated by a hero, whose tirades and descriptive rhetoric are ill-adapted to the living theatre. He despised the common stages, and never subdued his spirit to their demands; his gnomic and high-wrought style was addressed to the few, and his poetry appeals now, as in his own day. to those who can decipher what is authentic, powerful but crabbed.

BIBLIOGRAPHY.—*Editions: The Works of George Chapman,* ed. by R. H. Shepherd, 3 vol. (1874–75) includes doubtful plays, as does *The Traaedies and Comedies of George Chapman,* ed. by T. M. Parrott (1910–14). *The Poems of George Chapman,* ed. by Phyllis Bartlett (1941) includes all the minor nondramatic poetry. There is a critical edition, in old spelling, of *Chapman's Homer,* by Allardyce Nicoll, 2 vol. (1956). Individual plays have been published and edited as follows: *The Blind Beggar of Alexandria* and *An Humorous Day's Mirth,* in Malone Society Reprints, ed. by W. W. Greg (1928 and 1938 respectively); *Eastward Ho* (in Tudor Facsimile Texts [1914]), and ed. by C. H. Heriord and P. Simpson in their *Ben Jonson* (1925–52); *All Fools* and *Sir Giles Goosecap,* ed. by W. Bang and R. Brotanek in *Materialen zur Kunde des alteren englischen Dramas,* vol. xxvi (1909). F. L. Schoell attributed to Chapman an anonymous play *Charlemagne,* from manuscript Egerton 1994, and edited it (1920); the attribution was contested by G. H. Walter who also edited it for Malone Society Reprints (1938). Other plays doubtfully attributed to Chapman, but unlikely to be his, are *The Second Maiden's Tragedy, Alphonsus Emperor of Germany, Revenge for Honour* and *The Ball,* included in Shepherd's edition, and *Histriomastix,* attributed to him by Jean Jacquot.

Biography and Criticism: Jean Jacquot, *George Chapman, 1559–1634, sa vie, sa poésie, son théâtre, sa pensée* (1951), with full bibliography; Ennis Rhys, *Tragedies of George Chapman: Studies of Renaissance Ethics in Action* (1954). Earlier works include A. C. Swinburne, *George Chapman, a Critical Essay* (1875); F. L. Schoell, *Études sur l'humanisme continental en Angleterre à la Renaissance* (1926); P. V. Kreider, *Elizabethan Comic Character Conventions as Revealed in the Comedies of George Chapman* (1935); S. A. Tannenbaum, *A Concise Bibliography of George Chapman* (1938). (M. C. BK.)

CHAPMAN, JOHN (JOHNNY APPLESEED) (1774–1845), U.S. frontier nurseryman and folk character, was born in Leominster, Mass., Sept. 26, 1774. Little is known of him until he appeared in western Pennsylvania shortly before 1800. According to tradition, he had planted by 1801 a chain of seedling apple nurseries in advance of the settlements from the Allegheny to central Ohio. He spent about 25 years in north central Ohio. There the "Johnny Appleseed" stories largely originated, springing not only from his business, but from his eccentricities of manners and dress, Swedenborgian religious views, extreme kindness to wild animals, great generosity and unusual exploits of courage and endurance. By 1828 his nurserying reached northwestern Ohio and Indiana. From 1834 Chapman operated around Fort Wayne, Ind., where he died in March 1845.

The folk tales portray him on a spiritual mission preparing the wilderness for the westward movement. He has become the patron saint of American orcharding, floriculture and conservation. Late extension of the early oral tradition has been largely literary—stimulated notably by Henry Howe's *Historical Collections of Ohio* (1847, 1889), an article by W. D. Haley in *Harper's* (Nov. 1871) and later imaginative treatments such as those by Eleanor Atkinson, Vachel Lindsay, Newell Dwight Hillis and Walt Disney.

Wheeler, "John Chapman's Line of Descent From Edward Chapman of Ipswich," *Ohio Archaeological and Historical Quarterly* (Jan. 1939); Robert Price, *Johnny Appleseed: Man and Myth* (1954). (RT. P.)

CHAPMAN, JOHN (christened HENRY PALMER) (1865–1933), English Roman Catholic biblical and patristic scholar and spiritual writer. Chapman was born at Ashfield, Suffolk, on April 25, 1865. After private tuition he went to Christ Church, Oxford: obtained a first class in *Litterae humaniores* and became a deacon in the Church of England. He joined the Roman Catholic Church in 1890, was clothed as a Benedictine novice at Maredsous abbey, Belgium, and was ordained priest in 1895. After several years at Erdington abbey, Birmingham, he was appointed temporary superior of Caldey abbey (1913–14). He served as an army chaplain in World War I, and was subsequently prior (1922–29) and abbot (1929–33) of Downside abbey. He died in London on Nov. 7, 1933.

Chapman's earliest work to attract attention was his *Bishop Gore and the Roman Catholic Claims* (1905), but more important contributions to scholarship are *John the Presbyter and the Fourth Gospel* (1911) and *Notes on the Early History of the Vulgate Gospels* (1908). His *Studies on the Early Papacy* (1928) gathers together only a few of his many articles on early church history; similarly, his New Testament scholarship is inadequately represented by the posthumous *Matthew, Mark and Luke* (1937), in which he seeks to establish this order for the composition of the Synoptic Gospels. He wrote much on the spiritual life and on the theory and practice of contemplative prayer. A collection of his *Spiritual Letters* (published, with a memoir by G. R. Hudleston, in 1925) shows a deep and sympathetic feeling for his various correspondents. (J. D. A.)

CHAPONE, HESTER (née MULSO) (1727–1801), English writer, and one of the group of literary "bluestockings" who gathered around Mrs. Elizabeth Montagu, was born at Twywell, Northamptonshire, Oct. 27, 1727. The precocious but plain daughter of a beautiful mother who was jealous of her accomplishments, she began to write at an early age, and after her mother's death, studied assiduously as well as managing the household. In 1849 she met the learned Mrs. Elizabeth Carter, with whom she carried on a lifelong correspondence. Admiration for Samuel Richardson's *Clarissa* led to her becoming one of the little court of learned ladies who met to hear readings from *Sir Charles Grandison;* she is the central figure in a sketch of the group by Susannah Highmore. Her letters to Richardson show affectionate deference and the unaffected sprightliness he praised in her conversation. Through him she met the attorney, John Chapone, to whom she was married, with her father's reluctant consent: in 1760; her husband died within a year. For the rest of her life she combined literary with domestic activities; a much-loved daughter, aunt and friend; she is described by Fanny Burney as "the most superiorly unaffected creature." She gained a wider reputation for good sense and right feeling by her *Letters on the Improvement of the Mind* (1773), originally written to a niece, which brought many requests from distinguished persons to undertake their daughters' education. Her essays and poems were collected in *Miscellanies* (1775). She died, Dec. 25, 1801, at Hadley, Middlesex.

Her works, containing her correspondence with Richardson and Elizabeth Carter, and a life drawn up by her own family, were published in four volumes (1807).

CHAPPELL, WILLIAM (1809–1888), was a pioneer in English musical research. Born in London, Nov. 20, 1809, he was the eldest son of Samuel Chappell (d. 1834), founder of a music business that William and his two brothers continued. William's interest, however. was in old music. and he helped to establish the Musical Antiquarian society (1840), which issued valuable works by forgotten English composers. His *Collection of National English Airs* (1838–40), revised as *Popular Music of the Olden Time* (1855–59), was an anthology of and lively guide to traditional songs. Chappell died in London, Aug. 20, 1885. (P. M. YO.)

CHAPRA, a town and headquarters of Saran district. Bihar, India, is situated 30 mi. W. of Patna between the Gogra river and the embankment of the North Eastern railway. Pop. (1951) 64,309. The older western portion contains the principal bazaars. The newer eastern part grew up round the civil courts built in the 19th century. The town has two degree-granting colleges affiliated

to Bihar university, and parks and playgrounds in the central and eastern parts. Chapra is an important road and railway junction. The streets of the town, however, are mostly narrow and ill-kept.

Chapra. which was a village when the Mogul chief Baber visited it in 1529, grew in importance in the 17th century when the Dutch and British established saltpetre refineries there. (E. AH.)

CHAPTER HOUSE, the chamber or building in which the chapter or heads of monastic bodies assemble to transact business. Chapter houses occur in various forms — sometimes oblong, as in England at Canterbury or Exeter; sometimes octagonal, as at Salisbury or Westminster: occasionally circular, as at Worcester. Most are polygonal externally and vaulted internally; some. as at Salisbury. Wells, Lincoln, Worcester, etc., depend on a single slight vaulting shaft for all the vaulting support. English chapter houses are often provided with a vestibule; *e.g.,* Lincoln, Salisbury. On the continent of Europe chapter houses occur more rarely than in England and are almost always rectangular. (See MONASTERY; CATHEDRAL.)

In postmedieval times, occasions for building chapter houses in the proper sense were rare; but because the form was so characteristic of medieval architecture, and offered such opportunities for demonstrating medieval building techniques, 19th-century Gothic revivalists made considerable use of it in secular adaptations — typical examples being the chapter house adjoining the Oxford museum, or the library of the house of commons, Ottawa.

In the U.S. the term is sometimes used to refer to campus meeting or residence halls of the members of fraternities or sororities. (AN. G.)

CHAPU, HENRI MICHEL ANTOINE (1833–1891), French sculptor and portrait medalist, whose works were softened expressions of the neoclassic tradition, was born in Le Mée (Seine et Marne) on Sept. 29, 1833. He studied at the École des Beaux-Arts under James Pradier and Francisque Duret and, having gained the Prix de Rome in 1855, spent five years in Rome. His first success was attained by a figure of "Mercury" (1861); and his fame was established by his statue of "Jeanne d'Arc" (1870) representing her as a simple peasant. In 1872 Chapu undertook the monument to the painter Henri Regnault in the courtyard of the École des Beaux-Arts. In 1877 he completed the tomb of the comtesse Marie d'Agoult at Père Lachaise and in 1887 the monument to Archbishop Felix Dupanloup. Among his portraits were those of Léon Bonnat (Église St. Martin, 1864), Alexandre Dumas fils (Comédie Française, 1876) and J. E. Schneider (Le Creusot, 1878). The monument to the Galignani brothers (Corbeil, 1888), representing them in modern costume, excited much comment. The monument to Gustave Flaubert, with an allegorical figure of "Truth," was his last important work. His statuary representing allegorical and mythological figures was sincere in feeling and poetical in conception. Chapu died in Paris on April 21, 1891. The museums of Rouen and Bayonne contain a number of his drawings. (A. K. McC.)

CHAPULTEPEC, a rocky hill on the western edge of Mexico City, has long played a prominent role in the history of that city. On it, Spanish viceroys began the construction of a viceregal palace in the late 18th century, and in the 1860s the emperor Maximilian further beautified the palace and grounds. The area became a large and beautiful park. Chapultepec later became the summer palace of the presidents of Mexico and the home of the National Military academy. In 1937 the palace became a national museum with exhibits of historical interest. In 1945, a conference of American states signed there a convention for the maintenance of peace in the western hemisphere through collective security. (See PAN-AMERICAN CONFERENCES.)

To the Mexican people, Chapultepec has special significance as the scene of the last organized defense of their capital in the war between the United States and Mexico (see MEXICAN WAR, THE). In 1847 the invading army of the United States, under Gen. Winfield Scott, occupied positions just south and west of the city after winning a series of battles to the south on Aug. 19–20. Scott's decision to attack the city from the southwest required that his forces capture Chapultepec, but he hoped the defenders of Chapultepec could be compelled to retire by a bombardment. A day of artillery fire (Sept. 12) did not produce the desired results, and an assault on Chapultepec was ordered for the following day. After several hours of artillery bombardment the assault began at about 8 o'clock in the morning. The attackers moved through groves and across level ground, captured the first line of defense. and began the ascent of the rocky hill. At this point, it was discovered that the ladders for the scaling of the palace walls had been left behind, and there was an embarrassing delay. The defenders, who seem to have been reconciled to the loss of the hill, failed to take advantage of this situation. When the ladders finally arrived, the assault continued and the palace was captured.

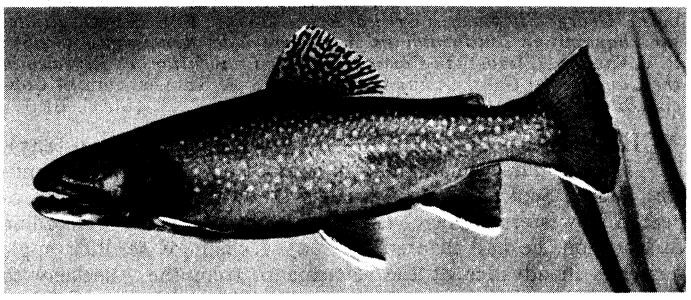
Though Scott had given no orders for further action that day, some of the U.S. forces, under impetuous commanders, moved against the city proper, which they entered after some minor opposition. During the night Mexican forces were withdrawn from the city and on the 14th, Scott entered the capital.

See R. S. Henry, *Story of the Mexican* War *(1950)*; C. *W.* Elliott, *Winfield Scott (1937).* *(H. W.* BY.)

CHAR, a name generally applied to four fishes of the genus Salvelinus, related to the salmon and included with them in the family Salmsnidae. Chars have smaller scales than most trout and salmon; however, there is considerable overlap. The best distinguishing characteristic of chars is the absence of teeth on the front part of the roof of the mouth (the vomer). Chars also have light spots, whereas most of their relatives have dark spots.

The arctic char (S. *alpinus*) inhabits the arctic and adjacent oceans and enters rivers and lakes to breed. Arctic char also has colonies restricted to certain fresh-water lakes, south of its present range in the sea, that it entered in glacial times.

The brook trout (S. *fontinalis*) has a native range of the cool streams of eastern North America but has been introduced elsewhere. It is usually found in small streams; however, some individuals migrate downstream and grow to maturity in lakes or in the ocean. These "sea trout" may attain a length of two feet, but their siblings that do not leave the creeks seldom exceed one foot. During the autumn females dig nests in the gravel and lay from 200 to 2,000 eggs, which hatch in one or two months.



TREAT DAVIDSON FROM NATIONAL AUDUWON SOCIETY

CHAR OR BROOK TROUT (SALVELINUS FONTINALIS)

The Dolly Varden trout (S, malma), which lives in northeastern Asia and northwestern North America, is less desirable than the other chars because it preys on salmon eggs and young.

The lake trout (S. namaycush), an inhabitant of lakes of northern North America, breeds in quiet water. The largest of the chars, the lake trout lacks the red spots typical of the other species; it may weigh as much as 100 lb. All four chars provide good sport and good eating.

See also SALMON AND SALMONIDAE. (C. HU.)

CHARABANC: see CARRIAGE: *Types* in *Use, 17th–19th* Centuries.

CHARACTER. In describing the psychological characteristics of any particular person it is customary to distinguish between two main aspects of mental life, which earlier writers commonly termed "intellectual" and "emotional." Emotional characteristics are those that are assumed to supply the energy or driving force for the person's actual behaviour; intellectual characteristics guide or direct his activities toward their conscious or unconscious goals. It would perhaps be more accurate to describe them as the "motivational" and the "directional" components. Later writers have introduced a cross classification,

and seek to distinguish those characteristics that are inherited or inborn from those that are acquired (*i.e.*, developed out of the inborn tendencies as a result of personal experience). The word "temperament" generally is used to designate those general motivational characteristics that are inborn, and the word "character" to designate those that are acquired. The sum total of these various traits — the directional and the motivational, the inborn and the acquired — integrated into one unique and distinctive whole. is termed "personality." Some psychologists prefer to distinguish three main aspects — the cognitive. the affective and the conative; the word "temperament" is then commonly restricted to the affective aspect (*i.e.*, the qualities of feeling only), and the word "character" used to cover the whole of the conative or moral aspect.

On the motivational side the chief innate bases of personality consist of the innate conative tendencies (usually called instincts) and the emotions or feelings that are associated with them — sex, anger, fear, joy, sorrow, self-assertion. self-abasement and the like. These are inherited by different persons with different degrees of strength; and this has given rise to the popular classification of temperaments into the sanguine, the melancholy. the phlegmatic and the choleric, the differences being really a matter of degree. Such emotional variations are largely the effect of biochemical differences, particularly those that result from variations in the functioning of the endocrine glands.

These traditional distinctions are to a large extent confirmed, and in minor respects modified or rectified, by the results of later statistical investigations. Assessments are obtained for the character traits of a representative sample of persons; either the traits or the persons can then be correlated, and the coefficients so obtained factorized by methods that are much the same as those used for factorizing intellectual abilities (see PSYCHOLOGICAL TESTS AND MEASUREMENTS: Tests of Personality *and Temperament:* Factor *Analysis*). The empirical study of the genetic components of character, however, is still in its early stages, and the theory of instinctive tendencies in man is largely a speculative inference from animal behaviour.

As a result of individual experience the primary instinctive and emotional propensities tend to become progressively organized about certain dominant ideas or thoughts, forming complex motivational systems that correspond roughly with what are popularly termed a person's "interests" — the various people or things that he likes or dislikes, admires or fears. The earliest interests usually are centred on the persons in the child's immediate environment; at a slightly later age interests may be developed for toys, games, close companions, and later still for teachers, school, hobbies and the like. As the child grows up, he develops interests for more abstract concepts — the school subjects that attract (or repel) him, the code of rules he seeks to obey. the ideal personages or characters whom he takes as models of conduct, and above all for himself. This last — the self-regarding sentiment or ego ideal as it is variously called — plays a dominant role in determining his social and moral behaviour (see EGO).

Many of these emotional systems, particularly in persons of unstable disposition, may be more or less unconscious, built up largely as a result of mechanical and even irrational associations and liable to conflict with other emotional systems or with the higher and more conscious levels of the child's personality: they are then termed "complexes." Those that are more completely conscious and more rationally formed are commonly termed "sentiments" (see SENTIMENT). In a fully developed and well-balanced personality all these various tendencies are integrated into a hierarchy of motives and ideals, the whole forming a stable and harmonious character. See also PERSONALITY; TEMPERAMENT.

CHARADE, a kind of riddle, probably invented in France during the 18th century, in which a word of two or more syllables is divined by guessing and combining into one word (the answer) the different syllables, each of which is described as an independent word, by the giver of the charade. Charades may be either in prose or in verse. The following is an example of a poetic charade:

My first is a Tartar,
My second a letter;
My all is a country,
No Christmas dish, better.

The solution is Turkey (Turk-e).

The most popular form of this amusement is the acted charade. in which the meaning of the different syllables is acted out, the audience being left to guess each syllable and thus, combining the meaning of all the syllables, the whole word. A brilliant description of the acted charade is given in Thackeray's Vanity Fair. In the United States the charade in somewhat different form was resurgent in the 1930s and 1940s and again after World War TI. It was called "The Game." Whatever group assembled was divided into two teams. Each team designated one member of the opposing team to personify a quotation, a person living or dead, a phrase or an idea in such manner that his teammates might guess the subject. The designated actor was not permitted to use his voice in any way or to indicate any inanimate object in the room for the guidance of his teammates. The object of the actor was to assist his teammates in guessing the subject in the shortest possible time. A timekeeper determined the team which had arrived at the proper answer in the shorter time and thus had won the contest.

CHARADRIIDAE, a family of birds including plovers. turnstones and surfbirds. Members are found in most parts of the world. See KILLDEER; LAPWING; PLOVER; TURNSTONE.

CHARADRIIFORMES, an order of birds, most members of which live on the water or near it. such as shore birds or "waders," gulls and auks. The young are active and down clad at hatching. See AUK; AVOCET; BIRD; CURLEW; GULL; KILLDEER; PHALAROPE; PLOVER; SANDPIPER; SHEATHBILL; SNIPE; TERN; WOODCOCK.

CHARCOAL. Charcoal is the residue obtained when a carbonaceous material of animal or vegetable origin is partially burned or heated in the absence of air. It is essentially an impure form of carbon (*q.v.*).

The process is often called destructive distillation when. as in this case, the material is decomposed into volatile and nonvolatile fractions. Coke (*q.v.*) is manufactured by the application of a similar process to bituminous coal and may be regarded as a special form of charcoal.

Various charcoals are given names which identify them with the materials from which they are derived: wood charcoal, blood charcoal, etc. Bone charcoal contains only about 12% carbon and consists principally of calcium phosphate and carbonate.

Wood Charcoal. — This material was produced for many centuries by stacking wood into heaps which were partially covered with earth to limit the access of air; the heaps were fired and the charcoal recovered but all by-products were uasted.

This process has been almost completely replaced by those using by-product ovens. In the older of these. cordwood is loaded into large steel buggies which run on standard rails. They are rolled into ovens heated by the combustion of coal, natural gas or the gas and tar formed during the carbonization. In the newer Stafford process dry wood in the form of relatively small pieces preheated to 300° F. is charged continuously into large cylindrical retorts. Once started, the process maintains itself by the heat liberated in the decomposition reactions.

The vapours from either of these processes are cooled to condense tar and pyroligneous liquor which form separate layers. The aqueous layer is redistilled to remove soluble tar. In the older recovery processes acetic acid was obtained by neutralizing the pyroligneous acid with lime. evaporating to dryness and liberating the acetic acid from its calcium salt by means of sulfuric acid By 1945 this process was used in only a few small plants, the others having adopted more economical operations depending upon rectification and selective solvent extraction.

The products obtained from the distillation of hardwood are as follows in per cent by weight: charcoal 25.2, methanol 1.9. acetic acid 2.9. tar and oil 5.0. gas 18.3, water. etc.. 46.7. The gas from the process consists mainly of carbon dioxide 53%, carbon monoxide 27% and methane 15%.

After the production of acetone by fermentation (1915) and later from propylene, its manufacture by destructive distillation of calcium acetate was abandoned. The commercial synthesis of methanol from carbon monoxide and hydrogen and the advent of cheap acetic acid made from acetylene or ethyl alcohol caused the prices of the principal by-products of the charcoal industry to decrease considerably. As a result, in 1940 only 9% of the methanol was made by wood distilfation and the large additional demand for methanol from which to produce the formaldehyde required for plastics and explosives needed in World War II was met by still greater expansion of the synthetic methanol industry.

Wood distillation may be expected to continue on a stable basis but from mid-20th century it supplied a diminishing fraction of the total market for all of its principal by-products with the exception of wood tar. The demand for charcoal is thus the factor which determines the magnitude of the wood distillation industry. In fact, interest has revived in charcoal processes in which the by-products are burned because of their low value. The chief use for charcoal is as a blast-furnace fuel although coke is much more commonly employed. Charcoal is also used as a cooking fuel; its clean flame and great ability to radiate heat recommend it particularly for broiling and it has long been the favourite fuel of outdoor cooks at picnics and barbecues. Charcoal is further employed for miscellaneous metallurgical purposes such as case hardening (*see* SURFACE HARDENING), in the manufacture of black powder and as a starting material for chemical synthesis. Carbon disulfide, important in the production of carbon tetrachloride (fire-extinguisher fluid and dry-cleaning agent) and of rayon and rubber accelerators, is made by the action of sulfur on charcoal. Sodium cyanide, important in the metallurgy of gold and silver, as a poison and in plastics manufacture! is made by passing ammonia over a sodium-charcoal mixture.

Activated Charcoal. — The ability of charcoal to deodorize air and decolorize solutions has long been known. These effects occur through the phenomenon of adsorption (*q.v.*) by which charcoal, in common with other solids of large internal area, attracts and holds on the surface of its pores various materials which while there sometimes undergo chemical change. Since charcoal adsorbs oxygen from the air, organic materials simultaneously adsorbed may be oxidized while held on the charcoal surface. Polymerization and hydrolysis frequently occur. Before 1900, R. von Ostrejko made the important discovery that the adsorptive power of charcoal may be strongly enhanced by partial oxidation at a bright red temperature in a current of steam or carbon dioxide. A similar effect is obtained by the action of oxygen (air) at much lower temperatures (300°–450° C.) but this reaction is exothermic and thus harder to control. The subjection of charcoal to the action of a limited air supply in the temperature range 800°–1,000° C. results in excellent activation; the chemical attack on the charcoal in this case is primarily by carbon dioxide formed in the reaction between carbon monoxide and inwardly diffusing oxygen. The product of such processes is called activated charcoal or active carbon.

Another method of obtaining activated charcoal is to carbonize organic material by heating it in the presence of certain solutions such as aqueous zinc chloride or phosphoric acid which exert a dissolving action upon the organic matter and a catalytic effect upon its pyrolysis. A higher yield of charcoal is obtained than in ordinary destructive distillation and the original cell structure, which is reproduced in ordinary charcoal with the utmost fidelity, may disappear completely; the resulting product having a black, glassy fracture. After the impregnated charcoal has cooled, it is extracted with water and acid to remove foreign materials and then dried.

During World War I, N. K. Chaney discovered that lignite. bituminous or anthracite coal may serve as an economical source of excellent activated charcoal if it is carefully carbonized and subjected to steam activation. Chlorinated coal behaves particularly well but requires a binder such as wood tar followed by recarbonization to form pellets which are mechanically strong.

Active carbon is manufactured for three principal purposes: (1) gas masks; (2) decolorization; and (3) water purification. The advent of chemical warfare in World War I sharply emphasized the value of active carbon in a respirator or gas mask. Removal of toxic vapours must be remarkably complete since a concentration of a few parts per million of such gases as phosgene may be fatal. Of all materials tried. only activated charcoal was satisfactory and by the end of the war the soldiers of all belligerent countries were wearing respirators containing it. The Allies employed partial oxidation processes and nut shells and hardwood were the principal sources of the charcoals employed. Germany used a zinc chloride process operated on pine wood.

After World War I active carbons were employed for the removal of gasoline vapours from natural gas and for solvent recovery in connection with such processes as the manufacture of artificial leather, pyroxylin window shades and metal lacquering where large quantities of relatively expensive solvents are evaporated. By 1930 the charcoal gasoline recovery process was almost entirely obsolete but installations employing active carbon were later used increasingly for solvent recovery where their slightly greater initial and operating costs were compensated for by their high efficiency, particularly where the material recovered was expensive or occurred at low concentration.

Bone charcoal towers were first used for decolorizing sugar solutions in 1811. Vegetable decolorizing carbons threatened to displace them after their commercial introduction around 1910 because only one-thirtieth the quantity of material was required and there was a consequent saving in time, fuel, wash water, building space and investment in equipment. Plants employing active carbon can operate efficiently on a much smaller scale than those using bone char, and hence are often built adjacent to the raw sugar mills to produce "plantation white" sugar. Sugar refineries with bone char towers already installed, however, have little incentive to change over to vegetable decolorizing carbons.

Where highly acidic solutions are decolorized, bone black is unsuitable because of its high ash content. Here decolorizing carbons replaced older forms of charcoal. A still later application of active carbon was in the elimination of the objectionable odour of city water which contains chlorophenols formed by the action of chlorine (introduced to kill bacteria) upon traces of phenols present in the water. Relatively small quantities of active carbon, introduced as a powder and removed by filtration or present as a bed of granular material through which the water trickles. will render the water palatable. The same may be said for colours and odours produced by algae growing in reservoirs.

CHARCOAL DRAWING: see CRAYON DRAWING.

CHARCOT, JEAN BAPTISTE ETIENNE AUGUSTE (1867–1936), French polar explorer educated as a physician, was born at Neuilly-sur-Seine on July 15, 1867, the son of the French doctor Jean M. Charcot (*q.v.*). He studied at the École Alsacienne, worked at the Hôpitaux de Paris from 1890 to 1894, when he was also connected with the Institut Pasteur, and was chief of the clinic of the faculty of medicine at Paris from 1896 to 1898.

Charcot led two major antarctic expeditions: in the "Français" (1903–05) and the "Pourquoi Pas?" (1908–10). During the first he wintered at Booth Island, charted parts of the Palmer archipelago, Graham Coast and Loubet Coast and made a reconnaissance southward to Adelaide Island. The second expedition greatly extended this work. Charcot wintered at Petermann Island in 1909 and charted the coast southward to Alexander I Island, discovering Fallières Coast and Charcot Island. He later published two comprehensive series of reports on the scientific results of these expeditions.

During World War I Charcot served under the British admiralty

with the rank of auxiliary lieutenant in the French navy. He had visited Jan Mayen in 1902 and every summer between 1920 and 1936 he took the "Pourquoi Pas?" on a research cruise, often to east Greenland, but also to Iceland, the Faeroes and the eastern North Atlantic. On Sept. 1j, 1936, the "Pourquoi Pas?" was wrecked off fceland and 39 men, including Charcot, were drowned.

In addition to medical works Charcot published *Le "Français" au pôle sud* (1906), *Le "Pourquoi Pas?" dans l'Antarctique* (1911; Eng. trans., 1912), *Autour du pôle sud,* 2 vol. (1912), *Christophe Colomb vu par un marin* (1928) and *La Mer du Groenland* (1929). (B. B. Rs.)

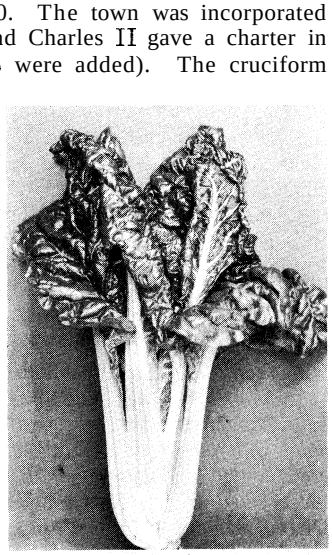
CHARCOT, JEAN MARTIN (1825–1893), French physician, one of the greatest figures in French medicine, a neurologist and teacher of enormous influence, was born in Paris on Nov. 29, 182j. In 1853 he took his M.D. at Paris, and three years later was appointed physician of the Central Hospital bureau. In 1860 he became professor of pathological anatomy in the medical faculty of Paris. and in 1862 began his connection with the Salpêtrière, where he created the great neurological clinic. He studied hysteria in relation to hypnotism and early stimulated Sigmund Freud's interest in investigating hysteria from a psychological point of view. In muscular atrophy Charcot differentiated between the ordinary wasting and the rarer amyotrophic lateral sclerosis (1874) and described with Pierre Marie the progressive neural or peroneal type (1886). He differentiated the essential lesions of locomotor ataxia and described both the gastric crisis and the joint affections (Charcot's disease). He distinguished multiple sclerosis from paralysis agitans. In diseases of the brain, the most notable contributions were his articles on cerebral localization, the studies of aphasia and the discovery of the miliary aneurysms and their importance in cerebral hemorrhage. Charcot greatly promoted the study of medicine in art *(see* his *Nouvelle Iconographie de la Salpêtrière,* 1888). He died on Aug. 16. 1893. His best-known works are *Leçons sur les maladies du système nerveux,* 5 vol. (1872–93) and *Leçons du mardi à la Salpêtrière,* 2 vol. (1889–90).

See F. H. Garrison, *Introduction to the History* of *Medicine,* 4th ed. rev. (1929).

CHARD, a market town and municipal borough in Somersetshire. Eng., 16 mi. S.S.E. of Taunton by road. Pop. (1961) 5,778. It lies on a hillside close to the Devon and Dorset borders and the runnels by the sides of the main street are said to flow. one south to the English channel. the other north to the Bristol channel. Industries include agricultural machinery, surgical supplies. lace. shirts and collars and dairy produce. The town takes its name from Cerdic (*q.v.*) who founded the kingdom of Wessex, and appears as Cedre in the Domesday Book. The bishop of Bath held Chard in 1086 and in 1234 his successor granted the first charter which was confirmed in 1253 (when a Monday market and a fair on July 25 were grantedj, 1280 and 1285. The corporation seal dates from 1570. The town was incorporated by grant of Charles I in 1642 and Charles II gave a charter in 1683 (when two more fair days were added). The cruciform parish church of St. Mary the Virgin is Perpendicular of the 15th century. The grammar school was founded in 1671 when William Symes gave his house for the purpose.

Another Tudor house is the court house of the manor which contains the room where Judge Jeffreys condemned to death 12 natives of Chard for taking part in the Monmouth rebellion.

CHARD (SWISS CHARD), a name given to the edible leaf beet *(Beta vulgaris* var. *cicla),* a variety of the beet (*q.v.*) in which the leaves and leafstalks. instead of the roots, have become greatly develoued. The plant is a biennial with somewhat branched and thickened but not fleshy roots and large leaves borne on stalks sometimes 2 ft. long and 1 in. to 3 in. wide. It is grown for the tender leaves and leafstalks; the former are boiled and served like spinach, the latter, like asparagus. Swiss chard is popular as a home-garden potherb because of its ease of culture, productiveness and tolerance to moderately hot weather. It furnishes an abundance of greens after the weather becomes too warm for growing spinach and other early greens.



J. HORACE MCFARLAND CO.

CHARD (BETA VULGARIS CICLA)

CHARDIN, JEAN (later SIR JOHN) (1643–1713), French traveler to the middle east and India. was born in Paris on Nov. 16, 1643, the son of a wealthy jeweler, and was given an excellent education. To gratify his ambition for travel he set out with a Lyons merchant for Persia and India in 1665. In Persia he profited by the patronage of Shah Abbas II and after a most successful journey returned to France in 1670, and there published his *Récit du Couronnement du roi de Perse Soliman III.*

In Aug. 1671 he set out again for Persia, this time passing through Smyrna, Constantinople, the Crimea and the Caucasus. He reached Ispahan in June 1673, spent four years in Persia, revisited India and returned to France by the Cape of Good Hope in 1677. Persecution of Protestants drove him in 1681 to settle in London where he became jeweler to the court and was knighted by Charles II. In 1683 he represented the East India company in Holland. He died in London on Dec. 2j, 1713.

BIBLIOGRAPHY.—The complete account of Chardin's travels appeared at Amsterdam in 1711, under the title of *Journal du voyage du chevalier Chardin.* The Persian portion is in vol. ii of Harris' *Collection* (1705), and extracts are reprinted by Pinkerton in vol. ix. The best complete reprint is by M. L. Langlès (1811). (K. M.)

CHARDIN, JEAN BAPTISTE SIMÉON (1699–1779), French painter. noted for his warm representations of domestic life. was born in Paris. Nov. 2, 1699, the son of a master carpenter. The boy never had a regular education. He learned painting from a modest artist. Pierre Jacques Cazes, and started by painting details in other artists' works and signposts for tradesmen. Chardin became known through the exhibition of the "Jeunesse" in 1728: he showed at least ten other paintings among them a still life. "The Skate" ("La Raie"), now at the Louvre (*see* STILL-LIFE PAINTING). The same year he was elected to the Académie Royale de Peinture et de Sculpture. Chardin began to add figures to his still-life paintings, showing scenes from the lives of the modest people among whom he spent his whole life. Among the pictures he sent to the salons were lively portraits of children. Chardin was elected treasurer of the academy. a job he kept for 19 years. aided by his second wife. Among his commissions was that of painting allegorical scenes and decorations above the doors at the castles of Bellevue and Choisy. During his last years. when he was over 70, Chardin still produced pastel portraits even superior to his earlier portraits in oils. His old age was saddened by reverses. Contemporary critics sometimes judged him severely for the revolutionary quality of his technique. when he showed himself to be a forerunner of divisionism. His whole life was spent in his own house in Paris and in his roorns at the Louvre. surrounded by his artist and writer friends. He died on Dec. 6. 1779.

CHARDZHOU, an *oblast* and town of the Turkmen Soviet Socialist Republic in the U.S.S.R. The *oblast* (area 36.100 sq.mi.), formed in 1939. is a long narrow region lying mainly astride the Amu-Darya (Oxus) river. which is navigable through-

out the region. The climate is continental with hot dry summers and relatively cold winters. Vegetation is of the desert variety and agriculture (cotton and silk) is confined to the banks of the river. The completion of the Kara-Kum canal would enable large parts of the desert region to be irrigated. In the 1960s an industrial region was created in the southeast of the oblast where there are deposits of superphosphates, common salt, sulfur, copper and coal.

The oblast is traversed by the Trans-Caspian railway, which crosses the river at Chardzhou. There is a branch line along the Amu-Darya from Chardzhou to Kungrad. near the southern shore of the Aral sea. The chief towns are Chardzhou, the administrative centre, and Kerki. The population was 320.797 in 1959, of which 191,559 was rural. It is composed of Turkmens, Uzbeks, Kazakhs and others. In the early 1960s there were more than 260 schools in the oblast as well as about 20 specialized training establishments.

The town of Chardzhou, located 290 mi. E.N.E. of Ashkhabad on the Amu-Darya, is a cotton and silk centre. Pop. (1959) 66,-000. An important river-rail transportation hub it also has shipyards, metalworks and fruit-canning plants. It was founded as a fort in the 1880s and at various times was called Chardzhui or Novy Chardzhui and Leninsk-Turkmenski. (G. E. WR.)

CHARENTE, an inland de'partement of western France, separated from the Bay of Biscay by Charente-Maritime, and elsewhere surrounded by the *départements* of Deux-Sèvres, Vienne, Haute-Vienne and Dordogne. Pop. (1954) 313,635. Area 2,306 sq.mi.

Most of the *département* was the old province of Angoumois, consisting of limestone plains below the western margin of the granite highlands of Limousin. In the northeast, in the district of Confolens bordering the highlands, are tracts of poor granitic sands, terres froides, but most of the *département* is fertile arable land on calcareous loams (terres *chaudes*). Cereals (wheat and corn) and fodder crops are extensively grown, but Charente is especially famous for its vineyards. These provide the wine for distilling brandy, so specially associated with the name of Cognac (*q.v.*), which lies in the west of the *département* in the valley of the Charente. The river is navigable for small barges as far as Angoulême, which has paper works and food canning industries. There is little industry elsewhere, and mineral resources are unimportant, although there are limestone quarries for building stone, gypsum workings, and clay is dug for scattered brick and tile works.

Charente is divided into the three *arrondissements* of Angoulême (the capital), Coniolens and Cognac. It forms the diocese of Angoulême and is associated with the *académie* (educational division) of Poitiers; its court of appeal is at Bordeaux. Charente is rich in Romanesque churches.

For the history oi the area, see ANGOULÊME; ANGOUMOIS; SAINTONGE. (AR. E. S.)

CHARENTE, a river of western France. flows westward from the margin of the Massif Central in the Haute-Vienne *département* to the Bay of Biscay. The Charente and its tributary the Tardoire descend from the pastoral uplands of Limousin to the lowlands of Angoumois, and the combined river flows west as a slow, meandering stream that receives few surface tributaries from the flanking calcareous platforms. The Boutonne river, its chief tributary, derives from the plain of Poitou to the north. Below its confluence, the Charente flows sluggishly past Rochefort through extensive alluvial flats into its silted estuary behind the island of Oléron. Below Angoulême, the Charente flows through what was formerly important vine-groning country; the valley market town of Cognac gives its name to the brandy for which the district is still famous. Many vineyards, however, were not re-established after the phylloxera plague of the 1870s and the rural economy has been reoriented by specialization upon dairying, organized through numerous co-operative dairies. The river is navigable for small craft as far as Angoulême. The limestone of the valleys is in places quarried for building stone and lime.

(AR. E. S.)

CHARENTE-MARITIME, a *département* of western France, comprising the ancient provinces of Saintonge and Aunis and a small portion of Poitou. Until 1941 the name was Charente-Inférieure. Area 2,792 sq.mi. Pop. (1954) 447.973. Its capital is at La Rochelle. Charente-Maritime extends along the coast of the Bay of Biscay from the Gironde estuary to the Sèvre river on the borders of Vendée and is bounded inland by Deux-Sèvres and Charente. The major physical features are aligned from southeast to northwest. the chalk platform of Saintonge being separated from the Jurassic limestone platform of Aunis by the valley of the Charente river. These salients of the low-lying coast are prolonged offshore by the islands of Oléron and RC; the re-entrants between are extensively silted and fringed with alluvial marshlands that have been progressively reclaimed. Silting has severely affected port activity, and, in spite of the modern development of an outport at La Pallice, La Rochelle has largely lost its once-important oversea trade, though it remains a major fishing port. Rochefort, up the estuary of the Charente, is a naval station, and Royan, on the north shore of the Gironde, is a much-frequented resort.

Oyster culture is carried on extensively in some coastal areas, especially in the Marennes, but agriculture is the predominant economic activity of the de'partement. The dry chalk and limestone platforms, with few surface streams, are open cam-*pagnes*, traditionally devoted to cereals, with vineyards especially along the valley sides. The intervening tracts of reclaimed marshes stand out in contrast as flat, amphibious areas, intersected by a network of drainage channels that are also much used for local transport. Some of the marshlands provide rich market gardens, and elsewhere there are lush meadows. Fodder crops are everywhere important. Vineyards are less important than they were before the phylloxera crisis at the end of the 19th century, and the smallholding economy has been rehabilitated by the development of co-operative dairying; the market towns have become important dairying centres. The chief product is butter, and skim milk helps to support an important pig-raising activity.

La Rochelle, Rochefort, Saintes (*qq.v.*), St. Jean-d'Angély and Jonzac give their names to the five arrondissements, and the de'partement forms the diocese of La Rochelle. Its court of appeal is at Poitiers, and for educational organization it is attached to the acade'mie (educational division) there.

For the history of the region, see AUNIS; POITOU; SAINTONGE. (AR. E. S.)

CHARES, a Greek sculptor and pupil of Lysippus (*q.v.*). Living in the city of Lindus on the island of Rhodes, he fashioned for the Rhodians a colossal bronze statue of the sun god, the cost of which was defrayed by selling engines of war left by Demetrius Poliorcetes after a siege in 303 B.C. The Colossus, often included among the seven wonders of the world, was 70 cubits (105 ft.) in height. The notion that it bestrode the harbour is absurd. It was destroyed by an earthquake after 56 years.

CHARES (4th century B.C.), Athenian general and mercenary commander. In 357 Chares was sent by the Athenians to regain the Thracian Chersonese from the Thracian king Cersobleptes. In the same year he was appointed to the command in the war of the Athenians with their allies known as the Social War (see GREECE: History) together with the general Chabrias; after Chabrias' death in the attack on Chios, Chares was associated with the generals Iphicrates and Timotheus. Chares, having blamed the subsequent defeat on his colleagues, was left sole commander. Receiving no supplies from the Athenians, however, he joined Artabazus, satrap of Phrygia, during the satraps' revolt against the Persian king Artaxerxes III. When Artaxerxes complained, threatening to aid the rebellious allies, the Athenians made peace with them (355) and recalled Chares.

In 349 Chares was sent to assist Olynthus (*q.v.*) against Philip II of Macedonia. but he returned having achieved nothing. Sent again in 348 he found Olynthus in Philip's possession. In 340 he commanded a force sent to aid Byzantium against Philip; unpopular because of previous plundering, however, he achieved little. Chares was defeated by Philip in 338 at Amphissa in Locris, and was one of the generals at the battle of Chaeronea (*q.v.*). After his conquest of Thebes (335), Alexander the Great is said to have

demanded the surrender of Chares among others. In 334, however. Chares was living at Sigeum in the Troad. In 332 he entered the service of Darius III of Persia, and commanded a Persian force in Mytilene, but he capitulated at the approach of a Macedonian fleet on condition of being allowed to retire unmolested. Chares is last heard of at Taenarum (Cape Matapan), and is thought to have died at Sigeum.

See Diodorus Siculus, Bibliotheca Historica, books xv, 75, 95, xvi, 7, 21, 22, *85–88.*,

CHARGE D'AFFAIRES (French, "in charge of affairs"), a diplomatic officer authorized to act for his country in the absence of an ambassador or minister plenipotentiary. See AMBASSADOR; DIPLOMACY.

CHARI: see SHARI.

CHARIBERT (d. 567), king of the Franks. was the eldest son of Clotaire I and Queen Ingund. At his father's death in 561 he received the best part of the kingdom, namely Paris and the whole western region southward to the Pyrenees. The poet Venantius Fortunatus extols his interest in classical literature but Saint Gregory of Tours represents him as despotic and dissolute. He repudiated his wife Ingoberga (the mother of his daughter Bertha, who married King Aethelberht of Kent) and maintained a series of low-born concubines. Still young, he died in Paris in Nov. or Dec. 567, whereupon his brothers divided his patrimony.

(JE. H.)

CHARIDEMUS (d. 333 B.C.) of Oreus in Euboea. Greek mercenary leader who fought sometimes on the side of the Athenians, at other times on that of their enemies. He fought under the Athenian general Iphicrates at Amphipolis (*q.v.*) about 367 B.C. but later joined Cotys, king of Thrace, against Athens. Soon afterward he was captured by the Athenians and re-entered their service. Discharged by the general Timotheus in 362, he offered during the satraps' revolt to join Memnon and Mentor, brothers-in-law of the satrap Artabazus in Asia Minor, but instead captured on his own account the cities of Scepsis, Cebren and Ilium in the Troad. After the release of Artabazus from captivity, he again joined Cotys, on whose murder (359) he became guardian to his young son Cersobleptes. In 357, when the Athenian general Chares (*q.v.*) arrived with considerable forces, the Thracian Chersonese (*q.v.*) was restored to Athens. This success was attributed to Charidemus, who received honours, including Athenian citizenship and a golden crown. In 351 he commanded the Athenian forces in the Chersonese against Philip II of Macedonia, and in 349 he superseded Chares as commander in the Olynthian War (see GREECE: *The* Macedonian Period). Achieving little success, he was in turn replaced by Chares. Alexander the Great of Macedonia demanded his surrender after the destruction of Thebes (335), but he escaped with banishment. He fled to Darius III of Persia, who, it is said, after receiving him well, executed him for criticizing the preparations before the battle of Issus (333).

See Demosthenes, Against Aristocrates; H. W. Parke, Greek Mercenary Soldiers (1933).

CHARIKAR, a town in Afghanistan, lies 35 mi. N. of Kabul at an altitude of 5,300 ft. Pop. (1959 est.) 15,000. Charikar, which is situated on the main road between Kabul and Mazar-i-Sharif, where it enters the Ghorband valley of the Hindu Kush, is well known for its pottery and fine grapes. (J. P. C. N. H.)

CHARING CROSS, the locality about the west end of the Strand and the north end of Whitehall, London, Eng., in the city of Westminster. There Edward I erected the last of the series of 13 crosses in memory of his queen Eleanor (d. 1290) which marked the stages of the funeral procession to Westminster abbey. The derivation from Edward's "dear queen" (*chère reine*) is apocryphal. The cross was destroyed in 1647, and in 1675 an equestrian statue of Charles I by Hubert Le Sueur was erected at the top of Whitehall, where several regicides were executed, at the place where the cross stood. The modern cross (1863) stands within the forecourt of Charing Cross railway station. Formerly an important terminus for the continent, the station is now the focus for London suburban services and mostly concerned with trains serving southern England. The name (Cyrring in 1000) may refer to the neighbouring sharp bend in the river Thames.

CHARIOT. The two-wheeled chariot is first attested in Mesopotamia in the early 3rd millennium B.C. Monuments from Ur. Khafaje and elsewhere depict heavy vehicles with two or four solid wheels in use in battle parades, their bodywork framed with wood and covered with skins.

By the middle of the 3rd millennium the draft pole of the chariots begins to differ from the straight pole of earlier four-wheeled vehicles and, with the aim of easier traction and greater speed, arches over the backs of the four onagers which draw it. By these modifications was born a war arm of great importance in the history of the ancient world.

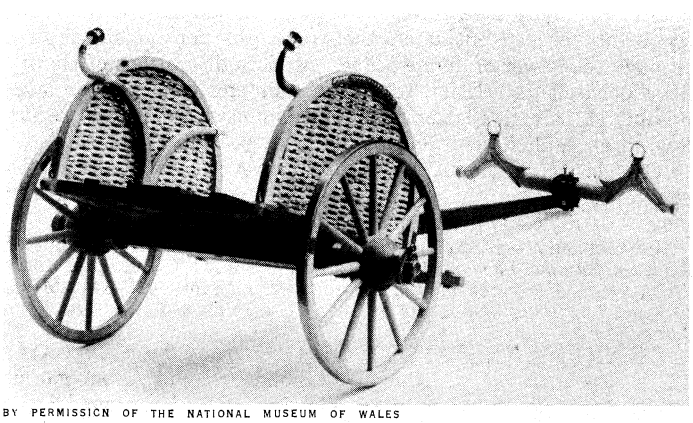
The earliest Mesopotamian chariots were mounted by both spearman and charioteer. although it is doubtful if fighting took place from the vehicle itself. Sometimes a single person was mounted, for it was probably primarily for speed of personal transport in battle that the chariot originated.

In western Asia the military importance of the chariot was greatly developed in the 2nd millennium by peoples with Aryan connections. It was probably in northern India that military demands led to the introduction of the light spoked wheel and the streamlined semicircular chassis with hind axle. Chariots of this type were introduced to Mesopotamia and Syria by Kassites and Mitanni and into 12th-dynasty Egypt by the Hyksos northerners. By 1435 B.C. Egyptians were making chariots out of light woods imported from northern Syria. and by the end of the century chariots with four-spoked wheels and light design were in use throughout the Levant and had been introduced to Minoan Crete and the southern European mainland.

Bronze chariot plaques and horse trappings from early dynastic Shang graves indicate that chariotry was introduced to the Chinese steppes by the 14th century B.C., but no reconstruction is possible of the earliest types. Chariots of *c.* 300 B.C. found in a burial at Liu-li-ko (Honan) have dished wheels, but otherwise are similar in construction to Celtic chariots in western Europe.

Numerous vase paintings of archaic Greek chariots as used in Homeric times indicate their similarity to earlier Mycenaean representations, with a body framework of bent rods and a bar joining the end of the upturned draft pole with the front of the chariot breast. Breastwork was made of wicker or leather straps, although chariots described by Homer as made of metal plates must have been more like the heavier metal-fitted chariots used by Hittite and Assyrian archers for warfare and hunting. Greek chariots in the 8th century B.C. used the four-spoked wheel attached to a fixed hind axle, although six-spoked wheels and medial axles were long in use in parts of western Asia. They were drawn usually by four horses, of which only the central pair was yoked, and were used not only for battle but also for racing. Chariot racing became popular in Greece and was a main part of the games at Olympia and Delphi.

There is no doubt that the chariot was in use in central and northern Europe before the 10th century B.C. Celtic peoples introduced its use to the British Isles about the 5th century B.C. The bodywork of Celtic chariots was somewhat heavier than that of Greece, and metal, sometimes inlaid with fine enamels, was



BY PERMISSION OF THE NATIONAL MUSEUM OF WALES

RECONSTRUCTION OF A CELTIC CHARIOT FROM LLYN CERRIG BACH. ANGLESEY. WALES (*c.* 1ST CENTURY B.C.)

extensively used for axle, draft pole and occasionally for solid metal wheels. On the fringe of the Celtic world, where the chariot remained in use until the 4th century A.D., small ponies, yoked four abreast, were used for draft.

In the Roman circus games chariot racing took foremost place, and chariotry and its consequent racing clubs began to play an important social role. Racing vehicles in use were the *biga* (two horses), *triga* (three) and *quadriga* (four), although as many as ten horses were harnessed on spectacular occasions and chariots drawn by dogs and even ostriches are instanced. The *biga* was the simplest chariot form yet devised: an elongated draft pole sitting on the axle and provided with seat and footrests for the leather-clad charioteer. The circus had to be rounded several times in the course of one race, a process involving many accidents and collisions. *See* CARRIAGE; CART AND WAGON; WHEEL; *see* also references under "Chariot" in the Index volume.

CHARITON OF APHRODISIAS in Caria (fl. not later than 2nd century A.D.), Greek novelist, wrote a romance *Chaereas and Callirhoe* which is generally accepted as the earliest extant Greek novel. The author's identity, which has been questioned, is established by inscriptional evidence at Aphrodisias. The main action of the novel, the story of which is complex but simply told, takes place in Syracuse, at the Persian court and with the Egyptian fleet. Callirhoe is the daughter of the historical Syracusan general Hermocrates (d. 407 B.C.).

CHARITY, one of the triad of Christian virtues, together with faith (*q.v.*) and hope. Of all the synonyms for love, charity is probably the most sublime and at the same time the most banal. Popular speech, exemplified by such expressions as "I am not looking for charity" and "Charity begins at home," emphasizes the condescension with which charity is often shown. But in the literature of Christian theology and ethics the term charity, as a translation of the Greek word *agapē* in the New Testament, denotes especially the answering love of man for God, called forth by the giving love of God for man as this was set forth in the life, teachings and death of Jesus Christ. St. Augustine summarizes much of Christian thought about charity when he says: "Charity is a virtue which, when our affections are perfectly ordered, unites us to God, for by it we love Him." Quoting this definition and others from the Christian tradition, the medieval theologians, especially Thomas Aquinas, placed charity into the context of the other virtues and specified its role as "the foundation or root" of them all.

Although the controversies of the Reformation dealt more with the definition of faith than with the definition of either hope or charity, the Reformers identified the uniqueness of God's *agapē* for man as unmerited love, and therefore they required that charity, as man's love for man, be based not upon the desirability of its object but upon the transformation of its subject through the power of divine *agapē*. Modern discussions of charity have debated its relation to other terms and concepts for love, notably to *erōs,* this latter being understood as not merely sexual love in an explicit sense but as desire or yearning.

The classic statement on charity, however, remains the 13th chapter of I Corinthians; subsequent expositions may well be viewed as little more than marginal glosses upon this.

CHARITY, INSTITUTE OF (INSTITUTUM A CHARITATE; I.C.; ROSMINIANS), a Roman Catholic religious congregation founded in 1828 by Antonio Rosmini-Serbati and approved Sept. 20, 1839. The primary object of the congregation is the sanctification of the souls of its members by the love of God. They engage in educational and charitable work. The motherhouse is at Rome; other houses are found in England, Ireland and the United States. Nuns of this congregation, called Sisters of Providence, with houses in Italy and England, engage chiefly in teaching; their habit is black, with a white veil. *See* WOMEN'S RELIGIOUS ORDERS.

CHARITY COMMISSIONERS FOR ENGLAND AND WALES were established by the Charitable Trusts act, 1853, to sit as a board. That act arose out of the initiative of Henry (afterward Lord) Brougham which led to the appointment between 1818 and 1835 of four statutory commissions whose reports to parliament — the printed Reports of the Former Commissioners for Inquiring Concerning Charities in England and Wales — collected existing information about charities. The fourth commission suggested legislative reforms. A select committee of the house of commons was appointed in 1835 to examine the reports, but attempts to secure legislation were unsuccessful until 1853'.

The object of the Charitable Trusts acts, 1853 to 1939, was to secure the better administration of endowed charities. The acts accordingly provided for control of dealings with capital endowments, required the rendering by trustees of annual accounts, gave the charity commissioners wide powers of inquiry and provided means of vesting property, appointing and removing trustees and remodeling trusts without resort to expensive legal proceedings. The charity commissioners were not themselves empowered, however, to administer or manage charitable trusts. Under the acts the secretary of the board of commissioners was the Official Trustee of Charity Lands, who held charity lands vested in him by an order of the court or of the charity commissioners. Certain officers of the board approved by the treasury constituted a body corporate, the Official Trustees of Charitable Funds, with power to hold securities and monies belonging to charities. Neither corporation might administer or manage any charity. The functions of the charity commissioners under the acts in respect of educational charities and certain classes of quasi-educational charities were transferred to the jurisdiction of the minister of education.

Following the report of a committee under the chairmanship of Lord Nathan on the Law and Practice Relating to Charitable Trusts, issued in 1952, and a White Paper on Government Policy on Charitable Trusts, issued in 1955, the Charities act, 1960, was passed to bring up to date the law on charitable trusts and the powers and functions of the charity commissioners. This act reconstituted the charity commissioners under simplified provisions for promoting the effective use of charitable resources. It also required the commissioners to set up a comprehensive register of charities, and to designate one of their officers official custodian for charities with power to accept the transfer to him of personal property and the status generally of a custodian trustee, in succession to both of the above corporations. (S. P. G.)

CHARITY OF ST. VINCENT DE PAUL, SISTERS OF (DAUGHTERS OF **CHARITY**; D.C.), a Roman Catholic religious congregation founded in 1633 by St. Vincent and St. Louise de Marillac (*q.v.*). Numbering about 43,000 in the early 1960s, the Sisters of Charity comprise the largest congregation of women. Their provinces all over the world are subject to the motherhouse in Paris, over-all supervision being in charge of the superior general of the Lazarists (Congregation of the Mission of St. Vincent de Paul). The habit is blue-gray with wide sleeves and apron, and a white linen winged cap. *See* WOMEN'S RELIGIOUS ORDERS.

CHARLATAN, a person who pretends to possess knowledge or ability, as in medicine. The word originally meant one who chatters to a crowd to sell his wares (Ital. *ciarlatano,* from *ciarlare,* "to chatter"). For a discussion of medical charlatans *see* QUACKERY.

CHARLEMAGNE (CHARLES THE GREAT) (742 or 743–814), king of the Franks from 768 to 814 and Western (Holy Roman) emperor from 800 to 814, was born on April 2, 742 or 743, the elder son of Pepin the Short and Berta (Bertrada). His baptismal name, Charles, was already a common one in his family (*see* CAROLINGIANS). He was anointed as king with his brother Carloman by Pope Stephen III (II) at St. Denis in 754. The brothers took possession in 768 of the two kingdoms destined for

them by their father shortly before his death. Charles's portion was a vast arc of territory stretching from southwestern France northward and then eastward into the Netherlands and Germany and half encircling Carloman's kingdom, which comprised central, eastern and southeastern France, southwestern Germany and the Alpine regions.

The political interests and aims of the brothers in no way disposed them to work together. Carloman gave Charles no help in 769 against a revolt in Aquitaine led by a certain Hunald (not the same person as the Hunald son of the duke Eudes). Charles, however, defeated the rebels and pursued them right into Gascony, forcing the duke of the Gascons, Lupus. to hand Hunald over to him and to swear allegiance. Charles and Carloman seem to have moved toward a reconciliation in 770, perhaps at their mother's instance. Charles's marriage with Desiderata, daughter of the Lombard king Desiderius, was probably a result of this *rapprochement.* Charles for a very short time adhered to the Lombard alliance (which Carloman steadily favoured) but then repudiated his wife and broke with Desiderius.

Lombards and Papal States.—On Carloman's death (Dec. 771), Charles annexed his brother's kingdom, but Carloman's widow and children took refuge at the Lombard court, which thenceforward became a centre of intrigue against Charles. This hostile power on his southeastern frontier was to draw Charles into many campaigns in Italy. These incursions effected the first major change in the balance of power in the peninsula to take place since the Roman empire had been divided into two.

The popes had long been searching for an ally of sufficient military strength adequately to check the alarming power of the Lombards; the Byzantine emperors, at war with the Muslims and facing serious dissensions within their own dominions, could give no effective assistance. The help of the Franks had already been solicited, and Pepin the Short, by a show of force, had constrained the Lombards to recognize the pope's authority over certain territories which they were either attacking or had already overrun (see PAPACY). Since then, however. pressure on the papal states had begun again, as some members of the Carolingian family and some Frankish magnates showed themselves willing to let the Lombards have a free hand. Immediately after his election as pope in 772. Adrian I revived the policy of alliance with the Franks. Desiderius was threatening not only the papal states but Rome itself; moreover he intended to force Adrian to anoint Carloman's sons. As this gave offense to the Frankish king no less than to the pope, Charles conducted two campaigns (773 and 774) against the Lombards, taking two armies into Italy. one through the Great St. Bernard, the other through the Mont Cenis pass. Desiderius was besieged in Pavia and after nine months was obliged to surrender. Charles deposed him and himself assumed the title "king of the Lombards." He showed prudence and restraint in administering his new kingdom; by appointing his young son Pepin as his deputy there, he left to it an appearance of autonomy, although Franks held the key posts. The Lombard duchies, particularly Benevento, remained virtually independent. Charles, however, confirmed (April 774) the so-called Donation of Pepin and also promised the pope the duchies and some remaining possessions of the Byzantines in northern Italy.

Bavarian and Avar Campaigns.—Charles was already planning other campaigns, both north and south of the Alps. To the north. Tassilo, duke of Bavaria, a member of the Agilolfing family, required constant and forcible reminders of the allegiance due from his house to the Carolingians, and he finally lost his crown and his duchy in 788. At this point Charles decided to attack the Avars (*q.v.*) who mere occupying the plain of the middle Danube and whose constant harrying of the surrounding Slavic tribes made the latter uncertain neighbours for the Franks. He destroyed the Avar cavalry in a series of campaigns between 791 and 802–803, advancing into their territory as far as northern Croatia and establishing a defensive, march in Carinthia, on the upper reaches of the rivers Drava and Sava. The archbishop of Salzburg was commissioned to evangelize all these outlying regions, to which Slavic or Germanic settlers returned.

Saxon Campaigns.—Charles also extended his kingdom toward the north and the northeast. A long struggle went on against the Saxons. These Germanic tribes, pagan and restless, had never respected any agreements made with the Franks by individual chieftains; their incessant raids and cattle thieving kept the whole Rhine valley in disorder. They also made impossible any effective consolidation of the missionary work that had been going on in that area since the mid-8th century. In reprisal for a Saxon raid on Hesse. Charles began a war of intimidation in 772. He destroyed one of their pagan shrines, of which the central feature, called the Irminsul, was an enormous tree trunk. Then. before withdrawing his army, he set up a military outpost in Saxon territory. At every opportunity. however, for instance while he mas conquering Italy in 773 and when he was again south of the Alps in 776, the Saxons destroyed the strongholds that he was gradually establishing among them. They massacred the few converts to Christianity and any who favoured the Franks. After each rebellion Charles returned and reinforced his line of outposts, for he still thought it feasible to evangelize the Saxons without completely annexing their territory. Then. while Charles was in Spain in 778, a Saxon chief, Widukind, roused all the tribes once more, massacred all the Christian priests and laity and laid waste the right bank of the Rhine. This final outrage made complete conquest necessary. It proved a long, arduous and bloody enterprise. Charles. however, was determined to succeed and collected a great army; in 785 Widukind was obliged to yield and Saxony was subjected to a reign of terror designed to enforce conversion to Christianity on pain of death. Another rebellion in 793 showed how superficial the appearances of subjection had been: laws even more savage were imposed, and whole groups were deported. At last in 797 Charles came to an agreement with the Saxon chiefs and brought the conquered territories under the common law of his kingdom. Thus, common misdemeanours, or breaches of ecclesiastical discipline, became punishable by payment of a *bannum,* or fine, instead of carrying the death penalty. Yet further years of strife and of mass deportations were necessary before the most easterly tribes, those settled on the lower Elbe and close to Denmark, were satisfactorily tamed.

The Frisians, over whom the Franks had already to some extent established their dominion, were altogether subdued by about 790.

Northern Frontiers.—These conquests brought the Frankish armies into contact with new races, particularly with the Slavs beyond the Elbe; some tribes from among them were faithful allies of Charles. In Denmark the Vikings were already very restive and the number and force of their sea-borne raids fully justified the naval defenses established by Charles on the northwestern coasts of his kingdom early in the 9th century.

In the northwest, Charles never succeeded in exacting permanent recognition of his authority from the Bretons; he remained content to keep a sharp eye on their movements. To protect Neustria against them, he established a fortified march ruled by a count to whom he delegated exceptional authority.

Spanish Frontier.—Aquitaine and its southern adjuncts had long posed a serious problem to Frankish kings. Charles recognized the local tradition of autonomy, making his son Louis king of Aquitaine in 781. The revolts ceased, although a large number of *vassi* (military servants of the crown) had to be established there to maintain order. Farther to the southwest, however, the Basques, who controlled one of the routes into Muslim Spain, were constantly making trouble on the frontier of Gascony (Vasconia) or beyond the Pyrenees. Charles, assessing the danger to which the Franks were exposed, accepted the invitation of Muslim rebels to intervene in Spain, intending to establish a Frankish outpost beyond the mountains. His expedition, however, in 778, was halted outside Saragossa, and he was obliged to retreat. At a place identified in later legend with the pass of Roncesvalles the Basques attacked the rear guard of his army and many of his leading warriors were killed.

Thereafter the Basques and even the Gascons were only kept in a semblance of restraint by regular punitive expeditions. After a Muslim raid in 793, which reached as far as Narbonne, Charles decided again to intervene south of the Pyrenees. A series of campaigns from 796 to 811 won him a foothold in Catalonia, where

he established his Spanish march. This provided asylum and land for all the Christian refugees from Muslim territory.

Church and Imperial Coronation. — Charles divided all his conquered lands into bishoprics, either restoring old sees or creating new ones for this purpose. He thus effected among the various populations a rapid if superficial conversion to Christianity. The northern Saxons and the Danes were to be evangelized from Bremen, the remaining Saxons, the Thuringians and the Slavs from Minden, Münster, Paderborn and Osnabriick, the eastern peoples from Salzburg. and the peoples of the Spanish march from Gerona.

As ruler of so vast a group of territories — one, moreover, on which he was seeking to impose unity by the profession of a common faith — Charles was indisputably the arbiter of the west. Furthermore, at the end of the 8th century, the church itself in western Europe looked for leadership to the Frankish king rather than to the pope. Continuing his father's policy of ecclesiastical reform, Charles had reintroduced the Gregorian chant and enforced throughout his dominions the use of the Roman liturgy and obedience to canon law. To the church council assembled by his order at Frankfurt in 794 came representatives from the entire Christian west, some even from Britain. At this council the Xdoptionist heresy. begun in Spain by Elipandus, archbishop of Toledo, and professed by one of Charles's subjects. Felix, bishop of Urgel, was formally condemned. It also fell to Charles rather than to the pope to combat the theological innovations of the Byzantines; in his *Libri Carolini* (790–791) he argued strenuously against the Iconoclasts.

The presence in Italy of a Frankish ruler who had little regard for the subtle evasions of Eastern diplomacy seriously threatened Byzantine interests; and these interests were further prejudiced by Charles's special connection with the papacy. The pope was indeed dependent upon Charles; neither the Donation of Pepin nor Charles's promises of 774 would be implemented unless the Frankish king showed the will and had the capacity to conquer Ravenna, Istria, Venice, Spoleto and Benevento for the pope. Charles seemed in no hurry to undertake this task, and his two visits to Rome in 780 and 785 gave Adrian I no satisfaction. In fact, however, Charles was then alternately campaigning against, and negotiating with. the Byzantines, and his activities showed clearly that the Frankish *patricius* had supplanted the pope as arbiter of Italian politics. After Adrian's death (795), four years' confusion in Rome put the papacy even more in Charles's power. In 799 the new pope, Leo III, was accused by his enemies of grave misconduct and was attacked during a procession. Charles then required the pope to clear himself of the charges against him by a solemn oath sworn in a court over which the Frankish king presided. This took place in Dec. 800. Two days later, on Christmas day, 800, Leo placed a crown on Charles's head, and the people acclaimed the king as emperor. Historians disagree seriously no less about the details of the ceremony than about the behaviour, motives and subsequent feelings of the two leading participants. All that seems certain is that the idea was not altogether new; and it is indisputable that Charles's success and prestige in every field of his activity justified the revival of the imperial dignity in his favour.

It is conceivable that Charles's negotiations with the Byzantines had touched on this possibility. His relations with Constantinople had certainly been improving gradually since his annexation of Istria in 788 and they deteriorated again after his coronation. After the accession in 802 to the Byzantine throne of the vigorous emperor Nicephorus I, war broke out. The point at issue was control of Venetia and the Dalmatian coast. When the Franks had conquered Venetia (810), the Byzantines decided to come to terms and peace was agreed in 812. Charles restored Venetia in return for recognition of his imperial title. The pope's expectations thus came to nothing.

Administration of the Empire. — Charles's acquisition of the imperial title marked the transition in his reign from the period of great conquests to that of administrative reorganization and recapitulation. Up to that time, military operations had often forged and maintained a direct contact between the sovereign and his free-born subjects, but now these ties were inevitably loosened and local authorities had to be set up to transmit the emperor's decrees. This task was performed by counts and bishops. They were apprised of the emperor's wishes either by written directives sent to the annual assemblies or by verbal instructions given by the *missi dominici*, the royal officials who were constantly on circuit throughout the empire. The information that they gathered, together with the inventories of lands and movables compiled at Charles's order, provided the government with the essential documentation on the empire. To sustain the vigour and incorruptibility of such a system, however, required an expenditure of energy of which Charles became less and less capable after 810. An alternative method of ensuring that the imperial will was obeyed was to increase the number of links that bound freemen to their king in a relationship of immediate personal dependence; apart from changes in the formalities of homage. this was achieved by grants of land to provide a livelihood for the king's faithful servants. The basic personal ties created in this way were destined to transform society during the 9th century.

Carolingian Renaissance. — The clergy also had an important part to play in the imperial administration, and Charles's continuation of Pepin's work of ecclesiastical reform bore fruit in a generation of churchmen whose morals and whose education were of a higher standard than before. The possibility then arose of providing, for the brighter young clerics and perhaps also for a few laymen. a more advanced religious and academic training. It was perhaps to meet this modest need that a school grew up within the precincts of the emperor's palace at Aachen. In order to develop and staff other centres of culture and learning Charles imported considerable foreign talent. During the 8th century England had been the scene of much intellectual activity: Alcuin (*q.v.*) of York was commissioned to transplant to the continent the studies and disciplines of the Anglo-Saxon schools Alcuin's many writings and letters made a solid contribution to contemporary learning; but their importance was probably outweighed by his vast educational work. From the school of calligraphy which Alcuin developed at Tours the use of a new script spread rapidly throughout the empire: this was the Carolingian miniscule, more legible and less wasteful of space than the scripts hitherto employed.

Christian refugees from Spain also contributed to this intellectual revival. Disputations with the Muslims had forced them to develop a dialectic skill in which they now instructed Charles's subjects. From Italy came grammarians and chroniclers, men such as Paulus Diaconus (*q.v.*); the formalist traditions in which they had been bred supplied the framework to discipline the effervescent brilliance of the Anglo-Saxons. Charles took a deep interest in all these intellectual pursuits. He also took care to make Aachen a worthy capital for his empire and encouraged projects for building new churches. Einhard, his biographer, who describes all Charles's enthusiasms, held, at any rate during the latter part of the reign, virtually the position of a minister of fine arts.

The "Carolingian Renaissance" which these diverse activities combined to produce was well established even in Charles's time; but its period of greatest brilliance came only after his death.

End of the Reign. — The emperor was an imposing figure, towering and powerful; he engaged with enthusiasm in all forms of sport, enjoyed good living and was not a man to deny himself his pleasures. His court was very far from being austere or puritanical: indeed, the scandals occasioned by his daughters' conduct are but the best-known among those which occurred there. In his latter years age and the toll taken by his past exertions, as well as by certain indulgences at which Einhard hints, began to weaken him. In 806 he decided to provide for the future of his empire and planned a division of territory between his sons, but after the death of his eldest son Charles of Franconia (811) partition was no longer necessary. Louis of Aquitaine (*see* Louis I the Pious) became the only possible heir, since Charles's bastard Drogo was a priest, while Bernard, son of Charles's second son Pepin of Italy (d. 810), was too young to exercise authority. Charles summoned Louis from Aquitaine in 813 and had him ac-

claimed emperor at Aachen, where there was no danger of pontifical interference.

The last few years of the reign were undistinguished. Many factions and coteries grew up and the court was rife with the sinister machinations of intriguers, such as Wala, cousin of the emperor and afterward abbot of Corbie. The conquests were over. the urge for reform played out; even the reins of government fell slack; scandal and intrigue alone held sway at court. Charles caught pneumonia and died at Aachen on Jan. 28, 814. His corpse was borne in a sarcophagus to the church that he had had built. It remained there undisturbed until its formal translation in 1165 on the occasion of Charles's canonization at the request of the emperor Frederick I Barbarossa by the antipope Paschal III. The decree of an antipope did not of course bind the church; nevertheless, the popular cult of Charlemagne mas fairly widely observed in Germany and France during the middle ages; so that he is now regarded as having been informally beatified. His feast is kept at Aachen on Jan. 28.

Legend fastened on Charles as soon as he was dead. It helped to create an image that neither he nor his successors could match. His reign overshadowed the future, and most of the problems that his successors had to face were implicit in the legacy that he left them.

CHARLEMAGNE LEGENDS. The stature and achievements of Charlemagne during his lifetime were such that almost before his death popular imagination had made of him a legendary figure. Stone, glass and parchment all contributed to the aggrandizement of his memory and it would be strange indeed if the spoken word did not play its role. The veneration of which he was the object in the churches of his capital city, Aachen, spread rapidly through the eastern half of his empire; already the *Gesta Karoli Magni (c.* 883), composed by Notker at St. Gall, appears to owe as much to popular anecdotes woven round the figure of the emperor as to his biographer Einhard, while by the end of the 12th century the *Vita sancti Karoli,* composed to substantiate the disputed canonization of 1165 and exploiting the corpus of treatises of which Charlemagne was already the subject, is conceived on purely hagiographic lines, even attributing miracles to him before and after his death. There is evidence that these ecclesiastical traditions had early spread into France. From these sources one sees the emergence of the figure of Charlemagne as the head of the re-created empire of the West, the champion of Christendom, the invincible warrior, the great political leader and dispenser of justice and even the martyr and saint.

In western Europe the earliest *chansons de geste* portray Charlemagne surrounded by his 12 peers (the number no doubt suggested by the apostles), a patriarchal figure with his flowing white beard, victoriously leading the Franks against the enemies threatening his frontiers, although his own deeds often pale in comparison with those of his barons. There runs through some of these poems a thread of historical verisimilitude: the *Chanson de Roland* is clearly based on Charlemagne's expedition into Spain in 778 *(see* ROLAND, LEGEND OF); the *Chanson des Saxons,* a poem composed by Jehan Bodel of Arras about 1200, but probably rewritten from a much earlier *Guiteclin,* narrates his struggles against the Saxons, albeit the poet is as much concerned with the amours of his principal characters as with the military prowesses of the emperor; the poems relating to Ogier the Dane *(q.v.)* are set against the background of Charlemagne's campaigns against Didier of Lombardy; and later *Fierabras* and the *Destruction de Rome* also relate of his deeds in Italy. Other epic poems were purely fictitious; thus the *Chanson d'Aspremont* (probably second half of the 12th century) leads Charlemagne in the company of a youthful Roland and in alliance with Girard de Fraite to the liberation of Rome from the Saracens and the conquest of Calabria, a theme which existed as early as the 10th century (for the Saxon poet Arnulf, elaborating on a statement of Einhard suggesting that the emperor had conquered the whole of Italy, refers to it, and his conquest of Calabria is specifically mentioned by Benoît du Mont-Soracte in his chronicle *c.* 968) and which may have owed its exploitation here in part to the campaigns of the Normans in Sicily from 1060 onward. Another theme exploited by the *chansons de geste* is that of the supposed pilgrimage of Charlemagne to Jerusalem, also of much earlier ecclesiastical origin and again referred to for the first time by Benoît du Mont-Soracte. This theme owes as much to Charlemagne's historical role against Islam in Spain and Italy as to references in the Carolingian annals to diplomatic relations between the emperor and the patriarch of Jerusalem and the caliph of Baghdad which were exaggerated and embellished to the point that 10th- and 11th-century annals portray the emperor in the Holy City. (A text composed at St. Denis about 1080–95, doubtless to give an aura of authenticity to the holy relics conserved there, shows him in the guise of a crusader liberating Jerusalem.) The 12th-century *Pèlerinage de Charlemagne,* described as a baroque epic, relates with a wealth of parodic material unexpected in so early a text various adventures, more appropriate to a lighter genre, of Charlemagne and his peers — Roland, Olivier, Guillaume d'Orange, Naimes of Bavaria, Ogier, Turpin and others. The object is to allow the emperor to demonstrate to his wife that he is without equal, and the whole is placed in the context of Charlemagne's pilgrimage to Constantinople and Jerusalem.

The cycle of poems of which the emperor is himself the principal hero is, for the most part, of more recent composition. *Berte aus grans pie's,* surviving in a late 13th-century version by the Brabantine poet Adenet le Roi *(q.v.),* tells the tale of the betrayal of his father Pepin by intriguers who placed a false bride in his nuptial couch instead of the Hungarian princess Berta, so that Berta spends long years in poverty and suffering, wandering in the forests; through the intervention of her mother the impostress is denounced and the true queen, who is to be the mother of Charlemagne, is eventually discovered. In *Mainet,* a no less fictitious narrative shows Charlemagne being brought up at a Saracen court to which he had been escorted to enable him to escape from the traitors who had poisoned his parents and were plotting his own death, the traitors Rainfroi and Heldri being the sons of those who had betrayed Pepin. A related poem. *Basin,* of which, however, no French version survives, told how Charlemagne, this time a grown man, foils the plot of Rainfroi and Heldri to kill him on the occasion of his coronation. These fictions, which have no vestige of historical veracity, at least exemplify how purely folklore themes, *e.g.,* the substituted bride, came to attach themselves to the figure of the emperor, already rich with legend; in the same way, the presence of Rainfroi and Heldri suggests that to some extent the events concerning Charles Martel, the emperor's grandfather, had come to be associated with Charlemagne, for these are clearly the Ragenfrid and Chilperic who plotted against Charles Martel.

No less apocryphal poems deal with the wars of Charlemagne against his rebellious vassals; *Les Quatre Fils Aymon,* set mainly in Wallonia, is like *Huon de Bordeaux* wholly fictitious, although perhaps, again, echoing faintly events of the reign of Charles Martel *(see* RENAUD DE MONTAUBAN; HUON OF BORDEAUX). Although the emperor does not figure in *Girart de Roussillon,* the poets having placed the long and complex narrative in the reign of Charles Martel (once mysteriously referred to as Charles the Bald), the historical *Girard de Viane* was a contemporary of Charlemagne. Other themes relating to the emperor are those developed in the 13th-century poems of which later derivatives exist in *Macaire* and *La Reine Sebile,* which recount the intrigues of Macaire against Charlemagne's wife Blanchefleur and the ensuing war between the emperor and his son Louis *(see* MACAIRE).

To this category also belong *La Chevalerie Ogier* and *Les Enfances Ogier,* concerned with Ogier the Dane.

It would serve no purpose to enumerate all the *chansons de geste* that feature Charlemagne; later poems elaborate on the themes of earlier ones. Thus in the probably late 12th-century *Otinel,* the eponymic hero, a converted Muslim, accompanies Charlemagne and Roland in an expedition into northern Italy; the *Anseis de Carfhage (c.* 1200), which perhaps reproduces an earlier poem, supposes that Marsile had escaped from the vengeance of Charlemagne after the battle of Roncesvalles and—in a narrative that combines themes of romance with those of the epic—a young Breton knight, armed with the emperor's own sword, wages war against Marsile but is victorious only with the aid of Charlemagne, now so aged and feeble that he has to be transported on a litter. *Gui de Bourgogne* (13th century) is also set in Spain, but this time during the 27 years that Charlemagne is supposed to have spent there before Roncesvalles, and now it is the youthful Gui who succours the emperor. A century later, the Franco-Italian *Entrke en Espagne* and *Prise de Pampelune* constitute a prologue to the *Roland.* These later poems, clearly inspired by their predecessors, testify to the continued vitality and popularity of the themes they exploit round the person of Charlemagne.

The purely clerical traditions frequently welcomed accretions from more popular sources; for example, the *Pseudo-Turpin,* a recension of the story of Roland, uncompromisingly exploits the *Roland* and was itself to serve as a model for Girard d'Amiens' dreary *Roman de Charlemagne (c.* 1300) and was also used *c.* 1232 by Aubri des Trois-Fontaines. who combined Einhard, the *Pseudo-Turpin,* William of Malmesbury and a variety of data from the *chansons de geste.* Through the medium of the Old French epic poems much of the Carolingian legend was propagated throughout Europe. In Italy the link of the Franco-Italian versions of the legend was early established and Andrea da Barberino wrote his *Reali di Francia c.* 1400. In Spain, apart from the *Roncesvalles,* the *Fuga del rey Marsín* and the *Nota Emilianense,* Rodrigo of Toledo referred to incidents of *Mainet* in his *Chronica Hispaniae (c.* 1284), as did the *Primera Crdnica General;* these, with the 14th-century *Gran Conquista de Ultramar,* which gives a different account of *Mainet,* prepared the way of Lope de Vega's, *Los Palacios de Galiana.* As early as the 12th century German ecclesiastical treatises incorporated material from the *chansons de geste;* the Bavarian Konrad wrote his *Ruolantes Liet (c.* 1170?), but even earlier *(c.* 1150) another Bavarian poet had composed a *Kaiserchronik* in which approximately 800 lines were devoted to Charlemagne and include a reference to his wife Berthe. There is also in the *Kaiserchronik* another theme, which had apparently originated in France: that of the emperor's unconfessed sin, first mentioned in the 10th-century *Vita sancti Aegidii* and later identified as his incestuous union with his sister, of which, according to some forms of the legend, Roland was the fruit. The *Vita sancti Karoli* clearly exploits the *Pseudo-Turpin* and early in the 13th century the poet known as the Stricker adapted the *Ruolantes Liet* and introduced into his *Karl* the theme of the substituted bride and that of Charlemagne's early years spent at a Saracen court. For the scholar, however, the Old Norse *Karlamagnussaga,* composed about 1230–50 on the initiative of Haakon IV of Norway, surpasses in importance these later derivatives, for the *Saga* appears to have used as its source versions of the Old French poems earlier than those that have survived. The Normans brought the poems to England and with the decay of Norman-French many were adapted in the 14th and 15th centuries into a series of metrical romances in English.

In France itself the Carolingian legends remained popular until recent times; many of them were rendered into prose in the course of the 14th and 15th centuries, under such titles as *La Conqueste que fit le grand roi Charlemaigne es Espaignes—the* source of Caxton's *Lyf of Charles the Grete* (1485). Many adaptations continued to be published in the "Bibliothèque des romans" and the "Bibliothèque bleue" in which form they still found readers until 19th- and 20th-century scholarship made the originals available.

But the great emperor has more humble claims to the perpetuity of the legends surrounding him, such as the tale of his conception in a cart, to be explained by nothing more sophisticated than a pun on the name of Char-le-magne ("the cart of the *Magne,* the great one"), which also seems to have some bearing on the "Charles's Wain" in the night sky (*i.e.,* the Plough or Dipper; for another view. *see* URSA MAJOR).

CHARLEMONT, JAMES CAULFEILD, 1ST EARL OF (1728–1799), Irish statesman, is chiefly notable for his political connection with Henry Flood and Henry Grattan in the patriot movement during the reign of George III *(see* IRELAND: *History).* He was born in Dublin on Aug. 18, 1728, the son of the 3rd viscount Charlemont whom he succeeded in 1734. For various early services in Ireland he was made an earl in 1763, but he disregarded court favours and cordially joined Grattan in 1780 in the assertion of Irish independence, being chosen commander in chief of the volunteer force. He was president of the volunteer convention in Dublin in Nov. 1783 and was a strong opponent of proposals for the union. Charlemont was keenly interested in literature and the arts. He was the first president of the Royal Irish Academy, and on the grounds of his house at Marino on the shores of Dublin bay he erected the celebrated Casino from the designs of Sir William Chambers. He died on Aug. 4, 1799.

CHARLEROI, a town in the province of Hainaut, Belg., lies on the north bank of the Sambre, about 30 mi. S. of Brussels. Pop. (1955): commune only, 26,078; including suburbs, 458,213. Charleroi was founded in 1666 by the marquess de Castel Rodrigo, the Spanish governor-general of the Low Countries, who named it after his sovereign Charles II of Spain. In the following year Charleroi was occupied by the French, who fortified it with six bastions, and subsequently it came under the domination of Spain, France. Austria and Holland and was besieged many times. The fortifications were finally dismantled between 1868 and 1871.

In the 18th century Charleroi's industries included coal mines, iron foundries, glass works, tobacco factories and woolen mills, and the products were exported via Brussels. During the 19th century there was great expansion when the Sambre was canalized and quays, factories, railways, roads and houses were built outside the town. It thus became the centre of a vast industrial region called *le pays noir* ("the black country").

The church of St. Christopher, begun in 1667. was entirely rebuilt during 1956–57, and the church of St. Anthony of Padua (1837) is an example of the neoclassic style. The town hall, inaugurated in 1936, is the most striking of the modern buildings; from its belfry the annual September procession of the Walloon festival proceeds. In the Palais des Expositions (1954) industrial exhibitions are held, and the Palais des Beaux-Arts, opened in Oct. 1957, contains a conference hall, lecture hall, exhibition room, dance hall, etc. Charleroi has an *université du travail* (business college) and a medical and surgical institute. The town is easily accessible by road, rail, water and air. It is connected by an electric railway with Brussels and Antwerp and by canal with

Brussels and the Scheldt. The airport is at Gosselies, about 4 mi. N. of the town.

CHARLES I THE GREAT: *see* CHARLEMAGNE.

CHARLES II THE BALD (823–877), king of France (*i.e.*, Francia Occidentalis, the West Frankish kingdom) from 843 to 877 and Western (Holy Roman) emperor from 875 to 877, was the son of the emperor Louis I the Pious by his second wife Judith. His birth in 823 disrupted the arrangements made in 817 for the succession. His half-brothers resented the prospect of Charles's receiving a share of their father's territory, and civil war ensued. Finally, however, he got the support of his half-brother Louis the German (842) and, under the treaty of Verdun (843) received all the lands west of a line roughly following the Scheldt, the Meuse, the Saône, the eastern mountains of the Massif Central and the lower reaches of the Rhône.

Until 864 Charles's position remained precarious. The counts had grown overmighty during the civil wars; but the young king meant to be obeyed and took advantage of a rebellion to behead two of the more notoriously insubordinate among them. The Bretons moreover had thrown off allegiance to the Carolingians and pressed eastward and Charles needed all his ingenuity to prevent their alliance with the Norman Vikings who attacked his long defenseless coast line almost every year after 844. The Viking menace helped Charles to solve one other problem, honever: by defending the people of Aquitaine against a Viking raid, he detached them from their allegiance to Pepin II, son and successor of the Pepin (d. 838) who had been made king of Aquitaine by his father Louis the Pious. Yet Charles himself was obliged to recognize Aquitanian separatism when he made his own son Charles king there in 855. From 856, however, Charles had to face an even more serious crisis. A fresh revolt of the magnates, impatient of subjection, coincided with a Norman attack of unprecedented strength. by which the raiders gained possession of the lower Seine valley. Occupied in dislodging them, Charles was betrayed by many of his counts and attacked Louis the German, who invaded his territory intending to depose and supplant him (858). Only the loyalty of the clergy and of a few counts saved Charles, and his authority was in some measure restored; but revolts, in which his son was now involved, continued in Aquitaine, and the Bretons remained dangerous. Furthermore, in order effectively to repel the Normans, Charles had to concede undue powers to local military leaders whose co-operation he needed.

Nevertheless after 864 Charles's power was fully established, and the great capitularies which he then issued imposed order and uniformity throughout his kingdom. His close collaboration with the church served to enhance his prestige and authority; the clergy, on their side. profited from his firm rule to revive some of the splendours of the Carolingian renaissance. During the years 850–880 many manuscripts were copied and illuminated, there was more building, schools were reconstituted and controversy bore witness to a renewed study of theology. The fame of Charles, acute and able sovereign of this civilized kingdom, spread throughout the west.

His capacity to profit from almost any situation brought Charles some questionable but rich prizes. When his nephew Lothair II of Lotharingia (Greater Lorraine) died in 869, Charles annexed that kingdom, but was eventually obliged to divide it with Louis the German (treaty of Mersen. 870). When his nephew the emperor Louis II died in 875, Charles not only took the kingdom of Provence but hastened to Rome and, on Christmas day 875, was crowned emperor by Pope John VIII, who preferred him to the rival claimants to the imperial dignity. Next, in Feb. 876. he was crowned king of Italy at Pavia. At the death of Louis the German (Aug. 876) Charles attempted to annex his kingdom, aspiring to recreate the empire of Charlemagne. In this, however, he failed.

To pursue his ultimate ambitions, Charles had had to make new concessions to the magnates. On his death, at Brides-les-Bains, on Oct. 6, 877, on his way back to France from Italy, he left to his son Louis II le Bbgue a kingdom in which the royal authority was still insecure.

CHARLES III THE FAT (839–888), Frankish king and emperor. was the youngest son of Louis the German and great-grandson of Charlemagne. He was the king of Swabia from 876, and in 879, on the resignation of his sick brother Carloman (d. 880), he took over the kingdom of Italy. He was crowned emperor by Pope John VIII in 881. By succeeding to Saxony on the death of his brother Louis the Younger (882) Charles became king of all the East Franks. Then, on the deaths of the West Frankish kings Louis III (882) and Carloman (884), Charles reunited under his rule the whole empire of Charlemagne with the exception of Burgundy, where the usurper Boso had set up a kingdom for himself. Because of illness (apparently epilepsy). Charles was listless in his duties and disappointed the hopes that he would effectively oppose the enemies of the kingdom and of Christendom. In spite of repeated expeditions to Italy, he failed to help the pope against the Saracens and the dukes of Spoleto. He led armies against the Vikings in the Netherlands (881) and when they were besieging Paris (886), but on both occasions bought off the invaders. His incompetence provoked a rising of the East Frankish magnates, and their leader Arnulf (*q.v.*), Charles's nephew, took over the government (Frankfurt, Nov. 887). Charles did not resist and died the following year at Neidingen on the Danube near Constance. His fall marked the final disintegration of the empire of Charlemagne. There is an edition of Charles's administrative documents by P. Kehr in the series *Monumenta Germaniae historica, Diplomata Regum Germaniae . . . Karolinorum,* vol. ii (1937).

CHARLES IV (1316–1378), Holy Roman emperor and king of Bohemia, the eldest son of John of Luxembourg, king of Bohemia, and Elizabeth, sister of the Premyslid Wenceslas III, was born at Prague on May 14. 1316, and first received the name of Wenceslas. In 1323 he went to the court of his uncle Charles IV of France, where he was given the name of Charles and where, in 1324, he married Blanche, sister of Philip VI. In 1330 he visited Luxembourg, and in 1331 he went to Italy, as his father's regent there. Returning to Prague in 1333, he was created margrave of Moravia by his father. Three years later he undertook the government of Tirol on behalf of his brother John Henry and became involved with the Wittelsbach family in a struggle for its possession. Charles's former teacher, Pope Clement VI, and those German princes who were opposed to the emperor Louis IV secured the election of Charles as German king at Rense on July 11, 1346. His alliance with the papacy earned him the nickname of "the priests' king" (*Pfaffenkönig*). In Xug. 1346 he fought at Crécy, where his father was killed. Now king of Bohemia. Charles returned to Germany and, after being crowned German king at Bonn on Nov. 26, 1346, prepared to attack Louis. In Oct. 1347, however, Louis died. Giinther of Schwarzburg, nominated as Louis's successor by the Wittelsbachs. was defeated by Charles in Jan. 1349.

In 1350 Charles was visited at Prague by Cola di Rienzi (*q.v.*), then "tribune" of Rome, who urged him to go to Italy, where the poet Petrarch and the citizens of Florence also implored his presence. Charles, however, held Rienzi prisoner for a year and then handed him over to Clement at Avignon. Four years later, Charles crossed the Alps, but without an army. He received the Lombard crown at Milan on Jan. 6, 1355, and was crowned emperor at Rome by Cardinal Peter of Ostia on April 5, entering and leaving the city the same day. In 1356 Charles promulgated the Golden Bull (*q.v.*), whose primary object was to regulate imperial elections.

Charles was unremitting in his efforts to secure other territories and to strengthen the Bohemian monarchy. To this end he pur-

chased part of the Upper Palatinate in 1355, and in 1367 annexed Lower Lusatia to the Bohemian crown. He made succession treaties with the Wittelsbach and Habsburg families, the first fruits of which were the inheritance of Brandenburg by Charles's son Wenceslas in 1373. The acquisition by his third marriage to Anna of Swidnica (d. 1362) of the duchies of Swidnica and Jawor (1368) completed the annexation of Silesia to the Bohemian crown. The powerful territorial complex of the Luxembourg house. however, was weakened by Charles himself. In 1377 he partitioned his territories: his first son, Wenceslas, received Bohemia, Silesia and Luxembourg; his second son, Sigismund, received Brandenburg; the youngest, John Henry. was enfeoffed with the duchy of Gorlitz; and Moravia was divided between Charles's nephews Jobst and Prokop.

In 1365 Charles visited Pope Urban V at Avignon and undertook to escort him to Rome. Then, on June 4, he was crowned king of Burgundy. During his later years the emperor took little part in German affairs but was able. by skilful diplomacy between pope and electors, to secure the election of his son Wenceslas as king of the Romans in 1376. He also negotiated a peace between the Swabian league and the house of Wurttemberg in 1378.

Charles had based his power on his rich Bohemian kingdom, which prospered under him. Prague was his imperial capital; there he established the Charles university in 1348, built the Charles bridge and the new district *(nove mesto)*. He imported French and German architects to complete the cathedral church of St. Vitus and to build castles modeled on French châteaux, for instance, that at Karlstejn. As margrave of Moravia, Charles had gained ecclesiastical autonomy for Bohemia with the creation of Prague as an archbishopric (1344), and in the Golden Bull he asserted and confirmed the autonomy of Bohemia as a kingdom. He was fluent in Latin. French, German, Czech and Italian and was a patron of letters; he entertained Petrnrch in Prague and by his invitation of Konrad of Waldhauser to Prague may be said to have initiated the Bohemian movement for church reform. Charles died at Prague on Nov. 29, 1378.

The emperor's autobiography, Vita *Caroli* IV, dealing with events down to 1346, is published in *Fontes rerum Germanicarum*, vol. i, ed. by J. F. Bohmer (1885). There is an English version in Bede Jarrett, *The Emperor Charles IV* (1935).

CHARLES **V** (1500–1558), Holy Roman emperor from 1519 to 1556, also king of Spain as Charles I from 1516, the last emperor to pursue the medieval ideal of universal empire and the last to be crowned by the pope, was born at Ghent on Feb. 24, 1500, the son of Philip the Fair of Habsburg (d. 1506) and Joan of Castile.

Youth and Character.— After the early death of his father in 1506 Charles was brought up at Mechelen at the court of his aunt Margaret, the regent in the Habsburg Netherlands. Life at her court was much as it had been with Charles the Bold, duke of Burgundy (d. 1477), under whom the culture of the former Burgundian court had shown a last burst of brilliance.

Charles V's outlook shows traits typical of the Burgundian chivalric ideal which he maintained throughout his life. French was the language of the Burgundian court and became for Charles the most natural form of expression, while his knowledge of German always remained scanty. Having grown up in surroundings where difference of nationality had no meaning, he was eminently suited, unlike his predecessors, to become the ruler of a world-wide empire. Two men particularly influenced the young Charles: his tutor the theologian Adrian of Utrecht. an outstanding representative of the *devotio moderna* (a religious movement widespread in the northern Low Countries); and his guardian, the strongly francophile Burgundian noble Guillaume de Croy, sieur de Chièvres.

The religious intensity of the *devotio moderna* made a deep impression on the young prince, who developed a simple but unshakable religious faith that stood him in good stead in the numerous crises of his reign. Charles firmly believed that his own and the empire's fate depended not on himself but on God. He always held it to be one of his most vital tasks to defend Christendom against its enemies and to preserve church unity from the divisive danger of Luther's preaching. This serious religious attitude did not imply any desire to avoid secular problems. It expressed itself, too. in the relatively blameless conduct of his personal life. Unlike many of his royal contemporaries, he largely refrained from extramarital relations. His liaison with Johanna van der Gheenst, the mother of Margaret of Austria (1522), occurred five years before Charles's marriage to the infanta Isabella of Portugal in 1526. and his fleeting affair with the Regensburg patrician's daughter Barbara Blomberg, the mother of Don John of Austria, happened seven years after Isabella's death in 1539.

Charles seems never to have been truly young. Many of his contemporaries have left observations on him, commenting for example on his measured deportment and his strong awareness of the respect due to him—though admittedly this characteristic may have largely resulted from the stiff and pompous ceremonial of the former Burgundian court. Indeed, the splendours of this ceremonial so pleased Charles that he later introduced it into the Spanish court. Although he early displayed strong self-confidence, he nevertheless allowed his advisers to influence him extensively even after he had taken up the government of his various territories. He did not develop a completely independent policy until the death of the chancellor, Mercurino Gattinara, when Charles was 30. Charles never overestimated his fair though not outstanding intellectual faculties; a most remarkable trait was his great circumspection; sometimes, indeed, he took a very long time to make important decisions. This may have resulted not only from extreme conscientiousness but also from a certain intellectual rigidity.

Political History of the Reign.—For Charles V, politics and religious politics formed an indivisible unity. Not only was he faced, as emperor, by the reforming movement in Germany, but, as king in Spain he inherited the traditional struggle of the Spanish kings with Islam.

Only at the very beginning of his career was Charles free from such problems, when in 1515 he came of age as duke of Burgundy. On Jan. 23, 1516, Ferdinand of Aragon, Charles's maternal grandfather, died. As a result, the problem of the succession in Spain became acute. since by the terms of Ferdinand's will Charles was to govern in Aragon and Castile only in the name of his mother, the mentally deranged Joan of Castile. Furthermore, the will provided that Cardinal Jiménes de Cisneros, archbishop of Toledo and one of Ferdinand and Isabella's most influential advisers, should direct the administration in Castile. The Spanish opponents of Ferdinand who had fled to Brussels succeeded in having the will set aside, however, and on March 14, 1516, Charles was proclaimed king in Brussels as Charles I of Aragon and Castile.

The young ruler, still strongly under the influence of his guardian, the francophile Chièvres, was eager for an early settlement of the Franco-Spanish dispute in Italy and, in the treaty of Noyon (Aug. 13, 1516), accepted terms that were, in fact, unfavourable to Spain. Not until Sept. 8, 1517, did Charles set out for Spain, landing on the coast of Asturias on Sept. 19; because of delays he missed a personal meeting with the regent, Jiménes, who died on Nov. 8, 1517. Charles did not manage affairs happily at the beginning of his rule in Spain. He brought in his train a number of Netherlandish nobles on whom he bestowed offices and clerical benefices, thus offending the Spaniards, who were further provoked by the frequently arrogant deportment of the foreigners. Besides, Charles's slight knowledge of Castilian Spanish made a bad impression when he appeared before the Castilian *Cortes* in Santiago in 1520. Having been elected German king in succession to his grandfather Maximilian I on June 28, 1519, he left Spain for Germany immediately after receiving a grant from the Castilian *Cortes* convened at Corunna. The Spanish nobility, hidalgos and towns had no sympathy with Charles's imperial aims, and this,

together with the perpetual friction between the Spanish and Flemish nobility, stirred up a ferment which broke out into dangerous revolt soon after the king had left Spain. The risings of the Comuneros and the Germania were suppressed only with the greatest difficulty by Adrian of Utrecht (now bishop of Tortosa), whom Charles had left as regent.

Thus, when Charles arrived in Germany for his coronation, which took place at Aachen on Oct. 23, 1520. he was already troubled with serious problems; and he was to find an equally complex situation awaiting him. The reforming movement begun by Luther had now reached such proportions that Aleandro. the papal nuncio, believed that the papal cause was almost lost. The emperor, however, showed himself determined to crush the reformers and believed that the edict published on May 26, 1521, at the Reichstag of Worms, would achieve this. The edict laid the ban of the empire on Luther and his followers and forbade the printing and spreading of Lutheran literature; but to no avail. Charles now delegated the further settlement of the Lutheran problem to his brother Ferdinand, whom he constituted as his representative in the empire, giving him, in 1522, the Habsburg lands within the empire as a hereditary possession. While Charles did maintain a keen interest in religious development in Germany after the edict of Worms, the empire's relations with France and the papacy engrossed his attention until the diet of Augsburg in 1530.

In Italy, the duchy of Milan was the centre of contention between France and Spain. After the battle of Marignano in 1515 the family of Sforza had had to surrender Milan to the French, whose position in the duchy was recognized by the treaty of Noyon (1516). The treaty had, however, provided no real solution to the problem, and Duke Francesco Sforza, seeking to regain his family's territories, gained the support of Pope Leo X and even of Charles V, who now felt it his duty to restore the duchy to its imperial allegiance. His conviction was strengthened by Mercurino Gattinara (chancellor since Oct. 16, 1518), a Piedmontese by birth, whose influence was decisive in reorienting Charles's foreign policy from the francophile direction it had taken under the influence of Chièvres. On May 28, 1521, Charles and Pope Leo signed a treaty whose aim was the restoration of Sforza. The treaty also ended the suspicions that had arisen between pope and emperor when Leo tried to prevent Charles's election in 1519. At the end of 1521 Henry VIII of England joined this alliance, but he hesitated for three years before actively entering the war against France. The war began at a time when it was imperative for the European powers to present a united front against the Turkish threat. The attacks of Sultan Suleiman were becoming critically serious, Belgrade fell in Aug. 1521 and Rhodes in 1522. In Jan. 1522 Adrian of Utrecht became pope as Adrian VI. In vain he exerted all his powers to persuade Charles V and Francis I of France to conclude an early peace; the war continued until at the battle of Pavia on Feb. 24, 1525, the French king was taken prisoner.

In the peace negotiations that followed, Charles himself ruined the chances of a genuine settlement, as he believed that he could now force Francis to restore the duchy of Burgundy. At the peace of Madrid (Jan. 14, 1526) Francis pledged himself to make the restoration, and the emperor, in the chivalrous spirit of the old Burgundian court, trusted the French king's word of honour. He was quickly disillusioned, for Francis, as soon as he was free, did his utmost to sabotage the terms of the treaty. Nor did he have difficulty in finding willing allies. The new pope, Clement VII, was strongly anti-Habsburg and, on May 22, 1526, together with Francis I, founded the League of Cognac. Clement VII's active anti-imperial policy immediately increased Charles V's difficulties in Germany. where the work of his brother Ferdinand to restrain the reformingmovement was greatly hindered: up to this time even harmonious co-operation between the pope and emperor had failed to arrest its expansion.

Just as. at the battle of Pavia, Francis I had unexpectedly fallen into the emperor's hands, so now the pope came into Charles's power. The imperial army in Italy, in arrears of its pay, marched on Rome of its own accord, sacked the city in May 1527 and took the pope virtually prisoner. This heavily compromised Charles's position, since this affront to the pope ran dead against his ideal of a joint universal monarchy of pope and emperor. When, however, Charles released Clement without attempting to secure a guarantee that ecclesiastical reform would be undertaken or a general council convened, the situation in Germany became yet more favourable to the reformers and the war in Italy continued. Only by temporarily abandoning his plans for a council did Charles achieve a reconciliation with the pope. and this was followed, on Aug. 5, 1529, by peace with the French king. Charles surrendered his claims on Burgundy and Francis renounced his claims on Milan and Naples, but neither party was satisfied with this compromise agreement. The treaty between Charles and Clement, had, however, smoothed the way toward the emperor's coronation by the pope at Bologna on Feb. 24, 1530. Charles, for whom the papal coronation was of great importance, had, until this time, styled himself "Roman emperor elect."

From Bologna the emperor went to Augsburg, where a diet had been convened to debate the religious question. Charles was by no means intransigent on this issue and hoped that it could be resolved peacefully. However, both the Confessio Augustana (see AUGSBURG CONFESSION) and the Apologia produced in its defense were unacceptable to him. When negotiations failed, however, Charles did not at once resort to war to enforce conformity on the Protestant estates. The siege of Vienna by the Turks (1529) had shown that the threat to Europe from the east was too great for Charles to allow the German situation to deteriorate into war. He was obliged to give provisional recognition to the Augsburg Confession and indeed right up to 1544 he was driven to compromise on the religious issue in order to buy the support of the Protestant princes and cities, which from 1531 were organized, for military and political purposes, in the Schmalkaldic league.

In 1532, faced again with a Turkish threat to the hereditary Habsburg lands, Charles granted a religious truce to the adherents of the Augsburg Confession. In exchange for further religious concessions, he received armed support (*Türkenhilfe*) powerful enough to resist the invaders though not sufficient to make any forceful counterattack. Soon after his return to Spain in 1533, however, Charles prepared a counteroffensive against the Turks in the Mediterranean.

In 1529 the conquest of Algiers by the corsair Barbarossa (*q.v.*) had made the struggle against the infidel of vital importance for the coastal populations of Spain and the western Mediterranean. When in Aug. 1534 Barbarossa, now Turkish admiral, captured Tunis, thus considerably extending the basis of his power, the emperor decided to reconquer the port. The successful expedition of 1535 gave Charles his first personal experience of warfare. Tunis was taken, but Charles missed the full measure of victory since Barbarossa evaded capture.

From Africa, Charles traveled via Sicily and Naples to Rome to realize his urgent wish for a general council to reform and reunite the church. To this the new pope, Paul III, was far more favourably disposed than Clement VII. The second essential condition for a council, however, was a reconciliation between the two greatest Catholic rulers, Charles and the French king; but this had already become impossible by the time that Paul promulgated the council. While the emperor was in Rome, Francis attacked the duchy of Savoy to reconquer Milan, though he had renounced it in 1529. On April 17, 1536, a few days after the French troops had entered Turin, Charles proposed, in the presence of the pope, the college of cardinals and the ambassadors of France and Venice, that he and the king of France should settle their dispute in personal combat. The winner should receive the duchies of Burgundy and Milan as his indisputable possessions and should be given command of a crusade against the Turks.

This manifestation of Burgundian chivalry did not have the results that Charles desired. He therefore decided to launch a campaign against France to prevent what seemed to him a dangerous drift in power. He first attacked Provence, hoping thereby to compel the French to withdraw in Italy; but the enterprise failed. Had Charles confined himself to clearing the French from Savoy, his action might have been justified as an attempt to restore the peace of 1529; but when he attacked French territory even be-

fore Francis had moved against Milan, he himself invited the charge of aggression. Thus political blunder was heightened by strategic failure. It was only after Charles, together with Ferdinand. had signed an alliance against the Turks with the pope and Venice, that Francis, who had long tended toward a *rapprochement* with the Turks, showed any willingness to negotiate. At Nice, in May 1538, Charles V, Francis I and Pope Paul met to discuss terms of peace. The agreement. however, left all the major issues between the Valois and Habsburgs unresolved and merely established a ten-year truce. Immediately after the congress Charles attended further discussions with Francis in Aigues-Mortes. He left this friendly encounter thinking himself now free at last to settle, once and for all, the German religious question and to launch a forceful drive against the Turks; but soon he saw he had misjudged again.

Charles had claims on the inheritance to the duchy of Gelderland and was determined to make them good, as the acquisition of this valuable duchy would round off the Habsburg territories in the Netherlands. In 1538, however, the estates of Gelderland elected William V, duke of the neighbouring Cleves, as the successor to Duke Charles; and when, in 1540, the duke of Cleves married a French princess the situation in Gelderland threatened new international complications. Francis I now seemed likely actively to oppose Habsburg territorial expansion on the lower Rhine. In 1541 the Turks made new advances. conquering the greater part of Hungary. In face of this danger, Charles, despite the failure of discussions between Catholics and Protestants in 1540–41, again extended the provisional toleration of the Xugsburg Confession. Charles attacked in the Mediterranean. In 1541 he led an expedition against Algiers. but had to abandon the campaign when autumnal storms wrecked his supply fleet.

After this disaster Charles returned to Spain. By this time tension between the emperor and the French king had grown to the point of imminent war. In 1540 Charles had enfeoffed his son Philip with the duchy of Milan and thus disappointed Francis' expectations that a French collateral line would be established there. Francis had allied himself with the duke of Cleves and with Christian III of Denmark and was preparing campaigns against Navarre and the Netherlands. In the summer of 1542 war finally broke out. The regent of the Netherlands, the emperor's sister Maria, now found herself wedged between Denmark and Cleves. Because of her diplomacy Henry VIII of England concluded an alliance with Charles at the beginning of 1543. but only in the spring did Charles himself decide to leave Spain for Gelderland. In the directive he left to his son Philip, the provisional regent in Spain, Charles wrote that he regarded the Gelderland operation of all his ventures to date as the most dangerous to his life, reputation and resources.

In 1544 the duke of Cleves mas expelled from Gelderland, but the international situation was not much improved. The king of France was now in open alliance with the Turks, and in 1542 the combined French and Turkish fleets had taken the town, though not the fortress, of Nice. Charles himself had earlier attempted to negotiate with Muslim Persia. For him the infidels proper were the Turks, now allied with the "most Christian king." Nevertheless the Franco-Turkish alliance, which was not generally approved even in France, made the princes of the empire more willing to assist Charles against the French. After the Danes had detached themselves from the French alliance (treaty of Speyer, 1544), Charles led a strong army into France from the east, intending to march on Paris. Though the campaign did not reach its goal, the French king was ready to come to terms. By the treaties of Crépy-en-Laonnois (Sept. 1544) Francis surrendered the first French settlements in Canada. Besides, he had to promise to send delegates to the oft-postponed general council and to give the emperor armed support should the Protestant estates of the empire refuse to attend; finally Francis was to equip a powerful army for the intended major offensive against the Turks.

At last Charles seemed to be set for his two grand designs. the restoring of church unity and the repulse of the Turkish menace—the more so since he was willing to make concessions to France. By the terms of Crépy he confirmed the renunciation of his claims on Burgundy and further agreed that Charles, duc d'Orléans (the youngest son of Francis I), was to marry either his niece the archduchess Anna with Milan as her dowry, or his daughter Maria, in which case the couple should become joint rulers of the Netherlands after Charles's death. Charles worked toward the fulfillment of these important decisions up to the end of 1544. He was criticized by two major parties at the Spanish court: the one regarded Milan as the foremost hindrance to peace, and wanted to see it surrendered; the other, true to traditional Aragonese policy, saw in Italy the master key to Europe and wished to surrender the supposedly valueless Netherlands. Economically and strategically Italy and the Netherlands were roughly equal in importance within Charles's universal empire; he decided to surrender Milan. In 1545, however, the duc d'Orléans died. His death nullified Charles's decision on Milan and revived the prospect of further conflict between Habsburg and Valois.

Before any new crisis developed. however, Charles took measures against the German Protestants who had refused to attend the council opened at Trent on Dec. 13, 1545. In 1541 Charles had already won over the Protestant princes Philip of Hesse and Joachim II of Brandenburg. Besides, the stanch Catholicism of William IV of Bavaria helped to heal the traditional antagonism between the Habsburgs and Wittelsbachs. An alliance between the emperor and the pope completed the diplomatic negotiations for the coming conflict with the Schmalkaldic league. Charles began hostilities early in July 1546. Although early in 1547 the pope withdrew his troops, Charles routed the league's army at Miihlberg on April 24. the Protestant elector of Saxony, John Frederick, being taken prisoner. The battle was the occasion for Titian's famous equestrian portrait in which, at his own request, the emperor was portrayed in the armour that he had worn at Mühlberg.

But victory soon was tarnished; in March the council decided to adjourn to Bologna in the papal states. where the emperor had no influence. There it was at first prorogued and then, in Sept. 1549, suspended by Pope Paul III. having completed only part of its work. At the very moment when Charles's ecclesiastical policy seemed within sight of success the necessary understanding between pope and emperor suffered another break. In June 1548, at the diet of Augsburg, the emperor dictated a provisional religious ordinance for the empire, the so-called Augsburg Interim. Charles did not, even now, abandon his hopes of church unity, but most of the Protestant princes assented to the Interim only with inner reservations; at some points, such as Magdeburg, armed resistance to the emperor continued.

It was, however, not merely the emperor's religious policy that caused anxiety: Protestant and Catholic princes alike were perturbed by Charles's plans for an imperial reform that aimed at enhancing the monarch's power in Germany. "German freedom"—the relative independence of princes of whatever religion—seemed to be in danger of falling under "Spanish servitude." Linked with these fears was a strong opposition to Charles's attempts to have his son Philip elected his successor in the empire. This attempt to maintain imperial unity shows that even as late as 1550 Charles had not identified himself nith the particular interests of his Spanish subjects but retained his idea of universal empire and conducted a policy transcending local concerns.

During 1551 the German opposition grew into an alliance with Henry II of France. In this way the conflict which had for so long dominated the politics of western Christendom reappeared in all its former ferocity. The emperor had received full warning of the storm that was brewing against him since 1551; but, as so often in similar situations, he did not seriously believe that his opponents would dare to march against him. In March 1552 he finally appreciated the true dimensions of the danger, but it was too late to prepare adequate defenses. He uas driven from Innsbruck and only found some sort of refuge at Villach in Carinthia. Meanwhile French troops captured the toun and fortress of Metz and pushed on to the Rhine.

These disasters did not indeed destroy Charles's faith in his grand political conception, but his sense of honour was utterly humiliated. Physically he was broken, being racked by gout. From now on his thoughts turned increasingly toward abdication.

In autumn 1552, after he had been compelled to yield further weighty concessions to the Protestant princes at the treaty of Passau, he left Austria intent on the reconquest of Metz. This campaign too fell short of his aims and early in 1553 he abandoned the hopeless siege. He now handed over all responsibility for German affairs to his brother Ferdinand and devoted the rest of his energies to negotiating the second marriage of his son Philip to Mary of England. In this he followed his long-established practice of marrying his numerous relations where there seemed to be most hope of furthering his grand political design. The conclusion of the marriage in 1554 gave great happiness to Charles, after a string of serious failures. Even when Philip remained king of England in name only it nevertheless appeared to Charles to offer a guarantee that the incipient revival of English Catholicism would proceed more rapidly and thoroughly than if Mary had been restricted to her English connections. Mary's marriage, however, remained childless. She died on Nov. 17, 1558, but Charles did not live to see England's return to Protestantism under Elizabeth I.

From 1554 at the latest, Charles's decision to resign the government of his various lands was firm; nevertheless, since Henry II of France had successfully resumed his predecessor's Italian policy, Charles could not responsibly envisage immediate abdication. Even though the position of the imperial army in Italy had improved, the political situation swung badly against Charles when, in summer 1555, Giampietro Carafa, a bitter enemy of Spain, became pope as Paul IV. However, the emperor no longer felt able further to postpone his resignation. At Brussels on Oct. 25, 1555, he handed his power in the Netherlands over to his son Philip, an occasion marked by all the pomp of the former Burgundian court. There followed. on Jan. 16, 1556, Charles's abdication in favour of Philip in Spain, the Italian lands and the colonies; and on Sept. 12, he renounced the imperial title in favour of his brother Ferdinand.

Early in 1557 Charles took up residence near the Hieronymite monastery of San Yuste in Spain. In no way a recluse, he followed the development of events with lively interest and often acted as adviser to Philip II on important decisions. He died on Sept. 21, 1558. shortly before completing his 59th year.

Problem of Finance. — Knowledge of the material conditions under which Charles worked is of comparatively recent acquisition, and much work on Charles's finance, for want of sifted sources, remains at best provisional and hypothetical. Former information was only fragmentary, dealing for example with the financing of his election as emperor in 1519. Mainly because of the great merchant banker Jakob Fugger, Charles was able to bribe the electors more heavily than his rival, the king of France; this turned the scale in his favour but saddled him with a debt of about 800,000 florins.

Charles V, like all early 16th-century rulers, relied on credit to wage his wars. Because of the contemporary methods of war, military disputes were liable to extend over many years, and the regular sources of revenue could not meet the costs. Charles was in fact favourably placed for raising credit since two of the most important money markets of the time, Antwerp and Augsburg, were within his domains. Genoa, of similar importance as a financial centre, was not an ally of the Habsburgs until the late 1520s. The commercial centres were not of course at the sole disposition of the emperor, but he could always count on receiving preferential treatment there.

The vast majority of Charles's debts were in the form of short-term bonds; *ie.*, letters of exchange which sometimes expired at the end of the quarter and seldom fell due later than a year after the date of issue. At times of severe financial need the emperor therefore had to conduct ceaseless negotiations to gain the funds to cancel his current letters of exchange. When for any reason this hand-to-mouth system broke down and the mercenary army could not be paid, there was an immediate danger that it would disperse, even when strategy might dictate that it must be ready for action. The short-term credits which provided Charles with most of his funds were issued at interest rates usurious by modern standards. The annual rate was never less than 12%, and with skill Charles's creditors could expect a return of 45% a year on their capital. In 1516 the emperor's fluctuating debts at Antwerp alone amounted to about 200,000 livres and in 1556 they had risen to 7,000,000 livres (at 40 Flemish groschen the livre). Less than 5% of his debts at Antwerp were consolidated at the end of his reign, that is on a long-term or permanent basis at relatively low interest (mostly 6.25%); and since all loans had to be guaranteed, Charles was continually mortgaging future taxation, or had to use the gold and silver armadas from America to satisfy his creditors. In fact the precious metals from America did not begin to play an important part in the imperial finances until the early 1550s, when the rich silver mines of Potosi were first systematically exploited. But even this new source of revenue was not sufficient to stabilize the precarious finances of Charles's later years, though he was still able to raise credit right up to his abdication. He experienced only the beginning of that period of total financial exhaustion which compelled his son Philip II to conclude in 1559 the treaty of Cateau-Cambrésis with an equally exhausted France.

World of Politics: Idea and Reality. — When, in 1519, Charles was elected emperor, more than 250 years had passed since the reign of Frederick II, the last great emperor. In this period the political structure of Europe had been radically changed, particularly by the rise of France. Already in the late middle ages French apologists had asserted that the king was equal to and independent of the emperor, at times even claiming that the kingship had a more ancient origin. In 1519 the French king Francis I stood as a rival candidate in the imperial election. The idea that the empire was the highest of secular authorities in Christendom and must maintain the peace, uphold law and protect the church had survived as a living ideal even when, with Maximilian I, it was in sharp conflict with the realities.

The source of Charles's concept of empire has been subject to much debate. The German scholars Karl Brandi and Peter Rassow agree that Charles's aim was to revive the medieval empire, while the Spaniard R. Menéndez Pidal regards Charles's political outlook as directly in the Spanish tradition of the "Catholic kings" Ferdinand and Isabella. Yet the Spanish historian J. Vicens Vives argues convincingly that Charles's political theories derived from various sources, above all from Erasmian humanism with its ideal of the *universitas christiana.* Vicens Vives' theory allows that Charles's ideas were influenced though not fully reoriented by the political traditions of Castile. When Hernán Cortés, the conqueror of Mexico, offered Charles an imperial title which the conquistador regarded as equal to the German, his offer was refused.

The substance of Charles's imperial theory has also been disputed. The question at issue is whether he regarded the empire simply as the highest-ranking secular authority in western Christendom, or whether he wished to build up a *monarchia mundi* in which he himself should stand as the undisputed lord above all other rulers. Many of his contemporaries believed that he did wish to set up such a universal monarchy. The grand chancellor Mercurino Gattinara, Charles's most influential adviser between 1519 and 1530, tried to convince the emperor that he must not merely maintain his empire but also extend it. However, it is doubtful whether the emperor accepted these views. Then and later he repeatedly declared that he had no intention of conquest nor, above all, any desire to provoke war within Christendom. Nevertheless, of his reign of. almost 40 years, about half was spent in war; besides Charles vigorously pursued his claims on the duchy of Burgundy. It may seem difficult to reconcile these two facts either with Charles's protestations of peaceful intentions or with his disclaimers of conquest.

On a less superficial view of the period, however, these contradictions are resolved, if not fully, in such a way as to leave the sincerity of the emperor beyond dispute. He regarded the duchy of Burgundy as a constituent part of the Burgundian inheritance that had come to him from his grandfather Maximilian I, and looked on the French royal house, which had held the territory since 1482, as intruders. The duchy of Milan, the other main point of contention between him and France. he claimed as a part of the empire. Charles regarded war on these issues as just, in accordance with the medieval conception of the *bellum justum.* Again the first war against the German Protestants was in his eyes

the ultimate instrument for restoring the unity of the church after his attempts at a peaceful solution to the problem had failed. In his second war in Germany *(1552)* he was, beyond all doubt, the victim of aggression. When the Protestant princes tried to rob him of the fruits of his victory of 1546–47 he had no choice but force, since he was committed to the restoration of the unity of the Catholic Church and faith with all the means at his disposal.

In retrospect one might think that Charles's universal policy and his attempt to realize his imperial idea were from the outset doomed to founder on the obstacles of European politics. Yet his power was more broadly based than that of any medieval emperor, embracing as it did gigantic and always growing territories in the new world. The sum of his resources, however. proved inadequate to discharge that massive undertaking that Charles regarded as his mission. The problems produced by his universal policy grew much beyond his financial means, and financial weakness was a main cause of that gap between aim and achievement reflected in his many compromise solutions.

Charles's political career in Europe was a series of compromises and failures, leaving his main goals unrealized. However; whereas the medieval ideal of empire had been centred on Europe, Charles applied it, beyond the confines of Europe, in the new lands discovered by the great explorers. Though he could not contain the Reformation in Europe, his rule gave scope to Catholic missions in the new world. As Spanish culture gained ground outside Europe, so the overseas parts of Charles's empire took on some significance in European affairs. Charles's reign marks one of the most important phases of European expansion, which led to the complex interdependencies observable in modern world politics.

Schalk (eds.), *Karl V., der Kaiser und seine Zeit* (1960). (E. H. H.)

CHARLES VI (1685–1740), Holy Roman emperor from *1711,* was born in Vienna on Oct. 1, *1685.* the second son of the emperor Leopold I and his third wife Eleonora of Neuburg. When, on the death of Charles II in *1700,* the Spanish branch of the house of Habsburg became extinct, Leopold proposed his son Charles as candidate for the Spanish succession. England, the United Provinces and finally Portugal recognized the candidature and in Vienna, in Sept. *1703,* Charles was proclaimed king of Spain as Charles III in opposition to Philip V, grandson of Louis XIV of France *(see* SPANISH SUCCESSION, WAR OF THE). Traveling through Germany, the United Provinces and England, Charles arrived at Lisbon in March *1704* and thence crossed into Spain. He remained in Spain until *1711,* mostly in Catalonia, where the Habsburg party was strong. At Barcelona, in *1708,* he was married to Elizabeth Christina of Brunswick-Wolfenbüttel (1691–1750), a Lutheran princess who accepted Roman Catholicism. He entered Madrid in *1706* and *1710,* but on both occasions he had to retire to Catalonia. On the death of his elder brother Joseph I on April 17, *1711,* Charles inherited the possessions of the Austrian Habsburgs. He left Spain with great reluctance in Sept. *1711* and was elected emperor on Oct. *12,* 1711, and crowned at Frankfurt on Dec. *22, 1711.* His wife remained at Barcelona as regent. to uphold his claims, under the protection of the able general Guido von Starhemberg, but the refusal of the European powers to tolerate the reconstruction of the empire of Charles V led to the treaty of Utrecht (April *11, 1713)* between Charles's former allies and France, by which the allies recognized Philip V as king of Spain. Charles continued at war with France but had to submit to necessity and at the peace of Rastatt (March *1714)* renounced his claims on the Spanish throne, receiving as compensation the Spanish Netherlands, Milan, Sardinia, Naples and parts of Tuscany. These lands were governed from Vienna by a Spanish council (*Consejo* de *España*), composed mainly of Charles's Spanish partisans, who were very influential with him. Nevertheless, Charles withheld his recognition of Philip V as king of Spain.

His experience in Spain had made Charles aware of the importance of maritime trade. He raised Trieste to the position of a major seaport, linking it by road to Vienna, and in *1722* he set up the Ostend company (*q.v.*) to develop trade with the East Indies. The company was successful but provoked protests from its English and Dutch rivals, so that in *1731* Charles agreed to its closure. From *1733* to *1735* the empire was engaged in the unsuccessful War of the Polish Succession, which brought the loss of Naples and Sicily. By the disastrous peace of Belgrade concluded with the Turks in *1739.* the empire lost nearly everything that had been gained by the treaty of Passarowitz, which had followed the successful war of *1716–18.*

Charles's ruling preoccupation, however, was to secure his inheritance against dismemberment. In *1713,* being still childless, he had begun to prepare a "pragmatic sanction" intended to regulate the succession. In *1716,* a son, Leopold. was born, but he died the same year, and in *1721–22,* after the birth of two daughters, Maria Theresa *(1717)* and Maria Anna *(1718).* Charles laid before the estates of the empire the famous pragmatic sanction (*q.v.*) settling the entire inheritance in the first instance on his eldest daughter. In *1724* a third daughter, Maria Amalia, was born to him, and Charles's main political aim was to gain European recognition for the dispositions he had made.

Charles died at Vienna on Oct. *20, 1740.* Despite his precautions his heiress had to face years of war before her position was established. *(See* AUSTRIAN SUCCESSION, WAR OF THE.)

Charles, like his father and brother, composed music and devoted much of his time to it. He also showed a special interest in architecture. In the Klosterneuburg at Vienna, known as the Austrian Escorial, he gave architectural expression to that "Spanish dream" which he never forgot.

CHARLES VII (1697–1745), Holy Roman emperor, known also as Charles Albert, elector of Bavaria, was born on Aug. 6, *1697,* the son of the elector Maximilian II Emmanuel. During the War of the Spanish Succession, Bavaria was occupied by the Austrians and, in *1706,* Charles Albert and his brother Clement, later archbishop of Cologne, were carried prisoners to Vienna. When his father was restored to his electorate after the war, Charles Albert was released, and in 1717 he led the Bavarian contingent of the imperial army which served under Prince Eugene of Savoy against the Turks. In *1722* he married Maria Amelia, the younger of the two daughters of the emperor Joseph I. Her uncle, the reigning emperor Charles VI, insisted that the Bavarian house should recognize the pragmatic sanction that established his daughter Maria Theresa as heiress of the Habsburg dominions. They did so, but with secret protests and mental reservations of their rights to the Habsburg lands, based on the will of the emperor Ferdinand I.

Charles Albert succeeded his father as elector on Feb. *26, 1726.* His policy mas to maintain good relations with the emperor while evading his obligation to accept the pragmatic sanction and intriguing to secure French support for his claims by marriage to the imperial throne. These claims were advanced immediately after the death of Charles VI (Oct. *20.* 1740), and Charles Albert now entered into the league against Maria Theresa. He was elected emperor in opposition to her husband Francis, grand duke of Tuscany, on Jan. *24, 1742,* under the title of Charles VII. and was crowned at Frankfurt am Main on Feb. *12.* But even while he was

being crowned Bavaria was being overrun by Austrian troops. During the War of the Austrian Succession Charles VII was a mere puppet in the hands of the anti-Austrian coalition, and although he was able to re-enter his capital, Munich, in 1743. he had immediately afterward to take flight again. He was restored by Frederick the Great of Prussia in Oct. 1744, but died at Munich on Jan. 20, 1745.

See P. T. Heigel, *Der österreichische Erbfolgestreit und die Kaiserwahl Karls VII.* (1877) ; F. Wagner, *Kaiser Karl VII. und die grossen Machte, 1740–1745* (1938).

CHARLES I (1887–1922), emperor of Austria and, as Charles IV, king of Hungary, was born at Persenbeug castle, Lower Austria, on Aug. 17, 1887, the eldest son of the archduke Otto and grandnephew of the emperor Francis Joseph. In 1911 he married the princess Zita of Bourbon-Parma. With the assassination of the archduke Francis Ferdinand on June 28, 1914, Charles became heir presumptive to the throne, since Francis Ferdinand's children were excluded from the succession by virtue of his morganatic marriage. In World War I Charles held military commands in Italy, Galicia and Rumania. On Nov. 21, 1916, he succeeded Francis Joseph as emperor of Austria. Charles's political judgment was sound, but he was slow to act. A compromise with the Czechs, planned at the beginning of his reign, was constantly postponed. In Aug. 1918 autonomy was promised to the various nationalities under the dual monarchy, but it was already too late; moreover, the exclusion of Hungary from the settlement made this, too, a half measure. Also, in July 1917, a generous political amnesty had been declared, but this merely accentuated domestic troubles. Nor did the assumption of the military high command by Charles himself increase confidence in the leadership of the army.

Charles had, however, a realistic appreciation of the international situation and worked toward peace. Besides the official peace resolutions passed in Dec. 1916 and March 1917, secret proposals were made to France and Great Britain through Prince Sixtus of Bourbon-Parma, a brother of the empress Zita. These remained fruitless since Charles could not persuade Germany to surrender Alsace-Lorraine and Belgium, nor would he surrender his own territorial claims in Italy. Charles's reputation in Austria suffered badly when, in April 1918, the French prime minister Clemenceau revealed the Sixtus negotiations. After the collapse of the Austro-Hungarian forces, Charles on Nov. 11, 1918, renounced all participation in affairs of state but made no formal abdication. He left Austria in March 1919 and was deposed by the Austrian parliament in April. In spring 1921 he made two attempts from Switzerland to gain a foothold in Hungary; after their failure he was banished from Hungary. He then went to Madeira at the end of Oct. 1921 and died there on April 1, 1922.

CHARLES I and **II,** kings of France: *see* CHARLEMAGNE; CHARLES II the Bald. The alternative system of enumeration whereby Charles the Bald is reckoned as Charles I of France and the emperor Charles III (*q.v.*) the Fat as Charles II of France is less common. *See* also CAROLINGIANS.

CHARLES III THE SIMPLE (879–929), king of France, a member of the Carolingian dynasty, was born on Sept. 17, 879, the posthumous son of Louis II le Bègue by his second wife, Adelaide. In 887, on the deposition of the emperor Charles III the Fat, who had taken possession of the West Frankish kingdom in 885, the boy Charles had an obvious claim to the kingdom as the only surviving grandson of Charles II the Bald, but in view of the need for a strong military leader, the magnates gave the throne instead to Eudes (*q.v.*), son of Robert the Strong, who was not a member of the Carolingian family. Eudes began his reign auspiciously, but his later military defeats swung opinion in favour of Charles, who was crowned by Fulk, archbishop of Reims, in Jan. 893. For five years he was constantly on the move, attempting to enlist support. After the death of Eudes in 898 he was recognized as king by all the magnates; but he saw that he would forfeit his throne if he interfered unduly in their affairs. He at last gained a chance to act decisively in 911, when the death of Louis the Child, the last Carolingian ruler in Germany, raised the question of the succession to his territories. Anxious to acquire a powerful principality in the east of his kingdom, he decided to establish himself in Lorraine. To free his troops for this purpose, he gave formal recognition to Viking occupation of Normandy (treaty of St. Clair-sur-Epte, *c.* 911).

Charles's preoccupation with Lorraine and his consequent prolonged absences from Neustria encouraged the magnates there to revolt. and in 922 they elected a new king, Robert I, the brother of Eudes. Charles killed Robert in battle in 923, but was subsequently taken prisoner. His wife Eadgifu and his son Louis (afterward Louis IV) took refuge in England with his father-in-law, king Edward the Elder. Meanwhile the magnates elected another king, namely Robert I's brother Rudolph (Raoul). Charles never succeeded in regaining power and died in prison at Péronne on Oct. 7, 929. He was the first Carolingian ruler of Francia Occidentalis to lose his crown.

See A. Eckel, *Charles le Simple* (1899). (J. DE.)

CHARLES IV LE BEL OR THE FAIR (1294–1328). king of France from 1322 to 1328, was the third and youngest son of Philip IV. He received La Marche from his father as an appanage in 1311 (it was raised to the rank of peerage in 1316). When his brother Philip V died in the night of Jan. 2–3, 1322, leaving one daughter and a widow with child (another daughter), Charles acted on the precedent established by Philip in 1316 and took the crown without difficulty, leaving to his t o nieces only their mother's dowry, the county of Burgundy.

The most important fact of his reign was the renewal of war with England. In 1323 Charles ordered the building of a bastide at St. Sardos, a small village of Agenais. Whereas Agenais was held by the English, St. Sardos itself depended on the abbot of Sarlat, in Périgord, who was a direct tenant of the French king and had concluded a treaty with Charles giving him joint rights over St. Sardos. The seneschal of Guienne and Gascony, however, to assert his English master's rights, stormed St. Sardos and hanged a number of Charles's officers. Edward II of England. whom Charles had summoned to do him homage for Guienne, Gascony and Ponthieu by July 1, 1324, failed to give satisfaction. Charles therefore pronounced the confiscation of these fiefs, and a French army occupied all Guienne and Gascony, except Bordeaux, Bayonne and St. Sever. In March 1325 Edward sent his wife Isabella (Charles's sister) to Paris to negotiate; and, as Edward did not wish to go to France to do homage, she obtained (Sept. 1325) that the fiefs should go to her son Edward, who would do homage. Charles, however, claimed to keep Agenais and La Réole, and Edward II rejected the arrangement. The fiefs were again confiscated, and the overthrow of Edward II prevented any English resistance. On March 31, 1327, Isabella, now regent of England, signed a treaty by which her son had to renounce Xgenais and Bazadais in order to recover the remainder of the fiefs.

To pay for the war, Charles had to put civil offices up for auction, to increase duties on trade and to make the salaries of the magistrates dependent on the exaction of heavy fines.

On the pretext of a crusade to free Armenia from the Turks, Charles obtained from the pope a tithe levied on the clergy, which he kept for his own use. As his predecessors had done, he confiscated the property of the Lombard bankers. He summoned a number of assemblies to obtain support for these measures and to try again to reform the coinage, but they were held only locally, in *bailliages* and *sénéchaussées*. In 1326 he was satisfied with a meeting of prelates and barons in Meaux, which accepted the principle of a subsidy for the war.

Charles died at Vincennes on Feb. 1,1328. He had been married three times, first to Blanche of Burgundy, who in May 1314 was convicted of adultery, then to Mary of Luxembourg (d. 1324) and thirdly to Joan of Évreux. He left one daughter by Mary; and his widow was with child.

See R. Fawtier, *L'Europe occidentale de 1270 à 1328* (1940) ; *J.* Viard (ed.), *Journaux du trésor de Charles IV le Bel* (1917). (F. CT.)

CHARLES V LE SAGE or THE WISE (1338–1380), king of France from 1364 to 1330. was born at Vincennes on Jan. 21, 1338, the eldest son of the duc de Normandie, later John II of France, and Bona of Luxembourg, daughter of King John of Bohemia. By the cession of Dauphiné to him by Humbert II of Viennois in 1349 Charles became the first heir apparent to the French crown to bear the title of dauphin. On April 8. 1350. he was married to his cousin Jeanne de Bourbon. John II in 1355 gave him the task of convening the estates of Normandy to raise subsidies to defend that province against the English (see HUNDRED YEARS' WAR). with whom Charles II the Bad, king of Navarre, was then in alliance; and on Dec. 7 the duchy of Normandy was conferred on Charles, who took formal possession of it at Rouen on Jan. 10, 1356. By the end of June 1356, however, the English were advancing from Guienne, and in September Charles took part in the battle of Poitiers (*q.v.*), in which John II was taken prisoner.

King's Lieutenant and Regent, 1356–64.—Charles left the battlefield in haste (perhaps on his father's orders) and reached Paris ten days later (Sept. 29) with the title of king's lieutenant. Promptly convening the estates-general to raise the money for the king's ransom, he found himself faced with demands that went so far as to require the dismissal of John's councilors and their replacement by 28 nominees of the estates. This mas the first time that the sovereign's absolute right to choose his councilors was contested and that the estates claimed to take a direct part in the royal government in this way. Charles tried to escape from the influence of the estates by going to Metz to greet his uncle the Holy Roman emperor Charles IV (Dec. 22, 1356), but when the estates met again in 1357 they repeated their demands and brought such pressure to bear, through the provost of the Paris merchants, Étienne Marcel (*q.v.*), and the bishop of Laon, Robert le Coq, that Charles had to yield. He issued a great ordinance of reform on March 3, 1357, and complied with the king of Navarre's demands in December.

Charles was determined, however, to put a stop to the revolutionary moves of Étienne Marcel, who had made him take the title of regent in order to show that he could do what he liked with the monarchy. Two of Charles's marshals, Jean de Conflans and Robert de Clermont, were murdered before his eyes in his palace in Feb. 1358. By March 27, Charles had already left Paris. Summoning the estates to Compitgne, he won assurances of loyalty from them and on Aug. 2 re-entered Paris in triumph. With him then were three men who were to be his best advisers after he became king: Jean and Guillaume de Dormans. later chancellors; and Pierre d'Orgemont, later president of the Paris *parlement.*

Order was restored in the kingdom's internal affairs, but Charles failed when he tried, in 1359, to resist the proposals for a treaty drafted by Edward III of England and John II in London. On his return to France, John signed the treaty of Brétigny (Oct. 2, 1360), then felt himself bound to go back to London, leaving Charles as regent again. John's death, on April 8, 1361, made Charles king of France.

Character of the Reign.—Of delicate constitution but quick-witted, Charles was to govern France as king in the same way as he had governed as dauphin—by avoiding conflict and by relying on persuasion (he was a good speaker) if not on practices that often came near to trickery. That was why contemporaries—including Christine de Pisan, author of the best sketch of him—called him "the Wise" (le Sage). This name, however. alluded also to other qualities of his, gentleness, generosity. chastity and a devoutness in religion that yet left a place for tolerance (for instance when he intervened in favour of the Jews in 1359 and to restrain inquisitorial activities in Languedoc in 1372). Furthermore. Charles had the strongest feeling for the greatness of the monarchy and for the supreme dignity conferred on the sovereign by his consecration as king. He desired, therefore. to live in splendour. Extant inventories show what rich treasures he had at the Hôtel de St. Pol in Paris, at Vincennes and at Melun. He had begun to build the Hôtel de St. Pol, which was to be his favourite seat, in 1361, since the old palace on the Île de la Cité mas not only so crowded with government offices as to be unrecognizable as a king's residence but also was defiled for him by the memory of the murders of 1358. Moreover, he commissioned the architect Robert du Temple to turn the stronghold and arsenal of the Louvre into a more cheerful palace with a façade of sculptures and a great spiral stairway rising from its inner courtyard. He also gave Paris a wider circuit of walls, with the Bastille, begun in 1370, to guard its eastern approaches. At Vincennes the donjon and the Sainte Chapelle, which he completed, can still be seen.

Charles liked the society of men of learning and collected books, forming the first royal library of France on three floors of a tower in the Louvre (he had additional books in his other residences). Some of the manuscripts, which his valet Gilles Malet catalogued, are now in the Bibliothèque Nationale. Together with ancient classical literature, ethical treaties. liturgical books and compilations of laws, Charles had scientific works on astronomy, surgery and natural history. Especially noteworthy, however, are the works dedicated to him personally by men of his onn chosen circle, scientists and philosophers, since the truly distinguishing feature of his government was his determination to act according to a carefully constructed system of principles to nhich he would adhere because he had approved them and because his inclination was always to govern from the study. Thus he asked Nicole Oresme to translate Aristotle for him and Raoul de Presles to translate St. Xugustine's De *civitate* Dei and prompted the composition (c. 1375) of the *Somnium viridarii* ("Dream of the Orchard"). This last nork. which was forthwith translated into French as Le *Songe* du *vergier,* formerly was attributed to Philippe de Mézières. It consists of a dialogue between a clerk and a knight, in nhich they discuss the great problems of the government of the kingdom and. in addition, the question of the French king's relations with the Holy Roman emperor. The emperor at this moment was still the king's uncle. Charles IV. At the latter's state visit to Paris (Jan. 4, 1378), on the occasion of a pilgrimage to St. Denis, Charles gave him a magnificent reception but took good care to do nothing that might imply recognition of the emperor as superior to the king of France.

Political Achievement.—The emperor's visit is rightly regarded as expressing his admiration of his nephew's achievement in restoring the kingdom to which he had succeeded. Charles had entrusted the conduct of military affairs to Bertrand du Guesclin (*q.v.*), whom he was to make constable of France in 1370. Having defeated Charles of Navarre's forces at Cocberel in May 1364, Du Guesclin had been less fortunate at Auray in the following September (in the War of the Breton Succession), but he succeeded in ridding France of the "great companies" of vagrant mercenaries by leading them away to Spain. Charles subsequently consolidated the defense of the country by his great ordinance of Jan. 1374, which organized the recruiting system, the administration and the command of troops and established a permanent army for France. The admiral Jean de Vienne was instructed to build up a neu fleet at Le Clos des Galées, near Rouen.

In his internal policy. Charles was concerned to extend the royal domain and to ensure its integrity: he introduced an oath into the coronation ceremony promising not to alienate any part of it and restricted the grants in appanage made to his brothers. He decided that the king of France should come of age on entering his 14th year. For the nomination of the chancellor of France, he relied on the council's choice. In financial matters. he introduced notable changes, in accordance with Nicole Oresme's theories on the lawfulness of the impost and its necessary permanence coupled with the indispensable stability of the coinage. The estates-general of 1355 and those of 1356–57 had already set up a special administration of their onn for the subsidies that they voted under the general description of *aides;* and the estates of 1363 had added a direct *fouage* ("hearth tax"), without establishing how long it was to be levied. Between 1372 and 1379 the nen tax-collecting agents, from being *élus* des *états,* nere turned into royal officials. *élus* de par *le roi,* controlled by nine "general superintendents."

Thus, although the troubles of the times contributed to it, the

transformation that the French monarchy underwent in the 24 years from 1356 was in a very large part due to Charles V's direct influence on the men and on the institutions of his time, both during his regency and in the 16 years of his reign.

Last Years.—The last crisis of the reign affected the whole church rather than the French kingdom. Charles, however, played an important part in it. He sent one of his most intimate advisers. the cardinal Jean de la Grange, bishop of Amiens, to Rome and associated himself with him in recognizing the antipope Clement VII (Robert of Geneva, elected on Sept. 20, 1378. in opposition to Urban VI). Charles must thus bear much of the blame for the great schism of the papacy. On the very day of his death, at Beauté-sur-Marne on Sept. 16, 1380, he declared himself still sure that Clement was "the true Shepherd of the Church."

The statue of Charles now in the Louvre in Paris originally stood in from the doorway of the church (no longer existing) of the convent of the Celestines, the foundation stone of which he laid in 1374. This statue and that of Jeanne de Bourbon, Charles's consort, are among the earliest masterpieces of the "realistic" style of sculpture in France. The recumbent figure of Charles among the tombs of the French kings at St. Denis was commissioned by him from the master-sculptor André Beauneveu.

CHARLES VI LE FOU OR THE MAD (1368–1422). king of France from 1380, was born in Paris on Dec. 3, 1368, the son of Charles V and Jeanne de Bourbon. Foreseeing that at his death an heir who was still a minor would encounter serious difficulties, his father in 1374 issued three ordinances to settle the question of his succession: the king was to come of age on entering his 14th year; till then. a regency was to be exercised by Louis of Anjou (the eldest of Charles V's brothers); and the guardianship of the young king was to be entrusted to the queen, assisted by Philip the Bold, duke of Burgundy, and her brother Louis II, duc de Bourbon. However, Jeanne de Bourbon died two years before Charles V. and when Charles VI succeeded to the throne on his father's death (Sept. 16, 1380) dissension broke out. Having dismissed Charles V's counselors, whom public opinion held responsible for oppressive taxation, the uncles of Charles VI decided that he should be crowned without delay and that they would share among themselves the powers of a sovereign who was still too young to rule effectively. Crowned at Reims on Nov. 4, 1380, Charles made his solemn entry into Paris on Nov. 11. His uncles completed their plans for the administration of the country with the ordinance of Jan. 28, 1381, which created a supreme council of 12 with Louis of Anjou at its head.

Following a year during which taxes had not been collected (after Charles V's decision at the end of his life to abolish the *fouage* or hearth tax), the inevitable resumption of the levying of *aides* led to insurrections in several towns (notably that of the Maillotins in Paris and of the Harelle in Rouen). On his departure for Italy to claim the kingdom of Naples (spring 1382), Louis of Anjou left the conduct of affairs in France to his brother Philip the Bold of Burgundy. Having negotiated a compromise with the Maillotins and taken Charles to Rouen to crush the Harelle, Philip next led Charles to the help of Louis of Male, count of Flanders, Philip the Bold's father-in-law, against the revolt led by Philip van Artevelde. On Nov. 27, 1382, the Flemish rebels were crushed in the battle of Roosebeke. Strengthened by this success, Charles returned to Paris on Jan. 11, 1383. to put an end to renewed agitation there by suppressing the provostship of the merchants and executing the leaders of the bourgeoisie, who had fomented the disorders. Having himself succeeded to the countship of Flanders in Jan. 1384, Philip the Bold then set about consolidating his position there in the face of constant English intervention and involved Charles in his policy. As German alliances were necessary for this, Charles was married. on July 17. 1385, to Isabella (*q.v.*) of Bavaria. daughter of Stephen, duke of Bavaria-Ingolstadt. It was Philip also who, by playing on his taste for knightly exploits, induced Charles to lead an expedition against William, duke of Gelderland, in Aug. 1388, in support of Jeanne of Brabant, the aunt of Philip's wife. Charles, however, made an early peace with William and returned to France. On Oct. 28 he arrived at Reims, where he had summoned his council.

At a meeting held at the archbishop's palace on Nov. 2, 1388, Charles, who was nearly 20 and found the guardianship of his uncles irksome, announced amid general approval that henceforth he alone would conduct the affairs of the kingdom. After trying in vain to persuade him to reverse his decision, his uncles withdrew, leaving the effective administration of the kingdom in the hands of the former officials of Charles V, known derisively as the "Marmousets" because of their humble origin.

The first concern of the king and his counselors was to reorganize the machinery of government and to reform certain institutions, and a start was made with the promulgation of several ordinances during the early months of 1389. In the following winter Charles visited Languedoc to put an end to the financial extortions of the duc de Berry (Jean de France) and, on his way through Avignon, discussed with the antipope Clement VII a plan for an expedition to install Clement in Rome and to facilitate the establishment of French princes in both northern and southern Italy. Informed of these discussions, Richard II of England, who was favourably disposed toward the Roman pope. Boniface IX, proposed the resumption of negotiations between France and England. These occupied the whole of 1391 and caused the postponement of the Italian venture.

At the beginning of April 1392, during talks at Amiens with the dukes of Lancaster and York about the possibility of ending the war with England, Charles fell ill for the first time with a kind of fever which produced convulsions. It is probable that his precarious mental stability had been finally undermined by the constant round of pleasures which his courtiers provided for him. Next, on June 13, in Paris, Pierre de Craon, cousin of John IV (Jean de Montfort), attempted to assassinate the constable of France, Olivier de Clisson. When Craon took refuge in Brittany, Charles insisted on setting out on a punitive expedition in July, though his brother Louis, duc d'Orléans, and his uncles tried to dissuade him. Another attack of fever compelled him to halt at Le Mans, but he resumed his journey on Aug. 4, a hot day. Next day, the sudden appearance in the middle of the forest of a man dressed in white who flung himself at the head of the king's horse brought on a violent fit of madness, and Charles was carried back to Paris in a litter.

With the effective disappearance of royal authority, there now began a long contest between the houses of Burgundy and Orléans. Philip of Burgundy promptly resumed control of the royal administration, leaving the task of keeping the king amused to the duc d'Orléans. On Jan. 28, 1393, during his first period of recovery. Charles nearly lost his life in a foolhardy masquerade (subsequently knoun as the "Bal des Ardents") in which four of his companions were burned to death. His feeble brain gave way completely, and henceforth he alternated between delirium and lucidity. In all there were 44 attacks of madness lasting from three to nine months, separated by intervals of sanity lasting from three to five months. In his madness Charles would tear his clothes, smash furniture and plates, fail to recognize the queen and imagine himself made of glass, so that he dared not move for fear of breaking. Recovering his reason, he would be full of remorse for his insane acts and obsessed with dread of another attack, but would still make an effort to rule again. Events however, were beyond his control: the Armagnacs (see ARMAGNAC) continued the struggle against the Burgundians after John the Fearless, Philip the Bold's successor, had had Orléans murdered (1407); the Burgundians allied themselves with the English; Henry V of England claimed the French crown and won the battle of Agincourt (1415). In Dec. 1418 the dauphin Charles pro-

claimed himself regent, but by the treaty of Troyes (1420) his mother disinherited him in favour of Henry V.

When Charles VI died. in Paris, on Oct. 21, 1422, he was widely mourned. In his lucid phases he had shown good intentions but his reign of 42 years was a disastrous one for France. The history of this long period of disorder was rather that of the kingdom than of the king, who, under tutelage from 1380 to 1388 and then for 30 years in the hands of doctors and quacks, existed only through those who ruled in his name. The reign was important precisely because of the king's impotence, which was fully exploited by those whose interest it was to weaken the royal power. The helpless witness of so many events, Charles yet remained a precious hostage whom the conflicting parties sought to possess.

D'A.)

CHARLES VII (1403–1461), king of France from 1422, was born in Paris on Feb. 22, 1403, the fifth son of Charles VI (*q.v.*) and Isabella of Bavaria. Created count of Ponthieu in 1404, he was betrothed in 1413 to Mary of Anjou, daughter of Louis II, king of Naples, and Yolande of Aragon. He spent the next three years in Provence and in Anjou with the family of his future wife, whom he was to marry in 1422. On April 5, 1417, the death of his brother John made Charles dauphin, at a moment when he was in Paris in the hands of the Armagnacs (see ARMAGNAC). His father subsequently appointed him lieutenant general of the realm (June 14; confirmed Nov. 6, 1417).

In the night of May 28–29, 1418, when the Burgundians were entering Paris, the dauphin left the city and retired to Bourges. As the constable, Bernard VII of Armagnac, was murdered by the Burgundian faction, the dauphin was now the leader of the Armagnacs. In his capacity as lieutenant general he proceeded to organize offices of government at Poitiers and at Bourges. At the end of the year he assumed the title of regent. He next made an attempt to reach agreement with John the Fearless, duke of Burgundy, but the Burgundian faction was finally antagonized when partisans of Charles, in his very presence, murdered the duke at Montereau (Sept. 10, 1419). This act frustrated hopes of national unity against the English. By the treaty of Troyes (May 21, 1420), Isabella of Bavaria recognized Henry V of England as heir to France instead of the dauphin, who was to be banished from the kingdom. Charles succeeded, nevertheless, in establishing his authority south of the Loire.

Accession.—Henry V died on Aug. 31, 1422, Charles VI on Oct. 21. Henry VI of England was then proclaimed in Paris as king of France. In Nov. 1422, however, the dauphin was crowned at Poitiers and took the title of king of France, as Charles VII. He was a prey to various influences: his Armagnac counselors; his mother-in-law, Yolande of Aragon; Richemont (*i.e.,* the earl of Richmond; see ARTHUR III), whom he appointed constable of France in 1425; and Georges de La Trémoïlle, Charles's own favourite, who exercised unlimited power till 1432. These conflicting influences led to private feuds among various Armagnac factions, particularly in Poitou.

End of the Hundred Years' War.—Charles VII sought help from other sources and in the years 1424–28 managed to arrange several periods of truce with Philip the Good, duke of Burgundy. The war with England, however, continued. In 1428, after reaching the banks of the Loire, the English laid siege to Orléans. Then Joan of Arc (*q.v.*) forced them to raise the siege in May 1429 and made her way to Reims, the traditional place of coronation for the French kings, where Charles VII was consecrated on July 17, 1429. After Joan had been taken prisoner (1430) private wars—notably between Richemont and La Trémoïlle—again broke out. Charles remained inactive, but French captains held the English forces in check. In 1434, houever, Charles secured an alliance with the Holy Roman emperor Sigismund; and on Sept. 21, 1435, after long discussions, the treaty of Arras was concluded between Charles of France and Philip of Burgundy. Then at last, freed from his former favourites' influence, Charles surrounded himself with men of action—Jean, comte de Dunois (*q.v.;* the bastard of Orléans), Richemont, Pierre de Brézé and Charles of Anjou—and began the liberation of France from English control. In 1437 Charles entered Paris, which became his capital once more, and in 1444 a truce was made between France and England. In 1440. meanwhile, Charles had had to quell the Praguerie, a revolt of the nobles led by his son the dauphin Louis (see LOUIS XI). After the death of Yolande of Aragon (1442), various mistresses used their influence with the king; Agnbs Sorel (*q.v.*) in particular had undisputed authority until her death in 1450.

To put an end to the activities of the Écorcheurs (bands of mercenary soldiers which were ravaging the whole of France), the king undertook the reorganization of the army, which was made a regular, paid force (ordinances of 1439, 1445 and 1448). The *compagnies* d'ordonnance, recruited from the nobility, formed an élite cavalry; the francs-archers ("infantry") were chosen from among the common people. The brothers Jean and Gaspard Bureau (*q.v.*) made the artillery a formidable weapon. Thus, when the English, despite Charles VII's diplomatic activity and Henry VI's marriage to Margaret of Anjou (the niece of Charles's consort), broke the truce in 1449, the battles of Formigny (1450) and of Castillon (1453) recovered Normandy and Guienne for France. In 1456 Charles signed a treaty of alliance with Christian I of Denmark, who promised to provide a fleet and an army for use against the English.

Ecclesiastical Affairs.—Charles added his efforts to those of the emperor Sigismund in an attempt to mediate between Pope Eugenius IV and the Council of Basel. In 1438 the council's decrees were approved by an ecclesiastical assembly at Bourges. The pragmatic sanction of Bourges, drawn up by this assembly, made certain concessions to the pope, but established the liberties of the Gallican Church (notably in the matter of the granting benefices) and abolished the annates. Up to the end of Charles's reign the papacy tried to have the pragmatic sanction abrogated and proposed in vain to the king a plan for a concordat. Calixtus III failed to persuade Charles to join the crusade against the Turks, and relations between Charles and Pius II were strained because of the prohibition on the levying of tithes in France.

Financial and Legal Reorganization.—At the beginning of his reign Charles had asked assemblies of the estates-general to grant him money. Gradually, however aides and *tailles* became permanent, the amount to be levied being fixed by the royal council. The estates of Languedoi'l made no attempt to conserve what rights they possessed and finally ceased to meet. Those of Languedoc continued meeting, but became less and less important as time went by. To ensure a more exact knowledge of the laws, an ordinance of April 1454 prescribed that compilations of regional customs should be made.

Foreign Relations.—On his eastern frontiers Charles tried to weaken and limit the power of Burgundy. In 1444 he made use of the Écorcheurs in two expeditions: one, led by the dauphin Louis, supported Austria and Zürich in their war with the confederation of Swiss cantons; the other laid siege to Metz, but failed to capture it, though Toul and Verdun recognized French sovereignty. Charles also concluded a series of treaties with German princes and took Luxembourg and Libge under his protection. In Italy René of Anjou was unable to reconquer the kingdom of Naples (1442) and Charles of Orléans failed to win Milan (1447). In 1452, by the treaty of Montil-16s-Tours, Charles VII undertook to support Milan and Florence against the Venetian league if they should need him, but in 1454 the Italian states, frightened by French encroachments, settled their differences. In 1458 John of Anjou occupied Genoa, which had called on Charles VII for support, but the intruder was quickly expelled.

Jacques Coeur (*q.v.*), a merchant who had at his disposal a large fleet, contributed greatly to the commercial expansion of France, both through his contacts with the counties of the east and through his numerous trading posts in Europe (at Bruges, Barcelona, Geneva and other places). After the disgrace of Coeur in 1451 Charles continued to develop French trade with north Africa, as well as with Spain and Scandinavia.

Last Years.—The end of Charles VII's reign was overshadowed

to some extent by the treason of the duc d'Alençon (Jean 11), who was sentenced to death in 1458 but kept in prison until the king's death. Far more distressing, however, were the intrigues of the dauphin Louis, both within France and with foreign powers. In 1452, against his father's wishes, Louis had married Charlotte, daughter of the duke of Savoy; and after the annexation of Dauphin6 by Charles VII (1456) he took refuge in Burgundy, remaining there until his father's death. Charles VII died at Mehun-sur-Ykvre on July 22, 1461.

CHARLES VIII (1470–1498), king of France from 1483, was born at Amboise on June 30, 1470, the only son of Louis XI of France and Charlotte of Savoy. Louis XI on his deathbed in 1483 entrusted his daughter Anne and her husband Pierre de Bourbon, seigneur de Beaujeu, with the care of Charles, and the Beaujeus conducted the government of France until 1492 (see ANNE of France; and FRANCE: History, for the events of these years). Charles, however, after his marriage to Anne of Brittany (1491), let his favourite, Étienne de Vesc, persuade him to free himself from the Beaujeus. With his mind full of glorious dreams derived from romances of chivalry, he then resolved to claim the rights of the house of Xnjou, to which Louis XI had succeeded, on the kingdom of Naples and to use this as a steppingstone to Constantinople and to his own coronation as emperor of the east. He sacrificed everything to this policy, signed the disastrous treaties of Étaples (1492) and Barcelona (1493) with England and Aragon to keep his hands free, and set out in 1494. Pope Alexander VI did what he could in support of his ally, the Aragonese dynasty in Naples, but was forced to treat with Charles when the French occupied Rome. Charles entered Naples on Feb. 22, 1495, and was crowned there on May 12. Already in March, however, Milan, Austria, Venice and the pope had formed the League of Venice against him, and after the indecisive battle of Fornovo (July 1495) he was forced to return to France. He was preparing a fresh expedition when he died after an accident at Amboise on April 8, 1498.

CHARLES IX (1550–1574), king of France from 1560 to 1574, was born at St. Germain-en-Laye on June 27, 1550, the second son of Henry II and Catherine de Médicis (*q.v.*). The death of his eldest brother, Francis II, made him king in 1560, under the regency of his mother. He was proclaimed of age on Aug. 17, 1563, after his 13th birthday (according to the custom of the kingdom), but remained almost always under his mother's domination, being incapable of choosing and following a policy of his own. His health was poor, and he was mentally unstable.

To strengthen the prestige of the crown, Catherine took Charles on a tour of France from 1564 to 1566. The kingdom, however, was torn by the hostility between Catholics and Huguenots (see FRANCE: History). The victories over the Huguenots won by his brother, the duc d' Anjou (afterward Henry 111), at Jarnac and at Moncontour in 1569 seem to have made Charles jealous of Anjou's glory, so that in 1571, when Gaspard de Coligny (*q.v.*) came to court, he was persuaded to favour the Huguenot plan for intervention against the Spaniards in the Netherlands: he sanctioned a defensive alliance with England (signed at Blois in March 1572) and Huguenot aid to the Dutch. This all came to nothing when Catherine, alarmed at the new policy and at Coligny's ascendancy, induced Charles to give permission for the massacre of St. Bartholomew's day.

The massacre apparently haunted Charles for the rest of his life. Thenceforward his health deteriorated and he became increasingly melancholy. He died at Vincennes, of tuberculosis, on May 30, 1574. Charles left no children by Elizabeth of Austria, daughter of the emperor Maximilian II, whom he had married in 1570, but he had one son, Charles, comte d'Auvergne and later duc d'Angoulême, by his mistress Marie Touchet.

Charles IX was by no means an imbecile. His education had been entrusted to the humanist Jacques Amyot, who had developed a love of literature in him. He wrote poetry and a work on hunting, *Traité* de la chasse royale (1625; modern ed. 1858), and was a patron of the Pléïade and of J. A. de Baïf's academy.

CHARLES X (1757–1836), king of France from 1824 to 1830, was born at Versailles on Oct. 9, 1757, the fifth son of the dauphin Louis (son of Louis XV) and Maria Josepha of Saxony. Baptized as Charles Philippe, he was given the title of comte d'Artois. The dauphin's second son had died in 1754 and the eldest died in 1761, leaving only the future Louis XVI and the comte de Provence, later Louis XVIII, as senior brothers to the comte d'Artois. He was married in 1773 to Thérèse of Savoy, whose sister Louise was already married to the comte de Provence. Their sons were Louis Antoine, duc d'Angoulême (*q.v.*), and Charles Ferdinand, duc de Berry (*q.v.*).

The comte d'Artois spent his early youth in scandalous dissipation, incurring heavy debts that had to be paid by the state. His service with the French army at the siege of Gibraltar in 1782 was undertaken rather for distraction than for any serious concern. In 1785, however, he began a lasting liaison with Louise d'Esparbès, comtesse de Polastron (d. 1805), and from that time he became less frivolous and took more interest in politics. In the events leading up to the Revolution he emerged as an opponent of concessions to the third estate.

In the night of July 16–17, 1789. two days after the fall of the Bastille. the comte d'Artois left France for the Austrian Netherlands, whence he soon proceeded to Turin in Piedmont. He thus became the first chief of the royalist emigration, as the comte de Provence did not join it until 1791, when the brothers established themselves in Germany, at Coblenz. After Louis XVI's execution (1793), Provence, as self-styled regent of France, nominated Artois lieutenant general of the kingdom. When Provence became titular king, as Louis XVIII, on his nephew Louis XVII's death (1795), Artois, as the king's brother, took the designation Monsieur. Meanwhile he had visited Austria, Prussia and Russia, lived for a year at Hamm in Westphalia and served with the English army in the Netherlands (1794).

In Aug. 1795 Monsieur went to England. Then he sailed for the Vendée, to lead the royalist rising there. He landed on the island of Yeu, but the insurgents on the mainland failed to seize a landing place for him on the coast, and the enterprise came to nothing. Monsieur then returned to England. After some time in London, he moved to Holyrood palace, Edinburgh, then back to London (1799–1809), then finally to Hartwell, where he remained until the Restoration (1814) enabled him to return to France. For the ten years of Louis XVIII's actual reign Monsieur was the leader of the Ultras, the party of extreme reaction. His younger son, the duc de Berry, was assassinated in 1820.

King of France.—Louis died on Sept. 16, 1824, whereupon his brother became king as Charles X. On May 29, 1825, he was crowned at Reims, with all the gorgeous ceremonial of the old regime. It soon became clear that he would pursue his policy of reaction. The former *émigrés* were awarded 1,000,000,000 fr. as compensation for their confiscated lands; and Gallicans as well as Liberals were alarmed at measures which increased the power of the clergy. Charles and his trusted minister, the comte de Villèle (*q.v.*), soon began to lose what popularity they had had. On April 29, 1827, the national guard in Paris, which he was reviewing, greeted the king with cries of "Down with the ministers!" He disbanded it next day.

The fall of Villkle's ministry at the end of 1827 made the king consent to try a more moderate policy. A government headed by the vicomte de Martignac (*q.v.*) took office In 1828, and the king declared that France's happiness depended on "the sincere union" of the royal authority with the liberties consecrated by the charter of 1814. Martignac tried to placate the Liberals, but Charles proved temperamentally incapable of playing the part

of a constitutional king as Louis XVIII had done. "I would rather hew wood," he explained, "than be a king under the conditions of the king of England." The Liberals, moreover, continued to obstruct all measures proposed by a ministry not selected from the parliamentary majority. When they finally joined with the extreme right to defeat Martignac (April 1829), the king lost patience. In Aug. 1829 he called on the extreme clericalist and reactionary Prince Jules de Polignac to form a government.

A formidable agitation sprang up, which only made the king more obstinate. In opening the session of 1830 he declared that he would "find the power" to overcome the obstacles placed in his path by "culpable maneuvers." The reply of the chambers was a protest against "the unjust distrust of the sentiment and reason of France": whereupon they were first prorogued, then, on May 16, dissolved. The result of the new elections was a large increase in the opposition; and Charles, on the advice of his ministers, determined on a virtual suspension of the constitution. On July 25 he signed four ordinances, three of which dissolved the new chamber, modified the electoral law and curtailed the liberty of the press. Issued next day, these provoked revolution.

July Revolution. — Charles had taken no precautions against a violent outbreak. From St. Cloud he went first to Versailles, then to Rambouillet, where he learned to his surprise that the insurrection could not be resisted. On Aug. 1 he appointed the duc d'Orléans, Louis Philippe (*q.v.*), lieutenant general of the kingdom; and on Aug. 2 he abdicated in favour of his grandson, the duc de Bordeaux (Henry V; see CHAMBORD, HENRI, COMTE DE). Finally, however, on the news of Louis Philippe's acceptance of the crown, he began a dignified retreat to the coast, surrounded by the infantry, cavalry and artillery of the guard. At Maintenon he dismissed most of his troops and went on with about 1,200 men to Cherbourg, whence he sailed for England on Aug. 16.

Last Years. — After some time at Holyrood palace again, Charles left for Bohemia, where he established himself in the Hradcany palace in Prague. There he spent the closing years of his life in religious austerities, intended to expiate not his failure as a monarch but the venial excesses of his youth. He died at Gorizia, in Friuli, on Nov. 6, 1836.

Leopold I of the Belgians, in a letter of Nov. 18, 1836, to Princess (afterward Queen) Victoria, wrote: "History will state that Louis XVIII was a most liberal monarch, reigning with great mildness and justice to his end, but that his brother, from his despotic and harsh disposition, upset all the other had done, and lost the throne. Louis XVIII was a clever, hard-hearted man, shackled by no principle, very proud and false. Charles X an honest man, a kind friend, an honourable master, sincere in his opinions, and inclined to do everything that is right."

CHARLES I (1600–1649), king of Great Britain and Ireland from 1625 to 1649, whose reign saw the outbreak of the English Civil War, was born in Dunfermline palace on Nov. 19, 1600, the second surviving son of James VI of Scotland and of Anne of Denmark. A sickly child, Charles was christened within a few hours of his birth and when his father became king of England (March 1603) he was temporarily left behind in Scotland because of the risks of the journey. Devoted to his elder brother, Henry, and to his sister, Elizabeth, he became lonely when Henry died (1612) and his sister left England to marry Frederick V, elector palatine of the Rhine (1613). Little is known about his childhood, but his governess, Lady Carey (afterward countess of Monmouth), protected him from some of his father's intellectual absurdities. He was created prince of Wales on Nov. 3. 1616.

All his life Charles had a Scots accent and a slight stammer. Small in stature, he was less dignified or soulful than his portraits by Van Dyck suggest. He was always shy and struck observers as being silent and rese ed. His excellent temper, courteous manners and lack of vices impressed all those who met him, but he lacked the common touch, traveled about little and never mixed with ordinary people. A patron of the arts (notably of painting and tapestry; he brought both Van Dyck and Rubens to England) and, like all the Stuarts, a lover of horses and hunting, he was much more fastidious than his father and the character of the court became less coarse as soon as he became king. His private life was proper and he was sincerely religious. From his father he acquired a high sense of duty as a king, but his earliest extant letters reveal a distrust of the unruly house of commons with which he proved incapable of coming to terms. Lacking flexibility or imagination, he was unable to understand that those political deceits which he always practised in order to uphold his authority would, if publicly exposed, impugn his honour and damage his credit. So all his life he was acting a part not only toward other people but toward himself.

Before succeeding to the throne, Charles, accompanied by the duke of Buckingham (see BUCKINGHAM, GEORGE VILLIERS, 1ST DUKE OF), made an incognito visit (1623) to Spain in order to conclude a marriage treaty with the infanta. Although Charles was attracted by the languorous Spanish princess, the mission failed because he would not become a Roman Catholic, while the Spanish government refused to make specific promises to help restore the elector palatine. Charles then suffered a revulsion against Spain and joined Buckingham in pressing his father for war against that country, while a marriage treaty (1624) was arranged on his behalf with Henrietta Maria, sister of the French king, Louis XIII.

Conflict With Parliament. — Charles I became king on March 27, 1625. He married Henrietta Maria soon afterward. When his first parliament met (June 1625) trouble immediately arose because of the general distrust of Buckingham. The Spanish war was proving a failure and the king offered no explanations in parliament about his foreign policy or its costs. Moreover, the temper of the house of commons was strongly Puritan, whereas the sympathies of the king were with what came to be known as the high church party. Thus antagonism soon arose between the new king and the commons, and parliament refused to vote him the right to levy tonnage and poundage (customs duties) except on conditions, though this right had been granted to previous monarchs for life.

The second parliament of the reign, meeting in Feb. 1626, proved even more critical of the king's government, though some of the former leaders of the commons were kept away because Charles had ingeniously appointed them sheriffs in their counties. The failure of a naval expedition against Cádiz in the previous autumn was blamed on Buckingham and the commons tried to impeach him for treason. To prevent this, Charles dissolved parliament (June 1626). The kingdom now became involved in a war with France as well as with Spain and, in desperate need of funds, the king imposed a forced loan, which his judges declared illegal. He dismissed the chief justice and ordered the arrest without cause shown of over 70 knights and gentlemen who refused to contribute. The court of king's bench ruled in a test case (known, inaccurately, as the Five Knights' case) that the king was within his prerogative in doing so. Nevertheless it created a sense of grievance which was ventilated in the next parliament.

By the time that Charles's third parliament met (March 1628), Buckingham's expedition to La Rochelle had been decisively repelled and the king's government was thoroughly discredited. The house of commons at once passed resolutions condemning arbitrary taxation and arbitrary imprisonment and then set out its complaints in the Petition of Right. The king, despite his efforts to avoid giving specific assent to this petition, was compelled to employ the regular form of assent to a private bill — Soit *droit fait* comme *est désiré*—though when later published the bill appeared without his original answer attached. After subsidies had been voted, parliament made ready to demand Buckingham's dismissal, but the king prorogued parliament on June 26, 1628. By the time it met again (Jan. 1629) Buckingham had been assassinated. In the fourth parliament, the house of commons objected both to what it called the revival of "popish practices" in the churches and to the levying of tonnage and poundage by the king's officers without its consent. The king ordered the adjournment of parliament on March 2, 1629, but before that the speaker was held

down in his chair and three resolutions were passed condemning the king's conduct. Charles I perceived that such behaviour was revolutionary: "This house," he said, "proceeds not upon the abuses of power only, but upon power itself." For the next 11 years he ruled his kingdom without calling a parliament.

"The Eleven Years' Tyranny." — On March 10, 1629, Charles published a lengthy declaration defending his treatment of the late parliament and justifying his religious policy and his levying of tonnage and poundage without parliamentary consent. In order that he might no longer be dependent upon parliamentary grants he now made peace with both France and Spain, for, although the royal debt amounted to over £1,000,000, the proceeds of the customs duties at a time of expanding trade and the exaction of traditional crown dues, such as knighthood fines, fines on landowners for breaches of the forest laws or of the statutes against enclosures and profits from the court of wards, combined to produce a revenue that was just adequate in time of peace. The king also tried to economize in the expenditure of his household. To pay for the Royal Navy, ship money writs were issued, first in 1634 to ports and later to inland towns as well. The demands for ship money aroused obstinate and widespread resistance by 1638, even though a majority of the judges of the court of exchequer found in a test case that the levy was legal (see HAMPDEN, JOHN; SHIP MONEY).

These in fact were the happiest years of Charles's life. At first he and Henrietta Maria (*q.v.*) had not been happy and in July 1626 he had peremptorily ordered all of her French entourage to quit Whitehall. However, after the death of Buckingham he fell in love with his wife and came to value her counsel. Their eldest son, the future Charles II, was born on May 29, 1630, and a succession of other children followed. Though the king regarded himself as responsible for his actions to God alone — the so-called doctrine of Divine Right of Kings — he recognized his duty to his subjects as "an indulgent nursing father." If he was often indolent, he exhibited spasmodic bursts of energy. He took over the work of reclaiming the fens in eastern England from the earl of Bedford. With the help of the archbishop of Canterbury, William Laud, he tried to enforce the statutes against enclosures. He gave orders for administrative reforms, although little impression was made upon the elaborate network of private interests in the armed services and at court. On the whole, the kingdom seems to have enjoyed some degree of prosperity until 1639 when Charles became involved in a war against the Scots.

Bishops' Wars and the Long Parliament. — The early Stuarts neglected Scotland. At the beginning of his reign Charles alienated the Scottish nobility by an act of revocation whereby lands claimed by the crown or the church were subject to forfeiture. His decision in 1637 to impose upon his northern kingdom a new liturgy, based on the English Book of Common Prayer and approved by the Scottish bishops, met with concerted resistance. When many Scots signed a national covenant to defend their Presbyterian religion, the king decided to enforce his ecclesiastical policy with the sword. He was outmaneuvered by a well-organized Scottish covenanting army and by the time he reached York in March 1639 the first of the so-called Bishops' Wars was already lost. A truce was signed at Berwick-upon-Tweed on June 19.

On the advice of Archbishop Laud and of the earl of Strafford, his able lord deputy in Ireland, Charles I summoned a parliament which met in April 1640 and offered to waive his right to ship money if the house of commons would vote him 12 subsidies. Under the leadership of John Pyrn the house insisted first on discussing grievances against the government and showed itself opposed to a renewal of the war against the Scots; so, on May 5, the king dissolved what was known as the Short parliament. The collection of ship money was resumed and so was the war. A Scottish army crossed the border in August and the king's troops panicked before a cannonade at Newburn. Charles, deeply perturbed at this second defeat, convened a council of peers on whose advice he summoned another parliament, the Long parliament, which met at Westminster in Nov. 1640.

In his opening speech Charles told the Long parliament that the Scots were rebels and that its first duty was to provide money to maintain an English army. Instead, the new house of commons condemned ship money, "innovations in religion," the conduct of the prerogative courts, the expensive levying of troops, Strafford's Irish policy and the Scottish wars, and made preparations to impeach Strafford and other ministers for treason. The king adopted a conciliatory attitude — he agreed to the Triennial act which ensured the meeting of parliament once every three years — but expressed his resolve to save Strafford, to whom he promised protection.

The trial of Strafford opened in March 1641. Charles, while outwardly conciliatory to the leaders of the commons and while attempting to build up a moderate party to support him in parliament, also planned to strengthen and sustain an army with which he could in a crisis impose his will. When it became clear that the case against Strafford might fail, a bill of attainder was introduced and pushed through both houses of parliament. The king failed in an attempt to put loyal troops into the Tower of London, and early in May a mob of Londoners intimidated the house of lords. At this point Strafford himself offered to set Charles's conscience at liberty and begged him to sign the bill of attainder. Though afterward he regretted his action, the king was persuaded that it was his public duty to do so, and Strafford was beheaded on May 12, 1641.

On the same day that he signed the act of attainder, Charles agreed to a measure whereby the existing parliament could not be dissolved without its own consent. He also accepted bills abolishing nearly all the prerogative courts, declaring ship money and knighthood fines illegal and in general condemning his methods of government during the previous 11 years. But though making these concessions, he visited Scotland in August to try to enlist support there. He agreed to the full establishment of presbyterianism in his northern kingdom and allowed the Scottish estates to nominate royal officials. His temporary popularity was undermined by a rumoured plot to kidnap the Scottish covenanter leaders, known as "the Incident," and Charles failed at that stage to create a royalist party in Scotland.

Meanwhile parliament reassembled in London after a recess and on Nov. 23, 1641, the commons passed by 159 to 148 votes the Grand Remonstrance to the king, setting out all that had gone wrong since his accession. At the same time news of a rebellion in Ireland had reached Westminster. When the king returned to London on Nov. 25 he gave a noncommittal answer to the Grand Remonstrance, published on Dec. 10 a proclamation upholding the Church of England (a movement to abolish the bishops had started in the lower house) and ordered a guard that had been placed round the house of commons to be withdrawn. Pym and the leaders of the commons. fearing that if an army were raised to repress the Irish rebellion it might be used against them, planned to gain control of the army by forcing the king to agree to a militia bill. When asked to surrender his command of the army, Charles exclaimed "By God, not for an hour." He observed from the division over the Grand Remonstrance that a royalist party was forming; and fearing an impeachment of his queen, he screwed himself up to desperate action. He ordered the arrest of one member of the house of lords and five of the commons for treason and went on Jan. 4 with about 400 men to enforce the order himself. However, the accused members escaped and hid in the City. After this rebuff the king left London on Jan. 10, this time for the north of England. The queen went to Holland in February to raise funds for her husband by pawning the crown jewels.

A lull followed during which both royalists and parliamentarians enlisted troops and collected arms. Not that Charles immediately gave up hopes of peace; with the advice of men like Viscount Falkland, Edward Hyde and Sir John Colepeper, who were members of parliament, he still tried to conciliate and had even offered (Jan. 1) John Pym the post of chancellor of the exchequer. But the queen urged him not to "yield everything." After a vain attempt to secure the arsenal at Hull, in April the king settled in York, where he ordered the courts of justice to assemble and where royalist members of both houses gradually joined him. In June the majority of the members remaining in London sent the king

the Nineteen Propositions. which included demands that no ministers should be appointed without parliamentary approval, that the army should be put under parliamentary control and that parliament should decide about the future of the church. Charles realized that these proposals were an ultimatum; yet he returned a careful answer in which he gave recognition to the idea that his was a "mixed government" and not an autocracy. But in July both sides were urgently making ready for war. The king formally raised the royal standard at Nottingham on Aug. 22 and sporadic fighting soon broke out all over the kingdom.

Civil War: the First Phase.—(For a full account of the fighting, see CIVIL WAR. ENGLISH. Here only the king's actions and movements are described.) In Sept. 1642 the earl of Essex. in command of the parliamentarian forces, left London for the midlands, while Charles moved his headquarters to Shrewsbury to recruit and train an army on the Welsh marches. A drawn battle was fought at Edgehill near Warwick on Oct. 23. The king addressed his troops in these words: "Your king is both your cause, your quarrel, and your captain. The foe is in sight. The best encouragement I can give you is that, come life or death, your king will bear you company, and ever keep this field, this place, and this day's service in his grateful remembrance." Charles I was a brave man but no general and he was deeply perturbed by the slaughter he saw on the battlefield. He rejected the advice of his nephew, Prince Rupert, and of others to make a dash for London. Instead he preferred to occupy Oxford in a leisurely way and only in mid-November advanced on London. He started to negotiate before forcing the Thames, thus giving time for a resolute defense force to gather at Turnham Green. The king then ordered a retreat. As Rupert had attacked at Brentford during a truce for negotiations, Charles was personally blamed for treachery. He withdrew to Reading and then to Oxford, where he set up his court and military headquarters.

In 1643 the royal cause prospered, particularly in Yorkshire and the southwest. At Oxford Charles dwelt pleasantly enough in Christ Church and met his council at Oriel, while All Souls was used as an arsenal and New College as a mint. The queen, having sold some of her jewels and bought a shipload of arms from Holland, landed in Yorkshire in February and joined her husband in Oxford in mid-July. Both by letters and by personal appeal she roused him to action and warned him against indecision; "delays have always ruined you," she observed. The king seems to have assented to a scheme for a three-pronged attack on London, from the west, from Oxford and from Yorkshire, but neither the westerners nor the Yorkshiremen were anxious to leave their own districts. So in August the king decided to besiege the city of Gloucester, which, since Bristol had fallen to Prince Rupert in July, was the only important parliamentarian stronghold left in the west. Essex, however, relieved Gloucester and, after the first battle of Newbury, fought on Sept. 20, Charles, though claiming the victory, ordered a withdrawal on Oxford.

In the course of 1643 a peace party on the parliamentarian side made some approaches to Charles in Oxford, but these failed and John Pym made a military alliance with the Scottish covenanters. The entry of a Scottish army into England in Jan. 1644 thrust the king's armies upon the defensive and the plan for a converging movement on London was abandoned. Charles was content to hold his inner lines at Oxford and throughout the west and southwest of England, while he dispatched Prince Rupert on cavalry raids elsewhere. The king ordered him to relieve York where a royalist army was besieged by the Scots and by two English parliamentarian armies, but his letter was badly expressed and Rupert imagined he must not merely save York but must beat the parliamentarian forces in the field. With the odds against him he suffered defeat at Marston moor on July 2. Meanwhile Charles, leaving Oxford, defeated a force under Sir William Waller at the battle of Copredy Bridge on June 29 and pursued the earl of Essex, who was moving west into Cornwall. Henrietta Maria had left Charles again in April. She gave birth to their youngest child, Henrietta, in Exeter (June 16) and then sailed to France. The king's campaign in the west was a success. The army under Essex was outmaneuvered and surrendered at Lostwithiel at the very end of August. On his return to his headquarters Charles was confronted by a large parliamentarian force at the second battle of Newbury, but he beat off his enemies and reached Oxford safely. He was not elated, however, and put out a number of peace feelers. These came to nothing, but he was cheered by reports that his opponents were beginning to quarrel among themselves.

The year 1645 proved to be one of decision. Charles may have had some foreboding of what was to come, for in the spring he sent his eldest son into the west with his ablest adviser, Edward Hyde; thence they escaped to France. On June 14 the Ne Model army, commanded by Sir Thomas Fairfax, defeated the king and Prince Rupert at the battle of Naseby. After the royal cavalry had suffered defeat the king himself tried to rally his infantry, but a Scottish professional soldier put his hand on the king's bridle and turned his horse's head and Charles found himself carried away from the battle. Prince Rupert was obliged to surrender Bristol on Sept. 11, and Charles, whose mind had been poisoned by hints of treachery, revoked his commission. Then the king. who was in south Wales, moved north in the hope of linking with the marquess of Montrose, his victorious commander in Scotland. He reached Chester, which he failed to relieve; then he wandered across to Newark, where he learned of the defeat of Montrose at Philiphaugh (Sept. 13). There also he saw Rupert, whose condemnation was revoked by a council of war. The king returned to Oxford on Nov. 5.

Civil War: the Second Phase.—The first phase of the Civil War was now virtually over. By the spring of 1646 Oxford was surrounded. Charles left the city in disguise with two companions late in April, and arrived at the Scots' camp at Newark on May 5. A few days later he accompanied the Scots to Newcastle. But the covenanters, having come to terms with the victorious English parliament in Jan. 1647, left for home, handing over Charles I to parliamentary commissioners. He was held at Holmby house in Northamptonshire where he lived a placid, healthy existence and, learning of the quarrels between the New Model army and parliament, hoped to come to a treaty with one or the other and regain his previous power. In June Cornet George Joyce with a force of some 500 men seized the king and carried him away to the army headquarters at Newmarket.

After the army marched on London in August, the king was moved to Hampton Court palace, where he was reunited with two of his children, Henry and Elizabeth. He escaped on Nov. 10, but his friends' plans to take him to Jersey and thence to France had been muddled and instead Charles found himself in the Isle of Wight, where the governor, Col. Robert Hammond, was loyal to parliament and kept him under surveillance at Carisbrooke castle. There Charles conducted complicated negotiations with the army leaders, with the English parliament and with the Scots; he did not scruple to promise one thing to one side and the opposite to the other. He came to a secret understanding with the Scots on Dec. 26, 1647. By this "Engagement" the Scots offered to support the king's restoration to power in return for the establishment of the Presbyterian religion in both kingdoms for the time being. Charles then twice refused the terms offered by the English parliament, known as the Four bills, and was put under closer guard, from which he vainly tried again to escape.

In Aug. 1648 the Scottish Engagers were defeated at the battle of Preston and the second phase of the Civil War was over. The army now began to demand that the king should be put on trial for treason as "the grand author of our troubles" and the cause of bloodshed. He was removed to Hurst castle in Hampshire at the end of 1648 and thence taken to Windsor castle for Christmas. On Jan. 20, 1649, he was brought before a specially constituted high court of justice in Westminster hall.

Execution of the King.—Charles I was charged with high treason and "other high crimes against the realm of England." He at once refused to recognize the legality of the court because "a king cannot be tried by any superior jurisdiction on earth." He therefore refused to plead but maintained that he stood for "the liberty of the people of England." The sentence of death was read on Jan. 27; his execution was ordered as a tyrant, traitor, murderer and public enemy. The sentence was carried out on a scaffold

erected outside the banqueting hall of Whitehall palace on the morning of Tuesday, Jan. *30, 1649.* The king went bravely to his death, still claiming that he was "a martyr of the people." A week later he was buried at Windsor.

CHARLES II (1630–1685), king of Great Britain and Ireland from *1660* to *1685,* was born at St. James's palace, London, on May *29, 1630.* the eldest surviving son of Charles I and Henrietta Maria. Up to the age of *12* Charles received, at the hands of Brian Duppa, bishop of Chichester, and William Cavendish, earl of Newcastle, a conventional princely education, in which the latter's concern for good horsemanship and other gentlemanly exercises was probably dominant. But during the *18* years after the outbreak of the Civil War (*q.v.*) in *1642,* he had to come to terms with defeat, isolation and the persistent humiliations of poverty. Thus the character of the boy is indistinct, but the young man emerges clearly in precocious maturity, sardonic, lazy, a born dissimulator, becoming skilled in the sort of moral evasions which make for ease even in adversity.

The Years of Exile.—The nature of his adversities invites respect for Charles, even though the long years of cheap dissipation in exile have tarnished the romance of his exploits. After being driven to take refuge in the west country by royalist defeats in *1645,* Charles moved to Scilly and then to Jersey, finally joining his mother in Paris by July *1646.* His father, now in Scottish hands, had granted her full control of his education "in all things except religion," and her supervision seems to have been close, but insufficient to prevent him fathering his first child, James, later duke of Monmouth. Thomas Hobbes, as a mathematician, was among his tutors.

Moving to the Netherlands, Charles made two unsuccessful attempts to save his father. In July *1648* he took part in a naval demonstration in the Thames, hoping to appeal to Londoners, and in Jan. *1649* he signed a blank paper for the insertion of any terms that would preserve his father's life. Although proclaimed king after Charles I's execution, he was more helpless than ever, penniless and at the centre of factious wrangling in an impotent court. Asserting his independence, he made his headquarters first at Jersey, then at Breda, and to the dismay of his council took up negotiations with the Presbyterian Scots. Terms were finally agreed on May 1, *1650,* by which he abandoned James Graham, marquess of Montrose, and accepted the Covenant in return for a faint prospect of support in regaining the English throne. He landed in Scotland on June *23.* Tne whole enterprise entailed a sacrifice of honour and conscience which could barely be sanctioned by Charles's claim that he was under pressure and therefore not bound by his word. Indeed, soon after the Scottish defeat at Dunbar (Sept. *1650)* he made an attempt to escape from his hosts but was thwarted, and after a series of public humiliations he was crowned king of the Scots at Scone on Jan. *1, 1651.* These months were among the bitterest in his life and the march into England was a welcome escape. It ended in defeat at Oliver Cromwell's hands in the battle of Worcester, Sept. *3, 1651.* Then began the *40* days' hiding, the concealment in the "royal oak" at Boscobel, the furtive journey through the west country and the eventual escape to France which he reached on Oct. *16.* He faithfully remembered to reward those who had assisted his escape.

A period of utter destitution followed, for he and his following were unwelcome in France. Charles quarreled with his mother and could gain little help from other European princes. The only comfort he could offer his advisers, Edward Hyde, Sir Edward Nicholas and James, marquess of Ormonde, was to remain true to the Anglican faith and vigorously counter his mother's attempt to convert his youngest brother Henry to Roman Catholicism. His firmness alienated potential Catholic support and reveals how strongly he adhered to his father's injunction that constancy in his religion would alone regain him his throne. Meanwhile, Cromwell's diplomatic successes closed France and the Netherlands to Charles, and in March *1655* a poorly co-ordinated royalist rising in England was crushed. Charles then turned to Spain, concluding a treaty in April *1656* which enabled him to live in the Spanish Netherlands. With some difficulty he detached his brother James from his command in the French army and gave him some regiments of Anglo-Irish troops in Spanish service, but this nucleus of a royalist army was doomed to inactivity by poverty. No attack on England could be mounted, and Cromwell's death in *1658* did little to improve Charles's prospects. A royalist rising of Aug. *1659* was betrayed and crushed, and in the confusion of parties which followed Richard Cromwell's retirement the conflicting ambitions of army leaders held the best hopes of negotiating a restoration. In the event it was Gen. George Monck, marching his formidable army down from Scotland, who successfully took advantage of the situation to impose his terms upon the council of state in London. Power now passed from the Republicans and Independents to the Presbyterians who saw in monarchy the only answer to imminent anarchy. A parliament was summoned for April *1660* and negotiations were opened with Charles *(see* ENGLISH HISTORY).

The Restoration.—By the declaration of Breda, issued on April 4, *1660,* Charles expressed his personal desire for a general amnesty, for liberty of conscience, an equable settlement of land disputes and full payment of arrears to the army, but he assigned the actual terms of such a settlement to parliament. The convention parliament. in which royalist peers and many young Cavaliers had found seats, imposed no terms beyond acceptance of the declaration, and Charles was proclaimed king on May *8. 1660.* On May *25* he landed at Dover and on May *29* was ushered into Whitehall by rejoicing crowds. In the Restoration settlement which took shape in the years following. Charles's role was often a passive one, but he intervened at once to temper the severity of the convention in its punishment of his enemies. The Act of Indemnity (Aug. *1660)* pardoned all treasons, felonies and other offenses committed since Jan. *1, 1637,* with few exceptions, and only *13* regicides and Sir Henry Vane (*q.v.*) were executed.

In its formal aspects the restored monarchy differed much from that inherited by Charles I, since the early enactments of the Long parliament survived. But the most effective limitation on Charles II's independence was the financial settlement. He was given an annual income which would have been inadequate even if its estimated yield of £1,200,000 had not been overoptimistic. Some attempt was made by parliament to deal with the disbanding of the army and the debts of both the crown and the revolutionary government, but the convention left Charles with a serious unsolved financial problem.

Charles was crowned on April *23, 1661,* and a month later the negotiations with Portugal for his marriage with Catherine of Braganza were completed. The treaty gave Charles a dowry of over *£300,000,* together with Bombay and Tangier and substantial trading privileges for English merchants. These material gains outweighed English distaste for a Roman Catholic consort, and French support countered Spanish and Dutch objections. The marriage took place on May *21, 1662,* and Charles confessed to his satisfaction.

During the early part of his reign, Charles mainly left the government in the hands of Edward Hyde *(see* CLARENDON, EDWARD HYDE, 1ST EARL OF), whom he made lord chancellor and earl of Clarendon. Clarendon was fairly successful in reconciling all classes under the throne, but apart from the financial problem, two aspects of the Restoration settlement left a legacy of discontent and increased Charles's difficulties. The land settlement left a small class of discontented Cavaliers who felt that their loyalty mas not appreciated and, having received no compensation for their losses in the Civil War, added bitterness to the

usual struggle for preferment at court and sorely tried Charles's generosity. However, it was the religious settlement which created the greatest unrest. The so-called Clarendon code uncompromisingly restored the Anglican Church, rejecting the toleration which Charles had promised at Breda. In an attempt to keep his word, Charles issued a declaration in Dec. 1662 reasserting his desire to relieve dissenters and attempting to suspend the penal laws, but parliament rejected any toleration when it met in 1663 and continued to harass the Nonconformists.

Thus parliamentary pressure restrained Charles in the exercise of his prerogative to dispense with legal penalties; in 1673 it was to deny that he had any such prerogative at all in religious matters. But in the 1660s the king still enjoyed the uncontradicted control of the executive, the judiciary and of foreign policy. The Militia act of 1661 confirmed his command of the armed forces, the Licensing act muffled the press and in 1664 the repeal of the Triennial act removed the offensive machinery which enforced frequent meetings of parliament.

Government and Foreign Policy.—Charles had entered with care and moderation upon his inheritance but he proceeded to enjoy it overfreely. His pursuit of pleasure was no new characteristic, but in the precarious financial condition of the government it laid dangerous strains upon parliament and his advisers. In 1662 parliament supplemented his regular revenue with a hearth tax. Although his income was still deficient it was so to a smaller extent than is usually claimed, and the lord treasurer, the earl of Southampton, had no doubt that the principal bar to solvency was the king's heedlessness.

Debt hampered the pursuit of a vigorous foreign policy. Dunkirk proved too costly to hold and its sale to France in 1662 underlined England's incapacity to defend its overseas possessions. Nevertheless, Charles endorsed the commercial rivalry with the Dutch which kept English interests alive in the Levant, Africa and the East Indies. By 1664 minor provocations had led to the war which was formally declared early in 1665 *(see* DUTCH WARS).

The Anglo-Dutch conflict fostered Charles's first political crisis. By the time the Dutch sailed up the Medway in 1667, burning English shipping, the combined effects of the Great Plague of 1665 and the Great Fire of London in 1666 upon a nation already exasperated by high costs, inefficiency and corruption had created a state in which exhaustion was overborne by a resolve to get redress. Clarendon was the obvious scapegoat and Charles. tired of the censorious old servant, was ready to sacrifice him to the ambitions of younger politicians. Parliament, however, went on to insist on a close inquiry into government expenditure, and Charles was wise to initiate a drive for the better management of his treasury. He was also obliged to organize or buy support in a house of commons which, transformed by maladministration and by-elections, now spoke with an altered, critical tone. Lord Arlington, assisted by Sir Thomas Clifford, created the nucleus of a court party which gave Charles a precarious control of domestic politics. Meanwhile the king sought greater security abroad than was offered by the popular Protestant triple alliance with the United Provinces and Sweden, formed in 1668. Through his sister Henrietta, duchess of Orléans, Charles embraced Louis XIV's terms for French assistance. He was to declare himself a Roman Catholic, restore that faith in England and engage in a joint land-sea war upon the Dutch, in return for military help and an annual subsidy. Of his advisers. Clifford, Arlington, the duke of Buckingham, Lord Ashley and the earl of Lauderdale, whose initials fortuitously made up the word Cabal, only the first two were trusted to sign the secret treaty, which Henrietta brought to Dover in May 1670, though all endorsed a feigned treaty which omitted the conversion clauses.

With money voted by a complaisant parliament to support the Dutch alliance, Charles prepared to further this "grand design." In Jan. 1672 he freed his revenue of liabilities by postponing repayment of money due mainly to London bankers—the "Stop of the Exchequer"—and on March 15 issued a Declaration of Indulgence suspending the penal laws against Protestant and Catholic nonconformity. The third Dutch War began two days later. England's naval contribution was unpopular and indecisive, and when parliament met in 1673 it forced Charles not only to withdraw the Declaration of Indulgence but also to accept the Test act which drove Roman Catholics, including Clifford and Charles's brother James, duke of York, from office. When Charles withdrew from the war in Feb. 1674 it was amid another political storm. Clifford was dead, Ashley, now earl of Shaftesbury, in opposition, and Buckingham, Arlington and Lauderdale under threats of impeachment. The man who could help Charles weather this was Sir Thomas Osborne, soon earl of Danby. As an Anglican country gentleman, hostile to France, his policies were calculated to reassure the commons and his financial acumen as lord treasurer promised to relieve the king. He successfully maintained an obedient court party in parliament and fostered the popular marriage in Nov. 1677 of Mary, daughter of the duke of York, to William of Orange. But Charles had maintained his secret negotiations with France and Danby was forced to be a party to them; consequently he was vulnerable to the rancour of Ralph Montagu, ambassador in Paris, who exposed Danby out of spite.

The "Popish Plot" and the Exclusion Crisis.—The exposure of the French negotiations was but one aspect of the great crisis of Charles's reign, the "popish plot"—an inflated tissue of fiction built round a skeleton of even stranger truths. After Titus Oates in Aug. 1678 revealed an intended Catholic insurrection, confirmed apparently by the letters of Edward Coleman and the murder of Sir Edmund Berry Godfrey (*q.v.*), the country was sufficiently inflamed to believe anything and bogus informers flourished unchecked. Parliament presided over the inquiries, encouraged by Shaftesbury, and Charles himself was obliged to acquiesce in the execution of 35 Catholic victims. But when the queen was accused and Danby threatened with impeachment, Charles dissolved the Cavalier parliament (Jan. 1679). He sent James. an avowed Catholic since 1668, abroad, but the problem of his succession to the throne had now been raised in an acute form. Charles was prepared to propose limitations on a Catholic king but refused to compromise the rightful succession. To emphasize the absence of any other heir he publicly affirmed the illegitimacy of his eldest son, the duke of Monmouth. The new parliament of 1679, however, which was preparing a bill for the exclusion of James, had to be dissolved quickly, and when its successor of Oct. 1680 repeated the attempt it was only by the narrowest of margins that the brilliant moderation of the earl (later marquess) of Halifax secured the defeat of the exclusion bill in the house of lords.

The campaign to bar the Catholic duke from the throne, drawing upon accumulated resentments against a corrupt and scheming court, had by now brought the London mob into politics, and Shaftesbury as a demagogue exercised an influence greater than he had wielded as a statesman. So Charles called his last parliament to meet at Oxford in March 1681, where, strengthened by a financial agreement with France, he felt safe in dismissing it after one week. The conflict between supporters and opponents of exclusion distinguished by the novel names of Whig and Tory, was now viciously fought at the level of local politics, and Charles showed little mercy in reducing borough corporations to obedience by threatening the forfeit of their charters. The discovery of the Rye House plot to assassinate him and his brother in 1683 brought the royalist reaction to its climax, and the execution of Lord William Russell and Algernon Sidney marked the collapse of the exclusionist cause. The country's mood of zealous loyalty was now almost as fervent as that which had greeted him in 1660, but far less deep-rooted, and although the last years of Charles were passed in tranquillity the apparent stability of the Stuart throne was deceptive.

Character.—Charles, whose life testified to a belief that "God will never damn a man for allowing himself a little pleasure," died at Whitehall palace on Feb. 6, 1685, after a hasty profession of the Catholic faith. The mixture of caution and indifference which had delayed this conversion until his deathbed is typical of him. He was fortunate enough to enjoy all the merits of his defects, and the tolerance which he brought to religious mat-

ters may have contributed more to the peace of his reign than was lost by his shifty insincerity. With this easy conscience went an easy manner. Charles was affable and familiar to a degree thought excessive in a king, and his wit has been described as more suitable for a private gentleman. But beneath the frivolity and licence was a mordant cynicism allied to an acute judgment of character. He was rarely deceived; his lasciviousness was quite unromantic. Consequently his mistresses exerted no positive influence upon his actions. Barbara Villiers, duchess of Cleveland, confirmed the nation's worst expectations by dominating the early years of his reign, embittering his wife and intriguing against Clarendon. and she occasioned Montagu's disastrous intervention in politics by demanding his dismissal. Above all she was expensive. Her sons by the king were Charles, Henry and George, dukes of Southampton, Grafton and Northumberland. Louise de Kéroualle, duchess of Portsmouth, enjoyed Charles' deep affection perhaps, but her French connection was less decisive than her sponsors hoped. By her Charles had Charles Lennox, duke of Richmond; by Nell Gwyn, Charles Beauclerk, duke of St. Albans; and by Catherine Peg. Charles Fitzcharles, earl of Plymouth. In all there were 14 acknowledged illegitimate offspring. Of these only James, duke of Monmouth, played a major role in English politics.

Charles paid a smaller price for his amours than for his laziness. He had a robust constitution, was tall and active and loved riding and sailing but, although capable of outsitting his advisers at the council board, hated routine and prolonged application. This failing vitiated those drives for economy which might have salvaged his credit or prevented dependence on the French alliance. Instead a state of nearly continuous financial crisis ensured that one of the positive political achievements of his reign was the development of greater parliamentary control over revenue and its expenditure, which was hardly offset by improvements in departmental efficiency at the treasury. The same lack of interest that allowed the admiralty to become a political football reduced the navy to a sad condition by the end of the reign.

More than its fair share of genius has brought distinction to an age that was not remarkable for public patronage of arts other than drama. Nonetheless, Charles actively shared the preoccupations of that sceptical, materialist century which gave birth to the Royal society under his charter, and he did something to foster technological improvements in navigation and ship design. John Evelyn, mourning his death, remembered all these things and many more: his fine physique, his natural kindness, the smell of his spaniels about the court. "The history of his reign." Evelyn wrote, "will certainly be the most wonderful for the variety of matter and accidents above any extant of many former ages," and the same complexity belongs to Charles's character.

Charles, careless of economy, turning abruptly on his heel when warned by an adviser that "He that will not stoop for a pin, will never be worth a pound," is perhaps typical of the king, but Charles chatting familiarly with Nell Gwyn over a garden wall or striding through St. James's park at his wonted large pace are images that fall far short of conveying the whole man.

CHARLES I (CHARLES ROBERT or CAROBERT of Anjou-Naples) (1288–1342), king of Hungary, was the son of Charles Martel of Naples and Clemencia, daughter of the emperor Rudolf I. He claimed the Hungarian crown, as the great-grandson of Stephen V. with the approval of the pope, and was crowned at Esztergom after the death of the last Árpád, Andrew III. in 1301. Ho ever, his claim was disputed and he was forced in the same year to surrender the crown to Wenceslas II of Bohemia, who in 1305 transferred his rights to Otto, duke of Lower Bavaria. Otto was taken prisoner by the Hungarians, and Charles was ,enthroned at Buda on June 15, 1309, and crowned at Székesfehérvár on Aug. 27, 1310. His foreign policy, aimed at the aggrandizement of his family, benefited Hungary greatly. His alliance with Poland for mutual defense against the Mabsburgs and the Czechs, made at Trencsén in 1335 and confirmed the same year at the brilliant congress of Visegrád, where the princes of central Europe met to settle their differences,led to a victorious attack by the Magyars and the Poles together on the emperor Louis IV and his ally Albert of Austria. Charles wished to unite the kingdoms of Hungary and Naples under his eldest son Louis, but was frustrated by Venice and the pope, who feared that Hungary might become the dominant Adriatic power. Charles balanced this setback by a pact (1339) with his ally and brother-in-law Casimir III of Poland, whereby they agreed that Louis of Hungary should succeed to the throne of Poland on the childless Casimir's death. A statesman of the first rank, Charles not only restored his kingdom to the status of a great power but also enriched and civilized it. He was pious, courtly and valiant, popular alike with the nobility, the clergy and the middle classes, whose welfare he did much to promote. His court was famous throughout Europe as a school of chivalry. Three sons, Louis, Andrew and Stephen, survived him. Charles died on July 16, 1342, and was buried beside the high altar at Székesfehérvár, the ancient burial place of the Arpbds.

See D. G. Kosbry, *A History of Hungary,* with bibliography (1941). (GE. GR.)

CHARLES I (1227–1285), king of Naples and Sicily, the first of the Angevin dynasty, was the son of Louis VIII of France and Blanche of Castile. Born in March 1227, a few months after his father's death, he grew up under the protection of his mother and of his elder brother, Louis IX. He received the countships of Anjou and Maine as appanages in 1232. He was married to Beatrice, daughter and heiress of Raymond Berengar IV of Provence, in 1246 and, with Louis IX's help, established himself effectively as count of Provence, despite the claims of James I of Aragon and the efforts of certain towns toward autonomy. Accompanying Louis on his Egyptian crusade (1248), Charles was taken prisoner with him (1250). Released, he returned to France and began to add to his domains. He even tried to acquire Hainaut in return for help to Margaret of Flanders. By intervening in the disputes between communes and feudal lords, he became himself lord and protector of certain lands in Piedmont. Friendly relations with Genoa gave him control of the routes into Italy from the west. After revolts in Provence and in Piedmont had been suppressed (1262), his position appeared incontestable.

Pope Innocent IV had already proposed that Charles take the crown of Naples and Sicily from Manfred, the bastard son of the Hohenstaufen emperor Frederick II (see NAPLES, KINGDOM OF; SICILY: *History*). Pope Urban IV repeated this proposal in 1263, and agreement was finally reached in 1265 between Charles and Urban's successor, the French pope Clement IV, who satisfied Charles's heavy demands for financial help. For military help Charles began negotiations with the Guelphs of northern Italy.

In June 1265, after narrowly escaping capture by Manfred's fleet, Charles arrived in Rome, where he waited to collect a powerful army. On Jan. 6, 1266, he received the crown of Naples and Sicily from the pope. Crossing the Neapolitan border at Ceprano, Charles moved toward Benevento where, on Feb. 26, 1266, after a hard-fought battle, Manfred was defeated and killed. Two years later Conradin (*q.v.*), last legitimate descendant of the Hohenstaufen, came to Italy hoping to win the support of the Italian Ghibellines, to start a revolt in the kingdom and to take it from Charles. Defeated and captured at Tagliacozzo (Aug. 23, 1268), Conradin was taken to Naples and executed.

Following the example of his Norman and Hohenstaufen predecessors, Charles sought to make his kingdom a great Mediterranean power. He accompanied Louis IX on the Tunisian crusade in 1270, where he fought with great valour. His expeditions in the Balkans gained him Albania, with Durazzo and Corfu, and Achaea. In 1277 he assumed the title of king of Jerusalem, after purchasing the right of succession from Mary of Antioch and Hugh III of Cyprus. In Italy. meanwhile, the pope looked to Charles to maintain political stability and gave him a free hand in the papal states, and Charles also took advantage of the troubles in Tuscany and Lombardy to bring several cities there under his suzerainty by intervening on behalf of the Guelphs. His ever increasing power, which he sometimes abused, finally alarmed some of his former supporters.

To finance his vast projects Charles relied on heavy taxation. In southern Italy, a poor land already bled white in Frederick II's wars, this taxation not only neutralized the effect of his legislative attempts to give the country a good administration but also provoked widespread discontent, which misgovernment by his French and Provençal officials rendered more acute—especially in Sicily, which had ceased to be the pivot of the kingdom since Charles had moved the capital from Palermo to Naples. Revolt broke out at Palermo on March 31, 1282, and led to the expulsion of the Angevins from Sicily (see VESPERS, SICILIAN). The rebels then appealed to Peter III of Aragon, who, as husband of Manfred's daughter Constance, presented himself as Manfred's heir. To settle the dispute it was naïvely suggested that Charles and Peter should fight a duel at Bordeaux, in the presence of the king of England, but neither of the contestants appeared on the appointed day (each accused the other of cowardice and bad faith). Savage land and sea warfare ensued. While the Sicilians and the Aragonese, having invaded Calabria, were trying to spread the rebellion to the mainland, Peter's fleet, under Giovanni da Procida, destroyed the Angevin fleet in the gulf of Naples (June 5, 1284) and took Charles's son prisoner. Preparing a counteroffensive, Charles died suddenly at Foggia on Jan. 7, 1285, leaving his kingdom in a state of chaos.

CHARLES II THE LAME (c. 1254–1309), king of Naples and, by title, of Sicily, was the son and heir of Charles I (*q.v.*). As prince of Salerno, he was married in 1270 to Mary, daughter of Stephen V of Hungary, while his sister was married to Mary's brother, the future Laszlo IV. In 1283, early in the War of the Sicilian Vespers, he presided as king's vicar over the parliament at San Martino in Calabria and had to make serious concessions to the nobility. Captured by the Aragonese in the sea battle of June 5, 1284, he was in their hands when his father died (1285). Negotiations for his release were prolonged by the papacy's resistance to the cession of Sicily to the Aragonese. Released at last under the treaty of Canfranc (in Aragon) of Oct. 4, 1288, Charles was crowned king by Pope Nicholas IV (May 29, 1289), absolved of his renunciation of Sicily (as prejudicial to papal suzerainty and exacted under duress) and encouraged in his resumption of war against the Aragonese, who moreover were maintaining themselves on the mainland in the vain hope of acquiring Naples as well as Sicily. Charles, however, relied more on papal diplomacy than on force to recover Sicily, and indeed Alfonso III of Aragon (d. 1291) and his successor James II (James I of Sicily from 1285) might have been ready to yield Sicily in return for other advantages. James in fact agreed, under the treaty of Naples (1295) with Pope Boniface VIII, Charles's protégé, to cede Sicily back to the church, but the Sicilians themselves repudiated James and took his brother Frederick as their king instead. Intent on independence, they fought bitterly for it even when Charles and James allied themselves against them. Finally, under the treaty of Caltabellotta of Aug. 1302, it was resolved that Frederick should have Sicily, with the title of king of Trinacria, until his death, when it should revert to Charles, whose daughter Eleonora he was to marry.

The Sicilian mar cost Charles huge sums. Partly to raise money, partly perhaps out of religious fervour, he sacked the Saracen colony founded by the emperor Frederick II at Lucera, selling the survivors and their goods at public auction. He did his utmost to restore Angevin power in Italy. Furthermore, he successfully exploited his Hungarian ,connections. When his brother-in-law Laszlo IV died childless (1290), Charles secured papal recognition of his own eldest son Charles Martel as king of Hungary in opposition to the last Árpád claimant, Andrew III. When Charles Martel died (1295). Charles II's Sicilian preoccupations prevented his giving immediate help to his grandson Charles Robert against other pretenders. but in 1308. because of Charles's diplomacy and to papal support. Charles Robert was accepted by the Hungarian diet as king (Charles I of Hungary). Charles II died in Naples on May 5, 1309. leaving his kingdom to his third son, Robert.

CHARLES III (CHARLES OF DURAZZO) (1345–1386), king of Naples from 1381 to 1385, represented the fourth or Durazzo branch of his great-grandfather Charles II's descendants (junior to the Hungarian, Neapolitan and Taranto branches). When his father, Louis of Durazzo, died in prison (1362), the childless Joan I of Naples took Charles, the last male of the Angevin dynasty living in Naples, under her protection, to mask her plans for leaving the Neapolitan crown elsewhere. Louis I (*q.v.*) of Hungary, however, who had his own designs on Naples, required her first to send Charles to learn soldiering in Hungary (1365), then to give him as wife his cousin Margaret of Durazzo, daughter of his uncle Charles by Joan's sister Mary and so next in succession to the throne (1375). When Joan supported the antipope Clement VII (a protégé of France) and adopted Louis of Anjou (the French king Charles V's brother) as her heir, Hungary supported Pope Urban VI, who declared Charles of Durazzo king of Naples. Defeating Otto of Brunswick (Joan's fourth husband), Charles entered Naples in July 1381. Joan died in prison next year, but Charles had still to contend not only with Louis of Anjou but also with the restless Neapolitan barons. Louis, however, died suddenly at Bari (Sept. 1384). Then Urban, who had come to Naples and wanted to share in the government, quarreled with the forceful Margaret of Durazzo and declared the dynasty to be deposed and excommunicated (Jan. 1385). Besieged in Nocera by Charles, he was rescued by partisans of his. Finally Charles, against Margaret's advice, left Naples for Hungary and was crowned in Buda as rival to Louis of Hungary's daughter Mary. Soon afterward he was assassinated there, on Feb. 27, 1386.

CHARLES II THE BAD (1332–1387), king of Navarre from 1349, was the son and successor of Joan of France, queen of Navarre, and Philip, count of Evreux (Philip III of Navarre; d. 1343). Married in 1352 to Joan, daughter of John II of France, he demanded Champagne, Brie and Angoulême as fiefs once held by his mother. As John had granted these to the constable of France, Charles of La Cerda, Charles II's supporters assassinated the constable (1354), but since Charles II was meanwhile negotiating with the English (see HUNDRED YEARS' WAR) John had to make terms with him, ceding extensive lands in Normandy. When Charles continued plotting with the English, John had him arrested at Rouen (April 1356). Soon afterward the English captured John at Poitiers. Escaping from prison in Nov. 1357, Charles began a series of treacherous dealings with every party in France: with the dauphin (later Charles V), for whom he did at least suppress the Jacquerie; with Étienne Marcel (*q.v.*) in Paris; and with the English again. Having made terms with the dauphin (1359), he recovered his Norman lands at the treaty of Brétigny (1360). He then went back to Navarre. In Spain he first supported Pedro of Castile against Peter IV of Aragon (1362), then allied himself with Peter IV and Henry of Trastámara against Pedro (1363). Then John of France died (1364) and Charles V decided to secure Normandy against the Anglo-Navarrese threat. Bertrand du Guesclin defeated Charles II's forces at Cocherel in May 1364, and Charles. faced with a Franco-Aragonese plan to partition Navarre (1365), had to accept the treaty of Vernon (1366), keeping some Norman lands but renouncing all his major claims in France in return for a vague offer of Montpellier. These setbacks forced him to ally himself again with Pedro of Castile, who offered him Guipúzcoa, Álava and part of Rioja (part of Libourne, 1366), and nhose English allies Charles allowed to cross Navarre to defeat Henry of Trastámara at Nájera (1367)—though he had also promised Henry not to do so.

In 1369 Charles appeared at Cherbourg in Normandy. He then reached an agreement with Charles V (March 1370), signed a treaty with Aragon against Henry of Trastámara (April) and

began new negotiations with England (June). These last came to nothing, and he had to treat with France again in 1371. In 1372, after papal arbitration, he had to restore Guipúzcoa, Álava and Rioja to Castile.

In 1378 Charles II's son and future successor Charles the Noble had to acknowledge evidence found in France, proving that his father had been planning not only a new alliance with England but also the poisoning of Charles V. This meant the final loss of all Navarre's Norman possessions except Cherbourg. An attempt to seize Logroño from Castile (1378) ended in defeat, and the treaty of Briones (1379) tied Navarre to Castilian policy. Charles died (of leprosy?) on Jan. 1, 1387. His daughter Joan married first John IV of Brittany, then Henry IV of England.

CHARLES III THE NOBLE (1361–1425), king of Navarre from 1387, mas born in France, at Mantes, the eldest son of Charles II the Bad, whom he succeeded. Unlike his father, he pursued a consistent policy of peace both with Castile (which in gratitude restored certain districts to Navarre) and with France. By the treaty of Paris (1404) Charles not only renounced the Navarrese claims to Champagne but also ceded Cherbourg (which he had recovered from the English in 1393) and the countship of Evreux to Charles VI of France in exchange for Nemours, which was raised from a countship to a peerage-duchy for him. He did much to promote the economic welfare of his kingdom.

By his marriage (1375) with Leonor of Trastamara, daughter of Henry II of Castile, Charles had nine children, all of whom died early except his daughter and successor Blanche, who was married first, in 1402, to Martin I of Sicily (d. 1409), then, in 1420, to the future John II of Aragon. Her son by this latter marriage, Charles, prince of Viana, was declared the eventual heir to the throne. Charles III died at Olite on Sept. 8, 1425.

CHARLES I, king of Spain: see CHARLES V (emperor).

CHARLES II (1661–1700), king of Spain from 1665 to 1700 and the last monarch of the Spanish Habsburg dynasty, was born in Madrid on Nov. 6, 1661, the son of Philip IV by his consanguineous second marriage with Mariana of Austria. Weak and unhealthy from birth (he was not weaned until four years old), the last Spanish Habsburg seemed to symbolize by his physical and moral infirmities the misfortunes of his country. Charles's reign, which began on the death of Philip IV in 1665, opened with a ten-year regency under the queen mother, during which the government was preoccupied with combating the ambitions of Louis XIV in the Low Countries and with intrigues at court involving the queen, her Jesuit confessor Johann Eberhard Nithard, her subsequent favourite Fernando de Valenzuela, and the king's bastard brother Don John (1629–79) of Austria. Charles II came of age in 1675. There were two phases in the period of the king's personal government; the first, concerned with resistance to the French imperialism of Louis XIV, ended with the peace of Rijswijk in 1697; the second, the last three years of the reign, was dominated by the succession problem, for by then it was clear that Charles, who had married in 1679 Maria Luisa of Orléans (d. 1689) and in 1689 Mariana of Neuburg (d. 1740), would father no children.

Between 1675 and 1697 while the French armies paused only to consolidate past victories and to prepare new ones, internal politics in Spain were divided between the frivolity of Valenzuela, the messianism promoted by Don John, and the intrigues at court, in which the queens, their confessors and the foreign ambassadors unceasingly badgered the unfortunate Charles. Any attempt, such as that made by the conde de Oropesa, to introduce a worthwhile government mas quickly frustrated. These machinations reached their peak over the succession problem, when the Austrian and French parties (see SPAIN: History) were prepared to use any means to gain the support of the wretched king. At this stage, however, Charles II rose above the atmosphere at court, and came to acquire true stature by his obstinate defense of the majesty of the crown and his determination to preserve its territorial integrity. In this latter aim he failed, for his death in Madrid on Nov 1, 1700, led to the War of the Spanish Succession and the dismembering of Spain's European possessions.

(J. RE.)

CHARLES III (1716–1788), king of Spain from 1759 to 1788, was born in Madrid on Jan. 20, 1716, the first child of Philip V's marriage with Isabella of Parma. He ruled as duke of Parma, by right of his mother. from 1732 to 1734, and then became king of Naples, where he served a useful apprenticeship in enlightened despotism. On the death of his half brother Ferdinand VI in 1759 he became king of Spain and resigned the crown of Naples to his third son. Ferdinand.

Charles III was convinced of his mission to reform Spain and make it a first-rate power. He brought considerable qualities to the task. In spite of a fanatical addiction to hunting, his frugality and his application to the business of government impressed foreign observers as well as his own subjects. His religious devotion was accompanied by a blameless personal life and a chaste loyalty to the memory of his wife, Maria Amalia of Saxony, who died in 1760. On the other hand he was so highly conscious of royal authority that he sometimes appeared more like a tyrant than an absolute monarch. His greatest quality, however, was his ability to select effective ministers and continually to improve his government by bringing in men of higher quality like the conde de Aranda and conde de Floridablanca. While conferring with them regularly Charles was also wise enough to give them sufficient scope for action.

The survival of Spain as a colonial power and therefore as a power to be reckoned with in Europe was one of the main objects of Charles's policy. His foreign policy, however, was not successful. Fearing that a British victory would upset the balance of colonial power, he signed the Family compact with France in Aug. 1761. This brought war with Great Britain in Jan. 1762. Charles overrated his own strength and prospects and those of his ally. Sharing in the defeat, he lost Florida and showed up Spanish naval and military weakness. In the American Revolution Charles III was caught between a desire to embarrass his colonial rival, which accounts for his undercover aid to the American revolutionaries from 1776, and fear for his own American possessions, which led him to offer his mediation in 1779. When Great Britain refused his conditions, he declared war. but at the same time he refused to recognize United States independence. Charles was more successful in strengthening his own empire. Commercial reforms, designed to open new routes and new ports for trade between Spain and the colonies, were undertaken from 1765. Territorial readjustments were carried out in the interest of defense, and a modern administrative organization, the intendant system, of French origin and already operating in Spain itself, was introduced. Released from the former commercial restrictions, secured against attack, and with the prospect of better administration, the Spanish empire under Charles III assumed a new look.

In Spain Charles was concerned to make himself more absolute and therefore better able to undertake reform. His ecclesiastical policy was conditioned by his determination to complete the subordination of the church to the crown. He allowed no papal bulls or briefs in Spain without royal permission. He particularly resented the Jesuits, whose international organization and attachment to the papacy he regarded as an affront to his absolutism. Suspecting their loyalty and obedience to the crown in the American colonies, he also chose to believe that they were the instigators of the violent riots in Madrid and elsewhere in 1766. After a commission of investigation, he ordered their expulsion from Spain and the colonies (1767). In 1773, co-operating with the court of France, Charles succeeded in procuring from the papacy the complete suppression of the society. Charles's opposition to ultramontanism also led him to curb the arbitrary powers of the Inquisition, while his desire for reform within the church caused him to appoint inquisitors-general who preferred persuasion to force in ensuring religious conformity.

Charles III improved the agencies of government through which the will of the crown could be imposed. He completed the process whereby individual ministers replaced the royal councils in the direction of affairs. In 1787 with the assistance of Floridablanca

he co-ordinated the various ministries by establishing a *junta de estado* whose regular meetings could produce a concerted policy. He tightened crown control of local government by stimulating his intendants and giving the council of Castile supervision of municipal finances. The objective of his government was to create the conditions in which industry and trade could improve. By the end of his reign Spain had abandoned its old commercial restrictions and, while still excluding foreigners, had opened up the entire empire to a commerce in which all its subjects and all its main ports could partake. Protected against foreign competition, the native cotton industry grew rapidly, and the state itself intervened in the production of luxury goods. Charles III's agrarian policy, however, timid in face of landed interests, failed to deal with the greatest obstacles to agricultural progress and to the welfare of the rural masses in Spain—untilled latifundia and strict entail. In fact strength rather than welfare was the aim of Charles III. Within these limits he led his country in a cultural and economic revival, and when he died, in Madrid, on Dec. *14, 1788,* he left Spain more prosperous than he had found it.

CHARLES IV (1748–1819), king of Spain from *1788* to *1808,* was the second son of Charles III of Spain and Maria Amalia of Saxony. He was born at Portici, Italy, on Nov. *11, 1748.* His elder brother being unfit to rule, Charles IV succeeded his father in *1788.* His political capacities were still untried, but he began by keeping Charles III's policy and ministers. Within four years, however, he had replaced the conde de Floridablanca by the conde de Aranda, and Aranda by Manuel de Godoy (*q.v.*). The political decisions of Charles IV have usually been attributed to the influence of his wife, Maria Luisa of Parma, a strong-willed and meretricious woman, eager to satisfy her passions and to gratify her lover Godoy. While Charles certainly possessed little intelligence or will power and undoubtedly listened to her and to Godoy, it was the French Revolution that disrupted the Spain of Charles IV and determined the course of his rule *(see* SPAIN: *History).* From *1796* Spain was dragged through France's nars in a satellite role. By *1808* Charles's son Ferdinand was heading an opposition faction which Godoy attempted to expose but which was highly useful to Napoleon. Threatened from within and without Charles decided to embark for America. He got no further than Aranjuez. There an insurrection, organized and led by the Fernandista party, broke out on March *17, 1808.* As a result Godoy was relieved of his offices and imprisoned, while Charles abdicated the crown to Ferdinand. He soon retracted and put himself at the mercy of Napoleon. The latter by threats and deception got the new king to leave Madrid and lured him to Bayonne for an interview. There he obtained Ferdinand's abdication of the crown in favour of Charles IV and, immediately after, Charles IV's abdication in his own favour (May *5, 1808).* Charles then retired to Rome where he died on Jan. *20, 1819.*

CHARLES VIII (KARL KNUTSSON) *(1408* or 1409–1470), king of Sweden from *1448,* was a scion of Sweden's highest nobility. In *1436* he joined the noble faction supporting the peasants' revolt against Eric of Pomerania, king of the Northern union of Denmark. Sweden and Norway. Without scruples, Charles played king, *riksrdd* and peasant leaders off against one another. In the end he helped to subdue the revolt. In *1438* he was elected regent of Sweden. Thus established, he led the Swedish resistance to Eric. who was deposed. When Christopher (*q.v.*) of Bavaria, already king of Denmark. was elected king of Sweden in *1440,* Charles could not but acquiesce. He was then accorded considerable advantages, which allowed him to establish himself at Viborg castle in Finland. In *1448* Christopher III died, and Charles succeeded in having himself elected king, though some powerful nobles were against him.

In his foreign policy Charles aimed at substituting Swedish hegemony in the north for the joint system of the Northern union. At home, he reclaimed many royal fiefs from the nobles, and penalized the church for its long abuse of its economic privileges. These policies he sought to strengthen by nationalistic propaganda. By *1457,* Charles had spent his resources in lost campaigns abroad, while at home church and nobility united against him. He had to flee, and Christian I of Denmark was elected king. Recalled in *1464,* Charles fled again in *1465* but was finally reinstated in *1467.* Henceforth he was king in name only; the real power lay with the nobles. He died in Stockholm on May *15, 1470.*

See I. Andersson, *History of Sweden* (1956). (G. T. WE.)

CHARLES IX (1550–1611), king of Sweden, was born Oct. *4, 1550,* the youngest son of Gustavus I Vasa (*q.v.*) and his second wife, Margareta Leijonhufvud, and by his father's will became in *1560* duke of Sodermanland, Narke and Varmland. In 1568 he was one of the leaders of the rebellion which deposed his half-brother Eric XIV and put his other brother on the throne as John III. His subsequent relations with John were uneasy. Charles was grasping, ambitious and tenacious of his rights as duke. while John was morbidly suspicious of his loyalty. Charles disliked John's religious policy: his own religious position was intermediate between Lutheranism and Calvinism, which he sought to unite in common action against Rome. He successfully excluded John's new liturgy from his duchy and gave asylum to Lutherans fleeing from the persecution in Sweden. When, in Nov. *1592,* John was succeeded by his son Sigismund, king of Poland since *1587* and a zealous Roman Catholic, Charles used the church's fear of Rome and the aristocracy's fear of absolutist rule by an absentee monarch to force Sigismund to guarantee Lutheranism in Sweden and to have himself appointed as regent, ruling in conjunction with the aristocratic council.

Charles, however, distrusted the nobility; he was ambitious, and perhaps already contemplated usurping the throne. By *1596* he had quarreled irrevocably with the council, and in *1597* summoned a diet to Arboga in defiance of the council's advice and of Sigismund's prohibition. The majority of the council now fled to Poland; Sigismund was defeated by Charles at Stångebro in *1598;* in *1599* he was deposed in Sweden and Charles became king in all but name, though he was not crowned until *1607.*

Charles had taken a savage vengeance on his noble opponents and throughout his reign his relations with the nobility remained tense. He relied on the political support of the commonalty, exploiting their social grievances and playing on their emotions by crude but effective demagogy. The deposition of Sigismund entailed a war with Poland; and though Charles succeeded in preserving Estonia for Sweden, he suffered at Kirkholm *(1605)* one of the most disastrous defeats in Swedish military history. His intervention in Russia, though perhaps necessary to prevent Polish control of that country, proved unfortunate; and his provocative policy toward Denmark led to a costly war *(1611)*

Charles was an excellent administrator, a fair theologian and a competent commander who appreciated the value of the new tactics used by the Dutch. He greatly benefited Sweden by his vigorous development of metallurgical industries, by introducing foreign technicians and entrepreneurs and by sponsoring the printing of the medieval "Land-Law." He is popularly honoured as the saviour of Swedish Protestantism. But he was not an attractive character; ruthless, unscrupulous and choleric, brutal and coarse in speech and action, he tried to rule by means of a diet subordinated to his will and by a system of delation and terror which reflected the insecurity of his position. In *1579* he married Maria of the Palatinate (d. *1589)* and in *1592* Christina of Holstein: the eldest son of this marriage was his successor Gustavus II Adolphus. He died on Oct. *30, 1611.*

CHARLES X GUSTAVUS (1622–1660), king of Sweden from *1654,* was born at Nyköping castle on Nov. *8, 1622,* the son of

John Casimir, count palatine of Zweibriicken, and Charles IX's eldest daughter Catherine. He received a thorough education, rounded off with an extensive tour abroad (1638–40). When he returned to the S edish court he became secretly betrothed to Queen Christina, then still a minor. In 1642 he joined the Swedish armies in Germany, under Lennart Torstensson. Back in Sweden in 1645, he found that Christina had broken their engagement. His efforts to regain her hand proved fruitless, but she secured his appointment as generalissimo of the Swedish forces in Germany (1648), though many nobles, including Axel Oxenstierna (*q.v.*), opposed this move. In 1649 she went further and declared him her successor; next year he was recognized as heir to the throne. After her abdication he was crowned king (June 6, 1654).

Charles's first task was to tackle the country's chaotic finances. In the *riksdag* of 1655, with support from the commons, he imposed the so-called Reduction, a law requiring nobles to give up a quarter of their crown land holdings; and he reserved the right of further such request, much though the nobles opposed him. Little, however, was done to carry out these measures: during most of his reign, Charles was too busy with his wars.

In 1655 the estates sanctioned war against Poland. Charles's own advice no doubt influenced the decision, but Sweden's role as a new great power was at stake. War was declared because the Polish Vasas claimed the Swedish crown; the real reason was a hope for territorial gains on the southern Baltic shore to form a link between Sweden's eastern and western possessions there and to advance toward control of the Baltic. Besides, Charles feared that the Russians might exploit a time of Polish crisis by moving west ard. The Poles would not ally themselves with him to check the Russians, so Charles had now to fight Poland.

At first success in Poland was so complete that Charles extended his aims. Before the end of 1655 Cracow had surrendered,' John Casimir, the Polish king, had fled to Silesia and Charles had had himself proclaimed king. Early in 1656 Frederick William, elector of Brandenburg, was forced into an alliance and had to acknowledge Sweden's sovereignty over East Pmssia. Yet despite his brilliant victories (*e.g.,* at Warsaw in July 1656), Charles could not subdue the growing opposition of the Polish guerrillas, and his various plans for the partition of Poland were never realized. In June 1656 the Russians had begun hostilities: the Swedish army in ravaged Poland was in danger. The Danish declaration of war in June 1657 therefore came almost as a relief. Charles left Poland with his army and directed a surprise attack against Denmark from the south—the stratagem that Torstensson had used against Christian IV in 1643. Jutland was occupied during the autumn of 1657, and early in 1658 the extremely severe frost led Charles to venture upon one of the most daring undertakings in modern military history—the crossing of the frozen Belts. In panic the Danes agreed to the hard terms imposed at Roskilde (Feb. 26, 1658) whereby Sweden received the provinces of Skåne and Bohuslan and other territories.

Charles now prepared for an attack on Brandenburg, which together with Austria had joined Sweden's enemies. For this, however, he required French or English support, and there was little likelihood of either. He therefore decided instead on a second attack on Denmark, as the Danes had become too friendly with the Dutch and stubbornly refused to comply with certain conditions of the peace. His aim this time was the complete conquest of Denmark and the creation of a unified northern state, but Copenhagen was energetically defended by the Danes. The Swedish position was already difficult when, on Feb. 13, 1660, Charles suddenly died in Goteborg at the *riksdag,* which had been summoned to decide on new taxes and levies. As a military commander Charles X was outstanding. In his campaigns he showed great daring, mobility and ruthless energy. As a diplomat and statesman he displayed the same qualities, but his active imagination and his fondness for new alignments to suit changing conditions make his plans seem somewhat hazardous and incoherent. In Oct. 1654 he had married Hedvig Eleonora of Holstein-Gottorp, by whom he had a son, Charles XI, who succeeded him.

CHARLES XI (1655–1697), king of Sweden from 1660 to 1697, was born in Stockholm on Nov. 24, 1655, the only son of Charles X Gustavus and of Hedvig Eleanora of Holstein-Gottorp. He succeeded to the throne before he was five years old and, the provisions for a regency made by his father being set aside, the nobility gained complete control of state affairs during Charles's minority. The new king was not a strong child, and the queen mother, in her natural and sensible desire to improve his physical health, managed to limit strictly the time he spent on bookish studies. The shortcomings of Charles's formal education were not therefore due to neglect, as frequently asserted, but to a calculated preference for open air pursuits. However, the king was always an eccentric speller and throughout life tended to prefer oral consultation with experts to the perusal of letters and memoranda. From childhood onward he sought comfort and support in religion, which increasingly coloured and dominated his life.

When Charles was declared of age in 1672, observers took for granted his devoutness but many were taken aback by his shrewdness in political matters. It became obvious that he had been considerably influenced by men of the royalist party within his household, who advocated the resumption of alienated crown lands both as a measure directed against the power and the riches of the nobility and as a means to provide a sound financial backing for increases in the armed forces without recourse to foreign subsidy treaties. Charles XI's shyness as well as his loyalty to the former regents postponed sweeping changes and rendered his assumption of personal government rather nominal in the years 1672–75. But the war in which Sweden thereafter became involved (see SWEDEN: ***History)*** sealed the fate of the regents and of the nobility as a class. King and country alike were indignant at the bad state of the army and navy; Charles now broke with the majority of the council and began to rely on military and civil advisers of the reform party. Once peace was restored in 1679, a reform program was put into effect: former regents and councilors found guilty of maladministration were heavily fined, alienated crown lands were resumed and a strong army and navy financed from the proceeds, and a bureaucracy loyal to the crown was recruited. Parallel with this development—indeed a necessary complement to it—absolutism gradually emerged as the form of government.

The decisiveness of Charles XI's personal initiative in the events of 1675 to 1693 must remain a matter of opinion, but the importance of the moral command of the king, earned by his patriotic and inspiring role in the war years, should not be underrated. Although the previously accepted picture of an iron-willed, dominating personality has to be modified to show a ruler less consistent, more easily swayed by advisers, the persistence with which Charles XI stuck to the main aims of the reform program provides the essential continuity in the revolutionary 1680s and '90s, transcending changes in policy and personnel within the royalist party. In the war years Charles XI, though no great tactician, had provided leadership and had shown a willingness to take risks which materially contributed to Sweden'' victory over Denmark; in the period of reform the king's drive, his suspicious control and his relentless devotion to hard work were significant factors in the success achieved. The military reorganization and the inspection and training of troops were of particular interest to him, as was the building of churches and the furthering of the religious instruction of his subjects. On religious grounds he objected to the serfdom which existed in the Swedish trans-Baltic provinces, but he was unable to abolish it owing to the opposition of the local estates.

In his personal life Charles loved very deeply his wife, the Danish princess Ulrika Eleonora, whom he married in 1680 and who bore him seven children before her death in 1693. He was a devoted father and his concern for the first-born boy (afterward Charles XII), his only son to survive infancy, found expression in a careful preparation of the prince for his future kingship.

Charles XI never felt well after his wife's death and he died, prematurely, of cancer of the stomach, in Stockholm on April 5, 1697. In adult life his temper had been hot; his long final illness he bore with marvelous patience. He was hated in his lifetime by those families hit by the resumption of crown land and by those who disapproved of the absolutist form of government, but the reforms carried out in his reign were of fundamental importance.

See A. Aberg, ***Karl** XI* (1958). (R. M. **HA.**)

CHARLES **XII** (1682–1718), king of Sweden from 1697 to 1718, was born on June 17, 1682, the second child and eldest (and only surviving) son of Charles XI of Sweden and Ulrika Eleonora of Denmark. His early childhood was happy and secure, but the close family circle was broken by Ulrika Eleonora's death in 1693. Charles XI's chief consolation in his grief was a close companionship with his heir, and from this time onward Prince Charles accompanied his father on travels of inspection, on military exercises and on all kinds of official occasions as well as sharing his leisure hours. Charles XI's death in April 1697 meant that Charles XII had to take on the burden of absolute kingship—he was the first and only Swedish king born to absolutism—when he was barely 15 years old. Charles XI stipulated a regency for his son, but the regents (possibly influenced by what had happened to the regents of Charles XI's minority) proved anxious to get the new king's concurrence in all decisions and the *riksdag* called in Nov. 1697 declared him of age.

Charles XII had been carefully prepared for his task; he had been given excellent tutors and governors and was reckoned a model pupil. He showed, however, signs of an exceptionally strong will and gave repeated proof of his obstinate adherence to those standards he accepted from the religious and moral teaching of his family and his governors. In adolescence he gave much anxiety to those responsible for his safety by a personal program for toughening his physique. In particular, his intrepid horsemanship and his predilection for risks worried the old and staid among the courtiers. His nature had been open and confiding; but on succeeding to the crown he forced himself to assume a noncommittal and inscrutable behaviour in public, though in private he was much influenced by the instructions which his father had left for his guidance in matters of policy and by the men who had been in his father's confidence, especially Carl Piper.

Military Leader, 1700–09.—In accordance with traditional Swedish foreign policy, Charles sanctioned the marriage of his elder sister Hedvig Sophia with the duke of Holstein-Gottorp in 1699. Negotiations for his own marriage to a Danish cousin, the daughter of Christian V, were begun on Denmark's initiative but were kept inconclusive by Charles's advisers till the outcome of Danish negotiations with other powers should be known. These negotiations led in fact to a coalition between Denmark, Saxony and Russia, which, by attacking Sweden in the spring of 1700, began the Northern War (see SWEDEN: ***History***). The speedy success hoped for by the three allied powers did not materialize; rumours of rebellion by the Swedish nobility in case of war proved false and Charles XII soon showed that he had inherited a predisposition toward military skill which he did all in his power to develop. The early campaigns—the descent on Zealand (Aug. 1700) which forced Denmark out of the war, the battle of Narva (Nov. 1700) which drove the Russians away from the Swedish trans-Baltic provinces and the crossing of the Düna (1701) which scattered Augustus II (*q.v.*) of Poland's Saxon troops—were all planned and controlled by the officers whom Charles XII had inherited from his father and who had been guiding his own education in the art and science of war; but the king gave valuable help in fostering morale by his courage, his willingness to take risks, his religiously coloured optimism and his faith in the just cause of Sweden as the victim of a concerted attack.

Charles's actual responsibility in planning and executing armed operations constantly increased, so that from 1702 he became the equal of Karl Rehnskiold and the superior of the rest of his officer corps. Also from 1702 the king began to take a greater part in political decisions, since the men who had done the preliminary work on such matters—Count Bengt Oxenstierna, Samuel Åkerhielm and Thomas Polus—died or retired through ill-health. Most significant of these personal decisions was that to fight Augustus II (elector of Saxony as well as king of Poland) in Poland and to transform Poland from a divided country, where Augustus had both partisans and opponents, into an ally and a base for the final campaign against Russia. This transformation was to be accomplished by dethroning Augustus and substituting a Polish-born king willing to co-operate with the Swedes. Charles argued that this might lead to the acquisition of the duchy of Courland by S eden, while Poland would be compensated by land in the east and southeast lost to Russia in the 17th century. By the time this program had been brought to success and Stanislaw Leszczynski elected king of Poland—Augustus being forced to accept the settlement by a Swedish invasion of Saxony in Sept. 1706—Charles XII had matured both as a general and as a statesman. The war effort in its military and organizational aspects absorbed nearly all his energies. He was deeply conscious of the issue at stake—the fight for Sweden's great power status—and showed a predilection for radical solutions which he hoped would safeguard this position more permanently than had the efforts of his ancestors.

Charles was not unmindful of Sweden's role in central and western Europe; his support of the Silesian Protestants against the Catholic Habsburg emperor was firmly based on the Swedish guarantee of the peace of Westphalia and he continued that policy of the "balancing role" between the great coalitions of the west to which Swedish rulers and statesmen since 1660 had aspired in the hope of achieving prestige and territory by armed mediation in suitable circumstances. His first necessity in 1706, however, was to secure Sweden's position in relation to Russia, which, under Peter the Great, had from 1703 onward made good use of Charles XII's campaigns in Poland to train its army and undertake a piecemeal conquest of the Swedish east-Baltic provinces. Charles's troops left Saxony to invade Russia in the late autumn of 1707. They won the battle of Holowczyn in July 1708, but Russian scorched-earth tactics forced Charles to abandon his route to Moscow and turn instead into the Ukraine. Thereafter the Russians interfered successfully with the Swedes' communications and by the summer of 1709 Charles XII had no choice between accepting battle with the Russians or withdrawing once more into Poland. In the hope of a successful outcome which would strengthen his position in negotiations with Turkey, Charles, though wounded in the foot and unable to lead the army in person, chose battle and attacked the Russian fortified camp at Poltava on July 8 (new style; June 27, old style; June 28, Swed. style). The attack failed, and three days later the bulk of the Swedish army surrendered to the Russians. Charles was by then already on his way to Turkish-held territory, where he hoped to find allies.

Exile in Turkey, 1709–14.—Turkey's desire to reconquer Azov from Peter the Great augured well for its co-operation with Charles XII, but in the event—in spite of four Turkish declarations of war against Russia—the Swedish king was unable to pursue his plans vigorously since the army expected from Sweden never arrived. He became the object of Turkish intrigues and at one time (Feb. 1713) had to fight a regular battle, the *kalabalik* of Bender (mod. Bendery), to avoid a plot to deliver him into the hands of Augustus of Saxony, now restored in Poland. The closing of the Turko-Habsburg frontier due to an epidemic of plague, and the determination of the anti-French alliance in the War of the Spanish Succession to prevent Sweden from using its bases in Germany to attack its enemies, further circumscribed Charles XII's freedom of action in these years. The Swedish council, virtually in charge of affairs at home during his absence, was preoccupied with threats to Sweden from Denmark. The administrative and financial reforms which Charles promulgated from Turkey in order to distribute the burden of the war effort fairly and to increase both resources and efficiency were on the whole sabotaged and were put into effect only after his return to Swedish Pomerania in Nov. 1714 (having posted and ridden incognito, but with imperial permission, through

Habsburg and German lands, from Turkey to Stralsund, in 14 days and nights).

East Years, 1714–18.—For more than a year Charles fought a delaying action in Pomerania to keep Swedish troops on German soil as long as humanly possible, attempting at one and the same time to restore the prestige of Swedish arms, to keep the war away from Sweden itself and to prepare his diplomatic offensive for splitting the coalition, now augmented by Hanover and Prussia. A subsidy treaty with France, intrigues with the Jacobites to threaten the elector of Hanover in his position as king of England, and separate negotiations with his enemies averted the danger to Sweden once Charles in Dec. 1715 had been forced to leave Stralsund and Wismar to their fate; and the projected invasion of Scania (Skåne) never took place.

From 1713 onward Charles had realized that sacrifice of territory would be necessary, but was set on retaining Sweden's great power status either by ceding land for money for a given number of years only, not in perpetuity, or by allowing outright cession only as the price for guaranteed and considerable military help. The complicated negotiations of the years 1715–18 for equivalents and compensations must be seen in this context. Charles XII argued that any satisfactory peace on these lines could only be gained if military action backed up the diplomatic effort; to some extent, therefore, all negotiations, and especially those with the Russians at Åland throughout the year 1718, were designed to gain time. By the autumn of 1718 Charles XII had collected an army of 60,000 men but his strategic plan was never fully unfolded, for at the siege of Fredrikshald (Halden) at an early stage in the invasion of Norway he exposed himself to fire from the fortress (as part of his morale-building example for troops digging trenches under bombardment) and was on Nov. 30, 1718, fatally shot through the head. Rumours that he had been killed by someone from his own side began to circulate shortly after his death. The historical debate on this question continues, but the weight of the available evidence favours the view that Charles XII was killed by an enemy bullet.

Character.— Charles XII was not the simple and uneducated soldier-king he has often been made out to be. His intellectual pursuits were many and varied. He was always interested in architecture and in painting; he had favourite books that accompanied him everywhere; he could quote contemporary Swedish poetry and liked to argue theology and philosophy. His real bent was mathematical and scientific. He liked travel and treasured the paintings and prints from the Holy Land and the near east which Swedes sent by him on expeditions from Turkey collected for him. He became increasingly occupied with new ideas in administration; with men like Casten Feif in Turkey he discussed the books of fashionable cameralists and economists and from these talks developed a correspondence, penned by Feif but frequently quoting the king's own words and penetrating comments, with learned men and practical reformers in Sweden. Against this background must be seen Charles XII's ordinances for a reshaping of the Swedish bureaucratic organization. Many of these reforms were far ahead of their time.

Charles's character was complex, involving opposing trends. Kindhearted, he had to steel himself to say no; yet by virtue of his own sacrifices and devotion to duty he came to demand if not equal at least considerable sacrifices on the part of those classes in Sweden who were lukewarm about the war effort once the years of bad fortune set in after 1709. A youthful longing for romantic love, to be loved for his own sake, had to be buried in the harsh life of the soldier and produced, not the profligate, but the ascetic and chaste leader whose habits of bachelorhood grew upon him to the extent that his surroundings hardly credited his reiterated, "I'll marry after the war is over." Affectionate to his family. he was torn in two by the factions within it which his own childlessness tended to produce.

In military matters Charles learned from experience to insist on utter secrecy and for this reason he kept even his own officers guessing until the last possible moment. He had a good eye for the strategic battle place; he was concerned—both by temperament and by the logic of the Swedish situation—with battles rather than with sieges. He believed in personal leadership in actual battle, founded on a psychological theory of the fighting qualities of the Swedish peasant, who, he argued, could only overcome his phlegmatic and cautious nature when seeing his king sharing the dangers of the fight. He was keenly interested in the improvement of tactics and worked continuously on evolutions and drills which he in person exercised with the various regiments in turn. His ideas on hygiene and his avoidance of camp quarters were based on experience and in many ways ahead of his time.

Firmly believing in his responsibility to God, Charles held that the fortunes of war had taught him that one could not always be lucky, but one could always be honourable. He was against double-dealing and against the easy pledging of one's word only to break it at the first suitable opportunity. A self-righteous contempt for the behaviour of rulers which did not fit into his own moral code is evident. He lacked psychological insight into men's motives, probably because of his early assumption of the crown, and having been born to absolutism did not realize the strength of the antiabsolutist forces in Sweden. However, he had no illusions about his real power: "They will not obey me now when I am alive," he said once in answer to an appeal to settle the succession: "how can I expect them to obey me when I am dead?"

See Frans G. Bengtsson, *Karl XII:s Levnad*, 2 vol. (1935–36; Eng. trans. by N. Walford, *The Life of Charles XII,* 1960); Otto Haintz, *Konig Karl XII von Schweden,* 3 vol. (1958). (R. M. HA.)

CHARLES XIII (1748–1818), king of Sweden from 1809 and Norway from 1814 to 1818, was born at Stockholm on Oct. 7, 1748, the second son of Adolphus Frederick. king of Sweden, and Louisa Ulrica, sister of Frederick II of Prussia. In 1772 Charles assisted his brother Gustavus III (*q.v.*) in his *coup d'état* against the regime of the Hat and Cap parties, and for his services he was created duke of Sodermanland. During the Russo-Swedish War (1788–90) he served as admiral of the fleet at the battles of Hogland (July 1788) and Öland (July 1789). In March 1792, Gustavus III died and Charles became regent for the young king, Gustavus IV Adolphus. The real ruler of the country, however, was G. A. Reuterholm (*q.v.*), under whom the regency. despite its liberal promises, slid into despotism, while indecision marked its foreign policy. On the accession of Gustavus IV in Nov. 1796, Charles lost his influence in politics. On March 13, 1809, however, Gustavus was deposed and Charles became regent again. He was proclaimed king of Sweden on June 6, 1809.

Charles had grown prematurely old: the government was taken over for him by J. Bernadotte *(see* CHARLES XIV) who landed in Sweden in Oct. 1810 and was adopted by Charles as his son. The only child of Charles XIII's marriage (1774) with his cousin Hedvig Elizabeth Charlotte of Holstein-Gottorp had died in infancy (1798). By the treaty of Kiel (Jan. 1814), which detached Norway from Denmark. Charles became the first king of Sweden and Norway. He died at Stockholm on Feb. 5, 1818.

See E. Hildebrand and L. Stavenow (eds.), *Sveriges Historia* till *våra dagar,* vol. x (1925), vol. xi (1923); I. Andersson, *History of Sweden* (1956). (E. O. H. J.)

CHARLES XIV JOHN (CARL JOHAN; originally JEAN BERNADOTTE) (1763–1844), king of Sweden and Norway, was born the son of an avocnt at Pau in Béarn, France, Jan. 26, 1763. In 1780 he enlisted in the French army and in 1790 became adjutant, in Nov. 1791 a sublieutenant. and in 1794 brigadier general. During the campaigns in Germany, the Low Countries and Italy he restrained his troops from plundering and gained a reputation as a disciplinarian. Bernadotte first met Napoleon Bonaparte in 1797, in Italy. Their relationship, at first friendly. was soon embittered by rivalries and misunderstandings.

In Jan. 1798 Bernadotte, expected to succeed Bonaparte in command of the army of Italy, was appointed ambassador to Vienna. but his mission ended in April. On Aug. 17, 1798, having returned to Paris, he married Désirée Clary, Napoleon's former fiancée and the sister of Joseph Bonaparte's wife, Julie.

Bernadotte campaigned in Germany during the winter following his marriage, and from July to Sept. 1799 he was minister of

war. His growing fame, however, and his contacts with the Jacobins, irritated the prominent director. E. J. Sieyès, who engineered his removal. In Nov. 1799 Bernadotte refused to assist Bonaparte at the coup *d'état* of Brumaire, but neither did he defend the Directory. He was a councilor of state from 1800 to 1802 and became commander of the army of the west. In 1802 he fell under suspicion of complicity in the Rennes plot and, although no evidence has been found that he was involved, it is clear that he would have favoured constitutional limitation of the powers of the first consul or even his overthrow. In Jan. 1803 Bonaparte appointed Bernadotte minister to the United States. but Bernadotte delayed his departure because of rumours of approaching war between France and England and remained in Paris inactive for a year. When, on May 18, 1804, Napoleon proclaimed the empire, Bernadotte declared full loyalty to him and, in May, was named marshal of France. In June he took up the post of military and civil governor of Hanover. While in office there, he attempted to set up an equitable system of taxation. At this time also he began to accumulate a sizable fortune with the "gifts" from Hanover and Bremen.

In 1805, Bernadotte was given command of the I corps during the Austrian campaign. Difficulties delayed his march toward Vienna, and in the battle at Austerlitz the corps played a dramatic but somewhat minor role; nevertheless Napoleon gave Bernadotte command of the occupation of Ansbach (1806) and on June 5, 1806. made him prince of Pontecorvo. Bernadotte and his corps did not participate actively in the battles of Jena and Auerstädt (Oct. 1806), but nevertheless he was given enlarged responsibility in the Polish campaign, and in Jan. 1807 he defeated the Russians at Mohrungen. In July 1807 Bernadotte was named governor of the occupied Hanseatic cities. He was scheduled to lead a campaign against Sweden but this was abandoned, and in 1809 he took part in the Austrian campaign as commander of the IX corps. In the battle of Wagram he lost more than one-third of his soldiers and then returned to Paris "for reasons of health" but obviously in deep disfavour. Napoleon, however, next put him in command against the threatened British invasion of the Netherlands; Bernadotte ably organized the defense, but the British Walcheren expedition was fatally weakened by disease and had to withdraw. When Bernadotte returned to Paris, political suspicions still surrounded him, and his position remained uncertain.

Dramatic new possibilities, however, now opened up to him: he was invited to become crown prince of Sweden. In 1809 a palace revolution had overthrown King Gustavus IV of Sweden and had put the aged, childless Charles XIII (*q.v.*) on the throne. The Danish prince Christian August had been elected crown prince but died suddenly in 1810, and the Swedes turned to Napoleon for advice. The emperor, however, mas reluctant to exert a decisive influence, and the initiative fell to the young Swedish baron Otto Morner. Mörner approached Bernadotte since he respected his military ability, his skilful and humane administration of Hanover and the Hanse towns and his charitable treatment of Swedish prisoners in Germany. The *riksdag*, influenced by similar considerations, by their regard for French military power and by financial promises from Bernadotte, abandoned other candidates, and on Aug. 21, 1810, Bernadotte was elected Swedish crown prince. On Oct. 20 he accepted Lutheranism and landed in Sweden; he nas adopted as son by Charles XIII and took the name of Charles John (Carl Johan). The crown prince at once assumed control of the government and acted officially as regent during the illnesses of Charles XIII. Napoleon now tried to prevent any reorientation of Snedish foreign policy and moreover sent an immediate demand that Sweden declare mar on Great Britain; the Swedes had no choice, but though technically in a state of war between 1810 and 1812 Sweden and Great Britain did not come to active hostilities. Then, in Jan. 1812, Napoleon suddenly occupied Swedish Pomerania.

Charles John was anxious to achieve something for Sneden which would establish him and his dynasty in power. To that purpose he could, as many Swedes wished, have regained Finland from Russia, either by conquest or by negotiation. Political developments, however, prompted another solution, namely the conquest of Norway from Denmark, based on a Swedish alliance with Napoleon's enemies. An alliance was concluded with Russia in April 1812, others mith Great Britain and Prussia in March and April 1813, the British granting a subsidy for the proposed conquest of Norway. Urged by the allies, however, Charles John agreed to take part in the great campaign against Napoleon and to postpone his mar with Denmark. The crown prince landed his troops at Stralsund in May 1813 and soon took command of the allied army of the north. Although the Swedish troops contributed to the allied successes, Charles John intended to conserve his forces for the war mith Denmark, and the Prussians bore the brunt of the fighting.

After the decisive battle of Leipzig (Oct. 1813) Charles John succeeded in defeating the Danes in a snift campaign and forced King Frederick VI of Denmark to sign the treaty of Kiel (Jan. 1814), which transferred Norway to the Swedish crown. Charles John now had dreams of becoming king or "protector" in France. But he had become alienated from the French people, and the victorious allies would not tolerate another soldier in charge of French affairs. Bernadotte's dream dissolved, and his brief visit to Paris after the armistice mas not glorious.

New difficulties recalled him to Scandinavia. The Norwegians refused to recognize the treaty of Kiel, and in May 1814 a Norwegian assembly adopted a liberal constitution. Charles John conducted an efficient and almost bloodless campaign and in August the Norwegians signed the convention of Moss whereby they accepted Charles XIII as king but retained the May constitution. Thus, when main force might have established any system (for a time at least), the crown prince insisted on a constitutional settlement.

At the congress of Vienna (1814–15) Austria and the French Bourbons were hostile to the parvenu prince, and the son of the deposed Gustavus was a potential pretender to the throne. But thanks to Russian and British support the status of the new dynasty was undisturbed, and in Sweden its opponents were very few. Upon the death of Charles XIII, on Feb. 5, 1818, Charles John became king of Sweden and Norway and the former republican and revolutionary general became a conservative ruler. His failure to learn Swedish increased his difficulties; yet his experience, his knowledge and his magnetic personal charm gave him preponderant political influence. Though blunt in speech, he was cautious and farsighted in action. His foreign policy led in a long and favourable period of peace. based on good relations nith Russia and Great Britain. In domestic affairs. farsighted legislation helped the rapid expansion of Swedish agriculture and the Norwegian shipping trade; in Sweden the famous Gota canal was completed, postwar financial problems were solved and during the reign both countries enjoyed a rapid increase in population. On the other hand, the king's autocratic tendencies, restrictions on the liberty of the press and his reluctance to introduce liberal reforms in commercial and industrial policy and in the organization of the Snedish *riksdag* led to a growing opposition, which culminated during the late 1830s and led to some demands for his abdication. In Norway there was opposition to the Swedish predominance within the union and to the royal influence over the legislature. But the king rode out the storms, and the jubilee in 1843 was an occasion for popular acclaim. Charles John died on March 8, 1844.

CHARLES **XV** (1826–1872), king of Sweden and Norway from 1859 to 1872, was born at Stockholm on May 3, 1826, the eldest son of Oscar I of Sweden and Norway and Josephine of Leuchtenberg In 1850 he married Louisa, daughter of Prince Frederick of the Netherlands. In 1857 his father was struck-by illness and Charles became president of the council (June) and regent (September). He succeeded to the throne when his father died (July 8, 1859). Though Charles tried to uphold his rights against the government and the *riksdag*, the royal power was

much curtailed during his reign. Among important new liberal measures enjoying his support was the *riksdagsordning* of 1866. nhich introduced a bicameral system instead of the old estates A champion of "pan-Scandinavianism" and political solidarity among the three northern kingdoms. Charles gave half-promises of help to Denmark on the eve of the German-Danish War of 1864 over the Schleswig-Holstein question, but Sweden's army was unprepared and the other powers abstained, so that Charles had to remain neutral. He died at Malmö on Sept. 18, 1872. Charles was a stylish and warm-hearted man with a vivid interest in the other sex and was much liked in both his kingdoms. He was an amateur painter and a poet. He left one child. Louisa Josephina Eugenia. who in 1869 had married the crown prince Frederick of Denmark. His brother Oscar II succeeded him as king.

CHARLES, PRINCE, OF LORRAIXE (1712–1730). field marshal in the Austrian service distinguished chiefly for his governorship of the Xustrian Netherlands. The youngest son of Leopold, duke of Lorraine, he was born at Lunéville on Dec. 12, 1712. After his eldest brother Francis had married the future empress Maria Theresa (Feb. 1736), he became an Austrian officer.

Charles's first taste of active service was against the Turks in 1737 and 1738. When the War of the Austrian Succession broke out in Silesia (1740), Maria Theresa made him a field marshal, and in May 1742 he had his first hostile encounter with Frederick the Great at Chotusitz. In 1743 he was successful against the French and Bavarians.

In Jan. 1744 he married Maria Anna of Austria, Maria Theresa's sister. He and his wife were made joint governors of the Austrian Netherlands. but the princess died within a few months. When hostilities began again (April 1744) Charles crossed the Rhine at the head of an Austrian army, but hurried back to Bohemia nhen Frederick reopened the Silesian war. He had an early success and the Prussians were quickly expelled. In 1745 he took the field again, but was defeated by Frederick at Hohenfriedeberg and at Soor. Later, as commander in chief in the Low Countries, he was heavily defeated at Roucoux by the French under Marshal Saxe.

Opinions differ as to Charles's ability as a commander; but he was a great success as governor of the Austrian Netherlands during the peace from 1749 to 1756, introducing some enlightened reforms. After the early reverses of the Seven Years' War (*q.v.*) Maria Theresa recalled Charles to supreme command. At the time of Frederick's great victory at Prague (1757) he was shut up in that fortress and took no part in Daun's relief of the city or in the victory at Kolin. Subsequently he beat the Prussians at Breslau; but, after his success over the French at Rossbach. Frederick returned to Silesia and inflicted a crushing defeat on Charles at Leuthen (Dec. 5, 1757). whereupon the prince nas relieved of his command. Shortly after he returned to Brussels as governor and remained there until his death at the castle of Tervueren on July 4, 1780.

See L. Perey, *Charles de Lorraine et la cour de Bruxelles sous le regne de Marie Thérèse* **(1903).** (C. N. B.)

CHARLES (KARL LUDWIG JOHAXN) (1771–1847), archduke of Austria and duke of Teschen, third son of the Holy Roman emperor Leopold II, was born at Florence (his father then being grand duke of Tuscany) on Sept. j, 1771. His youth was spent in Tuscany. at Vienna (1790) and in the Austrian Netherlands, where he began his career of military service in the war of the French Revolution. He commanded a brigade at Jemappes, and in the campaign of 1793 distinguished himself at the action of Xldenhoven and the battle of Neerwinden. In the remainder of the war in the Low Countries he held high commands, and he was present at Fleurus. In 179j he served on the Rhine. and in the following year he was entrusted with the chief control of all the Austrian forces on that river. At the same time he was given the rank of field marshal general of the empire (*Reichsgeneralfeldmarschall*).

Charles's conduct of the operations against Jourdan and Moreau in 1796 marked him out at once as one of the greatest generals in Europe. At first falling back carefully and avoiding a decision. he finally marched away, leaving a mere screen in front of Moreau; falling upon Jourdan, he defeated him in the battles of Amberg and Würzburg, and drove him over the Rhine with great loss. He then turned upon Moreau's army, which he defeated and forced out of Germany. For this campaign. one of the most brilliant in modern history. *see* FRENCH REVOLUTIONARY WARS.

In 1797 he was sent to arrest the victorious·march of Bonaparte in Italy. and he conducted the retreat of the overmatched Austrians with the highest skill. In the campaign of 1799 he mas once'more opposed to Jourdan. whom he defeated in the battles of Ostrach and Stockach, following up his success by invading Switzerland and defeating Masséna in the (first) battle of Zurich. after which he re-entered Germany and drove the French once more over the Rhine. Ill-health, however. forced him to retire to Bohemia, from which he was soon recalled to undertake the task of checking Moreau's advance on Vienna. The result of the battle of Hohenlinden, however, had foredoomed the attempt, and the archduke had to make the armistice of Steyer.

In the short and disastrous war of 1805 the archduke Charles commanded what was intended to be the main army. in Italy. but events made Germany the decisive theatre of operations, and the defeats sustained on the Danube neutralized the success obtained by the archduke over Masséna in the desperately. fought battle of Caldiero. With the conclusion of peace began his active work of army reorganization. which was first to be tested on the field in 1809. As field marshal of Austria (since the old empire was dissolved) and as president of the council of war, supported moreover by the prestige of being the only general who had proved capable of defeating the French. he promptly initiated a far-reaching scheme of reform. which replaced the obsolete methods of the 18th century. the chief characteristics of the new order being the adoption of the "nation in arms" principle and of the French war organization and tactics. The new army was surprised in the process of transition by the war of 1809. of which Charles was commander in chief; yet even so it proved a far more formidable opponent than the old. and, against the now heterogeneous army that Napoleon controlled *(see* NAPOLEONIC CAMPAIGNS) it succumbed only after a desperate struggle.

At the end of the campaign the archduke gave up all his military offices, and he spent the rest of his life in retirement; except for a short time in 181j when he was governor of Mainz. In 1822 he succeeded to the duchy of Saxe-Teschen. Charles married. in 1815, Princess Henrietta of Nassau-\Veilburg (d. 1829). He had four sons. the eldest of whom. the archduke Albert (*q.v.*), became one of the most celebrated generals in Europe. and two daughters, the elder of whom. the archduchess Theresa, was married to the king of the Two Sicilies in 1837. Charles died at Vienna on April 30, 1847.

The caution that the archduke preached so earnestly in his strategical works (*Grundsätze der Strategie, erlautert durch die Darstellung des Feldzugs von 1796 in Deutschland,* 3 vol., 1814; *Geschichte des Feldzugs von 1799 in Deutschland und der Schweiz,* 2 vol.. 1819), he displayed in practice only when the situation seemed to demand it. though, his education certainly prejudiced him in favour of the defensive at all costs. He was at the same time capable of forming and executing the most daring offensive strategy, and his tactical skill in handling of troops was certainly equal to that of any leader of his time, with the single exception of Napoleon.

As a military writer, his position in the evolution of the art of war is very important. and his doctrines had the greatest weight. Nevertheless. they cannot but be considered as antiquated even in 1806. Caution and the importance of "strategic points" are the chief features of his system. Charles's theory and his practice form one of the most curious contrasts in military history. In the one he was often unreal, in the other he displayed. besides great skill. a vivid activity that made him for long the most formidable opponent of Napoleon.

See O. Criste, *Erzherzog Carl von Österreich, 3* vol. **(1912).**

CHARLES OF BLOIS **(c.** 1319–1364), duke of Brittany. was the son of Guy of Châtillon, count of Blois, and Margaret of Valois, sister of Philip VI of France. His marriage (1337) to

Joan the Lame of Penthièvre (d. 1384), daughter of Guy of Brittany, count of Penthibvre, gave him a right to the succession to Brittany, of which Guy's elder brother John III was duke. When John III died (April 1341), Joan's right of succession was disputed by her surviving uncle John, count of Montfort-l'Amaury, though he had promised to recognize it. John of Montfort was supported by Edward III of England, but Philip VI supported Charles, who captured John at Nantes (1341), besieged his wife Joan of Flanders at Hennebont (1342) and took Quimper (1344). John, however, escaped from prison and defeated Charles's partisans at Cadoret (1345). When John himself died (1345), his widow defended the claims of his son, John IV of Brittany, and Charles was taken prisoner at La Roche-Derrien (1347). Joan the Lame then defended his rights against Joan of Flanders until his release in 1356. English successes prevented the French from giving much help to Charles, but the young Bertrand du Guesclin defended Rennes against Edward III in 1357. Finally Charles was defeated and killed at Auray (Sept. 29, 1364), and Joan of Penthibvre renounced Brittany by the treaty of Guérande (1365). Charles in his lifetime had been venerated as a saint and wonder-worker by the people, and a cult grew up round his grave and relics at Grâces, near Guingamp. A papal inquiry (1371) produced 194 testimonies to his holiness, and in 1904 his beatification was proclaimed.

CHARLES THE BOLD OR LE TÉMÉRAIRE (1433–1477), duke of Burgundy from 1467, was born at Dijon on Nov. 10, 1433, the son of the duke Philip the Good and Isabella of Portugal. French by his paternal ancestry, the count of Charolais (*q.v.*), as he was at first styled, was brought up in the French manner as a friend of the dauphin, afterward Louis XI (*q.v.*) of France, who spent five years in Burgundy before his accession. Betrothed in 1439 to Catherine (d. 1446), the dauphin's sister, and married in 1457 to Isabella (d. 1465), daughter of Charles I of Bourbon, Charles in fact showed no hostility to France until he took over the government of Burgundy in April 1465, during his father's last illness. On his father's death (June 15, 1467), Charles became duke. He then gave rein to his overriding ambition to make Burgundy wholly independent of France and to raise it, if possible, to a kingdom.

Charles was almost entirely successful until 1474. He extended his possessions, organized them as a state and freed them from French control. Much annoyed by Louis XI's repurchase of the towns on the Somme which had been temporarily ceded to Philip the Good by the treaty of Arras (1435), he entered upon his lifelong struggle against Louis and became one of the principal leaders of the League of the Public Weal. After the battle of Montlhéry (July 16, 1465), he forced Louis to restore to him the towns on the Somme in the treaty of Conflans (Oct. 1465) and to promise him the hand of his daughter Anne of France, with Champagne as dowry. But when Louis encouraged Dinant in its revolt against Burgundy, Charles sacked it (1466); and the Liégeois, whom the French were continually inciting to revolt. were defeated in battle and deprived of their liberties after the death of Philip the Good (1467). Charles moreover outdid Louis by obtaining the alliance of Edward IV of England, whose sister Margaret of York he married as his third wife (July 1468). Louis now tried negotiations with Charles at Péronne (Oct. 1468). There, in the course of the discussions, Charles was informed of a fresh revolt of the Liégeois, secretly fomented by Louis. Looking on Louis as a traitor. Charles nevertheless treated with him but at the same time forced him to remove Flanders, Ghent and Bruges from the jurisdiction of the Paris *parlement* and to assist in quelling the revolt; Libge was destroyed and the inhabitants were massacred. The truce was not lasting. Louis cited Charles to appear before the *parlement* of Paris and seized some of the towns on the Somme (1470–71). The duke retaliated by invading Normandy and the fle-de-France, ravaged the country as far as Rouen, but failed in an attack on Beauvais (1471–72). A truce was made (Nov. 1472) and Charles decided to wait, before renewing his attempt, for assurances of further help from Edward IV and for the solution of the problem relative to the eastern border of his states.

Charles wished to extend his territories as far as the Rhine and to make them into a single unit by acquiring the lands between Burgundy, Luxembourg and the Netherlands. He lost no opportunity: he purchased the county of Ferrette, the landgraviate of Alsace and some other towns from the archduke Sigismund of Austria in 1469; he secured for himself the inheritance of the old duke Arnold of Gelderland in 1473; and he set nominees of his own in certain other places and wished to do the same at Cologne, where he intended to install a garrison as it was both an important centre of trade and an imperial electorate. To achieve his territorial aims, it only remained for him to subdue the Swiss cantons and to get Lorraine from René II (René of Vaudémont).

Meanwhile Charles had been reorganizing his army and the administration of his territories. Statutes promulgated at Thionville (1473) instituted companies of four squadrons, at his expense, and made rules for discipline and tactics; Charles also had many excellent guns cast. He hired mercenaries and took many Italian *condottieri* into his service. Intending to centralize the government, he created by statute a single *chambre des comptes* for the Netherlands, a *chambre du trésor* to survey the administration of the domain and a *chambre des généraux* to control the collection of taxes. He exacted very heavy taxes indeed from the estates-general, which became a regular institution in his territories. Moreover, he established the *grand conseil* at Malines, with jurisdiction to supersede that of the *parlement* of Paris, which he no longer recognized, and another *parlement* meeting alternately at Beaune and at Dole.

It remained for Charles to acquire a royal title. For a short time he entertained designs on the imperial crown; but this he renounced. On the other hand, he believed that he had persuaded the emperor Frederick III, in the course of conversations at Trier (Trèves), to agree to cro n him king. The royal insignia were ready and the ceremony arranged. when Frederick precipitately fled by night (Sept. 1473). He probably was suspicious of the ambitious Charles.

In less than three years, Charles's dream vanished. The crown had slipped through his fingers. He was obliged to give up his plan of taking the little town of Neuss, which he had unsuccessfully besieged for 11 months (July 1474 to June 1475), from the citizens of Cologne. Moreover, the treaty of Picquigny (Aug. 29, 1475) concluded by Edward IV and Louis XI made certain the defection of his English ally. Attacked by René of Lorraine, who had signed an agreement with Louis XI (Aug. 1474), and by a coalition of the Swiss, Sigismund of Austria and the towns on the upper Rhine, Charles took Nancy in Nov. 1475; but in March and in June 1476, he was defeated by the Swiss, at Grandson and at Morat. Next October he lost Nancy. Then, on Jan. 5, 1477. a further battle was fought outside Nancy, and Charles himself was killed; his mutilated body was discovered some days later.

The fragility of his achievement is proved by its rapid disintegration during the minority of Mary, his daughter by Isabella of Bourbon. Yet Charles the Bold was not merely a belated representative of the chivalrous spirit; he was a man of wide knowledge and culture, already a prince of the Renaissance. His haste, his lack of adaptability and his obstinacy lost him much more than did his visionary approach and his boldness.

CHARLES (953–c. 992), duke of Lower Lorraine, was a younger son of Louis IV, king of France, and thus a member of

the Carolingian family. He received the duchy of Lower Lorraine in 977 from the emperor Otto II. with whom he allied himself against his own brother King Lothair. After Otto's death (983) he was reconciled with Lothair. When Lothair's son and successor Louis V died without issue in 987, Charles was the only Carolingian claimant to the French crown, but Hugh Capet was chosen as king instead and war broke out between them. Charles gained some successes and captured Reims (989) but was treacherously seized by Adalberon, bishop of Laon, in 991. Handed over to Hugh, he was imprisoned at Orléans with his wife and younger children and died in prison about 992. His eldest son Otto, duke of Lower Lorraine, died about 1012.

See F. Lot, *Les Derniers Carolingiens* (1891).

CHARLES II (1365–1431), duke of Lorraine, was the son of the duke John, whom he succeeded in 1391. Whereas Charles's grandfather, the duke Rudolph (Raoul), had always remained loyal to France, John had already been susceptible to Burgundian influences, and Charles brought Lorraine completely into the Burgundian camp. Married in 1393 to Margaret of Bavaria, daughter of the future German king Rupert, he disputed with the French king's agents at Toul (1402) and about Neufchâteau (1410) and withstood the encroachments of the duc d'Orléans (Louis de France), whose forces he defeated at Champigneulles in 1407. Openly siding with John the Fearless (*q.v.*), duke of Burgundy, he acted as his representative at the Council of Constance (1414) and entered Paris with him on July 24, 1418, with the title of constable of France.

In his first will (Aug. 13, 1407; confirmed Feb. 7, 1409) Charles even forbade his daughters to marry French subjects, but plans for marrying the elder one, Isabella, to John of Lancaster, duke of Bedford, came to nothing. and Charles finally married her in 1420 to René of Anjou, heir to the duchy of Bar. The union of Bar to Lorraine was ensured when Charles disinherited his nephew Antoine. comte de Vaudémont, in his second will (Jan. 13, 1425) and proclaimed female succession to the ducal crown of Lorraine (Dec. 13). Charles died at Nancy on Jan. 25, 1431.

See, in addition *to* histories of Lorraine, P. Géant, "Étude sur le règne de Charles II . . . ," *Annales de l'Est* (1902); *M.* Francois, *Histoire des comtes et du comté de Vaudémont* (1935). (MI. F.)

CHARLES III THE GREAT (1543–1608), duke of Lorraine from 1545 to 1608, was born at Nancy on Feb. 18, 1543, the son of Francis I of Lorraine and Christina of Denmark. On his father's death (1545) his mother became regent for him, and in 1552 he was taken to Paris by Henry II of France after the French seizure of Metz, Toul and Verdun. In 1559 he was married to Henry's daughter, Claude de France.

After the death of Francis II of France (1560), Charles returned to Nancy to rule his duchy. He maintained good relations with the Holy Roman empire and was able to extend his frontiers eastward by the acquisition of Bitche, Phalsbourg, Marsal and St. Avold. In the French civil wars between Catholics and Huguenots he long took no part, despite the activity of his cousins of the house of Guise, but in 1584 he adhered to the League. He then tried to set up his eldest son Henry to dispute the right of the Protestant Henry of Navarre (the future Henry IV of France) to the French succession. Consequently German Protestant mercenaries ravaged Lorraine on their way into France (1587), and in Jan. 1592 Henry IV declared war. Henry's conversion to Catholicism, however, made Charles more conciliatory, and hostilities between them ended in 1594.

The reign of Charles III was the most brilliant in the history of Lorraine. He reformed the judiciary and the finances and encouraged economic development, creating a royal salt monopoly and establishing new mines and glassworks. He founded the University of Pont-à-Mousson in 1572, which he gave over to the Jesuits to combat Protestantism. He encouraged art and enlarged his capital, Nancy. He died at Nancy on May 14, 1608.

(Ro. M.)

CHARLES IV (1604–1675), duke of Lorraine and Bar, was born at Nancy on April 5, 1604, the son of Duke Henry II's brother Francis of Vaudémont. Married in 1621 to Henry's daughter Nicole, he became duke consort when she succeeded as duchess in 1624. He and his father, however, wanted to abolish female succession to the duchies, and Francis was proclaimed Henry's rightful successor in Nov. 1625. A few days later he abdicated in his son's favour. Resenting French intervention in Lorraine, Charles let Mme de Chevreuse (*q.v.*) involve him in the English coalition against France in 1627. From 1629, moreover, he encouraged Gaston, duc d'Orléans (*q.v.*), against the French government. The French having made him sign the treaty of Liverdun in 1632 and occupied Nancy in 1633, he abdicated in Jan. 1634 in favour of his brother Nicolas Francis, who renounced his cardinalate and married Nicole's sister Claude. Charles then went first to the Spanish Franche-Comté, then to Germany, revoked his abdication and entered the Habsburg service. to fight at Nordlingen (1634) and in several campaigns on the French frontier (see THIRTY YEARS' WAR). Nicole having gone to France in 1634, Charles in 1637 went through a bigamous marriage with Béatrix de Cusance (1614–63), the widowed countess of Cantecroy. Asking Pope Urban VIII to annul his marriage with Nicole, he refused to leave Béatrix pending judgment and was excommunicated from 1643 to 1645. Meanwhile the treaty of St. Germain (1641) had restored his duchies to him, with some diminution, but the French occupied them again in 1644 as he had resumed his intrigues. He then re-entered the Habsburg service, remaining with the Spaniards after the peace of Westphalia (1648). In 1652 he led two incursions into France to help the prince de Condé during the Fronde (*q.v.*), but in 1654 the Spaniards arrested him for dealings with Cardinal Mazarin. Imprisoned first at Antwerp, then at Toledo until the peace of the Pyrenees (1659), he recovered Lorraine and Bar by the treaty of Vincennes (1661) and then arranged for them to pass on his death to France under the treaty of Montmartre (1662), which however was annulled by the treaty of Nomény (1663). Nicole having died in 1657, Charles married Béatrix when she was dying in 1663, though he had meanwhile entertained some alternative and quite unsuitable matrimonial plans. Finally he married the 13-year-old Marie d'Aspremont in 1665. Driven from Lorraine by the French again in 1670, he went again to Germany. He won the battle of Konzer Briicke against François de Créquy on Aug. 11, 1675, took Trier on Sept. 6, but fell ill on Sept. 18 and died at Allenbach, near Trier, on Sept. 20.

CHARLES V (1643–1690), duke of Lorraine and Bar, was born in Vienna in April 1643, the son of Charles IV's brother Nicolas Francis. Brought up in France from 1656, he escaped to the Franche-Comté during Charles IV's negotiations of 1662 and thence to Germany. The emperor Leopold I gave him a regiment in 1664, and he distinguished himself at the battle of St. Gotthard. He was a candidate for the Polish crown in 1668–69 and again. when the French were occupying Lorraine. in 1674. Recognized by all save France as his uncle's heir in 1675, he was never to possess his duchies. Promoted field marshal by the emperor in 1675, he took Philippsburg in 1676. He married Eleonora Maria, dowager queen of Poland and the emperor's sister, in 1678. The peace of Nijmegen offered him his duchies under conditions that he rejected. In 1683, with a weak imperial army, he opposed the Turkish advance on Vienna. Two months after the Turks had invested the city, Jan Sobieski's Poles and the Bavarian and Saxon contingents arrived to reinforce Charles, and on Sept. 12 the Christians routed the enemy and raised the siege. Advancing into Hungary, Charles besieged Buda (1684), stormed Neuhäusel (1685), finally took Buda (1686) and, in Aug. 1687, won the great victory of Mohács. Transferred to the Rhine for the War of the Grand Alliance, Charles took Mainz and Bonn in 1689 but died suddenly at Wels, in Austria, on April 18, 1690. As well as the military genius that made him one of Louis XIV's most respected adversaries, he had qualities of statesmanship: his *Testament politique,* written in 1687, foretold the development of the Spanish succession crisis and also proposed the transformation of the Holy Roman empire into a centralized state. At the peace of Rijswijk (1697) Lorraine and Bar were assigned to his son Leopold Joseph Charles (1679–1729).

CHARLES (1270–1325), count of Valois from 1285 and of Anjou and Maine from 1290, was born in March or April 1270,

the third son of Philip III of France and Isabella of Aragon. Son of a king, brother of a king, uncle of three kings and father of a king of France, he was never to rule as king himself, though he was pretender to two crowns. In 1284, during the papacy's dispute with Aragon over Sicily, Pope Martin IV recognized Charles as king of Aragon, but Philip III's campaign on his son's behalf ended disastrously. Philip, who died on his return from Spain (1285), left Charles the countship of Valois in appanage. In 1290 Charles married Margaret of Anjou, daughter of Charles II of Naples, who gave him Anjou and Maine as her dowry in compensation for his renouncing his Aragonese claims. His brother Philip IV moreover gave Charles the countships of Alençon (1291) and Chartres (1294). Charles's second marriage (1301), to Catherine de Courtenay, granddaughter of the Latin emperor of Constantinople, Baldwin II, gave him a claim to the Byzantine succession, and Pope Boniface VIII thereupon invited him to help the papal cause in Italy. Charles subdued Florence for the pope and fought for Charles of Naples in Calabria and Apulia, but the attempt to recover Sicily failed. Catherine having died in 1307, Charles next married Mahaut (Maud) of Chbtillon in 1308. He then gave up his pretensions to the Eastern empire and sought election to the Western, but Pope Clement V gave his support to Henry of Luxembourg. In France, meanwhile, Charles had loyally served Philip IV, commanding his armies in Guienne in 1295 and in Flanders in 1297, 1299, 1300 (when he reduced Guy of Dampierre to submission) and 1303. In 1304 he contributed to Philip's victory of Mons-en-Pevèle. He also served in the abortive Flanders campaign of 1314. When his nephew Louis X became king (1314), Charles led the reaction against Philip's old minister, Enguerrand de Marigny (*q.v.*). On Louis X's death (1316), he tried to become regent of France. After a last campaign in Guienne (1324), Charles died at Le Perray near Rambouillet on Dec. 16, 1325. He had had four sons and ten daughters. His eldest son, Philip, became king of France in 1328, the first of the house of Valois.

See J. Petit, *Charles de Valois* **(1900).**

CHARLES, JACQUES ALEXANDRE CÉSAR (1746–1823). French mathematician and physicist, was an acute physical researcher and inventor. He was born at Beaugency, Loiret, on Nov. 12. 1746. From being a clerk in the ministry of finance, he turned to scientific pursuits. He was the first, in 1783, to employ hydrogen for the inflation of balloons (see BALLOON). and about 1787 he anticipated Gay-Lussac's law of the expansion of gases with heat, which on that account is sometimes known by his name. He improved the Gravesand heliostat and the aerometer of Fahrenheit and invented a "thermometric hydrometer," a "goniometer by reflection" and many other ingenious physical devices. In 1785 he was elected to the Academy of Sciences, and subsequently he became professor of physics at the Conservatoire des Arts et Métiers. He died in Paris on April 7, 1823. His published papers are chiefly concerned with mathematical topics.

CHARLES, THOMAS (1755–1814), Welsh religious leader, a founder of Calvinistic Methodism (*q.v.*) in Wales and an inspirer of missionary activities, was born in Carmarthenshire on Oct. 14, 1755. and educated at the dissenting academy in Carmarthen and at Jesus college, Oxford. After holding curacies in Somerset, he settled in 1783 in the neighbourhood of Bala, Merioneth, his wife's home. He failed to find a living in the established church, but his wife's shop provided some economic security and in 1784 he joined the Methodist society at Bala and became, in effect, a free lance. From his student days he had been under the influence of the Methodist revival, and he was deeply concerned to evangelize and, with a view to evangelism, to educate. Himself training the teachers, he set up numbers of schools, which at first circulated like those founded earlier by Griffith Jones, rector of Llanddowror, but soon settled into Sunday schools. He compiled a dictionary of the Bible and edited a quarterly magazine, both in Welsh; he composed a catechism in Welsh and English, and set up a printing press at Bala. He made a plea for more cheap Bibles in translation, and helped to found the British and Foreign Bible society (1804), which printed a Welsh Bible in 1806, and the London Missionary society. In Wales Methodism was still nominally within the establishment, but few clergy besides Charles were sympathetic. The rapid growth of Methodist societies and associations as a result of his labours led, insensibly yet inevitably, to the demand for a separate organization with its own ministers. Charles, who like Wesley never repudiated his own episcopal orders, long opposed this, but in 1811 he drew up a form of ordination and himself ordained eight lay preachers. He died at Bala on Oct. 5, 1814.

See D. E. Jenkins, *Life of Thomas Charles* **(1908).** (G. F. N.)

CHARLES ALBERT (1798–1849), king of Sardinia-Piedmont from 1831 to 1849, a ruler whose character, motives and impact on Italian history have been much debated by historians, was born in Turin on Oct. 2, 1798, the son of Charles Emmanuel (1770–1800), prince of Carignano, and Christina, daughter of the former duke of Courland. Charles of Saxony. Just after his birth the French annexed Piedmont, but Charles Albert was not taken into exile in Sardinia with his cousin King Charles Emmanuel IV (who abdicated in 1802). Instead he spent his early years in France and Geneva. Prince of Carignano in succession to his father (1800), he received the title of count from Napoleon in 1810 and began his career by being commissioned in a French dragoon regiment. When his cousin Victor Emmanuel I was restored in Piedmont (1814), French influences were unfashionable in Turin, and in 1817 Charles Albert was married to Maria Theresa, daughter of the Habsburg grand duke of Tuscany. Their son Victor Emmanuel II, afterward king of Italy, was born in 1820.

The nature of the restoration in Piedmont gave rise to subversive discussion and conspiracy. There were among the younger nobility some who hoped for reforms and others, members of the revolutionary secret societies, who wanted a constitution based on the Spanish model of 1812. The excitement over the revolution of 1820 in Naples brought these elements together. Several of the leaders of the plot which now took shape were men well known to the young prince. The Austrian intervention against the Neapolitan revolution precipitated an outbreak, and early in March 1821 Charles Albert was told by some of his friends that a military coup was about to take place. Its aim was to persuade the king both to grant a constitution (its precise nature was vague) and to lead a war against the Austrians. Charles Albert's conduct at this point is very difficult to follow. Certainly he tried to hold the conspirators in check and seems to have promised to confer with the king as a go-between, yet he himself would not support the conspiracy. When the garrison of Alessandria detonated the plot by mutinying, Cesare Balbo (*q.v.*) tried to persuade Charles Albert to assume the leadership of the constitutionalist movement. Even the king was in fact prepared to give way, but news arrived of the decisions of the congress of Laibach (*q.v.*) and both he and Charles Albert hesitated too long. A rising took place at Turin; the king was unwilling to suppress the rebels firmly and abdicated in favour of his brother Charles Felix (night of March 12–13). Charles Albert found himself acting as regent for the new king, who was not in Turin at the time. He swore to observe the Spanish constitution (March 15)—in order, he later said, to prevent further disturbance. Charles Felix ordered him to report at Novara, where he was put under arrest while the movement was crushed with Austrian help. The episode ended with the exile of Charles Albert to Florence. He had by his actions won himself the suspicions of the legitimists and the hatred of the liberals, who from this time regarded him with deep distrust. He was restored to favour with the king after serving with the French army in Spain in 1823 and took an oath to maintain the existing institutions of the kingdom when he should ascend the throne. His reputation with the liberals, on the other hand, never fully recovered.

Charles Albert succeeded to the throne on April 27, 1831, at Charles Felix's death. Almost at once he was addressed by Giuseppe Mazzini (*q.v.*) in an open letter which urged him to be the Napoleon of liberty and national independence for Italy, but he showed no inclination to be anything of the sort and began his reign on a distinctly conservative note. He omitted the revolutionaries of 1821 from the operation of the usual accession amnesty. When another conspiracy was discovered in 1833 it was

punished by a wave of executions. Vincenzo Gioberti was exiled and Mazzini condemned in absentia. An oppressive censorship stifled the expression of thought: Cavour remarked that Turin was an intellectual hell. Nevertheless, there was some material and administrative progress; tariffs were reformed, the legal system was tinkered with, and the development of Genoa was pushed on by railway building, connecting that port with central Europe. In foreign policy as in domestic, the predominant tone was reactionary. The France of the July monarchy was regarded by Charles Albert's government both with suspicion as the source of liberal infection and with greed because it was a possible source of territorial acquisitions. Correspondingly, Piedmontese policy leaned hopefully toward Austria, and in 1842 Charles Albert's son Victor Emmanuel was married to a Habsburg. Piedmontese support was also forthcoming for the legitimists in Spain and Portugal.

This reactionary phase had already begun to show signs of change before the revolution of 1848. The first good relations with Austria gave way to rivalry when Charles Albert saw that he must attempt to capture the moral leadership of Italian nationalism for his house and began to hope for territorial gains in Lombardy. In 1845 he assured Massimo d'Azeglio that the liberals would find him at their service when the day came, but recommended that they should cease agitation until circumstances presented Piedmont with a favourable opportunity. Once more, his policy was equivocal and cautious. The repudiation of an agreement with Austria on the salt trade in 1846 was regarded by many as a hopeful sign, and the election of Pius IX to the papacy and the Austrian occupation of Ferrara encouraged Charles Albert to move more quickly. It seems, however, that the dismissal of the reactionary conte della Margherita (Clemente Solaro) from the foreign ministry and the beginnings of reform in 1847 were prompted especially by a growing awareness that Piedmont might lose the leadership of the Italian movement. There were abortive discussions with Tuscan and papal representatives about the possibility of a customs union. Finally, the concessions to constitutionalism made by Ferdinand II of the Two Sicilies forced Charles Albert's hand, and on March 5, 1848, he granted the constitutional *statuto* which was eventually to become the fundamental law of Italy down to the fall of the monarchy. It was not a democratic or radically liberal document: the king still retained control of foreign policy and his ministers were responsible to him and not to parliament.

The revolt at Milan against the Austrians in March 1848 forced Charles Albert to take up a definite position on the question of a national movement against Austria. Again he hesitated. He held up the formation of a defensive league because he both wanted Piedmont to have all the credit for victory over the Austrians and hoped for pickings in Lombardy to forestall any successful widespread republican movement. Unfortunately, much of the Piedmontese army was unavailable because it was deployed on the French frontier. He then refused co-operation from the radicals, would not accept their offer of the formation of a potentially dangerous Lombard army and won the hostility of Carlo Cattaneo (*q.v.*) by his demand that Lombardy should be immediately united to the crown of Piedmont. Eventually Parma, Piacenza, Modena and Lombardy were all temporarily annexed. The delays and shilly-shallying caused by Charles Albert's behaviour gave the Austrians under J. Radetzky time to recover and on July 24–25 the Piedmontese army was defeated at Custozza. Charles Albert refused an armistice the terms of which would have meant independence for Milan because he still hoped to acquire the whole of Lombardy for Piedmont; he left the city amid the insults of the populace and finally accepted terms on Aug. 9. After a stormy period of unstable government in Turin he again attacked Austria in March 1849 and was defeated after three days' fighting at Novara (March 23). Thereupon Charles Albert abdicated. He then went to Portugal, where he died four months later, at Oporto, on July 28, 1849.

Metternich remarked of Charles Albert that he was "ambitious as well as vacillating" and this explains much of his failure. Probably he damaged the cause of Italian unity more than he advanced it because of the alarm that he caused to other Italian monarchs and the distrust and hatred that he aroused for Piedmont among liberals and radicals; because he sacrificed Italian interests to those of Piedmont in his dealings with the Austrians; and because even in his own kingdom he achieved little in effective economic and administrative reform—as the work of Cavour was later to show. See further ITALY: History.

Luzio, *Carlo Alberto e Giuseppe Mazzini* (1923); C. Vidal, *Charles Albert et le Risorgimento italien 1831–48* (1927); N. Rodolico, *Carlo Alberto* (new ed. 1943); G. Falco, *Lo Statuto albertino e la sua preparazione* (1945). (*J. M.* Rs.)

CHARLES AUGUSTUS (KARL AUGUST) (1757–1828), grand duke of Saxe-Weimar-Eisenach, whose court was the great centre of intellectual Germany at the end of the 18th century and who is chiefly remembered as the patron of Goethe, was born at Weimar on Sept. 3, 1757, the son of Constantine of Saxe-Weimar-Eisenach (d. 1758) and Anna Amalia of Brunswick. In 1771 C. M. Wieland was called to Weimar to become the young prince's tutor. In 1774, on a journey to Paris, Charles Augustus visited Frankfurt, where he first met Goethe; at Karlsruhe he met Louise of Hesse-Darmstadt whom he married the next year. In Sept. 1775 Charles Augustus took over the government, and in November Goethe was called to Weimar as privy councilor. Now began a period of reform, fiscal, administrative, legal and above all educational, the philosopher J. G. von Herder (who was appointed superintendent and court preacher in 1776) being responsible for a reorganization of the duchy's schools.

Charles Augustus exercised great personal influence in German affairs and worked for German unity. Opposed to any further acquisition of German lands by the Habsburgs, he concluded an alliance with Prussia in 1785 and was a leading member of the league of princes (*Fürstenbund*) established under Frederick II of Prussia in the same year to withstand the German policies of the emperor Joseph II. However, he wisely refused the offer of the Hungarian crown, made to him in 1787 by Frederick William II of Prussia at the instance of the Hungarian malcontents. In 1788 he became a major general in the Prussian army. He was present, with Goethe, at the cannonade of Valmy in 1792, and in 1794 he took part in the siege of Mainz and the battles of Pirmasens and Kaiserslautern. He resigned his commission after the battle of Kaiserslautern but returned to Prussian service in 1798, with the accession of his friend King Frederick William III to the Prussian throne. On Oct. 14, 1806, after the battle of Jena, Weimar fell to the French, and Charles Augustus was forced to join the Confederation of the Rhine. From this time until after the Moscow campaign of 1812 his contingent fought under the French flag. In 1813, however, he joined the allies against Napoleon, and at the beginning of 1814 he took the command of a corps operating in the Netherlands.

At the congress of Vienna, Charles Augustus gained an extension of territory and the title of grand duke, but he protested against the reactionary spirit of the congress. On May 5, 1816, he granted a liberal constitution to his state, under article xiii of the Act of Confederation. He was the first German prince to do so; indeed his concession of full liberty to the press made Weimar for a while the focus of journalistic agitation against the existing order in Europe. In 1818 he lent his patronage to the founding of the Allgemeine Deutsche Burschenschaft (see BURSCHENSCHAFT). In the same year he was compelled to yield to the remonstrances of Prussia, Austria and Russia; the liberty of the press was again restricted in the grand duchy, though the era inaugurated by the repressive Carlsbad decrees (*q.v.;* 1819) was less oppressive in Weimar than in other German states.

Charles Augustus died on June 14, 1828. Under him not only the court at Weimar but also the university at Jena enjoyed a period of brilliance: in 1789 Schiller became a professor at the university, in 1798 Schelling and in 1801 Hegel began to lecture there. He himself took an informed interest in both literature and science and conducted a correspondence with Goethe (published in two volumes in 1863, edited by K. Vogel).

CHARLES EDWARD, THE YOUNG PRETENDER (1720–1788), known also as the "Young Chevalier," was the last serious Stuart claimant to the British throne. He was born in Rome on Dec. 31. *1720*. the grandson of King James II of England and elder son of James. the Old Pretender, by whom (as James III) he was created, at his birth, prince of Wales. the title he bore among the British Jacobites during his father's lifetime.

The Old Pretender had relied on foreign aid in his attempts to regain the throne; his son believed that a rising might succeed without invasion or outside support. Charles was sent to Paris in Jan. *1744*, his father having appointed him prince regent, to further a definite scheme for a French invasion, linked mith a Scottish rebellion. Bad weather and a strong English fleet in the Downs gave the French government an excuse to abandon the project, however, and Charles was left to a life of retirement in Paris. There he was led to believe by John Murray of Broughton that it was worth going alone to Scotland. Messages from his supporters in Scotland, discouraging an expedition without French support, failed to reach him, and Charles left Belle Île in the brig "Du Teillay" on July *5, 1745*, accompanied by a war frigate, the "Elisabeth," carrying supplies and ammunition. On July 20 the "Elisabeth" had to return to France after an encounter with the "Lion," an English man-of-war. Charles arrived in the Hebrides at Eriskay on July *23*, but receiving a cool reception he set sail again and reached the bay of Loch nan Uamh in Inverness-shire.

The Macdonalds of Clanranald and Kinlochmoidart, among others, attempted in vain to dissuade Charles from the rashness of an unaided rising, but Cameron of Lochiel and other chieftains now called out the clans. On Aug. *19*, in the valley of Glenfinnan, the standard of James III and VIII was raised. Within a week about *2,000* men, mainly from the Macdonald clan, had joined Charles. Sir John Cope left Stirling for Inverness on Aug. *20*, leaving the road to the south open. In the beginning of September the Jacobite army, reinforced by some accessions, notably by Lord George Murray, entered Perth. Crossing the Forth unopposed at the Fords of Frew Charles arrived within a few miles of Edinburgh. and on Sept. *16* his skirmishers routed Col. James Gardiner's dragoons in what was known as the Canter of Coltbrig. Some of Cameron's Highlanders having on the following morning, by a happy ruse, forced their way through the Canongate, Charles entered the city at noon. On Sept. *17* he publicly proclaimed James VIII of Scotland at the market cross and occupied Holyrood.

Cope had by this time brought his forces by sea to Dunbar. On Sept. *21* Charles met and defeated him at Prestonpans. He then returned to prosecute the siege of Edinburgh castle, which, however, he raised on Gen. Joshua Guest's threatening to lay the city in ruins. He still hoped for French assistance, definitely promised on Oct. *24* by secret treaty. At the beginning of November Charles left Edinburgh to invade England. He was at the head of at least *5.000* men, but the ranks mere gradually thinned by the desertion of Highlanders. Having passed through Kelso, on Nov. *10* he laid siege to Carlisle which capitulated in a week. Manchester provided the prince with 150 recruits under Francis Towneley. On Dec. *4* he had reached Derby, but his officers, jealous of each other and discouraged by lack of French and English support and the strength of the armies defending London, advised retreat. Charles headed northward on Dec. *6*. Closely pursued by the duke of Cumberland, he marched by way of Carlisle across the border and stopped to invest Stirling castle. At Falkirk, on Jan. *17, 1746*, he defeated Gen. Henry Hawley, who had marched from Edinburgh to intercept his retreat. The Jacobite army had been strengthened by Gordons, Mackintoshes and others. but the accessions were counterbalanced by desertions. A fortnight later, Charles raised the siege of Stirling, and after a weary march rested his troops at Inverness. Having taken FC. George and Ft. Augustus, and after t-arying success against the supporters of the government in the north. he at last prepared to face the duke of Cumberland, who had passed the early spring at Aberdeen On April *8* the duke marched thence to meet Charles, whose little army, exhausted with a futile night march, half-starving and broken by desertion, was completely worsted at Culloden on April *16, 1746*.

This decisive defeat sealed the fate of Charles Edward and the house of Stuart. Hunted hither and thither Charles, upon whose head a reward of £30.000 had been set a year before, was for more than five months relentlessly pursued by the troops and spies of the government. Helped by loyal supporters, in particular the devoted Flora MacDonald (*q.v.*), he wandered around the west of Scotland and the islands until the arrival of two French ships at Loch nan Uamh enabled him to sail for France. He reached Roscoff, near Morlaix, on Sept. *29, 1746*. He remained in France for two years, but after his brother Henry's acceptance of a cardinal's hat in July *1747*, he broke off communication with his father in Rome (who had approved the step), nor did he ever see him again. When, by the treaty of Aix-la-Chapelle (1748), France agreed to expel the Stuarts, Charles refused to go. His persistent refusal to leave was met with force; he was apprehended, imprisoned for a week at Vincennes and on Dec. *17* conducted to the French border. After a short stay at Avignon, which he was ordered to leave early in *1749*, Charles disappeared, probably retiring to Paris incognito. He was in London in *1750* and, it is thought, in *1754*, risking his safety to hatch futile plots. During the next ten years he wandered around Europe in disguise, accompanied by his mistress Clementina Walkinshaw. He tried to revive his hopeless cause, but his debauchery (he was drinking heavily) and his temper alienated his friends. On his father's death in *1766* he went to live in Rome, but the pope received him coldly and the great Catholic powers openly repudiated his title to the British throne. Charles, now calling himself count of Albany, married Princess Louise de Stolberg in *1772*, but the marriage was childless and unhappy and they were formally separated in *1784* (*see* ALBANY, LOUISE MAXIMILIENNE CAROLINE, Countess of). Lonely and ill, Charles summoned his daughter Charlotte Stuart. Clementina Walkinshaw's child. to Florence. She was declared legitimate and created duchess of Albany. She managed to reconcile Charles and his brother Henry, and in *1785* Charles returned to Rome. Charlotte looked after him until his death at the old Palazzo Muti on Jan. *31, 1788*. She never married, and died at Bologna in Nov. *1789*.

CHARLES EMMANUEL I (1562–1630), duke of Savoy, was born at Rivoli. Piedmont, on Jan. *12, 1562*, the son of Emmanuel Philibert (*q.v.*) and Margaret, daughter of Francis I of France. Succeeding his father as duke in *1580*. he soon showed himself a bold and intelligent statesman, prompt at intrigue and resolute in danger. His constant ambition was to secure for Savoy the marquisate of Saluzzo, Geneva and Monferrato (Montferrat). In *1588*, while the French were preoccupied with civil wars, he took Saluzzo, but subsequently his forces suffered reverses in Provence and the French invaded his territory. Finally Henry IV of France, in the treaty of Lyons (1601), acknowledged his title to the marquisate in exchange for the cession of Bresse, Bugey and Gex. Charles Emmanuel's final attempt on Geneva, a surprise assault (Dec. *23*, 1602), came to nothing.

When the treaty of Bruzolo (April *24, 1610)* between Savoy and France for concerted action against the Habsburgs had been made abortive by the assassination of Henry IV, Charles Emmanuel's designs on Monferrato had to be suspended till the death, in *1612*, of his son-in-law, Francesco Gonzaga. duke of Mantua. He then seized Monferrato *(1613)* and brought Savoy without allies into war with Spain. This lasted till *1617*. and though he had finally to restore Monferrato to Mantua, his European reputation was immeasurably enhanced by his performance.

In the Thirty Years' War (*q.v.*) Charles Emmanuel's policy was at first directed against the Habsburgs once more. When, however. in Dec. *1627*. the question of the succession to the Gonzaga dukes of Mantua arose, Charles Emmanuel secretly came to terms with Spain on the partitioning of Monferrato, thus contriving to

save Casale from Spanish occupation. Savoy, overrun by contending armies, suffered great hardships. Charles Emmanuel died at Savigliano, Piedmont, on July 26, 1630.

(R. Q.)

CHARLES FREDERICK (1728–1811), grand duke of Baden, was born at Karlsruhe on Nov. 22, 1728, the son of Frederick (d. 1732), heir apparent to the margraviate of Baden-Durlach, and Anna Charlotte of Nassau, and grandson of Charles William, margrave of Baden-Durlach (d. 1738). As a young man Charles Frederick visited France, the Austrian Netherlands, the United Provinces, England and Italy and studied for a time at the university of Lausanne. When he came of age in 1746 he succeeded to a well-ordered land which his grandfather had, by careful administration, restored after the ravages of the War of the Spanish Succession. During the peaceful first 50 years of his reign Charles Frederick and his advisers so continued this work that his government was admired throughout Germany and beyond. Benevolent despots have often been criticized for their paternalism, but here it proved a blessing, because Charles was a conscientious ruler whose foremost guide was the good of his people. His main concern was the improvement of agricultural techniques on the principles of the physiocrats, among whom he personally knew the marquis de Mirabeau and P. S. du Pont de Nemours. Industrial activity was stimulated. The emancipation of the peasantry in 1783 attracted widespread attention. Educational and ecclesiastical organizations were thoroughly reformed.

Charles Frederick and his wife Caroline Louise of Hesse-Darmstadt, whom he married in 1751, were devoted to art and science beyond mere patronage, and men such as Goethe, Herder, Klopstock, Voltaire and Linnaeus spent some time at the Karlsruhe court or corresponded with its rulers.

In 1793 Charles Frederick tried in vain to form an alliance with neighbouring states against the threat of revolutionary France; in 1796 he signed a truce with France and in 1797 was obliged to accept the peace of Campo Formio. As a result of territorial treaties from 1803 to 1810 Baden (*q.v.*) considerably enlarged its possessions, and in 1806 Charles Frederick assumed the title of grand duke. He died on June 11, 1811.

See F. Lautenschlager, *Bibliographie der badischen Geschichte,* vol. i, 2nd ed. (1930).

(M. KR.)

CHARLES MARTEL (*i.e.,* **THE HAMMER**) (c. 688–741), mayor of the palace in Austrasia from 717 and undisputed master of the Frankish kingdom from 725 to 741, was the illegitimate son of Pepin of Herstal, the Austrasian mayor of the palace, and Chalpaïda. Pepin, acting in the name of the Merovingian kings, had reorganized and reunified the Frankish realm; but the assassination of his surviving legitimate son in 714, followed a few months later by the death of Pepin himself, opened the way to renewed separatism and civil war. The Neustrians chose for themselves as mayor of the palace a certain Ragenfrid, under whom they immediately sought alliance with all the tribes surrounding Austrasian territory; the Frisians and the Saxons were particularly quick to throw off the Austrasian yoke.

The sole surviving claimants to supreme authority, apart from young Merovingian king Dagobert III, were Pepin's legitimate grandsons and Charles. Plectrude, Pepin's widow, imprisoned Charles and attempted to govern in the name of her grandchildren. In the anarchy which her rule engendered, Charles escaped, took command of the Austrasian forces, and defeated the Neustrians in battles at Amblhve near Liège (716) and at Vincy near Cambrai (717). He then wrested from Plectrude his father's treasure and the Austrasian territory nominally under her control.

Assured of Austrasia, Charles now attacked Neustria itself, finally subduing it after one last battle in 724. He also attacked Aquitaine, whose ruler, Eudes, had been an ally of Ragenfrid; but he did not gain effective control there or anywhere else in the south until later in his reign. He conducted long campaigns, some of which took place as late as the 730s, against the Frisians, Saxons and Bavarians: the Saxons in particular continued to raid his territory whenever opportunity offered.

Faced with adversaries from Africa and eastern Europe who fought on horseback, it was essential for Charles to provide his army with a strong cavalry force. To finance this costly enterprise, he appropriated some of the ecclesiastical lands recently acquired and consolidated by various fighting bishops, mostly in Burgundy. This action aroused no contemporary censure, and the tenure of the lands was to be regularized later under Charles's sons Pepin and Carloman, when it was decided that the warriors to whom they had been granted should hold them for life only, as *precaria,* the church being still the actual owner. Again, no contemporary disapproval was shown at Charles's severity toward bishops, such as Rigobert of Reims, who were resentful or tardy in surrendering their land. Charles, indeed, came himself of a family rich in saints and noted for its patronage of monasteries, and it was to him that Pope Gregory II wrote in 722 to enlist support for Boniface's mission in the Rhineland. From then onward Charles constantly supported Boniface and also helped Pirmin and Willibrord, apostles respectively of the Alamanni and of the Frisians.

Fresh events were destined to enhance Charles's prestige. Ever since their arrival in Spain in 711, the Muslims had been raiding Frankish territory in order to test the degree of resistance that a full-scale invasion of Gaul was likely to encounter. On one occasion, in 725, they had reached Burgundy and sacked Autun. Then, in 732, Abd-al-Rahman, governor of Córdoba, led an army against Eudes, duke of Aquitaine, who had contrived hitherto to maintain himself against the Muslims and had been intriguing continually with Abd-al-Rahman's rebellious subjects. Defeated, Eudes appealed for help to Charles, who had already disposed his cavalry near the Loire to defend the city of Tours. Tradition asserts that it was near Poitiers that the Muslim onslaught was broken by Charles's cavalry but it is impossible to identify the battlefield. The battle itself may indeed have been only a small engagement, but after it there were no more great invasions of Frankish territory by the Muslims. Moreover, Charles derived profit as well as glory from his victory: he was at last able to assert his authority in Aquitaine, where, having forced Eudes to swear allegiance to him, he allowed him to continue to rule as duke.

Between 733 and 739 Charles completely subdued the petty chieftains in Burgundy. His armed occupation of Provence and Septimania, made on the pretext of protecting these lands from Muslim attack, brought them again, after a long intermission, into the orbit of Frankish influence. Charles however could have had no success in southern France if the Lombards had not been willing to maintain a friendly neutrality.

Charles had now consolidated and stabilized his power, and he was careful to attempt no rash enterprise. If he put no king in the place of the Merovingian Theuderic (Thierry) who died in 737, he at least did not try to transfer the crown to his own dynasty; and when Pope Gregory III appealed to him in 739 for help against the Lombards, he considered the risk too great and withheld his aid.

In 741 Charles made a division of the Merovingian kingdom between his two legitimate sons, Pepin and Carloman, thus acting as if he were in fact king. He died on Oct. 22, 741, at Quierzy-sur-Oise, and was buried at St. Denis.

CHARLES D'ORLEANS: see ORLÉANS, CHARLES, DUKE OF.

CHARLESTON, a city of South Carolina, U.S., an important port of entry on the Atlantic coast, the seat of Charleston county and centre of a large urbanized area, is notable for indus-

tries, defense installations, and the beauty and historic interest of the city and its surroundings. It is situated on a peninsula between the estuaries of the Ashley and Cooper rivers, facing a bay, 73 mi. in length, leading to the Atlantic ocean.

History. — The settlement of Charleston in 1670 began the colonization of South Carolina. A friendly Indian led the colonists to a generally excellent harbour which proved to be the most defensible one in the region between Virginia and Florida. For security the town was begun on the west bank of the Ashley. At the time the lower part of the site of the present city was reserved for a port town. About 1672 this was laid out in streets and lots as a town, and in 1680 Charles Town was moved there.

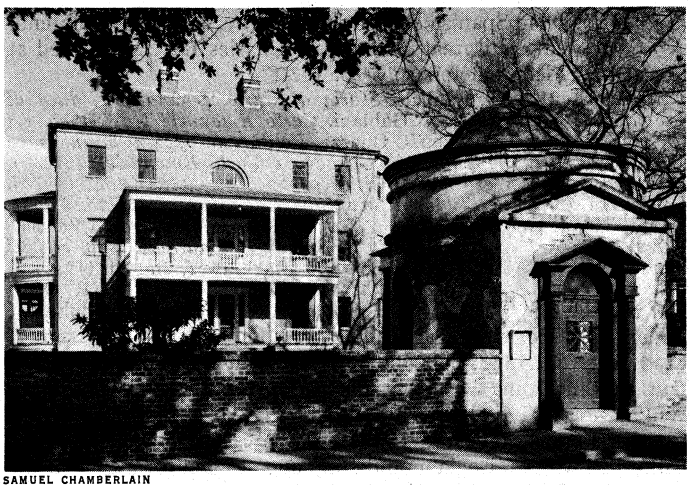
Through the colonial and provincial periods of South Carolina Charleston remained the civic centre of a closely integrated community. The colony grew up isolated from its fellows to the northward by distance and by dangerous Cape Hatteras, threatened by Spanish Florida to the south, and much more closely connected with Barbados and the other of the West Indies islands than with any other parts of British America. Colonization was at first pushed along the coast by plantation communities following natural intracoastal waterways. These remained the principal traffic routes of the rich plantation section, known as the low country, that was Charleston's particular area of the developed state. By 1674 rice began there its long career as the classic South Carolina staple. The town also came to be the centre of one of the most extensive and valuable Indian trades in the British colonies. Extended to the Mississippi by 1698, it kept South Carolina embroiled with Louisiana over the businesses with the great southern Indian tribes. In the War of the Spanish Succession Charleston's community ran deeply into debt attempting to destroy both Florida and Louisiana. The southeastern portion of the town was enclosed with fortifications. In 1706 an enemy flotilla was driven out of the harbour. Following this war the community had to fight another with an extensive Indian confederacy led by the Yemasees. It had also to clear its coast of large companies of pirates. The inertia of the proprietors of Carolina through these performances led to the revolt at Charleston that in 1719 introduced the royal government of South Carolina (see SOUTH CAROLINA: ***History***).

As the centre of a crown province, Charleston attained the wealth and liberal culture that caused it to be termed the Lima of North America. When the War of the Austrian Succession closed the principal markets for Carolina rice, in Spain, Portugal and their Wine islands (Madeira and the Canaries), indigo was introduced as a substitute. It remained one of Charleston's chief exports until its English market was lost by the American Revolution.

The state of South Carolina came into existence in Charleston on the formation of the provincial congress in Jan. 1775. On June 28. 1776, a British fleet commanded by Adm. Sir Peter Parker was defeated in the harbour by a half-finished fort on Sullivan's Island commanded by Col. William Moultrie. In May 1779 the town narrowly escaped capture by the land force of Gen. Augustine Prevost. On May 10, 1780, after a siege by land and water for 45 days, the town was surrendered to Sir Henry Clinton. It was evacuated by the British Dec. 14, 1782. Charleston lost much wealth and a number of excellent loyalist citizens by the break with the mother country.

In 1722 the town had been briefly incorporated as Charles City and Port. In 1783 it was incorporated again, under its present name. It ceased to be the capital of the state in 1790. Freed from British restriction, it throve until the War of 1812 as the winter port of the United States and by a large trade in the Caribbean. Tidal culture increased the rice exports. Cotton became a staple of the inner country and the development of the most valuable variety began near Charleston on the Sea Islands, whence it got its name. Increasing business with the inner country was facilitated by a canal connecting the Cooper with the Santee river system. After the War of 1812 the city suffered a long depression that was aggravated by the protective tariffs and that made Charleston the heart of the nullification movement of South Carolina in 1832.

As its senior civic centre, Charleston led the south's fight for states rights from the beginning to the formation of the Con-



SAMUEL CHAMBERLAIN

JOSEPH MANIGAULT HOUSE, CHARLESTON, S.C.; 1809

federate States of America, and South Carolina's ordinance of secession was passed in Charleston Dec. 20, 1860. The capture of Fort Sumter, in Charleston harbour, by Confederate forces on April 12–13, 1861, opened the war. Blockaded from May 1861, the port was served by a number of blockade runners. A Union army was defeated in sight of the city's steeples in 1862. From July 10, 1863 to Feb. 18, 1865, the harbour works were heavily and steadily attacked by land and water and the city harassed by bombardments. A siege marked by the extraordinary perseverance and ingenuity of both sides ended only when Sherman's advance through the state forced the evacuation of Charleston.

Population. — The city's population has a cosmopolitan background. West Indians predominated at first. Before 1700 there were added large proportions of Huguenots and of Puritans from England and New England and a lesser number of Scottish covenanters. The royal government after 1730 sent into the province numbers of Swiss, German and Ulster protestants. The American Revolution brought in a group of Hessians. Revolutions in France and Haiti and the Irish Rebellion of 1798 added notable groups to the population. At the same time Charleston contained the largest Jewish community in the United States. The descendants of African slaves, imported mostly in the 18th century, make up a large proportion of the city's population. Pop. (1960) 65,925; standard metropolitan statistical area (Charleston county) 216,382. (For comparative population figures see table in SOUTH CAROLINA: *Population.*)

Commerce and Industry. — The fertilizer industry, begun in 1867 and at first based on local minings of phosphoric marl, helped the city to recover from the great war losses and those inflicted by the Reconstruction government. In 1886 a severe earthquake seriously injured the city. The completion of jetties through the harbour bar in 1896 provided a deep-water entrance. In 1901 the navy yard was established on Cooper river. Expanded in both World War I and II, this became a U.S. naval base. A U.S. air force base was opened during World War II. Both wars stimulated the growth of the urbanized area. Its industrial development was promoted after 1942 by the Santee-Cooper hydroelectric project, which supplies a large amount of power and diverts to the Cooper river an estimated 10,000,000,000 gal. of industrial water daily. Major imports through Charleston harbour are petroleum and petroleum products, industrial chemicals and ores, and fresh bananas. Major exports are petroleum products, paper and wood pulp, fertilizer, iron and steel scrap. Major industries are paper and pulp mills, oil refineries, fertilizer works, metallurgical works and cigar and clothing factories.

Education and Cultural Activities. — Institutions of higher learning are the College of Charleston, founded in 1770 and taken over by the city in 1837; the Medical College of the State of South Carolina, a state institution founded in 1823; and the Citadel, the military college of South Carolina, created by the legislature in 1842. The principal cultural institutions are the Charleston Library society (founded 1748); the Charleston museum (1773);

the Caroiina Art association (1858), in the Gibbes Memorial Art gallery; and the South Carolina Historical society (1855). Cultural monuments are the Heyward-Washington house (1770) and the Joseph Manigault house (1803) maintained by the museum; the Nathaniel Russell house (c. 1806), maintained by the Historic Charleston foundation; and the Dock Street theatre (reconstructed 1937), maintained by the city. The Footlight Players and the Charleston Symphony orchestra are two of the more modern cultural organizations.

Features.—With buildings dating from 1686, picturesque streets and several notable parks and gardens. the city and its surroundings attract large numbers of tourists. White Point gardens in Charleston. better known as the Battery, stands at the southern extremity of the city overlooking the rivers and the harbour. It is conspicuous for its monuments and its military relics. The most celebrated of the out-of-town gardens are Middleton Place, a large formal garden of the mid-18th century; Magnolia gardens, with a superb collection of azaleas and camellias; and Cypress gardens. created from the romantic surroundings of the old water-reserves of a great rice-plantation. About Charleston are a number of fine beach resorts and hunting and fishing areas.

See also references under "Charleston" in the Index volume. (S. G. S.)

CHARLESTON, a city of central West Virginia. U.S., located at the confluence of the Kanawha and Elk rivers; the seat of Kanawha county and capital of the state of West Virginia. Pop. (1960) city 85.796; standard metropolitan statistical area (Kanawha county) 252,925. The metropolitan area includes the important suburban town of South Charleston, three miles distant. (For comparative population figures see table in WEST VIRGINIA: *Population.)*

Charleston was named for Charles Clendenin, the father of George Clendenin. who made the first settlement in 1788 and built Ft. Lee, where Charleston now stands. It was chartered as a town in 1794 by the Virginia assembly. Located on the route of migration to the Ohio valley. Charleston became a transfer and shipping centre. Daniel Boone and Simon Kenton. noted frontiersmen, operated in the area and Boone represented Charleston in the Virginia assembly. 1790–91.

Both Federal and Confederate troops occupied Charleston during the American Civil War and it contributed soldiers to both sides. In 1870 it was incorporated as a city by the West Virginia legislature. Its population at that time was only 3,160; by 1900 it was 11,099 and after that. with the increasing industrialization of the Kanawha valley, increased rapidly.

Charleston is the centre of coal and gas industries but its chief support comes from the large chemical manufacturing companies in the Kanawha valley. There are also important sheet glass and glass bottle manufacturing companies. Government is also an important function and employs a considerable number of people. A new capital aas completed in 1932 to replace the one destroyed by fire in 1921.

Charleston is the northern terminus of the 88-mi. West Virginia turnpike, completed in 1954. The city is served by several railways and river transport on the Kanawha is also important, shipping chiefly coal, gasoline and chemicals. The Charleston airport is the major airport of West Virginia.

Morris Harvey, a private liberal arts college founded in 1888, is located in Charleston. West Virginia State college is 16 mi. down the Kanawha river. Kanawha State forest is near the city. (K. K. McC.)

CHARLESTON, an informal dance of American Negro origin that can be done as a solo, with a partner or in a group. It consists of pivoting in on the ball of the supporting foot while raising the inactive leg (knee bent) at an oblique angle, followed by pivoting out on the supporting foot and stepping on the inactive foot (toes pointed out), the step being repeated on the other foot.

The Charleston music is in 4/4 time, the rhythm consisting of a dotted quarter note, followed by an eighth note tied to a half note—a syncopation which creates the jerky, staccato rhythm of the Charleston.

Frequently the Charleston step is interspersed with such strenuous movements as kicking forward and backward, diagonally across —in closed position or away from one's partner—in place or traveling forward (B. WE.)

CHARLESTOWN, a small section of the city of Boston (*q.v.*), Mass., U.S., separated from the main part of the city by the Charles river. The first settlement was made there in 1628 and the original large area of the town was continuously nhittled away as new cities and towns were formed from it. The remainder was annexed by Boston in 1874.

Charlestown lies on a small peninsula between the estuaries of the Mystic and Charles rivers. Several low hills dominate the area, including the famous Bunker and Breed's hills. Paul Revere crossed to the Charlestown shore on the evening of April 18, 1775, to await the signal to begin his famous ride. The British force in Boston landed on that same shore on the morning of June 17, 1775, to be repulsed again and again by the motley patriot force dug in on Breed's hill. The American forces finally withdrew, leaving most of Charlestown a smouldering ruin. A granite obelisk (220 ft.) on nearby Bunker hill commemorates the battle.

The G.S. navy established one of its more important navy yards in Charlestown in 1800. As the city grew older the size and character of its population changed. especially as waves of Irish and, later, Italian immigrants moved in. By 1860 the population was over 25,000. During the next century the area became run down.

Charlestown was the birthplace of Samuel F. B. Morse, inventor of the telegraph, and contains the grave of John Harvard, for whom Harvard university is named. (G. K. L.)

CHARLES WILLIAM FERDINAND (1735–1806), duke of Brunswick-Lüneburg-Wolfenbüttel, field marshal in the Prussian army. famed as a strategist and an enlightened ruler, was born at Wolfenbüttel on Oct. 9. 1735, the son of Charles I of Brunswick-Luneburg and Philippina Charlotte. a sister of Frederick II of Prussia. The prince received an excellent classical and French education and was brought up by the Protestant court chaplain J. F. W. Jerusalem in the spirit of rational Christianity. During the Seven Years' War (1756–63) Charles distinguished himself repeatedly and gained a great reputation both for his valour and for the special favour accorded him by Frederick II. In Jan. 1764 he was married in London to Augusta, the sister of George III, and in 1766 he undertook an extensive European tour. In 1780 his father died and Charles succeeded to the small and debt-ridden duchy. He zealously applied himself to government. reforming the administration and organizing the educational system on the principles of the Enlightenment. Under the influence of the educationalist J. H. Campe (d. 1818) he even attempted to rid the schools of all clerical influence, but failed through the resistance of the Lutheran clergy.

In 1773 Charles had become a Prussian general of infantry and thenceforward maintained a close political alignment with Prussia. He supported Frederick II's "league of princes" (1785) directed against the Austrian influence in Germany and sought to bring about better relations between Prussia and Great Britain-Hanover. In 1787 Frederick William II of Prussia appointed him field marshal and conferred on him the high command of the Prussian troops in the war against the Dutch patriots. This brief and bloodless campaign confirmed Charles's military reputation in Europe and in 1792 Frederick William gave him the command of the Prussian forces mobilized against revolutionary France.

Charles accepted the appointment rather from a military sense of duty than from conviction, for he was not in principle opposed to the aims of the Revolution. His reputation as an enlightened thinker uas such that even the revolutionary government had considered approaching him to reorganize the French army. Hence it is hard to understand how he signed the immoderate "manifesto" of July 25, 1792. This had been drafted by an *émigré* and announced humiliating punitive measures against revolutionary France, especially against Paris. As early as Sept. 1792 the hesitant Prussian advance on Paris was brought to a halt by the cannonade of Valmy (*q.v.*). The ensuing retreat of the allies was in the tradition of Frederick II's strategy. Using this strategy, Charles in 1793 regained Mainz. and defeated the French at

Pirmasens and Kaiserslautern; but in Jan. 1794, irritated by Frederick William's constant meddling in the conduct of operations, he resigned the high command. However, he gained influence, at the court of Berlin and advocated Prussia's joining the Grand Alliance against Napoleon. In 1806 he was sent on a diplomatic mission to St. Petersburg to improve relations between Prussia and Russia. In the same year he resumed the Prussian high command in the War of the Fourth Coalition against France, but sustained an annihilating defeat at the hands of Marshal L. N. Davout near Auerstadt (*q.v.*) on Oct. 14, 1806. Charles was fatally wounded and died at Ottensen, near Hamburg, on Nov. 10, 1806.

Charles preferred music to the distractions of court life and the joys of hunting and played the violin well. In his views, his manner of government and way of life he typified the enlightened despotism of 18th-century Germany. In appearance he resembled Frederick II of Prussia, whom he admired and whom he took as his example.

See S **Stern, Karl Wilhelm Ferdinand,** *Herzog zu* **Braunschweig und** *Lüneburg (1921).* (S. SK)

CHARLEVILLE-MÉZIÈRES, twin towns in northeast France. Ardennes (*q.v.*) *département,* are 83 km. (51.6 mi.) N.E. of Reims by road and 15 km. (9.3 mi.) S W. of the Belgian frontier. Pop. (1954) 33.609. Both Mézières and Charleville are built inside loops of the Meuse river, which separates them. Mézières is the prefecture.

Despite heavy damage in both world wars, Mézières, which lies to the south, still has traces of the early fortifications (those by Vauban were removed in 1886): the Milard tower (14th century); the King's tower (16th century); the Burgundy gate (14th century); and the citadel (16th century). The basilica of Notre Dame, begun in 1499, has a Gothic choir and nave; the west front, not completed until the end of the 16th century, is Renaissance. The prefecture was built between 1770 and 1790; the town hall is modern, rebuilt after World War I.

In contrast with Mézières, Charleville, on the north, is a rapidly growing town. It has the railway station, the chamber of commerce and the law courts and is also the commercial centre. The Place Ducale is a fine example of 17th-century French classic style. The poet Rimbaud was born near this square and composed his *Le Bateau ivre* near the old mill which still stands over the Meuse nearby. From Mont Olympe, across the Meuse to the north, fine views can be obtained of the twin towns. The municipal library has 50.000 books, of which 400 are manuscripts from the 11th to the 16th centuries, and there is a museum. South of Mézières is Mohon, which is included in the twin town.

Charleville-Mézières is on the main railway line from Calais and Lille to Metz and Strasbourg; another main line runs to Reims and Paris. The chief industries are construction of cranes and other heavy equipment, as well as the making of brushes, motor cars, bicycles and bricks.

Mézières, founded in the 9th century, was a stronghold belonging to the bishops of Reims, later passing to the counts of Rethel. The town grew by immigration from Liège (people fleeing first from the emperor Otto and afterward from Charles the Bold) and also as a result of concessions from the counts of Rethel. Its walls were built in the 16th century, and in 1521 it was successfully defended by the chevalier Bayard against the Imperialists. In 1815 it kept the Germans at bay for six weeks, and in 1871 the town capitulated only after heavy bombardment. Charleville was founded in 1606 and was laid out according to a plan. Charleville-Mézières was captured in Aug. 1914 by the Germans, who made Charleville the seat of their western high command. It was reoccupied on Armistice day, 1918. In World War II the twin town was occupied again by the Germans from May 1940 to Sept. 1945. (L. DE.)

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE (1682–1761), French Jesuit missionary, author of an early descriptive account of North America, was born at St. Quentin, on Oct. 29, 1682. In 1719 he was sent to Canada, where he had previously stayed for four years, to discover a new route from Acadia westward. Between 1720 and 1722 Charlevoix traveled up the St. Lawrence river, through the Great Lakes and down the Mississippi, was shipwrecked in the Gulf of Mexico and visited the island of San Domingo. He spent the rest of his life writing and teaching in France and died at La Flkche. on Feb. 1, 1761. Charlevoix, Mich., is named for him.

Charlevoix's works include *Histoire du Japon* (1715), *Histoire de Saint-Domingue* (1730), *Histoire et description générale de la Nouvelle France* (1744; Eng. trans., 1866–72) and *Histoire de Paraguay* (1756).

CHARLOTTE, empress of Mexico: *see* CARLOTA.

CHARLOTTE, a city of North Carolina, U.S., and seat of Mecklenburg county, in the southern part of the state about midway between Atlanta, Ga., and Richmond, Va., is a trading centre for the central Piedmont region in North and South Carolina. Manufacturing firms in the area are devoted principally to textiles, machinery, chemicals, food processing and printing. Government of the city follows the council-manager plan, which went into effect in 1929; that of the county is by commissioners.

Charlotte was incorporated in 1768, six years after the creation of Mecklenburg county, and named for Princess Charlotte of Mecklenburg-Strelitz, who became the wife of George III of England in 1761. On May 20 citizens of Mecklenburg celebrate the signing of the Mecklenburg Declaration of Independence (*q.v.*) in 1775. For a few days in 1780, Lord Cornwallis occupied the town and because of the hostile reception he received named it "the hornet's nest," since then the official emblem of the city. After the discovery of gold in Cabarrus and Mecklenburg counties, a branch of the U.S. mint was opened in Charlotte in 1837 and remained in operation until 1861. The building, removed in 1935 to a new site, serves as a museum. During the American Civil War a naval yard for the Confederacy operated in Charlotte. Near Charlotte, presidents Andrew Jackson and James Polk were born, and in 1865 the Confederate president, Jefferson Davis. fleeing from Richmond, met his full cabinet for the last time in Charlotte.

The first college in North Carolina, Queens College in the Town of Charlotte, was chartered by the colonial legislature in 1771. Disallowed by authorities in England, this became for a short time after 1777 Liberty hall. The present Queens college (Presbyterian) for women was chartered in 1857. The metropolitan area also is served by two other Presbyterian schools. Davidson college (at Davidson) for men, founded in 1837, and Johnson C. Smith university, coeducational, founded in 1867; and by two municipal junior colleges, Carver and Charlotte.

The population of Charlotte was 201,564 in 1960; that of the standard metropolitan statistical area (Mecklenburg county) was 272,111. For comparative population figures *see* table in *NORTH CAROLINA: Population.* (R. N. E.)

CHARLOTTENBURG, a town of Germany. on the Spree river, was incorporated in the greater Berlin scheme of 1912. nhich came into full operation in 1920. Its earlier name was Lietzenburg. The central part of the town is connected with Berlin by an avenue. the Charlottenburger Chaussée. The castle, built in 1696 for the electress Sophie Charlotte. queen of the elector Frederick, after whom the town was named, contains a collection of antiquities and paintings. In addition to the famous royal porcelain factory, there are many industries, notably ironworks, grouped along the banks of the Spree.

After World War II Charlottenburg was included in the British sector of west Berlin. In 1959 construction of a new university quarter, designed to house 5,000 students of Berlin's Technical university, was begun in the Am Knie part of Charlottenburg. (T. C. PE.)

CHARLOTTESVILLE, a city of central Virginia. U.S., seat of the University of Virginia, is located 70 mi. W. of Richmond in an immense natural bowl of the Blue Ridge mountain foothills. (For comparative population figures *see* table in *VIRGINIA: Population.)*

In colonial times Charlottesville was on a main trail from the Tidewater region to the west. Peter Jefferson, the father of Thomas, settled there in 1737. Seven years later Albemarle county was created, and in 1761 the county government moved to Charlottesville, named for the queen of George III. During the American Revolution numerous British and Hessian prisoners

captured at Saratoga were quartered there, and in 1781 Col. Banastre Tarleton raided the town in an attempt to capture Thomas Jefferson and other state officials fleeing westward after the fall of Richmond. The Central Virginia (later part of the Chesapeake and Ohio) railroad reached Charlottesville in 1848, ending the use of the nearby Rivanna river for commerce. During the American Civil War the buildings of the University of Virginia, founded by Jefferson in 1819 (see VIRGINIA: *Education*), were used for hospitals. Gen. Philip Sheridan's troops occupied the town but did little damage. Charlottesville was chartered as a city in 1880.

Overlooking the town is Monticello, home of Thomas Jefferson. who supervised its design and construction. The mansion, of red brick with white porticoes and an octagonal clerestory topped by a dome, contains numerous examples of Jefferson's inventiveness, including his one-armed writing desk, folding doors. disappearing beds and a wind-direction indicator. After Jefferson's death the estate suffered from periods of neglect but was restored after the Civil War and purchased in 1923 by a private foundation which turned it into a national shrine.

Other points of interest are the George Rogers Clark and the Lewis and Clark memorials, statues of Washington, Jefferson and Lee, and the James R. McConnell winged aviator memorial on the university campus. Industries, some of them attracted by the University of Virginia, include textiles, lumbering and precision instruments. (F. B. S.; X.)

CHARLOTTETOWN, the capital of the province of Prince Edward Island. Can.. and the seat of Queens county, is located on Northumberland strait. on the south shore of the island. Pop. (1961) 9 . The Charlottetown harbour and water-front facilities are excellent. Principal exports are agricultural products, chiefly potatoes. a famed product of the island; and principal imports are gasoline and oil. The city is the commercial centre of the province and has a large trade with Newfoundland Manufactures are woolen goods, canned goods, lumber and machine and foundry products.

There was a French settlement in the area in 1720, called Port la Joie. The present site was chosen after the island passed under British rule in 1763, and it was named in honour of Queen Charlotte. wife of George III. It was incorporated as a city in 1853.

The Provincial building (1844) contains the so-called Confederation chamber. nhere the first meeting to discuss the union of the colonies was held in 1864 (see CANADA: History), and the city was selected as the site of the 1964 Centennial Confederation building. The distinguished colonial mansion Government house. the official residence of the lieutenant governor of the province. was built in 1844. Educational institutions include Prince of Wales college (founded 1860) and a normal school, both supported by the province, and Saint Dunstan's university (1855), Roman Catholic. (FR. WA.)

CHARNAY, CLAUDE JOSEPH DÉSIRÉ (1828–1915), French traveler and archaeologist nho did much research on the origins of the prehistoric Mexican people. He started his travels in Mexico under a commission from the French ministry of education (1857–61). After visiting other parts of the world, he returned to the ruined cities of Mexico (1880–82), his expenses being paid by Pierre Lorillard of New York. Charnay gave the name "Ville Lorillard" to a great, ruined city near the Guatemalan boundary. Charnay elaborated a theory of Toltec migrations and considered the prehistoric Mexicans to be of Asiatic origin because he found evidence of similarities to Japanese architecture. Chinese decoration, Cambodian dress and the Malay language. His works include Les Anciennes *Villes du Nouveau Monde* (1885; Eng. trans., 1887). Charnay died at Paris in 191j.

CHARNOCK, JOB (d 1693). English founder of Calcutta. went to India in 1655 or 1656 and soon joined the East India company's service. He was stationed at Cossimbazar and then at Patna. In 1686 he became chief agent at Hugli. Besieged there by the Mogul viceroy of Bengal. he put the company's goods and servants on board his light vessels and dropped don n the river 27 mi. to the village of Sutanati, a place well chosen for the purpose of defense. which occupied the site of nhat is now Calcutta. It was only. honever. at the third attempt that Charnock finally settled down at this spot, and the later selection of Calcutta as the capital of British India was entirely due to his stubborn resolution. Charnock died in Calcutta in Jan. 1693.

See N. N. Raye, *The Annals of the Early English Settlement in Bihar (1927).*

CHARNOCKITE, a series of rocks first described from Madras, southern India, by Sir T. H Holland, who named this particular type of rock in honour of Job Charnock. the founder of Calcutta.

Composition. — The term charnockite is often limited to the characteristic hypersthene granite of the series. However. the charnockite series comprises rocks with chemical composition ranging from acidic granitic over granodioritic, dioritic and gabbroic to ultrabasic. (See GRANITE; DIORITE; GABBRO; see also PETROLOGY: Habit of Igneous Rocks; Chemical Characters.) Anorthosite is often associated with the charnockite series as, for example, in southwest Norway and the Adirondacks.

Members of the charnockite series contain certain characteristic minerals which distinguish these rocks from others of comparable bulk chemical composition. Hypersthene (see PYROXENE) is, for example, a typical mineral for all rock members of the series. The plagioclase of these rocks is usually antiperthitic (see FELDSPAR. *Unmixing* at Low *Temperature*). The alkali feldspar may be intermediate between ordinary microcline and orthoclase. a fine microperthitic texture being common. Dark colour and clouding of the feldspars are typical features of these rocks; so is a bluish tint in quartz. For these reasons hand specimens and outcrops of quartzo-feldspathic charnockites look considerably more basic than they really are. Some charnockites contain a bronnish-green hornblende of hastingsitic affinity and often rather rich in titanium (see AMPHIBOLE). The garnet characteristic for these types of rocks is enriched in the pyrope "molecule."

Occurrence. — Rocks of charnockitic affinity are found all over the world, preferably in deeply eroded Pre-Cambrian basements. In India they occur in the Nilgiri hills. the Shevaroys. in the Western Ghats and southnard to Cape Comorin. The charnockite area of Ceylon probably is a continuation of the Indian province.

Charnockites occur in South and Western Australia, in Enderby Land and Adélie Coast in Antarctica and on the Ivory Coast and in Uganda in Africa. Rocks belonging to the charnockite series are reported from Ellesmere Island and from five separate vast regions on the west coast of Greenland. In north Finland, southwest and west Norway and south Sweden rocks of this character have been studied. At several localities in the United States, Brazil and Canada charnockites and closely allied rocks are found.

Origins. — $$-hen Sir T. H. Holland described this type of rock for the first time. he — and probably most contemporary petrologists — assumed that they were of magmatic origin developed by fractional crystallization from a silicate melt. Later studies of field relationships combined nith laboratory studies have, however, made it clear that many if not all rocks of these characters are metamorphic — formed by recrystallization in closed or open systems at high pressures and moderately high temperatures.

For discussion of theories of rock formation see GEOCHEMISTRY. *Geochemistry of the Lithosphere;* METAMORPHISM. See also GRANULITE. (H. RG.)

CHARNWOOD FOREST, an upland tract with craggy Pre-Cambrian rocks and bracken-covered slopes in Leicestershire (*q.v.*), Eng., lying southwest of Loughborough and northwest of Leicester. Much of it is barren, and it has been extensively quarried. More than 6.000 ac. are over 600 ft. high; the loftiest point, Bardon hill. is 912 ft.

CHAROLAIS, an ancient region of France, in southern Burgundy, consisting of the country round Charolles (in the modern *département* of Saône-et-Loire). It was formed from the southern part of the countship of Autun with a district that Hugh IV, duke of Burgundy, detached from the countship of Chalon in 1239. Robert II of Burgundy gave it in 1275 to his niece Béatrix de Bourbon. Through a granddaughter of hers the seigniory passed to the house of Armagnac, under whom it acquired the

title of countship. In 1390 Philip the Bold, duke of Burgundy. bought Charolais back for the heirs of Margaret of Bavaria, wife of the future duke John the Fearless. Thenceforward the eldest son of the duke held the title of comte de Charolais in his father's lifetime, as did Philip the Good and Charles the Bold.

After Charles the Bold's death, Charolais was temporarily occupied by the French (1477), but at the final partition of the Burgundian inheritance between the French and the Habsburgs it was secured by the latter, though the duchy of Burgundy was held by the French. The Holy Roman emperor Charles V left it to his son Philip II of Spain. The kings of Spain, however, held Charolais as a fief of the kings of France, who levied taxes there and seized the countship a-hen they were at war with Spain. In 1684 the prince de Condé (Louis II de Bourbon), as the king of Spain's creditor, secured ownership of Charolais by a court judgment. Charolais long enjoyed administrative autonomy, having its own estates which met every third year until 1751, when they were incorporated with the estates of Burgundy.

See L. Laroche, "Le Bailliage comtal de Charolais," *Annales de Bourgogne* (1933). (J. *B.* R.)

CHARON, in Greek mythology, the son of Erebus and Nyx (Night), whose duty it was to ierry over the rivers Styx and Acheron those souls of the deceased who had duly received the rites of burial. In payment for this service he received the coin that regularly was placed in the mouth of the corpse. He is probably a product of popular belief and is not mentioned in Homer or Hesiod. He is represented as a morose and grisly old man. In Etruscan he is called Charun and appears as a death demon, armed with a hammer. Finally he came to be regarded as the image of death and of the world below. As such he survives in Charos, or Charontas, the angel of death in modern Greek folklore.

See the classical dictionaries, especially W. Roscher, *Ausführliches Lexikon der griechischen und rbmischen Mythologie.*

CHARONTON, ENGUERRAND: see QUARTON, ENGUERRAND.

CHARPENTIER, GUSTAVE (1860–1956), French composer, whose fame rests on one work, his opera *Louise,* was born at Dieuze, Moselle, on June 25, 1860. He studied at the Lille conservatory and later under Jules Massenet (*q.v.*) at the Paris conservatory, where he won the Prix de Rome (1887). The popularity of Louise, first produced in Paris at the Opéra-Comique on Feb. 2, 1900, and performed over 1,000 times there in the following 60 years, is probably due to the sentimental realism of the plot, to the picturesque setting (Montmartre), to the businesslike vocal writing in the Massenet tradition and to the mildly Wagnerian scoring. Julien (1913), a sequel to Louise, achieved less success. Earlier works included Les *Impressions fausses* for voice and orchestra (1895) and Chant *d'Apothéose,* written in 1902 for the Victor Hugo centenary. In 1902 Charpentier founded the Conservatoire populaire de Mimi Pinson, which provided free music lessons for working people. He died in Paris on Feb. 18, 1956. (F. E. G.)

CHARPENTIER, MARC ANTOINE (1634–1704), generally considered the most important composer of his generation in France, and writer of much music for plays, was born in Paris in 1634. On his return to France after studying in Rome with Giacomo Carissimi, he wrote the music for a new version of Molière's Le *Mariage forcé* (1672) and collaborated with him again in Le *Malade imaginaire* (1673). After Molière's death Charpentier continued to work for the Théâtre Français until 1685; his greatest stage work, *Médée,* to Corneille's text, was produced in 1693.

In his own lifetime he was considered by many to be a finer musician than Lully, who until his death in 1687 ruled French music with an iron hand. From 1680 to 1688 Charpentier was director of music to the princesse de Guise; from 1679 he composed music for the dauphin's private chapel; in about 1692 he began teaching composition to the duc d'Orleans, the future regent of France; and in 1698 his official functions were further increased when he was made *maître* de *musique* at the Ste. Chapelle in Paris.

His works include, besides 24 works for the stage (*comédie*-ballets, pastorales, etc.), many masses, motets, Te *Deums* and other sacred choral works; he made use of a comparatively large orchestra and double chorus. In his music for the sacred tragedies performed by the Jesuit community in Paris he established the oratorio in France, and one of these works, Le Reniement de St. Pierre, is considered his masterpiece. (B. P.)

CHARRIÈRE, ISABELLE AGNÈS ÉLISABETH DE (1740–1805), Dutch-born Swiss novelist, whose work anticipated early 19th-century emancipated ideas, was born at Utrecht, Oct. 20, 1740, the daughter of Baron van Tuyll van Seroskern van Zuylen. She married her brother's Swiss tutor and settled at Colombier near Neuchâtel.

Influenced by Diderot and Rousseau, she expressed critical views of aristocratic privilege, moral conventions (Trois femmes, 1797), religious orthodoxy and poverty but was opposed to revolutionary radicalism (Lettres *trouvées sous* la neige, 1794). Her novels, of which the most important are the excellent *Caliste,* ou lettres *écrites* de *Lausanne* (1786) and Lettres *neuchâteloises* (1784), abound in philosophic reflection, refined psychological observation and local colour but lack coherent plot. They reflect her solitude and inner contradictions, characteristic in many ways of an early type of emancipated woman. She died at Colombier, Dec. 27, 1805.

BIBLIOGRAPHY.—*Oeuvres complètes,* 3 vol. (1907–09) and *Lettres de Belle de Zuylen à Constant d'Hermenches 1760–75* (1909), both ed. by P. Godet; *Boswell in Holland . . . CHARRON, PIERRE (1541–1603), French philosopher and theologian, whose attack on traditional philosophical views and whose controversial form of skepticism made him one of the major contributors to the new thought of the 17th century, was born in Paris. He studied at the Sorbonne, Orléans and Bourges and became a lawyer. Later, he turned to theology and won renown, serving as preacher in ordinary to the queen of Navarre (Margaret of France), as theological adviser in several dioceses and as canon in Bordeaux. In 1589, in spite of his immense success, he tried to give up worldly pursuits and retire to a cloister. He was turned down because of his age. That same year, he met Michel de Montaigne (*q.v.*) and became his intimate friend and disciple. Charron died in Paris on Nov. 16, 1603.

In his major works, Les Trois *Vérités* (1593) and *De* la Sagesse (1601), which appeared after Montaigne's death (1592), Charron presented his mentor's skeptical views coupled with a fideistic advocacy of Catholicism. The first book was intended primarily as a Counter-Reformation tract against Calvinism. Charron began with a "Discours de la cognoissance de Dieu," showing that God's nature and existence cannot be known because of our weakness and God's infinitude. No rational knowledge of the divine is possible. Hence, one should accept Christianity by faith, remaining in the traditional church, and not adopt the dogmatic presumption of the Reformers, who try to measure God by their own lights.

The more sensational De la Sagesse examines what man can know outside of revealed truths. In a systematic form, Charron develops the skepticism of Montaigne, showing that "The only true principles men possess are revealed ones. Everything else is only a dream." The proper conclusion of the wise man is complete doubt, because of the weakness and unreliability of his mental capacities. The skeptical attitude will free us from prejudices and enable us to be dispassionate. Moreover, Charron insists, this attitude will help us to reach religious truth, since it will leave our minds "blank, nude and ready" to receive the revelation. The true skeptic will never be a heretic, since, in having no opinions, he cannot have the wrong ones.

The skeptic, Charron asserts, will live according to nature, if he has not received divine commands. Natural morality is that of the "noble savage." In his picture of the wise natural man, Charron presents one of the first modern moral theories developed apart from religious considerations. Thus he is important for having separated ethics from religion as an independent philosophical discipline.

De la Sagesse, which went through many editions, was im-

mensely popular and influential throughout the 17th century, being read by most thinkers in France and by many in England (the first English translation appeared in 1608). The work was immediately attacked as irreligious both because of Charron's natural moral theories and for its skepticism. Charron was accused of insincerity in his professed Catholic views and of undermining genuine religious belief. The Jesuit François Garasse called *De la Sagesse* the "breviary of the *libertins* ['freethinkers']" and accused the author of being a secret atheist. Charron was defended by prominent churchmen, including Claude Dormy, bishop of Boulogne, and the abbé de St. Cyran (Jean Duvergier de Hauranne, who succeeded in having Garasse's attack on Charron condemned by the Sorbonne in 1626). Charron's views were also admired by Cardinal du Perron, Pierre Gassendi, Gabriel Naudé and others. Many considered him a leading Counter-Reformer, who used skepticism as a means of destroying the arguments of the Calvinists.

From the 17th century onward there has been disagreement in assessing Charron's (as well as Montaigne's) real intentions. Was he raising doubts in order to make way for faith or to get rid of faith? His *Discours chrestiens* (1600) and his religious life would indicate that he was a sincere Christian, while some portions of *De la Sagesse,* together with his influence on several of the *libertins,* suggest that he was not. There is still genuine difficulty in determining his true views.

CHART, in navigation, a special type of map designed for use on sea and air voyages. The nautical chart, essential to marine navigation, informs the mariner of the nature and form of the sea bottom and gives the location of channels, aids to navigation, reefs and shoals. It affords an accurate graphical guide to hidden dangers and safe channels—knowledge which is necessary for efficient and safe ship navigation. The nautical chart usually is supplemented by official publications called coast pilots or by other types of sailing directions which provide pertinent descriptive details that cannot be shown conveniently on the chart itself.

Much more recent than the nautical chart is the aeronautical chart, which is essential to air navigation. Whereas a nautical chart is a graphic representation of an area consisting chiefly of water, the aeronautical chart, like a map, most often represents an area that is predominantly land. Aeronautical charts, being designed for one special purpose, often violate the established usage of conventional maps. They differ from maps that are prepared in accordance with definite conventions based on the relative importance of features to be mapped and the emphasis to be given each. Features normally included in an ordinary map often are omitted, while other features are exaggerated beyond topographic justification to enhance their landmark value. *See* MAP; NAVIGATION.

HISTORY OF NAUTICAL CHARTING

Early mariners ventured upon the sea with little to guide them save their own experience and instinct. Charting evolved slowly and painfully from obscure origins, with the first hydrographic charts making their appearance in the middle ages. The portolan charts, which marked the real beginning of the nautical chart, came into being in the 14th century. They carried descriptive notes, loxodromic (rhumb) lines and a network of lines corresponding to the principal points of the compass. Copies were reproduced by hand on skins or parchment by specialized draftsmen. No projection was used on these charts, but the coasts of the various countries were drawn in their correct relationship based on bearings, and actual distances were indicated between ports.

In 1569 Gerhard Kremer, better known by his Latin surname, Mercator, published his famous world map on a new system, which became known as the Mercator projection. His results were derived by mathematical formulas and originally were referred to as "a new proportion and a new arrangement of the meridians with reference to the parallels." Because of its improvement over methods existing before his time, Mercator's map or nautical chart of 1569 stands alone as the greatest achievement in cartographic history.

Great Britain.—Marine surveying basic to accurate charting developed slowly in England, and the charts published in that country as late as the 17th century were based on Dutch work. Until about 1675 no official charts of any coasts outside Europe were available to merchant ships. Navigators had to rely on sea atlases until John Seller in 1670 published his *Atlas Maritimus,* which soon was followed by his *English Pilot.* A milestone was achieved when a naval captain, Greenville Collins, produced Great Britain's *Coating Pilot* in 1693; this contained charts based on the first surveys to be conducted by an Englishman. A number of more complete editions of the *English Pilot* appeared between 1743 and 1761. Notable progress in marine charting was made during British colonial expansion on the North American continent in the 18th century. Between 1774 and 1783 British engineers, under the direction of Joseph Frederick Wallet des Barres, produced the noted Neptune series of hydrographic charts, which covered the Atlantic coast of colonial America from Maine to Florida.

FIG. 3.— CHART OF A SECTION OF THE ST. LAWRENCE RIVER, CANADA. ABOUT 100 MI. N.E. OF QUEBEC CITY; ORIGINAL MANUSCRIPT DRAWING BY JAMES COOK; 1760

The invention by John Hadley in 1731 of the reflecting octant, and the independent and nearly simultaneous discovery of the same principles by Thomas Godfrey in America, pointed the way to more accurate navigation. In the period 1729–60 John Harrison, a Yorkshire carpenter, developed his marine chronometer, which gave to the world an accurate timekeeper for determining longitude at sea.

Advancements during the 18th century were accelerated by the mariners' demands for an accuracy in keeping with new methods of navigation and also by the expansion of maritime commerce. The work of Alexander Mackenzie, Matthew Flinders, George Vancouver and William Bligh, as well as the massive work of James Cook, characterized this period, which immediately preceded the establishment of the British hydrographic office. Cook's contribution to world charting is the most outstanding example of the extent and quality of the work of the early marine surveyors. During his first voyage alone about 5,500 mi. of coast line were surveyed, with untiring devotion to accuracy and detail that has ever been an inspiration to the science of hydrography.

Until the formation of the hydrographic office in the British admiralty, charts were distributed to both the Royal Navy and the merchant fleet by private publishing firms. Even though the admiralty had commissioned many of the surveys, the charts themselves were published by a number of well-established firms. The fact that the publishers, whose decisions inevitably took into account salability, prescribed what charts would be available to mariners was a serious disadvantage. Many surveys commissioned by the admiralty lay untouched in admiralty files, and British navigators were thus deprived of a substantial amount of chart information.

The undigested mass of material accumulating in the admiralty offices at long last resulted in the issuance of an order in council dated Aug. 12, 1795, creating the post of hydrographer, and this was actually the birth of the hydrographic department of the admiralty. Alexander Dalrymple. a distinguished geographer with a long record of marine surveying as hydrographer to the East India company, was appointed the first hydrographer of the admiralty. With great energy and concentration, supported by a small staff, he reduced the huge mass of material into new engraved charts. Like the great Ferdinand Rudolph Hassler, who shortly afterward became the first superintendent of the coast survey in the United States, Dalrymple established from the beginning a high standard of accuracy and scientific integrity for the charts to be issued by the admiralty. He met the same type of pressures and opposition in England that Hassler later encountered in the United States.

In the first 15 years of the 19th century the "hydrographical" office, although not yet an admiralty department, expanded rapidly. A great deal of charting was accomplished under Capt. Thomas Hurd. Toward the end of his years as hydrographer, he made admiralty charts available to the public by removing them from the jealous privacy of naval use. For this act he earned the lasting gratitude of the merchant marine of succeeding ages. Captain Hurd is also remembered for his accomplishment of the first detailed hydrographic survey. This great scientific milestone, the survey of Bermuda (1791–99), set new standards of precision and thoroughness. Many famous hydrographers, such as the admirals Sir William Edward Parry, Sir Francis Beaufort and Sir William Wharton, subsequently made important contributions. Much credit also is due Vice-Adm. Sir John A. Edgell, whose term as head of the hydrographic department extended from 1932 to 1945. *(See* SURVEYING: *Hydrographic Surveying.)*

United States. — In the United States, nautical charting and hydrographic surveying came into being in 1807 with the creation of the survey of the coast for the primary purpose of producing charts of the coastal waters of the new republic. From the beginning, this great undertaking was based on a solid foundation of scientific accuracy. Superintendent Hassler prescribed a system of rigid triangulation control to ensure that the edges of a chart of any location would align with those of charts of adjacent areas. This new concept of co-ordinated surveys marked a new era in chart making.

The first chart produced by what is now the U.S. coast and geodetic survey was a stone engraving of Newark harbour issued in 1839; however, the early charts of the survey were produced mainly as copperplate engravings. Lithographic methods were employed in reproducing nautical charts as early as 1897. After 1916 copperplate engraving gradually was discontinued, until today all charts are produced by modern photolithographic methods.

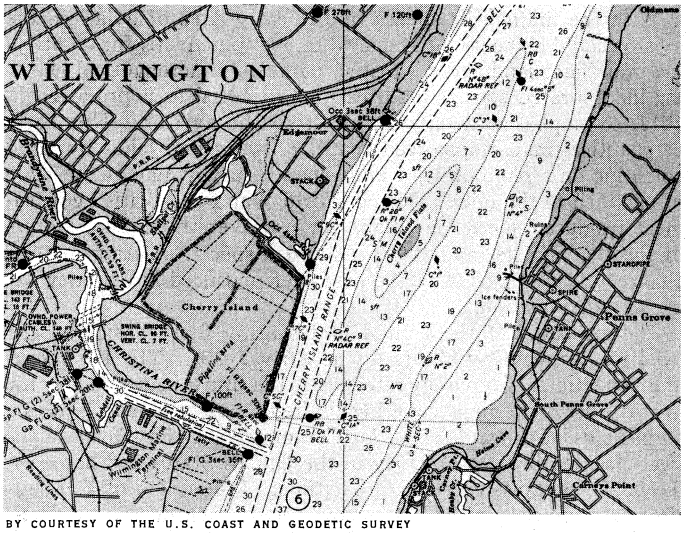
Charting in the United States, unlike that in Great Britain, is conducted separately to meet merchant-marine and naval requirements. Whereas the coast and geodetic survey produces charts of the domestic waters of the nation, charting to meet naval requirements of foreign areas is accomplished by the navy hydrographic office. These two agencies hold individual membership in the International Hydrographic bureau and work together closely in co-ordinating surveying and charting activities to ensure the best possible results.

The U.S. navy hydrographic office. one of the principal depositories and distributors of world navigational information. originated from the navy depot of charts and instruments, which was established in 1830. Future development of the navy hydrographic office was influenced greatly by Matthew Fontaine Maury, who assumed charge of the depot in 1842. He introduced an extensive system of collecting information from the logs of naval and merchant ships. This information was compiled into pilot charts. which enabled ships to shorten sea voyages by following the tracks prescribed by Maury. The depot also introduced trade wind charts, thermal charts and storm and rain charts.

International Hydrographic **Bureau.**—Under Maury's able guidance the first international marine conference was held in Brussels, Belg., in 1853 to promote a uniform system of observations at sea. This meeting was the forerunner of what was later to become the International Hydrographic bureau. This organization had its inception at an international hydrographic conference held in London in 1919 at the invitation of the British admiralty. After due consideration the seat of the organization was established in the principality of Monaco, where it has remained to this day. Notable achievements have been made by the International Hydrographic bureau in establishing, co-ordinating and promoting the highest possible collaboration and co-operation among the principal maritime nations of the world.

NAUTICAL CHART CONSTRUCTION

The compilation of a nautical chart requires strict cartographic application on a plane surface of all pertinent data concerning some particular navigable water area. The position of the features and the charted detail in the compilation must bear a correct



BY COURTESY OF THE U.S. COAST AND GEODETIC SURVEY

FIG. 4.— NAUTICAL CHART OF DELAWARE RIVER AT WILMINGTON, DEL.

mathematical relationship to the relative positions of terrestrial features that have been located by precision methods on the curved surface of the earth.

Chart Scales.—Charts made for marine navigation are designed with varying scales. Complete chart coverage of a coast consists of several different series of charts, each series made at a certain scale for a particular purpose and for specific coverage. The smallest-scale charts are for use in approaching a coast from the open sea while making a landfall. Larger-scale series are constructed for use in navigation in more constricted areas, where dangers are more critical. The largest-scale charts are the harbour charts, uhere it is necessary to show the greatest amount of detail.

Projection.— The parallels of latitude and the meridians of longitude constitute the framework of the chart and afford a means of placing every detail in its correct relative position. Therefore, the computation and construction of the projection are very important factors. Computations are made to the nearest thousandths of a millimeter. Mediums on which the chart drawing is made must be stable and resistant to shrinkage and distortion.

The Mercator projection is used almost universally for hydrographic charting. On this projection the meridians are parallel, equidistant straight lines which do not converge. as they do on a globe. The parallels of latitude are also straight lines and intersect the meridians at right angles. The spacing of these parallels of latitude on the meridians is determined by the law of the projection, in order that the scale along a meridian at any point will equal exactly the increase in scale along the parallel at that point. The published scale of a chart is generally the scale at the middle latitude. Variation in the chart scale north or south of the middle latitude is small or negligible, depending on the latitudinal extent.

The primary reason for world-wide use of the Mercator projection is that the rhumb line, which specifies the track of a ship on a constant compass course, is a straight line on the projection. Other advantages of this projection are its conformality (*i.e.*, the retention of correct angular relationships at each point). simplicity of construction and convenience in plotting positions from border subdivisions.

Symbolization **and** Other Features.— The finished nautical chart delineates nautical and geographical features, partly in the form of reduced outline and partly in the form of symbols of various kinds. Chart symbolization is no more than approved conventionalism, and symbols are employed which will best meet the needs of the potential user. In the early years of sea navigation many chart users were unable to read, and symbols that were pictorial representations of the charted features were of necessity employed. As the peoples of the world became more literate, symbolization underwent a slow change, until today charts are produced that reflect the ultimate in refinement, legibility, clarity and unity of style.

In addition to the proper use of conventional signs and symbols, close attention is given to details, such as lettering, place names, legends and notes, in order to produce charts that are legible and easily interpreted. **A** critical study of hydrography is made in order to secure a selection of soundings that will be simple, representative and practical. The cartographer must supply the artistic element indicative of good charting without sacrificing any essential details, and he must always present a faithful portrayal of the charted area. The hallmark of good charting is accuracy and simplicity.

Fixed aids to navigation and landmarks are usually plotted first so that placement of these important features can be readily verified in comparison with survey material subsequently applied. The amount of topography applied depends upon the needs of the navigator and the scale of the chart. Shore-line detail and all important topographic features visible from the waterway are reduced to chart scale and plotted in their exact geographic position. Vertical relief is represented by contours or form lines, sometimes supplemented by hachures in areas of bold or rugged terrain.

Hydrographic features are applied to the chart from various types of surveys. Information on such things as hidden shoals, rocks, reefs and underwater obstructions is checked meticulously in the examination of all source materials used. Indications of dangers, such as the presence of breakers and kelp, are also noted for charting. The soundings and depth curves that will delineate channels, navigable areas and shoals must be accurately positioned in the compilation. Floating aids that mark these features are also plotted. The finished drawing is a clear and complete portrayal of submarine relief. In general, the distribution of soundings to complete the compilation depends upon the scale of the chart, the number of shoals and the bottom configuration (see SOUNDING).

Auxiliary information, such as the chart title, geographic names, reference notes, data for magnetic compasses, cable and pipeline locations, and special anchorage or danger areas, is then added. Also included in the compilation are survey data and information received from miscellaneous sources. To provide maximum safety for navigation, all reported wrecks, uncharted reefs and shoaling in channels are represented. The published chart is the culmination of precise geodetic, topographic, hydrographic and cartographic work.

Colouring.—Charts are published in various colours. The principal reason for using colour in a map or chart is to aid in the selective reading of its content. On the nautical chart, all data that must be accurately positioned with respect to the chart projection are shown in black, as are the projection lines. Black is the most legible colour under all conditions of illumination. A buff tint makes the land area stand out from the water areas and also furnishes a good background for showing up black lettering of notes and place names on the chart. Since buff fades out under a red light, which is often used in night navigation, some charting agencies use a gray tint for the land areas. Blue tints mark the shallower water areas and indicate critical areas where dangers may exist. Green tint is used for marsh areas and also to mark the foreshore areas of the coast that extend between the high- and low-water lines. Magenta tints are generally used to indicate lighted aids to navigation and special water areas of importance to the mariner. Compass roses may also be printed in magenta. On modern charts brown and green are generally used for loran lines of position, each colour representing a pattern of position lines.

Depth Curves.— Sanding symbolization, a technique that used evenly spaced dots to bring out the gradation of depth, to emphasize dangers and to make channels and other safe waters apparent at a glance, was common practice when the copper engraver's art was needed to provide the selective reading quality of the chart. Copper engraving, however, could not meet the modern requirements for charts and has been replaced by photolithography. Sanding symbolization has been replaced by tinting. New techniques eliminate voluminous soundings so that depth configuration can be delineated more accurately. The appearance of present-day nautical charts differs considerably from those formerly printed from copper plates.

Echo-sounding equipment on merchant and naval ships enables

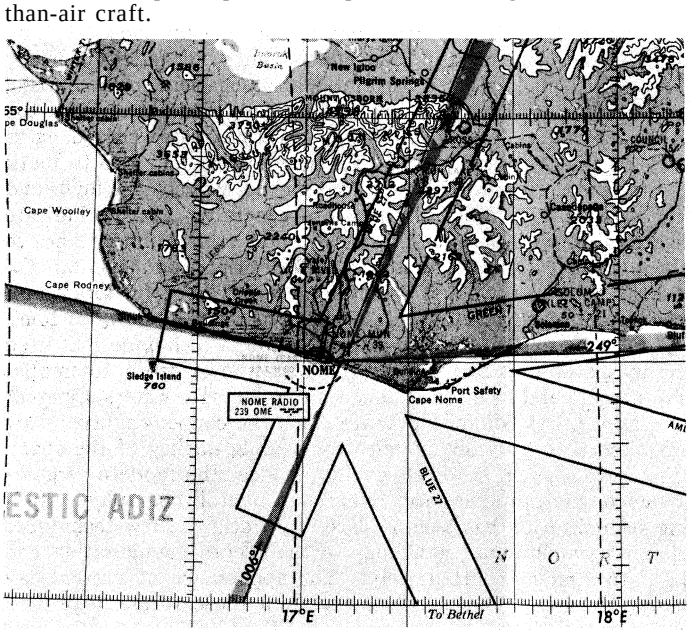
the navigator to determine water depths under his ship without slowing down or stopping (see ECHO SOUNDER). This technique resulted in the development of a new type of chart characterized by the special prominence given to depth curves. Prior to the introduction of echo sounding, charts were distinguished by many soundings and few depth curves. In contrast, nautical charts are now characterized by many depth curves and fewer soundings. Formerly. such charts were not possible. due to the fact that the delineation of depth curves, unless based on detailed and highly accurate hydrographic surveys, would serve to mislead the navigator and might, under certain conditions, give him a false sense of security.

The development of the new type of nautical chart was a logical outgrowth of the application of acoustics to marine surveying and to navigation. Echo sounding. together with improved methods of position determination, furnishes an economical means of obtaining a wealth of submarine information useful to the navigator. With the introduction of various electronic systems to marine navigation, the need developed for special treatment of nautical charts in order to show the intersecting sets of hyperbolas required for interpretation of the electronic navigation data. The standard nautical charts have been adapted for use with new electronic aids in such a manner as to make them practicable for all types of navigation. The charts are overprinted with the lattice system of lines in suitably distinctive colours, broken for soundings and other important details and fine enough not to interfere with hydrographic details.

Chart Revision. — Nautical charts require frequent revisions to ensure maximum safety in navigation. These revisions are made to portray the constant changes in coastal configuration caused by the forces of nature and the works of man. Examples of such changes are those caused by ocean waves and currents which move sand and sediment from one place to another, resulting in a corresponding shift of channels and sand bars and the build-up of tidal flats in certain areas. Engineering projects, such as channel-dredging operations and construction of new port and harbour facilities, are also shown.

AERONAUTICAL CHARTS

With the advent of modern aviation, the aeronautical chart came into being as a new type of navigational map. As late as 1927 Charles A. Lindbergh, in his historic flight across the Atlantic, had to use a variety of maps. including nautical charts on which rhumb lines had been drawn. The need for special maps or charts for air navigation was realized as early as 1888, when steps were taken in Europe to produce maps for the navigation of lighter-than-air craft.



BY COURTESY OF THE U S COAST AND GEODETIC SURVEY

FIG. 5.— AERONAUTICAL CHART OF APPROACHES TO NOME, ALASKA

With the limited air speeds of the early days of aviation, the aviator could make use of standard topographic maps for identifying prominent landmarks. British pioneers in aeronautical charting incorporated special features into an aerial map produced in 1912, to emphasize details pertinent to the aviator. This early aeronautical map emphasized roads, railways and lakes by hand colouring on a photoprint of an ordnance survey map at the scale of one inch to the mile. During World War I the British government produced special air maps for use over the coastal waters of the British Isles and also produced a special aviation map of France. These maps were the first ever produced in quantity for use in air navigation.

The air corps of the United States army first considered the need for aeronautical charts in the early 1920s. The U.S. coast and geodetic survey co-operated with the army in producing for military use strip maps covering limited areas between major air corps fields. Pursuant to the Air Commerce act of 1926, aeronautical charting became a reality in the United States and has been developed progressively since that time. Production of aeronautical charts in the United States now greatly exceeds that of nautical charts, with the U.S. coast and geodetic survey issuing annually about 40.000.000 charts of domestic areas to meet civilian and military requirements. The U.S. air force also has a greatly expanded aeronautical charting program, which includes the production of charts on a world-wide basis.

Chart Types and Format. — In contrast to the simple charts originally used, modern aeronautical charts are of numerous types and formats to accommodate the complexities of modern aviation. Included are a wide range of charts to meet specific needs for planning and for both instrument and visual (contact) flight operations. In the United States the sectional charts at the scale of 1:500,000, which cover the entire country in 87 sheets. constitute the basic series. The sectional charts are designed for contact flight of aircraft operating at slow to medium speeds. For this reason particular care is taken to show those items which are prominent and distinctive when viewed from the air. The basic norld-wide series is the world aeronautical chart series at the scale of 1:1,000,000, which provides coverage of the land areas of the norld in about 900 sheets. The smaller scale of these charts makes them more suitable than the sectionals for long-range, high-speed flights.

Various other types of charts are produced to satisfy the needs of aviation, such as aircraft position. jet navigation and instrument flight. The instrument series consists of radio-facility charts, which are designed for en route navigation; instrument-approach-procedure charts, used for airport approach and landing; and terminal-area charts.

Aeronautical charts constituted a new development in cartography, with the primary objective of providing rapid solution of problems inherent in determining direction and distances. The features stressed on the charts are clearly defined airway routes, prominent landmarks and the general trend of railways and highways and their intersections. Minor roads and other details that might confuse the aviator are omitted.

Projection. — Aeronautical charts require a suitable system of projection to facilitate laying out courses, fixing features and measuring distances. The Lambert conformal conic projection has world-wide application for the production of co-ordinated aeronautical charts within the middle latitudes. This projection permits a suitable junction between any number of charts in any direction for an area of limited latitudinal coverage. It is excellent for scaling distances in all directions over a large geographical area. Azimuths obtained from it correspond closely to directions on the earth, and it affords a simple and satisfactory solution for all problems of dead reckoning. The Lambert projection provides for practical great-circle navigation and is well suited for celestial navigation and for all types of radio navigation.

Symbolization. — The aeronautical data which provide the specific information required by the aviator are overprinted on a base chart which has been designed specifically to complement these data. The overprint includes the .symbolization mhich has been developed and standardized. This symbolization is entirely

different from that used on nautical charts, but it is designed to serve the same practical purpose in air navigation that nautical chart symbolization serves in sea navigation.

Chart Standardization.—International standardization of aeronautical charts is provided through the International Civil Aviation organization. with headquarters in Montreal, Can. See also NOMOGRAPHY; PHOTOGRAMMETRY. (H. A. KA)

CHARTER, a written instrument issued by a governmental body and conferring some right or privilege. such as the Great Charter of King John (see DIPLOMATIC; MAGNA CARTA). In modern times the term is used principally with reference to the privilege of carrying on business by way of a corporation or a company. Corporate charters today are typically issued by administrative officials pursuant to general statutes rather than by special legislative act. The charter is the basic document defining the powers of the corporation and regulating its government. (See CHARTERED COMPANY; COMPANY; CORPORATION.) As the equivalent of the term "charter party," the term is also commonly used in connection with the carriage of goods by sea. See AFFREIGHTMENT; MARITIME LAW. (B. CE.)

CHARTERED ACCOUNTANT, a public accountant who belongs to one of the chartered professional societies or institutes of accountants in Great Britain, the commonwealth and related areas. The term is often abbreviated to C.A. and is roughly equivalent to the U.S. term "certified public accountant" (C.P.A.). A chartered accountant must meet the standards of education and experience established by the society or institute. See ACCOUNTING.

CHARTERED COMPANY, the name given to a corporation enjoying certain rights and privileges. and bound by certain obligations, under a special charter granted to it by the sovereign authority of the state, such charter defining and limiting those rights, privileges and obligations and the localities in which they are to be exercised. The charter usually confers a monopoly upon the company in its sphere of operations. In Great Britain the sovereign has power at common law to incorporate by charter any number of persons desiring to be incorporated; formerly the pope, as well as the crown, possessed the power of creating corporations by grant. A charter may be granted for any period of time and may be renewed; for example, the British Broadcasting corporation was thus incorporated by charter for ten years in 1927, and its charter has since been renewed for further periods.

Medieval Companies.—The earliest English chartered companies were the Merchant Adventurers and the Merchant Staplers. These two were the only ones in existence up to 1550, and in the middle ages a large share of English trade mas in the hands of foreign merchants who were not resident in England and who carried on a ceaseless struggle with the English authorities. Merchants from Liibeck. Brunswick and Denmark had received a charter from Henry III in 1257, and the Hanseatic league (*q.v.*) continued to enjoy its privileges until the end of the 16th century. The Merchant Adventurers were of great commercial importance and mere largely responsible for establishing the eventual ascendancy of the English traders over their rivals from Germany and the Netherlands.

The early companies were regulated companies, deriving the principles of their organization from the medieval trade guilds. The regulated company was a corporation of merchants, each of whom traded on his own account but was subjected to a rigid set of common rules that regulated his operations within narrow limits.

Developments in the 16th–18th Centuries.—A great increase in the number and activities of the chartered companies took place during the second half of the 16th century, when the discovery of the new world, the glamour of the orient and the opening of new trade routes to the Indies had given a great stimulus to commerce, shipping and industry throughout western Europe. The English, French and Dutch governments were ready to assist trade and encourage exploration. Changes also occurred in the organization of chartered companies. The regulated company. which had been very convenient for trading with countries where conditions were stable, was not so suitable for ventures to remoter lands, where the risks, commercial and political, mere greater. To meet the requirements of the new trading conditions the joint-stock organization. where the capital was provided by shareholders who then participated in the profits from the joint enterprise. was evolved. In some cases the companies alternated between one form and the other according to prevailing circumstances. and in some joint-stock companies a certain amount of restricted individual trading was permitted. In all charters provisions were inserted designed to secure the "good government" of the company.

English Companies.—The Muscovy, or Russia, company, incorporated in 1555 as a sequel to the search for a northeast passage, was at first joint stock and later regulated. To this company England owed its first commerce with Russia, and in the 18th century the company enjoyed a large part of Russia's foreign trade. It also led to direct trade with the Levant and Persia. The Turkey company, founded in 1581, became the Levant company in 1592, after amalgamation with the Venice company (founded 1583). Both the Muscovy and Turkey companies had an important effect upon British relations with those empires. They maintained British influence and paid the expenses of ambassadors sent there. Other companies were established in this period for similar trading ventures: the Spanish company (1577, regulated), the Eastland company. for trade with the Baltic (1579, regulated), and the French company (1611. regulated). The first company for African trade was founded in 1585, and others were granted charters in 1588. 1618 and 1631.

But it was the chartered companies which were formed during this period for trade with the Indies and the new world which had the most wide-reaching influence. The East India company (*q.v.*) was established in 1600 as a joint-stock company with a monopoly of the trade to and from the East Indies. Its political achievements form a large part of the history of the British empire. and its economic power mas enormous. contributing substantially to the national wealth and causing the company to be the centre of most of the economic controversies of the 17th century.

In North America the importance of the chartered company lay in a different sphere: as a colonizing. rather than a trading, agency. The Hudson's Bay company (*q.v.*) was an exception. A joint-stock company founded for trade with Canada in 1670. it still exists as a commercial company and was launched as a result of attempts to discover a northwest passage, just as the Muscovy company arose from similar voyages of discovery to the northeast. It did not concern itself with colonization. But many of the British North American colonies were founded by chartered companies. Of the two classes of charters in force among the early American colonies, the first class was those charters granted to private individuals or to trading associations, which were often useful when the colony was first founded. but which were later withdrawn when the country had become settled and was looking forward to commercial expansion. The colonies were then brought under the direct control of the crown. and their trade subject only to regulation by the government. Thus the London company lost its charter in 1624 (see VIRGINIA: *History*). The substitution of royal and, later, of parliamentary control for that of the company was an important factor in the growth of the navigation acts. The second class of charters was those granted to the settlers themselves as a guarantee of their system of government. This, for example, was the effect of the charter granted to the Massachusetts Bay company (see MASSACHUSETTS: History). In the later 17th century, however, the cancellation or amendment of the charters and the growth of legislative assemblies tended to produce a uniformity of colonial practice, irrespective of the original character of the colony.

Chartered companies continued to be formed for the development of new trade. for instance the Royal African company in 1672, the short-lived Canary company in 1665 and the South Sea company in 1711. There was frantic speculation in the shares of the South Sea company. which resulted in a severe setback to joint-stock enterprise. The Bubble act of 1720 was designed to make it much more difficult to obtain a charter.

European Companies.—In France and the Netherlands, chartered companies had also been used for similar purposes by the

governments. In France from 1599 to 1789 more than 70 such companies came into existence. Under J. B. Colbert the French East India company was founded (1664), and the colonial and Indian trade was placed in the hands of chartered companies in which the king himself had large financial interests. The French companies, however, were largely destroyed by the "Mississippi scheme" of John Law (*q.v.*), in which trading companies like the Senegal and French East India companies were incorporated in a plan to take over the public debt. The financial crash in 1720 destroyed public confidence, and although the French East India company continued to trade until 1770, the chartered company was virtually dead before the Revolution finally destroyed all such privileges. In the Netherlands the Dutch East India and West India companies (*qq.v.*) were the basis of the commercial and maritime supremacy of the Dutch in the 17th century. The success of the East India companies caused the foundation of the Ostend company (*q.v.*), whereby the emperor Charles VI sought to acquire the trade of England and the Netherlands. In 1723 participation by British subjects in the company was made a criminal offense.

Later History. — The monopolistic character and privileges of the exclusive corporations created by charter, while in tune with the philosophy of the age of mercantilism and doctrines of economic nationalism, were repugnant to the individualistic outlook of the 19th century. In each country there had been criticism of the chartered companies from their beginnings, on the grounds that they prevented competition. The French companies were more exclusive than the English and Dutch although more fettered than their rivals by royal power. By the 19th century the old chartered companies had declined, and their political functions had been taken over by the state. Consequently when new chartered companies were created in Great Britain at the end of the 19th century to encourage colonial development, any monopoly of trade was expressly prohibited. The charters prescribed a detailed set of regulations for the administration of the territories, the treatment of natives and relations with foreign powers. It was on this basis that the British East Africa company (*q.v.*), the British South Africa company (*q.v.*), for the development of Rhodesia, and the Royal Niger company were granted charters. And, as with the old colonial companies, the state took over the political powers of the new companies when the colonies were established.

The development of the modern limited liability company under successive companies acts has led to a decline in the importance of chartered companies. Some of the older ones still exist, however, including the Hudson's Bay company, the London Assurance corporation (inc. 1720), the Peninsular and Oriental Steam Navigation company (inc. 1840), the British North Borneo company (incorporated 1881) and the British South Africa company. Although of importance in developing domestic commerce and industry and in rewarding inventors, the chartered company has a special place in the history of the growth of foreign trade, the encouragement of exploration and the development and administration of overseas territories. By fostering the principle and practice of joint-stock enterprises, chartered companies pioneered the modern trading company. *See* COMPANY; CORPORATION.

(F. W. Mu.)

CHARTERHOUSE, a corruption of the French *chartreuse* (Anglo-French *chartrouse)*; *i.e., maison chartreuse,* "house of the Carthusians" (*q.v.*). The name is found in various places in England (*e.g.,* Charterhouse on Mendip, Hinton Charterhouse) where the Carthusians were established but is usually applied to the Charterhouse, London. Near the old city wall, west of the modern thoroughfare of Aldersgate, a Carthusian monastery was founded in 1371 by Sir Walter de Manny (*q.v.*). After its dissolution in 1535, the property was owned, among others, by Sir Edward (later Lord) North and the 4th duke of Norfolk. In 1611 the Charterhouse came into the hands of Thomas Sutton (*c.* 1532–1611), of Knaith, Lincolnshire, who later settled in London. In the year of his death, he endowed a hospital on the site of the Charterhouse, calling it the hospital of King James, and he bequeathed money to maintain a chapel, hospital (almshouse) and school. This foundation was finally constituted to afford a home for 80 male pensioners and to educate 40 boys. The school developed, and in 1872 it was removed to new buildings near Godalming in Surrey. Famous old pupils include Roger Williams, founder of Rhode Island. Richard Crashaw, Richard Lovelace, Joseph Addison, Sir Richard Steele, John Wesley, Sir William Blackstone, William Thackeray and Lord Baden-Powell (*qq.v.*).

The pensioners or "brothers," who must be bachelors or widowers and members of the Church of England, occupy the picturesque buildings in Charterhouse square, London, which include a paneled chapel, containing the founder's tomb, and the fine dining hall, which was the old library. Many of the buildings were damaged in World War II. The master's house and adjacent buildings were burned out, but the chapel was unharmed. The notable ceiling and chimneypiece of the Elizabethan great chamber were completely restored after serious damage.

CBARTER PARTY: *see* AFFREIGHTMENT.

CHARTIER, ALAIN (c. 1385–c. 1433), French poet and political writer, whose style — didactic, elegant and latinate — was regarded as a model by succeeding generations of poets and prose writers. He was born at Bayeux probably in 1385, educated at the University of Paris and entered the royal service, acting in the dual capacity of secretary and notary to both Charles VI and the dauphin, later Charles VII. He also carried out diplomatic missions to the emperor Sigismond in Germany in 1424 and to Rome and Venice in 1425. Three years later he was sent to Scotland to negotiate the marriage of Margaret of Scotland with the future Louis XI; the famous story of the kiss later bestowed on him by Margaret, who claimed that she saluted the golden words not the ugly lips from which they came, is apocryphal. Nothing is known of his career after 1428 nor is it possible to determine the date of his death, which took place between 1430 and 1440, possibly at Avignon.

His work, which was written mainly during the years 1415–30, is distinguished by its variety of subject matter and form. Chartier — poet, orator, historian, moralist and pamphleteer — wrote verse and prose, Latin and French. His earliest known poem, the *Livre des quatre dames* (1415 or 1416), takes the form of a discussion between four ladies who have lost their *antis* at Agincourt. He used the same technique in the *Quadrilogue invectif,* a prose work written in 1422, where the dialogue is between France and the three estates of the realm. This work exposed the sufferings of the peasantry and the abuses of the feudal army, but maintained that the cause of France, though to all appearances lost, could yet be saved if the contending factions in the kingdom would lay aside their differences in face of the common enemy. Other prose compositions were the *Curial,* a description of the court of Charles VII, later translated into English by William Caxton, and the *Traitk de l'Espérance,* a long work concerned with moral, political and philosophical questions. His poems are mostly allegories in the courtly tradition but showing the influence of his interest in classical learning in their frequent Latinisms. They include *La Belle Dame sans merci, Le Lay de Paix* and *Brevaire des nobles,* of which the first, a tale of unrequited love, is the best known and was translated into English in the 15th century by Richard Ros. The first edition of his complete works appeared in 1489 under the title *Les Fais maistre Alain Chartier, notaire et secrétaire du roy Charles VI.* The last edition, *Les Oeuvres de maistre Alain Chartier, clerc, notaire et secrétaire des Roys Charles VI et VII,* was published in 1617.

BIBLIOGRAPHY.—There are modern editions of *Le Quadrilogue invectij,* with introduction by R. Bouvier (1944), and *La Belle Dame sans merci,* by A. Piaget, 2nd ed. (1949). *See* also E. *J.* Hoffman, *Alain Chartier: His Work and Reputation* (1942).

CHARTISM, the first specifically working-class national movement in Great Britain, took its name from the People's charter, a bill drafted and published in May 1838, based on six points: equal electoral areas, universal suffrage, payment of members of parliament, no property qualifications, vote by ballot and annual parliaments. These points were already familiar to radicals in 1838; what was distinctive about Chartism was its deliberate emphasis on working-class organization and objectives. Behind the six points lay not only distaste for the half-reformed political system brought into being by the Reform act of 1832: there was also hunger. despair and the dream of a new social order. Chartism, as Thomas Carlyle put it, was a "knife and fork question." It took shape against the economic depression of 1837 and 1838, and its fortunes moved with the trade cycle. Its waning coincided with the onset of the relative prosperity of mid-Victorian Britain.

The charter was drafted in London as a result of the initiative of the London Working Men's association, founded by William Lovett, among others, in 1836. Before it was published, however, there was evidence of increasingly vocal working-class discontent in other parts of the country. In Birmingham the Political union was revived in May 1837, when local unemployment reached an ominously high level. In the north of England there was a bitter protest movement, half-Tory, half-radical, against the introduction into the north of the new Poor law of 1834. The objectives of radical workingmen varied in different parts of the country as did the extent of their willingness to put their trust in middle-class leaders. The working classes in 1838 were heterogeneous in structure: there were sharp differences between the better-paid artisans and the poverty-stricken handloom weavers, between the workers in factories and those who worked at home, between the educated and the illiterate. As Chartism became a national movement, collecting varied local discontents, it inevitably reflected all these differences and in the long run suffered from them. It was the great achievement of Feargus O'Connor (*q.v.*) that he won a following in all parts of the country and made the original London sponsors of the charter seem too moderate and too weak. O'Connor addressed meetings everywhere and by the end of 1838 had taken over the leadership of a movement which he had not brought into existence. He had weaknesses as a leader, but it is difficult to see how Chartists could have been effectively led, given their social composition and aspirations.

The Chartist plan of campaign was to call a convention of delegates, which would sit as a rival to the house of commons and prepare a national petition for parliament. Elections for the convention took place at crowded meetings all over the country in the autumn of 1838. The Chartists explained that if the commons refused to accept the petition then they would fall back on "ulterior measures," including a general strike—the so-called "Sacred Month." There was little agreement between them, however, on tactics. Some leaders were more militant than others, and the militancy of the movement as a whole varied at different times. When the convention met in Feb. 1839, it was very soon torn by dissension. Some of the more moderate Chartists left its ranks, and in the course of heated debates there was little agreement about exactly what form "ulterior measures" would take.

In May the convention moved to Birmingham, where it immediately ran into difficulties. Riots led to the arrest of Lovett and J. Collins. two of the more moderate Chartist leaders. The rump of the convention returned to London, and when the petition was discussed in parliament (July 1839), only 46 members of parliament expressed any desire to discuss Chartist grievances in detail. From this point onward the position was confused. The convention was disbanded in Sept. 1839. There was talk in some Chartist circles at this time of co-ordinating the "physical force" of Chartism in various parts of the country, and in November there was a skirmish between Chartists and the military at Newport, known as the Newport rising. However, the rising was not supported by Chartists elsewhere. Its leaders, the most important of whom was John Frost, were sentenced to death, afterward mitigated to transportation. The police rounded up nearly every other Chartist leader in 1839, and many of them were sentenced to one or two years' imprisonment.

Emphasis was now placed by the more responsible Chartists on the need for improved organization—an emphasis which corresponded to the natural inclinations and traditions of the Scottish Chartist leaders. many of whom took the initiative. In Sept. 1839 the *Chartist Circular* was founded in Glasgow: its message was more restrained than that of O'Connor's *Northern Star*, which had first appeared in Leeds in Nov. 1837. In July 1840 the National Charter association was founded in Manchester in an attempt further to tighten and to centralize working-class organization. Ultimately, however, all such efforts were likely to founder because of working-class poverty and lack of political experience. Chartism could not vie with the far better-organized Anti-Corn Law league. Although the Chartists collected 3,315,752 signatures to their second national petition of 1842, parliament again refused to listen to their claims. The year 1842 was a bleak one in British social history, and in the north of England there were serious strikes and riots in the industrial areas.

With a revival of trade in the mid-1840s, largely as a result of the increase in employment generated by the construction of railways, Chartism lost some of its mass support. O'Connor, who maintained his supremacy despite fierce faction fights both locally and nationally, paid increasing attention to his land plan, a scheme for settling Chartists on the land as small holders by means of the National Land company. The scheme is explicable in terms of the social conditions of the age, yet it was a financial failure. Subscribers to the company numbered 70,000, and the opening in 1847 of the first estate—O'Connorville in Buckinghamshire—was heralded as the beginning of a new era which would eventually end female and child labour in the factories and restore the workingman to his proper importance. This conservative element in Chartism was by no means its only ideological component: some Chartists, like James Bronterre O'Brien, were genuinely radical; others, like George Julian Harney and a later convert, Ernest Charles Jones (*qq.v.*), were socialists.

The last great burst of Chartism was in 1848. In a year of bad trade at home and revolution on the continent, a third national petition was promoted and a national assembly summoned. The petition was to be presented by a procession of Chartists marching from Kennington common to the house of commons on April 10. The government took careful precautions, and the procession did not march. Thereafter, Chartism remained active in the provinces, but its appeal as a national mass movement was ended. O'Connor went insane, and Ernest Jones became the most prominent leader in the declining years of Chartism. Many of the people who had been Chartists continued to serve other working-class causes in changing economic and social circumstances, and the Chartist spirit and name lingered on long after the collapse of the organization. All but the last of the six points have since been secured: in that sense there has been a "victory of the vanquished."

CHARTRES, a city of northwestern France, capital of the *département* of Eure-et-Loir, 86 km. (53.4 mi.) S.W. of Paris by road. Pop. (1954) 26,478. Chartres is on the left bank of the Eure, on a hill crowned by its famous cathedral. the spires of which are a landmark on the plain of Beauce, "the granary of France." The Eure, which within the city divides into three branches, is crossed by several bridges, some ancient, and is fringed by remains of fortifications; the Porte Guillaume (14th century), most notable of the remains was largely destroyed in World War II. The steep. narrow streets of the old town contrast with the boulevards that encircle it and divide it from the suburbs.

The great cathedral of Notre Dame, one of the most magnificent examples of High Gothic architecture, was founded by Bishop Fulbert (11th century) on the site of a church that had been destroyed by fire. In 1194 another fire made new building necessary, and the present church was finished by the mid-13th century; there have been minor additions and alterations since that time. A fire in 1836 destroyed the upper woodwork. The statuary of the portals, the 13th-century stained glass and the Renaissance choir

screen are all unique. The south spire. the Clocher Vieux 1351 ft. high). dates from the 12th century; the Clocher Neuf (377 ft.) was not completed till the 16th century. The cathedral is about 440 ft. long. its choir measures 150 ft. across and the vaulting is 121 ft. high. (See also GOTHIC ARCHITECTURE; SCULPTURE: *Romanesque and Gothic.*)

Chartres also has several other churches of note: the abbey church of St. Pierre. chiefly 13th century, contains fine stained glass; St. Martin-au-Val is a 12th-century church. with a crypt rebuilt about 1000 with sculptures attributed to the 6th century; the church of St. Aignan is Renaissance. with windows dating from that time: the church of St. André is Romanesque. The museum. housed in the former episcopal palace (17th and 18th century) near the cathedral. contains 12 representations of the apostles in enamel (1547) by Léonard Limosin, among a large number of valuable exhibits.

Chartres is on the main line from Paris to Le Mans and Nantes. It is a market town for the region of Beauce. Industries include dour milling. timber sawing, brewing, distilling, iron and bronze founding, leather manufacture. dyeing and the manufacture of stained glass and glass for ships' portholes, billiard requisites, hosiery, agricultural machinery, cranes, electronic equipment. car accessories and plastic work.

Chartres was one of the principal towns of the Carnutes and by the Romans was called Autricum, from the river Autura (Eure). It was burned by the Normans in 858 and unsuccessfully besieged by them in 911. It was occupied by the English during 1417–32. Attacked unsuccessfully by the Protestants in 1568, it was taken in 1591 by Henry IV, who was crowned there three years afterward. During the middle ages Chartres gave its name to a countship held by the counts of Blois and Champagne and afterward by the house of Châtillon, a member of which in 1286 sold it to the crown. It was raised to the rank of a duchy in 1528 by Francis I. The Germans seized the town on Oct. 21. 1870, and used it as a centre of operations. In World War II it was again occupied by the Germans, from June 1940 until Aug. 1944.

CHARTREUSE, a liqueur made by the monks of La Grande Chartreuse, the motherhouse of the Carthusian order, near Grenoble. France. It is said that over 130 different herbs are used in its production, while the. flavour of angelica root is apparent. Some believe it to be the finest liqueur obtainable. The finer green chartreuse contains 55% alcohol and the yellow kind 43% (by volume).

In 1605 Maréchal d'Estrées gave the Carthusians of Paris the recipe for the elixir, and in 1735 the Parisian fathers passed the recipe to the monastery of La Grande Chartreuse, where Brother Gérôme Maubec, "a very clever apothecary," perfected it in 1757. The secret of the formula has remained with the monks ever since and has never been discovered by analysis. In 1792 the Carthusians were expelled by the Revolution but returned in 1616, when they began to commercialize their secret; by 1860 the sales of their liqueur were so large that they built a big distillery at Fourvoirie, five miles from the monastery. In 1903 they were again expelled from France and eventually found asylum at Tarragona in Spain, where they were able to buy a distillery. In the meantime the distillery at Fourvoirie had been sold by the French government together with the original trade-mark, under which an imitation liqueur soon appeared. The monks therefore adopted a fresh trade-mark. However, in 1929 the firm making chartreuse in France ceased operations. the field being left to the genuine chartreuse made at Tarragona, and in 1940 the monks were allowed to return to La Grande Chartreuse, after which they resumed manufacture there. Their original trade-mark was readopted at Tarragona in 1929 and is still in use. (C. C. H. F.)

CHARTREUSE, LA GRANDE, one of the world's most famous monasteries, the motherhouse of the order of Carthusian monks (*see* CARTHUSIANS) and model for all the other charterhouses of the Carthusians. It is situated in a solitary valley of the French Alps, about 15 mi, from Grenoble.

Founded in 1084 by St Bruno (q v), the original settlement took its name from the surrounding mountains of Chartreuse (Lat , Cartusia; English, Carthusian; anglicized. charterhouse). The first monastery was completely destroyed by an avalanche in 1132, and the monks rebuilt about one mile south in a more suitable location. where La Grande Chartreuse now stands. Apart from a few transepts of the ancient church very little remains of the 12th-century monastery, nhich was ravaged several times by fire. A considerable part of the present monastery dates from the 14th century: to this Dom Le Masson made major additions after a fire in 1676.

Entirely surrounded by a high enclosure wall, the monastery buildings comprise three functional groups: service facilities, conventual buildings and eremitical dwellings. Thirty-five monks' cells. each consisting of ambulatory. living-bedroom. oratory, workshop and private garden, open on the main cloister. The main cloister. longer than St. Peter's at Rome, measures 705 ft., and one section, the handsome Gothic north cloister, dates from the 14th century. The main cloister connects the monks' cells with the church. The principal conventual buildings, church, chapter and refectory, all of the 14th century, are grouped according to the traditional monastic plan around a small cloister. In the vicinity of the church. about 25 chapels serve for the celebration of private masses. Contiguous to the conventual buildings are vast pavilions for the reception of the priors who gather there annually for the general chapter.

In the workshops, utilities and barns, modern machinery and equipment fit more or less comfortably into the 17th-century architecture.

Characteristic of the Carthusian order's spirit, the buildings give the impression of exceptional solidity and stability. The massive stone construction, high slate roofs, cross-surmounted turrets and stately clock tower seem as eternal as the sheer limestone palisade of the Grand Som, which rises majestically to 6,000 ft., directly behind the monastery.

The monks, expelled in 1792 by the Revolutionary government, returned to La Grande Chartreuse in 1816. Again expelled in 1903, the community remained in exile until 1940, when political conditions once more permitted its return. Before the French Revolution the library contained a fine collection of books and manuscripts, most of which are now at the public library of Grenoble.

Classed as a historical monument by the government. La Grande Chartreuse is one of the most visited places in France, both because of the scenic beauty of the area and the spiritual and historic interest of the monastery. Visitors are not permitted to enter the monastery, but a Carthusian museum presents a comprehensive view of the monks' life and history. (S. M. B.)

CHASE, PHILANDER (1775–1852), U.S. Protestant Episcopal bishop and founder of Kenyon college, Gambier, O., was born in Cornish, N.H., on Dec. 14, 1775, the 15th child of Dudley and Allace Chase. He e'ntered Dartmouth college, Hanover. N.H., in 1791, graduating four years later. Brought up a Congregationalist. he became converted to the Protestant Episcopal Church during his sophomore year at college as the result of studying the Book of Common Prayer. After graduation, he went to Albany, N.Y., to study for the ministry under the Rev. Thomas Ellison, rector of St. Peter's church. He married Mary Fay in 1796 and. after her death. took a second wife, Sophia May Ingraham, in 1819. After being ordained deacon on May 10, 1798. he served for a time as itinerant minister in western New York state. then in the stage of early settlement. He became rector of Christ church. Poughkeepsie. N.Y., in 1799. In 1805 he was called to Christ church, New Orleans, La., where he was the first regularly settled Protestant minister. He served there until 1811. when he became rector of Christ church, Hartford, Conn. In 1817. feeling that the new settlements in the west offered the greatest missionary challenge. Chase went to Ohio, though he had no regular appointment and no assured means of support. In 1818 the few

Episcopal clergy in the state organized a diocese and elected him bishop. He was consecrated on Feb. 11, 1819. Believing that the needs of the west could best be served by western-trained clergy, he founded Kenyon college and its affiliated theological seminary, Bexley hall. in 1824, with the aid of iunds raised in England. He resigned his jurisdiction in 1831 in consequence of a dispute over the control of the college. After residing a few years in Michigan, he was elected first bishop of Illinois in 1835. He served in that position and as president of Jubilee college, which he founded in 1838, until his death on Sept. 20. 1852. He was presiding bishop of the Protestant Episcopal Church from 1843 to 1852, His *Reminiscences* were published in 1848.

See L. C. Smith, *The Life of Philander Chase* (1903). (W. W. Ms.)

CHASE, SALMON PORTLAND (1808–1873), U.S. senator. governor, secretary of the treasury and chief justice of the United States, was born in Cornish. N.H.. on Jan. 13, 1808. He graduated from Dartmouth college in 1826, and after conducting a school for boys in Washington, D.C.. and studying law under Attorney General William Wirt, was admitted to the bar in 1829. Chase settled in Cincinnati. O., in 1830 and edited the *Statutes* of Ohio (3 vol., 1833–35).

In the late 1830s Chase, influenced probably by James G. Birney (*q.v.*), associated himself with the politically active wing of the antislavery movement. His services as legal counsel for fugitive slaves, particularly in the famous case of John Vanzandt, one of the "conductors" of the Underground Railroad (*q.v.*), led him to become known as the "attorney general for runaway Negroes." Slavery was the central issue in Chase's political life. In 1841 he abandoned the Whig party and for seven years was the outstanding leader of the Liberty party in Ohio. His skill in drafting platforms and addresses is exemplified by the Liberty platform of 1843 and the Liberty address of 1845. Realizing that a third-party movement confined to a single issue could not succeed. he sought to capture the Democratic party for the antislavery cause. He took the lead during the campaign of 1848 in combining the Liberty party with the "Barnburner" faction of the Democratic party to form the Free Soil party (*q.v.*), and was influential in obtaining the nomination in that year of former Pres. Martin Van Buren as the Free Soil candidate for the presidency. In 1849 a coalition between the Democrats and a small group of Free Soilers in the Ohio legislature led to his election to the United States senate. In the senate (1849–55) Chase was a pre-eminent spokesman against the extension of slavery in the territories. He opposed the Compromise of 1850 (*see* COMPROMISE OF 1850), and in 1854 denounced Sen. Stephen A. Douglas' Kansas-Nebraska bill in the "Appeal of the Independent Democrats." His policy throughout was to restrict the expansion of slavery and to free the Democratic party from proslavery control. The passage of the Kansas-Nebraska bill and the subsequent troubles in Kansas ultimately convinced him of the futility of trying to influence the Democrats. and the dissolution of the Whig party opened the way for a new party organization. Chase was active in the formation of the Republican party to oppose the extension of slavery. He was the first Republican governor of Ohio (1855–59).

Chase was an active candidate for the Republican presidential nomination in both 1856 and 1860. Although. with the exception of William Seward, he was the most widely known Republican in the country, he failed to secure the nomination in either year, partly because the old-line Whig element could not forgive his long flirtation with the Democrats and partly because his uncompromising views on slavery were too well known. However, as secretary of the treasury during the first three years of the Civil War (1861–64), he rendered services of the greatest value. That period of crisis witnessed two great changes in U.S. financial policy: the establishment of a national banking system and the issue of inconvertible U.S. treasury notes (greenbacks) as legal tender. The former, Chase's own particular measure, was a most important contribution to U.S. economic development: to the latter he reluctantly acceded as a necessary measure of war finance.

Chase's chief defect as a statesman was an insatiable desire to become president. His willingness in 1864 to head an anti-Lincoln movement, while retaining his place in Pres. Abraham Lincoln's cabinet. verged on disloyalty and led to such "mutual embarrassment" that Lincoln accepted his resignation in June 1864. Nevertheless, several months later (Dec. 6, 1864) Lincoln, despite misgivings created by Chase's presidential ambitions, appointed him to the supreme court as chief justice. a position which Chase held until his death in New York city on May 7, 1873.

Chase assumed the chief justiceship at a time when the prestige of the court was at its lowest ebb. Although he was not a distinguished legal scholar and cannot be ranked among the foremost U.S. jurists, his political wisdom in handling the constitutional problems created by civil war and reconstruction preserved the court and did much to restore its prestige. In *Mississippi* v. *Johnson* (4 Wallace 475) (1867), and *Georgia* v. *Stanton* (6 Wallace 50) (186;). Chase led the court in refusing to enjoin the president or a member of his cabinet from enforcing the Reconstruction acts. In the important case of *Texas* v. *White* (7 Wallace 700) (1869), Chase declared secession a nullity and the federsl union indissoluble. Courageous stands against the military trial of civilians (*Ex parte Milligan*, [4 Wallace 2] [1866]) and against test oaths designed to penalize former Confederates (*Cummings* v. *Missouri*, [4 Wallace 277] [1867]; Ex *parte Garland*, [4 Wallace 333] [1867]) indicated that the Chase court would uphold traditional freedoms. Chase's best-known judicial opinions are those dealing with the constitutionality of the legal tender legislation enacted when he was secretary of the treasury. In *Hepburn* v. *Griswold* (8 Wallace 603) (1870), he wrote the opinion of the court declaring these acts unconstitutional, and in the *Legal Tender Cases* (12 Wallace 457) (1871), he vigorously dissented when a differently constituted court overruled its prior decision and upheld the legislation. The dignity and fairness with which Chase presided over the U.S. senate during the impeachment trial of Pres. Andrew Johnson. in spite of popular attack, redound to his credit, just as his continued attempts in 1868 and 1872 to attain the presidency reduced his influence.

A serious, dignified man of strong religious principles, Chase was respected for his ability and determination. He lacked magnetism, warmth and humour and often appeared self-righteous and opinionated. Nevertheless, he was one of the ablest leaders of the American Civil War period and deserves to be placed in the front rank of U.S. statesmen.

BIBLIOGRAPHY.—The standard biography is Albert B. Hart, *Salmon Portland Chase* (1899). A greater wealth of detail is to be found in J. W. Shuckers, *Life and Public Services of Salmon Portland Chase* (1874) and *R.* B. Warden, *Account of the Private Life and Public Services of Salmon Portland Chase* (1874) An objective portrayal is T. G. and M. R. Belden, *So Fell the Angels* (1956). (R. C. C.)

CHASE, SAMUEL (1741–1811), U.S. legislator and U.S. supreme court justice, was a signer of the Declaration of Independence. and while serving on the United States supreme court was the object of an unsuccessful impeachment trial inspired by Pres. Thomas Jefferson.

Born in Somerset county. Md., on April 17, 1741, Chase was admitted to the bar at Annapolis in 1761, and for more than 20 years was a member of the Maryland legislature. He took an active part in the resistance to the Stamp act. and from 1774 to 1778 and 1784 to 1785 was a member of the continental congress. He did much to persuade Maryland to advocate a formal separation of the 13 colonies from Great Britain. and signed the Declaration of Independence on Aug. 2. 1776. In 1791 he became chief judge of the Maryland general court.

Pres. George Washington, in Jan. 1796, appointed Chase an associate justice on the federal supreme court ivhere he was soon speaking his mind in a series of important opinions. Thus. in *Calder* v. *Bull* (3 Dallas 386) (1798), he contributed to later interpretations of the due process clauses by asserting that legislative powers over liberty and property were limited by "certain vital principles in our free Republican governments." When John Marshall became chief justice in 1801, Chase's influence declined sharply.

At the height of the struggle between the .Federalist and Jeffersonian-Republican parties, Justice Chase, a Federalist sympathizer. conducted his circuit court in so partisan a fashion as to

cause his impeachment. With President Jefferson's blessing, the house of representatives in 1804 voted to press charges. Six of the eight articles on which Chase was tried before the senate in Feb. 1805 charged him with improper and arbitrary actions at the treason and sedition trials of John Fries and James G. Callender in 1800. and two, with intemperate or political addresses to grand juries. The senate, on March 1, gave a verdict of not guilty on all counts. Chase remained in office until his death. June 19. 1811.

Many writers have conjectured that if Chase had been convicted, the Jefferson administration would have proceeded next against Marshall and other Federalist judges. Whatever may have been his initial plan, Jefferson later concluded that as a means of holding judges accountable, impeachment had proved a "bugbear" and a "mere scare-crow." Clearly, the acquittal, by creating the impression that justices were removable only for criminal conduct, reinforced the independence of the judiciary.

Beveridge, *Life of John Marshall*, vol. iii, pp. 169–222 (1919). (D. G. MN.)

CHASE, WILLIAM MERRITT (1849–1916), U.S. painter, perhaps the most important influence in establishing the fresh, spontaneous colour and technique that characterized much of American painting in the early 20th century. He was born at Franklin. Ind.. on Nov. 1, 1849, and studied under B. F. Hayes in Indianapolis and J. O. Eaton in New York city. In 1872 he went to Munich. where he studied with Karl von Piloty and met Frank Duveneck and J. H. Twachtman. He abandoned the dark palette of the Munich school in the 1880s.

From his return to the U.S. in 1878 until his death on Oct. 25. 1916, he taught continually. In New York city he established a school of his own. after having taught for several years at the Art Students' league. A worker in all mediums—oils, water colour, pastel and etching—he painted with distinction the figure, landscape and still life. He is probably best known by his portraits and his studies of studio subjects and dead fish.

Chase won many honours at home and abroad, became a member of the National Academy of Design, New York, and for ten years was president of the Society of American Artists. In 1912 he was awarded the Proctor prize by the National Academy of Design for his "Portrait of Mrs. H." At the Panama Pacific exposition (1915) a special room was assigned to his works. Among his most important canvases are "Ready for the Ride," "The Apprentice," "Court Jester," and portraits of his friends, the painters Whistler and Duveneck.

CHASLES, MICHEL (1793–1880), French mathematician, who specialized in geometry, was born on Nov. 15. 1793, at Épernon. He was educated at Paris, and engaged in business, which he later gave up for the study of mathematics. Chasles was made professor of geodesy and mechanics at the Polytechnic school and later professor of higher geometry at the Sorbonne. He and Jakob Steiner independently elaborated modern projective geometry. Chasles used his "method of characteristics" and his "principle of correspondence" to solve many problems; the solutions were published in a series of papers in *Comptes Rendus*. The problem of the attraction of an ellipsoid on an external point was solved by him in 1846. Many of his original memoirs were later published in the *Journal de l'École Polytechnique*. Chasles wrote two textbooks, *Higher Geometry* (1852) and *Conic Sections* (1865). His *Aperçu historique sur L'origine et la développement des méthodes en ge'ometrie* (1837) is a standard work, the subject being continued in *Rapport sur le progrès de la ge'ometrie* (1870). Chasles was the victim of a celebrated fraud; an impostor, Vain-Lucas, induced him to purchase various collections of faked letters from famous men of science, for a total of nearly 200,000 fr. He died in Paris on Dec. 18, 1880. (O. OE.)

CHASLES, (VICTOR) PHILARÈTE (EUPHÉMON) (1798–1873), French scholar and writer who was a pioneer in comparative European literary history and criticism. Born at Mainvilliers (Eure-et-Loir) on Oct. 8. 1798, he was brought up in Paris, where his father became a member of the Convention. Apprenticed at the age of 15 to a printer, Philarète was imprisoned under the restored Bourbons for his Jacobin opinions, after which he went to England for five years. Returning to France in 1823, he soon afterward began writing for various periodicals, including the *Journal des débats* and the *Revue des deux mondes*. His connection with the latter came to a stormy end, resulting in a lawsuit in 1854. In 1837 he became curator of the Bibliothèque Mazarine and in 1841 he was elected to the chair of comparative literature at the Collkge de France. He died at Venice on July 18, 1873.

Chasles is best known for his essays collected under the title *Etudes de la littérature comparée* (1846–75), of which *Études sur le XVIII^e siècle en Angleterre* (1846) is the most famous.

See E. M. Phillips, *Philarète Chasles, critique et historien de la littérature anglaise* (1933).

CHASSERIAU, THEODORE (1819–1856), French painter, who sought to combine the classicism of Ingres with the romanticism of Delacroix. was born on Sept. 20. 1819, at Samana in the Dominican Republic, where his father was French consul As a boy of 11, Chassériau entered the studio of J. A. D. Ingres where he remained until Ingres left Paris for Rome in 1834 His first pictures shonn at the Paris salon in 1836 won immediate success, confirmed three years later by the "Vénus Marine" and the "Suzanne" (both now in the Louvre. Paris). Late in 1840 Chassdriau visited Rome to see Ingres but began to feel dissatisfied with the work of his former master. His portraits of this period, "Lacordaire" (Salon, 1841) and "Les Deux Soeurs" (Salon. 1843), both in the Louvre, were, however, still in the Ingres tradition. After about 1843 the influence of Ingres's rival, Eugène Delacroix. made itself felt. both in style and in choice of subject matter. Chassériau was deliberately attempting to combine the rhythmical linear qualities of Ingres with the colouristic methods of Delacroix. The 15 Othello etchings (published 1844) and the paintings of Moorish and Jewish life that followed Chassériau's visit to north Africa in 1846 were reminiscent of Delacroix. though Chassériau was able to add an exotic quality of his own.

Chasskriau was an important figure in the revival of monumental painting in France. He decorated (1841–43) the chapel of St. Mary of Egypt in the Church of St. Merri, Paris, and the main staircase of the Cour des Comptes in the Palais d'Orsay with allegorical scenes of war and peace, etc. (1844–48) This was followed by commissions for two frescoes at St. Roch. Paris (1853–54), and for the choir vault of St. Philippe-du-Roule (a "Descent From the Cross," 1854–56). Apart from the last-named. none of these paintings has survived intact, though fragments of the Palais d'Orsay decorations are preserved in the Louvre. Chassériau died in Paris on Oct. 8, 1856. He a-as a prolific draftsman, and most of his sketchbooks are now in the Louvre. After his early death his influence continued in the work of his friends and pupils, Gustave Moreau and Puvis de Chavannes.

See monographs by V. Chevillard (1893), H. Marcel (1911) and L. Bénédite (1932). (A. Bs.)

CHASSEURS, originally a term used in the French army to designate light-infantry or cavalry regiments After World War I the term also was applied to armoured units

Light-infantry units known as *chasseurs à pzed* have been in continual existence since 1743 except for the period 1840–70 By the outbreak of World War I there mere 30 battalions of *chasseurs*, of which 12 were knonn as *chasseurs alpins* These latter nere specially trained and equipped for mountain warfare After World War II *chasseurs* mere formed as independent battalions for administrative purposes, but were grouped into demibrigades of three battalions for war. They mere distinguished from line infantry by their dark blue uniforms. Just prior to World War II a few battalions were integrated into armoured divisions as motorized infantry and called *chasseurs porté*.

The light cavalry (*chasseurs à cheval*) regiments were first instituted in 1779 They performed notable service in the European

campaigns of the second empire. At the close of World War I they were represented by five regiments of *chasseurs d'Afrique,* originally recruited in 1831 for service in Algeria.

The number of such cavalry units was increased following World War I. and they were progressively reorganized into light armoured battalions. In the process, the term *chasseurs de churs* mas added to distinguish units specifically designed as tank-destroyer units The original connotation of *chasseurs* to designate lightly equipped units has been lost in the armoured branch of the French army. After the early 1950s this traditional term was used to designate light-, medium- and heavy-tank as well as armoured reconnaissance units. (B. H T)

CHASTELARD, PIERRE DE BOSCOSEL DE (1540–1563). French courtier whose name is inseparably connected with Mary Stuart. Born in Dauphiné in 1540. he first met her at the court of Francis II and was later a member of the retinue which accompanied her to Scotland in 1561. He revisited Edinburgh the next year, spent the winter at court and fell in love with Mary, who is said to have encouraged his passion The young man hid himself under her bed, where he was discovered by her maids of honour. Mary pardoned the offense. but Chastelard was so rash as again to violate her privacy. He was discovered a second time. seized. sentenced and hanged the next morning. His story is the subject of Algernon Charles Swinburne's verse drama *Chastelard* (1865)

CHASTELLAIN, GEORGES (1415?–1475), Burgundian chronicler and one of the leading court poets, had many literary admirers and followers. among them Jean hlolinet. Pierre Michault, Jean Meschinot and Guillaume Flameng. Born in Alost, Flanders, he served Philip the Good, duke of Burgundy. until in 1435, after the peace of Arras, he abandoned soldiering He spent the next years in France mainly as secretary to Pierre de Brézé, seneschal of Poitou During this period his services were used to try to improve relations betneen Philip the Good and Charles VII of France. His affection for France remained even when, in 1446, he entered Philip's household There too he nas used on secret and diplomatic missions, and in 1455 he was also appointed Burgundian historiographer. About 1463 his disciple and successor. Jean Molinet, became his secretary. Chastellain died at Valenciennes in 1475, on March 20 according to his epitaph, on Feb 13 according to the treasury accounts of the town Only about one-third of his *Chronique des Ducs de Bourgogne* has survived. a complete copy. presented to the queen of Hungary in 1524 by his natural son, Gautier, has never been traced. The most complete (though faulty) edition of his extant works is that of Kervyn de Lettenhove *(Oeuvres de Georges Chastellain,* 1863–66), consisting of five volumes of the chronicle and three of other works.

The chronicle extends, with lacunae. from 1419 to 1474. Its interest lies in the descriptive and factual information it contains and in its shrewd assessment of contemporary figures and motives. Though paid by Burgundy. and not impartial, Chastellain does not hesitate at times to lay blame upon his patrons The growth of middle-class political self-consciousness. however, meets with scant sympathy in his chronicle.

Chastellain's other work consists of formal poems of little interest; works addressed to fellow writers. *e g., L'Épistre à Jean Castel* and *Les Douze Dames de Rhétorique;* political pieces. *e.g., Le Thrône Azuré,* addressed to Charles VII after the defeat of the English in Normandy; *Les Paroles de trois puissants princes* on the political motives of Philip the Good Charles VII of France and Henry VI of England; *Le Dit de Vérité* on the discord between France and Burgundy; *Le Lyon Rampant* on the struggle between Louis XI of France and the duchy of Burgundy; *Le Temple de Boccace,* dedicated to Margaret of Anjou; and the *Déprécation* for Pierre de Brézé imprisoned by Louis XI; and didactic works and plays. often allegorical in form, and, like all Chastellain's writing, somewhat Latinized in style

CHÂTEAU, the French word for "castle" *(q v)*. The development of the castle in the 15th and 16th centuries into houses arranged rather for residence than defenses led to a corresponding widening of the meaning of the term château which came to be applied to any seigniorial residence and so generally to all country houses of any pretensions *(cf.* the Ger. *Schloss).*

The French diitinguish the fortified from the residential type by describing the former as the *château fort,* the latter as the *château de plaisance* The development of the one into the other is admirably illustrated by the châteaux scattered along the Loire. Of these, Langeais, still in perfect preservation, is a fine type of the *château fort,* with its 10th-century keep and 13th-century walls. Amboise (1490), Blois (1500–40), Chambord (begun 1526). Chenonceaux (1515–60) and Azay-le-Rideau (1521) *(qq.v.)* may be taken as typical examples of the *château de plaisance* of the transition period, all retaining some of the architectural characteristics of the medieval castle. *See* also RENAISSANCE ARCHITECTURE: *Fmnce.* (T. F. H.)

CHATEAUBRIAND, FRANÇOIS RENE DE CHATEAUBRIAND, VICOMTE DE (1768–1848), French author and politician, was one of the first romantic writers in France, a distinguished if rather erratic politician and an outstanding figure in the early part of the 19th century. He was born at St. Malo, Brittany, on Sept. 4, 1768. His father was an eccentric and impecunious Breton noble, who, to maintain his just claim to noble birth, invested the family fortune in the estate of Combourg, near Dol, which carried with it the title of count. When Chateaubriand was nine, the whole family moved there, and the half-derelict medieval castle, with the ancient oak woods and wild heaths that surrounded it, became the familiar background of his yourh. He was the youngest of the family; the elder brother and the three elder sisters soon made their way out into the world, but he shared a remote life with his youngest sister, Lucile, a plain and delicate girl of a strange intensity of feeling. Chateaubriand went away to school, first at Dol and then at Rennes and Dinan, but the holidays were long, and the romantic solitudes of Combourg were more congenial than the dusty classrooms of clerical schools. By the time he was 17, he succeeded in escaping from their walls and settling at Combourg.

He had no purpose in life but an idle melancholy, in which Lucile shared. Her natural piety had become obsessive; her father turned it into a useful channel by getting her accepted as an associate of the noble canonesses of Argentière, where in time, when she was a full canoness, she might hope for a little house and a modest income of her own. Meanwhile, the brother and sister spent their days wandering round the Breton countryside. in an atmosphere compounded of boredom and sensitivity that fostered little but imaginative dreams. Very gradually these began to find expression in verse. (Lucile's *Oeuvres* were edited, with a memoir, by Anatole France in 1879). After Chateauhriand had been at home nearly three years, it was suddenly decided by his father that Chateaubriand must take the commission his brother offered him in the regiment of Navarre

His sojourn with his regiment did little but mend his manners; his father's death did nothing to mend his fortunes. He led a much more normal life, however, in the homes and among the friends of his married sisters, in Brittany and Paris; a life that was suddenly ended by the French Revolution. By the autumn of 1790 his regiment was in insurrection. He refused to join the royalists at Coblenz but sailed in April 1791 from St. Malo for Baltimore, Md., to discover the United States.

He did not get very far: Baltimore, Philadelphia, New York, Albany and Niagara falls. He found the towns provincial and ordinary enough and much of the country flat and uninteresting; but he rode to Niagara falls with a party of fur traders, through virgin forest; he met Cayuga Indians (thau were taking dancing lessons from a wandering Frenchman) and spent some days in their company, went on to visit the Onondagas and met other less sophisticated redskins in the romantically unspoilt country near Niagara. Finally, he visited the falls. It is not

surprising that Chateaubriand began to write a prose poem that was to be an epic of the savages.

He reached the shores of Lake Erie and there learned of the flight of Louis XVI to Varennes. For the first time he was conscious that he owed obligations to the monarchy, as well as to the "ideas of 1781"; he decided to return to France.

He found western France ravaged by the revolutionaries and his family sheltering in St. Malo. He was penniless; they solved the problem by marrying him to an heiress of 17, Céleste Buisson de la Vigne. She was pretty in a pink and white way, but had neither features, grace nor flexibility of mind. They went to Paris but soon realized that the Paris of the Revolution was too unsettled and. above all, too expensive for them. In June 1792 Chateaubriand and his elder brother left Paris under false passports and succeeded in joining the royalist armies at Coblenz. He took part in the siege of Thionville, where he was wounded. Discharged from the army and growing more and more ill from his infected wound, he made his way slowly and with infinite hardship to Brussels. There he fell ill with smallpox, but his brother found him and got him to Jersey. There, in the charge of some of his Breton kin, he recovered a measure of health; and thence he sailed in May 1793 for England.

London was full of French refugees trying to keep alive on the shilling a day that the government allowed the *émigrés*. Chateaubriand was too proud to take it and paid for his half share in a cousin's garret in Holborn by translations. At the same time he began to write an essay on revolutions, which his Breton friends assured him might well find a publisher. Holborn proved too expensive, and he moved to Marylebone; finally another Breton found him a small teaching post at Bungay, Suffolk, which he took up in the autumn of 1793.

Suffolk gave him back a measure of health and just enough to live on but bored him profoundly. He polished the essay on revolutions; he translated some Ossianic imitations and even had them published; and he had flirtations first with the wife of a neighbouring parson and then with the daughter. It all ended dramatically when he had to admit he was already married; he wisely decided to return to London.

The news from France was tragic. His brother and his sister-in-law had died on the scaffold with her grandfather Chrétien de Malesherbes, who had dared to defend Louis XVI; his own wife and his sisters were imprisoned at Rennes, his mother in Paris.

Back in London Chateaubriand worked steadily at the Indian epic he had first envisaged in America. *Les Natchez* (of which no more than half was ever written) is a hotchpotch of a book, sometimes tiresome, sometimes silly and often beautiful, alike in its descriptions of scenery and in its depiction of human passion. Chateaubriand was a natural colourist and had learned from English poetry that colour could be admitted even to *le style noble;* and though he had seen very little of America he had ridden through virgin forest and had slept in the tents of the Indians, at a time when he saw and felt everything with the acute sensibility of youth.

By the end of 1796 he learned that his mother and sisters had been released and that Lucile had married a man much older than herself. Early the next year the first volume of his "Essay on Revolutions" was published in London, to shock his *émigré* friends by its rejection of Christianity. It brought him, however, into a more intellectual and more fashionable circle of London French, and there he made one true and real friend in the journalist Louis Fontanes (*q.v.;* later marquis de Fontanes).

Fontanes returned to France in July 1798, and Chateaubriand began to write a romantic account of Christianity — ultimately famous as the *Génie du christianisme* (1802) — which gave him the entrée to the pious royalist circles of London. Fontanes, meanwhile, was making himself acceptable to Napoleonic society in Paris and was soon in a position to invite Chateaubriand to join him. They met in Paris in May 1800 and were soon joined by Céleste, who had earlier been released from prison.

Chateaubriand found that his London reputation had not preceded him and that his writings were unknown in his own country. He set to work on free-lance journalism, on the *Gdnie* and on the revision of his Indian epic. A fragment of it appeared as *Atala* in April 1801 and had an instantaneous success. It combined the apparent simplicity of a classical idyll with the more troubled beauties of romanticism. He was able to live under his own name, with his own passport, and to move among the noble and impoverished society that maintained pre-Revolutionary standards of taste, even in Napoleonic Paris. In the *salon* of Pauline de Beaumont he found not only society but a woman to love and to cherish him. With her encouragement he finished the *Gdnie,* of which the most finished and most admired section was the episode called *René,* which told the story of a sister's passion for her brother, set in an ancient castle in the depths of the woods — a clear reminiscence of his youth at Combourg. The whole book was finally published a week after Napoleon had signed a concordat with the pope; it has remained the symbol of an epoch.

The book secured a measure of recognition even from Napoleon, though he and Chateaubriand had a natural antipathy for each other. In 1803 Chateaubriand was appointed first secretary to the embassy at Rome, under Napoleon's uncle, Joseph Fesch. He loved Rome and hated the ambassador; and when Pauline de Beaumont joined him, it was only to die. Finally at the end of 1803 he was made chargé d'affaires in the tiny republic of the Valais; but when he reached Paris, it was in time for the execution of the duc d'Enghien, and he at once resigned from the service of the emperor.

Chateaubriand spent the next years in domestic life and literary work, consoling himself with many love affairs. He and his wife lived economically in and near Paris, until in July 1806 he decided to make a journey to Jerusalem in search of literary material. He succeeded in leaving his wife at Venice and went on through many adventures to Corfu, the Peloponnese, Athens, Smyrna, Constantinople, Jerusalem, Alexandria, Carthage and Spain. The *Itinéraire de Paris à Jérusalem,* three volumes (1811), which was the literary fruit of the tour, was unduly stuffed with secondhand scholarship; but the firsthand part of it is fresh and delightful. Secondary books were *Les Martyrs* (1809) — which even contemporaries found dull — and the more acceptable *Aventures* du *dernier Abencdrage.* On the strength of the three books Chateaubriand stood for the French Academy and was elected.

The return of Louis XVIII in 1814 revived Chateaubriand's hopes of a political career. In 1815 he was created a viscount and a member of the house of peers, but he had none of the antennae of a politician and remained primarily a writer, and a writer more interested in his own view of history than in political fact. It was a time of financial difficulties. The only sunshine came from the beginning of a liaison with Madame Récamier, which was to illumine the rest of his life, and the chief occupation in starting the *Mémoires d'outre-tombe,* which are, perhaps, his most lasting monument. He and his wife settled, too, in a house in the rue du Bac that was to be his home until his death.

In 1820 he was nominated ambassador to Berlin. He did not take up the post until Jan. 1821 and hated it. By July political changes imposed his resignation; by Jan. 1822 a further change made him ambassador to London. It was for him the crown of his political career; that he, who had almost starved in London as a refugee, should now represent his country there could not but be the sweetest of time's revenges. From 49 Portland place he did his work well, at least from the point of view of prestige; but the drearier and more political side of diplomacy he despised. His *Mémoires,* however, progressed apace.

He was appointed as a French representative to the congress of Verona (1822); and at the end of its unfruitful negotiations found himself offered the ministry of foreign affairs under the comte de Villèle. It was delightful to return to Paris. and to Mme Récamier, with a position and an income, and 1823 brought the final satisfaction of a successful war against Spain. The bill for it brought him political disgrace.

The rest of his life was passed as a private individual and a spectator, but for a year in Rome as ambassador under Charles X in 1828–29. He remained loyal to his king at the revolution of 1830. He lived mainly in France, with occasional sojourns in Switzerland and a visit to London, where he was very kindly re-

ceived by the comte de Chambord. He died on July 4, 1848, as the revolution was imminent, and was buried on the island of Grand BC, near St. Malo.

BIBLIOGRAPHY.—*Les Oeuvres complètes* of Chateaubriand were printed in 28 vol., 1826–31; in 20 vol., 1829–31; and, notably in 1858–61, in 20 vol., with an introductory study by Sainte-Beuve. The principal authority for Chateaubriand's biography is the *Mémoires d'outre-tombe* (1849–SO), of which there is an English translation by A. Teixeira de Mattos, *The Memoirs of . . . Chateaubriand,* 6 vol. (1902), based on the edition of Edmond Biré, 4 vol. (1899–1901). *See* also *Souvenirs et correspondances tirés des papiers de Mme Récamier,* ed by Mme Ch. Lenormant, 2 vol. (1859); Comte de Marcellus, *Chateaubriand et son temps* (1859), *Souvenirs diplomatiques; Correspondance intime de Chateaubriand* (1858); C. A. CHÂTEAU-GAILLARD, on the Seine river near Les Andelys in the *de'partement* of Eure, is one of the most imposing ruins of medieval architecture in France. For a description of it *see* CASTLE. It was built on the order of Richard I Coeur-de-Lion of England to defend the dukedom of Normandy against the king of France, Philip II, after a truce in Dec. 1195. Work was begun in 1196 and the castle completed in 1198. It formed part of the fortified line between Norman and French Vexin, including the castles of Gisors and La Roche-Guyon. Its site, on a high spur of rock overlooking the river, afforded great advantage to the defender, who merely had to guard the southern end. Château-Gaillard defied medieval artillery, and it was only after a long siege (Sept. 1203–March 1204) that Philip II succeeded in taking it. After this, the French easily conquered Normandy.

The castle was later used as a prison for Philip IV's adulterous daughter-in-law Margaret of Burgundy; for David II, king of Scotland, who took refuge in France (1334); and for Charles II the Bad, king of Navarre (1356). It was taken and retaken by the English during the Hundred Years' War (1419, 1429, 1449). Château-Gaillard ended its usefulness during the civil wars of the 16th century. Henry IV took it in 1591 and ordered the outer works to be pulled down, and finally the cardinal de Richelieu had the donjon dismantled.

CHÂTEAU-RENAULT, FRANÇOIS LOUIS ROUSSELET, MARQUIS DE (1637–1716), French admiral who served with distinction in Louis XIV's wars, was born on Sept. 22, 1637, probably at Chlteau-Renault in Touraine. He served in the army under the vicomte de Turenne in Flanders in 1658 but transferred to the navy in 1661, his first experience in fighting at sea being against the Barbary pirates. Captain in 1672 and squadron commander in 1673, he took part in various campaigns in the Dutch war (1672–78), fighting against M. A. de Ruyter and other Dutch admirals in the North sea and the Mediterranean. Promoted lieutenant general in 1688, Chbteau-Renault conveyed an expedition to Ireland in 1689 to help James II in his plan for the reconquest of England. He landed the troops at Bantry bay and engaged the English fleet under Adm. Arthur Herbert (later earl of Torrington; *q.v.*) on May 10–11 but could not follow up an initial success. Next year he commanded the vanguard of the comte de Tourville's fleet in the battle of Beachy Head (*q.v.*), in which he was chiefly responsible for the defeat of the Dutch ships. In 1696 he was entrusted with bringing a squadron from the Mediterranean to Brest to join the Brest squadron for an attack on England, but the weather delayed him on the way and the enterprise came to nothing. From 1697 to 1700 he was in command at Brest. In 1701 he was created vice-admiral.

Early in the War of the Spanish Succession, Chlteau-Renault had the important task of escorting the Spanish treasure fleet from America to Europe. As the Spaniards would not let him take it to a French port and as the English were attacking Cadiz, he brought it into Vigo bay, where Adm. Sir George Rooke surprised him (Oct. 1702). Unable to save his ships, he had to set them on fire, losing part of the treasure. Louis XIV, not holding him responsible for this disaster, made him a marshal of France in 1703 and governor of Brittany in 1704. Chbteau-Renault died in Paris on Nov. 15, 1716.

CHÂTEAUROUX, MARIE ANNE DE MAILLY-NESLE, DUCHESSE DE (1717–1744), mistress of Louis XV of France, was born in Paris on Oct. 5, 1717, the fifth daughter of Louis de Mailly, marquis de Nesle. She was married in 1734 to the marquis de La Tournelle, who died in 1740. Her eldest sister, Louise Julie, comtesse de Mailly (1710–51), had been succeeded as the king's mistress by the next eldest, Pauline Félicité, marquise de Vintimille (1712–41). After the latter's death, Madame de La Tournelle, backed by the duc de Richelieu, was installed at Versailles as the king's acknowledged mistress (Dec. 1742), despite Cardinal Fleury and the comte de Maurepas: her price included the dismissal of Madame de Mailly from court and the title of duchesse de Chbteauroux for herself (1743). She incited Louis to look for military glory and received a letter of thanks from Frederick II of Prussia for her part in negotiating the alliance of 1744. Louis allowed her to join him with the army in Flanders in June 1744, dismissed her under pressure from the church during his illness at Metz in August but recalled her to court on his recovery. She died, suddenly, in Paris, on Dec. 8, 1744.

See E. and *J.* de Goncourt, *La Duchesse de Chdteauroux et ses soeurs,* new ed. (1889); also the *Histoire de Madanze de Châteauroux tirée des mémoires de la duchesse de Brancas* (1919).

CHÂTEAUROUX, a town of central France, capital of the *de'partement* of Indre (*q.v.*), situated on the left bank of the Indre river, 88 mi. S. of Orléans on the main line of the Paris-Toulouse railway. Pop. (1954) 36,016. The old town, close to the river, forms a nucleus around which a newer and more extensive quarter, bordered by boulevards, has grown up; the suburbs of St. Christophe and Déols lie on the right bank of the river. Châteauroux owes its name and origin to the castle founded between 935 and 950 by Raoul, prince of Déols, which later passed to Henry II of England, falling eventually to the Condé family (1612). The present Chbteau-Raoul dates from the 14th and 15th centuries. The old Église des Cordeliers (13th century) and St. Martial are the finest monuments. The library contains a manuscript (about 1270) of the *Chanson de Roland* and the 15th-century "Bréviaire Parisien" manuscript, and the Bertrand museum houses Napoleonic collections. Châteauroux has tribunals of first instance and of commerce, a board of trade arbitrators and a chamber of commerce. Textiles and machinery are manufactured, and there is a state tobacco factory. (Y. E.)

CHÂTEAU-THIERRY, a town of north-central France, *de'partement* of Aisne (*q.v.*), 90 km. (55.9 mi.) E.N.E. from Paris by road, on the right bank of the Marne. Pop. (1954) 7,939. On the top of a hill are the ruins of a castle, said to have been built by Charles Martel for the Frankish king Thierry IV; the chief relic is a gateway flanked by massive round towers. Also interesting are a 15th-century belfry, the church of St. Crépin and the late-16th-century mansion in which fabulist Jean de La Fontaine was born. Chbteau-Thierry is on the main railway line from Paris to Chblons-sur-Marne, Nancy and Strasbourg. The main industries are the manufacture of mathematical and musical instruments, biscuits and other foodstuffs. White wine and other local agricultural products are traded. Gypsum, millstone and paving stone are quarried in the vicinity.

Formerly the capital of the district of Brie Pouilleuse, Château-Thierry received the title of duchy from Charles IX in 1566. It was captured by the English in 1421 and by Charles V in 1544 and was sacked by the Spanish in 1591, in the Fronde wars in 1652 and by Bliicher's Prussians in 1814. The Russo-Prussian forces were defeated by Napoleon in the neighbourhood. In World War I it was the farthest point reached by the German offensive of May–

July 1918. The 2nd and 3rd divisions of the American Expeditionary force were sent to assist the hard-pressed French forces; at Chbteau-Thierry a U.S. machine-gun battalion took part in the successful defense of the river crossing, while to the west of the town the 2nd division fought the fiercely contested engagement of Belleau Wood. *(See* BELLEAU WOOD, BATTLE OF; MARNE, BATTLES OF THE). In World War II the town was under German occupation from June 1940 to Aug. 1944. (C. PR.)

CHATELAIN (Fr. *châtelain,* from *château*), in France, originally an officer with functions equivalent to those of the English castellan or the German *Burggraf* ("burgrave"); *i.e.,* the commander of a castle. With the growth of the feudal system, however, the title gained in France a special significance as implying the jurisdiction of which the castle became the centre. The chatelain in Carolingian France was an officialof the count; with the development of feudalism the office became a fief and so. ultimately, hereditary. The chatelain was thus largely the equivalent of the viscount (*q.v.*); sometimes the tno titles were combined, but more usually in those provinces where there were chatelains there were no viscounts, and vice versa. The title, however, continued also to be applied to the inferior officer,or concierge chatelain, who was merely a castellan in the English sense.

The power and status of chatelains necessarily varied greatly at different periods and places; occasionally they were great nobles with an extensive jurisdiction.

The *châtellenie (castellania),* or jurisdiction of the chatelain, as a territorial division for certain judicial and administrative purposes, survived the disappearance of the title and office of the chatelain and continued till the French Revolution.

In Germany the *Burggrafen* were at first royal castellans; later they were appointed by lesser princes. In some towns, moreover, there was a *Burggraf* with police functions over the market who judged commercial disputes.

CHÂTELET, GABRIELLE ÉMILIE LE TONNELIER DE BRETEUIL, MARQUISE DU (1706–1749), French mathematician, physicist and philosopher who did much to free French thought from subservience to Cartesianism, was born in Paris on Dec. 17, 1706, the daughter of Louis Nicholas le Tonnelier, baron de Breteuil. An accomplished linguist and musician, she became prominent in the social life of the time. She was married at 19 to the marquis Florent du Chbtelet, and they had three children: but before and after her marriage she had alliances with other men, the most important being that with Voltaire, dating from 1733.

Influenced by Samuel Koenig, she wrote *Institutions de physique* (1740), a work pervaded by the views of Leibniz; but her most important contribution to thought was the first French translation of the *Principia Mathematica* of Sir Isaac Newton. The long sojourns at the chateau of the Du Chbtelets in Champagne provided a haven for writing, as well as refuge from the Paris police whenever it became necessary for her to extricate the intemperate Voltaire from personal and political difficulties.

Mme du Chhtelet and Voltaire in 1738 competed independently for a prize offered by the Académie des Sciences for an essay on the nature of fire; and although the prize was won by Leonhard Euler, her *Dissertation sur la nature et la propagation du feu* was published in 1744 at the expense of the Académie. She also wrote *Réponse à la lettre de Mairan sur la question des forces vives* (1741) and a number of posthumously published treatises on philosophy and religion.

Voltaire and Mme du Chbtelet (or du Chbtelet-Lomont) continued to live together even after she had transferred her affections to the poet Jean François de Saint-Lambert; and when, on Sept. 10, 1749. she died in childbirth at the court of Stanislas of Poland in Lunéville, these men and her husband were with her. She had worked until the end on the translation of the *Principia,* and this was published. with a preface by Voltaire and under the direction of A. C. Clairaut. in 1756. The many hundreds of letters that passed between Mme du Chbtelet and Voltaire are assumed to have been destroyed; but others were included in Voltaire's *Correspondence* (ed. by Theodore Resterman, 24 vol., 1953–57).

Wade, *Voltaire and Madanze du Châtelet: an Essay on the Intellectual Activity at Cirey* (1941), and *Studies* on *Voltaire: With Some Unpublished Papers of Mme du Châtelet* (1947); Frank Hamel, *An Eighteenth Century Marquise, a Study of Emilie du Châtelet and Her Times* (1910); A. Maurel, *The Romance of Madame du Châtelet and Voltaire* (1931); and Nancy Mitford, *Voltaire in Love* (1957). (C. B. BR.)

CHÂTELET, in Paris, the principal seat of common-law jurisdiction under the French monarchy from the middle ages to the French Revolution. The building itself (demolished between 1802 and 1810) was originally a little fort (Lat., *castellum;* French, *châtelet,* diminutive of *chateau),* on the right bank of the Seine, guarding the northern approach to the Île de la Cité. First mentioned in the 9th century, it was rebuilt by Louis VI and considerably adapted under Charles V. It was generally known as the Grand Châtelet to distinguish it from the Petit Chbtelet, on the left bank of the Seine. at the end of the Petit Pont. Rebuilt by Philip II and later by Charles V, the Petit ChLtelet was demolished in 1782.

In the 12th century the Grand ChLtelet became the seat of the royal *prkvdt* ("provost") of Paris, who was the successor of the *chiitelains-vicorntes* of Paris *(see* CHATELAIN). The *pre'vdt* had jurisdiction over the whole "*vicomté* and *prévôté* of Paris," which was a bailliage in all but name and. as such, the most important in the kingdom. This jurisdiction was over matters of common law, both civil and criminal, and the *prévôt,* as *bailli royal,* judged appeals from all royal and seigniorial courts within the area of jurisdiction. The legal terms and the procedure are recorded in the *Grand Coutunzier de France,* compiled late in the 14th century by Jacques d'Ableiges, an advocate at the Chbtelet. The Chbtelet also heard uncontested cases, and notaries attached to it could deal with proceedings anywhere in the kingdom. In addition, the *pre'vdt* had administrative and financial functions, and the *procureur du roi* ("king's procurator") had not only judicial duties but also the control of the trade corporations of Paris.

Originally there were two *prévôts,* chosen from the bourgeoisie of Paris and acting together, but from 1261 a single *pre'vdt* was appointed. This officer, commonly called the *grand prévôt,* was thenceforth a figure of considerable importance. From the beginning of the 15th century he had three immediate subordinates, the *lieutenant particulier,* the *lieutenant civil* and the *lieutenant criminel,* whose jurisdiction was considerably expanded after 1674, when Louis XIV bought up all the surviving seigniorial rights of legal jurisdiction in Paris and amalgamated them. The Nouveau ChLtelet, which was then set up as a presidia1 court and a *prévôté* like the original one, ceased to function separately in 1684.

Cases were then handled by about 60 counselors, divided among the various chambers. Judgment was passed on behalf of the *pre'vdt* by the *lieutenant civil,* whose appointment was worth more than that of a counselor of the *parlement.* In 1667 Louis XIV created a lieutenant general of police, commonly called "Monsieur de Paris." This officer was often to work with the king on the most confidential matters. He was given authority over the *commissaires-examinateurs* of the Chbtelet, a permanent staff, in existence since 1327, who from 1419 were spread over the various quarters of Paris and, from an original 12. rose in number to 48 in the 16th century. They were responsible for security and public order, for the supervision of the prisons, including the Bastille (*q.v.*), and also for the regulation of the food supply of Paris.

The jurisdiction of the Chbtelet was abolished by the law of Aug. 24, 1790. Its archives are now in the Archives Nationales in Paris.

CHÂTELLERAULT, a town of west-central France, in the *département* of Vienne (*q.v.*), 34 km. (21.1 mi.) N.N.E. of Poitiers by road. Pop. (1954) 20,764. The old town has many 15th–17th-century houses, among them the Maison des Sybilles, the house where René Descartes spent his childhood (now a museum); there is also a 15th-century château. In the south is the 17th-century Hôtel Sully and the church of St. James. In the new

part of the town are found the *hôtel de ville,* the church of St. John the Baptist, the *hôtel des postes* and the Collbge René Descartes. Châtellerault is on the main line from Paris and Tours to Bordeaux and Spain. The main industry is armaments manufacture; cutlery, camping equipment, plywood and clothing manufactures are significant.

Châtellerault (or Châtelhérault: Castellum Airaldi) derives its name from a 10th-century fortress built by Airaud, viscount of the territory. In World War II the town was occupied by the Germans from June 1940 to Aug. 1944. (B. PE.)

CHATHAM, WILLIAM PITT, 1ST EARL OF (1708–1778), one of England's greatest and most famous statesmen, whose combined vision and practical ability led to a remarkable increase in English possessions and influence, was born at Golden square, Westminster, on Nov. 15, 1708. His father was Robert, son of the famous Gov. Thomas "Diamond" Pitt of Madras; his mother, Harriet Villiers, daughter of Viscountess Grandison. He was the fourth child of a family of seven, most of whom showed signs of mental instability. He was educated in the classics at Eton and Trinity college, Oxford. At Eton he made friends with many who later became his political associates, and especially with George Lyttelton, Henry Fielding, Charles Pratt and Charles Hanbury Williams. He left Oxford after only one year, partly because of the persistent gout from which he already suffered, and spent several months studying law at the University of Utrecht. A large number of deaths among the influential members of his family when he was still only 20 left his career uncertain, but his steps were guided toward politics by the marriage, in 1728, of his brother to Christian Lyttelton, sister of his school friend George Lyttelton. Through the Lytteltons the Pitts became connected with the widely ramified clan of the Temples and Grenvilles, one of the most powerful groups in the landowning oligarchy, which, under the Hanoverian monarchs, virtually governed Britain. The leader of the group, Viscount Cobham, wielded great wealth and patronage, and it was through his gift that William, in 1731, was appointed a cornet in the king's own regiment of horse, which later became the 1st dragoon guards. This commission brought him an income of £150 a year and an introduction to court and public life.

Early Parliamentary Career. — In 1735 he entered the house of commons as member for Old Sarum, one of his brother's pocket boroughs, which later became the most notorious example of all rotten boroughs. He belonged inevitably to the group of "Cobham's cubs," the connection of family friends and place hunters whom Cobham was mobilizing to oppose the ministry of Sir Robert Walpole. Calling themselves "patriots," they joined with discontented Whigs like Lord Carteret and William Pulteney and Hanoverian Tories like Sir William Wyndham to rally the opposition forces behind the prince of Wales, Frederick Louis. At a time when a regular standing opposition in parliament was generally regarded as factious and even traitorous, since ministers were the king's ministers, it became common for political groups opposed to the government to seek respectability by alliance with the heir to the throne. Since it was normal for Hanoverian monarchs to be in a state of violent hostility with their eldest sons, royal power was habitually divided against itself. Politicians excluded from office looked to "the rising sun," and the prince of Wales used both his own patronage and the hopes of future office to unite them against his father and his father's ministers. At this time Viscount Bolingbroke was especially active in his efforts to form in this way a solid opposition to Walpole. So Pitt entered parliament at a crucial stage of party development. His maiden speech provoked reprisals from Walpole, who deprived him of his military commission in an effort to "muzzle this terrible cornet of horse."

In 1737 the prince of Wales made him a groom of the bedchamber with a salary of £400 a year. Despite his status as a relatively poor dependent of a powerful Whig clan and as a pensioner of the prince of Wales, Pitt already showed that independence of mind and appeal to popular support which were to gain him unique personal prestige in English political life. His talents as an orator had become clear. His exploitation of the position of patriotic martyr, by driving around the southern counties after his dismissal by Walpole, showed a readiness to appeal to public opinion outside parliament, as well as his lively sense of the histrionic. He repeatedly referred to the "voice of England," which had to be sought outside parliament because parliament was so packed with place men and sinecurists. He claimed to speak for the commercial interests and even the colonists overseas, both scarcely represented in the commons. Although the member for Old Sarum could hardly claim to represent such interests directly, he more and more put forward arguments that would logically deny the whole system of oligarchical control over the electorate and over parliament. If he was a Whig he was, par excellence, a wayward Whig, using, in the cause of opposition, arguments that carried far beyond the close oligarchy enjoyed by the Whig families.

When Walpole at last fell from power in 1742, he was replaced by a ministry which included his old colleagues the duke of Newcastle and Lord Hardwicke, with Carteret as secretary of state. Pulteney was silenced by a peerage. The "boy patriots," of whom Pitt was by now the acknowledged parliamentary leader, were still excluded from power. They were left with no option but to oppose Carteret even more vehemently than they had Walpole.

From 1741 to 1748 Great Britain was engaged in the complex diplomacy and strategy of the War of the Austrian Succession. The chief menace to British security was Bourbon power in Europe, and the aim of British policy was therefore to diminish French power in every way possible. Pitt differed from Carteret more about means than about ends. George II and Carteret saw the issue as primarily a continental one and aimed at a coalition of German states, led by Britain and Hanover, to support Maria Theresa of Austria in her struggle against France. Pitt insisted that Great Britain should concentrate on attacking France where it was most vulnerable and where British naval power would bring the greatest advantage — that is, in France's colonial possessions, which obstructed British enterprise and expansion in America and India. He accordingly attacked, in a series of great speeches, the government's policy of continental alliances and subsidies and exploited the unpopularity of the royal connection with Hanover. Carteret was condemned as "a Hanover troop minister" and as "an infamous minister who seems to have renounced the name of an Englishman." It was possible to be a "patriot" in a new and additional sense and to appeal to every sort of national and popular prejudice. When Carteret was forced to resign in 1744, Newcastle and his brother Henry Pelham took office. They wanted to include Pitt, but George II had been so offended by Pitt's attacks on Hanover that he refused to accept him. During the Jacobite rising of 1745 Pitt gained new stature as the one statesman of effectiveness and vigour, and the rising was itself a further argument against the continental policy of the king. In Feb. 1746 the king agreed to appoint Pitt joint vice-treasurer of Ireland at £3,000 a year, and two months later he became paymaster general of the forces.

Paymaster General. — Pitt's first ten years in parliament had been spent in opposition. and he had earned a formidable reputation as a malcontent. His acceptance of the paymastership, which was notoriously the richest plum of place hunters, at first caused bewilderment and recriminations, even from his friends. It seemed that the "patriot" had been bought by the government. But it gave Pitt a further opportunity to earn a unique reputation for honesty and disinterestedness. He renounced for himself all the rich perquisites of the office except its official salary of more than £4,000. He also introduced many useful reforms in the administration of the office and dramatically regained his reputation for both scrupulous honesty and efficiency. He held the office for nine years and left it still a poor man.

But a legacy of £10,000 from the old duchess of Marlborough enabled him to indulge in more lavish expenditure and generosity. He spent a good deal on landscape gardening and bought South lodge at Enfield. In 1754 he married Hester Grenville and thereafter found, in a supremely happy home life, a new source of strength and escape from his somewhat solitary existence. In policy he supported the Pelhams' alliance with Hanover but tried to strengthen British naval power as the chief weapon of both of-

fense and defense. When Henry Pelham died, in 1754, Pitt hoped to become leader of the house of commons. The duke of Newcastle, jealous of Pitt's abilities and distrustful of his only serious rival, Henry Fox, maneuvered into office a colourless nonentity, Sir Thomas Robinson. Pitt and Fox joined in baiting and ridiculing Robinson, but when he was driven to resign, it was Fox whom Newcastle took in as secretary of state. Pitt transferred his attacks to the Newcastle-Fox combination, likening it to "the conflux at Lyons of the Rhbne and the Sabne: this a feeble, languid stream, and, though languid, of no depth—the other a boisterous and overbearing torrent—but they meet at last." The jibe cost him the pay office, from which he was dismissed in 1755.

War Minister.—The outbreak of the Seven Years' War gave Pitt his supreme opportunity for statesmanship. It began with heavy losses and considerable confusion of policy. The popular demand for Pitt became irresistible, and he declared, "I know that I can save this country and that no one else can." In Nov. 1756 he formed a ministry which excluded Newcastle, with the duke of Devonshire as its nominal head. In June 1757 Newcastle returned to office on the understanding that he should control all the patronage and leave Pitt to conduct the war. It proved to be an admirable division of labour.

Pitt determined that it should be in every sense a national war and a war at sea. He got rid of the German mercenaries who had been sent over to resist invasion and revived the militia, which he made into a serviceable defense force. He re-equipped and reorganized the navy. He sought to unite all parties and public opinion behind a coherent and intelligible war policy. He seized upon America and India as the main objects of British strategy. He sent his main expeditions to America, to ensure the conquest of Canada, and supported the East India company and its "heaven-born general," Robert Clive, in their struggle against the French East India company. He also subsidized and reinforced the armies of Frederick II the Great of Prussia, so as to engage the main French armies on the continent, while he used naval power to harrass the French on their own coasts, in the West Indies and in Africa. He chose good generals and admirals—James Wolfe and Jeffrey Amherst, and Edward Boscawen, Edward Hawke, Charles Saunders, George Pocock and Charles Watson—and he inspired them with a new spirit of dash and enterprise. Against so resolute and concerted a policy the Bourbon powers even in alliance could not prevail. At the treaty of Paris in 1763 Great Britain remained supreme in North America and India, held Minorca as a Mediterranean base and gained territory in Africa and the West Indies. Pitt had given Britain a new empire as well as preserving and consolidating the old.

But before the war ended Pitt had been forced to resign. In 1760 George III came to the throne resolved, as was his chief adviser, the earl of Bute, to end the war as speedily as possible. When Pitt failed to persuade his colleagues to forestall Spain's entry into hostilities by an immediate declaration of war he resigned, in Oct. 1761. He had tended to concentrate the whole conduct of government into his own hands and had worked with a furious energy. His haughty and aloof manner, which alienated so many of his colleagues, and his highhanded treatment of affairs, rendered tolerable only so long as he was proved right, had earned him respect and admiration but little friendship. When his resignation was accompanied by the grant of a peerage to Hester and an annuity of £3,000 a year for himself, there was again an outburst of abuse and scurrility. Just as when he had accepted the pay office, this acceptance of a peerage and a pension seemed to be the result of a political bargain and a sordid anticlimax to a brilliant career. As rewards for his immense services they were meagre enough, but it is some measure of the unique repute for high-minded disinterestedness which he had won that his acceptance of them should provoke so much bitter disillusionment. His effigy was burned in the City, and Hester was reviled as Lady Cheat'em.

He attacked the terms of the treaty of Paris as an inadequate recognition of Great Britain's world-wide successes. The intense unpopularity of Bute and Pitt's role as champion of national rights soon restored his popular appeal. But his career as a war minister was now over. He had delivered 115 speeches since he had entered parliament and more than half of them had been concerned with war or preparations for war. As a supremely successful secretary of state during the Seven Years' War he had combined colonial and naval operations with containing operations in Europe, and had shown that they were not alternative theories of strategy but were complementary. The rest of his political career was devoted to attempting a similar reconciliation of principles: of imperial power with constitutional liberty.

Later Years.—When Bute resigned in April 1763, he was succeeded by George Grenville. Pitt's attacks on his administration completed the breach between the two brothers-in-law. He condemned the action taken by the ministry against John Wilkes for his attack on the king's speech in no. 45 of the North Briton, and opposed Grenville's Stamp act. He took no active part in politics between 1764 and 1766, and was now becoming subject to the recurrent fits of manic-depressive insanity which were to cloud the rest of his life. In 1765 he was left, by Sir William Pynsent, the estate of Burton Pynsent in Somerset, worth more than £3,000 a year. In Jan. 1766 he re-entered the stage with a passionate appeal for imperial liberty. Of the American colonists, who had resisted the Stamp act, he proclaimed, "as subjects they are entitled to the common right of representation, and cannot be bound to pay taxes without their consent." He supported and defended their resistance and demanded the complete repeal of the Stamp act. This was done, but it was replaced by a Declaratory act maintaining the right of taxation. Grenville's successors, the Rockinghams, found their position equally untenable, and in July 1766 the king asked Pitt to form a ministry drawn from all sections of the house.

The idea of an all-party ministry had long haunted English politics. Parties were regarded as factions and the unit of parliamentary politics was not party but aristocratic group connection. Every ministry was a combination of several such groups and the groups excluded tended to form an opposition until some of them, at least, were offered places. While the notion of a regularly formed opposition was viewed with much distrust, it was natural to seek strength for government in a "broad-bottomed" or all-party administration. Pitt had propounded the view that a ministry should be formed on the principle of "measures and not men"; that is, that ministers should be appointed for their abilities and policies, and not because of their group connections. This has often been assumed to mean agreement with the aims of George III, who in his efforts to recover for the crown the use of royal patronage, which the first two Georges had allowed to fall into the hands of the Whig oligarchy, was seeking a ministry similarly united on principles rather than on group affiliations. But Pitt's interests were different. He was not concerned with attacking the system of group connections; rather, he wanted to insert himself, alongside the oligarchic leaders, as an individual who would be indispensable to any effective administration. He played, by instinct and temperament, something of a lone hand in politics. His main principle was that the king's government must be carried on, and what he wanted was strong, coherent and efficient administration. In 1763 he told the king that "it cannot be carried on without the great families who have supported the Revolution Government, and other great persons of whose abilities and integrity the public have had experience, and who have weight and credit in the nation." He repeatedly showed that he had no wish to destroy the oligarchic groups, but was perfectly willing to collaborate with them as long as they would acknowledge his own unique position and influence. Accordingly, his ministry of 1766 included Henry Conway and Lord Northington from the previous ministry, Lord Camden, Lord Grafton and Lord Shelburne, who were his own followers, and Lord North and Charles Townshend. It could have worked well only if Pitt himself had remained in active control over it. But he accepted an earldom and took the almost sinecure post of lord privy seal. The "great commoner" retired to the lords and fell ill for another two years. The luckless duke of Grafton was left in nominal control of the government just when the disturbances in America and in Middlesex,

over the Wilkes elections case, were reaching their climax.

The new ministry was probably doomed to failure from the start. Its members held contrary views about America, and had little harmony of temperament or purpose. It is doubtful if even Chatham could have made them into a team; certainly the indolent Grafton could not. Engulfed in a black fit of insanity, Chatham withdrew completely and, in 1768, resigned office. His own chancellor of the exchequer, Townshend, imposed a series of duties on the American colonists which brought in little revenue but caused widespread discontent. Chatham appeared in the lords in 1770 to launch a savage attack on the ministry and on the house of commons for its surrender to the wishes of the king in the Middlesex elections, when it not only expelled Wilkes but also illegally declared the defeated candidate, H. L. Luttrell, elected. He supported the City in its protests against the government and demanded a dissolution to get rid of a subservient commons. He even proposed a measure of parliamentary reform to strengthen the county representation as against the boroughs, the "rotten parts" of the constitution. In the following year he pressed for triennial, instead of septennial, elections as a method of bringing the commons more closely into touch with public opinion in the country. His early "radical" propensities came more into the open.

During the last ten years of his life, 1768–78, he acquired a group of followers of his own, including Grafton, Shelburne, Camden and Isaac Barré. In parliamentary action he was driven to rely more upon this group and less upon his own eloquence and popularity. Instead of being able, in Burke's words, "to keep hovering in air, over all parties, and to souse down where the prey may prove best," he was driven into active alliance with the Rockingham group. He was forced into the normal Whig procedure of negotiating group alliances and in his deliberate disruption of the Grafton ministry in 1770 he acted little differently from the ordinary party man in opposition. The end of his career showed that there was little permanent place, in 18th-century politics, for one who claimed to depend primarily upon a personal reputation for ability and disinterestedness. In the end he, like the king himself, found that he had to come down into the arena and deal with politicians and group connections on their own ground.

His last years were clouded by illness, and only on rare occasions did he emerge from seclusion to appeal for a more generous and understanding treatment of America. Yet he broke with the Whig groups when they were prepared to recognize the independence of the 13 colonies and when the Americans had allied with Britain's traditional enemy, France. His last speech in the lords was a protest against any diminution of an empire based on freedom. In 1775 he hurriedly introduced a bill designed to suspend repressive measures in Boston, maintain the legislative authority of parliament over the colonies and yet use the continental congress established at Philadelphia as a body for assessing the monetary contributions of each colony. The bill was summarily rejected, but it is the best indication of how Chatham would have handled the American problem.

After 1771 it was his practice to emerge only occasionally, as the elder statesman, to promote or attack individual measures, but not to attempt, as in 1770, to overthrow the ministry as a whole. He spent most of these years enjoying the life of a country gentleman or in gloomy seclusion as an invalid. He died at Hayes, Middlesex, on May 11, 1778, and was buried in Westminster abbey.

Character and Influence.——Chatham remains a brilliant and dominant yet enigmatic figure in 18th-century history. Even the fragmentary reports of his speeches which survive endorse his contemporary reputation as one of the greatest orators that England has ever known. As a war minister he combined immense breadth of vision with brilliant executive ability. As a statesman he raised British power and prestige to great heights and added large territories to Britain's overseas possessions. As a man he was a model of devotion to his family as well as of unstinted public service. But his genius was erratic, his political behaviour at times factious and at variance with his professed principles. The penalty of his eminence was a certain isolation. He had the defects of spiritual pride and haughtiness, which were perhaps the natural counterparts to his great talents.

His role in the development of the English party system is ambiguous. He did not seek to destroy the system of aristocratic patronage and group connection in politics, yet in effect he did much to undermine their power and to introduce into parliamentary life the force of public opinion. By his sustained and vigorous opposition to such ministers as Walpole, Carteret, Fox, Bute, Grenville and Grafton, he established a powerful tradition of the merits and rights of an organized opposition in parliament; yet this development seemed to be denied by his support for the idea of an all-party administration based on "measures and not men." He had a less profound insight than his contemporary, Edmund Burke, into the basic implications of a constitutional parliamentary system. He remains, nonetheless, one of the greatest geniuses of statecraft in British history.

CHATHAM, the county seat of Kent county, Ont., Can., is 15 mi. up the Thames river from Lake St. Clair, 64 mi. S.W. of London and 40 mi. E, of Detroit. Chatham is served by Canadian Pacific and Canadian National main lines and a Pere Marquette branch line. Small lake freighters along the river connect the city with the Great Lakes. Situated on an extinct lake plain, Chatham is a processing centre for farm products. It has a beet-sugar refinery, canneries, tobacco curing plants, a meat-packing plant and several light metal-fabricating industries. Named after Chatham, Eng.. it was first settled about 1800. An outlet of the Underground Railroad for fugitive slaves, it was the scene of the "convention" held by John Brown preceding his raid on Harpers Ferry in 1859. Pop. (1961) 27,447. (G. FN.)

CHATHAM, a port and municipal borough in the parliamentary division of Rochester and Chatham, Kent, Eng.. on the right bank of the river Medway 10 mi. above its confluence with the Thames, and about 30 mi. E.S.E. of London by road. Pop. (1961) 48,989. Area 6.8 sq.mi. Though a distinct borough, it is coterminous with Rochester (*q.v.*) on the west and forms, with it and Gillingham (*q.v.*) on the east, one large conurbation, of which Chatham is the principal shopping, commercial and entertainment centre. Industries include flour mills, timberworks, etc., but by far the biggest employer is the royal naval dockyard.

Chatham (Ceteham, Chetham) belonged at the time of Domesday to Odo, bishop of Bayeux. It later formed a suburb of Rochester, but Henry VIII and Elizabeth I established a dockyard and an arsenal. The dockyard was altered and improved by Charles I and Charles II and became the chief naval station of England. In 1708 an act was passed for extending the fortifications of Chatham, and the town grew around the dockyard.

The royal naval dockyard is situated to the north of the town, on a point, partly of reclaimed marsh, beyond which the sharply curving river widens from about 400 yd. to its broad tidal estuary. The dockyard covers more than 500 ac. and has a river frontage of more than 3 mi. It is equipped both for building and repairing naval vessels of all kinds. There is a church in the dockyard, and near at hand are the royal naval, royal marine and royal engineers' barracks. Chatham has a number of memorials to members of the services in various campaigns. A series of open spaces on the hill east of the town are known as the "Chatham lines." On this hill a number of forts were erected to defend the port during the Napoleonic Wars; conspicuous on the heights is the Royal Naval War memorial. Just below Fort Amherst is the town hall. Fort Pitt was adapted to house a girls' technical school. High street is formed by part of ancient Watling street connecting Canterbury and London.

St. Mary's church occupies a site in similar use since Saxon times. Norman and Early English features from the old church. which was destroyed by fire, are incorporated in the present 18th-century building (thoroughly restored in 1903). The church contains a memorial to Stephen Borough (d. 1584). who in 153'3 pioneered an Arctic sea route to Archangel. Near the railway station is a monument to Thomas Waghorn (d. 1850), a Chatham man who founded the overland route to India. St. Bartholomew's chapel, originally attached to the hospital for lepers founded by Gundulph, bishop of Rochester in 1078, is partly Norman. The hospital still has connections with Rochester cathedral. The Hospital of Sir John Hawkins, knight, in Chatham, for ex-seamen and ex-shipwrights of Chatham and Sheerness dockyards, was founded in 1592 by Sir John Hawkins and rebuilt in the middle of the 18th century. The fund called the Chatham Chest, originated by Hawkins and Drake in 1590. was incorporated with Greenwich hospital in the early 19th century.

Charles Dickens and his family lived from 1817 to 1821 in a house at Ordnance terrace, where his father worked in the navy pay office, and Chatham people were the originals of certain characters in Sketches by *Boz* and *David Copperfield.*

Chatham was constituted a parliamentary borough by the Reform bill of 1832. In 1918 the municipal boroughs of Chatham, Gillingham and Rochester combined to return two members to parliament. The town, with the suburb of Luton, was incorporated in 1890.

CHATHAM ISLANDS, a small group of islands in the Pacific ocean. forming part of New Zealand since 1842. They lie 467 nautical mi. E. of Lyttelton in South Island. The three main islands are Chatham (the largest), Pitt and Rangatira. Chatham (344 sq.mi.) rises to 938 ft. in the south and has a large number of small lakes and Te Whanga a shallow lagoon of 72 sq.mi. It is about 38 mi. long and 25 mi. in maximum breadth. Pitt (24 sq.mi.), 13 mi. from Chatham, has the highest point in the group (971 ft.). There are several small. rocky islets. The geological structure is mainly volcanic rocks with schists, and the presence of Tertiary limestone suggests that the islands were once part of New Zealand.

There are no indigenous mammals, and the reptiles belong to New Zealand species. The birds have been heavily reduced. The original forest vegetation (containing many New Zealand species) has been greatly modified since the arrival of Europeans. Large areas are now under English grasses though there are still extensive areas of swamp, bog, heath and dune. The climate is mild, with mean temperatures ranging from 45.4" F. in July to 57.6" F. in January. Rainfall averages 33.4 in. annually and is recorded on half the days of the year. Prevailing winds are southwesterly.

The islands were discovered in 1791 by Lieut. W. R. Broughton in H.M.S. "Chatham." He called the natives Moriori or Maioriori. Their language was akin to the Maori of New Zealand, but they differed physically. In 1835 they were overwhelmed by 800 Maori landed from a European vessel. The last pure Moriori died in 1933.

Europeans have lived in the group since 1840. After 1860 pastoral farming became increasingly important, and many large sheep stations were established. Chatham Island exports annually about 3.000 bales of wool, 20.000 head of sheep and 250 head of cattle. Breeding ewes and rams (mostly Romneys) are in constant demand in New Zealand, but shipping is expensive and, except in summer, irregular. Occasionally airplanes are chartered to carry passengers to New Zealand, with which there is a radio-telephone link.

Population at the 1961 census was 487 (316 Europeans). Most Maori have some Moriori or European ancestry. There is a cottage hospital and primary school at Waitangi (pop. 140), the main settlement and port of entry, which is on Petre bay on the southwestern side of the island. The islands are administered by a resident commissioner (who is also a magistrate) appointed by the New Zealand department of island territories. (R. M Fr.)

CHATSWORTH, the principal seat of the dukes of Devonshire, in the parish of Edensor. Derbyshire. Chatsworth house stands close to the left bank of the Derwent river. $2\frac{3}{4}$ mi. E.S.E. of Bakewell. The park is more than 11 mi. in circumference. The house is built around a large open courtyard. which has a fountain in the centre. The gardens are adorned with sculptures by Caius Gabriel Cibber. and its fountains, designed by Sir Joseph Paxton (*q.v.*), are said to be surpassed only by those at Versailles. The house contains a library and art collection. which includes works by Sir Joshua Reynolds, Hans Holbein, Albrecht Diirer, Hans Memling, Bartolome Murillo, Carlo Dolci, Paolo Veronese, Titian, Michelangelo. Leonardo da Vinci and Correggio, and sculptures by Antonio Canova, Bertel Thorvaldsen, Sir Francis Chantrey and R. J. Wyatt. Beyond the river, and immediately opposite the house, is the model village of Edensor: of Saxon origin, it was almost entirely rebuilt by the 6th duke. The parish church. built by Sir Gilbert Scott to replace a much older building, contains a brass in memory of John Beaton, confidential servant to Mary Stuart.

Chatsworth (Chetesworde, Chattesworth, "Ceatt's homestead") took its name from Ceatt, one of its Saxon owners. It was entrusted by William I to the custody of William Peverel. It afterward belonged for many generations to the Leech family and was purchased in the reign of Elizabeth I by Sir William Cavendish. husband of the famous Bess of Hardwick. In 1553 he began to build Chatsworth house, which was completed. after his death, by his widow, later countess of Shrewsbury. Mary Stuart spent several years of her imprisonment there under the care of the earl of Shrewsbury. During the Civil War, Chatsworth was occupied as a fortress by both parties and subsequently pulled down. The present house was designed by William Talman and Thomas Archer for the 4th earl (created 1st duke in 1694). Although a marble slab in the Great hall states that it was begun in 1688. work was already in progress in 1687. The long north wing was added (1820–27) by Sir Jeffry Wyatville for the 6th duke, who also extended the east side (1827–34) and rebuilt the interior of the south wing.

CHATTAHOOCHEE, the river which inspired Sidney Lanier's poem "The Song of the Chattahoochee," is formed in the Blue Ridge mountains in northeastern Georgia by the confluence of several headstreams. It flows southwestward across northern Georgia to West Point, south of which its course forms the Georgia-Alabama and Georgia-Florida boundaries until it joins the Flint river at Chattahoochee, Fla., where the combined waters of the two streams form the Apalachicola river. Northeast of Atlanta, Buford dam forms Lake Lanier, a popular recreational centre which serves as a storage reservoir and regulator of Atlanta's nater supply. West Point, 235 mi. from the Chattahoochee's source. is the northernmost of a group of five large textile towns in the central Chattahoochee valley; the others are the Alabama towns of Lanett, Shawmut, Langdale and Fairfax. North of Columbus, Ga.. are two hydroelectric dams: Bartlett's Ferry dam (145 ft. high, 1.975 ft. long) and the smaller Goat Rock dam. The Chattahoochee is navigable from Columbus to its mouth. Southeast of Columbus lies the Providence canyon area, created by severe dissection in unconsolidated sandy soils which has produced gullies as deep as 300 ft. and as nide as 200 ft. South of Fort Gaines, Ga.. stands the Kolomoki mound (57 ft. high and 56 to 66 ft. wide at the top), thought to be a prehistoric Indian burial ground. The Jim Woodruff dam spans the river 201 mi. from West Point, where the Chattahoochee joins the Flint.

(M C. P.)

CHATTANOOGA, a city of Tennessee. U.S., on the Tennessee river at the southern boundary of the state adjoining Georgia. is the seat of Hamilton county and is in the geographic centre of the Tennessee Valley authority's (TVA) development area. Pop. (1960) city 130.009; standard metropolitan statistical area (Hamilton county in Tennessee and Walker county in Georgia) 283,169. (For comparative population figures see table in Tennessee: *Population.*)

Chattanooga is known for its scenic and historic sites. Within the city limits is Missionary ridge, nhich affords an impressive vantage point. Nearby Lookout and Signal mountains offer unusual views including Moccasin bend and the canyon of the Tennessee river. Detached sections of the Chickamauga and Chattanooga

National Military park on Orchard knob, Missionary ridge and Lookout mountain are in the city's environs although the main part is nearby in northern Georgia. Ascending Lookout mountain is a steep-incline railway. Inside the mountain is a cave with a 145-ft. waterfall and atop are the gardens and odd rock formations of Rock City.

Approximately 7 mi. by river above Chattanooga is the TVA dam which impounds the water of 59-mi.-long Lake Chickamauga, a centre for boating, swimming, fishing and other outdoor sports.

History. — During the American Revolution and the years following, the Chickamauga Indians, a splinter tribe of the Cherokee, roamed from their strongholds on the river to bring war to the southeastern frontier. After their destruction in 1794 the Cherokee, who rapidly became highly civilized, dominated the region. About 1815 John Ross (*q.v.*), later a Cherokee chief, established a landing on the river in what is now downtown Chattanooga, which became known as Ross' Landing. Brainerd mission, located about five miles from the landing. was opened in 1817 by the American Board of Commissioners for Foreign Missions and continued service to the Cherokee until the removal of the latter to Indian territory (now Oklahoma) in 1838.

Even before removal was effected settlers began moving into the area of Ross' Landing. which they renamed Chattanooga, the aboriginal name for Lookout mountain; it means "rock rising to a point." In 1839 Chattanooga was incorporated as a town; in 1851 the state legislature granted a new charter and complimented the community by designating it a city. The settlement benefited from its location on the river but the construction of railroads in the 1850s was more important in its development. In 1860 the population numbered 2.545, but because of its junction position the community was more important than this size might indicate. The following year the city voted with Tennessee to secede although the county, like most of eastern Tennessee, favoured remaining in the union.

In 1863 the town and environs became the site of the battle of Chickamauga (*q.v.*) and the campaign for Chattanooga *(sze* CHATTANOOGA, BATTLE OF). A national cemetery was dedicated that year and four years later, a Confederate burial ground. At the end of hostilities many veterans of both armies settled in Chattanooga and helped foster an early spirit of reunion. In 1877 David M. Key of Chattanooga was appointed postmaster general by Pres. Rutherford B. Hayes and thus became the first southerner and former Confederate officer to hold a cabinet post in the federal government. Adolph S. Ochs (*q.v.*), through the columns of his paper, strongly encouraged a balanced economy for the new south and helped to eliminate the past bitterness. The Chickamauga and Chattanooga Sational Military park, created in 1890, was dedicated in 1895 and during the Spanish-American War nas used as a training centre. In 1904 a permanent post. Ft. Oglethorpe. was established just north of the park. It was an active installation until 1946 and was a training centre for both World Wars I and II.

For a number of years after the American Civil War the city placed its economic hopes in the iron industry but by 1900 it was evident that development in this field was not feasible and industry began to diversify. The growth of the textile industry, the insurance business and the bottling of Coca-Cola, a process which originated in the city, gave momentum to that trend.

The creation of the Tennessee Valley authority on May 18, 1933, was of major significance to the city. Authorized by referendum in 1935, the municipally owned Electric Power Board of Chattanooga was established to distribute energy in the area and purchased the facilities of the privately operated company. After that date the use of electrical power multiplied many times and electrical heating and cooling of homes became general. TVA flood-control measures protected the city from major inundations; barge traffic supplemented other carrying facilities; and new recreational opportunities based on the lakes were provided A major urban-renewal project and a system of freeways were further developments.

Transportation and Industry. — The site of Chattanooga always an important transportation centre, is at the intersection of several highways. It has good rail and air service and the 9-ft. channel of the Tennessee river is navigable all year for barge traffic. Travel facilities combine with the scenic and historic attractions in a multimillion-dollar tourist business. Three large insurance companies have home offices in the city. Principal industries are the manufacture of textiles, steam boilers, nuclear reactors, gas, coal, electric stoves, plumbing supplies, farm implements, machinery, bathtubs, soil pipe, structural steel, furniture, chemicals, paper, glass bottles, ceramic products, cement, beverages, medicines and candy.

Education and Cultural Activities. — Interest in cultural affairs is manifest in the opera association, the symphony, the little theatre and the Hunter Art gallery. In addition to public schools the educational institutions include three private schools, Baylor and McCallie for boys: and Girls' Preparatory, as well as parochial schools. There are two church-related colleges, Southern Missionary college at nearby Collegedale, founded in 1916 and controlled by the Seventh Day Adventists, and Tennessee Temple college, begun in 1946 and supported by the Highland Park Baptist church of the city. The University of Chattanooga, established in 1886, is a private coeducational institution; Cadek Conservatory of Music and Chattanooga college (an evening college) are two of its divisions.

See G. E. Govan and J. W. Livingood, *The Chattanooga Country, 1540–1951: From Tomahawks to TVA (1952).* (J. W. Lt.)

CHATTANOOGA, BATTLE OF, a decisive engagement of the American Civil War fought in late Nov. 1863. The city of Chattanooga. on the Tennessee river, had strategic importance because it was the junction point of railroads to Atlanta. Ga., and Memphis, Nashville and Knoxville. Tenn., all vital connections for the Confederacy. In Sept. 1863 Gen. William S. Rosecrans, commanding the Federal army of the Cumberland, had maneuvered Gen. *Braxton Bragg* and his army of Tennessee out of the city without a fight. But *Bregg,* reinforced by troops of Gen. *Joseph Johnston* and Gen. *James Longstreet,* had turned on him at Chickamauga. Ga.. on Sept. 19–20 and swept him and his staff back into Chattanooga. Only the firm stand of Gen. George H. Thomas (the "rock of Chickamauga") had prevented a rout of the Federal army.

Bvagg failed to follow this victory with an assault on Chattanooga which, his critics argue, would most certainly have been successful. Instead he took up positions on Missionary ridge and Lookout mountain with outposts on Raccoon mountain, from which he controlled the river: the main roads and the railroads into the city. There he waited for Rosecrans to be starved into withdrawal or surrender. To bring supplies from Bridgeport. Ala., less than 30 mi. away, Rosecrans relied upon a 60-mi. route through the Sequatchie valley, parts of it steep and mountainous. much of it wet and muddy and exposed to frequent Confederate cavalry raids. But the Union had no intention of surrendering Chattanooga without a fight. On Oct. 16, Ulysses S. Grant became commander of the newly created division of the Mississippi. A week later he was in the city, where Thomas had succeeded Rosecrans. He directed the campaign to relieve the besieged army, reinforce it and seize the offensive. On the night of Oct. 26, on pontoon boats built in Chattanooga, 1.500 troops floated down the river. slipped past the Confederate positions and gained a foothold on the southern bank of the river at Brown's Ferry, 3 mi. below Lookout mountain. They enlarged the bridgehead the next day and drove the Confederate sharpshooters from positions on nearby Raccoon mountain. The "cracker line" to the city was now open.

Gen. Joseph Hooker: who had brought Northern reinforcements by rail from the army of the Potomac, marched to the base of Lookout mountain. Meanwhile Gen. William T. Sherman was making his slow way from hlemphis, rebuilding railroad as he came. *Bragg,* apparently feeling secure in his position overlooking the city. sent *Longstreet* with 20.000 troops. a third of his army, in a futile effort to drive Gen. Xmbrose E. Burnside from Knoxville. By Nov. 23 Grant was ready to make his move. Sherman crossed the river at Brown's Ferry. marched east of Chattanooga, moved his troops across the river again. near Chickamauga creek, and assaulted the Confederate right at the northern end of Missionary ridge, but without notable success. Hooker then struck at

the left flank of the Confederates on Lookout mountain. He fought his way up through fog and mist and in the "battle above the clouds' drove an inferior force from the position.

At 3:30 P.M. on Nov. 25 occurred perhaps the most dramatic and inexplicable event of the entire war. Two of Thomas' divisions moved out from the centre for what was intended to be a demonstration to assist Sherman. Ordered to take the Confederate rifle pits at the base of Missionary ridge, the men without further orders stormed up to the top and captured the crest. Possibly *Bragg's* men were demoralized by watching the build-up of Union strength in the valley below and by realizing that they could not depress their artillery sufficiently to sweep the bluecoats from the mountainside. Whatever the reason, the Confederate centre was broken and soon *Bragg* was in retreat into Georgia. Losses of men were less than at Chickamauga—5,824 Union and 6,667 Confederate—but the result was completely decisive, ranking in importance with Vicksburg and Gettysburg in the same year. The way was open for Sherman's march to Atlanta and on to Savannah in the following year. *See* also AMERICAN CIVIL WAR. (C. W. TE.)

CHATTEL, a term synonymous in English law with personal property (*q.v.*).

CHATTEL MORTGAGE, a transaction by which an owner of personal property transfers the property to a creditor for the purpose of securing payment of the debt (*see* MORTGAGE). A chattel mortgage should be distinguished from a pawn or pledge (*q.v.*). In the former, only title is transferred, while in the latter there is a transfer of possession. It may be distinguished from a conditional sale on the same grounds (*see* SALE OF GOODS; INSTALLMENT CREDIT; BILL OF SALE). Because of the danger of misleading other creditors and the opportunity for fraud, all states of the United States require that a chattel mortgage be recorded in some public office. (E. G. S.)

CHATTERER, the general name applied to the members of the family Cotingidae, South American woodland birds. feeding mainly on fruit; the best known are the brightly coloured cocks of the rock, umbrella birds and bellbirds (*qq.v.*). One of the most exotic of the cotingas is the pompadour chatterer, *Xipholena pompadora*, having brilliant raspberry-coloured hairlike plumage and white wings. Chatterer was once inappropriately applied to the waxwing (*q.v.*).

CHATTERJI, BANKIM CHANDRA (BANKIM-CANDRA CATTOPADHYAY) (1838–1894), Indian author, whose novels firmly established prose as a literary vehicle for the Bengali language and helped create in India a school of fiction on the European model, was born near Naihati in Bengal on June 27, 1838. of an orthodox Brahman family. He was educated at Hooghly college, at Presidency college, Calcutta, and at the University of Calcutta, of which he was one of the first graduates. From 1858, until his retirement in 1891, he served as a deputy magistrate in the Indian civil service.

Some of Bankim Chandra's youthful compositions appeared in the newspaper *Sambad Prabhakar,* and in 1858 he published a volume of poems entitled *Lalifa O Manas.* For a while he wrote in English, and his novel *Rujmohan's Wife* appeared serially in *Indian Field* in 1864. His first notable Bengali work was the novel *Durgesnandini,* which features a Rajput hero and a Bengali heroine. In itself it is of indifferent quality, but, in Tagore's words, it took "the Bengali heart by storm," and with it the Bengali novel was full born. *Kapalkundala,* a love story against a gruesome background of Tantric rites, was published in 1866; and *Mrinalini,* which was set at the time of the first Muslim invasion of Bengal. in 1869. *Banga Darshan,* Bankim Chandra's epoch-making newspaper, commenced publication in 1872, and in it some of his later novels were serialized. *Bishabriksa,* which poses the problem of widow remarriage, and *Indira* were published in 1873; *Yugalanguriya* in 1874; *Radharani* and *Candrasekhar* in 1875; *Rajani* in 1877; *Krishnakanter Uil,* nhich the author considered his greatest novel, in 1878; *Rajsimha,* a story of Rajput heroism and Muslim oppression, in 1881; *Anandamath,* a patriotic tale of the revolt. of the sannyasis against the Muslim forces of the East India company, in 1882; *Debi Caudhurani,* a domestic novel with a background of dacoity, in 1884; and finally, in 1866, *Sitaram,* a marital tangle and a struggle of Hindus against Muslim tyranny. To *Banga Darshan* Bankim Chandra also contributed articles on religious. historical, scientific and other subjects. His later writings include *Kamalakanter Daptar* (1885), a collection of serious and humorous sketches by a drug addict; and *Krishnacarit* (1882) and *Dharnzatattva* (1888), essays on religion and political science.

Bankim Chandra's novels are exciting to read, but structurally they are faulty. Serial publication was partly responsible for imperfect integration of the various episodes. Evolution of plot depends too frequently on chance or supernatural intervention, and characterization is often subordinated to an overriding didactic purpose. His achievements. however, outweigh these technical imperfections. To his contemporaries his voice was that of a prophet; his valiant Hindu heroes aroused their patriotism and pride of race. He taught that orthodox Hinduism, cleansed of excesses, was undeniably the religion of India, well able to prevail against the doctrines of Christianity and the Brahmo Samaj. In him nationalism and Hinduism merged as one; and his creed was epitomized in the song Bande Mataram ("Hail to thee, Mother") —from his novel *Anandamath*—which later became the *mantra* ("hymn") and slogan of Hindu India in its struggle for independence. He died on April 8, 1894. *See* also BENGALI LITERATURE.

CHATTERTON, THOMAS (1752–1770). England's chief poet of the Gothic revival and youngest writer of mature verse, was born posthumously at Bristol on Nov. 20, 1752. His father had been schoolmaster of Redcliffe and subchanter in the cathedral—a man proud and dissipated, toying with magic and collecting books and Roman coins; his widowed mother, who opened a little sewing school, was a nonentity. and his sister's mind was periodically deranged. He had a tearful childhood, choosing the solitude of an attic and making no progress with his letters; yet his playmates accepted his illusion of being their chief, and when five he asked a potter to paint on a promised cup an angel with a trumpet "to blow his name about." Over the street mas the incomparable church of St. Mary Redcliffe, where his uncle was sexton; Chatterton moved in the old aisles with solemn self-deception, aloof from his family and an anachronism in a bustling city. Suddenly, he could read and write far in advance of his years; the means were all old—music folios, a black-letter Bible, and Redcliffe muniments filched by his father. There began his voracious scribbling; dying at 17, he yet left over 600 printed pages of verses, besides prose pamphlets and letters. At seven, he was entered at Colston's school, on the site of the Whitefriars and nith every boy tonsured like a little monk, yet a spartan place turning out tradesmen, craftsmen and mariners, nith nothing in its curriculum save writing, accounts and formal religion; he acquired no language but English. and all his humane studies were pursued independently. Yet his first known poem. "On the last Epiphany," published in the local newspaper when he was ten, is a scholarly little piece, with Miltonic echoes tempering the trite hymnody; "A Hymn for Christmas Day" (a little later) uses the same vocabulary, in skilful stanzas, for a clear yet paradoxical statement.

In 1763 he produced his first individual poem, satirizing a Redcliffe churchwarden for destroying a medieval cross; slight as it is, it puts a boy of 11 in the van of the Gothic return, along with "Ossian" (1762–63), *The Castle of Otranto* (1764) and Percy's *Reliques of Ancient English Poetry* (1765). He was drawing too, concocting rough but enthusiastic architecture and heraldry, and salvaging from his mother's dressmaking patterns any Redcliffe archives with writing on them. This was the next stage of the mischief. He was perhaps no more than 11 years old when he showed a Colston's usher an old parchment inscribed with the pastoral eclogue "Elinoure and Juga," supposedly of the 15th century; it nas, indeed. in rhyme royal. but with help from Spenser in the final Alexandrines, and from Gray and Milton in the doleful music, which shines through its spate of added *-e* end-

ings, its vowels changed at whim, and its words culled or coined haphazardly. Fatally, it deceived its readers, and thereafter a merely puerile deception, to mystify and impress, became a separate poetic current, so that Chatterton's output is best treated in two parts, the antiquated and the acknowledged.

Out of his loneliness and his dreams, he erected a past that was an allegory of his present, set near Our Lady on the Red Cliff in the 15th century; its hero and interpreter was the fictitious Thomas Rowley, a gentle, dreamy priest, with a patron such as Chatterton never found. Just when Thomas Rowley was invented is uncertain; the idea must have been long germinating, and the name is from a civilian's brass at St. John's, Bristol, but he comes to full life as confessor and secretary of the authentic William Canynges. with the additional duty of collecting antiquarian documents and pictures. Further, a pleasant coterie gathered round Canynges, writing one another verses and taking parts in Rowley's plays. Too much has already been said, in sheer mockery of the bogus Middle English, in Skeat's 1871 edition, which insensitively modernized the spelling and replaced fine ghost words (*i.e.,* pseudoarchaisms of Chatterton's own coining) by Victorian rationalizations, thereby effacing the music. It is admittedly true that Rowley's calligraphy lacks contractions and has too many capitals; metrically he anticipates Spenser, Surrey, and (in "Battle of Hastings") the unlikely Pope; his rhymes are often correct only to modern ears or made correct by wrenchings of spelling, grammar and vocabulary; his syllable counting is too modern for his century; and "so haveth I" was the idiom of no age or dialect. Rowley's diction is likewise full of glaring revelations of his method: he adopted the blunders of recent glossaries; and ten Anglo-Saxon words from William Somner's 1659 dictionary, all suspiciously beginning with *a,* occur in "The Ryse of Peyncteynge yn Englande," sent to Horace Walpole. Yet Somner, peeps at Chaucer and odd excerpts from *The Faerie Queene* proved too slow a vehicle, so the indifferent dictionaries of John Kersey and Nathan Bailey were recruited, with any alteration that poetry demanded. The Rowleian canon is full of happy plagiarisms, such as a song in *Blla* remembering one in *Hamlet,* and fragments from as far apart as *Chevy Chase* and Nicholas Rowe.

All this is mentioned because. marvelously. the young poetry bursts through these musty tricks without further inhibition. Into the Romley poems Chatterton threw all his genius, and they, not his cross-grained satires, mark him as an early romantic, a pioneer in metrics and sentiment. Were they merely contemporary poems in period dress, they would still have their music, pathos, nostalgia and warmth, and the racked pride of their heroes. But, more, they catch the authentic spirit of Rowley's age; unlike the Gothic mutterings of the early revival, Chatterton speaks out here with understanding, using his antique jargon for a whole and fastidious vision of the landscape of poetry. The best of balladry sits with Syr Charles Bawdin on his sledge in the "Bristowe Tragedie." where "syx mynstrelles . . . tun'd the strunge bataunt," that noble but unknown instrument. In the play *Blla,* one can almost believe that Chatterton was no longer composing in English and translating into Rowleian; the language is as consistent and credible as the thesis that Bristol was the headquarters of resistance to the Danes. The characters, too, develop organically in a mere 1,250 lines: Ælla with his tragic flaw of impetuosity, Celmonde destroyed by lust yet dying brave and repentant (so that his "O! I forslagen be!" is silly only to the pedant), Hurra the chivalrous foe, Birtha all womanly. Varied riches of revelry, victory. abduction, suicide are conveyed in many metres, including lyrics where Rowley almost reaches his heights. One shows the metrical dexterity of alliteration and internal rhyme in the line "Comme, wythe acorne-coppe & thorne"; in another, a boy of 15. of no poetic "school," declares that "Wommen bee made, notte for hemselves, botte manne, Bone of hys bone, and chyld of hys desire." And Ella's address to his troops, beginning importantly in the cleared air of a new scene, "Now havynge done oure mattynes & oure vowes," continues for nearly 100 lines of sustained pride and passion that illuminate the twofold mystery and tragedy of Chatterton's anonymity and suicide. *Ælla* ranks Chatterton among poets; the other Rowleiana have the same gusto put to less purpose, and though one can still share the poet's delight in Redcliffe church, "The pride of Brystowe and the Western lande," he apparently made little systematic study of medieval antiquities, getting half-digested material from such things as Weever's *Ancient Funerall Monuments* and Verstegan's *A Restitution of Decayed Intelligence.* He appears earliest as a metrical innovator in "The Unknown Knight," where he rediscovers the principle of equivalent substitution of feet in couplets of four-stress lines, known in the middle ages, alive in Spenser, but tidied away by 18th-century pens until its supposed "new" appearance in Coleridge's *Christabel* at the close of the century. All these skills were certainly Chatterton's own; there was no tutor, friend or talented parent to help with his effusions, and it is clear that the music of his poetry was a rhythm natural to him and easily acquired from others, so much so that even in a factual letter of 1768 "a very good Mistress of Nature to discover a *demon* in the habit of a parson" has a Shakespearean cadence that may come from a speech of Edmund's in the second scene of *King Lear.*

Meanwhile, on July 1, 1767, he was apprenticed to John Lambert, a Bristol attorney. It was a menial and empty job, tying him to a lonely office for 12 hours daily with no duties save copying legal precedents. He ate with servants and slept with the footboy. His two hours' evening freedom and what he was allowed of Sunday were spent at home, or roaming the scenic spots and antiquities near Bristol, or with a little circle of young bucks and scribblers; he also mentions actors at the Theatre Royal and may sometimes have escaped early enough to attend. But his working day passed mainly in his own creative writing, which could be turned to a little profit in the pages of *Felix Farley's Bristol Journal* and to rather more from three Bristol gentlemen who credited and welcomed the works of Rowley; their motives were variously antiquarian research (for which "A description of the Mayor's first Passing over the Old Bridge" was obligingly discovered), crude curiosity and a desire for family trees, and their influence led to forgery and mystification rather than to inspiration. *Felix Farley,* of course. and *The Town and Country Magazine* wanted up-to-date contributions in verse or prose, and the acknowledged works now began to oust Rowley. Chatterton's amatory verses, sometimes written for other youths, are addressed to girls with cacophonous names, and a pretense of love struggles through acrostics, the Pantheon and the Muses; Sally Clarke would have charmed Saul on the harpsichord, but the latest poems contain some impudent and sinister stuff.

In his elegiac poems he is at his worst, and even a friend sincerely mourned, the usher Thomas Phillips, is given a fulsome treatment of the "deathy tomb," and the "pitchy vapour," the pathetic fallacy and an affectation of utter despair; changes between drafts of the poem suggest falseness—"cheerful" becomes "frugal," and "friendship's potent spells" become "necromantic spells." Even his poem on a suicide, which perhaps suggested the form of his own, contains the deplorable line, "The blood-stained tomb where Smith and comfort lie." Yet the elegies not of mourning have a Gothic quality; one even parodies the Gothic mode with adders. meteors, cataracts. blasted oaks and the snap ending "lady Betty's tabby cat is dead." Nearer to his taste are the African landscapes (in his "African Eclogues"), where his imagination brims to wild, hectic scenes and, far ahead of his time, to the horrors of the slave system; the juvenile ferocities are deserved, and Gaira, whose beloved has been stolen by the whites, can cry, "O could I throw my javelin from my eyes!" The landscape, often conventional. is still sharply defined at moments, such as when the hero "gained a mountain glaring with the dawn."

As for his satires, his bulkiest work and the main occupation of his last days, they may now seem brilliantly precocious exercises in unmeant fury. their rolling oratory derived from Charles Churchill, their quips tedious, their political sentiments ephemeral, their asterisked names unintelligible. Yet now and then the poet brushes aside the hack, and even in the filthy *Exhibition* there is a nistful glance (from his final sojourn in London) at a Bristol evening "Flying on silken wings of dusty grey." There is admirable wit in "Kew Gardens." when he hints at Ossian: "Alas! I was not born beyond the Tweed!"; realism in "February," when,

after some zodiacal stuff, "the spruce mercer trembles in his shop"; and always the gift of phrase—"the drilling rain," the enraged dowager who "dined upon her nails."

In his now irksome life, other dangers began to jostle: free thought, M'ilkesism, contempt for Bristol and his dowdy family, a philandering attitude to local girls, and the "death" of Rowley. Dodsley the publisher did not rise to a bait, apparently never answering Chatterton's letter offering some of Rowley's manuscripts; Horace Walpole did and was the more severe when he was advised by friends that the manuscripts were modern. Chatterton rewarded him with bitter yet noble lines. By a mock suicide threat (the "Last Will and Testament—of me, Thomas Chatterton of the City of Bristol"), he forced Lambert to release him from his indentures, and set out for London with a few guineas, to storm the city by satires and pamphlets. A naughty, swinging burletta, *The* Revenge, was decently paid for, but the ruin of his chosen party and the death of a prospective patron quenched his hopes. Only one friend came to comfort him—his own creation Rowley, with that most pathetic of his poems, "An Excelente Balade of Charitie"; and with little left but his pride Chatterton took arsenic in his garret in Brooke street, Holborn, on the night of Aug. *24,* 1770

The aftermath was fame. After controversy between the "Rowleians" and those who rightly saw Chatterton as the sole author, came the just tributes of many poets: Coleridge wrote him a "Monody," Wordsworth saw him as "the marvellous Boy." Shelley gave him a tearful stanza in "Adonais," Keats dedicated "Endymion" to him and was greatly influenced by him; Crabbe, Byron, Scott. Rossetti and various poetic endeavourers added their praise. In France the romantics hailed his example, and Alfred de Vigny's absurdly inaccurate play *Chatterton* was the model for an opera by Ruggiero Leoncavallo.

Meyerstein, *A Life of Thomas Chatterton* (1930), a brilliant 600-page account of the poet and his poetry, superseding all previous studies *The Works* were first properly edited by R. Southey and J. Cottle (1803); the editions normally used are by W. W. Skeat (1871) and Sidney Lee (1906). *The Exhibition* is printed only in Esther P. Ellinger, *Thomas Chatterton, the Marvelous Boy* (1930). An important body of cuttings and plates is in British museum library C. 39. h. 20 (1). (A. B Co.)

CHATTI, a powerful German tribe who in the 1st century B.C. lived near the upper Visurgis (Weser) river, from whom the modern German *land* of Hesse derives its name (*Hessi* or *Hassi* being identified with Chatti). They soon expanded across the Taunus mountains to the Moenus (Main) river valley. The Chatti defeated the Cherusci (*q.v.*) and became the most dangerous German opponents of the Romans during the 1st century A.D.; in *83,* however, the emperor Domitian drove them back from the Taunus and constructed his *limes* (defensive frontier line) up the Lagona (Lahn) river and across to the Main. They were allies of the rebel governor of Upper Germany, L. Antonius Saturninus, in *89* and raided Roman territory in *162,* 170 and *213.* They were perhaps incorporated in the coalition of the Franks in the 3rd century A.D.

See Tacitus, *Germania.* (G. E. F. C.)

CHAUCER, GEOFFREY (c. 1340–1400), the great English poet, was born *c. 1340,* probably in London. His father and grandfather were prosperous vintners, who at times held offices connected with the king's court. The family derived from Ipswich. Suffolk. but Chaucer's father moved to London. became a prominent citizen and at one time lived in Thames street. where Chaucer may have been born. The first record of Chaucer himself, however. is in the account book of Elizabeth, countess of Ulster, for 1357, which shows him as a page in her service. Nothing is known of his education, but he may have attended a grammar school. Either formally or informally he learned Latin and French. and as a page he would be instructed in courtly behaviour and in bearing arms. In 1359 he served on a military expedition in France and was taken prisoner near Reims, being ransomed soon after. It is possible, as J. M. Manly has suggested (see *Bibliography,* below). that he then spent some time studying at one of the Inns of Court in London, where a good though expensive general and legal education suitable as a preparation for a career at court was given to the sons of nobles and rich men.

BY PERMISSION OF THE HUNTINGTON LIBRARY, SAN MARINO, CALIF (HM EL 26 C9)

EQUESTRIAN PORTRAIT OF CHAUCER, MINIATURE ILLUSTRATION FROM THE ELLESMERE MANUSCRIPT. IN THE HUNTINGTON LIBRARY, SAN MARINO, CALIF.

By Sept. *12. 1366.* he had married Philippa, to whom at that date a payment mas made as one of the queen's ladies in naiting. She was probably the daughter of one of the queen's knights from Hainaut, Sir Payne Roet. Philippa, on the death of the queen in *1369.* became for a time lady in waiting to John of Gaunt's second nife. Constance. queen of Castile. and probably died late in *1387.* Her sister Catherine after the death of her husband Sir Hugh Suynford in *1372,* became governess to John of Gaunt's children, then his mistress and finally, in *1396,* his third wife.

This close family connection with Gaunt, who was the third surviving son of Edward III and uncle of Richard II, no doubt benefited Chaucer beyond the gifts occasionally ,recorded to him and his wife, but in his middle years at least Chaucer in political matters seems to have belonged to the "king's faction" or "court party" (led by Sir Simon Burley. tutor to Richard II) rather than to Gaunt's Lancastrian faction. On June 20, *1367,* Chaucer was granted an annual salary of *so* marks (£13 6s. *8d.j* as one of the four *valecti* ("yeomen of the chamber") of the king's household. and in the following year he was appointed one of the king's 40 esquires, a position he retained till 1378 or later. Among the varied political and social duties attached to this position was that of entertaining the court with stories. songs and music. In *1369* John of Gaunt's wife, Blanche. duchess of Lancaster, died and Chaucer composed an elegy of *1,334* lines in octosyllabic couplets in her honour. In *1368, 1369* and 1370 he made trips abroad on the king's business. to France and possibly to Italy. On Dec. 1, 1372, he left on a longer journey as one of three commissioners to negotiate a trade agreement with Genoa and also. on his own, to perform a secret mission to Florence. It was presumably on this journey that he acquired that knowledge. perhaps unique in England at that time. of the Italian works of Dante and Boccaccio that was to become so important for his poetry. He returned in May 1373. In April 1374 he was granted a pitcher of wine daily, and on May 10 he obtained the lease of the dwelling house above the city gate of Aldgate, both probably made along with a new appointment, as comptroller of the customs and subsidy of wools, made on June *8.* 1374, at £10 a year, with annual gratuity of £6 13*s.* 4*d.* (multiply at least *60* times to get the rough modern equivalent; the modern equivalent in U.S. dollars of the £10 being thus roughly *$1,680).* Five days later he received an annuity of £10 for life from Gaunt. His prosperity was increased by other fees and rewards. which testify to his competence and the favour he enjoyed. He retained this appointment till *1386,* and in these *12* years, during which he was responsible for personally performing such duties as keeping the accounts. he went abroad several times to France and once to Italy on ambassadorial missions and royal marriage negotiations. In the same period he probably composed *The House of Fume, The Parliament of Fowls, Troilus and Cviseyde* and minor works. besides translating Boethius' *De consolatione philosophiae.* Two sons (all that is known of his family) were probably also born to him during this time. A reference to his daily accounts and his evening reading in the earlier part of this period is found in *The House of Fame,* 11, 641–660. In *1382* he was made in addition comptroller of the petty customs; he was allowed to appoint a permanent deputy, a privilege he also applied for in *1385* for his main comptrollership. He was ap-

pointed justice of the peace for Kent in Oct. 1386 and in Aug. 1386 knight of the shire to attend the parliament held in October.

Probably in 1389 he went to live in Kent. The house over Aldgate was leased to another man in Oct. 1386, and in December he lost his two comptrollerships, probably as a result of the shift of power from the friends of the king to the so-called lords appellant (*see* RICHARD II) who later were responsible for the death of several of Chaucer's friends and associates. Chaucer lived quietly for the next two or three years, possibly going to Calais for a time in 1388, and apparently short of money, for he began to be sued for debt in April 1388, and he sold his crown pension for a lump sum at about the same time. In May 1389 Richard II reasserted himself against the appellants and on July 12 Chaucer was appointed clerk of the king's works, responsible for maintaining the Tower, Westminster palace and other buildings. In 1390 he was responsible for erecting the scaffolding for the famous jousts at Smithfield and in the same year served on a commission to survey the banks of the Thames between Woolwich and Greenwich. In September he was robbed on journeys near London two or three times in four days, losing £20 of the king's money. Some time before June 22, 1391, he was appointed deputy-forester of the royal forest of North Petherton, Somerset; he relinquished his clerkship on June 15, 1391. In the last decade of the century Chaucer received among other gifts an annuity of £20 in Feb. 1394 from the king and Christmas gifts from Henry, earl of Derby (son of John of Gaunt and the future Henry IV), so that he was probably not poor, though small borrowings from the exchequer suggest that he may have been short of ready money. A suit against him for debt in 1398 seems to have arisen out of transactions during his clerkship and he obtained letters of protection for two years. When Richard II was deposed and Henry IV was received as king on Sept. 30, 1399, Chaucer, like nearly everyone else, acquiesced in the change and he addressed the new king in a graceful, witty poem entitled The Complaint of Chaucer to his Purse. He was rewarded in October by a new annuity of 40 marks (more than £16), and by the confirmation of his former grants from Richard. In Dec. 1399 he took a lease of a house in the garden of Westminster abbey, and probably in Oct. 1400 he died. He was buried in the abbey, a signal honour for a commoner, and his tomb, still to be seen, became the nucleus of the later Poet's corner.

These details of a successful career as courtier, diplomat and, to use a modern term, "senior civil servant" are supplemented by a very few autobiographical remarks in Chaucer's own poetry. The passage in The House of Fame already referred to is the fullest. The confession of unsuccessful love at the beginning of The Book of the Duchess is mere literary convention. Chaucer introduces himself into several other poems, notably The Prologue to the Legend of Good Women and The Prologue to Sir Thopas in The Canterbury Tales. The first passage tells of his devotion to books, except in the springtime: the second presents him half-jokingly as fat, silent, downlooking, strange. His opinions, to judge from the poems, were, like Shakespeare's, those of his time: orthodox, respectable and devout; it is his genius which is unique. There are no contemporary comments on his personality, unless we except John Lydgate's remark that he had heard that Chaucer was no carping critic of other poets (C. Spurgeon (ed.), *Five Hundred Years of Chaucer Criticism and Allusion*, vol. 1, p. 4; 1925). There are a few miniature portraits in manuscripts, all made after his death. The most authentic is the likeness his friend and literary disciple Thomas Hoccleve caused to be made in what is now the British museum manuscript Harley 4866. It shows Chaucer a little plump, with gray hair and two-pointed beard, in black hood and gown, holding beads, and with a calm, serious expression. The most interesting portrait occurs in the frontispiece to the manuscript of *Troilus and Criseyde* in Corpus Christi college, Cambridge, which shows a younger Chaucer with brown beard reading a poem from a wooden pulpit to a brilliant company, centred on the young Richard and his queen.

WORKS

The *Troilus* frontispiece shows the essential nature of Chaucer's audience and mode of publication. He wrote primarily for a relatively small group (of which he was himself a respected member) of the most important and cultured people in the land, and his poems were in the first instance read aloud to this highly sophisticated courtly audience. They were also disseminated in manuscript for a somewhat wider audience in court and city, and among country gentry. None of these contemporary manuscripts survives. In the 15th century the poems were copied and recopied, and it is from copies of copies that Chaucer's original must be reconstructed. The *Canterbury Tales* was always the most popular of his works and there are 84 full manuscripts or fragments, of which the Ellesmere manuscript (in the Huntington library, California) is the best: there are 20 manuscripts of *Troilus*, 14 of *The Parliament* and 3 each of The Book of the Duchess and The House of Fame. Chaucer gives lists of his works in The Prologue to the Legend of Good Women, the *Introduction* to the *Man of Law's Tale* and in the *Retractation* at the end of *The Canterbury Tales*. With the aid of these and internal evidence, such as astronomical references and the use of sources, the canon and chronology of his works can be stated with fair but not complete certainty.

The Book of the Duchess is one of the few poems with a certain date, since it commemorates the death of the duchess Blanche in 1369. The indirect narrative mode establishes a delicate tone of feeling, in which sorrow and praise unite with tenderness, and yet there is no intrusion on Gaunt's personal grief. The blend of gladness for what the lady was and sorrow for her loss is characteristic. The poem is somewhat too discursive, but even this fault (shared with *The House of Fame*) has its compensation in providing a kind of personal richness which is absent in the later, more disciplined works.

The House of Fame, 2,158 lines long but unfinished, is written in the same rather rough octosyllabic metre as The Book of the Duchess, and although it shows a knowledge of Dante and Boccaccio it is still, like the earlier poem, close in type to the French love vision. It is remarkable for the autobiographical passage already mentioned, and for the delightful comedy of book ii, when an eagle carries the alarmed poet high into the sky and delivers a lively lecture on the physical properties of sound. Chaucer describes himself here for the first time, as he always did later, as an outsider in the affairs of love, yet interested in love above all things. The combination of many subjects, the mingling of light and serious moods, make the poem strikingly unusual, for all its dependence on tradition. It was probably written between 1374 and 1382.

The Parliament of Fowls, 699 lines long, was probably written toward the end of the same period. The summary of Cicero's *Somnium Scipionis* at the beginning gives the story of the love vision and love debate a ground note of philosophical inquiry. Chaucer's new Italian reading, especially the *Teseida* of Boccaccio and the *Inferno* and *Purgatorio* of Dante, has here been much more fully assimilated. *The Parliament* is the most successful of the poems of Chaucer's early maturity, rich in bright description and in implication. The tone is light and vigorous; it includes without loss of unity touches of self-mocking description. Scipio's vision among the stars, a luscious description (from the *Teseida*) of Venus and the speeches of the birds' debate, variously noble, courtly, downright, racy: cynical. All the narrative and dramatic variety centres on the problem of love, that universal medieval theme.

The *House of Fame* and *The Parliament of Fowls* have often been taken as poems written in connection with events at court (as The Book of the Duchess certainly was), or as veiled petitions for reward. The most popular of such theories associates *The Parliament* (of which the pivot is a refusal to marry) with the marriage of Richard II and Anne of Bohemia in 1383, though a number of other occasions have also been suggested. Chaucer does make occasional undisputed references to contemporary persons, such as that to the duchess Blanche, or to the queen (in *Troilus* i, 171), or as a special case in *The General Prologue* to *The Canterbury Tales*; but no conclusive evidence has ever been produced to prove that The House of Fame and The Parliament

are allegories of events at court. or that they are petitions for reward. That they may be so remains always a possibility, but in the present state of knowledge such possibilities add little to appreciation of the art and value of the poetry.

The depth of Chaucer's art was increased by his intimate knowledge of Boethius' *De consolatione philosophiae* which he translated from the Latin, probably in the early 1380s. This noble work, one of the most famous in Europe from the 6th to at least the 16th century, deeply affected Chaucer's thought on those problems of God's foreknowledge and man's free will. of fortune. suffering and destiny, which so constantly interested him. *The Consolation* is one of several long pieces of prose translation from Latin or French sources that bear witness to Chaucer's serious interests. Another is *The Astrolabe,* an unfinished elementary treatise on astronomy written in 1391 for his little son Lewis. *The Equatorie of the Planetis,* a more advanced astronomical treatise (ed. by D. J. Price, 1955), may also be by Chaucer and the manuscript may even be in his own hand. The somewhat tedious *Melibeus* in *The Canterbury Tales* is a serious treatise on social and personal justice, on the need to love God, to obey the law, etc. *The Parson's Tale,* which concludes *The Canterbury Tales,* is an immense sermon on penance, containing, among much else, a treatise on the seven deadly sins. These translations remind us of the serious, orthodox bases of Chaucer's attitude to life.

Troilus and **Criseyde.**—*Troilus and Criseyde* probably followed closely after. or was contemporary with, the translation of the *De consolatione,* whose influence pervades the poem. The *Troilus,* which seems to have been completed by 1385, is 8.239 lines long. written in the same "rhyme royal" stanza form as *The Parliament,* and divided into five books. It is a work of full maturity and arguably Chaucer's greatest: rich in vivid realistic touches and convincing dialogue, yet learned and magnificent; noble, tender and sympathetic. yet humorous, even with a touch of cynicism. Everywhere it is penetrated by Chaucer's compassionate and keen observation of the contradictions of earthly life that give rise both to humour and tragedy. Before Chaucer, Troilus had been long famous in medieval times as a lover whose love was betrayed and whose iate was part of the fate of Troy, of whose warriors he was supposed to be among the best. Boccaccio had taken the various episodes of his story scattered through the long medieval accounts of the Trojan War and retold it. with some changes, in a single swift passionate plot in his poem *Il Filostrato.* Here Criseida is a rich and amorous young widow, and Troilo a full-blooded young man whose passionate affair with Criseida is helped on by Criseida's cousin Pandaro. Chaucer's adaptation oi this vivid sensual poem has been much studied, for though he followed Boccaccio's story in outline. translating much of the actual Italian text, he added many details. either invented or taken from earlier accounts of Troilus' story. and he entirely altered the spirit of Boccaccio's poem. (It has been suggested by R. A. Pratt that he may have taken many hints from the French translation oi *Il Filostrato* by Pierre de Beauvoir.) The first two books of *Troilus and Criseyde* describe in fascinating detail how Troilus falls in love with the reluctant Criseyde and how Pandarus, by somewhat shady dealing. brings her to love Troilus. The second book is especially delightiul for its comedy of social intrigue. The third book, in which the love affair is consummated. continues the intrigue, but develops also a deeper tenderness and culminates in a noble philosophical song in praise of love. The fourth and fifth books tell how Criseyde is sent to join her father who has deserted to the enemy, and how "with wommen fewe, among the Grekis stronge." Criseyde is quickly wooed and won by "sudden Diomede." and breaks her faith to Troilus. After a period of misery Troilus is killed in the fighting: at the end his soul is carried into the heavens. from where he sees and laughs at the misery of this world. The poem's final stanzas are a condemnation of worldly vanity and a call to "yonge, fresshe folkes" to set their hearts on God.

Chaucer makes his Troilus more innocent, more courtly, than Boccaccio's Troilo. He makes Criseyde, on whom he lavishes all his art and tenderness. more delicate, timid, loving and vulnerable than Boccaccio's heroine, and without her ready wantonness. Chaucer turns Pandarus into a far more complex figure than Pandaro. He makes him into Criseyde's uncle, of uncertain age; still the most intimate companion of Troilus (who must be imagined to be about 20). and yet much more experienced than he. Chaucer further enriches his poem with innumerable touches and occasionally whole episodes (such as Pandarus' visit to Criseyde in book ii) of lively social detail, by which he elaborates character. feeling and event. He transports the reader into a peculiarly intimate vision of 14th-century courtly life. Even more. Chaucer deepens the scope of the poem with philosophical reflections. sometimes putting them into the mouths of the characters, sometimes expressing them in the course of the narrative or in the magnificent preludes to each of the five books. The result is a poem very different from Boccaccio's. Boccaccio uses his hero to convey his own feelings; Chaucer, on the other hand, is detached from, though deeply compassionate toward. his lovers as, for proper appreciation of the poem. the modern reader must be. Chaucer's poem is contemplative in spirit, and hence necessarily, in its richness, slow moving. If it has a fault. it is that we are made to dwell too long on Troilus' misery in the fifth book; but this is a defect of its virtue—the maturity of outlook which appeals to the reader who wishes to see life whole and steadily, rather than to one who wishes only to identify himself with the hero of an energetic story. The ending has been held to be, not without some reason, strange, inconsistent and artistically at fault; but it is better regarded as an extreme example of Chaucer's ambivalent view of the world as good in essence, because it was made by God, but also bad, in that it has been spoiled by man's sin. And although worldly pleasures are great. they are inextricably linked with misery, and cannot compare with the pleasures promised in heaven. This complex attitude is the key to the quality of much of Chaucer's greatness, for it enables him to respond keenly to the mixture of good and bad in the world, to be at the same time satirical and tolerant, to be compassionate without sentimentality, cheerful without insensibility, idealistic without absurdity and to contemplate with serenity whatever life offers.

The Legend of Good Women.—His next major poem. *The Legend of Good Women,* is something of a decline after the *Troilus,* though the prologue has great charm and several points of interest. After the famous passage about the poet's love oi books and greater love of the spring. it tells of his devotion to the daisy—a charming example of the refined, literary and indeed rather precious 14th-century courtly sensibility. Then in a dream the god of love reproaches the poet for treating women badly in some of his writings, so the poet promises to write a series of stories about women who were faithful in love, "Cupid's saints." Chaucer may have projected as many as 25 oi these stories. but only nine survive. the last unfinished. In one version of the prologue it is stated that they are to be presented to the queen. Most critics ieel that they are at best patchy, and Chaucer himself may have tired of them. The prologue, with the poet's characteristically self-mocking presentation of himself, is unquestionably the most delightful part, and has also the interest of being an almost unique example of the poet's revision, for it exists in two versions. The first version (and probably the individual *Legends* as well) seems on internal evidence to have been written *c.* 1386, and exists in 11 manuscripts: the second, revised version was probably written *c.* 1395, and exists in only one manuscript. (The view presented here. though generally accepted. is opposed by some scholars who, like W. W. Skeat, reverse the order of composition.)

The Canterbury Tales.—*By* 1387 Chaucer had a few tales. like the early *Life of St. Cecilia* (which became *The Second Nun's Tale)* and the story of Palamon and Arcite (*The Knight's Tale),* which he must have wished to use in some larger scheme. Men in the 14th century liked collections of varied short stories. Chaucer's friend and contemporary, the poet John Gower, made one in English, the *Confessio amantis,* which Chaucer knew; and the most famous of a number of Italian collections is of course Boccaccio's *Decameron,* although there is no evidence that Chaucer knew it. Chaucer's own collection of short stories, *The Cant-*

erbury Tales, is unique in the variety of the tellers of the tales, in the vividness with which the tellers are described and in the developing dramatic relationships between tales and tellers. Chaucer planned a huge scheme. There were to be roughly 30 pilgrims (including the poet himself) described on a pilgrimage from the Tabard inn in Southwark, a suburb of London, to the famous shrine of St. Thomas Becket in Canterbury cathedral, and back again. Each pilgrim was to tell two stories going and two returning. But only 22 stories were in fact completed, including those that had been written earlier. The scheme obviously changed under Chaucer's hands, and Chaucer did not live long enough to revise completely even those sections he had more or less finished, though some of these sections had been circulated even before his death. It is impossible to date the individual tales precisely, save that with the exceptions already noted they mostly belong to the period after 1387.

The Canterbury Tales begin with the general *Prologue* of 858 lines of five stresses each, in rhyming couplets. After the deservedly famous opening lines describing the spring, in which the extremely conventional theme is treated with great freshness, he describes the group of pilgrims one by one in a series of brilliant brief portraits. The medieval ideal of the threefold structure of society — knighthood, clergy and plowmen — is represented by the noble portraits of knight and squire, parson and clerk, yeoman and plowman. Most of the other pilgrims are drawn from the miscellaneous variety of 14th-century society, both ecclesiastical and secular, which consciously or unconsciously evaded the ideal classification. There is a group of clerics and officials connected with the church, each of whom in some way breaks rules that should be obeyed, ranging from the charming prioress, too keen to be thought a lady, to the gross and oppressive summoner and the contemptible. fraudulent pardoner. The remainder of the pilgrims come from what would now be called the middle class, and range from the rich and slippery lawyer: who was probably connected with the court, to the cheating miller and beery cook. None of these persons is poor, and almost all are in some degree the objects of Chaucer's comic satire. The satire is occasionally no more than a mere touch, as with the franklin, a rich and respectable country gentleman; or a gentle irony, as with the prioress; or an amused revelation of roguery of difierent kinds, as with the miller, reeve and manciple. In other cases the satire is sharper, if more veiled, and may well be personal, as with the physician. lawyer and merchant. Sometimes the satire is openly and strongly hostile, as with the friar and summoner) while the portrait of the pardoner is almost savage. The variety and complexity of the poet's attitudes is great, and the subtle shades of feeling in many of the portraits, especially those of the monk and the wife of Bath, defy brief analysis. Chaucer rejoices in his characters at the same time that he mocks them. The characters are types, but they are also individuals, and some at least of the descriptions are unquestionably portraits of people known to Chaucer's own circle. Harry Bailly, host of the Tabard, was certainly a real person, records of whose activities exist; and J. M. Manly showed good grounds for suspecting that the lawyer, for example, mas one Thomas Pinchbeck, sergeant-at-law, whom Chaucer had no reason to love. Plausible originals have also been suggested for the shady merchant. the piratical shipman, the tricky. touchy reeve and others. In other poems Chaucer shows a range of feeling and description which far surpasses the general *Prologue,* but in its vivid sense of living people and in the subtlety and richness that underlie its apparent simplicity, the general *Prologue* is the most remarkable poem that Chaucer ever wrote: of its age. yet astonishingly original, and always making an instant appeal: for all its subtlety.

The static characters of the general *Prologue* are set in motion in the short links between the tales. and these snatches of realistic comedy, the most original things Chaucer ever wrote, make a delightful framework to the tales. The tales themselves are as varied as the tellers and in many cases represent the summit of Chaucer's art, though a few, like *The Physician's Tale* and *The Manciple's Tale,* are relative failures. and the prose treatises do not aim at an artistic effect. Many of the tales are written in the five-stress line, rhyming in couplets. nhich Chaucer first introduced into English in *The Legend* of *Good Women.*

Courtly romance in *The Canterbury Tales* is represented in differing nays by *The Knight's Tale* and *The Squire's Talr. The 'Knight's Tale* is of a splendour comparable with the *Troilus,* and like it is translated from a poem of Boccaccio's, *La Teseida.* Chaucer improves on his source by drasticaliy reducing the length, but he also makes additions, especially from Boethius. and like the *Troilus, The Knight's Tale* is philosophical and contemplative at heart, for all its colourful description and action. *The Squire's Tale,* which is unfinished, has a fine courtly festival. and describes magical wonders. In contrast to the nobility. the courtly idealism and fine sentiment of these tales (with which might be bracketed the pleasant *Franklin's Tale)* are a number of fabliaux, comic anecdotes somewhat outspoken but not offensive. Four of them are part of the quarrels between miller and reeve. friar and summoner.

These stories, based on anecdotes common to 14th-century Europe, far transcend their sources; *The ;Miller's Tale* and *The Reeve's Tale* particularly are perfect in poetic artistry and perhaps the funniest tales in English. Again in piquant contrast are the serious and devout tales of miracles of the Virgin, told by the lawyer and the prioress. The prioress' brief tale of a murdered child, beautifully told in seven-line stanzas with deep devout tenderness, is not less perfect, nor less typical of Chaucer, than the tales of the miller or the reeve. Two tales are particularly the product of the characters' own interests, and are more purely though ironically dramatic than many of the others. These are the tale of the wife of Bath, which has a delicate charm, an unusual touch of mystery and a vein of strongly felt morality; and the powerful tale of the pardoner, who tells how three thieves sought out death. Each of these tales is preceded by a prologue of self-revelation, rightly famous for satirical and sympathetic insight; the wife of Bath's prologue is probably the greatest example of "high comedy" in English. Comedy of other types, brilliantly various mixtures of satire, realism, farce, learning, burlesque and parody, is found in Chaucer's *Tale* of *Sir Thopas,* in *The Nun's Priest's Tale* of the cock and the fox and in *The Canon's Yeoman's Tale* about fraud in alchemy. An unusual variation of Chaucer's typical mixture of the serious and the comic is found in *The Clerk's Tale.* Here the story of the heroine Griselda's exemplary patience, beautifully and seriously told, is mockingly turned against women in a final satirical *envoi* of great technical brilliance.

Besides the tales mentioned. and one or two others, there are the serious prose treatises, one of which, *Tlze Parson's Tale,* brings the fragments of the great scheme to a conclusion. It is followed by the *Retractation,* in which the aging Chaucer, in a spirit somewhat resembling that of the end of *Troilus and Criseyde,* condemns all his secular works and commends his "moralities" and "homilies."

Other Works. — Apart from the works already noticed there are several which Chaucer mentions as his but which are lost. Chaucer also says he translated *Le Roman de la Rose.* An incomplete Middle English translation of the *Roman,* over 7,000 lines long, in octosyllabic metre, survives in one manuscript, and it is usually agreed by scholars that Chaucer probably wrote the first 1,705 lines of this in youth. The original *Roman* is the most important single literary influence on Chaucer's writings, for in it he found not only the vision of idealized love (*fine amour*) to which he was constant from youth to age. but also the suggestion and poetic example for much of the philosophizing. the scientific interest. the satire and even the comic bawdry of his maturest work.

He wrote also a number of shorter poems, including several rather frigid love poems, some pleasant addresses to friends, a brief. biting curse on Adam, his scribe, for making so many mistakes. and several short personal pieces based largely on Boethius. expressing resignation and contempt for the world. The third stanza of *Truth* is a particularly clear expression of what may be taken as Chaucer's considered attitude to life — optimistic, resolute, devout, unillusioned. unworried.

That thee is sent, receyve in buxumnesse[1],
The wrastling for this world axeth[2] a fal.
Her is non hoom[3], her nis[4] but wildernesse:
Forth, pilgrim, forth! Forth, beste[5], out of thy stal!
Know thy contree, look up, thank God of al;
Hold the heye[6] weye, and lat thy gost[7] thee lede;
And trouthe thee shal delivere, it is no drede[8].

[1]obedience [2]asks for [3]home [4]is *not* [5]beast [6]high [7]soul [8]doubt

Versification and Language.—Chaucer's metre is extremely skilful and varied; his verse is notably musical, especially if read with the pure vowel sounds of his time, though it is rarely lyrical. He began by imitating the fashionable French octosyllabic verse, but since English is a more heavily stressed language than French. and has a strong tradition of accentual verse in which the number of syllables is easily varied. his "octosyllabic" verse has often more or fewer than eight syllables. and seems rougher than that of his French masters. But Chaucer gives an indication of how deliberate his handling of the metre is when he comments in 1. 1098 of *The House* of *Fame* on his practice of occasionally omitting the first unstressed syllable of the line. French also gave him precedent for a longer line, but it was almost certainly the example of Dante and Boccaccio which led him to introduce into English the regular use of the five-stress, basically ten-syllable line of which he became one of the great masters. He never aimed, however, at the regularity which Dryden and Pope later attained. Often one of the five stresses is lighter than the others, and there is very often an extra syllable at the end of the line. Lines of 9 or 12 syllables are not uncommon, and the pause in the line was probably longer than a modern reader is accustomed to. Much of the variety of the verse is due to his masterly skill in varying the position of the pause.

Chaucer's language. which is the chief but by no means an insuperable bar to enjoyment of his poetry by a modern reader, was the dialect of the court and the City of London. This dialect was predominantly that of the southeast midlands, but it had a number of forms from nearby dialect areas, such as Kentish. It is the chief ancestor of modern standard English—not because Chaucer used it but for more complex reasons—and it is thus easier for. the modern reader to understand than other medieval dialects in which great poetry was written. Its chief difficulty is perhaps its vocabulary, for it has many words now obsolete. or used in a different sense. Nevertheless it has more familiar than unfamiliar words, and the patient use of a glossary is soon rewarded. Chaucer did not invent many words, but he is often the earliest writer, or among the earliest, in English whose use of a word is recorded. and to his contemporaries his language seemed notably fresh, modern and rich. The other well-known difficulty lor the modern reader is the presence in many words of a decayed form of an earlier full inflection, represented by a final *-e* or *-es,* which must be lightly pronounced even when occurring at the end of a line, thus:

And smalë fóweles máken mélodýe.

Chaucer took some licence in pronouncing or not pronouncing the final -r, because the use of this inflection was rapidly dying out in his time. Furthermore, his usage was often obscured because even 1 jth-century scribes nere often unfamiliar with the pronunciation of the inflection, and so sometimes either left it out, although it was needed for the metre, or added an unnecessary final *-e* But the pronunciation of the inflections given in modern edited texts soon'becomes familiar. and if the vowels are pronounced as in modern French, and all the consonants given their full value, a very tolerable rough approximation to Chaucer's pronunciation may soon be achieved even by the reader who lacks knowledge of philology. Philologists have of course constructed an almost complete idea of Chaucer's pronunciation

Reputation.—Chaucer in his own time and ever since has been recognized as one of the greatest English poets. His contemporaries and immediate successors praised him for his art. for the splendour of his verse, for his learning and for being "the first finder of our language." He was so fashionable in the middle of the 16th century that it was said that "the fine Courtier wil talke nothyng hut Chaucer." Scholars and poets praised him. Shakespeare does not mention him, but echoes him several times. In the 17th and 18th centuries his obsolete language and the change of taste lessened his popularity, except for enthusiasts and poets, of whom Dryden, who wrote the first literary criticism of Chaucer of a modern kind, was the chief. Only in the 18th century begins that praise of his humour which, justified in itself, has sometimes tended to obscure those other qualities of nobility, learning and art which earlier centuries more easily recognized. Modern scholarship begins with T. Tyrwhitt's edition of *The Canterbury Tales* (1775–78), but did not much develop beyond this until F. J. Furnivall founded the Chaucer society in 1868. Since then Chaucer has been extensively studied, especially in the 20th century by U.S. scholars.

In summary, the impression left by the whole body of Chaucer's work is one of great variety. His settings vary from palaces to humble homes. from the realistic to the fantastic; his style ranges from a simple and earthy directness to elaborate splendour. His stories vary from mildly bawdy tales to saints' lives told with a pure and sweet devotion, from philosophical romance to courtly elegy. His humour, occasionally broadly farcical, often of the subtlest delicacy, is all-pervading; yet the feeling most frequently expressed by him is a tender pity. Many of his tales reveal a remarkable range of knowledge of books, yet he has the full measure of everyday life from court to village street. Only an intimate presentation of the lives of the labouring poor is lacking. With all this variety his works yet convey a feeling of a strong, unified personality and of a sincere, orthodox! Christian philosophy and morality. Perhaps the secret of his greatness lies in this capacity to behold and harmonize the contradictory nature of life's experiences; to maintain in equilibrium a set of ambivalent responses to the whole of life; to remember that after woe comes joy, and after joy comes woe:

Swich is this world, whoso it may beholde.

He is both sophisticated and simple. humorously detached and worldly, yet compassionate and convinced that this world is not all.

BIBLIOGRAPHY.—The fundamental bibliographical works are: E. P. Hammond, *Chaucer, a Bihliographical Manual* (1908); *D.* D. Griffith, *Bibliography of Chaucer, 1908–1953* (1955).

Life: The earlier lives of Chaucer are useless. The foundation of accurate knowledge is *The Life-Records,* published in parts by the Chaucer Society (1871–1900). Details discovered later are listed in the bibliographies, but J. M. Manly, *Some New Light on Chaucer* (1926), should be specially noted. On the facts thus recorded are based the sketches in modern editions and biographies.

Editions: The multiplication of manuscripts in the 15th century was succeeded by many printed editions in the late 15th and 16th centuries, by William Caxton and others. The first collected edition, *The Workes of Geffray Chaucer,* was ed. by W. Thynne (1532). This and subsequent editions by Thynne, and the editions by J. Stow (1561) and T. Speght (1598), also printed and sometimes wrongly attributed to Chaucer a mass of inferior 15th-century poems—a process of accretion which continued as late as the 18th-century editions. The prints of manuscripts and the studies published by the Chaucer Society made posssible the first satisfactory edition of Chaucer by W. W. Skeat, 6 vol. (1894), with a 7th vol. (1897) containing the spurious poems. Though out of date, this edition contains much of value, especially in the notes and glossary. It is the basis of many minor editions. The best modern edition is in 1 vol. by F. N. Robinson (1933; rev. ed., 1957) with excellent introductions, text and compressed notes, and a useful but somewhat inadequate glossary. There is an important edition by J. M. Manly and E. Rickert of *The Text of the Canterbury Tales,* 8 vol. (1940), and by R. K. Root of *The Book of Troilus and Criseyde* (1926). There are many minor editions of the poems.

Modernizations and translations: These begin with Dryden in the late 17th century There have been many attempts at modernization or translation from the 18th century onward, by Pope, Gay and Wordsworth among others In the 20th century the translation into verse of *The Canterbury Tales* by N Coghill (1951) is perhaps the most popular There are many others Parts of Chaucer's work hale been translated into French, Italian, Spanish, German, Dutch, Swedish, Danish, Czech, Russian and Japanese.

Scholarship: The large number of specialist studies is listed in the bibliographies. Important literary background material is given in the *Sources and Analogues of Chaucer's Canterbury Tales,* ed. by W. F. Bryan and G. Dempster (1941). *See* also J. M. Manly, *Some New*

Light on Chaucer (1926); C. S. Lewis, *The Allegory of Love* (1936); T. A. Kirby, *Chaucer's Troilus: a Study in Courtly Love* (1940); W. Clemen, *Der junge Chaucer* (1938); J. A. W. Bennett, *The Parlement of Foules* (1957). The social background is described by G. G. Coulton, *Chaucer and His England* (1908), and by E. Rickert (comp.), *Chaucer's World*. ed. by C. C. Olson and M. M. Crow (1948). Most notable among studies of the scientific background is W. C. Curry, *Chaucer arid the Mediaeval Sciences* (1926). Chaucer's language and versification have been studied by B. ten Brink, *Chaucer's Sprache und Verskunst* (1884). Eng. trans. by M. B. Smith, *The Language and Versification of Chaucer* (1901); there is a 3rd German ed., rev. by E. Eckhardt (1920). H. Kokeritz, *A Guide to Chaucer's Pronunciation* (1954) is for the nonphilological student. Language and versification are also discussed in most modern editions.

Criticism: Among many critical studies may be mentioned H. S. Bennett, *Chaucer and the Fifteenth Century* (1947); G. K. Chesterton, *Chaucer* (1932); G. L. Kittredge, *Chaucer and His Poetry* (1915); J. L. Lowes, *Geoffrey Chaucer* (1934); P. V. D. Shelly, *The Living Chaucer* (1940); J. Speirs, *Chaucer the Maker* (1951); C. Muscatine, *Chaucer and the French Tradition* (1957). For a brief survey of Chaucer's life and work and Chaucerian criticism, *see* D. S. Brewer, *Chaucer* (1953). (D. S. B.)

CHAUEN: *see* XAUEN.

CHAULIAC, GUY DE (GUIDO DE CAULIACO) (*c.* 1300–1368), French surgeon and one of the most learned men of his time, was born at Chauliac. Auvergne. He took holy orders and studied at Toulouse, Montpellier and Paris. and then went to Bologna to study anatomy under Nicolo Bertuccio. Chauliac's book *Chirurgia magna* (1363) passed through many translations and was for a long time the standard work on the subject, though it tended to retard progress in surgery by advocating meddlesome treatment of wounds. It was first printed in French at Lyons in 1478. In his *Capitulum singulare* he qualifies as an important medical historian. He operated for hernia and cataract. which had previously been treated mainly by charlatans. and left a description of the narcotic inhalation given to patients. He died on July 25. 1368, at Xvignon, where he was physician to the pope.

See Fielding H. Garrison, *Introduction to the History of Medicine,* 4th ed., pp. 156–158 (1929); Arturo Castiglioni, *History of Medicine,* ed. by E. B. Krumbhaar, 2nd ed., pp. 345–347 (1947).

CHAUMETTE, PIERRE GASPARD (1763–1794), French revolutionary, distinguished as a popular leader, as a social reformer and as a promoter of the cult of Reason, was born at Nevers on May 24, 1763, a cobbler's son. After going to sea as a cabin boy, he returned home in 1783 to resume his interrupted studies, took up botany, moved about France and finally reached Paris as a medical student in 1789. In the course of the Revolution, he joined the Cordeliers club, subscribed to the petition of July 17, 1791, demanding the king's abdication and, after the rising of Aug. 10, 1792, represented the Théâtre Français section in the Paris commune. In Dec. 1792, he became *procureur gdnéral* of the commune. Concerned for the people's material and moral welfare, he improved conditions in hospitals, organized decent burial for the poor, forbade whipping in the schools and suppressed lotteries, prostitution and the display of obscene books and engravings. A relentless enemy of the Girondins, he contributed actively to their destruction. In the campaign against the Roman Catholics, he made the commune forbid priests to officiate outside churches (Oct, 1793) and organized the first ceremony of the worship of Reason, in Notre Dame, with an actress personifying the new goddess (Nov. 10). He next had the Paris churches closed (Nov. 23), and they remained so despite his conceding freedom of worship on Robespierre's intervention two days later. Though he did nothing to help the Hébertists in the crisis of March 1794, he was nevertheless arrested on their overthrow, brought before the Revolutionary tribunal and on April 13, 1794, executed. He had seemed dangerous to the committee of public safety not only as the sponsor of atheism but as a potential leader of the Parisian sans-culottes. Selections from his papers were edited by A. Aulard in *Mémoires de Chaumette sur la Révolution du 10 août 1792* (1893), by M. Tourneux in *Procès-verbaux de la Commune de Paris du 10 août 1792 au 1er juin 1793* (1895) and and by F. Braesch in *Papiers de Chaumette* (1908). (A. So.)

CHAUMONT (CHAUMONT-EN-BASSIGNY), a town of eastern France, capital of the *département* of Haute-Marne (*q.v.*), is situated on high ground at the confluence of the Marne and Suize, 100 km. (62 mi.) N. of Dijon by road. Pop. (1954) 16,945. The church of St. John the Baptist dates from the 13th century; the choir and lateral chapels belonging to the 15th and 16th. The sculptured triforium (15th century), the spiral staircase in the transept and a Holy Sepulchre are of interest. An 11th-century keep is the principal relic of a château of the counts of Champagne; the rest of the site is occupied by the law courts. Chaumont is on the main railway from Paris to Basel, Switz. The main industries are glovemaking and leather dressing. The town has trade in grain, iron (mined in the vicinity) and leather.

Chaumont received a charter from the counts of Champagne in 1190. In 1814 Great Britain, Austria, Russia and Prussia concluded at Chaumont the treaty by which they bound themselves to prosecute the Napoleonic War to a successful issue. Chaumont was occupied by the Germans in 1870–71 and again from June 1940 to Sept. 1944.

CHAUNCEY, ISAAC (1772–1840), **U.S.** naval officer, was born at Black Rock, Conn., Feb. 20, 1772. He entered the navy from the merchant service as a lieutenant in 1798 and became a captain in 1806. During the War of 1812 he took command on Lake Ontario at Sackets Harbor. N.Y., in Oct. 1812; he prepared for action with skill and energy but failed in strategy. Commodore Sir James Yeo expected him to attack or blockade Kingston, Ont., across the lake from Sackets Harbor, a key point on vital lines of supply by water for all British operations to the westward. Instead, Chauncey sailed with his squadron on April 25, 1813, and captured York (now Toronto). Yeo countered by attempting to take Sackets Harbor. This attack on his base brought Chauncey back, and he then permitted the British to move supplies with almost complete freedom for nearly two months. Thereafter both commodores exercised great care to avoid decisive action, although Yeo was slightly more aggressive in 1814.

After the war Chauncey commanded in the Mediterranean from 1816 to 1818. During his later years he served as commissioner of the navy and was president of the board of naval commissioners from 1837 until his death at Washington, D.C., Jan. 27, 1840.

See Dudley W. Knox, *A History of the United States Navy* (1948). (J. B. HN.)

CHAUNCY, CHARLES (1592–1672), American clergyman and second president of Harvard college, described by Cotton Mather as "a most incomparable scholar." was born at Yardley-Bury. Eng.. in Nov. 1592, and attended Trinity college, Cambridge. He was in turn vicar at Ware and at Marston St. Lawrence, but twice incurred censure from the authorities for nonconformity. His formal recantation in Feb. 1637 caused him lasting self-reproach. In the same year he emigrated to America, where he was an associate pastor at Plymouth, then pastor at Scituate, Mass., and, from 1654 until his death, president of Harvard college. He died on Feb. 19, 1672. His writings include: *The Plain Doctrine of the Justification of a Sinner in the Sight of God* (1659) and *Antisynodalia scripta Americana* (1664).

CHARLES CHAUNCY (1705–87), American clergyman and great-grandson of the above. a leader of the liberals of his generation, was born in Boston: Mass., on Jan. 1, 1705, and graduated at Harvard in 1721. In 1727 he was chosen as the colleague of Thomas Foxcroft in the First Church of Boston, continuing as pastor until his death. He condemned the Great Awakening as an outbreak of emotional extravagance in his sermon "Enthusiasm" and in his *Seasonable Thoughts on the State of Religion in New England* (1743), written in answer to Jonathan Edwards' *Some Thoughts Concerning the Present Revival of Religion in New England* (1742). Before and during the Revolutionary War he ardently supported the patriot party. He died in Boston on Feb. 10, 1787. His publications include: *Salvation* for *All Men Illustrated and Vindicated as a Scripture Doctrine* (1782) and *Five Dissertations on the Fall and Its Consequences* (1785).

For the elder Chauncy *see* Cotton Mather, *Magnalia Christi Americana* (1702); W. C. Fowler, *Memorials of the Chaunceys* (1858). For the younger Chauncy *see* P. L. Ford, *Bibliotheca Chaunciana* (privately printed, 1884); Williston Walker, *Ten New England Leaders* (1901).

CHAUSSON, ERNEST AMADÉE (1855–1899), French

composer who was one of the group of folloners of César Franck. Born in Paris on Jan. 21, 1855, he studied under Massenet at the Paris Conservatoire and from 1880 to 1883 was a private pupil of Franck His early works include songs on poems by Leconte de Lisle, notably "Le Colibri." Later he set poems by Paul Verlaine and cycles of poems by Maurice Bouchor (*Poème de l'amour et de la mer*), Jean Cros (*Chanson perpétuelle*) and Maurice Maeterlinck (*Serres chaudes*) His orchestral works include the Symphony in B flat (c 1890) and the *Poème* for violin and orchestra (1896). His principal chamber works are the Concert for violin, piano and string quartet (1890–91) and the Piano Quartet (pub. 1917). Well-to-do and generous, Chausson was secretary of the Société Nationale de Musique and did much to encourage contemporary French music. He was killed in a bicycle accident at Limay, Seine-et-Oise, on June 10, 1899. His opera Le Roi Arthus was posthumously produced at Brussels (1903). His last work, a string quartet, was completed by Vincent d'Indy. Though it is harmonically indebted to Franck and Wagner, much of Chausson's music is nostalgic and melancholy in mood. The more powerful aspects of his work are displayed in his symphony and in the song cycle Serres chaudes.

See Charles Oulmont, Ernest *Chausson* et la bande *à* Franck (1935); **La** Revue musicale, special number on Chausson (Dec. 1925).

(E. LR.)

CHAUTAUQUA, the westernmost county in New York, U.S., and the home of the adult education program of the same name. The county is known for agricultural products, grapes. vegetables, fruits and dairy products. Its northern extremity is bordered by Lake Erie and an excellent port is located at Dunkirk. Food and metal products are manufactured there. Chautauqua lake, 18 mi. long and 3 mi. wide, is popular for summer and winter sports. Chautauqua institution, located on the lake shore in the township of Chautauqua, presents summer programs in religion. education, music, art and drama; for the history of the institution and its influence see LYCEUMS AND CHAUTAUQUAS. A teachers' college at Fredonia (*q.v.*) and a community college at Jamestown (*q.v.*) offer collegiate instruction for the youth of the county.

See Helen G. McMahon, Chautauqua County, a *History* (1958).

(A. W. B.)

CHAUTAUQUAS: see LYCEUMS AND CHAUTAUQUAS.

CHAUVINISM, a term for excessive and unreasonable patriotism, of which the nearest English equivalent is "jingoism" (*see* JINGO). The word derived from the name of Nicolas Chauvin, a French soldier born at Rochefort, who was wounded many times during the French Revolutionary and Napoleonic wars but who, satisfied with the reward of military honours and a small pension, retained a simple-minded devotion to Napoleon. He came to typify the cult of military glory that was popular after 1815, among the veterans of Napoleon's armies. During the 1830s this aggressive if brave militarism came to be ridiculed in vaudeville, caricature and lampoon, and *chauvinisme* came to mean any kind of ultranationalism, whether Bonapartist or not. When the third republic experienced conflicts between the civil and military authorities, it was applied to the militarist groups hostile to the republic which were accused of wanting to turn the whole state into a barracks. Meanwhile the word had spread outside France (*e.g.*, Italian sciovinismo). (D. TN.)

CHAUX DE FONDS, LA, an industrial town in the Swiss canton of Neuchâtel, is about 25 km. (16 mi.) N.N.W. of Neuchâtel by road and 5 km. (3 mi.) from the French frontier. It stands at a height of about 3,250 ft. in a valley of the same name in the Jura. Pop. (1960) 38.906, chiefly Protestant and French speaking; of the Catholic faith, the majority are Old Catholics. The town is mainly modern and is laid out on a regular plan. It is the headquarters of the Swiss watch chamber of commerce and a centre of the watchmaking industry. There are schools of watchmaking and of industrial art. The museum contains interesting collections, especially the large section devoted to horology. The nearby forested Jura mountains are handy for day or week-end excursions. Railways run to Neuchâtel and Biel as well as to Besançon in France.

CHÁVEZ, CARLOS (1899–), foremost Mexican conductor and composer whose music skilfully combines elements of indigenous folk songs and advanced modern techniques, was born in Mexico City, June 13, 1899. He studied with Manuel Ponce, and at the age of 19 completed his first symphony. In 1921 he wrote his first significant work in a Mexican style, a ballet El fuego *nuevo*. After traveling in Europe and in the United States, he became conductor of the Orquesta Sinfónica de México (1928) and director of the national conservatory in Mexico (1928–34). He also appeared as guest conductor with major U.S. orchestras. An articulate uriter and lecturer, Chávez published numerous essays on Mexican music and a book, Toward a New Music (1937); in 1958–59 he was Charles Eliot Norton lecturer at Harvard university. His lectures at Harvard were collected in a book Musical *Thought* (1961). The music of Chávez is unmistakably Mexican in its melodic patterns and rhythmic inflections, but he seldom makes use of actual native tunes, preferring the more sophisticated method of adumbrative stylization. His works include Sinfonia de *Antigona* (1933); Sinfonia India (1936); Sinfonia *Romántica* (1952); Piano Concerto (1938–40); *Violin* Concerto (1949). His Toccata for percussion instruments (1942) is an interesting experiment in modern sonorities. (N. SY.)

CHAYOTE (Sechium edule), a slender scrambling perennial vine of tropical America, cultivated for its edible fruits and tubers. It belongs to the gourd family and is also known as christophine. The plant is suitable for growing near the Gulf of Mexico, along the Atlantic coast through South Carolina and in California. The fruit is generally pear shaped, furrowed, green or white, three to four inches long and fleshy; it encloses a single seed one to two inches long. (J. M. BL.)

CHEADLE AND GATLEY, an urban district (1894) in the Cheadle parliamentary division of Cheshire, Eng.. 7 mi. S.S.E. of Manchester and 3 mi. S.W. of Stockport. Pop. (1961) 45,599. It comprises the three ancient townships of Cheadle Moseley, Cheadle Bulkeley and Stockport Etchells (Gatley). Though the district has been occupied since Roman times, Cheadle is a modern suburban town and primarily a residential area. Its chief manufactures are chemicals, drugs, accumulators and bricks and there are large engineering works.

CHEB (Ger. EGER), an ancient city of the West Bohemian region, Czech., is situated in the Ohre valley on the spurs of the Fichtelgebirge which lie on the German border between Bavaria and Bohemia. Pop. (1957 est.) 20,058. The grim, ruined castle, built of great lava blocks, was completed by Frederick Barbarossa. In it Wallenstein's officers were assassinated in 1634, shortly before the murder of the leader himself in the town hall. The market place survives as a relic of medieval German settlement. although the south part of the town was much damaged in World War II. The history of Cheb has been full of violence, for it guards the easiest approach to Bohemia from the northwest. It passed in the 13th century from Swabian rulers to Otakar of Bohemia, and was battered in the Hussite wars, in the Thirty Years' War and again in the War of the Austrian Succession. In the 19th century its importance as a military strong point, a railway junction and a textile and machine manufacturing town grew steadily. It was almost entirely a German city until the expulsion of the Germans after World War II. (H. G. S.)

CHEBICHEV, PAFNUTIY LVOVICH (1821–1894), one of the most distinguished of Russian mathematicians, was born at Borovsk on May 26, 1821. Educated at the University of Moscow in 1859, he became professor of mathematics in the University of St. Petersburg, a position from which he retired in 1880. He became a correspondent in 1860, and in 1874 *associé étranger* of the Institute of France. He was also a foreign member of the Royal Society of London. He wrote much on prime numbers; particularly the number of primes below a certain bound, and devoted much attention to the problem of obtaining rectilinear motion by linkage. The "Chebichev's parallel motion" is a three-bar linkage, which gives a very close approximation to exact rectilinear motion. His mathematical writings covered a wide range of subjects, including the theory of probabilities, quadratic forms, orthoganal functions, theory of integrals, gearings, the construction of geographical maps, formulas for the computation of volumes, etc. He

also published a *Traité de* la *théorie des nombres.* He died at St. Petersburg on Dec. 8, 1894. His works were published in a French edition, *Oeuvres* (1899–1907); and in a five-volume Russian edition (1946–51). (O. OE.)

CHEBOKSARY, a town and capital of the Chuvash Autonomous Soviet Socialist Republic of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the right bank of the middle Volga opposite Sosnovka, between Gorki and Kazan. After the town was connected by railway to Kanash and thus to Moscow (360 mi. distant) and Kazan in 1939 it grew rapidly, from 31,000 inhabitants to 83,000 (1959). Manufactures include electrical apparatus, tractor spare parts, matches, sawed timber and a range of textiles and foodstuffs. Across the Volga a power station uses local peat. There are agricultural and pedagogical institutes and other educational and cultural foundations. (R. A. F.)

CHEBOYGAN, a city of Michigan, U.S., and the seat of Cheboygan county, is on Lake Huron at the northern tip of Michigan's "mitten." It commands a view of the historic Straits of Mackinac with its chain of islands. Settled in 1857, Cheboygan (at first called Duncan and later Inverness), was incorporated as a village in 1871 and as a city in 1889. It originated as a lumbering town on the Cheboygan river but later became a commercial fishing centre and the home of such varied manufactures as cement products, tools and dies, paper supplies, precision instruments and rustic furniture. The icebreaker "Mackinaw" of the U.S. coast guard is based there and the University of Michigan has a biological station nearby. Dairy farms and apple orchards border the city. Numerous inland lakes as well as proximity to lakes Huron and Michigan make Cheboygan a busy resort area in summer; skiing, ice skating and ice fishing attract winter sports enthusiasts. The name Cheboygan is an Indian word meaning "place of entrance," "portage" or "harbour" and probably refers to the river. For comparative population figures *see* table in MICHIGAN: *Population.* (B. L. F.)

CHECHEN-INGUSH AUTONOMOUS SOVIET SOCIALIST REPUBLIC, in the Russian Soviet Federated Socialist Republic of the U.S.S.R., lies on the northern flank of the Greater Caucasus range. Pop. (1959) 710,424. Area 7,452 sq.mi. Physically it falls into three regions. In the south is the main Caucasus range, the crestline of which forms the republic's southern boundary. The highest points are Mt. Tebulos-Mta (14,744 ft.) and Mt. Shan (14,531 ft.). The chief rivers of this area are the Argun and Assa, tributaries of the Sunzha. The second region is the foreland, consisting of the broad valleys of the Terek (*q.v.*) and the Sunzha, which cross the republic from the west to the east, where they unite. These valleys are separated by the Sunzha and Terek ranges, which rise to 2,132 ft. and are themselves separated by the Alkhan-churt valley. Thirdly, in the north are the level, rolling plains of the Nogai steppe. The great variety of relief is reflected in the soil and vegetation cover. The Nogai steppe is largely semidesert with sagebrush vegetation and wide areas of sand dunes. This gives way toward the south and southwest, near the Terek, to feather-grass steppe on black earth and chestnut soils. Steppe also occupies the Terek and Sunzha valleys. Up to 6,500 ft. the mountain slopes are densely covered by forests of beech, hornbeam and oak, above which are coniferous forests, then alpine meadows and finally bare rock, snow and ice. The climate varies, but is in general continental. Summers in the north are hot and dry (July average temperature 77° F.) and winters moderately cold (January average 25°). Rainfall is 8–16 in. a year. In the mountains temperature conditions are less extreme and the rainfall rises to 16–20 in. a year.

The republic was formed in 1936, after the amalgamation of the Chechen and Ingush autonomous *oblasts,* but lost its status during World War II, when it became Grozny *oblast.* It was re-established as an autonomous republic in Jan. 1957 when various boundary changes took place. The republic lost the northern part of the Nogai steppe, but its southern boundary was extended to the Caucasus crest. It is not known in what proportions the inhabitants belong to the two national groups, the Chechen and the Ingush, but in the U.S.S.R. as a whole these peoples are said to number 419,000 and 106,000 respectively. At the time of the 1926 census Chechen formed 58% and Ingush 13% of the population. These nationalities are Muslims and are two of the many Caucasian mountain peoples speaking Japhetic languages. Traditionally independent, they made prolonged resistance to Russian conquest, in the 19th century especially, with other Caucasian tribes which, under the leadership of Shamil (*q.v.*), were temporarily successful while the Russians were occupied with the Crimean War. The Russians in later incursions, however, employed large forces; Shamil was captured in 1859 and many of his followers migrated to Armenia. The Terek river remained a Cossack defensive frontier until the 1860s. The constant skirmishes of Chechen and Russians along the Terek form the background to *The Cossacks* by Tolstoi, who, like M. Y. Lermontov, served in the frontier fortress of Grozny. Of the present population 41.2% (293,039) are urban dwellers, the bulk of whom live in the capital, Grozny (*q.v.*), which has 240,000 inhabitants. Population density varies greatly, being lowest in the dry steppe and highest in the valleys of the foreland region.

The backbone of the economy is petroleum. Drilling is mainly in the lower Sunzha valley between Grozny and Gudermes and in the Sunzha and Terek ranges, especially around Malgobek. There are also new wells in the Nogai steppe. Large-scale production of petroleum began in 1896. By the early 1930s the area was producing about one-third of Soviet oil, but this proportion has fallen greatly, because of exhaustion of older wells and the growth of new oil fields. Refining is concentrated in Grozny, one of the largest centres of this industry in the U.S.S.R., while pipelines run to the Caspian at Makhachkala, to the Black sea at Tuapse and to the Donets basin (Donbas). The great refining capacity of Grozny outstripped the slackening pace of local petroleum production and oil is now imported from the Volga-Urals area. Benzine is a major product, Grozny petroleum having the highest benzine content of the U.S.S.R. Natural gas is also found in the area and by the early 1960s production amounted to more than 7,000,000,000 cu.ft. annually. Gas pipelines run to the Donbas and Moscow.

Engineering, particularly the manufacture of machinery for the petroleum industry, is concentrated in Grozny, as is the chemical industry. Timber-cutting is important in the mountains, the timber, mostly beech, being made into furniture, parquet flooring and musical instruments at small centres on the railways in the valleys. Food processing is well developed, especially canning of fruit and vegetables.

Agriculture is largely concentrated in the Terek, Sunzha and Alkhan-churt valleys and, for the most part, requires artificial water supply. Nearly 200,000 ac. are irrigated, while other areas depend on artesian wells. Spring wheat, barley and millet and winter rye are dominant crops in the Terek valley, winter wheat, maize (corn), sunflowers, 'mustard, rape and flax in the Sunzha valley. Vineyards are common and a wide range of fruit and vegetables are grown. Livestock husbandry is rather poorly developed but is the major use of both the dry steppe (especially for sheep) and the mountain pastures. There is considerable transhumance between these areas.

The main axes of communication are the railways following the Terek and Sunzha valleys, forming links with Astrakhan and Baku on the Caspian and with Tuapse and Rostov on the Black and Azov seas. A motor road joins Grozny to Ordzhonikidze, and thus to the Georgian military highway across the Caucasus.

(R. A. F.)

CHECK (CHEQUE), a bill of exchange drawn on a bank and payable on demand. It has proved in practice to be a most useful device and has become the chief currency of domestic commerce in the U.S. and Great Britain. (*See* COMMERCIAL PAPER.)

As a negotiable instrument, a check is a written order to pay money and it may be transferred from one person to another by endorsement and delivery or, in certain cases, by delivery alone. Negotiability can be restricted by appropriate words such as those provided by restrictive endorsements, or by the check form itself. Most checks are "order" checks reading "Pay to the order of." This form requires that the person whose name is on the check, known as the payee, must endorse the check before it is paid or

transferred. 'Pay Bearer" checks do not require endorsement and may be negotiated by delivery only. but in practice drawees usually require endorsement. Endorsement is the signature of the payee or other holder of a negotiable instrument, usually written on the back of the check. As it appears on the face of a check. the word "pay" means payment in legal tender, the legal medium of exchange Most checks however. are not "paid" in currency but by the debiting and crediting of bank deposits. In fact, the major monetary functions of commercial banks are the creation of demand deposits and the transfer of deposit credits upon the orders (checks) of depositors.

The usual form of a U.S. bank check carries at the top the date of issuance, the name of the bank upon which it is drann space for a number for convenient identification and a printed number for use in bank clearing operations. Across the middle are the printed words, "Pay to the order of" and a space wherein the name of the payee may be written. There is also a space for writing the whole amount in figures. On the next line, the amount in dollars is written out and the cents are usually shonn in figures. At the bottom appears the signature of the drawer. To collect or "cash" the check, the payee must endorse it on the back exactly as his name is written on the face of the check. When so endorsed, the check is good in the hands of anyone. Most business checks are printed on a safety paper that makes erasure and alteration of a check difficult. Business firms often take the further precaution of using a machine that perforates the figures as it prints them.

When a check is presented for payment to the bank on nhich it is drann it is carefully examined by bank officials. They note the date. signature and endorsement; make sure that the nriter of the check has sufficient funds in his account to "cover" the check; and determine that the writer of the check has not placed a stop-payment order on it. A bank is usually responsible to its customers for paying raised or altered checks or checks on nhich the customer has ordered that payment be stopped. It is generally held that the debt for which a check is given is not extinguished by the mere delivery of the check; a check is only a conditional payment until it is finally honoured.

"Check kiting" is a procedure whereby checks written on accounts in separate banks are used to generate short-term purchasing power through the use of the bank's credit. A depositor nith accounts in two banks may build up his balance in Bank A by depositing a check drawn on Bank B. although his balance in Bank B (perhaps an out-of-tonn bank) is not sufficient to cover the check. He makes the check good before it is presented for collection but in the meantime has made use of the bank's credit. Many banks prevent this practice by refusing to credit any check for deposit until the collection has been made.

A cashier's check is issued by the bank against itself and is signed by the cashier or some other bank officer. It is the close equivalent of cash and has unquestioned acceptability as exchange. It is frequently used by persons who have no bank accounts.

A certified check is a depositor's check that has been guaranteed by the bank upon which it is drawn. and it is so stamped. By certifying a check the bank becomes responsible for its payment and sets aside for that purpose the amount that must be paid. Certified checks and cashier's checks are used in almost all large financial transactions because they are equivalent to cash. are easier to handle, prove good faith and establish definite ability to fulfill a contract.

Travelers' checks are cashier's checks sold to travelers that require two signatures by the payee. One signature is placed on the check in the presence of an issuing agent; the other signature is for purpose of identification arid is placed on the check when it is cashed. Purchasers of travelers' checks are guaranteed reimbursement by the issuers of the checks if they are lost or stolen.

Fundamentally. there are two kinds of payment money in a modern economy. currency and checks. The effective real money supply is the total of demand deposits in banks (75%–80%) and currency (20%–25%). Although deposit money is not legal tender, checks are freely accepted in payment because they may readily be converted into currency and because the government assures the ultimate safety of bank deposits. Checks, used as money. have many advantages. They have a lower risk of loss by theft; they eliminate the need to make change; they are easily transported, accounted for and handled; and they act as payment receipts. The chief disadvantage of checks is their reduced acceptability.

Over 90% of all transactions are paid by check in the United States and the Commonwealth of Nations. More than 12,000,000,000 checks are written annually in the Cnited States alone and the number is steadily increasing. The sorting and allocation of checks to the correct banks and depositors is known as check clearing. Clearings are accomplished either by direct presentation, by correspondent banks. through local clearinghouses such as those in New York and in Chicago or by the federal reserve banks in the United States. The task is so substantial that electronic equipment has been developed that can sort and scan checks at a rate of over 750 per minute. When magnetic ink characters are placed in a prearranged position on a check, the machines are able to "read' amounts of money and names of drawee banks, and thus to handle all sorting and accounting for many accounts. See BANKING; CURRENCY; MONEY; MONEY ORDER.

See also references under "Check" in the Index volume.

(O. R. *G.*)

CHECKERS. Checkers. known as draughts in Great Britain, is one of the world's oldest intellectual pastimes. The game is played by millions of persons and has virtually the same rules throughout the English-speaking world. Its rudiments are simple, yet its expert play is so profoundly intricate that no champion can truthfully state that he has nothing more to learn. According to its many devotees, the game's fascination increases in proportion to the player's insight into its strategies, and the skilled player finds in it an inexhaustible appeal and lifetime hobby.

GENERAL INSTRUCTIONS

The game is played by tn-o persons who occupy positions opposite each other across a board of 64 light and dark squares. the same as a chessboard. The 24 playing pieces are disk shaped and of contrasting colours (whatever their colours, they are identified as Black and White). At the start of the game each contestant has 12 pieces arranged on the board as shon-n in fig. 1. The single corner is to. the left and the double corner to the right. While the diagram establishes the setup of the pieces, the actual playing is always done on the dark squares; the board customarily is shown in reverse for clarity. A half turn of the actual checkerboard from the position shown will bring it into the proper placement for playing on the dark squares.

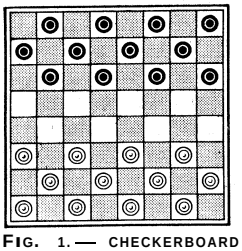

FIG. 1.— CHECKERBOARD OR DRAUGHTBOARD SET FOR PLAY

Mechanically. the play consists of advancing a man diagonally forward to an adjoining vacant square. If an opponent's piece is in such an adjoining vacant square, with a vacant space beyond, it must be captured and removed by jumping over it to the empty square. If this square presents the same situation. successive jumps in a straight or zigzag direction must be completed in the same play. When there is more than one way to jump the player has his choice. When a man first enters the king row (squares 29, 30, 31, 32 for Black and 1, 2, 3, 4 for White in fig. 2), it must be crowned by the opponent who places another piece of the same colour on it. A man reaching the king row has finished its move. As the king has the added privilege of moving and jumping backward. this rule has an effect on strategy. A win is scored when an opponent's men are all captured or blocked so that he cannot move. When neither side can force a victory and the trend of play becomes repetitious a draw game is declared.

Standard Tournament Rules.—The official board used in tournaments is of 2-in. squares; the checkers are round and of a diameter not less than $1\frac{1}{4}$ in. or more than $1\frac{1}{2}$ in.

At the beginning of a game, lots are cast for choice of colours. The first move is made by the player of the Black pieces. Thereaiter. the colours alternate with each succeeding game.

;Moving.—If a move is not made by the end of five minutes, time is called, and if it is not completed by the end of another minute the game shall be adjudged as lost through improper delay.

Capturing.—When there are two or more ways to jump. five minutes shall be allowed; but where there is only one way to jump, time is called at the end of one minute; and at the expiration of another minute, the game is forfeited by the delaying player.

Touched Pieces.—If a person whose turn it is to play touches one of his playable pieces, he must play it or forfeit the game. Once he has moved a playable piece toward another square, it must be moved in that direction.

The Huff.—The huff or blow (picking up a man for not jumping) has been abolished. All jumps must be completed, and all jumped pieces must be removed from the board.

Kings.—When a single piece reaches any of the squares on the opposite extreme side of the board, by reason of a move or jump. it becomes a king; and that completes the play. The piece then must be crowned by the opponent by placing a piece on top of it. A king, once crowned: can move forward or backward one move at a time but can jump one or more pieces in any direction.

Draw Game.—A draw is declared when neither player can force a win. When one side appears stronger, the player with the weaker side can request the referee for a count on moves. and from that point the player with the stronger side must show a decided advantage within 40 of his own moves, and failing in this must concede a draw.

Conduct.—During a game, neither player can leave the board without permission of the referee. If permission is granted, his opponent may accompany him. Anything that may tend to distract or annoy an opponent is forbidden. and any player so acting after being warned can be penalized with the loss of the game. Any spectator giving warning either by signs or remarks shall be ordered from the room. Similar rules are enforced for smoking or talking near the playing boards.

HISTORY

There is good evidence of the game's ancient origin. both factual and circumstantial. That checkers was played in the days of the earlier Pharaohs is well authenticated by Egyptian history and the British museum contains specimens of primitive boards quite similar to the modern ones. The roots of checkers are intertwined with those of chess. a sister game. and there is some conjecture over priority. Checkers being simpler in form, it is reasonable to presume it was devised first, and that chess followed as an elaboration. Plato and Homer mention checkers in their works and the Romans are believed to have imported it from Greece. Comparison of these games of antiquity with the modern pastime may be speculative; nevertheless, the earliest publications on record show the 12 men on each side and the conventional board.

Antonio Torquemada of Valencia. Spain. published the first book on checkers in 1547. Other Spanish issues followed and in 1650 Juan Garcia Canalejas published a notable volume containing games and traps that are still dependable. The Spaniards may have received their knowledge from older sources in Arabia through the Moors.

William Payne, a mathematician, was the pioneer of English draughts literature and his book, *Guide* to the *Game of Draughts*, appeared in 1756. A striking feature of Payne's book is the dedication by Samuel Johnson, who was exceedingly fond of the game. In 1800 Joshua Sturges brought out a treatise that served as a textbook for nearly half a century until the advent of Andrew Anderson's elaborate compilation in 1848. Thereafter the literature grew at a rapid pace and by 1900 the books counted up in the hundreds. In newspaper columns and periodicals a student could find games and problems. analyses by critics; reports on tournaments, matches and correspondence play, together with notices of simultaneous and blindfold entertainments by itinerant champions.

After 1900 the growth of scientific play was stepped up by the advancement of U.S. players. who made rapid progress. spurred on by their first team match with a representative British group in 1905. The contest was on the two-move restriction style of play. at which the U.S. aggregation was no match for the more seasoned Scots masters, the greatest of their day, and the U.S. was defeated by a score of 73 to 34 and 284 draws. A second international match in 1927, staged in New York city, found the U.S. team in front by 96 wins to 20 losses and 364 drawn games.

Opening **Restrictions.**—At first all expert play was unrestricted or go-as-you-please, the opening moves being left entirely to the discretion of the individual. But during one of the Wyllie-Martins matches in 1863 an episode occurred which crystallized the need for widening the game's scope. A variation of the Glasgow opening (since dubbed "Martins' rest") was repeated 21 times. This act was attributed to the fear each player had of the other and paved the way for gradually introducing the two-move restriction. where the first move on each side is determined by lot, compelling the handling of 43 openings and tremendously increasing the sweep of the game. Three-move or the American restriction was adopted in the United States in 1929, raising the playable openings to 137. Launched explicitly to forestall lengthy heats of drawn games in tourneys between overcautious experts whose forte was safety first, it was expected that the plurality of openings would nullify the advantages of "the book" (proven lines of published play) and produce pure cross-board checkers, long the ideal of many players. This assumption quickly proved erroneous for the newest restriction presented many unbalanced games, structurally feeble at the start, requiring still greater efforts of study and private research. Three-move restriction is handicap checkers and has trebled the professional's labour. Eleven-man ballot, removing one piece by lot from each side at the start. increases the openings into the thousands and is a generator of originality. But aside from a few proponents it failed to gain favour.

It is interesting to note that the original game of go-as-you-please remained the most popular mode of playing checkers, and likewise had its champions. One of its strongest adherents was Melvin Pomeroy. who not only proved his invincibility at this style of play, but redemonstrated its scope by defeating Alfred Jordan in a go-as-you-please match contested in 1914. Jordan, who won the two-move championship of England. was anxious to annex the free-style title. In a return match, in 1915, Pomeroy was again victorious, winning three games and leaving Jordan scoreless. He retained the title until his death in 1933. Later matches between Millard Hopper and Tom Wiswell for the go-as-you-please championship presented added proof that the original method of playing checkers was far from being exhausted.

In the United States matches are officially endorsed by the American Checker federation, which recognizes the international aspects of the game and works in harmony with the English and Scottish Draughts association.

PLAYING THE GAME

General Principles.—Thenotation used in describing the game is based on numbering the squares on the board as shown in fig. 2. The Black pieces always occupy squares 1 to 12, and the White pieces invariably rest on squares 21 to 32. The beginner should learn to play slowly and with care, studying every possible move at his command and evaluating it in relation to his opponent's possible countermove. When possible, he should play with better players, for each defeat will point out flaws in his game.

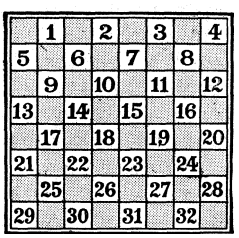

FIG 2—CHECKERBOARD NOTATION BLACK OCCUPIES SQUARES 1 TO 12, AND WHITE 21 TO 32

Centre *Moves.*—Checker men should be moved toward the centre of the board, producing a wedge-shaped formation. Each advanced piece should be backed up and supported so that the ranks are solidly massed. Such a phalanx is a powerful attacking force and can strike at any weak point in an opponent's game.

Side Moues.—A move to the side of the board, especially at the start of a game. is tactically weak. Side moves hinder the mobility of the pieces, and the piece on the side is often referred to as one handed. It can attack in only one direction, nhile a checker in the centre can advance on both the right and left diagonals. This does not mean that side moves are invariably weak, for there are

exceptions wherein such a play is proper and advantageous.

Key *Squares.*—Control of the centre of the board is also a prime objective and the player should try to occupy squares 14, 1j, 18 and 19. These are known as key squares. and possession of more of them gives a commanding position from which a player can launch a powerful attack. If an adversary has control of one or more of these squares, it is generally wise to exchange men so that these pieces are removed while the capturing men take over these points of control.

King Row. —A player should never attempt to hold the king row intact. This is a fallacy with beginners predicated on the premise that by withholding four men in the king row, an opponent can be prevented irom securing a king. Obviously! if a player follows this precept he will have only eight checkers left as fighting forces, and if his opponent attacks with ten men, his superiority in field forces will wield a winning advantage, enable him to crack the king row. secure a king and bring it out to mop up the retreating single men. The sound and orthodox king-row defense employs only two checkers which are retained on squares 1 and 3 or 30 and 32. If pieces are kept on these squares it will be discovered that an opponent can only enter the king row by forming a bridge: posting checkers on squares 10 and 12 or 21 and 23. Such bridge positions are extremely weak for the pieces on squares 10 and 23. and are subject to attack by an adversary's king. In the case of the men posted on squares 12 and 21, the bridge is not dangerous. but the piece that enters the single corner for a king generally finds itself locked in. The best way to pierce the two-man king-row defense is to line up three pieces and swap off the defending pieces.

First King.—The early acquisition of a king is a tactical advantage. especially when it can be put to the maximum of power. The first king decides many contests and when possible it is often a wise plan to sacrifice a checker in order to crown and attack from the rear.

Reducing Forces.—When a player is a checker ahead, it is wise to make judicious exchanges of men in order to reduce the forces. Some opponents may resent this swapping off as unsportsmanlike hut experts all recognize it as a legitimate tactic for retaining the advantage and developing a final victory.

Strokes and Shots.— These trick plays are usually the chief resources with which the skilled player annihilates the beginner. It behooves the novice to learn the mechanics of these plays before attempting to handle his entire army of checker men. An insight into these clever maneuvers will often lead a player to delve deeper into the advanced features of the opening and mid-game formations.

The nemesis of the tyro is the simple two-for-one shot. Several examples follow: White on squares 21, 17 and 18; Black on squares 9. 10 and 11. White gains a man by moving 1; to 14, Black capturing 10–17 and White rejumping from 21 to 5. Another instance: White on 25, 22 and 18; Black on 7, 9 and 11. White gains a checker by the exchange of 18 to 14. Again. White on 2j and 30 and Black on 17 and 18. The winning move is 25–22. Still another form: White on 28 and 32, Black on 20 and 18. It will be seen that White's move 28 to 24 ends the game. These simple strokes arise in a variety of ways on either side of the board, and often during a game when the player's attention may be distracted by the number of checkers on the board.

The following two-for-one is a recurrent booby trap. White on 18, 22 and 25; Black on 11, 13 and 15; with Black to move and win by 13–17. A similar situation: White on 18, 20, 22, 25 and 29; Black on 6, 7, 11, 13 and 1j. White wins by 20–16.

Another clever dodge is the slip shot. White on 18, 24. 27 and 32; Black on 5, 9, 11 and,20. To the uninitiated the position appears innocent, but it is White's move and he gains a surprising win by 27–23, 20–27, 18–15, 11–18, 23–14, 9–18, 32–14. Trick plays like this one will leave a novice flabbergasted.

Another brilliant combination that might salvage many a lost game is the in-and-out shot. White on 7, 26 and 30; Black on 4, 18, 21 and a Black king on 16. White is a man down and about ready to resign but it is Black's move and being anxious to start another checker for a king he moves from 4 to 8. This move leaves him open to the following situation: White proceeds to win the game by moving 30–26, forcing Black to jump into the king row by 21 to 30. Black must remain there to be crowned before jumping out and this delaying action gives White what is called a waiting move. Taking advantage of it. White pushes his checker irom 7 to 3 and when the Black king jumps out (compulsory) 30–23, the newly crowned White king captures three Black checkers and lands in position to block the surviving Black piece. Experts win many a game on sacrifices: squeeze plays and compound strokes that include variations from minor to major tactics.

Although cross-board talent is an important weapon, it is outweighed by knowledge. Thus, the strongest natural player may be at a disadvantage if he is maneuvered into a cook (privately analyzed departure from established book lines) and has to search for the right reply across the board. However, cross-board ability is not guesswork, but a methodical process based on experience. The time limit of five minutes (with a minute's grace) per move governing official contests may seem like an eternity to the uninitiated, but it is often insufficient to cope with the ramifications of a new position which an opponent may have explored for many hours prior to the contest. In cases of this kind, it is generally wise to play safe and try to run for a draw game. as advocated by the English authority Alfred Jordan.

Opening Game.— In contesting a checker game the adept player relies materially on what is termed forcing. If he can steer the game into familiar channels he often has a distinct advantage over his opponent. and quite naturally both players vie for their favourite lines of play. An elementary example of the value of known lines is exemplified in the Canalejas stroke, one of the oldest opening losses and consequently a favourite line against a beginner.

If an uninformed player has the Black checkers and starts his game by moving from 11 to 16, an expert can assume that his intentions are to continue this checker to the side of the board. Having in mind the possibility of making a startling finish to the game, the experienced player moves 23 to 18 as White's reply. Black continues 16–20 and White baits the trap for the stroke by playing 24–19.

At this stage, 8–11 looks like a satisfactory reply but it loses by a remarkable combination thus: 19–15, 10–19, 18–14, 9–18, 22–8, 4–11, 27–24, 20–27, 31–8 and White demolishes the Black forces, gains a checker and is on his way for a king. Note the alternate ways of forming the same trap:

11–16, 24–19, 16–20, 23–18, 8–11
12–16, 23–18, 16–20, 24–19, 8–12
12–16, 24–19, 16–20, 23–18, 8–12

The expert player has many opening and mid-game losses and uses his knowledge to telling effect on the unlearned player. Assuming the checkerboard is set up for the start of a game, it will be found that the Black checkers have a choice of seven opening moves. While all are considered drawable, Black's side move of 9–13 forms what is known as the Edinburgh and is considered the weakest. On the other hand, 11–15, known as old faithful, is considered strongest as it permits Black to occupy the centre of the board. Because of its known advantage. 11–15 has been more extensively played and analyzed than any other opening. Many of Black's starting moves have quaint names which are of British origin: 12–16 forms the Dundee; 11–16, the Bristol; 10–15, Kelso; 10–14. Denny. Black's move of 9–14 is referred to as the double corner. The White replies to Black's starting moves also form many additional openings. for example: 11–15, 24–20 is Ayrshire lassie. 11–15, 24–19 is second double corner; 11–15, 23–18 forms the cross; and 11–15, 21–17, 9–13, the switcher. There are additional name formations stemming from other combinations of moves. but because of their profundity many devotees are content to specialize in just a few openings and try to force them upon an opponent. In this respect. 9–14 as Black's opening move became quite popular as it immediately forced the double corner opening and eliminated considerable study of the many formations arising from 11–1j. Obviously, in playing restriction checkers. where the first two or three moves are determined by lot, it is impossible to narrow the scope of the game. Assuming the student first wishes to gain proficiency at checkers before delving into re-

stricted play, he would be interested in finding a safe reply to Black's opening move of 11–1j. There is no better choice for the beginner than to reply **23–18**. forming the cross opening. The name implies a crossing of the board. but it can also define a crossing up of an opponent. Exhibition checkerists use the 23–18 reply to 11–15, there being numerous ways to trap the Black pieces.

The following instructive game will illustrate some of the many pitfalls, and if learned should help win many checker games. The game is listed in columns as is customary in checker books. and the moves continue from the bottom of one column to the top of the next. The alphabetical annotations are also a standard format and should be referred to as the game is reviewed on a numbered checkerboard. As in all games, the opening move is Black.

Cross Opening

11–15	9–14–B	11–15–D	15–24	15–24	24–31
23–18	18– 9	17–13	22– 6	26–22–I	30–26
8–11	5–14	1 –	1–10	13–17–J	31–22
27–23	22–17	13– 9–F	28–19–G	22–13	25– 2
4– 8–A	1j–18–C	6–13	11–15	2– 6	White has
23–19	26–22	25–20	31–26–H	32–27–K	an easy win.

(A) 10–14 is Black's strongest reply here and forces White to exchange by 23–19 or 22–17 to avoid a cramped game.
(B) Again 10–14, exchanging pieces is recommended. However, the tyro invariably plays 9–14.
(C) 11–16 loses by an explosive shot. White moves 31–27 and aiter Black jumps 16–23. captures three Black checkers.
(D) 11–16 again loses for Black at this stage, continue: 22–15, 16–23, 31–27 (star move), then 10–19, 17–10 (star move), and no matter which way Black jumps, White wins neatly. If 6–15. then 27 to 18 to 11 to 4. Again, if Black captures 7–14, White takes 27–18 to 9, 6–13, 24–15 and has a winning game.
(E) 8–11 loses immediately by 24–20, 15–24, 22–8. .
(F) White starts a clever arrangement to lure Black into a thrilling finish.
(G) The White piece on 19 is a decoy inviting 11–15.
(H) An unexpected sacrifice with skullduggery involved.
(I) Black now realizes the strategy of White's sacrifice for the 22–17 move poses a threat of a two-for-one shot, which could give White access to the king row.
(J) Black, assuming he has found an escape, decides to give up a checker. Actually, he has fallen into the trap. His draw move was 14–17.
(K) The unexpected pulverizer, a powerful in-and-out shot that should be studied.
(Considerable play on the cross opening can be found in T. Wiswell and K. Grover, Let's Play Checkers, 1940.)

Having seen some of the opening and mid-game pyrotechnics, it might be interesting to learn how a dramatic situation can arise during the closing moves of a game A fine example is the 14th game played in the 19j1 world's championship go-as-you-please match As the game neared its end. Tom Wiswell had a slight advantage but seemingly not enough to secure a win. It nas at this point that one of the most remarkable problems in checkers arose on the board, enabling Wiswell to score a victory.

Black—Tom Wiswell				White—Millard Hopper	
10–15	29–25	15–24	22–18	10–17	6–10
22–18	8–11	18– 9	12–16	21–14	14–17
15–22	25–22	1– 5	18– 9	31–26	21–14
25–18	6–10	32–28	16–20	14– 9–B	22–17
11–15	23–18	5–14	9– 5	3– 7–C	9– 5
18–11	9–14	28–19	24–27	5– 1–D	2– 6
8–1j	18– 9	7–11	31–24	7–10	10– 1
24–19	5–14	26–22	20–27	1– 6–E	17–10–F
15–24	27–23	11–15	23–18–A	10–14	Black
28–19	11–1j	30–25	27–31	25–21	won
4– 8	22–18	15–24	18–14	26–22	

(A) White appears to be escaping.
(B) Aiter this move, White relaxes under the impression that danger is past.
(C) Black discerns a combination 12 moves ahead and sets a trap.
(D) Into the trap from which there is no escape. 25–21 draws.
(E) White cannot pitch 9–6 and play 1–6 as Black threatens 26–30.
(F) Locked in the double corner. A brilliant finish that depicts the strategy oi checkers.

Efficiency at checkers is based on mathematical exactness and timing. and offers the chance for creative ingenuity. The following game betneen Walter Hellman and Marion Tinsley on this style of play illustrates the perfection of the master's game.

Black—Walter Hellman				White—Marion Tinsley	
9–13	29–25–C	14–23	21–14	11–16	27–23
22–18	5– g	27–18	13–17	19–15	19–26
11–15–A	23–18	3– 7	14– 9	16–19	30–23
18–11	16–20	22–17	7–11	23–16	22–26
8–1j	24–19	9–13	9– 5	12–19	23–19–E
21–17–B	4– 8	17–14	17–22	31–27	eventually
13–22	25–21	6–10	18–14	6– 9	drawn
25–11	10–14	32–27	2– 6	14–10	
7–16	26–22–D	10–17	27–23	9–14	

(A) One of the weakest of the three-move openings.
(B) Strongest. but 24–20 is second best.
(C) 24–19 is equally powerful for White, also 24–20.
(D) An unexpected deviation. The usual continuation is 26–23.
(E) A \veil-played game on a dangerous opening.

End Game Finesse. — It takes two kings to oust and corral one sheltered in the double corner. Therefore. an advantage of one piece is usually enough to win. But two kings caught together in the single corner can be held there by one king. For example: Black kings on **29** and 2**j**, White king on **26**. Blackplaying cannot release himself. One piece can bottle up three in the single corner in a few situations.

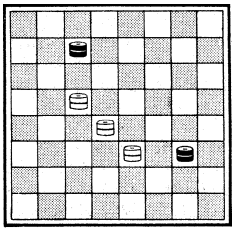

FIG. 3.— WHITE TO PLAY AND WIN

In fig. 3, where White has three kings attempting to overcome a Black king lodged in each double corner. White must compel an exchange to win. Though puzzling to many the solution is easy. A sequence of correct moves is necessary and one wrong play retards the win by several moves. Play from the illustrated setting: 18–1**j. 24–28 23–27.** 6–1. 14–10. 28–32. 27–24. **1–j** (or **32–28. 24–19. 28–32.** 10–6. White wins). 10–6. 5–1. 24–19. White wins. Every move executed by a skillful player is carefully planned with a definite objective; nothing is left to luck.

The Move. — An elemental force in checkers is the move or opposition. Simply stated, it means having the last move to pin down the rival pieces. As the move changes with almost every exchange, it is not significant until the end game when the trading of pieces can be controlled. The move itself is not always vital, although in most cases it is necessary to have the move to win or draw many of the standard positions. A classic example of the power of the move is first position. In fig. **4,** White having the move, it is his turn to play and he proceeds to win as follows: **27–32, 28–24, 23–18** (avoiding the **24–19** swap which would change the move and allow Black to draw), **24–28** (A), 1**8–15, 28–24** (if **12–16,** 15–11, 16–19, **32–27, 28–32,** 27–31, **32–28, 11–16,** R'hite wins), **32–28, 24–27, 15–18,** 12–16, **28–32, 27–24, 18–15,** 24–28, 15–11, **16–19, 32–27. 28–32. 27–31,** 19–23, 11–1**j, 32–28. 15–19,** White wins. (A) **12–16,** 18–15, **16–20** (if 16–19, 32–27, White wins — an example of an exchange that does not alter the move), **15–18,** 24–19, **32–28, 19–16.** 18–23, 16–11, 23–19, 11–8, **28–32.** 11–15, **32–27,** White wins. There are many variations to first positions.

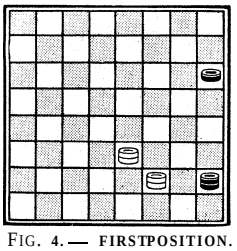

FIG. 4.— FIRSTPOSITION. WHITE TO PLAY AND WIN

Payne's draw has been the means of avoiding defeat in contests among players of various grades. It consists of Black kings on **14** and **1j** and a Black single man on 13, and White kings on 22 and **26**. White has the move and plays **26–23;** continue, **14–17,** 23–26, 15–10, **22–18.** 17–21, **18–22,** 10–14, **26–30,** 21–17, 30–26, drawn. Black also must exercise care or he will lose this tricky position.

VARIATIONS

Spanish Checkers. — (often called pool checkers). In this game the single checkers can jump backward as well as forward, and a king can move over any number of empty squares along the same diagonal, and jump any pieces along the way. If by switching to a crossing diagonal he can capture additional men, he is qualified to do so.

Turkish Checkers. — All **64** squares are used in this game, the men move to the sides or straight forward, but not backward.

There are 16 men to a side, 8 each on the second and third rows to commence. Captures are made either to the side or forward; the maximum take is enforced. Pieces are removed one by one when captured. The king has a sweep of any number of squares.

Losing Checkers.—As the name implies the object of this game (applicable to any game of checkers) is the reverse of the regular play. The first one succeeding in giving away his men or immobilizing them wins.

(T. WL.)

CHEDDAR, a town in the Axbridge rural district of Somerset, Eng.. 20 mi. S.W. of Bristol by road. Pop. (1951) 2,600. To the west lies the low Axe valley, to the east rise immediately the limestone Mendip (*q.v.*) cliffs (600–800 ft.) of the spectacular Cheddar gorge (National Trust), which is a narrow, winding pass, nearly 2 mi. long, with beautiful stalactitic caverns, of which Cox's and Gough's are best known. In Gough's cavern human remains have been found of the Stone Age period as well as tools, animal fossils and a flaked amber. Iron Age and Romano-British remains were also found there. Long hole, Soldier's hole and Chelm's Combe shelter have also yielded a wide variety of remains. Cheddar gorge is also known for the beauty of its precipitous white cliffs with their rare limestone flora. The only known British locality for the Cheddar pink *(Dianthus caesius)* is there and other rarities include blue gromwell, honewort and white rock rose. The manor of Cheddar mas a royal demesne in Saxon times. and the witenagemot mas held there in 966 and 968. It was granted by King John in 1204 to Hugh, archdeacon of Wells. The bishop of Bath and Wells granted it to the king in 1553. It is now owned by the marquess of Bath. The market and stock fairs have long been discontinued, the former in about 1690. The name of Cheddar is given to a well-known species of cheese (*q.v.*), the manufacture of which began about the 16th century; strawberries are plentiful in the neighbourhood.

CHEDUBA ISLAND lies in the Bay of Bengal, 10 mi. from the coast of Arakan, Burma. It forms part of the Kyaukpyu district of Arakan. The island extends about 20 mi. in length from north to south and 17 mi. from east to west. and its area of 220 sq.mi. supports a population of 46.723. The channel between the island and the mainland is navigable for boats. Cheduba mas a stopping place on the historically important coastal trade route from Bengal. India, by way of Akyab and Pegu to lower Burma and Indonesia. It was along this route that civilization spread from India to Burma in the early years of the Christian era. Buddhism arrived later by the same way, as did also the earliest contacts with the East India company. Small craft still call at the island on their way from Chittagong, Pak., and Akyab to Rangoon. Slight volcanic activity is shown by the presence of mud cones emitting steam and sulfurous fumes. There are oil and gas seepages but extensive exploration has failed to locate a field of economic importance.

(L. D. S.)

CHEESE is the food made by coagulating milk. removing the whey and preserving the curd. Milk is coagulated by the enzyme rennin or by an acid, or both, acting upon casein, the chief protein of milk.

Coagulation of milk is the first essential step in converting milk into cheese. The rennin used for this purpose is obtained in a salt-brine extract from the fourth stomach of young, preferably milk-fed calves; this solution is called "rennet extract" or "rennet." Rennin causes casein particles to coalesce in the presence of soluble calcium salts of milk and to form curd. The acid used to coagulate milk is developed by microorganisms that convert lactose (milk sugar) into lactic acid. When enough acid develops in the milk, a soft gel (the curd) is formed by the particles of casein made insoluble by the acid.

Milk at the moment of coagulation contains all of the milk constituents, including most of the fat, casein and other water-insoluble substances. The curd is cut or broken to release the whey, or waterlike fraction, which contains the water-soluble constituents. The curd always retains a portion of the whey.

TECHNOLOGY OF CHEESE MANUFACTURE

Milk Sources.—Hundreds of varieties of cheese are made from milk of the cow, ewe or goat, and occasionally from water buffalo, mare, llama or yak. This is accomplished by variations of treatments of milk, curd and cheese.

The milk itself is varied by choosing it from certain animals, or by adjusting its fat content. Biological agents in the milk are controlled by heating or pasteurizing it, and by adding enzymes or cultures of bacteria. molds or yeasts. Milk is clarified to control eye (hole) formation in Swiss, or it is homogenized to make smaller fat globules for desired curd properties or to hasten actions of enzymes that produce flavour.

Handling the Curd.—Curd formation is varied by changing temperature. time and acidity for coagulation and by altering amounts and proportions of rennet and acid.

Curd is manipulated differently for each variety to control the speed and extent of removing the whey. This is done through cutting, stirring, heating. removing free whey, pressing and salting.

Ripening and Curing.—The series of biological and chemical processes that begin in the newly made curd and continue more or less rapidly until the cheese is eaten are known as "ripening" or "curing." Before cheese is ripened it is said to be "fresh" or "green"; after ripening it is "cured," "aged" or "ripened."

When cheese ripens it undergoes profound physical, biological and chemical changes. These changes are affected by such factors as moisture, temperature and acidity. These changes alter the elasticity, plasticity, solubility, moisture, freezing point and density as nell as the flavour of the product. The nature of the chemical changes can be classified broadly as the breakdown of fats to fatty acids, proteins to amino acids and lactose (milk sugar) to such products as lactic, acetic and propionic acids, diacetyl, and carbon dioxide. The flavourful products of ripening include volatile fatty acids, ketones, esters. alcohols, amino acids, ammonia, hydrogen sulfide and many others.

Food Values.—Cheese making reduces ten volumes of milk to about one volume of cheese. Whole-milk cheeses such as Cheddar and other common hard varieties contain approximately 38% moisture, 33% fat, 24% protein, 1.7% salt and 4.3% other milk solids. Such cheese contains most of the fat, casein. calcium, vitamin A and small amounts of solids from the residual whey. The food energy value of such cheese approximates 1,780 cal. per pound. In converting 100 lb. of milk into cheese approximately 90 lb. of mhey is removed. This mhey contains about 4.9% lactose, 0.9% proteins, 0.45% fat and fatlike substances. 0.6% ash and a small amount of lactic acid. The whey is concentrated or dried and used for human food in processed cheese products, baking, candymaking (confectionery) and other foods. Whey is used for animal feed as a liquid, concentrate or dry powder.

HISTORY

Ancient Origin.––Cheese making probably originated when man first took milk from wild or domesticated animals. Any milk, if not used promptly, sooner or later sours to form acid curd, which naturally releases whey and leaves semisolid curd. This was probably the first form of cheese. Primitive people still use this procedure or mix milk with juices or extracts of certain plants or animal tissues that turn milk into curd and whey. The Old Testament contains several references to curd and cheese; "cheese of the kine" was given to King David, indicating that milk from cows, and presumably other animals, was being used for cheese making before 1100 B.C. The Greeks and Romans also knew and valued cheese before the Christian era. Early people living in northern Europe and England made simple types of curd and cheese, which the Romans observed and used. When methods for cheese making improved, they were kept secret as long as possible; some are still secret today.

Effect of Environment. — Man through the ages has adapted his cheese making to take advantage of his environment. The heating and kneading of curd, as used in making Provolone cheese *(see* below), produces the keeping quality needed to preserve curd under the climatic conditions of Mediterranean countries, where this type of cheese originated. Similarly good keeping properties characterize the Egyptian Domiati, which is made for preservation in salt brine. The loosely knit structure of French Roquefort develops blue mold only in a cool, wet atmosphere such as occurs naturally in the caves of Roquefort. These typical examples suggest why certain cheeses are historically associated with areas where man needed and made the food.

Factory Methods. — Cheese was first made commercially on a small scale as a home or farm enterprise; some is still made that way. The factory system of manufacturing was developed about the middle of the 19th century to improve the uniformity and quality of the product and the efficiency of production and marketing. The first cheese factory is said to have been built in 1851 near Rome, N Y., by Jesse Williams; in England, the first cheese factory was built in 1871 at Longford, Derbyshire. The first factories received the milk of only a few farms. Capacities increased manyfold as transportation facilities, control of milk quality, knowledge of the principles of cheese making and mechanical methods of handling milk and curd improved. In Europe and parts of the U.S., the marketing of cheese developed through cheese fairs or cheese boards in market towns, but these have largely died out as factory production increased. By the early 1960s, complete mechanization of cheese making had been introduced for some varieties. The cheese moves from factories to warehouses, where carefully controlled temperatures and humidities can be provided for the most efficient ripening of cheese from many factories. In the warehouse the product is analyzed, graded and sorted. At the warehouses, factories or special packaging centres the cheese is placed in protective wrappers or other containers before being shipped to stores and consumers.

VARIETLES OF CHEESE

Varieties of cheese can be classified for general consideration according to consistency (soft, semisoft, semihard, hard). methods of manufacturing (acid or rennet curd) and the degree or type of ripening (unripened, mold-ripened, etc.). Brief descriptions of outstanding characteristics of selected varieties are given below for the more important classes.

Blue is a semihard, mold-ripened cheese made in all dairy countries. It is sometimes known as blue-mold or blue-veined cheese. It is made from cows' milk, which may or may not be homogenized.

Spores of *Penicillium roquefortii* are mixed with the milk or the curd. This mold. during three to six months of ripening, grows in small irregular natural openings and machine-made perforations in the cheese: it sporulates to give the typical blue or greenish-blue streaks in the uhite cheese and eventually the characteristic flavour. The cheese is heavily salted. It is sometimes waxed or wrapped during ripening to minimize the gron th of microorganisms on the surface, but usually it is scraped and wrapped in foil for marketing. The odour of the ripened cheese is fragrant and pungent, the taste is salty and tingling and the consistency is crumbly or sliceable and soft to semihard. This cheese contains about 40% moisture and 32% fat. Similar, but not identical, varieties are numerous and include Italian Gorgonzola, English Stilton, French Fromage Bleu, Danish Danablu, the well-known French Roquefort (see *Roquefort,* below) and Nuworld, a "colourless" modification made with the white mutant of *P. roquefortii.*

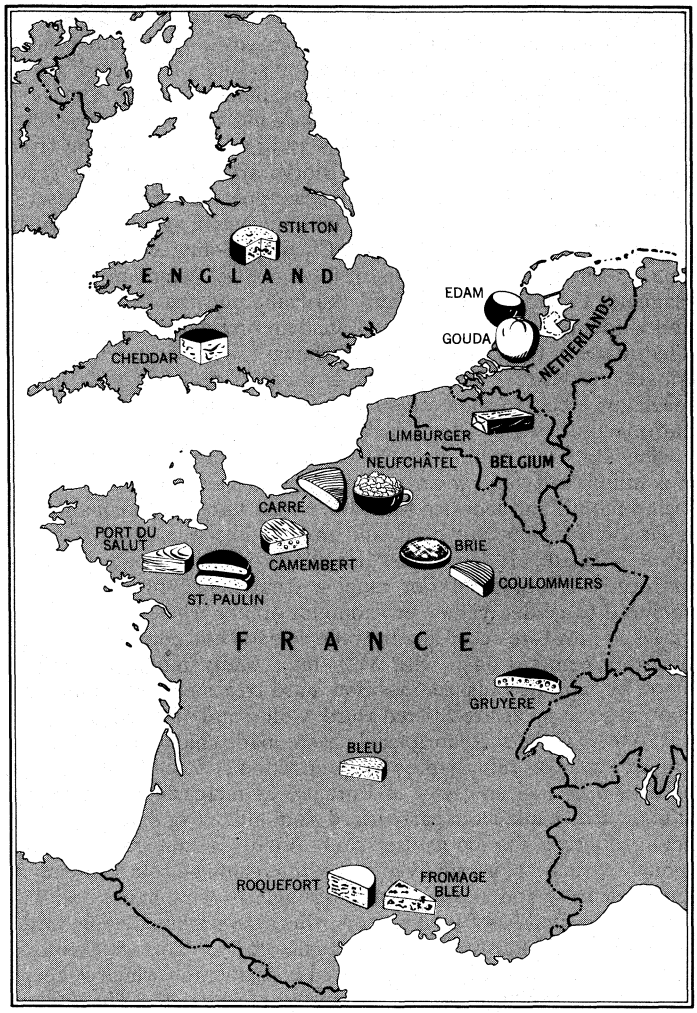

FIG. 1.— CHEESES OF BELGIUM. ENGLAND, FRANCE AND THE NETHERLANDS AND THE AREAS IN WHICH THEY ARE PRODUCED

Brick is a semihard, brick-shaped cheese developed in the U.S. about 1880. It slices easily without crumbling and has small holes of irregular shape. The cheese has a sweetish taste and a faint aroma of Limburger character. This aroma, which diffuses into the cheese from the surface, is developed by microorganisms and yeasts that are encouraged to grow on the surface by washing it occasionally with weak brine, turning, rubbing and holding for two weeks in a wet room at 60° F. The product is ready to use in a few weeks but keeps for months at low temperatures. It contains about 43% moisture and 30% fat. Similar kinds of cheese are Muenster and Tilsiter.

Camembert is a small, mold-ripened cheese made from cows' milk with rennet. It originated about 1791 in France and is now made in many countries. It is ripened with *Penicillium camemberti,* which is mixed with the milk or placed on the surface of the cheese during or after salting. The mold forms a thick, white layer on the surface and causes the cheese to soften from the outside to the centre. The fresh curd is acid to taste and white in colour after salting. The ripened product is yellowish in colour and waxy, creamy or almost fluid in consistency, depending upon the extent of ripening. The flavour varies from mild to strong as the cheese ripens. It contains about 52% moisture and 26% fat. Similar varieties are Brie and Coulommiers.

Cheddar cheese is one of the most widely knomn and used varieties. It is a hard cheese made from cows' milk with rennet, moderate acid development, heating and salting of the curd before pressing. It is made in cylindrical and block forms, and in various sizes, *e.g.*, 5-lb. midgets, 12-lb. long horns, 20-lb. daisies, 20-, 40- or 60-lb. blocks. 75-lb. cheddars and mammoths ranging from 300 lb. up to 3 tons and more. Blocks are often cut into small pieces that are sealed in protective wrappers for retail sales.

This cheese originated several hundred years ago (probably in or before the sixteenth century) in Cheddar, Somerset, Eng. Early English settlers made it in America. It is most commonly made in England, Canada, New Zealand, Australia and the United States, and is identified accordingly as Canadian or English Cheddar, etc. That made in the United States is knomn as American Cheddar or American cheese. The product is usually identified with brand marks or labels to show its quality (state brand. U.S. no. 1, etc.) and place of origin (New York, Wisconsin, etc.).

Cheddar has a mild aroma that becomes more intense with age; it is mildly salty and when fully ripened gives a tingling sensation in the mouth and leaves a taste like sweet nuts. The consistency is elastic, firm but not hard, and smooth like wax or cold butter when crushed. It has a few irregularly shaped openings and a uniformly coloured interior ranging from light amber when uncoloured to golden yellow or cadmium orange when coloured. It varies in moisture according to trade demand and country of origin but approximates 36% with 34% fat. Many modifications are made by varying milk composition, curd treatments and moisture content; examples are Stirred Curd, Colby and Washed Curd.

Cottage is the soft, unripened cheese made chiefly in the United States. where its rapidly growing production is second only to that of Cheddar; its popularity in Europe was increasing in the early 1960s. It is made from pasteurized skim milk coagulated by lactic acid-producing microorganisms and usually minute amounts of rennet extract. It is usually mixed with cream and sold as creamed cottage cheese and as such contains about 79% moisture and 4% fat. One pound has a food energy value of approximately 640 cal., compared nith 470 for the uncreamed variety. Cottage cheese is commonly packaged in closed. waxed containers in uhich it keeps fresh for a week or more nhen properly refrigerated. The flavour is mildly acid, the consistency is soft enough for the cheese to be served with a spoon, the appearance is granular or glossy (when creamed) and the colour is white or creamlike. Similar varieties are Dutch. Pot. Quarg and Schmierkase.

Cream cheese is the soft. unripened product made from pasteurized homogenized mixtures of milk and cream that are coagulated nith lactic acid-producing cultures and a little rennet. The curd is drained in muslin bags and pressed or it is centrifuged to remove nhey. The fresh curd may be reheated and homogenized with a stabilizer, such as gelatin or agar, to give smoothness and to improve the keeping quality. The flavour is mildly acid. the consistency is smooth and the colour is white. It is usually sold in aluminum foil or glass containers, in nhich it keeps fresh for three weeks or more nhen refrigerated. It contains about 34% fat and 53% moisture. In England. double cream cheese has about 60% fat and is made from cream containing 48% fat; single cream cheese in England has about 45% fat and is made from renneted, pasteurized cream containing 18% fat. Similar varieties are Neufchâtel (loner fat). Bakers' cheese (no fat), Carré and Fromage à la Crème.

Edam is a hard, ripened, ball-shaped cheese made from cows' milk. It originated in and is still manufactured in the Netherlands. The curd is formed with rennet and finally pressed, usually in ball-shaped forms, to remove the whey It is salted and held briefly in the factory before being sold at weighing houses in such colourful and ancient markets as Alkmaar, Neth., and then ripened further in a warehouse. There it is graded, smoothed (if necessary) in a turning machine, coloured red, oiled and wrapped for distribution. The surface may be protected by immersing the cheese in red paraffin wax or sealing it in tin cans. It is a sweet-curd cheese with a mild aroma and a slightly salty, tangy taste when ripened; its consistency is firm. and its interior is uniformly coloured yellow with few if any holes. The Netherlands cheese commonly has about 38% moisture and 32% fat. It is often made with less fat and sold under government label for use in warm countries. In the United States a similar cheese with the same name is made. but it usually is loaf shaped.

Gorgonzola is the semihard, blue-molcl-ripened cheese made from cows' milk. It is named after the village of Gorgonzola near Milan, Italy, and is the Italian form of Blue cheese, which it resembles closely in quality and composition. This cheese is usually made in cylindrical form about 12 in. in diameter and 6 in. high.

Gouda is a semihard or hard cheese made from corns' milk. It is produced in the Netherlands, where it originated. and in many other dairy countries. It is a sweet-curd cheese made much like Edam but with more fat and in a different shape. It is commonly made in wheels 12 in. in diameter by 4 in. thick. A smaller size made like a flattened ball 4 in. in diameter and 2 in. thick is called Baby Gouda and is commonly sold in a heavy, red wax coating under a transparent wrapper. The flavour resembles that of Edam; the consistency is semihard, and when sliced the cheese often shows round as well as irregularly shaped openings and a uniform, yellowish colour. Moisture approximates 42%, and fat 28%.

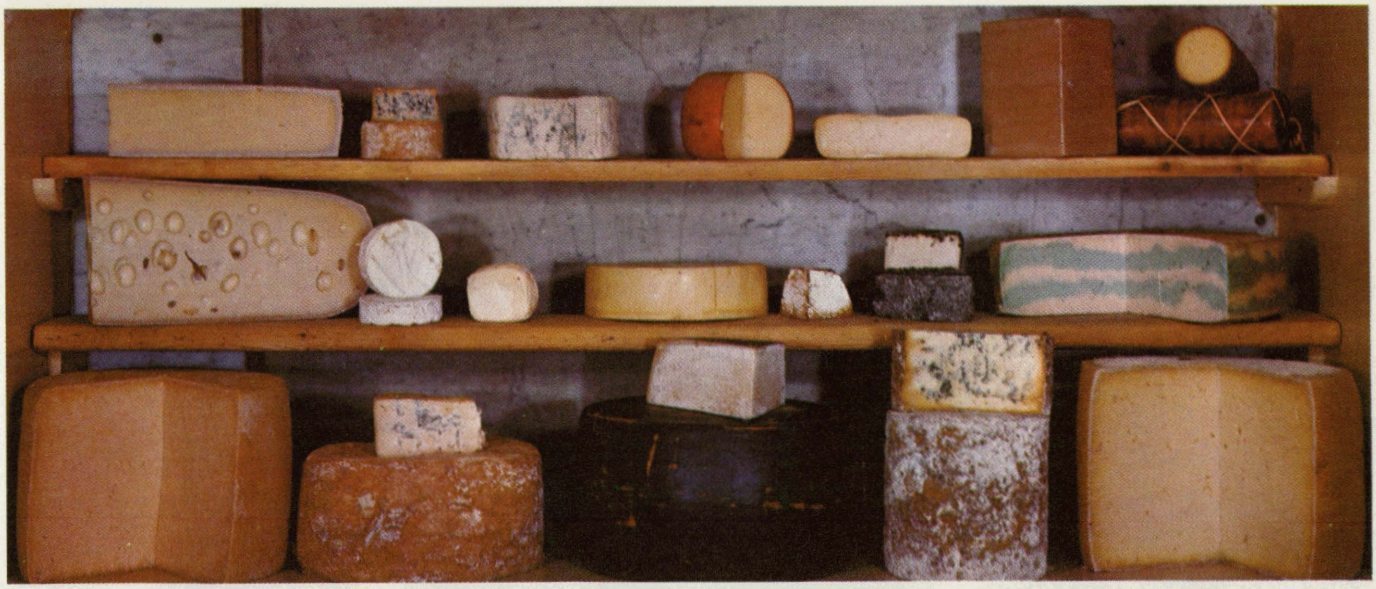
Limburger is a soft, ripened cheese made with rennet from cows' milk. It originated in Belgium and was named for the town of Limburg, where it was first marketed. It is popular in Germany. Austria and the United States. Its strong flavour and soft consistency are derived largely from the effects of extensive protein hydrolysis induced by the growth of yeasts and other microorganisms on the surface of the cheese. It is made and ripened much like Brick cheese but in smaller sizes ranging from 4 to 32 oz. It contains about 47% moisture and 26% fat. Similar cheeses are German Backstein, Belgium Romadur and French Void.

Mozzarella is the soft and usually unripened Italian cheese made from cows' milk by the *pasta filata* method (see *Provolone,* below). It is shaped by hand or machine into balls (approximately 12 oz.) and usually packaged in sealed wrappers for merchandising. It is bland in flavour: soft in consistency and light in colour. Moisture approximates 46% and fat 23%. It became an important product in the United States after World War II because it mas used in making pizza. Scamorze is a similar Italian cheese.

Parmesan is the name commonly used outside Italy for the cheese that has been made there for centuries under the local name of Grana; the Italian name refers to its granular appearance when broken. The cheese is low in moisture and ripens in one or two years in cool, well-ventilated storage. The surface is protected by occasionally rubbing it with vegetable oil. The ripened cheese has a pleasing, sharp aroma and a salty, meaty taste. It is difficult to cut and is usually grated and used for flavouring foods. It contains about 29% moisture and 28% fat. The cheese is frequently grated, further dried and packaged in small shaker-type containers for home use. Similar varieties are Parmigiano, Reggiano, Lodigiano and Emiliano.

Port du Salut is a semisoft, ripened cheese made from cows' milk. It was first developed by Trappist monks about 1865 at the abbey at Port du Salut near Laval, France. Its production spread to other abbeys of the order in Europe, Canada (at Oka. Que.) and the United States (Trappist, Ky.). The cheese is cylindrical in shape, approximately 6 in. in diameter and 2½ in. high. It is a sweet-curd cheese that is ripened in a cool, moist room for about six weeks while it is turned, rubbed and washed occasionally to control mold growth and other surface changes. It is usually waxed or sealed in tight wrappers and widely distributed in the United States. Its flavour is sweet, mild and very slightly salty. Its consistency is soft and very smooth when crushed. It slices easily, and the cut surface shows a slightly glossy appearance with a few small: irregularly shaped holes. The colour is a rich, creamy yellow. The cheese ripens in 8 to 12 weeks and keeps well for several months at 45° F. or lower. It contains about 43% moisture and 29% fat. Similar varieties are Trappist, St. Paulin and Oka.

Processed cheese is made by grinding and melting together different lots of cheese of the same or different varieties. Most



Popular cheeses *of* **Europe**
Top row: **Gruyère, Bresse** bleu, Roquefort, Edam, **Belpaese, Gjestost,** Hungarian Trappist

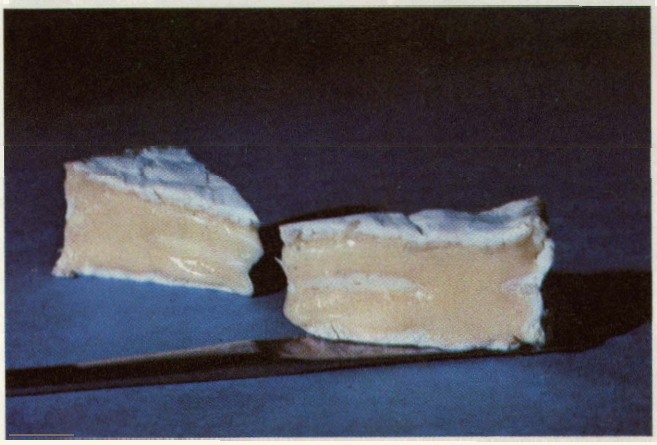
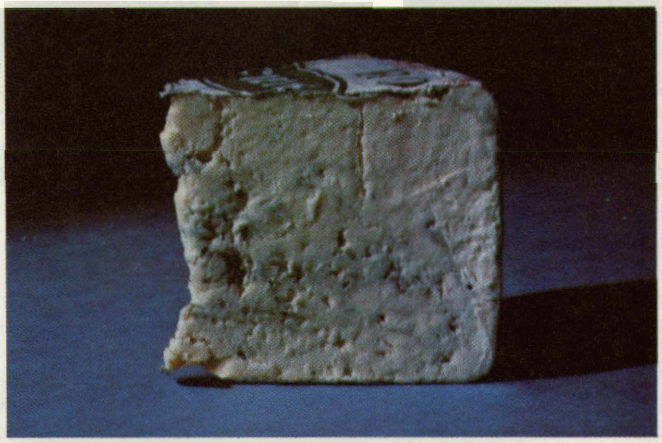
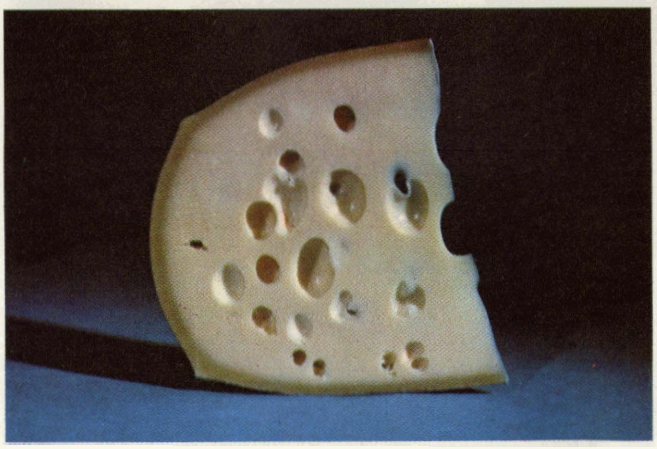
Bottom row: Cheshire, **Gorgonzola,** Parmesan, **Stilton,** Cheddar



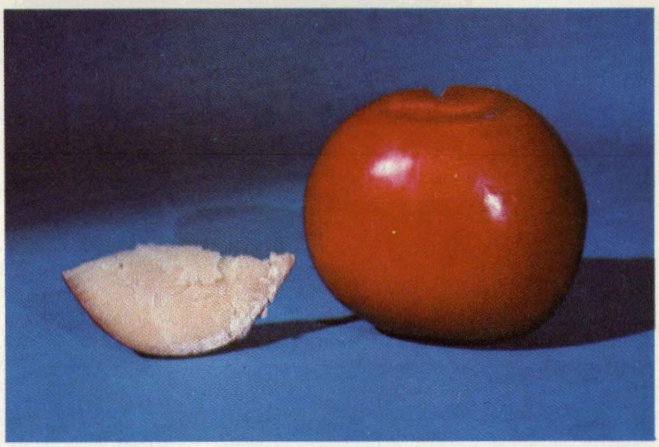
Camembert, soft cheese made from cows' milk. The creamy texture is **produced** by the action of an outer coating of ***Penicillium camemberti*** mold which prevents the cheese from hardening **as it** ripens



Roquefort, semisoft **cheese** made from ewes' **milk.** The **sporulation** of ***P. roquefortii*** mold **during** the ripening **period causes** the greenish-blue marbling **characteristic** of this **cheese**



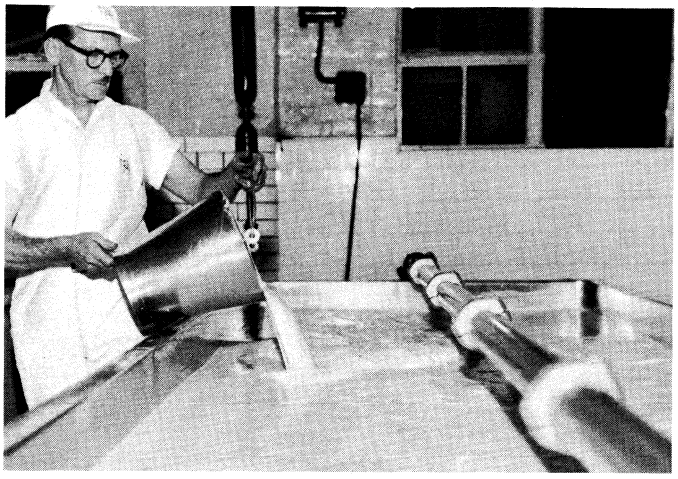
Swiss, hard cheese made from cows' milk. As the cheese ripens, **it** is kept at **72°** F. in order to produce carbon dioxide which, with the help of added bacterial cultures, creates the holes, or "eyes," **in** the cheese



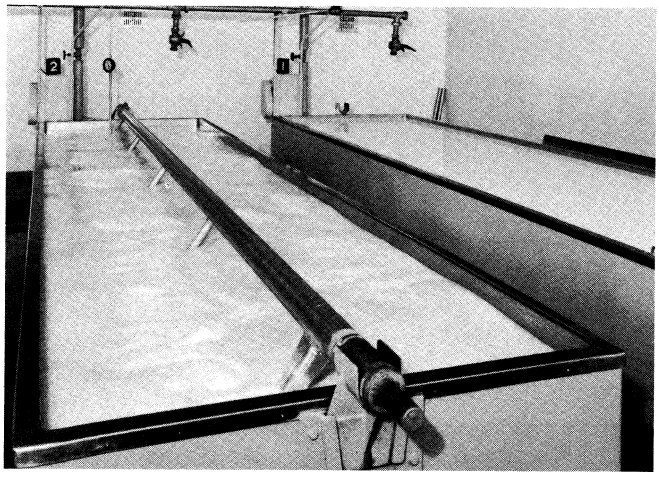
Edam, hard cheese made from cows' milk. Its familiar red coating is applied after ripening by dipping the pressed cheese into red-coloured paraffin

EUROPEAN CHEESES

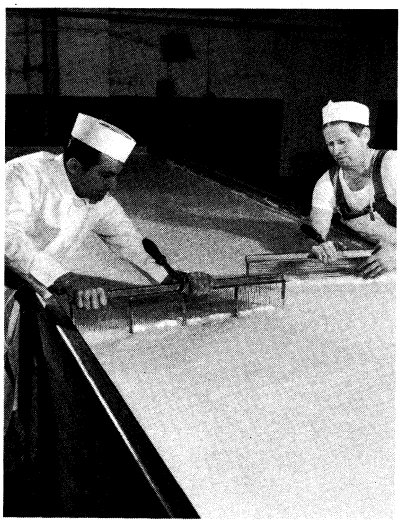
CHEESE



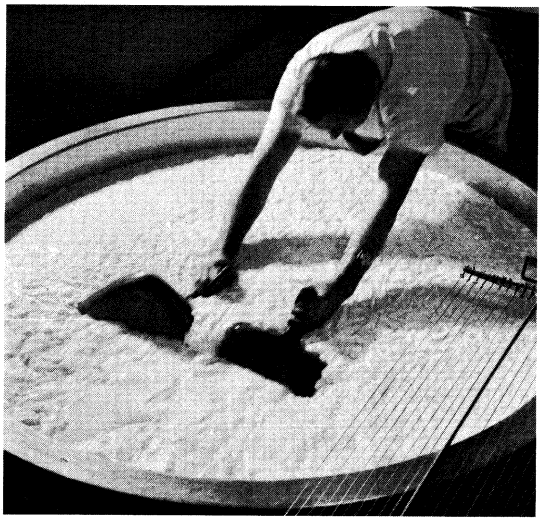
Rennet extract, the curdling agent used in cheese making, being added to a vat of warm milk. The action of the enzymes in the rennet causes the milk proteins to coagulate, producing a junketlike curd in the milk



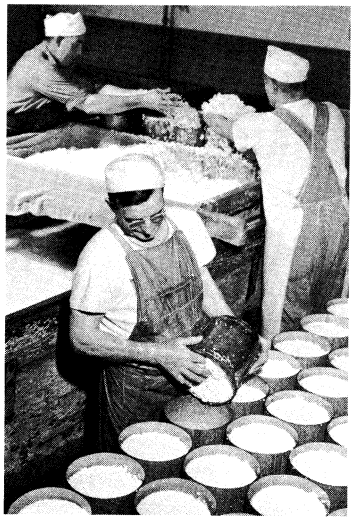
Automatic paddles stirring the milk-rennet mixture in order to keep the rennet evenly distributed throughout the milk and to prevent it from settling on the bottom before the enzymes begin to act on the milk proteins



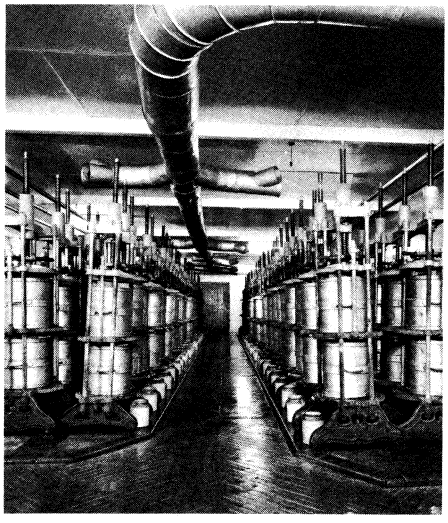
Cutting the curd with cheese harps into small cubes to facilitate draining off the whey, the liquid residue from the coagulated milk



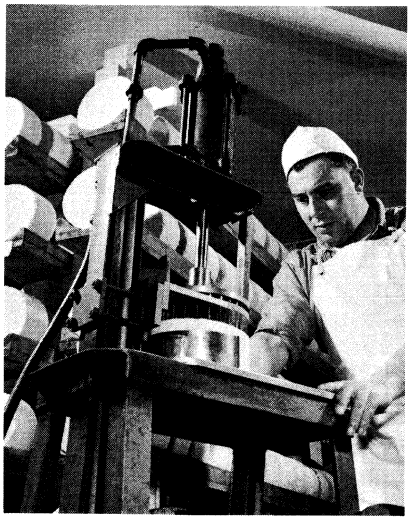
Swiss cheese curd, after cutting, being broken into smaller particles before draining. The curd is lifted from the whey in one large mass and pressed into a wheel



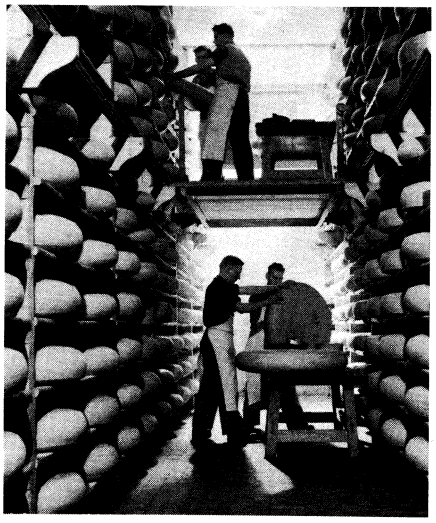
Drained curd being placed into hoops for pressing. In the back curd is being tossed in the air to further draining



Press room where the hoops containing cheese curd are subjected to high pressure to expel excess moisture and to form an outside coating



Additional holes being punched into blue cheese. During the ripening period mold grows in these and the natural openings in the cheese loaves



Wheels of Swiss cheese being stored in curing cellars where they are kept at controlled temperatures until they ripen

STAGES IN THE CHEESE-MAKING PROCESS

varieties of cheese, when sufficiently ripened, may be used for making pasteurized process cheese, cheese foods and cheese spreads. Blending and heating the natural cheese produce uniform quality and keeping properties but reduce flavour intensity. The hot. melted cheese is poured into lined boxes or other containers and sealed to protect it. Small amounts of water. cream, seasoning. colouring, acid and emulsifying salts may be incorporated. Composition approximates that of the original cheese. Proceised cheese was developed commercially after 1912, and the large volume produced has had a generally stimulating, competitive effect on production, packaging and merchandising of natural cheese.

Cheese foods and spreads may contain the above additives and also milk, skim milk, whey or their concentrate?. Cheese foods contain more moisture than processed cheese; cheese spreads contain more moisture and less fat than either of the others. Fruits, vegetables or meats are sometimes added to these blends.

Provolone is the semihard, pear-shaped. Italian cheese weighing about 10 lb. that is made from cows' milk by the *pasta filata* method. Smaller styles made from identical curd are Provolette and Provoloncini. When made in a sausage shape. it is known as Salame; in the shape of a small sausage it is called Salamini. This cheese is unique because when the necessary acidity has developed during curd making the curd is made plastic by heating and kneading it in hot water until it can be stretched into ropelike strands, or threads (hence *pasta filata*). These strands are gathered into a ball and worked and molded by hand to make a crevice-free cheese of the desired shape and size. The shaped cheese is chilled in cold water, salted in brine and smoked. It ripens in three to six months. The cheese is mild to sharp and smoky in flavour. It slices without crumbling, is smooth when crushed, has few if any openings and is uniformly light in colour. It contains about 40% moisture and 28% fat. Similar cheeses are Italian Caciocavallo, Rumanian Kaskaval (made from ewes' milk) and Italian Mozzarella.

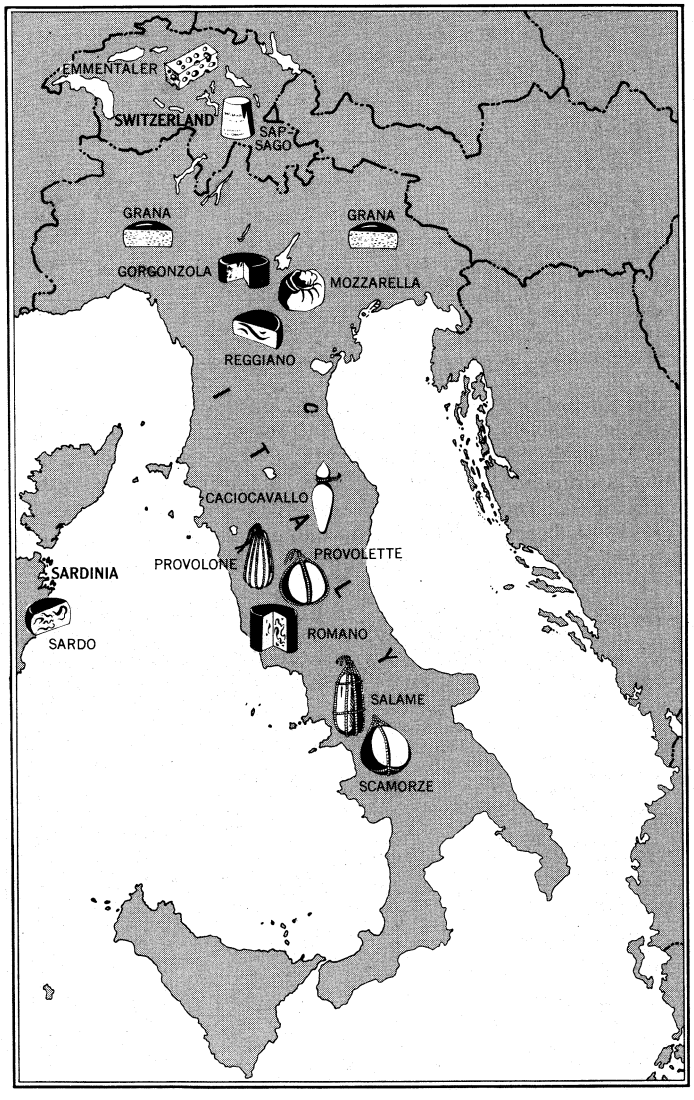


FIG. 2.— CHEESESOF ITALY AND SWITZERLAND AND THE AREAS IN WHICH THEY ARE PRODUCED

Romano is a hard, ripened Italian cheese of the Grana (Parmesan) type. It is commonly made from cows' milk and therefore identified as Romano Vacchino. Large amounts are made in Italy, Sardinia and the United States. It is made somewhat like Parmesan except that mildly lipolytic enzymes are added to the milk in paste or extract form to give the characteristic piquant flavour. The pressed curd is heavily salted; this accounts for the slight saltiness of the flavour. The cheese is ripened at about 55° F., turned, scraped and rubbed with olive oil to protect the surfaces. It may be used as table cheese after five months' ripening and, after further aging, for grating purposes. Its consistency is hard, granular and brittle when thinly sliced. It has few, if any, small irregular holes, and the colour is nhite to very pale yellow. Romano contains about 32% moisture, 27% fat and 6% salt. Similar varieties are Pecorino Romano (from ewes' milk), Caprino Romano (from goats' milk), Sardo and Romanello (little Romano).

Roquefort is the semisoft cheese that is made from ewes' milk and ripened for three to five months with the blue mold *Penicillium roquefortii* in caves in or near Roquefort, France. Its manufacture there dates back at least to the beginning of the 18th century. It is characterized by a rather sharp, piquant flavour and a white curd mottled by blue veins of mold. The curd was formerly made by shepherds, but now the milk is collected at factories and made into curd that is taken to the caves. The name "Roquefort" is trade-marked. (See *Blue* above.)

Sapsago is a hard cheese made from skim milk in the canton of Glarus, Switz., and in Germany. It is known also as Schabzieger, Griinerkase and Glarnerkase and is said to have been made in the 13th century. The cheese is prepared by heating partially soured skim milk and precipitating the curd by adding sour whey. The drained curd is salted and heavily pressed. It is ripened under light pressure for five weeks, then is ground, heavily salted, thoroughly mixed with dry, powdered leaves of the aromatic clover *Melilotus coerulea* and pressed into truncated cones 4 in. high for further curing of five months. It has a sharp, aromatic and pungent flavour, is so hard it must be grated for use and its colour is pale green. It contains 38% moisture or less, about 5% fat and 5% salt.

Stilton is made in Leicestershire and Derbyshire. Eng., and a limited quantity is exported. The curd is drained slonly in hoops and is not pressed. Blue veins develop from introduction of the mold *Penicillium roquefortii.* The flavour is clean and mild, the texture open and flaky and the body firm and velvety. White Stilton, highly acid and free from mold, also is made.

Swiss is a hard cheese made from cows' milk by a process that originated in the Emme river valley (Emmental) in the canton of Bern, Switz. It is one of the world's most famous varieties. The essential process is followed in the Cnited States and most other dairy countries. Because of its large wheels (about 36 in. diameter by 6 in. thick) and its popular appeal, it is often called "king of cheeses." Sniss curd is formed by rennet; after the usual cutting, stirring and heating to about 125° F., all the curd from 2,000 lb. of milk is lifted from the mhey in one mass in a fine-mesh net and pressed into the typical wheel. It can be shaped in blocks, salted and then wrapped in film to prevent drying. The cheese is salted in strong brine. Holding the cheese at 72° F. stimulates the production of carbon dioxide, nhich forms the characteristic glossy holes, or "eyes," in six to eight weeks. Complete ripening takes three to six months. Pure cultures of *Streptococcus thermophilus, Lactobacillus bulgaricus* and *Propionibacterium shermanii* are used to control development of acid, eyes and flavour. This sweet-curd cheese has a pungent, sweetish odour and a taste that is faintly salty when fresh and pleasingly sharp

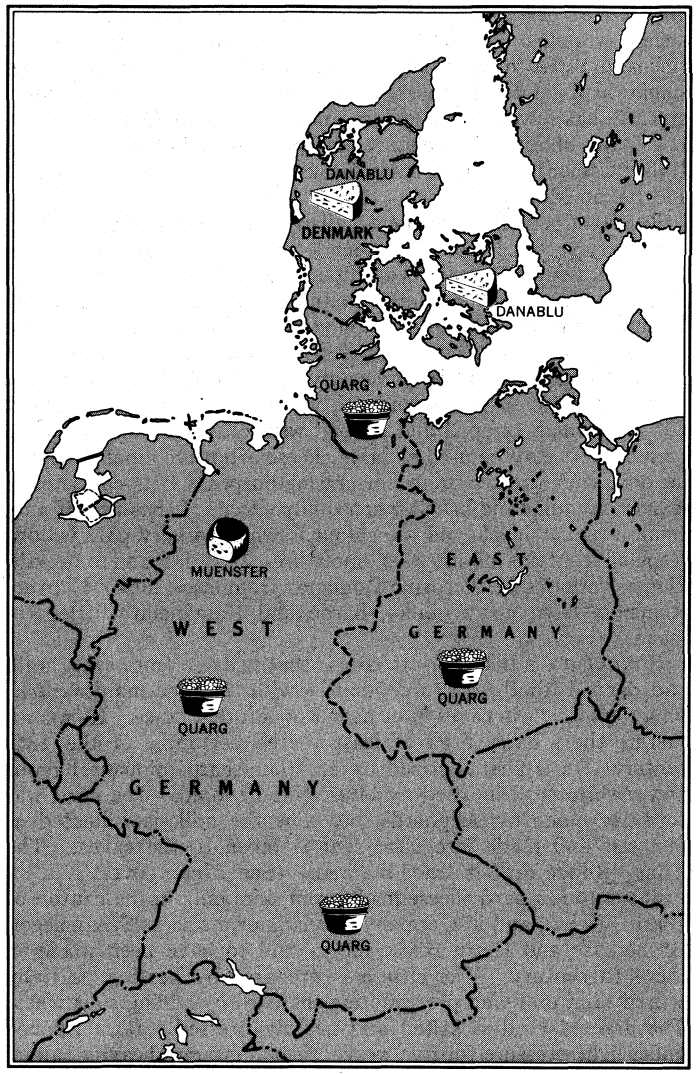

FIG. 3.— CHEESESOF DENMARK AND GERMANY AND THE AREAS IN WHICH THEY ARE PRODUCED

when fully ripened. The consistency is firm and elastic, and the cheese is easy to slice; the interior is a uniform light yellow in colour with holes about § in. in diameter spaced 2 or 3 in. apart. It has approximately 39% moisture and 28% fat. Swiss made in the Emme valley (Emmental) is known as Eminentaler; exports from Switzerland are labeled "Switzerland cheese." A variety similar to Emmentaler is made in France under the name of Gruyère.

PRODUCTION, TRADE AND CONSUMPTION

Many factors affect the production of cheese; an important one is the skill of the men and women who make it. Other basic influences are the number and productivity of cows. Cheese has always been made after other, and usually more profitable, outlets for milk have been satisfied. The milk proteins, fat and some of the other milk solids are concentrated and preserved when surplus milk is made into cheese. Production is also affected by the price of cheese. Prices vary on unregulated markets according to supply and demand. Demand is affected by consumer reactions to quality, convenience and advertising, as well as food value cost and palatability of competitive food products, especially meat. Wholesale markets exist in many parts of the world including England, Canada and the United States. Weekly transactions on the Wisconsin cheese exchange at Green Bay, Wis., for example, reflect all of these influences to some extent.

TABLE I.—*Approximate Percentages of Total World Production of All Cheese by Certain Countries*

Country	Percentage of world production*	Country	Percentage of world production*
Argentina	3.9	New Zealand	3.8
Australia	1.8	Norway	1.1
Austria	.8	Peru	.3
Belgium	.5	Portugal	.3
Brazil	1.2	South Africa	.4
Canada	1.7	Spain	.7
Denmark	2.9	Sweden	2.0

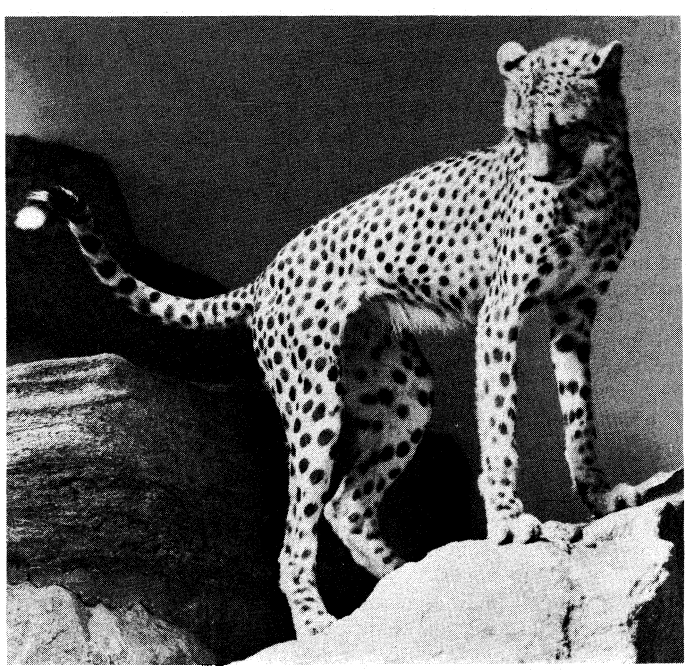
CHEETAH (Acinonyx *jubatus*), a slender, long-legged carnivore of the family Felidae that lives on open plains from southern Africa to India. It reaches a length of *3* to *4* ft. with the tail accounting for another *23* ft.; it stands, on the average, $2\frac{1}{2}$ ft. at the shoulder and weighs about *100* lb. The colour of the coarse, crisp fur is sandy yellow, white below, with numerous small black spots and a black streak down the face from the corner of the eye. A variety with the spots partly confluent forming stripes and blotches has been erroneously separated as the "king cheetah." The litter is said to number from two to four. Cheetahs hunt alone or in small parties, stalking their prey, usually the smaller antelopes, and then running it down in a final rapid sprint; they are probably the fastest animals over a short distance and can attain *65* to *70* m.p.h. The cheetah has long been domesticated



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

CHEETA (ACINONYX JUBATUS)

in Asia and used for coursing game; it is not, however, bred in captivity but captured when adult in nooses set around the trees used for claw sharpening. After a period of severe discipline the newly caught cheetah becomes docile and obedient to its trainer. It is taken into the field hooded and chained in a low cart without sides; when the game is about *200* yd. distant the cheetah is unleashed. The cheetah differs from other cats in that it lacks sheaths for retracting its claws.

CHEFOO (YEN-T'AI), former treaty port of Shantung province, on the rocky north coast of the Shantung peninsula, People's Republic of China. The port, officially Ten-t'ai, is one of the few deepwater anchorages along the coast free from silting and sheltered by outlying islands that have been linked together by breakwaters to form a well-protected harbour. Pop. *(1953) 116,000.* The port was opened to foreign trade in *1863* following its occupation by French and British naval units three years before. Western traders soon began the export of strawbraid for hats, pongee silk cloth and tussore silk yarn, and ladies' hair nets; European missionaries trained women and girls in lace-making and needlework which became the basis of a large export industry. The peninsula is famous for apples, pears, peanuts and grapes that ripen well during the long, dry summer. Missionaries improved the local crops and helped establish a grape wine industry that still flourishes. For many years the port was a well-known summer resort for U.S. naval personnel and foreign tourists. Chefoo has had active trade with Antung across the Gulf of Chihli and with Japan. Until *1956* transportation with the hinterland was limited to mule trains and carts and eventually motor trucks. In that year a branch of the Tsingtao-Tsinan railway was opened from Lantsun, *114* mi. S.W., presumably to supply a port of naval significance and to bring farm, fish and salt produce of the area into the interior. (TE. H.)

CHEJU-DO (QUELPART or CHEJU ISLAND; Japanese, SAISYUTO), an island *60* mi. S.W. of Korea, once used as a place of political exile. It has an area of *718* sq.mi. and measures *40* mi. from east to west and *17* mi. from north to south. It rises gradually from the seaboard, is heavily wooded and is cleared for cultivation to a height of *2,000* ft. The island is composed of a core of volcanic material which rises symmetrically to the crest of Halla-san, *6,450* ft. in height. There are several crateriform hills, out of which volcanic material has flowed. The soil along the coastal areas is finely disintegrated lava. The population *(1960)* of *281,720* was Korean by race and language. Since this population included many refugees driven to the island by the Korean War (1950–53), there were more women than men.

The valleys and slopes are carefully cultivated in fields divided by stone walls. The islanders manufacture, for export and local use, fine bamboo hats and mats, and wooden combs. For fishing the natives use double-decked raft boats, similar to those of southern Formosa. A valuable product of Cheju-do is a species of clam, the shell of which furnishes a specially iridescent mother-of-pearl that the natives sell to the Japanese for inlaying lacquer. Seaweed and shellfish are also obtained by organizations of skilled women divers. The upland areas were formerly used for pasturing ponies whose hair was used for weaving old-style Korean hats, but this industry has declined in favour of cattle raising.

Cheju (pop. [1960] *68,090)* is the principal city and the capital of the province. The island was formerly a part of South Cholla (Chel-la) province but in *1948* was given independent status. It is divided into counties and has *90* villages and towns.

(S. McC.)

CHEKE, SIR JOHN *(1514–1557)*, English classical scholar who played a prominent part in the revival of Greek learning in England. was born at Cambridge on June *16. 1514.* There, at St. John's college, where he became a fellow in *1529,* he adopted the principles of the Reformation. On the foundation of the regius professorships in *1540,* he was elected to the chair of Greek, and with Sir Thomas Smith, who shares with him the credit for the establishment of Greek studies at Cambridge, he introduced the Erasmian pronunciation of Greek there. Although at first it was strenuously opposed, Cheke ultimately triumphed. On July *10. 1544,* he was chosen tutor to Prince Edward, remaining after the prince became king as Edward VI. Cheke was member for Bletchingly in the parliaments of *1547* and *1552–53.* He was made provost of King's college, Cambridge, in *1548* and was one of those appointed to draw up a body of laws for the governance of the church. He was knighted in *1552* and became a secretary of state and privy councilor in *1553,* keeping his offices during Lady Jane Grey's nine-day reign. In consequence Queen Mary imprisoned him in July *1553* and confiscated his wealth. Released in Sept. *1554* and allowed to travel abroad, he finally settled at Strasbourg, teaching Greek for a living. In *1556,* on his return from a visit to Brussels to see his wife, he was treacherously seized by

order of Philip II of Spain, hurried over to England and again imprisoned in the Tower of London. Cheke, terrified by the threat of the stake, gave way and was received into the Roman Catholic Church after being cruelly forced to make two public recantations. He died in London on Sept. 13, 1557.

Cheke was the author of several works of theology and classical scholarship. He also translated Greek authors and lectured admirably on Demosthenes. Among his most interesting works are *The Hurt of Sedition* (1549), written on the occasion of Ket's rebellion, and *The Gospel According to St. Matthew . . . Translated (c.* 1550; ed. by James Goodwin, 1843).

See John Strype, *The Life of the Learned Sir John Cheke (1705).*

CHEKHOV, ANTON PAVLOVICH (1860–1904), internationally famous Russian playwright and short-story writer, was born at Taganrog on Jan. 17 (old style; Jan. 29, new style), 1860. But for the fact that his grandfather had saved up enough money to buy his freedom from his master, a rich landowner, Chekhov would have been born a serf. His father, Pavel, owned a small grocery shop in Taganrog, where as a small boy Chekhov was left to serve the customers. With his two elder brothers Chekhov received his education first at a Greek preparatory school and then at the Taganrog secondary school. During his last three years at school Chekhov had to fend for himself, for his father, being more interested in local politics and the church choir than in keeping an eye on his business, had gone bankrupt and had to flee from his creditors to Moscow with his family. It was during these three years that Chekhov acquired his strong sense of independence and responsibility which enabled him to become the sole provider of his family in Moscow when he arrived there in 1879 to study medicine on a scholarship from the Taganrog municipality. He did this by writing humorous stories for the St. Petersburg and Moscow popular magazines.

Chekhov's real literary career, however, began a year after he had taken his medical degree with his first visit to St. Petersburg in Dec. 1885. There to his astonishment he discovered that he had become a famous writer and was horrified at the happy-go-lucky way in which he had been writing his stories. A letter he received from the veteran novelist Dmitri Grigorovich a short time after his return to Moscow, hailing him as a writer of genius and cautioning him against frittering away his talent on trifles, decided Chekhov to devote himself entirely to literature. It was through Grigorovich that Chekhov obtained an introduction to the influential newspaper publisher Aleksei S. Suvorin, whose close friend he became and in whose daily, *Novoe Vremya,* some of his most famous stories were published.

At the age of 23 Chekhov contracted tuberculosis, a disease to which he was predisposed by heredity (many of his relations, including his second brother, died of it) and which he seems to have been successful in concealing from his family for 14 years. He, too, died of it, at the early age of 44.

Chekhov's fame as a playwright began with the production of his full-length play *Ivanov* in 1887. Between 1886 and 1890 Chekhov fell under the spell of Tolstoi's teachings, though he did not himself meet Tolstoi till 1895. It was chiefly as a result of his Tolstoian convictions that he made his arduous journey to the island of Sakhalin to study the appalling conditions under which the convicts were forced to live, for which he declared every man in Russia ought to feel responsible. He left for Sakhalin in 1890 and published his impressions of the journey in 1894 under the title *The Island Sakhalin.* On his return he went for his first trip abroad with Suvorin, visiting Austria, Italy and France. He went abroad again by himself for health reasons in 1894, 1897–98 and 1900–01, staying mostly in Nice. During his stay in Nice in 1898 he took a great interest in the Dreyfus affair. His championing of Dreyfus' cause brought him into sharp conflict with Suvorin and was responsible for the breaking up of their friendship.

In 1892 Chekhov acquired the 300-ac. estate of Melikhovo in the province of Moscow. There he lived with his parents and his younger sister Mary, writing and giving free medical treatment to the peasants in the neighbourhood. He took an active part in combating the famine of 1891 in the Russian central provinces, in dealing with a cholera epidemic in his own district and in helping with the census of 1897, and he was responsible for the building of several village schools. In 1899 his health forced him to sell his estate and settle in the Crimean seaside resort of Yalta. The last period of his life (1896–1904) is particularly notable for his work as an innovator of drama and for his close connection with the Moscow Art theatre, one of whose actresses, Olga Leonardovna Knipper, he married in May 1901. He mas elected honorary member of the Russian Academy of Science (literary section) in 1900 but resigned when the election of Gorki, whom he had befriended in the Crimea, was annulled at the behest of the tsar. He died at the Black Forest spa of Badenweiler on July 1 (O.S., 14, N.S.), 1904.

Short Stories.—Broadly speaking, Chekhov's short stories can be divided into three periods: (1) the bread-and-butter period (1880–86) when Chekhov used to toss off hundreds of humorous tales, some of them mere comic incidents showing here and there a keen sense of the social scene and of the incongruities of life, some revealing a deep feeling for human injustice and suffering; (2) the brief Tolstoian period during which he became conscious of his social and artistic responsibilities as a writer (1886–90); and (3) the period of his complete artistic emancipation (1891–1904).

Chekhov's first story, "A Letter to a Learned Friend," was published in *Stvekoza,* a St. Petersburg comic magazine, in Jan. 1880 and was signed "-v." His subsequent stories began to appear regularly in St. Petersburg and Moscow popular magazines under the signature of Antosha Chekhonte. Already in what Chekhov himself described as his "thoughtless and frivolous" stories his characteristic quality of digging below the surface of life, exposing the hidden motives of his characters and revealing the influence of the prevailing social forces upon them can be easily discerned. His real chance as a writer came in 1882 when he became a regular contributor of short stories to *Oskolki,* a popular St. Petersburg weekly magazine for which he wrote about 300 stories. These included such miniature masterpieces as "A Daughter of Albion" (1883), "The Surgery" (1884), "A Chameleon" (1884), "A Dead Body" (1885), "Sergeant Prishibeev" (1885), "Misery" (1886) and "The Chorus Girl" (1886), some of them based on his experience as a medical practitioner in a small country town near Moscow. After his visit to St. Petersburg in 1885, he made his first entry into the daily press, becoming a regular contributor to *Peterbuvgskaya Gazeta,* for which he wrote, in 1885, "The Gamekeeper" and "The Burbot," in which he showed himself to be a descriptive writer of great originality, and, in 1888, the rather macabre slum story "Sleepy." A few months later he became a contributor to *Novoe Vremya* in which appeared some of his finest pieces of that period, such as "Easter Eve" (1886), "The Rolling Stone" (1887), "Happiness" (1887), an impressionistic story in which Chekhov, in his own words, described "a plain, night, pale sunrise, a flock of sheep, and three human figures discussing happiness," and his famous children's story "Kashtanka" (1887). His unfinished work "The Steppe" (1888). which he intended to make into a novel and for which he had undertaken a journey through the steppe region of southern Russia, he published in the March number of *Severny Vestnik,* his entry into the world of the so-called "fat" or intellectual monthly periodicals.

All the stories Chekhov wrote between 1886 and 1890 bear traces of Tolstoian philosophy of which he had certainly been more than a warm adherent at the time. The most Tolstoian of them, however, such as "The Cossack" (1887), "The Meeting" (1887) and "A Misfortune" (1886), he did not include in his collected works, while others, such as "Excellent People" (1886), "The Beggar" (1887), "The Bet" (1888) and "The Shoemaker and the Devil" (1888), he thoroughly revised. The most remarkable story written during his Tolstoian period is "A Boring Story," in its revised version a philosophic disquisition on art, the theatre and life in general, dealing more particularly with the life story of a stage-struck girl in many respects similar to the story of Nina in *The Seagull.* It was published in *Severny Vestnik* in 1889.

Between 1886 and 1890 were published four volumes of Chekhov's short stories entitled *Pëstrye rasskazy* (1886; Eng. trans. "Motley Stories"), *Nevinnye Rechi* (1887; Eng. trans. "Innocent Speeches"), *V sumerkakh* (1887; Eng. trans. "In the Twilight") and Rasskazy (1889; Eng. trans. "Stories"), all of them going through several editions during his lifetime. For the volume *V* sumerkakh Chekhov was awarded the Pushkin prize by the Russian Academy of Science.

Chekhov began his period of maturity as a creative writer by two stories in which he challenged the chief tenets of Tolstoi's teachings. In the first, "The Duel," his major work of 1891, he attacked Tolstoi's argument in The Kreutzer Sonata about the ideal of Christian love being incompatible with sexual love. In the second, "Ward No. 6," the only major and marvellously integrated work of art he wrote in 1892, he condemned the chief tenet of Tolstoi's faith, nonresistance to evil. Four years later he resumed his criticism of Tolstoi's ideas and exposed with devastating effect the tragedy of the people who tried to put them into practice in his two stories: "The House With the Attic" and "My Life," both written in 1896. Among the other masterpieces Chekhov wrote between 1891 and 1903 are "The Grasshopper." "A Woman's Kingdom" and his study of megalomania, "The Black Monk," all written in 1892; "The Student" (1894), in which he attempted to meet the accusation that he was a pessimistic writer; "Three Years" (1894). a story of Moscow life, including a great deal of autobiographical material; "Ariadne" (1895); "Peasants" (1897), a sombre description of the appalling conditions under which the peasants in the Russian central provinces were forced to live, which brought Chekhov into conflict with the censors who accused him of blaming the authorities for the peasants' illiteracy; "Ionych," a most perfect example of Chekhov's genius for compressing a man's life within 24 pages, "About Love," "The Man in a Case" and "Gooseberries," all written in 1898; "The Lady With a Lapdog," the story of an ordinary pickup developing into a great passion, and "In the Ravine," written in 1899; "The Bishop," the only story Chekhov wrote in 1901; and his last story, "The Betrothed," a girl's revolt against her middle-class environment, written in 1903.

In 1899 Chekhov entered into an agreement with the St. Petersburg publisher Fedor Marx for the publication of a complete edition of his works, which, with the exception of the royalties from his plays, he sold for 75,000 roubles. During the following three years he was largely occupied with the most thoroughgoing revision of his stories, completely rewriting some of his earlier ones and weeding out those which he did not consider worthy to be reprinted.

Dramatic Works.—It is mainly as a playwright that Chekhov won his fame outside Russia. He began his work as dramatist during his last years at school in Taganrog, where he took an active part in the life of the local theatre, appearing on its stage in several plays, and where he wrote two full-length plays and a one-act comedy, none of which has been preserved. On his arrival in Moscow he wrote another four-act play which he tried unsuccessfully to have performed at the Moscow State (Maly) theatre. This play. which is of quite inordinate length, has been preserved. Its title page is missing and it is known by its hero's name as Platonov. It represents Chekhov's first attempt to paint a large canvas of the social forces that were molding Russian life in the last decades of the 19th century. It contains a gallery of well-realized, if at times rather theatrical, characters belonging to different strata of Russian society and shows the clash between the economic forces these characters represent. Platonov, the 27-year-old hero of the play, is a typical rebel against his environment, an idealist who is aware of the folly, laziness and ineptitude of the people around him but is too weak to do anything about it.

In 1887 Chekhov wrote his first successful play Ivanov, performed on Nov. 19 of that year in Moscow and with even greater success on Jan. 31, 1889, in St. Petersburg. Ivanov shows a great advance on *Platonov* in that it is much more compact and its characters are much more true to life, but it is still full of overdramatized situations and is much too conventional technically. Chekhov wrote his next play, Leshi (Eng. trans. The *Wood Demon*), in 1889, during his brief period as a Tolstoian disciple. It is essentially a morality play in which vice is converted to virtue instead of virtue triumphing over vice. Chekhov's main idea in writing this "lyrical play." as he called it, was to show life on the stage "as it really is." In this he failed, for what he actually produced was a revival of an old romantic stage convention with all its incongruous crudities and not the illusion of real life. The play, in fact, teems with coincidences and *deus ex machina* situations. It was a complete failure when produced at a private theatre in Moscow in Dec. 1889 and Chekhov refused to include it in the edition of his collected works.

During his first period as a dramatist Chekhov wrote a number of one-act comedies, the most successful of which were *Medved* (1888; Eng. trans. The Bear) and *Predlozhenie* (1889; Eng. trans. The Proposal), as well as *Na bolshoi* doroge (Eng. trans. On fhe *Highway*), "a dramatic study in one act," which the censor banned as being "gloomy and sordid."

There is an interval of seven years between Chekhov's first and second periods of playwriting. During this interval Chekhov perfected his technique of the play of "indirect action," a play. that is, in which the dramatic action takes place off stage and the action of the play is concentrated on the reaction of the characters to the dramatic events in their lives. Chekhov's fame as an innovator of the art of drama rests entirely on this new technique of writing dramatic dialogue. A Chekhov indirect-action play cannot be read, for it only assumes shape and form on the stage. It has to be treated by a producer in the same way as a conductor treats the score of a symphony. It is, in fact, a dramatic score whose manifold themes and climaxes must be carefully studied prior to any production.

Chekhov's first indirect-action play, Chaika (1896; Eng. trans. The Seagull), was booed off the stage when first performed in St. Petersburg on Oct. 17, 1896. Its failure was due solely to the failure of the producer and actors to grasp the full implications of Chekhov's new dramatic method. On its performance by the newly founded Moscow Art theatre on Dec. 17. 1898. it was a resounding success, but this again was due to the novelty of the inspired stage direction of its producer, Konstantin S. Stanislavski, rather than to its own intrinsic merits as a work of art. In The Seagull the action flows logically and naturally out of the interplay of theme and character which have become completely integrated. Indeed, so complete is this synthesis of theme and character that an illusion of real life is created on the stage. Its chief theme, what makes a creative artist, deals with one of the most important problems in the world of art. Chekhov's second play in the new manner, Dyadya *Vanya* (1897; Eng. trans. *Uncle Vanya*), a thoroughly revised version of The *Wood* Denzon stripped of its Tolstoian ideology and its melodramatic situations, was produced by the Moscow Art theatre on Oct. 26, 1899 and has proved to be one of the most successful plays in the repertoire of the theatre. Both structurally and psychologically it is not only one of the most compact of Chekhov's great plays but also one of the most dramatically expressive. Its main theme is not, as is often assumed, frustration, but courage and hope. Chekhov's most profound dramatic work. *Tri* sestry (1901; Eng. trans. *The* Three Sisters), is also a most perfect example of his indirect-action technique. It is a play which deals with the inmost mysteries of man's soul, the purpose of man's existence and the ultimate values of life. It was first performed by the Moscow Art theatre on Jan. 31, 1901, and published in the monthly periodical Russkaya *Mysl* in February of that year. Chekhov revised the text of the play in 1902 for the seventh volume of his collected works. His last play. *Vishnevy* sad (1903; Eng. trans. The Cherry Orchard). was first produced by the Moscow Art theatre on his last birthday, Jan. 17, 1904. It is a high comedy in which the great brooding intelligence of its creator is contemplating man's folly and a world on the brink of dissolution with the quizzical eye of the born humorist. Its main theme. the passing of the old order, is symbolically represented by the sale of the cherry orchard. In the final scene the sound of the ax felling the cherry trees is merged with the realization of the born serf, the butler

Firs, that the old order was wrong and that, whatever the younger generation may make of the new order, the past is dead.

Chekhov called The Seagull and The Cherry Orchard comedies and The Three Sisters a drama, and it is well to remember that he never used his terminology idly. A drama in Russian literary usage is halfway toward tragedy and what distinguishes The Three Sisters from Chekhov's two great comedies is that it completely lacks the elements of high comedy that are so characteristic of them. Chekhov considered Uncle Vanya old-fashioned because, since it was a revised version of a play of his earlier period, he could not satisfactorily apply the principles of the indirect-action play to it and for that reason he subtitled it: "Country Scenes in Four Acts."

Each of Chekhov's four dramatic masterpieces requires a perfect understanding of its themes, but what is most essential to bear in mind is the gradual increase in dramatic tension in the first two acts and the way this works up to a crescendo in the climax in the third act. The failure to observe this carefully built-up climax and the marvelous piling up and interweaving of the various themes in the play till they converge in one focal point at the end of the third act has repeatedly led to the total disintegration of the dramatic action of the play and its transformation into the all too familiar play of inaction and mood against which Chekhov protested so violently in the Moscow Art theatre productions of his plays.

CHEKIANG *(CHE-CHIANG SHENG), one of the smaller but most densely populated provinces of China. Area 39,305* sq.mi.; *pop. (1957 est.) 25,280,000. It is the most northerly of the coastal provinces of south China where the southwest to northeast coastal ridges begin to sink beneath the Yangtze delta. These ridges, in the eastern and southern parts of the province, are cut by many gorge rivers and provide hundreds of rocky off-shore islands that attract Chekiang fishermen. The northern and western sections, drained by the Ch'ien-t'ang river into* Hangchow *bay. are on the* Yangtze *delta and surrounding foothills. These densely settled lowlands extend in a crescent from the port of Ningpo to Huchow (qq.v.) near the southern shore of Lake* T'ai.

The crops — wheat, beans, rice, cotton, tea and silk — typify mid-China and the overlap of north and south. This is part of the premier quality silk area of the country, both for yarn and woven fabrics, while around Hangchow *(q.v.) grows one of China's finest green teas, the famous Lung-ching or Lungtsing leaf. Chekiang is mainland China's biggest source of marine products, most of which are landed at Ningpo. Salt is produced along the coast. Upstream from Hangchow, the provincial capital, is an area noted for handmade paper where bamboo is converted into fine Chinese writing paper, and rice straw into coarser types. During the 12th and 13th centuries Hangchow. then* known *as Linan. was the capital of the southern Sung dynasty which stimulated for a time the production of light green celadon porcelains in Lung-ch'uan, southwest Chekiang. For centuries Chinese have visited the tomb of Y o Fei, a Sung general and national hero, in Hangchow, while many other monuments, temples and villas around West Lake (Hsi Hu) mark the city's long history in producing scholar-officials, artists and poets.*

Light industry and handicrafts characterize Chekiang manufacturing. Huchow and Hangchow *are renowned for plain and self-figured silks, while tapestry has become important in* Hangchow; *scissors, fans and various carvings are further specialties. Later mechanized industries in* Hangchow *are jute spinning and weaving, cigarette manufacturing and cotton weaving.* Wenchow *(q.v.) is an important commercial centre on the Wu river in southern Chekiang. One of China's largest hydroelectric power projects, capacity of 580,000 kw., is scheduled for the Hsin-an or upper Ch'ien-t'ang river to meet power demands in the Yangtze delta cities. Heavy industry does not seem likely to develop in Chekiang.*

The central part of Chekiang province is a major fluorite producer, while a large iron ore deposit has been reported around Shao-hsing in the northeast. Hangchow *is the southern terminus of the Grand canal, originally 1.286 mi. long. Chekiang is well supplied with railways to Shanghai, southwest to Ch'ang-sha in Hunan. and from* Hangchow *to* Ningpo. *(TE. H.)*

CHELATES: *see* CO-ORDINATION *COMPOUNDS.*

CHELCICKY, PETER *(c.* 1390–*c.* 1460), *Czech religious and political writer, the most eminent thinker of the Hussite movement, was born and lived in southern Bohemia. Chelcicky, who deliberately chose the life of a working farmer, had no academic training and, although a great admirer of John Wycliffe, could read only those of his Latin works which were translated into Czech. He pursued the critical assumptions of Wycliffe and John Huss to their logical conclusion, rejecting all authority except the New Testament and denying the necessity and lawfulness of coercive government in a Christian community. He condemned war and capital punishment, objected to towns, commerce and oaths, declared that a Christian should not serve as magistrate, judge, juryman or soldier and advocated a return to the primitive Christian order which, he believed, existed before the emperor Constantine I the Great's time. Chelcicky's teaching, which inspired the Bohemian Brethren and, through them, the Polish Brethren, is most fully expounded in Sit Viry ("Net of the Faith"), written in 1440 and first printed in 1520. His utopian anarchism was a powerful influence on political thought down to Tolstoi.*

See P. Brock, The Political and Social Doctrines of the Unit of Czech Brethren (1957). (R. R. Bs.)

CHÉLIFF, *the longest river in Algeria, is about 422 mi. long but unnavigable. The source of its farthest tributary, the Oued Sebgag or Touil, is in the Djebel Amour of the Saharan Atlas. For most of the year in crossing the steppes of the high plateaus this stream is a chain of marshes and muddy pools, being almost entirely dried up when it is joined by the second main tributary, the Oued Nahar Ouassel. This oued (stream) rises in the Tiaret on the southern side of the Ouarsenis massif of the Tell Atlas and flows eastward to join the Oued Sebgag at Chabounia. The combined streams spread out in marshes near Bou Ghezoul before turning abruptly north to pass more swiftly through the Tell Atlas in a series of entrenched meanders. Below Dollfusville the river swings to the west, flowing for about 145 mi. parallel with the coast in a depression between the Dahra and Miliana massif and the Ouarsenis of the Tell Atlas, reaching the Mediterranean about 8 mi. N. of Mostaganem. This depression. now filled with alluvial deposits, was formerly a gulf of the sea and is now known as the plain of the* Chéliff; *it is followed by the main east-west railway line. Two constrictions in the valley permit a subdivision into the plains of Affreville, les Attafs and* Orléansville, *named after the central market towns.*

The river receives a number of tributaries from the Dahra and Ouarsenis but never attains much size. Its flow is irregular, the maximum being Nov. to March (usually running in spate in Dec. *and Jan.), and by late summer the river is reduced to a chain of muddy pools. The* Chéliff *plains being on the lee side of the coastal ranges experience a moderate but irregular rainfall* (Orléansville, *average 16.3 in.). Evaporation is intense and the enclosed valley becomes* intolerably *hot in summer* (Orléansville, *mean daily maximum July–Aug. 99° F.). Cereals are the principal crops of both Europeans and Algerians; yields are uncertain, being dependent upon rainfall. Progress has been made with irrigation projects, including the establishment of pumping stations tapping underground water supplies and the construction of dams at Lamartine (near* Orléansville) *on the Oued Fodda and Ghrib (near Dollfusville) on the* Chéliff. *Hydroelectric power is generated at both. Irrigation improves yields and allows the replacement of annual crops by fruit trees such as olives, figs and apricots; it also sustains a small area under cotton centred on* Orléansville. *(A. B. M.)*

CHELLEAN, the name formerly applied to an early Stone Age industry characterized by crudely worked hand axes. As the implements from Chelles, which is near the right bank of the Marne in France and which gave the name to the industry, are now grouped with the Acheulean, the term Chellean, in the sense of earliest hand-ax culture, has been replaced by Abbevillian (*q.v.*). (K. P. O.)

CHELM, a Polish town near the eastern frontier, lies 65 km. (40 mi.) E.S.E. of Lublin. Pop. (1960) 31,000. The town is situated in the marshy valley of the Uherka, a tributary of the Bug. Deposits of writing chalk, sand and loam contributed to the development of a mineral industry. The site is that of a pre-Slavonic fort. The settlement obtained town rights in 1233 and was joined to Poland in 1377. At the third partition of Poland (1795) it was transferred to Austrian rule and after 1815 was included in the Polish kingdom, under Russia. During the German occupation in World War II two concentration camps were set up in the town, where about 90,000 persons were exterminated. After Chelm was liberated in 1944, the manifesto of the Polish Committee of National Liberation was published there on July 22. (T. K. W.)

CHELMSFORD, FREDERIC JOHN NAPIER THESIGER, 1ST VISCOUNT (1868–1933), British statesman who, as viceroy of India, shared in reforms which set India on the path to self-government, was born in London on Aug. 12, 1868, the eldest son of the 2nd Baron Chelmsford. Educated at Winchester and Magdalen college, Oxford, he was called to the bar in 1893, was a member of the London School board from 1900 to 1904 and served on the London County council in 1904–05. In 1905 he succeeded his father as Baron Chelmsford and was appointed governor of Queensland, Austr. He held that office until 1909 when he became governor of New South Wales. He was an active and popular governor at a time of political conflict and labour unrest. Knighted in 1912, he left Australia in 1913 and served in India with the Dorset regiment during the early part of World War I.

From 1916 to 1921 he was viceroy of India. The outstanding feature of his period of office were the deliberations which culminated in the Montagu-Chelmsford reforms, based on the joint report of the secretary of state for India, E. S. Montagu, and of Chelmsford himself. The central and provincial legislatures were increased in size and given elected majorities. In the provinces the system of dyarchy was introduced, whereby certain departments of government were transferred to the control of ministers responsible to the legislature while control over the remaining departments was reserved to officials responsible to the governor. In addition, the number of Indians on the viceroy's executive council of seven was increased from one to three. The reforms were implemented in 1919, but before then there were serious riots in Gujarat and the Punjab. Another problem was the nonco-operation advocated by Mahatma Gandhi and adopted in 1920 by the Congress party, which boycotted the first elections to the reformed councils. However, the reforms were welcomed by more moderate nationalists. On his retirement in 1921 Chelmsford was created a viscount. He was first lord of the admiralty in Ramsay MacDonald's Labour government of 1924. He died on April 1, 1933. (KE. A. B.)

CHELMSFORD, FREDERIC THESIGER, 1ST BARON (1794–1878), lord chancellor of England and one of the most popular leading counsels of his day, was the third son of Charles Thesiger and was born in London on April 15, 1794. Young Frederic Thesiger was originally destined for a naval career, and he served as a midshipman in 1807 at the second bombardment of Copenhagen. His succession to a valuable estate in the West Indies and the subsequent destruction of this by a volcano led first to his leaving the navy and then to his being called to the bar in 1818.

In 1824 he distinguished himself by his defense of Joseph Hunt for the murder of William Weare, and eight years later at Chelmsford assizes he won a hard-fought action to which he attributed so much of his subsequent success that when he was later raised to the peerage he assumed the title Lord Chelmsford. In 1834 he was made king's counsel and in 1835 was briefed in the Dublin election inquiry that unseated Daniel O'Connell. In 1840 he was elected M.P. for Woodstock. In 1844 he became solicitor general and in 1845 attorney general, holding the latter post until the fall of the Peel administration on July 3, 1846. In 1852 he became M.P. for Stamford.

On Lord Derby's coming into office for the second time in 1858, Sir Frederic Thesiger was raised straight from the bar to the lord chancellorship. In the following year Derby resigned. Again in 1866, on Lord Derby's coming into office for the third time, Chelmsford became lord chancellor for a short period until Derby's retirement. He was a Conservative politician at a time when Whig administrations predominated, or he would almost certainly have left a greater name than he did.

Chelmsford died in London on Oct. 5, 1878.

His eldest son, Frederic Augustus, 2nd Baron Chelmsford (1827–1905), earned distinction as a soldier, while the third son, Alfred Henry Thesiger (1838–80), was made a lord justice of appeal and a privy councilor in 1877.

See *The Victorian Chancellors (1906–08)* by J. B. Atlay, who had access to an unpublished autobiography of Chelmsford.

CHELMSFORD, a market town, municipal borough (1888) and the county town of Essex, Eng., in the Chelmsford parliamentary division, 29 mi. E.N.E. of London by road. Pop. (1961) 49,810. It lies in the Chelmer valley at the confluence of the Can and has communication by river with Maldon and the Blackwater estuary 11 mi. to the east. Chelmsford (Celmeresfort in Domesday Book) consisted of two manors: Moulsham and Bishop's hall. Excavations established that the Moulsham district is the site of the Roman Caesaromagus, a small town of 20–30 ac. Early in the 12th century Bishop Maurice built the bridge over the Chelmer which brought the road from London directly through the town.

In 1225 Chelmsford was made the centre for the collection of fifteenths (taxes of one-fifteenth imposed on personal property) from the county of Essex, and in 1227 it became the regular seat of assizes and quarter sessions. The diocese of Chelmsford, established in 1914, coincides with the county of Essex. In 1951 the 15th century parish church of St. Mary, a Perpendicular building largely rebuilt after 1800, became the cathedral. Historic buildings include the grammar school founded in 1551 by Edward VI, New Hall (now a convent and school) and Boreham house. The Shire hall (1790–92) is by John Johnson, and there is a county museum. In 1199 the bishop obtained the grant of a weekly market, and in 1201 he obtained that of an annual fair, later discontinued.

There is an agricultural market and a corn exchange in the centre of the town square. Chelmsford is also an industrial centre, and its major industries include the manufacture of ball and roller bearings, radio, electrical and engineering equipment. There are also maltings, corn mills, optical instrument making and confectionery manufacture in the town. From the premises of G. Marconi's Wireless Telegraph company the first wireless telephone broadcasting service in the world was transmitted on Feb. 23, 1920.

CHELSEA, a western metropolitan and parliamentary borough of London, Eng., bounded on the east by the city of Westminster, northwest by Kensington, southwest by Fulham, and south by the Thames river. Pop. (1961) 47,085. Area 1 sq.mi. A pleasant residential district, its main thoroughfares are Sloane street, running south from Knightsbridge (part of which is in Chelsea) to Sloane square, and King's road, a commercial highway named in honour of Charles II and recalling the private road from St. James's palace to Fulham, leading west from Sloane square. The main roads south join with the Chelsea, Albert and Battersea bridges over the Thames. The Chelsea embankment, planted with trees and lined with fine houses and public gardens facing the river, stretches for more than a mile between Victoria and Battersea bridges.

Chelsea, especially the riverside district, has many historical associations. At Cealchithe a synod was held in 785. A similar name occurs in a Saxon charter of the 11th century and in Domesday Book. The manor was originally in the possession of Westminster abbey, but its history is fragmentary until Tudor times. Henry VIII acquired it, and also the estate of Sir Thomas More

in Chelsea, in 1536 and passed it to his wife Catharine Parr. It fell afterward to the Howards and the Cheynes, and later to the Cadogans. The memorials in Chelsea Old church (All Saints) include those of Sir Thomas More (d. 1535); Sir Hans Sloane (d. 1753); Thomas Shadwell, poet laureate (1692); George Woodfall, the printer of Junius (1805); and many others. The church. which had never been spoiled, was ruined in World War II, though most of the fine monuments were rescued. many almost undamaged. The chancel and Lawrence chapel were rehallowed by the bishop of London in 1954. In 1819 the larger church of St. Luke's was built as a parish church. The new Church of Scotland church of St. Columba, designed by Sir Edward Maufe, was opened in 1955. It stands at the western end of Pont street and is of white stone. The original church was destroyed in World War II.

From the 18th and 19th centuries Chelsea has been a literary, artistic and (by mid-20th century) a Bohemian quarter; the Chelsea Polytechnic, with its art school and college of science and technology, was opened in 1895. Francis Atterbury and Swift lived in Church lane; Gay. Steele and Smollett in Monmouth house. Joseph Turner, J. S. Sargent, Whistler, Leigh Hunt. Carlyle, the "Sage of Chelsea" (whose house no. 24. formerly no. 5, Cheyne row is preserved as a public memorial), Lord Courtney, Count D'Orsay, Oscar Wilde, George Eliot (who died there as Mrs. Cross). and Isambard Brunel are connected with Chelsea. At Lindsey house Count Zinzendorf established a Moravian society (c. 1750). Sir Robert Walpole's residence was extant till 1810. and until 1824 the bishops of Winchester had a palace in Cheyne walk. Queen's (Tudor) house was the home of D. G. Rossetti.

Ranelagh (*q.v.*), in the second half of the 18th century, and Cremorne gardens (q v.), in the middle of the 19th, were famous places of entertainment. Don Saltero's museum contained curiosities from Sir Hans Sloane's famous collections. In 1722 Sloane gave to the Apothecaries' guild the grounds of the Physic garden (established 1673), which in 1902 ceased to be maintained by the society though still used for research purposes. Cotton seed from the garden sent in 1732 helped to establish the American cotton industry. The original Chelsea bunhouse. claiming royal patronage, stood until 1839, and one of its successors stood until 1888. The celebrated Chelsea china factory, founded in 1745, was moved to Derby (*q.v.*) in 1784. Chelsea Royal hospital (*q.v.*) for invalid soldiers, initiated by Charles II, was opened in 1692. The picturesque building by Sir Christopher Wren, the great hall of which was damaged during World War II, stands in extensive grounds which include the former Ranelagh gardens, site of the annual flower show of the Royal Horticultural society.

Crosby hall, with new buildings adjacent to it, was opened in 1927 as a residence hall for university women. The hall, built by Sir John Crosby in Bishopsgate in 1466. was moved thence to a site on Sir Thomas More's former garden in 1910 to save it from demolition. The town hall, the centre of municipal activities in the borough, was built in 1886. The Chelsea public library contains an excellent collection relating to local history.

CHELSEA, a city of Suffolk county, Mass., U.S., 2 mi. N E of Boston (q *v.*) and a part of the Boston metropolitan area Settled in 1624 as Winnisimmet by Samuel Maverick, a trader, it was important to Boston, then an island, as the quickest route north. It became a town (Chelsea) in 1739 and a city in 1857. Its growth as a manufacturing and shipping city in the late 1800s destroyed its early role as a summer resort. On April 12, 1908, one-third of the city was destroyed by fire.

Chelsea's 3 mi of waterfront on Boston harbour are dominated by wholesale oil plants It is also a junk salvage centre. Chelsea is connected to Boston by the 2-mi. Mystic River (toll) bridge Large numbers of persons of Russian, Lithuanian, Polish and Italian origin live there. For comparative population figures see table in MASSACHUSETTS: *Population.* (R. C. Mo)

CHELSEA, THE ROYAL HOSPITAL, a home for "worthy old soldiers broken in the wars" in Chelsea, Eng., was founded by Charles II and completed in 1692. The king gave the site of the building and headed the list of subscribers, among whom was Sir Stephen Fox, the paymaster general, who was made responsible for the general administration of the buildings. Sir Christopher Wren was appointed architect, his plans being influenced to some degree by the Invalides in Paris and Kilmainham hospital in Dublin, both built for former soldiers. The Royal Hospital, Chelsea, has an establishment of 558 in-pensioners, organized in six companies and housed in two main blocks. Each man has a cubicle to himself and, except for the infirm, who are fed in their wards, eats in the Great hall which with the chapel forms the central part of the building. After the infirmary, built by Sir John Soane, nas bombed and destroyed in 1941, sick in-pensioners were nursed in an infirmary at Leatherhead, Surrey.

Candidates for admission must be in receipt of a pension, either for service or for a disability; they must be at least 55 years old, be able to look after themselves and have had an army character of not less than "very good." In-pensioners may revert to out-pension at their own request but are not then eligible for re-admission. The Royal hospital is regulated by royal warrant and controlled by a board of commissioners, of whom the paymaster general is the chairman and treasurer. After nearly 300 years, the responsibility of the board for the administration of pensions and for cases of commutation passed to the army pension office in 1955, when it was set up. The military trophies and standards which under the orders of William IV were kept at the hospital have mostly been returned to the regiments which captured them, but there is a fine collection of pictures and medals in the Great hall and adjoining rooms. (N. W. D.)

CHELTENHAM, a municipal and parliamentary borough of Gloucestershire. Eng., about 96 mi. W.N.W. of London. Pop. (1961) 71,968. The town lies where the Chelt, a small tributary of the Severn, breaks the western escarpment of the Cotswold hills. It is a residential, tourist and sporting centre and is also visited for its medicinal waters. There are three saline springs, the Pittville, Montpellier and Central spas. During the 20th century a number of light industries were established in and around the town. Four miles west is Staverton airport.

There was an early settlement at Cheltenham, and a church existed there in 803. The manor belonged to the crown and was granted to Henry de Bohun, earl of Hereford, in the 12th century. In 1252 it was bought by the abbey of Fécamp in Normandy and afterward belonged to the priory of Cormeilles. France. In 1415 it was confiscated, but at the dissolution it returned to the crown. It then became the property of the Dutton family. The town is first mentioned in 1223, when the benefit of the markets, fairs and hundred of Cheltenham was leased to it for three years. Henry III renewed the lease in 1226 and in 1230 granted a Thursday market and a three-day fair on July 24. It was governed by commissioners from 1852 to 1876, when it was incorporated. It became a parliamentary borough in 1832, returning one member. After the discovery of the mineral springs in 1716 and the erection of a pump room in 1738, Cheltenham rapidly became fashionable, the visit of George III and the royal princesses in 1788 ensuring its popularity. As an inheritance of those times the town is graced by delightful Georgian buildings, wide tree-lined avenues and open spaces. Gustav Holst (*q.v.*) was born there in 1874.

Cheltenham is a well-known educational centre, the principal institutions being Cheltenham college (founded 1841); Cheltenham Ladies' college (1853); Dean Close school (1886); a grammar school (founded 1586; rebuilt 1883); and teachers' training colleges. The town hall, the opera house and the civic playhouse are used for entertainments. After World War II festivals of contemporary British music and literature were established as annual events. Race meetings are held under National Hunt rules, and county matches are played on the cricket ground with an important cricket festival in August.

CHELYABINSK, an *oblast* (administrative division formed 1934) of the Russian Soviet Federated Socialist Republic, U.S.S.R., covers an area of 33,938 sq.mi., mostly along the eastern slopes of the Ural mountains at their southern end. A winding panhandle in the northwest of the *oblast* stretches across the series of parallel ranges of the Urals on to the western flank, while a small area in the extreme east extends out onto the West Siberian plain. The northern part is drained by the Miass and Uy rivers, flowing east to the Tobol, while the south is drained by the upper reaches

of the Ural river flowing to the Caspian. The higher mountain areas are clothed in mainly coniferous forest, and the lower, eastern parts are open Black Earth steppes with groves of birch and other trees in the north. This reflects the difference in rainfall from 27 in. in the west to 12–15 in. in the east.

The population of Chelyabinsk oblast at the 1959 census was 2,976,625 of which 2,273,197 or 76% were urban. The largest towns are Chelyabinsk, the administrative centre (688,000), Magnitogorsk (311,000), Zlatoust (161,000). Kopeysk (160,000), Miass (99,000), Korkino (85.000) and Troitsk (76,000).

The main lines of communication are the east-west Trans-Siberian and north-south Urals lateral railways, which intersect at Chelyabinsk. The oblast is a major mining and industrial region. Its large-scale heavy industry is primarily based on local supplies of ores: magnetite iron ores from Mt. Magnitnaya near Magnitogorsk and from Bakal (one of the richest deposits in the country, with high quality ores up to 65% metal), titanium-magnetite ores near Zlatoust, nickel at Verkhni Ufaley, and supplies of chromite, copper and zinc. Coking coal comes from Karaganda in the Kazakh Sóviet Socialist Republic or from the Kuznetsk basin of Siberia, but lignite is mined in the oblast (more than 20,000,000 tons annually), together with some anthracite near Magnitogorsk. Iron and steel plants are located in Magnitogorsk, Chelyabinsk, Zlatoust and Asha. There is widespread heavy engineering. including the production of steel tubing, vehicles, tractors, combine harvesters and other agricultural machines. rolling stock, machine tools and instruments. A chemical industry is based on coke by-products. Agriculture plays a secondary role, but is important in the steppe areas, where considerable acreages were plowed under the Virgin Lands project (1954–57). Wheat is the main crop. but potatoes and vegetables are grown in quantity for the towns. Beef, dairy cattle and sheep are important. (R. A. F.)

CHELYABINSK, chief town of Chelyabinsk oblast of the Russian Soviet Federated Socialist Republic. U.S.S.R.. is situated on the eastern flank of the Ural mountains. on the Miass river about 900 mi. from Moscow. Pop. (1959) 688,000. Founded in 1658, the town began to grow with the coming of the Trans-Siberian railway in 1892. Thereafter growth was continuous and Chelyabinsk, given added impetus during World War II. became one of the largest industrial cities of the U.S.S.R. The town is well served by railways; apart from the Trans-Siberian, lines run north and south to link up with other Ural industrial centres. On the basis of iron ore from nearby Bakal, coking coal from the Kuznetsk basin and local lignite (at Kopeysk and Korkino). large-scale heavy industry has developed, producing iron and steel, rolled steel, ferroalloys, tubes, steel pressings, zinc. bulldozers, scrapers and tractors, oil-drilling equipment. electrical and power machinery and machine tools. The tractor works, built in 1930–33, are the largest in the U.S.S.R. A thermal electric station. using the lignite, provides power to the city and a wide area. The town has institutes of mechanical engineering, mechanization of agriculture, and pedagogical, medical and polytechnical institutes; there are also two theatres and a philharmonic hall. (R. A. F.)

CHEMICAL ACTION: see REACTION KINETICS.

CHEMICAL APPARATUS. The manipulation of the gases, liquids and solids dealt with in the chemical laboratory requires a variety of specialized apparatus. Many of these items have counterparts in the home, since operations such as heating, cooling, solution, etc., are a necessary part of our daily life. There is no fundamental difference between the laboratory Bunsen gas burner and the burner on the conventional kitchen gas range. Frequently, the chemist uses the same glassware for a chemical manipulation that is used for cooking in the home kitchen. In general, however, he must conduct his work with great care; the reagents are often corrosive and the apparatus may be subjected to extremes of temperature or pressure. Over a period of many years there has been devised a large number of items to meet these and other special requirements.

Since chemical reactions can take place in the solid, liquid or gaseous phase a considerable proportion of laboratory apparatus is devoted to the processes of solution, extraction, filtration, precipitation, evaporation, distillation and desiccation. For these purposes flasks, beakers, suction pumps, suction flasks, water baths, funnels, fractionating columns and stills are employed. Gases are manipulated in drying towers. aspirator pumps, gas generators, wash bottles and related tubing. Typical analytical chemical apparatus illustrated below includes crucibles, neighing bottles, burettes, pipettes, graduates and volumetric flasks.

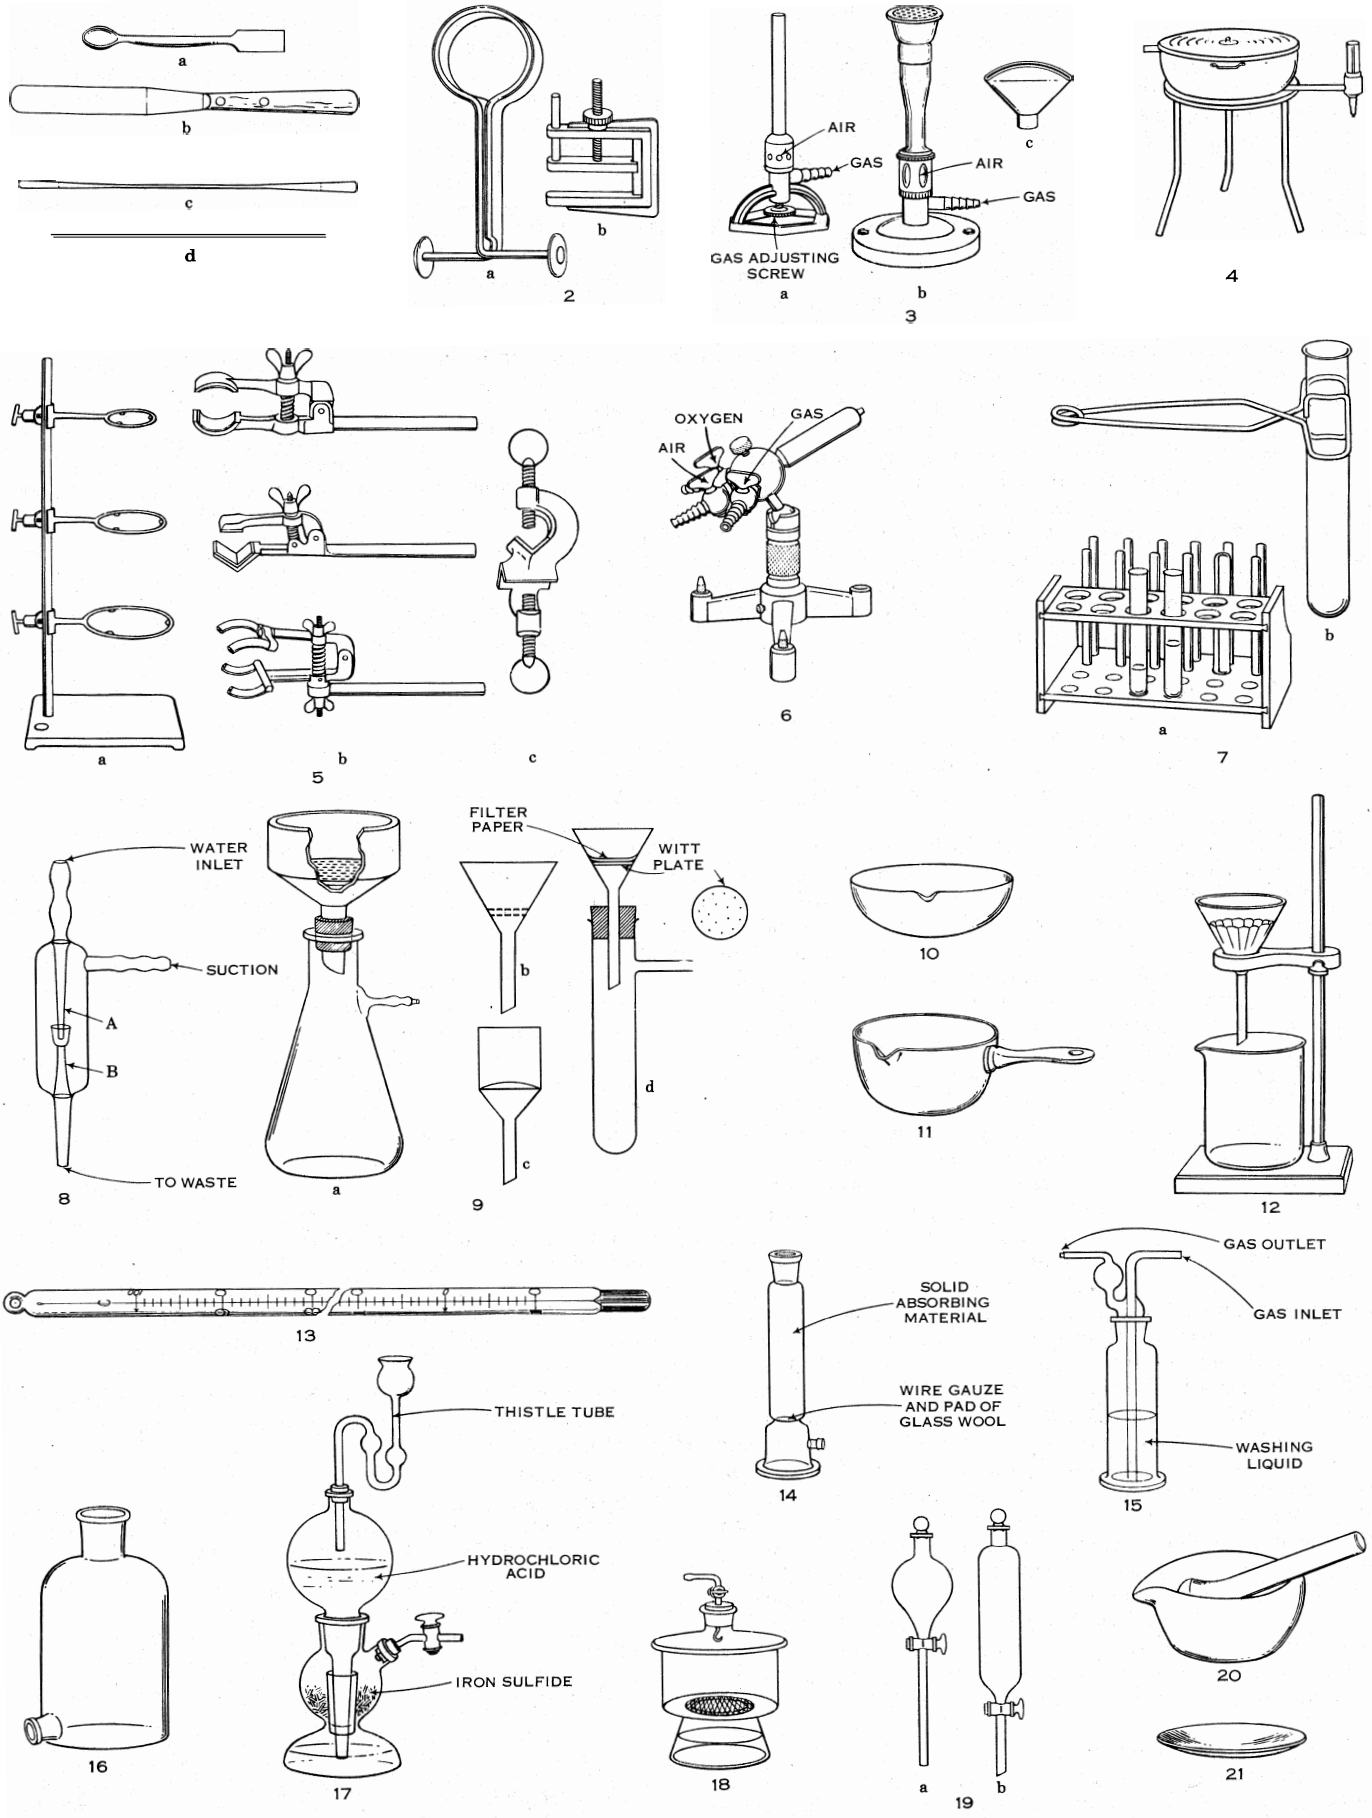
Different pieces of apparatus may be connected with glass, rubber or plastic tubing. Stoppers of rubber or cork are used to make renewable seals at certain points such as thermometer inserts or connections between tubes. There is available a complete selection of glass apparatus such as flasks, condensers, columns and stopcocks comprising units of various sizes which fit together with either standard taper or hemispherical (semiball) joints to form gastight and liquid-tight seals. Since this glassware may be arranged at will to perform a large variety of unit operations it is gradually supplanting cork and rubber stopper closures in the more advanced laboratories. In order to ensure uniformity between the products of several manufacturers the United States bureau of standards has established tolerances for these joints and certifies master joints of steel for their checking. Both types of joints may be lubricated with rubber-petrolatum or synthetic (Silicone) greases to render the joints completely gastight.

Physical measurements are an important part of laboratory practice and a chemical laboratory may employ a variety of measuring instruments. Mercury or liquid-in-glass thermometers, bimetallic thermometers, resistance thermometers and thermocouples are used for temperature measurement, whereas mercury or other fluid manometers and Bourdon gages are used to measure pressures. The chemical balance (see BALANCE) is used for weighing and it is constructed in many modifications depending upon the capacity and sensitivity demanded. The spectroscope (see SPECTROSCOPY) or spectrograph measures either the absorption or emission of light, and the colorimeter is used for exact colour comparison as in analytical determinations. Electrical measurements form the basis for the determination of hydrogen-ion (*q.v.*) concentrations using the *p*H meter, and reduction potentials are charted by the polarograph. Electrometric titrations as well as dyestuff indicators serve to determine the end-point in analytical titrimetry while burettes are available to measure amounts of liquids as small as .001 ml. with analytical accuracy. The index of refraction of light determined with the refractometer (*q.v.*) furnishes a useful guide to the purity and identity of chemical compounds, nhile the microscope makes it possible to manipulate and to observe beyond the capacity of the unaided eye. (*See* CHEMISTRY: Analytical Chemistry.) Laboratory technique is constantly being refined and improved. For the manipulation of a few milligrams of scarce or valuable material there has been developed a group of miniature beakers, flasks, funnels, etc., which is called microchemical equipment. Although some of these are merely small-scale models of the larger apparatus, others in the group are truly novel in design and are cleverly adapted to ultra-precise work. A few pieces of microchemical equipment are illustrated below.

The following list refers by number to the figure numbers of the accompanying illustrations of apparatus commonly used in a chemical laboratory.

General Apparatus

1. Spatulas and spoons, for dealing with small quantities of material without touching by hand. They may be made of (a) porcelain, (*b*) steel, (c) silver or other corrosion-resistant materials.
2. (a) Pinchcock or spring clip (Mohr's pattern). (*b*) Screw clamp or clip (Hoffmann).
3. (a) Bunsen burner (Tirrill type) with adjustable gas and air flow. (*b*) Meker burner for producing an intense flame over a broad area. Used for heating crucibles to high temperatures. (*c*) Wing-top which slips onto top of Bunsen burner to form "fish-tail"-shaped flame.
4. Water bath and rings on tripod. The bath is nearly filled with water which is heated by a burner underneath. Removal of one or more of the rings enables any circular vessel (*e.g.*, an evaporating basin) to rest in the hole of appropriate size, and its contents are slowly heated or evaporated. A constant-level device maintains the level of the water in the bath and obviates refilling.



FIGS. 1 AND 9 FROM LOUIS FIESER, "EXPERIMENTS IN ORGANIC CHEMISTRY," COURTESY D. C. HEATH & COMPANY

FIGS. 1–21.—COMMON CHEMICAL APPARATUS (THE NUMBERS REFER TO DESCRIPTIONS IN THE TEXT)

5. (a) Support with iron rings, (b) clamps and (c) clamp holder (boss).
6. Blast lamp or blast burner. Separate valves are provided for controlling the flow of oxygen and air which are mixed and fed to the gas through a central tube. The gas issuing from the outer sleeve iorms a brush flame or a fine-pointed flame depending upon the adjustment of the mixture.
7. (a) Test-tube stand and test tubes. (*b*) Spring-clamp test-tube holder.
8. Water-jet suction pump, for use with filter flask and either Biichner funnel (see fig. 9) or Gooch crucible (see fig. 33). The stream of water is broken up at the jet A and entrains air in its passage down the tube B. This is capable oi reducing the pressure as low as the vapour pressure of water.
9. Apparatus for filtering by suction. (a) Biichner iunnel fitted with a cork or rubber stopper into a filter flask which is attached to a suction pump (see fig. 8) by means of rubber tubing. A circle of filter paper is placed on the perforated bottom and the material retained by it can be sucked dry, washed and pressed. (*b*) Hirsch funnel. (*c*) Sintered-glass funnel. (*d*) Ordinary funnel.
10. Evaporating dish or basin (porcelain or glass).
11. Casserole (porcelain).
12. Filter stand, funnel and beaker for gravity filtration. A filter paper is folded so as to fit into the funnel as shown; it retains solids while liquids filter into the beaker.
13. Mercury-in-glass thermometer. Numerous scales are available for both higher and lower temperature ranges.
14. Drying tower. Similar in function to fig. 15, but used where gases have to be passed through a granulated solid.

    Wash-bottle for gases (Drechsel pattern). If the gas is bubbled through the liquid it can be freed from one or more impurities, *e.g.*, it can be dried by passage through concentrated sulfuric acid, or freed from carbon dioxide by a solution of sodium hydroxide.

    Aspirator bottle. A cork carrying a tube is inserted into the top opening while a stopcock may be attached to the lower opening and the bottle is filled with water. On opening the stopcock, water will flow out and this will draw air through the tube which may be attached to any other apparatus.

    Kipp gas generator. Hydrochloric acid (HCl) is allowed to run down the central tube and rise so as to act on the iron sulfide; if the tap is open hydrogen sulfide gas (H_2S) is expelled by the pressure of the "head" of acid; when the stopcock is closed the gas forces the acid into the top bulb and no more gas is produced. If marble (calcium carbonate) is used instead of iron sulfide, carbon dioxide (CO_2) is obtained. It may also be used to generate hydrogen gas by zinc metal and dilute sulfuric acid.

    Desiccator. Concentrated sulfuric acid, granular calcium chloride or other desiccant is kept in the bottom; the material to be dried is spread on a watch glass or evaporating dish resting on the gauze or on a perforated porcelain plate. An accelerated drying effect is produced by evacuating the desiccator through the stopcock tube by means of the suction pump shown in fig. 8.

    Separatory funnels: (a) pear-shaped—also called a dropping funnel; and (*b*) cylindrical. If ether has been used to extract an organic substance from water, two layers are formed and the lower (aqueous) layer can be run off. Similarly, if chloroform had been used instead of ether, the low-er layer would be the chloroform extract.
20. Pestle and mortar (of porcelain).
21. Watch glass for covering beakers while evaporating liquid. It is usually supported on glass U-shaped rods hung on the edge of the beaker.

    Stopcocks or taps. (*a*) A half turn shuts off the flow. (b) Three-way oblique bore plug. A half turn connects the lower limb with the left hand tube. (*c*) T-bore stopcock.

    Distillation with a fractionating column. The liquid in the round-bottom flask is boiled and the vapours pass through the column where partial condensation occurs. The reflux liquid washes the ascending gases which then pass into water-cooled condenser where they are condensed to a liquid. A thermometer indicates the temperature of the condensing liquid and an adapter leads to the receiver which is an Erlenmeyer flask.

Apparatus Used in Analysis

Crucible and lid made of porcelain, quartz or platinum. Used for igniting precipitates.

25. Clay triangle for supporting crucible on tripod or ring.
26. U-tube. May be filled with granulated soda-lime to absorb carbon dioxide, or with pumice soaked in sulfuric acid to absorb water vapour. The ground-in stopcocks can be turned to shut off connection with the outer air.

    Absorption bulb (Turner). Used for the absorption of carbon dioxide formed by the combustion of steel in oxygen. The stopper may be rotated so as to close both openings after the combustion has been completed.
28. Weighing bottles, for protecting material from the air while it is being weighed. A portion of the contained substance is shaken out and the whole reweighed, the amount of material thus taken being the difference in weight.
29. Wash bottle. A fine stream of water (or organic solvent) can be directed where required.
30. Dropping-bottles. (a) By slightly pressing the rubber nipple and releasing the pressure, a few drops are drawn up in the glass tube and can be squeezed out one at a time when the nozzle is withdrawn. (*b*) Liquid flows along the capillary tube at A when the bottle is tilted, and a drop falls from B, air entering through another channel at C. Used chiefly for indicators.

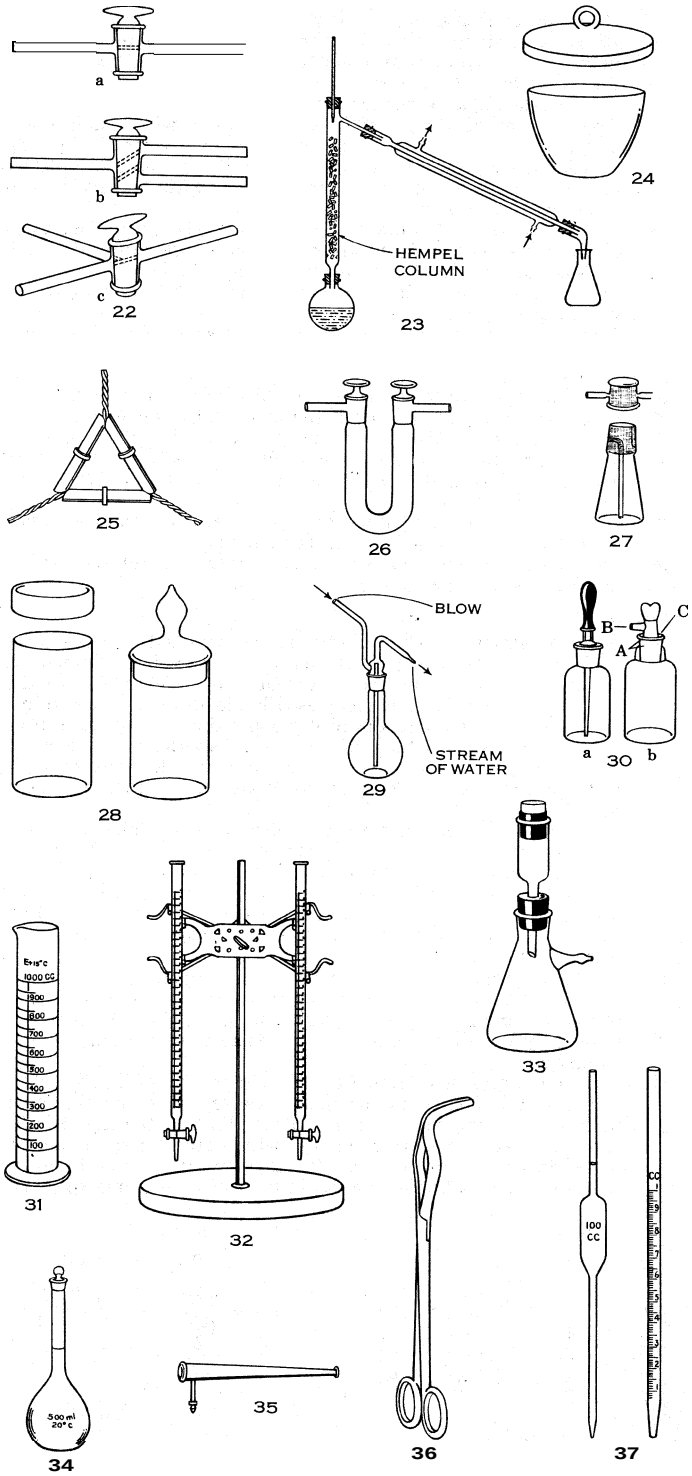


FIG. 23 FROM LOUIS FIESER, "EXPERIMENTS IN ORGANIC CHEMISTRY," COURTESY D. C. HEATH & COMPANY

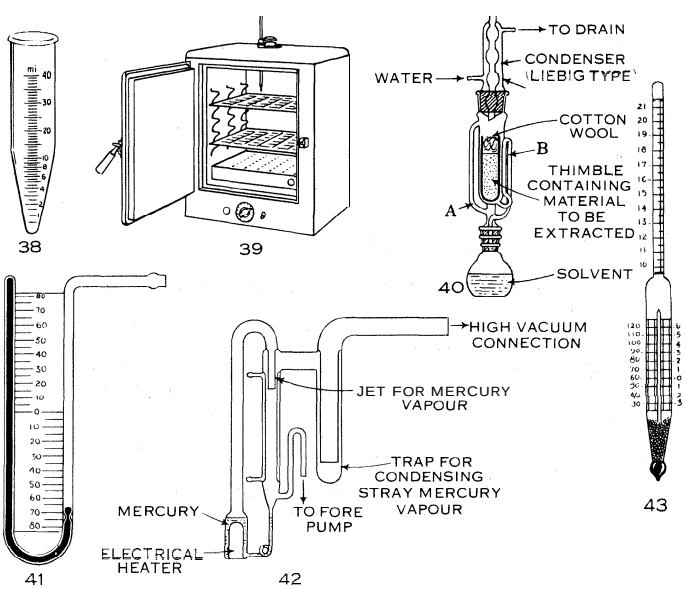
FIGS. 22–37.— CHEMICAL APPARATUS USED FOR ANALYSIS

31. Graduate or measuring cylinder.
32. Burettes in stand. Used for titrations. The volume of liquid delivered is accurately read on the graduated scale (see CHEMISTRY: *Analytical Chemistry*).
Gooch crucible atop rubber cone, glass adapter and filter flask. The bottom of the crucible is perforated with small holes, and a mat of asbestos is formed on it by pouring in a pulp of asbestos and water, sucking it nearly dry and completely drying it in the oven. Used for filtering, washing, drying and weighing precipitates.
Volumetric flask. Contains the stipulated volume when filled to the mark with a liquid at 20° C., the temperature at which it was calibrated. Used for preparing "standard" solutions, *i.e.,* solutions containing a definite quantity oi solid dissolved in an exact volume of solution.
Mouth blowpipe; used for directing a small flame jet onto the substance being analyzed (usually supported on a block of charcoal).
36. Crucible tongs; may he tipped with platinum ior refined work.
37. Pipettes (not to scale). (a) If the pipette at leit is filled exactly to the mark by suction it will then deliver the stipulated volume on draining for 15 sec. after continuous flow has ceased. (b) The pipette at right can be used to add small quantities that are read off on the scale.
38. Graduated conical centrifuge tube for measuring small volumes of centrifuged solid or liquid at the bottom.
39. Electrically heated oven with thermostatic control for drying precipitates to constant weight.

Special Apparatus

40. Soxhlet extractor. The material to be extracted is placed in a "thimble" of filter paper. Ether or other volatile solvent is boiled in the flask and passes through the side tube A to the reflux condenser C. The condensed liquid drops into the thimble where it accumulates until it reaches the level of the top of the side arm B, and then siphons over into the flask. Several complete cycles are permitted to occur beiore the solvent flask is disconnected and the solvent evaporated to leave the extracted material.
Mercury manometer ior vacuum distillations. The left-hand tube is completely filled with mercury as shown. When the side tube is connected to a system being evacuated the level in the left-hand tube drops while that in the right-hand tube rises, and the difference in height between the tops of the two mercury columns indicates the pressure in the system in millimetres of mercury.
Mercury vapour diffusion pump for producing high vacuum. The high velocity jet of mercury vapour permits diffusion of the other gases in the system into it. These are then removed by the fore pump after condensing the mercury in the condenser.
Hydrometer for determining the specific gravity of liquids. The instrument is floated in the liquid and the point on the scale in the stem coinciding with the suriace level of the liquid indicates the specific gravity compared with water. A thermometer in the lower portion indicates the temperature of the liquid at the same time. Usually the liquid is brought to some specified temperature before the specific gravity is determined.
44. Microchemical equipment. (E. B. Hg.)



FIGS 38–43 — CHEMICAL APPARATUS USED FOR ANALYSIS, AND SPECIAL APPARATUS

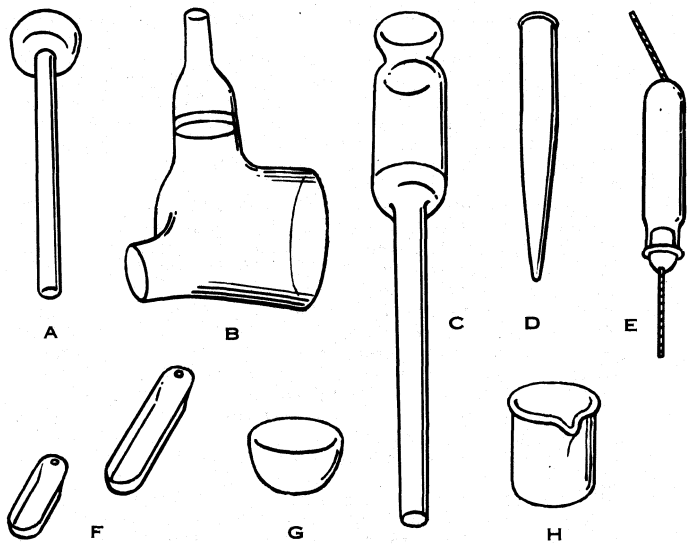


FIG. 44.—MICROCHEMICAL EQUIPMENT

Shown in approximately actual size are: (A) Porcelain filter stick for sucking liquids away from solids; (B) microfilter beaker; (C) sintered glass funnel; (D) microcentrifuge tube; (E) weighing tube (for protecting sample in boat from air during weighing); (F) microcombustion boats (small and medium size); (G) 1-ml. porcelain crucible; (H) 1-ml. glass beaker

CHEMICAL CYCLES IN NATURE. Living plants take inorganic (nonliving) substances from their surroundings and convert them into carbohydrates. proteins, fats and other compounds. These products are used by the plant either as energy sources or are built into the plant structure. Animals that eat the plants use the conversion products in similar ways. When the plants and animals die. decomposition, mostly by bacterial action, converts the carbohydrates and other organic materials back into basic raw materials. These are then available for use by new generations of plants. If these cyclic processes did not occur, life as it now exists on earth would become impossible after a relatively short time because the materials needed to support it would be tied up in unusable forms. These cycles come in all sizes, ranging from that occurring in a tiny lichen-encrusted depression on a rock to the largest of all—the one involving the whole earth. None of them, except the largest. is an entirely closed system; some, and often a large part. of the substances involved in each cycle come from outside the cycle and some are lost to other cycles. The most important of these exchanges occurs between the land and the ocean, the latter acting as a reservoir that holds a very large proportion of the inorganic (nonliving) substances.

Probably most of the chemical elements participate in these cycles, but information has been accumulated only on those that are the major components of plant and animal bodies; *i.e.,* hydrogen, oxygen, carbon, nitrogen and phosphorus (see separate articles on these elements). The first four commonly occur in volatile forms and can, therefore, escape from the ocean and be returned to land. Even so they spend a major part of the time in the ocean; on the average, a water molecule spends about 50.000 years in the ocean to each one spent on land and a carbon dioxide molecule spends about 120 years in the ocean to each one spent in the atmosphere. Phosphorus and metallic elements such as potassium and calcium do not form volatile compounds and consequently are largely lost to reuse by land plants and animals once they enter the ocean. Only $\frac{1}{200}$ of the phosphorus annually carried into the ocean by rivers is returned to land by the actions of men and other animals. By contrast, the water that flows from the land to the ocean — about 6.500 cu mi annually — is replaced each year by evaporation from the ocean surface.

These cycles would quickly come to a halt if the energy required to run them were not supplied by the sun. The sun's heat evaporates water and dissolved gases from the surface of the oceans, the land and bodies of fresh water, and provides energy for the

winds that move the water vapour and other gases until the water falls as rain, snow or dew, and the gases are used by plants, animals, bacteria or fungi, or are redissolved in water. The sun's light enables green plants and some bacteria, both on land and in the upper layers of the ocean. to carry out photosynthesis (*q.v.*), an energy-storing reaction that converts water, carbon dioxide and light energy into oxygen and energy-rich carbohydrates. It is estimated that each year about 80,000,000,000 tons of carbon dioxide are converted by land plants and about 600,000,000,000 tons by marine plants, mostly one-celled phytoplankton. (E. I. Rabinowitch. *Photosynthesis* and Related Processes, vol. i, ch. 1, 1945.) Respiration by the plants, by animals that eat the plants, by animals that eat the plant-eating animals, or by bacteria and fungi that decompose dead plants and animals then reverses the process, forming carbon dioxide and water from the carbohydrates and oxygen in a series of steps that release the energy in amounts suitable for use in life processes.

Connected with the carbon cycle and supplied with energy by it are a number of other cyclic processes, some of which form and decompose biologically important compounds containing nitrogen or phosphorus while others convert gaseous nitrogen into forms usable by plants. The fact that forests and meadows and the animals living in them persist for long periods of time in the same place when undisturbed by man and yet do not smother under dead leaves, grass or animal bodies suggests that most of these processes are approximately in balance in nature. See NITROGEN, FIXATION OF. (E. W. FA.)

CHEMICAL EQUILIBRIUM. A chemical reaction may, under appropriate conditions of temperature, pressure and concentration, proceed not to completion but to a state of balance between all the reactants and products. The incompleteness of the reaction is caused by the fact that the reaction is reversible; *i.e.*, by the fact that the products of the reaction in one direction, as soon as they begin to form, begin to react to produce the original reactants. A balance. called equilibrium, is attained when the two opposing reactions go on at equal rates; there is then no net change in the amounts of the substances involved. A change in temperature, pressure or concentration may temporarily upset the equality of the two rates so that one reaction gains over the other until equilibrium is again established.

It is not easy for a reader unfamiliar with chemistry to visualize simultaneous, opposing chemical reactions; so it is well to begin with a more "physical" equilibrium. that between a liquid and its vapour. The change from one to the other is quite reversible; liquids evaporate and vapours can be condensed to liquids. But if some liquid is introduced into a large, evacuated vessel. held at constant temperature, molecules rapidly pass from the liquid into vapour, until they reach a certain concentration, or pressure, at which the number evaporating per second per square centimetre of surface is just balanced by the number of vapour molecules being recaptured by the liquid per second per square centimetre. If some of the vapour is pumped out, the two rates are thrown temporarily out of balance; evaporation proceeds at the previous rate uhile condensation is reduced, but this difference of rates builds up the concentration of vapour till the balance is again restored. A rise in temperature brings about a new equilibrium. because the molecules are all made to move faster, making it easier for them to escape from their mutual attraction in the liquid and requiring a higher concentration of them in the vapour to restore equilibrium. The essential test for a state of equilibrium is the ability of the system to readjust so as to neutralize, so far as possible, the effect of the change. This general principle is known as the theorem of Le Chatelier. It applies not only to a physical equilibrium, such as that between liquid and vapour, but equally to a chemical equilibrium. such as that between calcium carbonate. $CaCO_3$, and its decomposition products. solid calcium oxide. CaO. and carbon dioxide gas, CO_2, the chemical equation for which is, $CaCO_3 = CaO + CO_2$. The reversibility of the reaction is proven on the one hand by the decomposition of limestone by heating in a lime kiln and, on the other, by the ability of CaO to absorb CO_2 at ordinary temperatures. The reversibility of a reaction is often indicated by writing double arrows with the equality sign. thus $\rightleftharpoons$, often abbreviated to $\rightleftharpoons$. These representations should not obscure the significance of the equality sign, which is the conservation of atoms and masses. The two reactions are complete under the respective conditions just stated, hut this reversibility indicates that there are intermediate conditions under which equilibrium is possible. The relation between temperature, *t*, in degrees centigrade, and equilibrium pressure, P, in atmospheres, for this particular equilibrium is as follows:

t	842	855	869	904	937
P	0.45	0.53	0.67	1.16	1.77

An equilibrium involving two or more visually detectable and mechanically separable phases, solid, liquid or gas, is called a heterogeneous equilibrium; one existing within a single phase, either liquid or gas, is a homogeneous equilibrium. As an example of the latter we may consider the partial ionization of acetic acid into charged ions, according to the equation, $HC_2H_3O_2 \rightleftharpoons H^+ + C_2H_3O_2^-$. If one gram-molecule, or mole, of the acid is dissolved in one litre of water, at 25° C., equilibrium is reached almost instantly with 0.0042 moles each of H^+ and $C_2H_3O_2^-$ and 0.9958 moles of un-ionized acid. If a little sodium acetate is added, which ionizes almost completely into Na^+ and $C_2H_3O_2^-$, the rate of reaction to the left is increased but the reaction to the right proceeds as before; consequently, the concentration of the H^+ is quickly reduced to such a value that the rates are again equal. Similarly, the addition of H^+ from another source, such as hydrochloric acid, would reduce the concentration of $C_2H_3O_2^-$ to a new equilibrium value. Dilution of the solution with water would diminish the rate of collision and recombination of the two ions until enough additional ions are formed to enable their rate of recombination again to equal their rate of formation. The fraction of the acid existing as ions is therefore increased by dilution.

These relations may be given an approximate quantitative formulation. The number of moles of acetic acid per litre decomposing per second into ions depends, at any one temperature, only on its concentration, which is customarily expressed by the formula in parentheses. The velocity of the reaction to the right, v_1, is $v_1 = k_1(HC_2H_3O_2)$ where k_1 is the constant of proportionality. The velocity of the reaction to the left. v_2, is similarly given by $v_2 = k_2 (H^+)(C_2H_3O_2^-)$. At equilibrium, $v_1 = v_2$; therefore $(H^+)(C_2H_3O_2^-)/(HC_2H_3O_2) = k_1/k_2 = K$, the equilibrium constant. Its value for acetic acid can be obtained from the set of equilibrium concentrations previously given, as 1.8×10^{-5}. This constant expresses the strength of the acid and is valid for any set of concentrations at 25° C. In a solution of 0.1 mole of acetic acid per litre, for example, $(H^+) = (C_2H_3O_2^-)$ and $(HC_2H_3O_2)$ is still approximately 0.1; therefore, $(H^+)^2 = 1.8 \times 10^{-6}$ and $(H^+) = 1.3 \times 10^{-3}$. Again, in a mixture of an equal number of moles of $HC_2H_3O_2$ and $NaC_2H_3O_2$, $(HC_2H_3O_2) = (C_2H_3O_2^-)$ and hence $(H^+) = 1.8 \times 10^{-5}$. We thus have the means, by altering the relative amounts of acetic acid and acetate ion, of establishing any desired acidity through a wide range.

The following examples illustrate equations for equilibrium constants corresponding to equations for chemical reactions.

$$2SO_3 = 2SO_2 + O_2 \text{ (all gases)}: \frac{(SO_2)^2(O_2)}{(SO_3)^2} = K$$

Since the concentration of a gas is proportional to its partial pressure in a gas mixture, this equilibrium may also be expressed in terms of partial pressures, $P^2_{SO_2} P_{O_2} / P^2_{SO_3} = K_p$.

$$CO_2 + C \text{ (solid)} = 2CO; \ (CO)^2/(CO_2) = K \text{ or } P^2_{CO}/P_{CO_2} = K_p$$

Note that the concentration of solid carbon is not susceptible to change and therefore need not be expressed in the equilibrium equation.

$$3Fe \text{ (solid)} + 4H_2O \text{ (gas)} = Fe_3O_4 \text{ (solid)} + 4H_2 \text{ (gas)}$$
$$P_{H_2}{}^4/P_{(H_2O)4} = K; \text{ or } P_{H_2}/P_{H_2O} = K'$$
$$Ca(OH)_2 \text{ (solid)} = Ca^{++} + 2OH^-; \ (Ca^{++})(OH^-)^2 = K$$

The effect of total pressure upon an equilibrium involving gases

is to favour the state with a smaller number of gas molecules. Thus, in the following equilibriums, $H_2+I_2=2HI$, $2SO_2+O_2=2SO_3$, $N_2+3H_2=2NH_3$, CO_2+C (solid) $=2CO$, increasing the total pressure would have no effect upon the first; it would shift the second to the right, the third still more to the right and the fourth to the left. Each effect can be calculated quantitatively from the expression for the equilibrium constant and the condition that the total pressure is the sum of the partial pressures.

The effect of temperature upon an equilibrium depends upon the heat absorbed or evolved when the reaction occurs under equilibrium conditions. If a vessel containing an equilibrium mixture is transferred from a lower to a higher temperature, heat will, of course, flow into the mixture, and it will shift the equilibrium in that direction which absorbs heat. In the reactions,

$$H^+ + OH^- = H_2O + 13.7 \text{ kg.cal.}$$
$$N_2 + 3H_2 = 2NH_3 + 24.0 \text{ kg.cal.}$$
$$H_2 + I_2 \text{ (gas)} = 2HI - 2.8 \text{ kg.cal.}$$

the equilibriums are shifted by rising temperature in favour of the substances on the left-hand side, in the first two cases. and in favour of more HI, in the third. The effect of changing temperature is given quantitatively by the approximate equation,

$$\log \frac{K_1}{K_2} = \frac{\Delta H}{4.575} \frac{(T_2 - T_1)}{(T_1 T_2)}$$

where ΔH is the heat, in calories, absorbed by the reaction as written, and K_2 and K_1 are the equilibrium constants at the respective temperatures. T_2 and T_1, on the Kelvin scale.

The Haber process for.the chemical utilization of the inert nitrogen of the air furnishes a striking instance of the practical fruits of the principles of equilibrium. The reaction, $N_2+3H_2=2NH_3$, does not take place at all when nitrogen and hydrogen are brought together under any ordinary conditions, whereas ammonia is easily decomposed on moderate heating. The principles of equilibrium teach that the equilibrium would be displaced in favour of ammonia by increasing pressure and lowering temperature. But lowering temperature normally decreases the velocity at which equilibrium is approached; so a compromise is necessary here, and a catalyst to increase speed is indicated. Proceeding in this way. Fritz Haber mas able to obtain a small equilibrium concentration of ammonia, from which he calculated the equilibrium constant and the effect of temperature thereon. With this knowledge the desirable conditions could be predicted for obtaining an industrially profitable equilibrium concentration of ammonia.

Catalysts have been developed which cause the reaction to proceed at reasonable speed at 500° C. assisted by pressures of the order of 100 atm.. pressures unprecedented in technical processes at the time of Haber's investigation. These high pressures also shift the equilibrium strongly in favour of ammonia since four molecules become two in the reaction. Even so, the conversion to ammonia in one contact with the catalyst is only about 10%, but by liquefying and removing this ammonia. and repassing the nitrogen and hydrogen, augmented. over the catalyst. the equilibrium amount is again obtained, and so on.

See THERMODYNAMICS. (J. H. HD.)

CHEMICAL INDUSTRY. The chemical industry is one of the great giants of the technological world—making products used in practically every aspect of life. From such ordinary raw materials as coal, salt, limestone, sulfur, air, water and petroleum, the chemical industry turns out a prodigious number of compounds that are essential to the operations of every other industry.

In size, the chemical and allied products industry was the fourth largest in the United States in the early 1960s, surpassed only by petroleum refining and its related industries, primary metals and transportation equipment.

Some chemicals, such as aspirin and baking soda, are familiar to nearly everyone, but many more are as far removed from the average consumer as is the factory from the department store. There are two reasons for this anomaly. In the first place, the chemical industry is its own best customer, converting many of its chemicals into "intermediates" or building blocks that it uses to produce such materials as dyes, drugs, explosives, flavourings and plastics. Secondly, myriads of chemicals enter the processing industries where they are utilized to make the thousands of mass-produced items. The distinction between the processing group, which uses chemicals as a means to make something else, and the chemical industry proper, which manufactures chemicals as end products, appears to be disappearing as the chemical industry continues to expand its boundaries in all directions. This trend toward a merging of the groups accelerated after World War II as many chemical manufacturers became producers of semifinished or consumer products such as man-made fibres, fabric coatings, detergents, etc.

In entering these new fields, some chemical companies became affiliated with processing companies. On the other hand, many processing companies became important chemical manufacturers and many suppliers of raw materials to the chemical industry are themselves becoming important chemical manufacturers. Typical is the increasing expansion of the petroleum refining companies into chemical products manufacture. Also in the chemical industry are food processors and manufacturers of light metals.

The result of all of this expansion has been the creation of an enormously complicated industry—with a talent for reducing everything but its own particular make-up to a precise mathematical formula. The chemical industry, which cannot be defined with scientific accuracy, means many different things depending upon how it is classified by the statisticians. In the United States, government officials, for purposes of convenience, have reduced it to a category called "chemicals and allied products." Establishments in this major group manufacture three general classes of products: (1) basic chemicals such as acids, alkalies, salts and organic chemicals; (2) chemical products to be used in further manufacture such as man-made fibres, plastics materials. crude animal and vegetable oils, dry colours and pigments; and (3) finished chemical products to be used for ultimate consumption, such as drugs, cosmetics and soaps, or to be used as materials or supplies in other industries, such as paints, fertilizers and explosives.

Under this classification, the chemical process industry includes companies that manufacture such allied products as drugs, soaps, paints, fertilizers, vegetable and animal oils and a number of miscellaneous related products. Excluded, however, are companies engaged in the production of iron and steel, in petroleum refining. and in the manufacture of pulp and paper, rubber products, leather products and glass. Omission of the latter categories does not mean. of course, as one authority has commented. "That their operations are any less 'chemical' in nature than those used in the manufacture of soap, paint and many other products officially classified within the chemical industry. Their exclusion has probably been due primarily to the combination of their empirical origin, large size, simple product structure and well-defined markets." (John H. Perry, *Chemical* Business Handbook, McGraw-Hill Book Company, Inc., New York, 1954.)

Grouth rate of the industry in 1940–60 was 7% per year, as compared with 3% for all industry. After World War II only one other industry, transportation equipment, exceeded chemicals in growth rate, according to statistics from the U.S. department of commerce.

Foundation of the Chemical Industry.— Regardless of how its operations are classified. or whether its sprawling plants shadow the Rhine or the Mississippi, the chemical industry has one great task: to take a relatively few fundamental raw materials and combine and recombine them into combinations and transformations of substances that are new and needed. In the chemical industry, this function is called synthesis and is understood to mean the building up of a compound for useful purposes by the union of simpler compounds or elements. Essentially, then. the industry depends upon the application of scientific principles for utilitarian purposes, and it is in the final analysis the offspring of chemistry and economics.

It was Nicolas Leblanc who united the two in the waning years of the 18th century nhen he set out deliberately to make soda ash (sodium carbonate) out of salt. Leblanc, of course, was not the

first to put chemicals to work in the service of man. Centuries before, the ancient Phoenicians, Egyptians and Chinese had experimented with chemical processes in carrying out their dyeing, leather tanning and glassmaking activities. Their work was really an art rather than a science, however, since the first great principles of chemistry were not to be discovered until hundreds of years later.

In fact, it was not until about Leblanc's time that the foundations of modern chemistry were laid by Antoine Lavoisier, Joseph Priestley and Henry Cavendish (*qq.v.*). All three were far greater chemists than Leblanc, but it is to him rather than to the more celebrated trio that the title of founder of the chemical industry belongs — and for a very important reason. For unlike the rest of the chemists of his period, Leblanc was determined to make a chemical discovery that would have commercial application. He is generally credited with being the first person to carry out successfully a deliberate plan to convert one or more chemical products into different products, keeping in mind not only the product desired but the economics of the process as well. This remains the aim of the modern chemical industry: to produce new and better products economically.

A prize of 12,000 fr. offered by the French Academy of Sciences to anyone who could work out a method for making cheap alkali led to Leblanc's accomplishment in 1790. Now widely recognized as the most important industrial chemical process of the 19th century, it involved the treatment of salt (sodium chloride) with sulfuric acid to obtain salt cake, or sodium sulfate. This salt cake was then roasted with limestone or chalk and coal to produce black ash, which consisted primarily of sodium carbonate and calcium sulfide. Leblanc dissolved the sodium carbonate with water and then crystallized it.

As a result of his efforts, Leblanc won a little fame but no lasting fortune. During the French Revolution, his patents and factory were confiscated. In addition, there is no record that he ever collected his prize money. Eventually, Napoleon restored his works but Leblanc was never able to raise the capital to reopen them. Destitute and despondent, he committed suicide in 1806.

After Leblanc's death, his process was neglected in France, but it became extremely important in England as a source of alkali for the soap and textile industries. With the growing demand for their product the soda ash producers' business became increasingly complicated. Starting out with a comparatively simple process, they soon learned one of the fundamental truths of the chemical industry — that the manufacture of chemicals is a little like walking — one step inevitably leads to another. Alkali manufacturers, since they require sulfuric acid in their operations, began to make their own acid by burning sulfur or pyrites. Those who used roasted pyrites usually relied on mixed sulfides of copper and iron, and from this it was fairly easy to make copper sulfate and ferrous sulfate.

Utilization of By-Products. — Eventually too, the soda ash makers learned how to utilize the by-products that resulted from their operations. Some of these chemicals, at first regarded as nuisances, in time became as important as the soda ash itself. One of these was hydrochloric (muriatic) acid, formed as a result of the reaction between the salt and sulfuric acid. In the beginning, it belched out of the alkali factory smokestacks as a foul-smelling gas that destroyed vegetation for miles around. In response to complaints from the irate citizenry, the alkali makers desperately sought a way to get rid of these objectionable fumes.

James Muspratt (1793–1886), the first Britisher to manufacture alkali on a large scale, constructed skyscraper chimneys — one almost 300 ft. high — in the futile hope that the vapours would drift away on the clouds. Finally, William Gossage found that the gas could be absorbed by passing it through towers packed with coke over which water trickled. This produced commercial hydrochloric acid and more difficulties because there was no great demand for this by-product. In fact, for awhile it was put in casks, carried out to sea and dumped overboard. Then it was found that the surplus hydrochloric acid could be oxidized with manganese dioxide to make chlorine, which could be combined with slaked lime to form bleaching powder. The reaction left behind a residue of manganese chloride, however, that had to be discarded until Walter Weldon (1832–85) invented a process that enabled manufacturers to recover the manganese and use it again, thereby reducing costs. Around the same time, Henry Deacon discovered a way to oxidize hydrochloric acid to chlorine without using manganese dioxide. Ultimately, a method for recovering the expensive sulfur from the mountains of alkali waste piled up during the last stage of the Leblanc process was also found.

Organic Chemicals. — As the British alkali producers gradually became manufacturers of most of the important "heavy chemicals" they laid the foundation for what is now called the inorganic branch of the chemical industry. The chemicals in this category are all derived, directly or indirectly, from the inanimate material of the earth's crust. In contrast to these materials, almost all of which stem from minerals, are the organic chemicals, so-named because in the early days of the industry they were all obtained from living organisms. From plants and animals come a wide assortment of organic substances including fibres, such as cotton and silk; drugs, such as quinine; acids, such as tartaric and citric; and even such natural plastics as rubber.

Although these natural organic compounds had been known to man for centuries, it was not realized until the 19th century that they all contain carbon as a constituent element. Further studies revealed that carbon is able to combine freely with itself to form long chains — some of them intricately branched — as well as rings. In addition, it was discovered that carbon could unite with other elements such as nitrogen, hydrogen, oxygen, sulfur, chlorine, bromine and iodine. 'Once these facts became part of scientific knowledge, chemists set to work to create their own substances using carbon as the basic building block. In the beginning, they were satisfied only to imitate nature; later, however, they learned how to make a vast number of new substances not found in any part of the animal or vegetable kingdoms.

William Henry Perkin (1838–1907) was the first to make one of these synthetic organic chemicals commercially. For his efforts, he was knighted in England and honoured by the rest of the world as the founder of the other great half of the chemical industry — the synthetic organic segment. At the time of this discovery in 1856, Perkin was 18 years of age and home on Easter vacation from the Royal College of Chemistry in London. Working in a make-shift laboratory fitted out in his father's house, he was trying to find a way to synthesize quinine. For his raw material, he chose coal tar, a heavy black liquid by-product of the gas works. It was a happy choice, for this material turned out to contain about a dozen primary products that chemists have been converting ever since into plastics, paints, perfumes, dyes, medicines, printing inks, building materials, weed killers and insecticides.

When Perkin set to work, however, little was known about coal tar except that it contained benzene. That much had been established by his teacher, the great A. W. von Hofmann, who had prepared aniline from benzene. But neither professor nor pupil had any reason to suspect the tremendous potentialities of either chemical until Perkin happened to treat a salt of aniline with potassium bichromate. Instead of obtaining the white crystals of quinine he was seeking, he found himself with an unpromising tarry black solution. Into it, for reasons which he was never able to explain, Perkin tossed a piece of silk and drew out a beautiful mauve-coloured cloth. He had made the first synthetic dye and laid the foundation for the great new field of pure and applied coal-tar chemistry. Withdrawing from college, Perkin set up a factory and by Dec. 1857 was supplying his colouring to silk dyers. Within a few years many more such new dyes were manufactured by the oxidation of aniline and other aromatic amines as factories sprang up all over Europe.

Despite all these discoveries, however, the structure of these dyes remained a mystery until Friedrich von Kekulé announced his theory of the benzene ring in 1865. Once this doctrine was formulated chemists understood exactly how the six atoms of carbon in the benzene molecule are linked together in a circle with an atom

of hydrogen attached to each. Using this concept as an architect would a blueprint, they were then able to build millions of new compounds.

Carl Graebe and Carl Liebermann were the first to apply this new structural principle to the dyestuff industry with their synthesis of alizarin from another coal-tar chemical, anthracene. Using natural alizarin, obtained from madder root, as their starting point they established its structure and then duplicated it synthetically in the laboratory in 1868. Within a few years, they had worked out an industrial process that soon drove the natural dye off the market. Adolph von Baeyer 30 years later figured out the molecular make-up of natural indigo, and later a process for its industrial synthesis was developed that produced a material that quickly took the place of the old plant dye.

As a result of Baeyer's discovery, the Badische Anilin und Soda Fabrik, which had spent $5,000,000 and 17 years in chemical research on this problem, gained a virtual monopoly, and Germany strengthened its standing as the world's dominant dyestuff producer—a position it held for more than 50 years. Unlike the rest of the world, Germany recognized the tremendous importance of these new rainbow dyes from the beginning and did its best to foster and encourage their production.

Instead of letting the valuable raw materials essential for their manufacture drift off in smoke from wasteful beehive ovens, Germany installed by-product coke ovens and recovered the essential coal-tar crudes. Thus it had a plentiful supply of benzene and a number of closely related "primaries" such as toluene, phenol, naphthalene and anthracene that it could use for making not only dyes but also hundreds of other valuable organic compounds. For example, when benzene is treated with sulfuric acid and then caustic soda it is converted to phenol, an intermediate for aspirin, methyl salicylate (oil of wintergreen) and phenol-formaldehyde plastics. Naphthalene when treated with air under special conditions gives phthalic anhydride, which can be combined with glycerin to make resins, the basis of many paints and surface coatings. When treated with other chemicals, phthalic anhydride forms polyesters, plastic materials used in boats, fishing rods and wall panels. Toluene can be converted into the intermediates mononitrotoluene and dinitrotoluene, and then into trinitrotoluene (TNT), the explosive. By means of another process, toluene can be made the starting point for the manufacture of saccharin.

Despite their versatility, these products were not considered important outside Germany until World War I. Then Great Britain. France and the United States realized how necessary these coal-tar crudes were for their economy—indeed for their survival—and they began a frantic effort to build up a full-scale organic chemical industry. Although handicapped by many difficulties in the beginning, this industry grew rapidly with the result that after World War II the United States greatly exceeded Germany as a producer of organic chemicals.

Petrochemical **Industry.**—Meanwhile, in their search for additional raw materials for organic chemical synthesis, chemists turned to petroleum and natural gas, giving rise to the petrochemical industry. Chemists had been interested in oil ever since Benjamin Silliman, the younger. had made the first careful and studied fractional distillation of oil about 1855. In the beginning, his process was used by others to obtain coal oil for lamps and thus save the world from the "threat of darkness" occasioned by the shortage of whale oil. Some time later the higher boiling fractions produced by Silliman's process were discovered to be useful as lubricants, and only about 40 or 50 years later was a lower fraction, gasoline, put to work in automobiles.

The increasing demand for gasoline led to the so-called catalytic or thermal cracking of petroleum, which yields light oils corresponding to gasoline and heavier oils and gases such as methane, ethane, ethylene, propane and propylene. These gases, first used for fuel or even wastefully burned as flares, proved to be an important source of chemical raw materials. Together with natural gas, which is essentially methane, they are the starting point for the production of a large number of compounds that comprise five major groups of end products: synthetic rubber, plastics, textiles, detergents and agricultural chemicals.

The chemical industry first utilized these hydrocarbons about 1920 when isopropyl alcohol was manufactured from cracking plant propylene. A few years later, commercial production of ethylene glycol was achieved using natural gas fractions as the starting material. Pioneer research on ethylene was done by G. O. Curme and his associates, who are generally credited with laying the foundations of the petrochemicals industry in the U.S., where all of the pioneering work was done.

The importance of petrochemicals increased enormously during World War II as shortages of many vital chemicals previously obtained from other sources became acute. As a result of this expansion, petroleum became an additional source of the important benzene, toluene and xylene, which previously had been obtained only from coal tar. Also of increasing significance in the petrochemicals industry was the use of methane as a basic material for the manufacture of methanol and ammonia and for the production of acetylene, which previously had been obtained exclusively from calcium carbide.

Because petroleum can be made to yield such an assortment of useful products its utilization as a source of raw materials for the chemical industry ranks along with Leblanc's process and Perkin's discovery as one of the great milestones in the history of industrial chemistry.

Solvay Process.—The development of the Solvay process for making alkali ranks as another important chemical landmark. Commonly referred to as the ammonia-soda process, it was first put into successful commercial operation in 1865 by Ernest Solvay, who started a plant at Couillet in Belgium.

Solvay's process operates on the following principles. Salt (sodium chloride) is treated with ammonia and carbon dioxide to form ammonium chloride and sodium bicarbonate. The sodium bicarbonate can be converted with heat into soda ash (sodium carbonate). Carbon dioxide lost during this reaction is recovered and used over again in the first step of the operation. The ammonium chloride can be heated with lime, yielding ammonia, which can be circulated back for reuse, and calcium chloride.

For some years after this process was introduced, it encountered stiff competition from the Leblanc method. Ultimately, however. the cheaper Solvay soda ash drove its rival off the market.

Electrolysis.—Another important development that proved of major significance in the chemical industry was the commercial application of electrolysis. This principle had been demonstrated in 1800, the same year that Alessandro Volta discovered the electric battery. Not long after that, several important discoveries were made that established electricity as a useful tool in the chemical industry. In 1886 Charles Martin Hall discovered the electrolytic process for producing aluminum from alumina (aluminum oxide) dissolved in molten cryolite. By 1900 several plants in the U.S. were producing caustic soda (sodium hydroxide), chlorine and hydrogen by electrolyzing salt. For a while the chlorine was converted with lime into bleaching powder in a manner reminiscent of the old Leblanc process, but in time chemists learned how to liquefy chlorine gas and ship it safely in cylinders.

Production of Sulfuric Acid.—During the same period that electrolysis won commercial acceptance, a new mining process was developed by Herman Frasch that freed sulfuric acid producers from their dependence upon Sicilian sulfur and other sulfur-bearing materials. In 1891 he figured out a way to bring to the surface the sulfur that lay 500 ft. underground in Louisiana. His process involved sinking three concentric pipes—one to carry superheated water down to melt the sulfur, another to blow in compressed air to force the sulfur out and the third to carry the melted sulfur to the surface. It worked perfectly and gave the industry a less costly and much more pure raw material.

Once Frasch sulfur became available, chemists set to work to develop a process that would take full advantage of its extraordinary purity (more than 99%). Out of their efforts came an improved and more economical contact process utilizing the first commercially successful vanadium catalyst. This produced sulfuric acid, the "pig iron of the chemical industry," much less expensively.

Haber Ammonia Process. — To assure a supply of saltpetre in the event that the Chilean nitrate deposits (the world's principal supply) should become exhausted, chemists attempted to find a way to take nitrogen from the air and to combine it with other elements to make useful compounds, in imitation of a process employed by certain nitrogen-fixing bacteria that live on the roots of leguminous plants. In 1908 a German, Fritz Haber (*q.v.*), developed a process that could be used anywhere that coal and water could be brought together economically.

Using a catalyst made mostly from iron and employing extremely high pressure and moderately high temperatures, he caused nitrogen from the air to combine with hydrogen in the ratio of one atom to three, producing ammonia. The ammonia may be used for the production of fertilizers, or it may be oxidized to nitric acid for explosives or the production of nitrates for use as fertilizers. It is also possible to convert it into urea, which is useful in making both fertilizers and urea-formaldehyde plastics.

Polymerization. — During this same period a Belgian chemist, Leo Baekeland, working in a New York laboratory, produced phenol-formaldehyde resins, considered to be the "first modern plastics." In making this new synthetic, he used a principle called polymerization by which simple molecules are linked in chains or rings to form giant molecules (polymers). Baekeland was the first to make successful use of polymerization commercially when he founded his own manufacturing company in 1910.

From a modest beginning that year, industrial plastics by the early 1960s were filling needs ranging from toys for children to structural materials for skyscrapers, from sheer fabrics to rocket nose cones. The plastics industry in the United States in 1958 turned out almost 4,500,000,000 lb. of products valued at approximately $2,000,000,000. The growth was attributed to the ability of the industry to engineer materials to meet specific needs, and to produce them at a cost that made their use feasible. (See PLASTICS.)

Development of Atomic Energy. — The chemical industry made important contributions to the development of atomic energy; industrial chemists, together with their colleagues in the universities, teamed up with physicists, engineers, military and governmental administrators to produce fissionable materials. The chemical industry's role in this group effort was a complex one, beginning with the mining of the ore and continuing through nearly every stage of the entire undertaking.

Through the use of organic phosphate, a practical way was found to extract uranium from ores that had been considered marginal. After initial processing, the uranium goes to chemical refineries where, through a series of complicated reactions, various impurities are removed and it is converted into uranium oxide powder — commonly called brown oxide. This in turn is converted through an industrial chemical process to green salt (uranium tetrafluoride), which may be used for one of two purposes. It can be converted into uranium hexafluoride and fed to gaseous diffusion plants where uranium-235 (present in 1 part in 140 of natural uranium) is concentrated; or, it can be reduced to uranium metal used in the reactors that produce plutonium. The plutonium is then separated from the parent uranium in chemical plants. The uranium-235 and plutonium may be fabricated into weapons, or put to work for peace.

Continuing its key role in the development of atomic energy, the chemical industry in the early 1960s was concerned with the production of certain materials for construction of nuclear reactors and associated equipment, of fuels for nuclear reactors, of radioisotopes for industrial and medicinal use and of radiation-resistant materials.

Fundamental Characteristics. — The result of all these developments was to produce an industry that has been credited with turning the 20th century into a veritable "chemical century." The chemical industry is, in a sense, a great creative dynamo that uses its energies to devise new processes and molecular motifs to serve industry better. In carrying out this task, it displays certain fundamental characteristics. The first of these is progressiveness: it is constantly seeking to improve old manufacturing techniques and to invent new ones. As a consequence, the chemical industry invests heavily in research and development. In this highly competitive industry, a vigorous research program to discover new products or processes or to improve present ones is essential to success.

One inevitable result of all this scientific investigation is rapid obsolescence of both plant and equipment. Often a process still in pilot plant stage will be made obsolete by one newly developed in the laboratory. Fortunately for the industry, it is flexible enough to keep pace with this ceaseless change.

This flexibility is a characteristic that the industry demonstrates over and over again. It can, for example, manufacture a particular product from completely different raw materials and by a variety of different methods. Ethanol, for example, may be produced by synthesis from petroleum ethylene or by fermentation of molasses. There are, for example, at least four processes in use for making phenol from benzene, and about ten processes for making acetic acid, starting with three raw materials.

This same versatility extends to the chemical manufacturing units themselves, making it possible, for instance, for a producer to convert a polygasoline plant in a relatively short time into a plant producing intermediates used in making alcohol for plasticizers or in manufacturing synthetic detergents such as sulfonated alkyl benzenes.

The variety of alternatives available to the industry, together with the extraordinary proliferation of products that it turns out, explains why the chemical industry is justly considered to be extremely complex. It is virtually impossible, as the Leblanc process demonstrates, for the chemical industry to make one product by itself. The necessity for finding uses for its "extras" provides the chemical industry with an ever-present challenge.

End Products. — In accepting this challenge, the chemical industry has become a contributor to all the basic fields of life including food, shelter, transportation, health and communication. By so doing, the industry has contributed immeasurably to a world-wide rising standard of living.

To help feed an expanding world population, the industry plays a role in all aspects of food from its production to its purity, properties, preparation, preservation, transportation and presentation. For crop farmers, it has developed whole new families of agricultural chemicals for killing weeds and insects and rebuilding the soil. For stock farmers, it has helped in developing the science of animal nutrition, and produces animal feed supplements, such as amino acids, synthetic vitamins, antibiotics and antioxidants, that promote animal health, quality and growth. For food processors, the industry learned how to manufacture flour improvers, synthetic vitamins, artificial sweetening agents, food preservatives and a variety of plastic films that have revolutionized the packaging of all food products.

To help clothe an expanding world population, the chemical industry discovered and produced the man-made fibres that have revolutionized the textile industry. No longer is there competition between man-made and natural fibres. Rather, the emphasis is on blending man-made and natural fibres so as to make the best use of all available materials for apparel, decorating and industrial service. Furthermore. chemists have discovered ways of modifying the natural fibres to produce new and improved materials. Fabrics, through chemical treatment, may be made resistant to shrinkage, water, wrinkles, sunlight and moths and other pests. The fabrics are, in short, engineered for the services they are expected to perform.

The industry also supplies materials that enable man to construct better houses and office buildings, and to furnish them more attractively. Plastic wall-paneling, draperies, table tops. furniture upholstery, long-lasting and easy-to-apply paints and stain-resistant enamels for appliances earned a respected place in the construction and decorating fields. And as polymer technology advanced from an art to a science, man learned to engineer synthetic materials for specific jobs: urethane foams for furniture cushioning; vinyl flooring to replace wood or marble tile; reinforced polyesters for furniture or for home swimming pools; plywood bonded with superstrong adhesives for subflooring, sidewalls

and roofing; resilient, moth-proof carpeting from man-made fibres; plastic insulation; and adhesives for prefabricated houses.

With the assistance of the chemical industry, the world moved faster and more surely from its horse-and-buggy era into the age of swift transportation and travel. Chemicals added to fuel and lubricants helped make engines work better and last longer. Truly synthetic lubricants, for specialized uses, became available. Synthetic rubbers, created from simple chemical compounds, were used for improved tires and other rubber products, while natural rubbers were improved by chemical additives and chemical treatments. Wear-resistant, colour-stable acrylic coatings imparted beauty to the automobile's exterior, and foam rubber cushions upholstered with plastic or man-made fibre fabrics added comfort and attractiveness to the interior. For aircraft, the chemical industry created fire-resistant hydraulic fluids, additives for fuels, lubricants and superstrong synthetic adhesives to replace rivets for some uses, and recovered magnesium from sea water for use as a lightweight structural material. And for the journey to outer space, the chemical industry engineered the materials—fuels, lubricants, plastics and ceramics, to name but a few—that can withstand the rigours of space travel.

As a result of the partnership between medicine and the pharmaceutical segment of the chemical industry, new drugs were discovered and developed to fight disease and lengthen life. Products that prevent disease include such vaccines as those for smallpox, typhoid, and, more recently, the Salk vaccine for poliomyelitis. Typical of drugs that cure disease are the sulfas and the antibiotics. Chemical products used to control illness and promote health are the hormones, such as cortisone and hydrocortisone, antihistamines (for control of allergies), psychosedatives (popularly known as tranquilizers) to control some mental disorders, hypoglycemic agents to reduce the high sugar level associated with diabetes and diuretics, for treating some circulatory or kidney disorders. In the early 1960s pharmaceutical research was focused strongly on virus-caused diseases and on cancer.

Such fields as publishing, telephony, telegraphy, radio, television, electronic computing and photography could not exist without the products of the chemical industry. Pen and ink, paper and pencil, wires and cables, sound recording and videotape, transistors and diodes, all depend upon one or more essential chemicals. And the past is but a prelude to the future: as new needs arise, the chemical industry, servant of all other industries, will supply the materials to meet these needs.

CHEMICAL WARFARE. Chemistry has affected military science throughout recorded history. It was not, however, until the 20th century that chemical warfare in the modern sense of the term became a distinct feature of military operations. Modem chemical warfare represents essentially the application of chemical energy in military action, in contrast to physical energy as represented by the impact of bullets or the shock of explosives. The substances employed in chemical warfare are known as chemical agents. Those that react directly on the human body are called war gases. A second group of agents are smokes that are useful in obscuring the vision of the enemy. Incendiaries or fire producers comprise a third group.

In each case the desired effect is achieved by chemical reactions that take place after the appropriate agent has been released to atmospheric conditions. It is to be noted that these reactions are not necessarily instantaneous, as is the case when firearms or explosives are employed; chemical warfare agents may act slowly and continue to be effective for extended periods of time.

Modern chemical warfare is a product of industrial chemistry. Most of the chemicals used in manufacturing chemical warfare agents have been known for many years, some of them for centuries. To use certain of these chemicals (as, for example, chlorine) for the production of chemical warfare agents is to compete with the vital needs of industry. It has been only in relatively recent years that the chemical industries of the industrial nations have developed adequate production capacities to provide significant quantities of these basic chemicals for military use, as well as to meet the needs of industry.

HISTORY

The application of chemical warfare really began before recorded history with the use of fire, smoke and noxious gases to overcome an opponent. History records that a highly combustible mixture of chemicals called Greek fire (*q.v.*), invented about 670 A.D., was used as an incendiary in land and sea warfare for many centuries—as late as the middle ages. For many years, until the late 19th century, the American Indians made effective use of incendiary arrows in attacks on white settlers. Smoke was used by the forces of King Charles XII of Sweden in crossing the Dvina river (1701). The observation of the opposing Polish-Saxon army was obscured by burning large quantities of damp straw. During the Peloponnesian War between Sparta and Athens (431–404 B.C.) burning pitch and sulfur a-ere used to produce suffocating gases. At the siege of Sevastopol in the Crimean War, Lord Dundonald proposed (1855) the use of burning sulfur on a large scale under favourable wind conditions. The British government, however, declined to permit this method of warfare. Similarly, during the American Civil War, it was proposed (1862), and disapproved by the U.S. government, that artillery shells containing chlorine be employed by the Union forces.

The science of chemistry advanced rapidly during the 18th and 19th centuries, and the use of toxic substances in war was foreseen and considered at The Hague International Peace conference of 1899. At this conference a resolution was offered "to abstain from the use of all projectiles, the object of which is the diffusion of asphyxiating or deleterious gases," on the grounds that this method of warfare was inhumane. The United States did not support the resolution, principally because the inhumane aspects of this type of warfare were not clearly established. A further reason offered was that such restrictions to inventiveness were not of themselves conducive to world peace. The other great powers supported the resolution, however, except that Great Britain's vote was contingent upon unanimous acceptance.

World War I.—Use of chemicals as weapons during World War I was logical because the principal combatant nations were highly developed scientifically and industrially. A stalemate had been reached when both sides entrenched themselves so firmly that advance was impracticable without terrific losses. Means were sought to restore open warfare. At the outbreak of the war, none of the combatant nations was prepared to use or defend itself against chemicals.

The introduction of gas as an effective weapon in modem warfare actually dates from April 22, 1915, when the Germans launched a cylinder attack with chlorine against the Allied position in the Ypres salient where the British and French lines joined. Although intelligence reports had given warnings of an impending attack, little credence was given to them by the Allies. The attack came as a complete surprise to unprotected troops; its success was so far beyond German expectations that adequate reserves to exploit the breakthrough for a decisive stroke had not been provided. Within a few days Allied troops were equipped with pads of cotton dipped in a chemical solution and tied over the nose and mouth. These were soon followed by a crude form of respirator (protective mask) which was continually improved throughout the war both for comfort and efficiency. As protec-

tion was obtained against one chemical, the offense sought for and introduced new agents. These frequently required radical changes in the mask. Since cloud gas attacks were launched by releasing the gas from cylinders in friendly territory and allowing it to drift to the enemy, the users were dependent on favourable wind conditions and were limited in the type of agents which could be used successfully. Gas-filled projectiles soon appeared on the battlefield and an extensive and ever-increasing use of gas-filled artillery, mortar and projector shells occurred from 1916 to the end of the war.

With the Germans taking the lead, many varieties of war gas were introduced on the battlefields. In July 1917 the Germans began using mustard gas. which caused severe, slow-healing burns on the skin and damage to the respiratory tract. It was difficult to provide effective protection against this agent, which accounted for the majority of gas casualties. Next to mustard gas, chlorine and chlorine-phosgene mixtures were the greatest producers of gas casualties.

The number of gas casualties as compared to casualties from other means (bullets, high explosives, disease, etc.) increased in the last months of the war, although deaths among gas casualties were few. For example, in the Somme offensive against the British and French (March 1918) the Germans conducted a ten-day artillery bombardment (Ypres-San Quentin area) in which they used over 500,000 mustard gas shells. Gas casualties produced in this bombardment alone totaled over 7,000, but only 87 deaths resulted directly from gas. Also, the American expeditionary forces (A.E.F.), who participated as an organized force during the last nine months of the war, sustained nearly 27% of their total casualties from gas, yet only 2% of these casualties died from the effects of gas. In contrast, 26% of the total A.E.F. nongas casualties resulted in death.

Both sides had plans ready for increased chemical warfare activity in 1919. had the war continued. The British, for example, planned on loading 20% to 30% of all types of artillery shells with toxic chemicals, and the German artillery shell program provided for up to 50% gas ammunition.

Post-World War I.—In the field of international agreements, the subject of toxic chemical warfare was considered by the League of Nations, with inconclusive results, on two principal occasions: the Geneva Traffic in Arms conference (1925) and the General Disarmament conference (1932–34). (See DISARMAMENT.)

All major world powers maintained chemical warfare research and development facilities after World War I. Between 1918 and the middle 1930s a limited quantity of defensive equipment for military personnel, principally protective masks, and a limited quantity of chemical warfare munitions were manufactured. Chemical warfare preparedness of the major powers, along with other military preparedness measures, was accelerated during the 1930s because of the unrest throughout the world, typified by the warfare in China, Ethiopia and Spain. As World War II approached, civil defense measures of the major powers, particularly the United Kingdom, included means of passive defense against chemical attack.

During World War II and the Korean conflict there was considerable military use of nontoxic chemical agents; *i.e.,* smokes and incendiaries. Smoke was disseminated on land and sea and from the air by devices ranging from burning-type smoke pots to aircraft spray tanks. Incendiary materials were used in a variety of bombs. grenades and flame-throwing devices.

During the entire period from the end of World War I to the end of hostilities in Korea only two instances of the use of toxic chemicals in warfare were recorded. These were by the Italians against the Abyssinians (1935–36) and by the Japanese against the Chinese (1937–42). In both cases blister gases were used. The Italian use of mustard gas in aircraft spray and aerial bombs was reported to be highly effective against the unprotected Abyssinians. A particularly successful use of mustard gas by the Italians occurred near Makale. Aby. (Jan. 1936). Within four days one of the finest armies of Haile Selassie lost its effectiveness as a fighting unit. The Japanese used both gas shells and gas bombs. As in the case of the Abyssinians, the Chinese had no protective devices to employ. Although the Japanese use of gas was reported with frequency. in no case was it employed on a grand scale. The most effective attack occurred when quantities of gas-filled artillery shells were fired on Ichang, a town on the Yangtze from which the Chinese had succeeded in driving the Japanese (Oct. 1941). Relief of the hard-pressed Japanese forces resulted, with the Chinese withdrawing along the entire Ichang front. A strong protest and a threat of "retaliation in kind and in full measure," announced by Pres. Franklin D. Roosevelt to the Japanese government (June 5, 1942), were instrumental in preventing recurrence of these incidents during the remainder of the fighting.

World War II and Korean War.—Throughout World War II the Allies maintained a policy of using toxic chemicals in retaliation only. President Roosevelt's 1942 pronouncement to the Japanese was followed (June 8, 1943) by a statement that "Any use of gas by any Axis power. . . will immediately be followed by the fullest retaliation upon . . . military objectives throughout the whole extent of such Axis country." Prime Minister Winston Churchill issued similar warnings to the Axis powers. Preparation for gas warfare, however, was not neglected by either side. The Germans. in particular, were well prepared at the outset of the war. Their failure to employ gas can be attributed in part simply to a policy not to use it except in retaliation; in part to their awareness of Allied readiness, offensively and defensively, for gas warfare; and in part to the fact that it was unnecessary, militarily, for them to use gas at the outset of the war. Later, when situations more suitable for the use of gas arose, Germany had lost aerial supremacy. At this time Germany stood to lose on the strategic side any advantage that might have been gained tactically by the use of gas. To the German high command there was obviously no profit in releasing gas on the beaches of Normandy or Anzio if this would mean a retaliatory showering of toxic chemicals on German cities, already hard pressed by Allied bombings. Perhaps the most significant development in chemical warfare occurred during World War II with the German discovery of a new series of chemical agents called nerve gases. These agents (called Tabun, Sarin and Soman by the Germans) were found to be much more toxic than any previously discovered, and vastly more toxic than World War I agents. Although the Germans had some of these agents in limited production at the close of World War II, none was used during the conflict.

Nor was poison gas used during the Korean war of the early 1950s. But it was not considered an obsolete weapon on that account. Because of the giant strides made in means of delivering agents to the target, and because of the marked increase in toxicity of agents, gas was still regarded as a powerful instrument, useful particularly when material destruction is not desired or when the enemy is dug in too firmly even for nuclear weapons to dislodge him.

CHEMICAL AGENTS

The term gas is applied to those chemical agents used in war which, by ordinary and direct chemical action, produce a toxic or powerful irritant effect on the human body. Solids, liquids or true gases may be so employed; however, in their actual use in the battle area, the solid or liquid is converted by normal or artificial volatilization into a true gas or is disseminated as minute solid or liquid particles called aerosols. Irritant smokes are types of aerosols included under the term gas because their principal use is for their physiological effect.

Classifications.—From the military viewpoint the most important classifications of chemical agents are in accordance with (1) physiological effect; (2) persistency; and (3) tactical use.

Physiological effect classifies the chemical according to its primary action on the human body even though it may produce other secondary effects. The severity of effect is roughly proportional to the concentration (amount present in a unit volume of air) and the time of exposure.

Choking gases (lung irritants) act on the respiratory system and are often lethal. When breathed, they irritate and inflame the interior portion of the bronchial tubes and lungs, cause coughing, impede breathing and, in severe cases, acute pulmonary edema

will result. Chlorine, phosgene and diphosgene are examples.

Blister gases (vesicants) attack any part of the body with which the liquid or vapour comes in contact, especially moistened parts. They are absorbed or dissolved on exterior or interior parts of the body, followed by production of inflammation. burns and destruction of tissue. There is no immediate pain and effect is delayed for some period after exposure. Protection against this class of agents is very difficult because of their insidious action. Examples are mustard gas, lewisite and ethyldichlorarsine.

Sneeze gases (sternutators or irritant smokes) are disseminated into the air as minute solid or liquid particles which, if inhaled. cause sneezing. intense pain in the nose, throat and chest followed by violent nausea, headache, mental depression and physical weakness. No fatal cases have been recorded from this class; effect. although severe, is temporary, lasting about 12 hours. The charcoal and soda lime mixture of the gas mask canister will not remove these small particles from the air. A most efficient mechanical filter is necessary to give protection. Diphenylaminechlorarsine, an aromatic arsenical derivative, is an example of a sneeze gas.

Tear gases (lachrymators) irritate the mucous membrane around the eyes, causing intense smarting and a profuse flow of tears with resultant hampering of vision. Effect from concentrations in the field is only temporary, recovery being complete within a few minutes after removal from the contaminated area. Chloracetophenone, bromobenzylcyanide and xylyl bromide are examples.

Blood gases (systemic poisons) directly affect the heart action or nerve reflexes, or interfere with absorption and assimilation of oxygen by the body. Carbon monoxide and hydrocyanic acid, which pertain to this class, have never been effectively used in war because they are lighter than air and do not remain for long on a given ground area.

Nerve gases inhibit the normal action of the body enzyme, cholinesterase, thereby causing an accumulation of toxic amounts of acetylcholine. This leads to continual stimulation of the parasympathetic nerve system. The vapours. when inhaled, may cause nausea, vomiting and diarrhea; these effects may be folloaed by muscular twitching and convulsions. Even in low concentrations the vapours cause eye pupils to contract; vision becomes difficult and headache may result. After short exposure a sense of tightness in the chest may be noticed. Small amounts of liquid nerve gas on the skin may cause salivation and a twitching of the affected area. Severe cases of nerve gas poisoning rapidly result in convulsions, coma and—unless promptly treated—death.

The persistency of a chemical agent is determined by the length of time it will maintain an effective concentration without being renewed. Chemicals that remain effective for longer than ten minutes after release in the open are defined as persistent. Usually dispersed in the liquid state, persistent agents contaminate the ground on which they are released and continue to give off dangerous vapour for long periods. Nonpersistent gases are those whose effectiveness in the open continues for less than ten minutes. They vaporize rapidly, forming concentrated clouds that drift with the wind, increasing in size but becoming diluted in gas content until they finally disappear.

Tactical classification, which is influenced by the persistency, is based on the primary military objective for which any particular chemical is used in the field. War gases are thus classified as casualty or harassing agents; smokes as screening agents; and the various fire producers as incendiaries.

Chemical Agents Described.—No attempt will be made to enumerate all of the chemical agents that might be used in war. Many thousands of compounds have been thoroughly studied, but only a relatively few have been selected for actual development and test under field conditions. Continued effort undoubtedly will result in new chemical agents or better ways to produce those already known.

To be useful as a chemical warfare agent. a material must meet certain requirements. It must give effective physiological action, screening power or incendiary action. It must be stable in storage and resistant to the effects of moisture. It must be economical to manufacture from easily procurable, nonstrategic raw materials. It must be safe to handle, transport and load in munitions, and must not have any corrosive effect on ordinary steel. It must be capable of dissemination in effective quantities under field conditions. And, in the case of a gas, it must be heavier than air, readily compressible to the liquid state and easily vaporized when released. Brief descriptions of a few chemical agents follow.

Phosgene under ordinary conditions is a colourless, nonpersistent gas with an odour varyingly described as a new-mown hay, green corn or green apples. Tactically, it is classified as a casualty agent. At low temperatures it is a clear, colourless, mobile liquid, which boils at 8.3° C. Under ordinary summer conditions, it will disappear from a given locality about as fast as the wind moves. Even in winter it evaporates rapidly. In a light wind an effective concentration of phosgene can readily be produced. It is used commercially for dye manufacture. During World War I it was first employed by Germany in Dec. 1915, in a cloud gas attack from cylinders.

Mustard gas is a compound of carbon, hydrogen, sulfur and chlorine. It should not be confused with the true natural mustard oil or the artificial compounds having similar properties. It was because of its sharp pungent odour and vesicant properties, which resembled but greatly exceeded those of natural mustard oil, that British soldiers first called it mustard gas. The commercial product is a heavy oily liquid of dark colour and in low concentrations has the distinct odour of garlic or horseradish. This product freezes at about 10° C. It is a persistent vesicant agent that is also very effective as a lung irritant. In vapour form, after prolonged exposure, it attacks the whole respiratory system producing inflammation of the trachea and bronchi with necrosis of the mucous membrane and development of secondary bronchitis or bronchopneumonia. Upon slight contact with the liquid it is absorbed in the skin and produces serious burns. First employed by Germany at Ypres in July 1917, it was thereafter known to the French as Ypérite. It hydrolizes slowly and may be neutralized by intimate mixture with bleaching powder, steam or gaseous chlorine.

The nerve gas Tabun is a colourless to brownish liquid with a low freeing point, 49° C. For all practical purposes it is odourless. It is typical of the nerve gases in that it is a quick-acting casualty gas that causes its effects on man through the respiratory tract or through the skin. In the latter case. a small drop absorbed through the skin may cause death within 15 minutes, unless appropriate first-aid treatment is quickly administered. Unlike the effect of blister gases no harm is caused to the surface of the skin by contact with the liquid agent.

Hydrocyanic acid is a paralysant that acts on the central nervous system to produce quick death. It has a slight odour, resembling that of bitter almonds. This agent, long known as one of the deadliest of compounds, was used in artillery shells during 1914–18. However, its usefulness was limited, principally due to the rapid dissipation of the agent in the field because of its high volatility. Somewhat better success in building up effective field concentrations may be obtained by delivering the agent to the target in gas bombs of large volume; when this is done, a phenomenon of cloud cooling occurs, permitting a nonpersistent gas cloud to remain in the target area for several minutes.

Diphenylaminechlorarsine, better known as adamsite, is representative of the large group of irritant smokes which may be used in war. Physically, in pure form it is a bright canary-yellow crystalline solid. Commercially, it is produced in a dark green or sometimes brownish colour. In its solid state it is almost odourless, but when dispersed as an irritant smoke, a hazy yellow cloud is formed that has a smoky odour. The first symptoms are usually a burning sensation in the nose and throat. Adamsite is classified as a nonpersistent harassing agent, but as such is extremely potent because very small concentrations with a brief period of exposure will prove effective. The headache, nausea and vomiting which it causes, followed by physical debility, render a person practically helpless. Effective use of the irritant smokes is largely dependent on penetration of the filtering device used with the gas mask.

White phosphorus, a pale yellowish, translucent crystalline solid of waxy consistency, is very active chemically and combines readily with oxygen. Unless protected from air it will burst spontaneously into flame. White phosphorus can be loaded into shells. bombs or grenades. When the bursting charge explodes the solid phosphorus is broken into small fragments which are scattered in the air. The heat of explosion assists their immediate ignition. forming a cloud of phosphorus pentoxide. This smoke has the highest known obscuring power, yet is harmless when breathed. Fragments of considerable size are scattered about and continue to burn for some time, thus prolonging the emission of smoke. In addition. white phosphorus has limited incendiary value against readily combustible matter. Physiologically it may be classed as a casualty agent, since its ignited particles cause painful flesh burns that heal very slowly. Although primarily used for smoke production within the enemy lines, white phosphorus is also a formidable weapon against machine gun nests or troop concentrations.

FS, a mixture of about 55% sulfur trioxide and about 45% chlorosulfonic acid. by weight, is an excellent cheap liquid smoke for release from containers or for dispersion from airplanes.

Metal incendiaries include those consisting of magnesium, in various forms, and powdered aluminum mixed with powdered zinc and iron oxides. Metal incendiaries were much used by the Germans against the United Kingdom in the early part of World War II and by the Allies in air raids against Japan in the latter stages of the war. Typical oil incendiaries are mixtures of gasoline with heavier oils, or with an aluminum soap thickener. The latter incendiary mixture (commonly called Napalm) saw much effective use during World War II and the Korean conflict in tank and portable flame throwers, as well as in the wing-tank type fire bombs, dropped principally from fighter-bomber aircraft. (See also FLAME THROWER; INCENDIARY MIXTURES; NAPALM.)

The table briefly summarizes characteristics of some important chemical agents used in war.

Characteristics of Some Important Training, Toxic and Riot Control Chemical Agents

Class	Common and chemical name	Physical state at 68° F. and 760 mm pressure	Physiological effect	Rate of action	Persistency*	Odour
Choking gas	Phosgene (carbonyl chloride)	Colouriess gas	Affects lungs and results in damage to the capillaries. Causes edema of the lungs (air cells become so flooded that the victim dies of oxygen deficiency)	Immediate to 3 hr.	Nonpersistent	New-mown hay, green corn
Choking gas	Diphosgene (trichloromethyl chloroformate)	Colourless liquid	Same as for phosgene	Usually delayed 3 hr. or more	Moderately persistent	New-mown hay, green corn
Blister gas	Distilled mustard [bis(2-chloroethyl) sulfide]	Colourless to pale yellow liquid	Blisters, destroys tissue, injures blood vessels. Conjunctivitis (inflammation) of eyes. Erythema (reddening of skin). Inflammatory reaction of nose, throat, trachea, bronchi and lung tissue	Delayed usually 4 to 6 hr. but periods as late as 24 hr or more have been observed	Highly persistent	Garlic or horseradish
Blister gas	Nitrogen mustard [methyl bis (β-chloroethyl) amine hydrochloride]	Dark liquid	Irritates eyes in dosages which do not damage skin or respiratory tract. Erythema (reddening oi the skin). Blisters in erythematous areas. Affects respiratory tract. Bronchopneumonia may appear aiter first 24 hr. Following ingestion or systemic absorption, causes injury to intestinal tract.	Delayed 12 hr. or longer.	Persistent	Fishy or musty
Blister gas	Lewisite [dichloro(2-chlorovinyl)-arsine]	Dark oily liquid	Effects similar to mustard gas and in addition acts as a systemic poison, causing pulmonary edema, diarrhea, restlessness, weakness, subnormal temperatures and low blood pressure.	Immediate irritation, delayed blistering	Persistent	Geranium
Nerve gas	Tabun (cyanodimethylaminoethoxyphosphine oxide)	Colourless to brown liquid	Inhalation produces nausea, vomiting and diarrhea followed by muscular twitching and convulsions. Even low concentration causes eye pupils to contract. Liquid on skin penetrates very rapidly. Primary physiological action is on the sympathetic nervous system causing a vasoparesis.	Immediate to 1S min.	Moderately persistent to persistent	None when pure; otherwise faintly fruity
Nerve gas	Sarin (fluoroisopropoxymethylphosphine oxide)	Colourless liquid	Same as ior Tabun	Immediate to 15 min	Nonpersistent to slightly persistent	None when pure
Nerve gas	Soman (fluoromethylpinacolyloxyphosphine oxide)	Colourless liquid	Same as ior Tabun but Soman acts faster and in lower concentrations. In equal concentrations Soman produces much more severe effects.	Immediate to 1S min.	Persistent	Fruity; with impurities, odour of camphor
Training agent	Chlorine	Greenish-yellow gas	Powerful irritant, first on upper and then on lower respiratory tract. Also irritates eyes..	Immediate	Nonpersistent	Pungent, such as bleaching powder
Blood gas	Hydrogen cyanide	Colourless gas or liquid	Interferes with utilization oi oxygen by the body tissue or hemoglobin. Also poisons the central nervous system.	Immediate to 15 min.	~persistent	Slight resembling bitter almonds
Blood gas	Cyanogen chloride	Colourless gas	Similar to action of hydrogen cyanide.	Immediate	Nonpersistent	Irritating and lachrymatory properties; conceals odours
Blood gas	Arsine (arsenic trihydride)	Colourless gas	Interferes with functioning of the blood and damages liver and kidneys.	Delayed from 2 hr. to 11 days	Nonpersistent	Practically odourless when pure; otherwise garliclike (metallic taste)
Vomiting gas	Adamsite idiphenylaminechlor arsine)	Yellow to green solid	In progressive order: Irritation of the eyes and mucous membranes, viscous discharge from the nose, sneezing, coughing, severe headache, acute pains and tightness oi chest, nausea and vomiting.	1 min.	Nonpersistent	None
Tear gas	Chloracetophenone	Solid	Lachrymates. Also irritates upper respiratory passages. In high concentration, irritates the skin, especially on moist parts of the body.	Immediate	Nonpersistent	Apple blossoms

*Length of time an agent normally remains effective in the open at the point of dispersion. A nonpersistent agent is one whose effectiveness dissipates in 10 min. or less.

Dispersion of Agents.—Chemical warfare agents are dispersed either as liquids, aerosols or gas clouds. The agents may be released upon an area rather than upon a pin-point target. Once released, the agents travel with the air and wind currents, gradually diffusing to a point of noneffectiveness. This diffusion process varies with the agent employed and with temperature, wind speeds, terrain and other considerations. Once released in a target area, the behaviour and effectiveness of chemical warfare agents are greatly dependent upon the weather. The more numerous and larger the air currents, the more widely the chemical clouds are dispersed. Under more stable meteorological conditions; *i.e.,* low wind speed and slight turbulence, chemical clouds remain near the ground and may travel for long distances before being dissipated. Under less favourable conditions more munitions per target area are required to achieve the tactical result desired. Large area attacks can be made with wind speeds up to 12–15 m.p.h., whereas small area attacks are generally not effective in wind speeds of over 6 m.p.h. The degree to which temperature variations limit the tactical use of chemical agents is dependent on the physical properties of the particular agent; generally, however, the higher the temperature the less effective is a given quantity of any agent. Humidity does not seriously decrease the effectiveness of most war gases. High humidity coupled with high temperature increases the effectiveness of some blister gases such as the mustards. Rainfall reduces the effectiveness of chemical clouds and may even cause them to be ineffective. Heavy rainfall also will wash away persistent liquid agents. Snow reduces the evaporation of persistent agents so that little vapour hazard exists, but contact with the liquid still presents a hazard. When the snow melts, the vapour hazard of the persistent liquid agents reappears. The behaviour and effectiveness of chemical agents are affected by the contour and conditions of the surface of the ground and by the presence or absence of trees and vegetation.

Military Application.—Chemical warfare agents may be employed in either tactical or strategic operations. Chemical munitions differ in several important respects from conventional high explosive munitions and atomic or thermonuclear devices. The most important properties of chemical warfare attack are selectivity, persistency, area coverage, freedom of trajectory pattern and mobility. The effects of chemical agents range from harassment of personnel to instantaneous lethal effect. Chemical agents also permit interdicting and obscuring target areas. The flame and incendiary agents are also capable of materiél destruction. The highly persistent agents can be employed to deny terrain to the enemy unless he is willing to absorb a high number of casualties by crossing or occupying the contaminated area. The wide range of agent-munition combinations permits a range of effectiveness in the area of release from a few minutes' duration to indefinite periods ranging into days and months. Compared with conventional high explosives, which act instantaneously at the impact point, chemical munitions afford a distinctly wider range of effectiveness. Conventional, atomic or thermonuclear munitions have a definite radius of effectiveness. Chemical agents, on the other hand, are effective not only in the area of release but also for considerable distances downwind from the place of release. Chemical agents, moreover, flow with the air currents. Thus, being independent of trajectory in the area of release, they will penetrate defenses that normally give full protection from the effects of other weapons systems. The mobility of toxic gas clouds may be from 5 to 25 times as large as the area of release.

PROTECTION

Having in mind the three distinct types of agents employed in chemical warfare, protection is of interest principally against war gases, since nontoxic smokes are relatively harmless (except in confined spaces) and protection against incendiary agents is limited to measures customarily followed in fire fighting. In considering protection against war gases, it is necessary to distinguish between the direct effect on the respiratory organs and the effect on the body caused by contact of the agent with the body surface.

For protection against lung irritants, of which phosgene is typical, the gas mask is the primary protective device. The principle on which the military mask is based is that of filtering out or neutralizing noxious substances that may be present. in inspired air. In order to accomplish this, air before it reaches the lungs must first pass through a filtering element containing materials that act mechanically or physically or react chemically with the toxic agents. For this reason a characteristic feature of the protective mask (from which the original U.S. designation "gas mask" was derived) is a tight-fitting facepiece so designed as to prevent air from reaching the respiratory organs from any direction except through the filter. (*See* figure.) Since the mask must necessarily cover the entire face in order conveniently to permit normal respiration, it incidentally affords protection against lachrymators which, when the eyes are unprotected, cause eye irritation.

The principal materials used in protective mask filters (or canisters) are charcoal and soda lime. Charcoal absorbs and holds a relatively large volume of poisonous gases. Soda lime supplements the action of charcoal by neutralizing any toxic materials that might eventually be released by the charcoal and otherwise would pass to the lungs with incoming air. Having a proper balance of charcoal and soda lime the gas mask may be worn with safety even after it has been used in concentrations of war gases.

Besides soda lime and charcoal, masks are sometimes provided with some means of mechanical filtration to strain out finely divided solid particles (toxic smokes), which severely irritate the nasal passages. The life of a gas mask filter depends on two factors: the length of time it has been exposed in gas attacks and the concentrations of gas that have been encountered. Military masks generally remain serviceable even after use in several gas operations. When the capacity of the filter is approaching exhaustion a slight odour of gas can be detected. This indicates that replacement with a fresh filter is necessary.

Although it is possible to design filtering devices that will neutralize any toxic substance, it is not feasible to combine in one mask protection against all of them. Military masks are accordingly constructed with a view to counteracting the chemicals that are thought most likely to be used in war. The introduction of new types of military gases in the future will undoubtedly be followed by appropriate modification of masks now considered standard. For safeguarding personnel who must perform functions which are extremely difficult to accomplish while wearing the mask (*e.g.,* eating) gasproof installations may be provided. These are known as gas shelters or collective protectors. A typical installation is equipped with a filter similar in principle to that used in the protective mask, although much larger. Incoming air is drawn through this filter and is thus purified; other outside air is excluded, so that all air within the enclosure may be inhaled safely.

Protection by filtration applies only to those chemical warfare agents that are dispersed as true gases and are therefore injurious when breathed. Agents such as mustard gas that are dispersed in liquid form and attack the body through the skin surface necessitate the use of special protective clothing. To insure complete protection for persons obliged to remain in contaminated areas, fabrics used in this clothing must be treated with moisture-resisting compounds (*e.g.,* oilskins), and garments must be designed positively to exclude air at all points. The gas mask is invariably worn with protective clothing to prevent inhalation of noxious fumes which are always present where liquid agents are released.

Ground or other surfaces saturated by persistent (liquid) chemicals may be treated to hasten decomposition of toxic materials. Chlorine is most effective for this purpose and is commonly applied in the form of chloride of lime.

The effective use of antigas equipment is dependent on thorough military training and organization. Gas defense organization, based on the assignment of suitable gas specialists to various units, insures attention to all features of chemical security, including such matters as the alerting of troops to gas attack and the degassing of areas contaminated with persistent chemicals.

All measures for protection against gas contribute toward the development of gas discipline. When this is high, military organizations are able to face gas attacks with confidence born of the knowledge that gas casualties will be light and that gas will not

unduly impede the attainment of objectives.

Self-Aid and First Aid.—Individuals who have been subjected to a chemical attack may take measures themselves (self-aid) to neutralize or to minimize the effects of the agents. Others may administer the same or more complicated nonmedical measures as first-aid treatment. Speed is an essential element in either self-aid or first-aid treatment against the effects of the war gases. Use of devices such as the protective mask (respirator) is another essential element in the treatment of chemical warfare casualties. With contamination by certain agents, such as the blister and nerve gases, however, personal decontamination of the eyes, face, neck and head areas is necessary before donning the mask. The military forces provide certain ointments, decontaminants and antidotes for use in specific self-aid and first-aid techniques. Military forces. moreover, prescribe a progressive treatment technique to be followed once the agent has been identified through sensory or mechanical detection means or through preliminary diagnostic evaluation of the physiological effects. Effective self-aid and first-aid measures for civilians can be achieved only if the civilian population is provided with the necessary items for the treatment of chemical warfare casualties. To be adequate. civilian defense planning must include provision for such decontaminants, antidotes and ointments as are necessary to neutralize or minimize the effects of the various agents which might be employed by an enemy.

CHEMILUMINESCENCE is light of chemical origin. This includes all forms of radiation—whether visible, infrared or ultraviolet—emitted in excess of the black body radiation, where the energy is supplied from simultaneously occurring chemical reactions. Chemiluminescence is most commonly generated by oxidation. The light emitted can usually be ascribed to the transfer of the energy of oxidation to a molecule not itself undergoing oxidation in which light is thus generated. A large number of substances. such as formaldehyde, dioxymethylene, paraldehyde, acrolein, lophine, glucose, lecithin and cholesterin, luminesce if slowly oxidized in alkaline alcoholic solution (B. Radziszewski, 1877–83). Another group of chemiluminescences described by M. Delépine (1910–12) is connected with the oxidation of sulfur compounds. The widespread luminescence of living organisms such as fireflies and luminous bacteria was shown by R. Dubois (1885–87) to be based on the oxidation of a substance of unknown structure. luciferin, in the presence of an enzyme luciferase. When the chemiluminescence occurs in living things it is called bioluminescence. See also LUMINESCENCE. (M. POL.; X.)

CHEMIN DES DAMES, BATTLE OF THE, sometimes known as the battle of the Aisne and part of the 1918 German offensive on the western front in World War I. At the end of May 1918 the Germans assembled 41 divisions on the stretch of iront running 24 mi. N.W. from Reims, held by 11 French and 5 British divisions. This area included the Chemin des Dames ridge, regarded as an exceptionally strong and well-organized defensive position. At 1 A.M. on May 27, the Germans opened an intense bombardment, which included gas shells, and at 3:40 A.M. the 17 assault divisions advanced. They made rapid progress and by evening German infantry were swarming over the still intact bridges over the Aisne river and had reached the Vesle on a 9 mi. front. By June 3, their centre had advanced 30 mi. to the Marne at Château-Thierry. Meanwhile Gen. Henri Philippe Pétain had directed large reserves (25 French and 2 American divisions) to the threatened area; but the German advance had lost its momentum, and on the evening of June 3, the German crown prince ordered the offensive to stop.

CHEMISTRY (ARTICLES ON). Chemistry is concerned with the properties of matter — broadly. with its structure. composition and susceptibility to change. Like physics, it has undergone a vast evolution in theory since the invention of quantum mechanics and statistical mechanics. There is no better way to communicate the new developments than to retrace the steps of the scientists who first arrived at them. For this purpose. CHEMISTRY begins with a general historical survey; also. each of its major divisions — inorganic. organic, physical and analytical chemistry — includes a further summary of the series of discoveries that led to present-day knowledge.

Since chemistry seeks to investigate all the properties and mutations of matter, it is closely allied with many sciences, and particularly with physics. The collaboration of physics and chemistry in the exploration of the atom is illustrated in the section of PHYSICS: GENERAL SURVEY headed *The Electrical Nature of Matter*, and in such articles as ATOM; NUCLEUS; NEUTRON; RADIOACTIVITY. ARTIFICIAL; RADIOACTIVITY, NATURAL; SPECTROSCOPY; and X-RAYS.

Every substance so far found in nature or produced in the laboratory consists of one or more of the hundred-odd species of atom that have been identified as elements. ELEMENTS, CHEMICAL. gives a general discussion of these, and data on the atomic number, atomic weight, terrestrial abundance, etc. of each. The factors governing distribution of the elements are reviewed in GEOCHEMISTRY. Many articles are devoted to individual elements, their properties, industrial applications, etc. Another series of articles deals with groups of elements. *e.g.*, ALKALINE EARTHS; PLATINUM METALS; TRANSURANIUM ELEMENTS; etc. Also, important compounds and groups of compounds are treated in individual articles—*e.g.*, ACETYLENE; AMMONIA; NITRIC ACID AND NITRATES; ACIDS AND BASES: AZO COMPOUNDS; HYDRIDES.

Many of the elements as found in nature are mixtures of atoms that have identical chemical properties but vary slightly in nuclear mass. ISOTOPE discusses these chemical siblings and their significance in atomic energy and biochemical experimentation.

One of the most important principles in the study of the chemical elements was arrived at by a method of startling simplicity. This is the discovery, described in PERIODIC LAW. that when the elements are arranged in groups according to atomic weight. the positions on the chart correspond to similarities in chemical properties.

The factors determining the capacity of an atom for combining with other atoms are discussed in VALENCE. Among the articles dealing with other aspects of chemical combination and interchange are CO-ORDINATION COMPOUNDS; ION EXCHANGE; POLYMERIZATION and RESONANCE.

In many cases, chemical properties are keyed to the architecture of atoms or of the molecules in which they are grouped. Among the articles treating of the relationship between the properties of chemical compounds and the configuration of their building blocks are CRYSTALLOGRAPHY; ISOMERISM; MOLECULE, CHEMICAL; and STEREOCHEMISTRY.

BIOCHEMISTRY surveys the role of chemistry in the study of plant and animal life. Among other articles dealing with the chemistry of living matter are CARBOHYDRATES; CHLOROPHYLL. CHEMISTRY OF; ENZYMES; PROTEINS; PHOTOSYNTHESIS; and PROTOPLASM.

Articles dealing with laboratory equipment and techniques include CHEMICAL APPARATUS; CHROMATOGRAPHY; INDICATOR, CHEMICAL; POLAROGRAPHY: ULTRAMICROCHEMISTRY, etc.

The survey article CHEMICAL INDUSTRY is supplemented by articles on individual operations and processes—*e.g.*, ALKALI MANUFACTURE; ATOMIC ENERGY; DISTILLATION; HYDROGENATION; NITROGEN. FIXATION OF; PHARMACOLOGY; etc. Many articles discuss the chemistry of materials of commerce—*e.g.*, COAL TAR; GLASS; PLASTICS; RUBBER; etc. The contributions of chemistry to the economics of agriculture by the creation of new uses for farm products are treated in CHEMURGY.

Two articles that present a significant contrast are ALCHEMY and SCIENTIFIC METHOD. The relationship of chemistry to sci-

ence as a whole is discussed in SCIENCE. Scientific approaches to the philosophical question of the origin of matter are summarized in COSMOGONY.

The chemists responsible for the major achievements described in the above articles are represented by biographical articles—*e.g.*, BERZELIUS, JÖNS JACOB; DALTON, JOHN; KEKULÉ VON STRADONITZ, FRIEDRICH AUGUST; LAVOISIER, ANTOINE LAURENT; LIEBIG, JUSTUS VON; VAN'T HOFF, JACOBUS HENDRICUS.

For information on any phase of chemistry, the reader should make use of the Index—a guide to individual articles on the subject as well as to relevant sections of other articles.

CHEMISTRY is the science that deals with the nature of and the changes in the composition of matter. It once was regarded as a well-defined, separate science, but now the border lines between chemistry and other sciences have almost completely disappeared in some areas. Since 1885, for example, certain portions of physics and chemistry have been united in a new joint discipline, physical chemistry. From about 1900, biology and chemistry have been joined in another new scientific area. biochemistry. Inasmuch as the techniques and subject matter of chemistry are sometimes shared with related fields of study, a comprehensive view of modern chemistry must take into account the relationships between chemistry and these other fields. For a survey of important separate articles in the various fields of chemistry, see CHEMISTRY (ARTICLES ON).

This article is divided into the following sections and subsections:

I. HISTORY OF CHEMISTRY

A. PRESCIENTIFIC PRACTICAL CHEMISTRY

Chemistry was not recognized as a science in its own right until about the 16th century, but its subject matter had been an object of human concern from the earliest days of primitive man. Early man could not avoid noticing the material changes with which chemistry is concerned, and he learned to utilize some of the natural changes for his own benefit. The discovery of fire, for instance, gave him a tool with which he soon learned to bring about some of these changes deliberately, and even in the most primitive times the utilization of metals became extremely important. Copper, Bronze and Iron apes succeeded eath other. each representing a further step in the development of metallurgical technology. As civilization developed, technological skills broadened, and in the early cultures of Egypt and Mesopotamia a practical chemistry of high quality already existed.

It is true, of course, that the practitioners of this chemistry did not think of their arts as in any sense chemical. They were artisans. workers in metals, dyes, perfumes and drugs. They often worked in close association with temples, and they made luxury articles for the priests and nobles as well as cheaper imitations for the poorer citizens. Most of their methods were kept as trade secrets, to be handed down from father to son. but enough written records have been preserved to show their techniques for preparing glazes and perfumes and for assaying gold, silver and other metals. When considered in conjunction with the pieces of apparatus that have been found in archaeological excavations and the analyses of other objects recovered from the ruins, the records

of techniques disclose much of the nature of the technological processes used by the ancients. Many of their methods of distillation, digestion and extraction of natural products formed the basis on which later alchemists and chemists developed their own methods and ideas.

The chemistry of these ancient civilizations was essentially practical, but most of its theoretical explanations of natural events had a mythological and magical character. Nevertheless, some of the concepts greatly influenced later and more rational thinkers. In particular, the Rilesopotamian idea that the world was made up of a number of contraries, such as male and female, hot and cold, wet and dry, and so on, was taken over by Greek thinkers. Equally important was the idea that events in the macrocosm, the great world of the sun, moon and stars, were paralleled by events in the microcosm, the small world of man. This idea was originally of astrological origin, but it fitted well into the biological bias of many Greek thinkers and became an important factor in their explanation of many chemical facts.

1. Greek Classicists.—The concepts and techniques developed by the older civilizations reached the Greeks through the city of Miletus in Ionia and were organized by the Ionian school of philosophers that began with Thales in the 6th century B.C. These Ionian philosophers were cosmologists who sought to explain all the workings of nature in the simplest and most logical terms; *i.e.*, in terms of purely physical phenomena. They wished to find a single basic substance from whose changes all the visible alterations around them could be understood. They were greatly impressed by the changes of state produced by temperature. Liquid water could be converted to solid ice or to gaseous steam (air). Thus it was natural that the earliest choices for a primal substance were made in terms of physical properties. Matter could exist in the form of a solid, a liquid or a gas, and these states could be equated with earth, water or air. The changes between the states were brought about by heat; that is, by fire. Therefore the primal substance must be similar to, or identical with, one of these. Thales thought this substance must be water; Anaximander conceived of a rather indefinite mass out of which matter was created; Anaximenes chose air as the basic material; and Heraclitus chose fire. All, however, believed that each of these substances could be converted to the others under the proper conditions. Heraclitus further amplified these ideas by the concept of constant change, a sort of dynamic equilibrium ("everything flows"), and by bringing in the old concept of contraries whose combinations gave material substances.

These physical explanations of the behaviour of the macrocosm were applied by philosophically minded physicians to the microcosm (man). The interaction of biological and physical speculations produced the idea that the innate heat observed in living animals was the same as the fire that composed material objects, and that it could bring about many changes that would now be called chemical. This process of "coction," represented by digestion in animals and by the cooking of food, became a familiar idea. Almost all later Greek thinkers used biological and physical explanations interchangeably.

The next great theoretical advance was made by Anaxagoras, who assumed that all material objects were made up of infinitely small particles, which he called "seeds." On the principle that like attracts like, he assumed that the seeds of flesh, for example, would aggregate to produce flesh itself.

Empedocles generalized this idea by reducing the infinite number of types of seeds to four, the atoms of earth, air, water and fire. This was the basis for the four-element theory that dominated scientific thought in one form or another for 2,000 years.

The atomic theory was best expressed by Leucippus and his pupil, Democritus of Abdera, who proposed a true kinetic theory of atoms moving in a void. The size and shape of the four kinds of atoms explained many of their properties. The theory of Democritus was completely materialistic. It became the basis for the later Epicurean school of philosophy and so was preserved for future generations, but it was strongly opposed by the more mystical philosophers who had made up the school of Pythagoras and who now became influential in Greek philosophical thought under the leadership of Socrates, and especially of Plato.

Plato.—Plato was not basically interested in physical theory; his speculations concerned instead the moral and ethical nature of man. He was enough of a philosopher, however, to wish to explain the nature of the world, and he did so in his dialogue *Timaeus*. He drew on much of the previous thinking of the various philosophical schools, and he added his own teleological preconceptions, holding that everything was designed by nature for the best of all possible worlds. The system of cosmology that he proposed was, in his own words, "as probable as any other." He accepted the four elements of Democritus, but his atoms were geometrical abstractions: fire was composed of tetrahedral atoms whose sharp points gave them their penetrating power; earth was made up of cubical atoms that were the most stable and solid of the four forms; water consisted of icosahedra, and air of octahedra. By rearrangements of the bounding planes of these figures the atoms could be converted into each other. This concept of the interconvertibility of the atoms gave a theoretical basis to later alchemy.

Aristotle.—The abstract theories of Plato were brought into closer touch with reality by his great pupil, Aristotle. Though Aristotle took all fields of philosophy for his own, he was basically a scientist who did his best work in the biological field. His explanations of the composition and changes of matter were the standard of scientific thought until the 17th century.

Aristotle assumed a primal matter, as had the Ionian philosophers. Upon this matter were impressed various forms, and the differences in material objects resulted from these different forms impressed on the primal matter. Thus, as in the thinking of Plato, any material could be converted into any other. However, Aristotle made the picture more concrete than had most of his predecessors. Turning to the concept of contraries proposed by Heraclitus, he assumed that there were four qualities, heat, cold, moisture and dryness, which combined to make up the atoms of the physical world. Obviously, heat and cold could not combine, nor could moisture and dryness, since these nullify each other, but heat and dryness could combine to form atoms of fire; heat and moisture could give air atoms; cold and moisture would make up water, and cold and dryness could produce earth. Thus, the changes in matter resulted from impressing on the primal matter various changes of qualities, and changes in qualities could produce changes in form. Changes in the combinations of the four atoms could then bring about a second type of change to produce such visible materials as stones, blood or flesh, and combinations of these gave a third type of combination that produced faces, hands and so on. Aristotle worked out explanations of both physical and biological phenomena in the greatest detail.

2. Emergence of Alchemy.—Alexandria.—With the death of Aristotle, the classical period of Greek philosophy ended, and scientific leadership passed gradually from Athens to the Hellenistic city of Alexandria in Egypt. Under the stimulus of the work at the museum, which was actually a great research institute, science flourished and a combination of factors led to rapid advances in chemistry. Alexandria was a place where many cultures met and mingled. Greek philosophy, which had tended to become very abstract, met practical oriental technology that had been highly developed for hundreds of years. Oriental mystical religions also flourished in Alexandria. From these three sources—Greek philosophy, oriental technology and oriental religious mysticism—first alchemy and later chemistry were born. *(See* ALCHEMY: Early History and Philosophical **Basis.)**

The earliest alchemists were artisans who were stimulated by the philosophers to attempt to explain the nature of their technical processes in terms of philosophical theory. The idea of the interconvertibility of matter led them to believe that the imitations of gold they had made for their poorer customers might become true gold and that they could make this precious metal from baser materials. This was for a long time the practical goal of the alchemists, but their theoretical speculations and actual laboratory work went far beyond this. They learned much true chemistry from preparing metals and reagents that changed the metals to make them resemble gold externally. The Alexandrian alchemists greatly improved chemical apparatus and learned many

new reactions of inorganic substances.

Gradually, however, the mystical ideas that had entered alchemical thought from the oriental religions became dominant in Alexandrian alchemy. The perfection of metals into gold was thought to be merely a symbol of the perfection of the human soul. Interest in actual laboratory work declined, and chemical discoveries nearly ceased in the Byzantine empire during the 4th and 5th centuries.

Syriac *Translations.*—At just this period, however. the religious controversies in the early Christian church resulted in the splitting of the Nestorian body from the Orthodox Church. The Nestorians were driven into Asia Minor, where they established a number of important schools and taught the theoretical principles of the Greek philosophers. They translated most of the Greek writings into their own language. Syriac, and much of the valuable Greek literature was thus preserved when western Europe fell into what is called the dark ages.

Arabic Golden Age.—The Nestorians soon came into contact with the rising Arab empire, and under the encouragement of enlightened caliphs in Baghdad a new set of translations of the Greek authors was made, this time from Syriac into Arabic. In the golden age of Arabic science, the 8th to the 11th centuries, a number of physicians and alchemists once more turned to actual laboratory work. They took over the Aristotelian theories of nature and used them to explain chemical changes and the elements that resulted from combining Aristotle's four qualities. However, they modified these somewhat by assuming that the Aristotelian elements formed a second set of contraries, sulfur and mercury, from which metals were then composed. This sulfur and mercury were not the physical substances, which were well known at the time, but rather represented the qualities of earthiness and combustibility (sulfur). and lustre and fluidity (mercury). Thus the idea of qualities in the Aristotelian system became converted to the concept of the existence of more or less immaterial "principles" that conferred certain physical properties on material substances. This idea was first set forth in the writings of the Muslim sect of the Isma'iliya, a group with strong mystical and alchemical interests. They ascribed these writings to a perhaps mythical alchemist, Jabir ibn Hayyan, and the works became so popular that later generations had no doubts as to his actual existence. Other Arabian physicians and chemists, such as Avicenna (Ibn Sina) and al-Razi, introduced a number of important substances into chemistry, including the caustic alkalies (*e.g.,* sodium hydroxide) and ammonium chloride.

Introduction Into *Western* Europe.—After the 11th century, Arabic alchemy, like the Hellenistic alchemy before it, began to lose its practical character. At this time, however, western Europeans were beginning to awaken from the long period of scientific inactivity that had followed the fall of Rome. There was much curiosity among them regarding the science of the Arabs, and schools arose in Spain and Sicily for translating the ancient Arabic manuscripts, many of ahich had come from the Greek through Syriac. Scientific works of all types, including many of the alchemical manuscripts, were at this time translated into Latin.

These were seized upon with enthusiasm in the west, and the practice of alchemy began to flourish. Actually, it was superimposed upon the craft of metalworking, ahich had been continued as a practical art throughout the middle ages. Now these artisans, like their Alexandrian predecessors, found a theoretical basis for their practical observations, this time in the form of the sulfur-mercury theory of the composition of metals. The new approach was summarized in .the extremely popular works of an author who wrote under the name of Geber, pretending to be the Arabic alchemist Jabir ibn Hayyan. He was probably in reality a practicing Spanish alchemist. His books, written about 1310, reveal great technological advancements in laboratory operations. They describe methods for assaying metals and for preparing and purifying reagents. These directions possess a clarity and lack of mysticism of a high order. It was at about this time that the art of distillation improved to such an extent that mineral acids and alcohol were obtained for the first time.

The alchemy of the 13th and 14th centuries was notable for its practical application of chemical apparatus and methods in laboratory work, but, as in the Hellenistic and Arabic periods, it eventually began to shift its emphasis in the direction of mysticism and charlatanism. In this case, however, it was not necessary that a new culture should take it over in order to revive its progress toward the science of chemistry. Although one branch of alchemy became and remained abstruse and impracticable, the other did not die out.

Predominance of *Practical* Alchemy.—The scientific revival that took place in the early Renaissance brought about conditions for the encouragement and further development of the practical branch of alchemy. This was first revealed in a series of books on practical procedures. In the 16th century appeared the works of Hieronymus Brunschwigk on distillation and the excellent books of Vannoccio Biringuccio, Georgius Agricola and Lazarus Ercker on mining and metallurgy. New metals and compounds were described in these publications. The use of chemical remedies in medicine was advocated with considerable violence by Theophrastus Bombastus von Hohenheim, called Paracelsus, who founded the school of iatrochemistry that tried to introduce chemical remedies into medicine and was thus the forerunner of pharmacology. The abundance of new information that could not be fitted into the framework of the Aristotelian theory now demanded a whole new theoretical approach.

At this time, Paracelsus modified the sulfur-mercury theory of metallic composition by adding a third component, salt, as a constituent of the metals. He felt that this was necessary to account for the stability (earthiness) of metals, and so sulfur now became merely the principle of combustibility. Mercury still conferred metallic lustre and fluidity. This formulation by Paracelsus became known as the tria prima theory.

B. Chemistry as a Science

1. Developments From 1597 **to** 1700.—Chemistry by this time was becoming recognized as a science. Its methods of that era were discussed in what is often described as the first textbook of chemistry, the *Alchymia* of Andreas Libavius, published in 1597. He declared, "Alchemy [that is, chemistry] is the art of producing magisteries and of extracting pure essences by separating bodies from mixtures." Magisteries signified reagents and the methods of their use.

Developments were rapid in the 17th century. Acids, bases and salts were studied, and a beginning was made in the use of the balance and the quantitative study of reactions. Chemical theory also began to change sharply at this time. Iatrochemists devoted most of their attention to developing new chemical remedies. Many, especially in France, were pharmacists; these included Christopher Glaser and Nicolas Lémery. They wrote textbooks of chemistry that were little more than collections of recipes. They prepared many of their remedies by distilling animal or vegetable substances, and they observed that in their distillations they often obtained a volatile liquid, an inflammable oil, a heavy fluid, a water-soluble substance and a solid residue. Since they believed that by their distillations they were "analyzing" materials into basic constituents, they felt that there must actually be five elements out of which all matter was built. Thus, in the 17th century various chemists held to theories that accepted the existence of one, two, three, four or five basic elements.

New and Old Ideas.—The astronomical and physical theories of Copernicus and Galileo influenced chemistry at this time. In particular, the older Greek atomic theories, as preserved in the Epicurean poem De *rerum natura* by the Roman writer Lucretius, began to be revived in one form or another. Pierre Gassendi and René Descartes were influential in this revival. The application of these ideas to chemistry was the chief work of Robert Boyle, who in his "corpuscular theory" attempted to expel all the occult influences from chemistry and to explain chemical reactions on a purely mechanical basis. In his famous book The Sceptical *Chymist* (1661) he attacked the Aristotelian theory of the four elements, the tria *prima* theory of Paracelsus and the idea that distillation could yield the basic elements of matter. His own definition of an element had a decidedly modern ring. In his labora-

tory he discovered many new chemical facts and processes.

It cannot be said that Boyle succeeded immediately in establishing his mechanical philosophy in the minds of his contemporaries, but he did encourage them to think more rationally, and his ideas eventually resulted in great progress. Nevertheless, at almost the same time Boyle was doing his work, the theory of the *tria* prima took on a new and important form.

In Germany J. J. Becher renamed the three principles of Paracelsus as the vitreous, fatty and fluid earths that respectively conferred the properties of body, combustibility and density with metallic lustre on substances. It is noteworthy that at this time all idea of the importance of air as a constituent of matter had disappeared from the minds of chemists. Air was thought to be an unreactive medium that was usually present but acted only as a physical agent. Even the Belgian physician and chemist, J B van Helmont, who in the mid-17th century discovered carbon dioxide and proposed the name "gas" for it, did not believe that this gas possessed any properties other than physical ones. Thus Becher concentrated his attention on solids as the sole constituents of matter.

The *Phlogiston* Theory.—The ideas of Becher were taken up by his pupil, Georg Ernst Stahl, who gave special prominence to the fatty earth described by his master. Stahl called the fatty earth "phlogiston," and upon it he erected the first great generalization of chemistry. Phlogiston to him was the fire principle. When a body burned, phlogiston was lost. Men had long felt, as they watched a flame, that something was departing. The idea was quite logical nhen the object burning was an organic substance, since in this case only a small residue was left behind. Stahl felt that the rusting of metals was also a form of combustion, and so he applied his theory chiefly to metals. Thus he believed that when a metal was converted to its calx (oxide, in modern terms) phlogiston was lost. Therefore the calx was a simple body and the metal a compound one, composed of calx plus phlogiston. The function of air, which was known to be necessary for the reaction to occur, was merely to carry away the phlogiston as it was liberated. By this theory it was possible to explain most of the reactions that are now ascribed to oxidation or reduction, though the mechanisms of the phlogiston theory were the exact reverse of those now accepted.

The major objection to the phlogiston theory, *i.e.*, that the calx was heavier than the metal from which it was derived, was of little significance to Stahl, since he thought of phlogiston as a more or less immaterial "principle" rather than an actual substance. As chemistry advanced and chemists applied quantitative methods more frequently, such a view became impossible to them. To the later phlogistonists, phlogiston became as much a substance as any other material with which they worked in the laboratory, and much ingenuity was expended in accounting for the effect of its loss or gain on the weights of the substances involved in its reactions. Sometimes it was even thought that phlogiston had a negative weight. When hydrogen was discovered, some chemists thought that it was pure phlogiston.

2. Understanding of Combustion (1700–1800).—In the 18th century a series of discoveries made it possible to understand the nature of combustion. This could not have been grasped until the chemistry of gases was worked out. The English botanist Stephen Hales showed that many substances evolved "airs" when they were heated, and he devised a pneumatic trough for collecting such airs. Hermann Boerhaave, an influential Dutch teacher of chemistry, began to suspect that air might take part in a chemical reaction. This was shown to be true by Joseph Black in Edinburgh in 1756 when he demonstrated the uptake of carbon dioxide by quicklime (calcium oxide) to form chalk (calcium carbonate), and the reverse of this process when chalk was heated. Because of the radically new idea that a gas could be present in a solid, he called carbon dioxide "fixed air." His work was eagerly continued by other chemists, and a number of new gases were discovered. This line of investigation culminated in the discovery of oxygen almost simultaneously by K. W. Scheele (1772) and Joseph Priestley in 1774.

All the necessary information was now at hand for the overthrow of the phlogiston theory and the establishment of the true nature of combustion. This was accomplished by Antoine Laurent Lavoisier, the "father of modern chemistry," between 1770 and 1790.

Lavoisier made quantitative studies of the gain or loss of weight when tin, lead, phosphorus and sulfur underwent reactions of oxidation or reduction and showed that the newly discovered oxygen was involved in all these reactions. He was thus led to an understanding of the actual nature of the reactions that were occurring. He formulated the explanation of combustion and the composition of metals and their oxides that was still accepted in the early 1960s. All forms of the sulfur-mercury theory were finally abandoned. Lavoisier's definition of an element was essentially modern, and it did away with the confusion that had long prevailed in the thinking of chemists as to the number of elements.

Lavoisier also was active with Guyton de Morveau and several other chemists in devising the modern system of chemical nomenclature and in demonstrating that respiration in animals is a special form of oxidation. He performed the earliest true biochemical experiments in his studies on respiration.

Although a number of older chemists, including Priestley, stubbornly tried to retain some form of the phlogiston theory, they quickly lost ground, and by 1800 practically everyone recognized the correctness of Lavoisier's oxygen theory.

3. Studies of Chemical Composition (1800–1900).—*General.*—During the 18th century quantitative methods had come into common use. and many minerals had been analyzed and new elements discovered. Much attention had been devoted to the subject of affinity. This mas the name given to the force that held chemical compounds together, and it was thought that the strength of affinity of a given group of elements could be measured by noting the ease with which one element could replace another in a given compound. Although elaborate tables of relative affinities had been drawn up by Torbern Bergman, there was no satisfactory explanation of the nature of the forces involved.

By 1808 it was accepted that chemical compounds had fixed compositions. An explanation for this fact was offered in the first truly chemical atomic theory, that of John Dalton of Manchester, Eng. He assumed that each element consisted of its own type of atoms, each with its characteristic size and weight. Thus the idea of atomic weights was introduced. Dalton had no means, however, of calculating true atomic weights or the number of atoms present in a compound. He assumed, however, that the constant composition of compounds was due to the combination of a constant number of atoms in them. He made a number of rigid postulates that greatly limited the generality of his theory.

These limitations were largely removed by the investigations of J. L. Gay-Lussac into the combining ratios of various gases. He demonstrated that equivalent amounts of different elements could combine with each other but made no distinction between atoms and molecules, and so the distinction between atomic and molecular weights could not be made. In 1811 Amedeo Avogadro pointed out that equal volumes of gases should contain equal numbers of molecules, and from this the distinction between atoms and molecules could be derived, but Avogadro's work was disregarded for nearly 50 years.

Meanwhile the great Swedish chemist Jons Jacob Berzelius had been carrying out a large number of analytical studies of minerals and, on the basis of the Dulong-Petit rule that the product of the atomic weight and the specific heat was a constant, had drann up a table of atomic weights that was, in the main, accurate. But his results were not accepted by most chemists, who preferred to use equivalent weights as determined in the laboratory, even though these were very relative and differed when derived from different compounds.

Berzelius made many contributions to chemical theory, including the description and naming of the phenomena of catalysis and isomerism, and the invention of the modern system of chemical symbols. His major theoretical contribution was his dualistic or electrochemical theory of atomic combination, in which he sought to settle the old problem of the nature of affinity. He was greatly impressed by the newly discovered process of electrolysis and the separation of gases and metals at the poles of a Voltaic pile.

He believed that all atoms were electrically charged, both negatively and positively, but that the positive charge predominated in some and the negative in others. Negatively charged atoms would then be held to positively charged atoms by electrostatic forces. This theory of chemical affinity worked well for many inorganic salts, which were the substances most studied at the time of Berzelius, and his theory was widely accepted among chemists.

The accumulation of compounds of carbon that resulted from the intensive study of organic chemistry in the first half of the 19th century soon showed the inadequacy of the dualistic theory. In particular. the substitution of elements such as chlorine for hydrogen in organic compounds could not be explained by Berzelius, since these atoms should carry opposite electrical charges and so could not occupy the same position in a compound held together by electrostatic forces. Organic chemists therefore tended to think of radicals, that is, groups of atoms that acted as a unit in chemical reactions. These radicals were believed to combine with elements in much the same way that simple substances combined in water or ammonia, so that two radicals joined to an oxygen atom (to form an ether; were said to belong to the water type, and three radicals joined to a nitrogen atom (to form an amine) were said to be of the ammonia type. The attempts to fit all organic compounds into a few rigid types proved difficult, and new types were constantly being proposed. The failure to agree upon the use of molecular or atomic weights or of equivalents in writing formulas further added to the confusion, and at one time various chemists were proposing 19 different formulas for acetic acid.

The water-ammonia type theory at least suggested that individual atoms could hold only a limited number of atoms of other elements or radicals, and the studies of metalloorganic compounds by Edward Frankland in the 1850s strengthened this idea. The concept of "affinity units" passed gradually into the modern concept of valence. This was a major step in making possible the elucidation of the nature of organic compounds.

Organic Compounds (1858–1900).—In 1858 Friedrich von Kekulé and Archibald Scott Couper independently proposed the tetravalence of the carbon atom and its ability to link with other carbon atoms to form long chains. The way was thus opened for the development of the structural theory of organic compounds. The major portion of this development was carried out in the 1860s by A. M. Butlerov. The explanation of the nature of aromatic compounds as ring structures was made by Kekulé in 1865 (See also *Organic Chemistry* below.)

Once an understanding of the structure of organic compounds had been reached. it became logical to extend the flat formulas that were at first written on paper into three dimensions. This extension was made simultaneously by Jacobus Hendricus van't Hoff and J. A. Le Bel in 1874 when they postulated a tetrahedral carbon atom. The field of stereochemistry (q *v.*) was thus opened. It became possible to explain many puzzling properties of organic compounds by this concept. and a number of workers developed the idea over the following 30 years. At the end of the 19th century. Alfred Werner applied stereochemical ideas to complex inorganic compounds of platinum and similar metals and explained the nature of many previously misunderstood compounds.

Atomic Weights and the Periodic Law.—In 1860 the first international chemical congress met at Karlsruhe. Ger., in an attempt to settle the confusion in chemical theory. especially in regard to atomic weights. At the congress, the Italian chemist Stanislao Cannizzaro revived the Avogadro hypothesis and showed how atoms and molecules could be distinguished from each other. This concept mas quickly accepted, and true atomic and molecular weights were recognized. This in turn made it possible to complete earlier tentative studies that had attempted to classify the properties of elements in terms of their atomic weights. Between 1869 and 1871 D. I Mendeléyev and Lothar Meyer offered their versions of the periodic table, and Mendeléyev, on the basis of his table. predicted the existence and properties of three then-unknown elements. When these were discovered (gallium in 1875. scandium in 1879 and germanium in 1886) and their properties were found to agree with Mendeléyev's predictions, the periodic law (*q.v.*) was accepted, and inorganic chemists had a systematic generalization upon which to build their science.

4. The Founding of Physical Chemistry (1875–87).—During the first three quarters of the 19th century the major developments in chemistry had occurred in the inorganic and organic fields, While the science of physics had been developing as rapidly as had chemistry, there was relatively little scientific contact between the followers of the two disciplines, and there was often even a certain sense of antagonism between many individual physicists and chemists. Nevertheless, rapid developments in the field of energy relationships could not fail to attract the attention of some chemists who were concerned uith the study of affinity and reaction rates.

It was these studies that finally led to the establishment of the science of physical chemistry. In 1850 Ludwig Wilhelmy showed that the rate of hydrolysis of cane sugar could be calculated by a mathematical equation; this marked one of the first occasions in which a mathematical formula was used to express a chemical process. Wilhelmy's work was followed by a number of studies of reactions that involved equilibria. and these led in 1863 to the formulation of the lam of mass action by the Norwegian chemists C. M. Guldberg and Peter Waage This law permitted prediction of the direction in which a reversible chemical reaction would proceed in terms of the concentrations of reactants involved It was soon shown to have far wider consequences than had originally been foreseen. Chemists began to think in terms of the kinetic properties of atoms. and to explain the mechanism of chemical reactions from this viewpoint.

At nearly the same time the ideas of thermodynamics. which physicists had been developing from the days of Sadi Carnot. began to penetrate into chemistry The way for this was paved by studies on heats of reaction made around 1850 by G. H Hess in Russia. Pierre Eugène Berthelot in France and Julius Thomsen in Denmark In 1869 A F Horstmann utilized the principle of entropy for the first time in chemistry. The mathematical basis for the treatment of heterogeneous equilibria and the derivation of the phase rule were given by an American. Josiah Willard Gibbs, in 1876–78. The importance of his work for both pure and applied chemistry uas not recognized. however, for 20 years.

Electrochemistry, which had been important ever since the discovery of the Voltaic pile in 1800, played a part in the establishment of the dualistic theory and in the isolation of a number of metals by the electrolytic process As chemists continued to study conductivity in solutions they realized that salts behaved in unpredicted ways in the dissolved state The studies of F. Kohlrausch and J. W. Hittorf indicated that in an electrical field salts broke up into charged ions The theory of electrolytic dissociation. which was first announced by Svante Arrhenius in 1884, showed that such ions existed at all times in solution. even in the absence of an electrical field. This idea revolutionized the theory of solutions. (See ELECTROCHEMISTRY.)

All of these studies represented a growing interest in the physical properties and behaviour of chemical compounds. but they mere not united into an organized branch of chemistry until Wilhelm Ostwald wrote a general textbook of physical chemistry (1885–88) and, assisted by van't Hoff and Arrhenius established a specialized journal in this field in 1887. From this time on. physical chemistry ranked with the inorganic and organic branches as a full specialty of chemistry. (*See* also *Physical Chemistry* below.)

5. **Changes in Structural Concepts After** 1895.—As a result of studies in all branches of chemistry, the behaviour of chemical elements and compounds by the end of the 19th century had come to be explained in terms of the properties of individual atoms. The organic chemist thought of the atoms as tetrahedra with valence bonds projecting out at the angles. The physical chemist considered them to be balls bouncing in all directions and sometimes carrying an electrical charge that modified their properties. Some leading chemists, such as Ostnald. insisted that, since all the evidence for their existence was purely circumstantial atoms probably did not exist at all. No chemist had the least idea that there might be a possibility of a subatomic structure. It was at this time

that a completely new field was opened by studies made by physicists on atomic structure and by the discovery of radioactivity. The concept of atoms had to be changed radically.

Physicists had for a long time been studying the nature of the radiation produced by electrical discharges in rarefied gases. Some of the resulting rays were found to be composed of charged particles, negative in the case of cathode rays and positive in the case of canal rays (now called positive rays). After Arrhenius announced the ionic theory, it was natural to assume that the cathode and canal rays were produced by particles that must be ionic in character. In 1895 W. C. Röntgen discovered X-rays, which were very penetrating but did not consist of charged particles. They were of the same nature as ordinary light. Detailed study of the cathode rays led to the discovery of the electron by Joseph John Thomson (later Sir) in 1897. Its charge was determined by Robert A. Millikan in 1911. The electron came to be recognized as the unit of negative electricity, identical no matter from what element it was obtained. Positive (canal) rays were composed of ions of different elements. Thus the atom was made up of electrons and ions, a structure that recalled the dualistic theory of Berzelius.

The attention of chemists was attracted to these studies, after the discovery of radioactivity by A. H. Becquerel in 1896, by the extensive investigation of uranium ores by Marie and Pierre Curie. By the end of the 19th century their investigations had led to the discovery of polonium and radium. *(See* also RADIOACTIVITY, NATURAL; RADIOACTIVITY, ARTIFICIAL.)

Ernest (later Lord) Rutherford and his students discovered at the beginning of the 20th century that new elements were produced during radioactive decomposition, and that the rays given off in this process consisted of helium ions, electrons and X-rays. On the basis of these discoveries Frederick Soddy worked out the mechanism and pathways of radioactive disintegrations and showed that elements with the same chemical properties but with different atomic weights could exist. He called such elements isotopes. Chemical proof of the existence of isotopes was obtained by T. W. Richards and O. Honigschmidt, who found that samples of lead from different radioactive sources showed different atomic weights when studied by classical quantitative methods. The mass spectrograph designed by F. W. Aston proved the existence of isotopes for nearly all elements in 1919. *(See* also ISOTOPE.)

In 1913 H. G.-J. Moseley, on the basis of X-ray spectrography, discovered that each element had a characteristic atomic number that represented the positive charge on the central nucleus. These numbers agreed with the position of the elements in the periodic table and placed this arrangement on a much sounder basis in theory than it had possessed when the classification was made according to atomic weights. The discovery of isotopes was already making the older basis of arrangement suspect.

All these discoveries, coming with extreme rapidity in the first 15 years of the 20th century, compelled chemists to reorganize their thinking completely. It was obvious that in the subatomic structure could be found an explanation of affinity and valence, the phenomena that had puzzled chemists for so long. The first major attempts to utilize these new ideas in explaining the nature of chemical combination were made by G. N. Lewis, W. Kossel and Irving Langmuir in 1916–20. They reconciled the old dualistic theory of Berzelius as it had been modified by the electrolytic dissociation theory of Arrhenius with the affinity unit concept of the organic chemists when they distinguished between ionic and covalent bonds. The picture of the atom as a sort of solar system with a heavy central nucleus and electrons revolving about it in shells, as proposed by Niels Bohr in 1913–14, fitted this explanation very well, since all valence forces could be attributed to the number of electrons in the outermost shell. *(See* also ATOM.)

The importance of the positions of these electrons and their interrelations in complex organic molecules was soon realized by C. K. Ingold and others and their early investigations were quickly supplemented by the work of numerous other chemists who attempted to explain the mechanisms of organic reactions in terms of electron structures. The quantum theory was applied in a mathematical treatment of valence forces and led to the concept of resonance. Work in this direction by Linus Pauling did much to explain the nature of the chemical bond. *(See* also RESONANCE, THEORY OF.)

Physicists continued to develop powerful tools, such as the cyclotron, for the study of atomic structure. These tools in turn supplied the chemist with new elements to fill the empty spaces in the periodic table, and even to furnish elements beyond uranium, which had been considered the last and heaviest element. The discovery of atomic fission in the late 1930s resulted in increases in the number of new elements and the radioactive isotopes of even the normal stable elements. After World War II, these new materials became generally available and radioactive isotopes came into wide use as tracers that were employed to follow the course of chemical and biological reactions. As a result of work with the new elements and tracers, many important discoveries were made in the field of reaction mechanisms.

6. Biochemistry. — Biochemistry was recognized as a specialty branch of chemistry at about the beginning of the 20th century. From the time of Lavoisier physiologists occasionally had used chemical methods and ideas to explain biological phenomena. Biological studies were made by some chemists, notably Justus von Liebig, who investigated many agricultural problems around 1840. Louis Pasteur, W. Kiihne and others studied the nature of enzyme action in the latter half of the 19th century, and in 1897 Eduard Buchner showed that enzymes could function independently of the living cell and therefore probably were chemical compounds. However, not much progress was made in understanding the chemistry of the living organism until the brilliant studies conducted by Emil Fischer between 1890 and 1910 revealed the basic chemical structures of such important cellular constituents as carbohydrates and proteins. After 1910 such studies became common, and the new specialty of biochemistry could be considered to have taken its place alongside the older branches of chemistry.

Progress in this field was very rapid, since the methods of all the other branches of chemistry were available to it. Therefore knowledge of the chemical nature of vitamins and hormones was accumulated quickly, especially in the 1930s. The study of energy metabolism soon revealed the complexities of carbohydrate metabolism in the living cell and the enormous importance of phosphate esters in plant and animal life. Applications of this knowledge to an understanding of the nature of photosynthesis followed. Rapid improvements in the isolation and study of individual proteins opened new prospects for a comprehension of the function of these indispensable compounds, and the study of the nucleoproteins opened the way to an understanding of the nature of life. *(See* BIOCHEMISTRY.)

7. The Chemical Industry. — The development of the chemical industry has had important effects on chemistry itself and on the entire world. Small local factories for supplying soap, alum, acids and other basic chemical products existed in most countries after the middle ages. As society became more complex, larger sources of the most important chemicals had to be developed. This need was felt very strongly during the French Revolution and the Napoleonic Wars. Attempts then were made for the first time to employ scientists to work out the production of chemical substances. From this effort came the Leblanc soda process, the Gay-Lussac tower process for making sulfuric acid and methods for the manufacture of beet sugar.

When William Perkin discovered the first aniline dye in 1856, he founded an industry that was centred first in England and France but came to be centralized in Germany by the late 19th century. The Germans developed enormous dye factories that also manufactured drugs and organic intermediates; these could be used to manufacture other new materials. In these factories was developed the pattern of industrial research that later became standard throughout the world. The team system of research by groups of scientists, often employing the services of an academic consultant, grew up in these factories and was so successful that by World War I Germany controlled the world chemical market. The important Haber process for the synthesis of ammonia was developed under these conditions, and the synthetic nitrates the Germans obtained from the process permitted them to continue

the war after the first year, when their supply of Chilean nitrates for the manufacture of explosives was exhausted.

The Allies were forced in 1914 into a frantic development of their own chemical industries. After the end of the war, all major nations built up their industries with large research staffs patterned after the German system. This resulted in a greatly increased demand for trained chemists and was at least partially responsible for enormous increases in the growth of science and the rate of discoveries. (*See* CHEMICAL INDUSTRY.)

8. Chemical Societies. — Chemistry became an organized profession during the 19th century, when chemical societies were founded in all the leading nations. Nearly all these societies established journals to report the scientific work of their members; as specialized branches of the science developed, new journals were founded in each specialty. Abstract and index journals were added as the need for them developed. With the enormous growth of chemical literature, especially after World War II, the chemical profession found that one of its major functions had become the control and organization of this literature. *See* CHEMISTRY, SOCIETIES OF. (H. M. L.)

II. INORGANIC CHEMISTRY

A. INTRODUCTION

Inorganic chemistry, which is concerned with the study of the elrments and compounds other than those of carbon, was developed primarily through the investigations of minerals, whereas organic chemistry resulted from the study of substances of plant or animal origin. Although it was recognized that the two classes of substances were amenable to the same general chemical laws, it was supposed that a fundamental difference existed between the mineral (inorganic) substances and those which were the products of life processes (organic). However, during the middle of the 19th century it mas found that organic substances could be prepared from their elements or from inorganic compounds, a fact that gave great impetus to the study of organic substsnces in the latter half of the 19th century. Nevertheless, it is usual and convenient to divide chemical substances arbitrarily into the two classes but to include the oxides of carbon, the carbonates, metallic carbonyls and certain other simple compounds of carbon as well as water and ammonia in the domain of inorganic substances. For detailed discussions of the chemical elements, *see* the article on each element.

1. Early Discoveries. — The earliest discoveries in inorganic chemistry were made in the metallurgical and medical arts and in the domestic economy of the ancients. Gold, silver, copper, tin, iron and lead, some of the simpler alloys, metallic salts and mineral products, and the rudiments of metallurgical. glassmaking. enameling, painting, dyeing, alchemical and medical arts were known to the ancient Chaldeans, Hindus, Chinese, Egyptians and Greeks many centuries before the Christian era. By about the middle of the 17th century, the alchemists were acquainted with most of the common metals, their alloys and salts, a few acids, alkalies, medicinal minerals and nonmetallic elements. In 1733 G. Brandt of Sweden isolated cobalt, and in 1750 A. F. Cronstedt prepared metallic nickel. These discoveries were followed by Henry Cavendish's recognition of elementary hydrogen in 1766 and by the isolation of nitrogen by Daniel Rutherford in 1772, manganese by J. G. Gahn in 1774, oxygen by Priestley in 1774, chlorine by Scheele in 1774 and molybdenum by P. J. Hjelm in 1782. Cavendish in 1784 made the far-reaching discovery that water is composed of two volumes of hydrogen to one of oxygen, and in the following year he succeeded in synthesizing nitric acid by passing electric sparks through moist air. His further discovery that a minute residue of the air would not combine with oxygen was ignored for more than a century until Lord Rayleigh and Sir William Ramsay proved in 1895 that the inert residue consists of a mixture of four of the inert (noble) gases, argon, krypton, neon and xenon.

Other elements discovered during the 18th century include uranium, zirconium, titanium, tungsten (wolfram), platinum, beryllium, chromium, tellurium and a number of the rare-earth metals. The quantitative studies of chemical reactions by Lavoisier and others during the last part of the 18th century led to a clarification of the nature of combustion and the abandonment of the doctrine of phlogiston. Laws governing chemical combinations were formulated and the atomic theory announced by Dalton in 1803 was generally accepted. (See *History* of *Chemistry* above.)

At the beginning of the 19th century the discovery of methods for the generation of electric current gave to chemistry a most effective means for separating compounds into their elements. By the use of electrolysis, Sir Humphry Davy in 1808 decomposed the supposed elements soda and potash and isolated the metals sodium and potassium. Shortly thereafter he obtained magnesium, calcium, strontium and barium from their respective oxides. With the new tools and techniques, chemistry and other sciences underwent a rapid growth. In addition to the striking developments in analytical and preparative chemistry there were numerous advances in the theoretical sciences; physical laws and principles were found to be applicable to chemical phenomena.

Among all the advances in theoretical, descriptive and industrial chemistry that took place in the 19th century, the two events that perhaps contributed most to inorganic chemistry were the formulation of the periodic law and the discovery of the electron. The periodic law (*q.v.*) and the periodic classification of the elements announced by Mendeléyev (1869) are the great fundamental generalizations of chemistry, stimulating to research and serving as a framework for the organization of the vast amount of factual material that had been gathered previously but organized only to a limited degree. The discovery of the electron (1897) and the later development of quantum mechanics (1923) provided a foundation for the theoretical understanding of the nature of the binding forces in chemical molecules. A systematic description of chemical behaviour will be given after a brief introduction to chemical formulas and a few of the basic concepts.

2. Symbols and Formulas. — The chemical symbol for an atom of an element is either the capital letter of its English or Latin name, as C for carbon and K for potassium (Latin, *kalium*), or the capital letter followed by a small letter as Co for cobalt and Cr for chromium. A symbol is not merely an abbreviation but has a quantitative significance. It may represent one atom of the element whose weight relative to an arbitrarily selected unit is a number known as the atomic weight (*q.v.*), or it may represent a gram atomic weight (or gram atom), which consists of 6.023×10^{23} atoms of the element and whose weight expressed in grams is numerically equal to the atomic weight. For example, the symbol C may stand for one atom of carbon whose relative weight is the pure number 12.010; or if more convenient it may stand for 12.010 g. of carbon, which contains 6.023×10^{23} atoms. (*See* AVOGADRO'S CONSTANT.)

A chemical formula represents a molecule of a substance that may be either an element or a compound. Since the formula is composed of symbols it shows qualitatively the constituent elements and quantitatively the number of atoms of each element in the molecule. Thus O_2, the formula for oxygen, indicates that the substance is an element and that a molecule of it consists of two atoms; He, the formula for helium, indicates that the molecule is monatomic and is identical with the atom; H_2O signifies that a molecule of water consists of two atoms of hydrogen and one atom of oxygen, and, since it contains more than one element, that the substance is a compound. Chemical formulas are established by experimental methods that involve a chemical analysis and the determination of the molecular weight of the substance. Empirical formulas are those that indicate the simplest ratio between the numbers of the component atoms while molecular formulas indicate the actual number of atoms of each element in one molecule of compound; *i.e.*, in the smallest portion of the compound that can exist as a separate entity. The empirical formula of hydrogen peroxide, for example, is HO but the molecular formula is H_2O_2. Empirical and molecular formulas of inorganic compounds are often identical. The establishment of an empirical formula requires only a chemical analysis of a compound and the atomic weight of the constituent elements, but that of a molecular formula requires, in addition, the molecular weight of the compound.

Once the molecular formula of a compound is determined it may

be used in turn to calculate the molecular weight by addition of the atomic weights of all the atoms in the molecule. Hence the formula implies the molecular weight, which may be a pure number expressing the relative weight of the molecule on the same arbitrary standard used for atomic weights, or the formula may represent a gram molecular weight or mole, which consists of 6.023×10^{23} molecules of the substance and whose weight in grams is numerically equal to the molecular weight. (See MOLECULE, CHEMICAL.) (J. B. Ps.)

Many substances known only in solid and liquid states are not constructed of discrete molecules. For example, a crystal of sodium chloride is made up of sodium ions, Na^+, and chloride ions, Cl^-, held together primarily by the electrostatic attraction of ions of opposite charge. Each sodium ion is surrounded by six equivalent chloride ions arranged at the corners of a regular octahedron; each chloride ion is surrounded by six sodium ions in the same way. There are no identifiable molecules with the composition NaCl; in fact, the crystal may be considered as one giant molecule. In such cases the formula written is the simplest possible consistent with the known structures of the ionic units. Examples of such substances are: C (diamond), Fe_2O_3 (iron [111] oxide, or ferric oxide), SiO_2 (silicon dioxide), Na_2CO_3 (sodium carbonate, composed of Na+ ions and CO_3^{2-} ions), $Na_2H_2P_2O_6$ (disodium hypophosphate, composed of Na+ ions and $H_2P_2O_6^{2-}$ ions).

3. Nomenclature. — Compounds containing atoms of only two elements are called binary. It is conventional to write the formulas for binary compounds with the more electropositive element first and more electronegative element second; for example, HCl (hydrogen chloride), Cl_2O (dichlorine monoxide), OF, (oxygen difluoride). Exceptions are made for CH, (methane) and NH_3 (ammonia). The electropositive element is named by its usual name; the electronegative element is given the suffix *-ide*. (The two elements of a binary compound have different powers to attract the electrons in the chemical bond between them. Electronegativity is a measure of this attraction for electrons in the bond.)

Many substances can be considered to be related to binary compounds in which either the electropositive or electronegative atom is replaced by a group of atoms, known as a radical. If the radical is an electronegative group (an anion). it usually has the suffix -ate, such as in $NaNO_3$ (sodium nitrate), K_2SO_4 (potassium sulfate). $NaClO_3$ (sodium chlorate). Anions derived from the same central atom but with different numbers of oxygen atoms are distinguished by the suffix *-ite* and prefixes hypo- and per-, as in the series: NaClO (sodium hypochlorite), $NaClO_2$ (sodium chlorite), $NaClO_3$ (sodium chlorate). $NaClO_4$ (sodium perchlorate). In naming the acids corresponding to these salts, the ending -ate is replaced by *-ic*, and *-ite* by *-ous*, as in HClO (hypochlorous acid) and $HClO_4$ (perchloric acid).

In the series of chlorine compounds above, chlorine is said to exist in four different oxidation states, each characterized by an oxidation number. There is some arbitrariness in the definition of oxidation number, but it is generally the charge, in electronic units, on an atom if all the electron pairs used in chemical bonds are given to the more electronegative atom in each bond. Some simple rules conforming to this definition are as follows:

(1) The algebraic sum of the oxidation numbers of the atoms of a molecule or ion must equal the charge on the molecule or ion. (Thus the oxidation number of a chemically free element is always zero, and the oxidation number of a monatomic ion is the ionic charge; *e.g.*, for Fe^{2+} the oxidation number is 2+.)

(2) The oxidation number of fluorine in compounds is always 1−.

(3) The oxidation number of oxygen is 2−, except when bonded to fluorine (as in OF_2, when its oxidation number is 2+) or another atom of oxygen (as in H_2O_2, in which case its oxidation number is 1−).

(4) The oxidation number of hydrogen is 1+, except in hydrides of more electropositive elements (as in LiH), where it is 1−.

Then the following oxidation numbers can be assigned to the chlorine atom in the above-mentioned compounds: NaClO 1+, $NaClO_2$ 3+, $NaClO_3$ 5+, $NaClO_4$ 7+. Many metals produce cations (electropositive radicals) in more than one oxidation state. In naming these compounds, the oxidation state of the metal is shown by a Roman numeral in parentheses following the name of the metal. This system replaced an older one in which the suffixes *-ous* and -ic were used to designate the lower and higher oxidation states, respectively, for elements having two oxidation states. The older system is ambiguous when several oxidation states are known for an element. Examples of the two types of nomenclature are: $Fe(OH)_2$, iron (II) hydroxide (or ferrous hydroxide); $Fe(OH)_3$, iron (III) hydroxide (or ferric hydroxide). Note the existence of iron compounds with higher oxidation states such as $BaFeO_4$ (barium Eerrate [VI]) and $BaFeO_3$ (barium ferrate [IV]).

4. Inorganic Chemical Reactions. — A large fraction of the reactions in inorganic chemistry can be placed in one of two categories: acid-base reactions (see ACIDS AND BASES) and oxidation-reduction reactions (see OXIDATION AND REDUCTION). In acid-base reactions, a pair of electrons is completely or partially transferred from an electron donor atom or molecule (the base) to an electron acceptor atom or molecule (the acid). The following are examples of acid-base reactions:

$$\underset{\text{acid}_1}{H_3O^+} + \underset{\text{base}_1}{:\ddot{O}:H^-} \rightleftharpoons \underset{\text{acid}_2}{H_2O} + \underset{\text{base}_2}{H_2O} \quad (1)$$

$$\underset{\text{acid}_1}{HClO} + \underset{\text{base}_1}{H_2O} \rightleftharpoons \underset{\text{acid}_2}{H_3O^+} + \underset{\text{base}_2}{ClO^-} \quad (2)$$

$$\underset{\text{acid}_1}{H_2O} + \underset{\text{base}_1}{:\ddot{Cl}:\ddot{O}:^-} \rightleftharpoons \underset{\text{acid}_2}{HClO} + \underset{\text{base}_2}{OH^-} \quad (3)$$

$$\underset{\text{acid}}{BF_3} + \underset{\text{base}}{:NH_3} \rightarrow BF_3NH_3 \quad (4)$$

$$\underset{\text{acid}_1}{Co(NH_3)_5Cl^{2+}} + \underset{\text{base}_1}{H_2O} \rightleftharpoons \underset{\text{acid}_2}{Co(NH_3)_5H_2O^{3+}} + \underset{\text{base}_2}{Cl^-} \quad (5)$$

These various acid-base reactions have more specific names. The first is called neutralization, as in the addition of an acid solution (such as hydrochloric acid) to a basic solution (such as sodium hydroxide) to produce a neutral solution of a salt (in this case sodium chloride). Since the sodium ions and chloride ions do not participate in the reaction, they are not shown in the equation.

Reaction 2 is the dissociation of a weak acid. Some acids such as nitric acid (HNO_3) and perchloric acid ($HClO_4$) dissociate completely in water to give hydrogen ions (H^+ or H_3O^+ cations) and anions (NO_3^- or ClO_4^-). These are called strong acids. Other acids such as hypochlorous acid (HClO) and nitrous acid (HNO_2) are only partly dissociated to hydrogen ions and anions, and most of the acid exists in solution as undissociated molecules of HClO or HNO_2. These are called weak acids and are characterized by a dissociation (ionization) constant K_A, which is a measure of the degree of dissociation. If the concentration of an acid in solution is represented by [HA] moles per liter, and the concentrations of hydrogen ion and anion by $[H^+]$ and $[A^-]$, respectively, then

$$K_A = \frac{[H^+][A^-]}{[HA]}$$

Strong acids have large values of K_A, weak acids have small values. By the same method, bases are classified as strong and weak bases according to their basic dissociation constant K_B.

Reaction 3 is referred to as hydrolysis. If a salt of a strong base and a weak acid, such as sodium hypochlorite (Na^+ClO^-), is dissolved in water, the hydrolysis reaction takes place to produce some HClO molecules and some OH^- ions, which make the solution basic. Similarly, a salt of a weak base and a strong acid, such as ammonium chloride ($NH_4^+Cl^-$), will hydrolyze in water to give an excess of hydrogen ions that makes the solution acid.

Reaction 4 is the formation of an addition compound. The ammonia molecule has one unshared electron pair that can be partially accepted by the boron trifluoride to form a covalent bond.

Reaction 5 is a substitution, or displacement, reaction. in which one of the atoms or radicals in a co-ordination complex is replaced by another atom or radical from the solution. Reactions of this type are also important in organic chemistry.

Oxidation-reduction reactions are those in which the oxidation

number of one or more elements is changed. An element is said to be oxidized in a reaction if its oxidation number increases. It loses a number of electrons equal to the change in oxidation number. An element is reduced if its oxidation number decreases by accepting electrons from the element that is oxidized. The element that is oxidized is called a reducing agent; the element that is reduced is called an oxidizing agent. The following are examples of oxidation-reduction reactions (the oxidation states of the oxidizing and reducing agents and of the oxidation and reduction products are shown in parentheses):

$$\underset{\text{reducing agent}}{Mg^{(0)}} + \underset{\text{oxidizing agent}}{Cu^{++(2+)}} \rightarrow Mg^{++(2+)} + Cu^{(0)} \quad (6)$$

$$\underset{\text{reducing agent}}{C^{(0)}} + \underset{\text{oxidizing agent}}{O_2^{(0)}} \rightarrow C^{(4+)}O_2^{(2-)} \quad (7)$$

$$\underset{\text{reducing agent}}{5H_2O_2^{(1-)}} + \underset{\text{oxidizing agent}}{2Mn^{(7+)}O_4^-} + 6H^+ \rightarrow 5O_2^{(0)} + Mn^{(2+)} + 8H_2O \quad (8)$$

$$\underset{\text{reducing agent}}{Cl_2^{(0)}} + \underset{\text{oxidizing agent}}{Cl_2^{(0)}} + 4OH^- \rightarrow 2Cl^{(1-)} + 2Cl^{(1+)}O^- + 2H_2O \quad (9)$$

In reaction 4, chlorine acts both as oxidizing and reducing agent; such a reaction is called disproportionation.

For each element that is known in two different oxidation states, a "half reaction" may be written, such as $Fe^{2+} \rightarrow Fe^{3+} + e^-$, where e^- represents an electron. If this half reaction has a large thermodynamic tendency to go from left to right, the species of lower oxidation number is called a strong reducing agent. If the half reaction has a large tendency to go from right to left, the species of higher oxidation number is called a strong oxidizing agent. Thus a series can be constructed in which an oxidizing agent can oxidize the reduced form of any element lower in the series.

It should be pointed out that many reactions that are energetically possible take place at rates that are too small to produce any observable change. This is particularly true for oxidation-reduction reactions. For example, hydrogen and oxygen can be kept together indefinitely at room temperature without measurable reaction. even though there is a very strong thermodynamic tendency for a reaction to form water. If there were chemical equilibrium between the oceans and the atmosphere, the nitrogen, oxygen and water would have combined to form nitric acid! So two questions must be answered for oxidation-reduction reactions: first, is a given reaction thermodynamically possible? and second, does it proceed at an appreciable rate?

B. Chemical Properties of the Elements

The chemical properties of the elements must be discussed in relation to the periodic table (see Periodic Law). In the table, the members of a vertical column all have the same configuration of outer electrons (valence electrons). Among the elements of one column, there are marked similarities in the formulas of compounds formed, and in chemical and physical properties of the elements and their compounds. There are variations, however, of properties within a column of the periodic table because of the increasing size of atoms or ions in successive periods. Therefore, for each column of the periodic table, it is appropriate to discuss the compounds and properties typical of the group of elements, and then the gradations of properties within the group.

In some parts of the periodic table, new electrons are added to underlyinq shells, rather than to the valence shell of electrons, so that the number of valence electrons remains constant for several elements in a row. In these cases, the properties of the elements arc similar. and are best discussed together. The elements concerned are the transition metals (from scandium to zinc and the corresponding groups of the second and third long periods), and the rare earths (the lanthanide series, from cerium to lutetium, and the actinide series from thorium to lawrencium). (See Elements, Chemical; Valence.)

1. Hydrogen. — Hydrogen is discussed separately because of its unique electronic structure, a single electron. This electronic configuration is given the symbol $1s^1$, indicating that the 1s orbital is occupied by one electron.

In the elemental form, two hydrogen atoms share their two electrons to form a covalent bond in the molecule H_2. Since this is the simplest possible molecule involving a two-electron bond, it has been of great importance in theoretical chemistry. It has been possible by the Heitler-London method and other quantum mechanical calculations to describe quantitatively the properties of the hydrogen molecule on a purely theoretical basis. Because of the enormous complexity of problems involving many particles, it has not been possible to make similar exact calculations of the properties of more complex molecules such as F_2, but the success of the treatment for hydrogen indicates that the fundamental nature of covalent bonding is understood.

Hydrogen can share its electron with more electronegative elements to form compounds of the 1+ oxidation state, such as H_2O and HCI. Most of these binary compounds are gases at room temperature. Binary compounds of hydrogen with the Group VI and VII elements dissolve in water to give acids; *i.e.*, they dissociate to give hydrogen ions and anions. The hydrogen ion does not exist in solution as a bare proton but is solvated (combined with solvent molecules) by one or more water molecules to give species such as H_3O^+ or $H_9O_4^+$. Since solvation takes place for all ions in solution, and often to an unknown extent, it is customary not to specify the degree of solvation in a chemical equation unless there is specific concern for reactions involving the solvent molecules. Hence the hydrogen ion in solution is usually written as H^+ or $H_{(aq)}^+$.

Hydrogen can accept an electron from an electropositive element to form a hydride ion H^-, which exists in salts such as NaH, sodium hydride. This contains hydrogen in the 1− oxidation state, analogous to halides. Hydrides of the alkali metals and alkaline earth metals are salts, forming ionic lattices similar to the corresponding halides. They react with water to liberate hydrogen.

2. Group I, the Alkali Metals. — The atoms of these elements (lithium, sodium, potassium, rubidium, cesium and francium) have only one valence electron outside the inner core of electrons of inert gas configuration (see Inert Gases below). The alkali metals are the most electropositive of all the elements; *i.e.*, they lose the valence electron very easily to give ions of charge 1+. For example, the metals reduce water to give hydrogen gas in the reaction:

$$2K + 2H_2O \rightarrow 2K^+ + 2OH^- + H_2$$

No other oxidation states are known besides O and 1+.

The metals are soft and easily cut; they react readily with oxygen of the air, and are usually kept under an inert liquid, such as kerosene. Within this group of elements, the reactivity increases from lithium to cesium. (Little is known about francium, since it is radioactive with a short half-life and exists only in very minute quantities in nature.)

The alkali metals form compounds with the electronegative elements, such as the halogens (Group VII) and the oxygen group (Group VI), as well as with hydrogen. In all cases, the alkali metal atom is in the 1+ oxidation state, and the compounds are held together by almost purely ionic forces. These compounds are usually very soluble in water, and only a few salts involving complex anions (*e.g.*, $K_3Co(NO_2)_6$) are sufficiently insoluble to be of use in gravimetric quantitative analysis.

The oxides of the alkali metals dissolve in water to give strongly basic solntions. Salts of the alkali metals and strong acids give neutral solutions (such as sodium chloride or sodium sulfate); salts from weak acids give basic solutions (such as sodium carbonate or sodium phosphate). It should be pointed out that the chemistry of the ammonium ion (NH_4^+) is similar in many ways to that of the alkali metal ions, differing primarily in that ammonium hydroxide is a weak base.

3. Group II, the Alkaline Earths. — The atoms of Group II elements (beryllium magnesium, calcium. strontium, barium and radium) have two electrons in an s orbital outside a closed shell of

inner electrons, giving a valence electron configuration s^2. With the exception of beryllium, these electrons are readily lost to an oxidizing agent to produce ions of charge $2+$. The more reactive members of the group, calcium, strontium, barium and radium, react with cold water like the alkali metals:

$$Ca + 2H_2O \rightarrow Ca^{2+} + 2OH^- + H_2$$

These metals are powerful reducing agents, but less so than the alkali metals of Group I.

As in the case of the Group I elements, the alkaline earth metals form binary compounds with the more electronegative nonmetals to give compounds such as calcium fluoride (CaF_2), calcium oxide (CaO), calcium nitride (Ca_3N_2) and calcium carbide (CaC_2). In all their compounds the alkaline earth elements have an oxidation state of $2+$.

Compounds of Group II elements are bound by principally ionic forces. Several compounds, especially with divalent anions, have very low solubility in water (*e.g.,* calcium carbonate, barium sulfate).

The oxides react with water to give the hydroxides, which are less soluble in water than the alkali metal hydroxides. The solutions are basic because of the dissociation:

$$Ca(OH)_2 \rightarrow Ca^{2+} + 2OH^-$$

The solubilities of the hydroxides increase in the series from beryllium to radium.

In each column of the periodic table, the elements are progressively more metallic from top to bottom; in each horizontal row, the elements are less metallic from left to right. As a result, the first member of a column often bears strong similarities to the elements in the next column to the right. For example, lithium resembles the alkaline earth metals more than the other alkali metals in its reactivity toward water; beryllium hydroxide is amphoteric, like aluminum hydroxide, while none of the other Group II hydroxides are amphoteric. (A hydroxide or oxide that can react with either acids or bases is said to be amphoteric.) (See ALKALINE EARTHS.)

4. Group III Elements. — These elements (boron, aluminum, gallium, indium and thallium) have three electrons in the valence shell, giving a configuration s^2p. The degree of metallic or electropositive character has a wide range in this group. Boron is a nonmetallic element: solid boron is a poor electrical conductor and its oxide, B_2O_3, is acidic. (It dissolves in water to give boric acid, a weak acid, and dissolves in bases to give borates.) Boron forms a remarkable series of compounds with hydrogen that are discussed in BORON.

Aluminum and the other Group III elements are metals. The hydroxides have very low solubility in water but dissolve in acids to give solutions containing the ion in the $3+$ oxidation state, such as Al^{3+}. The amphoteric hydroxides of aluminum and gallium also dissolve in strong bases to give solutions of aluminates and gallates, containing the ions $Al(OH)_4^-$ and GaO_3^{3-}.

Binary compounds formed in reactions between Group III elements and the halogens differ considerably in properties from the halides of Groups I and II. This does not represent a sudden change in the type of chemical bond between the metal and halogen but reflects the differences in structure of the molecular units, In the sodium chloride crystal, for example, each sodium is bound to six chlorines and each chlorine to six sodiums, so that the entire crystal is one large molecule. In order to melt or vaporize sodium chloride, it is necessary to break strong Na—Cl bonds. In boron trichloride, BCl_3, each boron atom is attached to only three chlorine atoms (because of the very small size of the B^{3+} ion) so that BCl_3 molecules exist as discrete units. In the solid state these molecules are attracted to one another only by weak van der Waals' forces, *i.e.,* the forces attracting the molecules to each other, so that they are easily separated in melting and vaporization. As a result, boron trichloride is a gas at room temperature (boiling point 13° C.). Similarly aluminum trichloride forms molecules, of the formula Al_2Cl_6, that remain as separate units in the solid. This solid melts at 194" C., much lower than sodium chloride or magnesium chloride.

In addition to the usual $3+$ oxidation state, compounds of thallium are known in which thallium is in the $1+$ state. These compounds resemble analogous Group I compounds in many properties: TlOH, for example, is a strong base.

5. Group IV Elements. — The elements of Group IV (carbon, silicon, germanium, tin and lead) have four electrons in their outermost shell, with configuration s^2p^2. As in the case of Group III, there is a marked trend from nonmetallic to metallic properties from top to bottom of the column. Carbon exists in two crystal modifications: graphite and diamond. In graphite each carbbn atom is joined to three others in a plane, forming layers that give graphite its characteristic cleavage. In diamond, each carbon atom is surrounded by four others at the corners of a regular tetrahedron, producing a continuous three-dimensional network. Silicon, germanium and gray tin also have the diamond structure, and, like diamond, are poor electrical conductors when they are very pure. High temperatures or the presence of impurities makes these crystals into moderately good conductors: they are called semiconductors and are of great importance in electronics. Lead and white tin behave as metals.

The highest oxidation state of the Group IV elements is $4+$. The oxides of the $4+$ state range from acid in the case of CO_2 and SiO_2 to amphoteric for GeO_2, SnO_2 and PbO_2. The carbonate ion, CO_3^{2-}, has a planar triangular structure. There are many anions involving Si^{4+}, all built from a tetrahedral unit SiO_4. These units may be isolated as SiO_4^{4-} ions, joined in long chains to give SiO_3^{2-}, or joined in double chains, sheets or three-dimensional frameworks to give other more complex formulas. The chemistry and structure of silicates are important since these compounds constitute the great majority of the mass of the earth.

Compounds are also known containing germanium, tin and lead in the $2+$ oxidation state. The $2+$ state is more stable relative to the $4+$ state in the heavier members of the group, so that the Sn^{2+} ion is a good reducing agent, being easily oxidized to Sn^{4+}, whereas PbO_2 is a strong oxidizing agent, being easily reduced to Pb^{2+}.

All the Group IV elements form hydrides: CH_4, SiH_4, GeH_4, SnH_4 and PbH_4, all of which are gases at room temperature. Carbon forms thousands of hydrides of more complicated structure in which there are carbon-carbon bonds. There is much less tendency for the other elements in this group to form long chains and rings. The largest known silicon hydride (silane) molecules contain a chain of six silicon atoms; germanium hydrides are known only up to Ge_3H_8, and none are known for tin and lead except SnH_4 and PbH_4. It is the extraordinary ability of carbon atoms to form carbon-carbon bonds that results in the fact that compounds containing carbon far outnumber compounds without carbon. This is the reason for treating carbon chemistry in the separate field of organic chemistry.

6. Group V Elements. — The Group V elements (nitrogen, phosphorous, arsenic, antimony and bismuth) have valence electron configuration s^2p^3. In the elemental form, nitrogen and phosphorus are nonmetallic, arsenic and antimony exist in both metallic and nonmetallic forms, and bismuth is a metal.

All the elements of this group have compounds involving the $3-$, $3+$ and $5+$ oxidation states. For nitrogen, compounds are known for every oxidation state from $3-$ to $5+$. In the $3-$ oxidation state, the three p electrons are shared with a more electropositive element, hydrogen, to give a series of hydrides: ammonia (NH_3), phosphine (PH_3), arsine (AsH_3), stibine (SbH_3) and bismuthine (BiH_3). These compounds are gases that decrease in stability and increase in acidity in the order shown. Ammonia dissolves in water to give the weak base, ammonium hydroxide; phosphine is almost insoluble in water and gives neutral solutions; stibine is slightly acidic and can form salts, such as Na_3Sb, sodium antimonide.

By sharing the three p electrons with a more electronegative atom, such as a halogen or oxygen, elements of Group V form compounds of the $3+$ oxidation state. These include a series of trihalides such as NF_3, PCl_3, AsF_3, etc. The molecules of these compounds as pyramidal in shape, with the Group V atom above a planar triangle of halogen atoms. They are gases, volatile liquids or solids at room temperature; all are reactive and strongly acidic.

For example, phosphorus trichloride reacts readily with water to give phosphorous acid and hydrochloric acid.

Except for N_2O_3, which is stable only at very low temperatures, the oxides, of empirical formula M_2O_3, are stable solids formed by burning the elements in air. They are anhydrides of the corresponding oxy-acids. For example, phosphorus (III) oxide dissolves in water to give phosphorous acid, H_3PO_3, which is a weak dibasic acid. (The suffix *-ous* distinguishes it from phosphoric acid, H_3PO_4, which contains phosphorus in the $5+$ oxidation state.) The more electropositive nature of the heavier elements of the group is shown by the behaviour of the compounds H_3MO_3 or $M(OH)_3$. As mentioned above, phosphorous acid dissociates only as a weak acid and forms salts such as sodium phosphite, Na_2HPO_3; arsenious acid reacts with bases to give salts such as silver arsenite, Ag_3AsO_3; antimony forms both anions (antimonite, SbO_2^-) and cations (Sb^{3+} and SbO^+); bismuth forms only cations. Bi^{3+} and BiO^+.

The $5+$ oxidation state is achieved by the sharing of all five valence electrons with a more electronegative element. Thus there exist pentahalides and pentoxides of all the elements of the group except nitrogen. In order to use all five electrons for covalent bonding, it is necessary to unpair the two electrons in the s orbital of the valence shell and promote one to a d orbital. This is possible only for elements beyond neon in the periodic table, since in the first horizontal row of eight elements there are no low-energy d orbitals available.

The pentahalides are reactive compounds, strong acids, strong halogenating agents and oxidizing agents. The common oxy-acids are nitric acid (HNO_3), phosphoric acid (H_3PO_4), arsenic acid (H_3AsO_4), etc.

The properties of nitrogen differ considerably from those of the rest of the group in several ways. First, because the atom is smaller, it tends to form compounds of lower co-ordination number for the same oxidation state. Whereas phosphorus and the heavier members form anions with formulas such as PO_4^{3-}, in which the phosphorus atom is surrounded tetrahedrally by four oxygen atoms, nitrogen has room for only three oxygen atoms, and forms the planar ion NO_3^-. Second, because only four bonds can be formed without using d orbitals, nitrogen has no pentahalides. Third, the tendency to form multiple bonds is much greater for elements of the first horizontal row of the periodic table than for elements below the first row, so that nitrogen forms very stable multiply bonded molecules such as N_2 and NO; this property has a large effect on the oxidation-reduction reactions involving nitrogen compounds.

7. Group VI Elements. — The Group VI elements (oxygen, sulfur, selenium, tellurium and polonium) have six electrons in the outer shell. giving configuration s^2p^4. Oxygen and sulfur are nonmetallic; elemental selenium exists in both nonmetallic and metallic forms; tellurium and polonium are metallic.

These elements can accept two electrons from an electropositive element to form an ion with the electronic structure of an inert gas: s^2p^6. This electronic configuration is particularly stable and inert. Two of the p electrons in the neutral atom are unpaired and available for the formation of two covalent bonds with more electropositive atoms, such as hydrogen. In each of these cases, the Group VI element is in the $2-$ oxidation state, and the binary compounds are oxides, sulfides, etc. This is the oxidation state of oxygen in almost all its compounds.

Compounds in which there is an oxygen-oxygen bond are called peroxides and contain oxygen in the $1-$ oxidation state. Their chemistry is particularly interesting in that they can be reduced to give oxides ($2-$ oxidation state) or oxidized to give (0 oxidation state). There are also analogous compounds with sulfur-sulfur bonds (compare hydrogen peroxide, H_2O_2, with hydrogen disulfide, H_2S_2).

The Group VI elements can share their two available p electrons with a more electronegative atom, such as a halogen, to give compounds of the $2+$ oxidation state, such as oxygen fluoride (OF_2), sulfur dichloride (SCl_2), tellurium dibromide ($TeBr_2$), etc. Most of these are unstable gases or liquids.

For the members of the group heavier than oxygen, all four p electrons may be shared in covalent bonds with halogens or oxygen to give the tetrahalides such as SF_4, $TeBr_4$, the dioxides SO_2, SeO_2, TeO_2 and the oxy-acids such as H_2SO_3, all involving the $4+$ oxidation state. Sulfur dioxide and sulfurous acid are good reducing agents. Selenium dioxide and tellurium dioxide are poor reducing agents but can act as oxidizing agents by being themselves reduced to elemental selenium and tellurium.

The highest oxidation state of the Group VI elements is $6+$, attained by sharing all six of the valence electrons with halogens or oxygen. The only known hexahalides are SF_6, SeF_6, TeF_6. They are all gases at room temperature, and are unreactive. The trioxides SO_3, SeO_3, TeO_3 dissolve in water to give the acids: sulfuric acid (H_2SO_4), selenic acid (H_2SeO_4) and telluric acid (H_6TeO_6). Of these, the first two are strong dibasic acids, the third is a very weak dibasic acid. Selenic and telluric acids are good oxidizing agents.

Sulfur also forms a series of dibasic oxy-acids containing sulfur-sulfur bonds. These include thiosulfate ($S_2O_3^{2-}$), dithionate ($S_2O_6^{2-}$) and the polythionates ($S_nO_6^{2-}$, in which $n = 3, 4, 5, 6$).

8. Group VII, the Halogens. — The halogens (fluorine, chlorine, bromine, iodine and astatine) have seven electrons in the valence shell, with configuration s^2p^5. The elements are all nonmetallic and form diatomic molecules, such as F_2 and Cl_2. At room temperature fluorine and chlorine are gases, bromine is a volatile liquid and iodine and astatine are solids.

The halogens are the group most commonly chosen to illustrate the properties of the periodic table. They show a strong resemblance to one another in the formulas and properties of the compounds they form; the gradation of these properties within the group is usually clear.

The Group VII elements can acquire an inert gas electronic configuration by accepting one electron from an electropositive atom to give a halide ion (see *Inert Gases* below). The $1-$ oxidation state will also be produced by sharing the unpaired p electron with a more electropositive element, as in hydrogen bromide (HBr). Since fluorine is the most electronegative of all elements, all its compounds except F_2 involve the $1-$ oxidation state.

The halogens form binary compounds (halides) with all the elements except the inert gases. (Some of the properties of these compounds have been discussed in earlier sections.) In general, the electronegativity of atoms in a row of the periodic table increases from left to right, so that the halogens are the most electronegative elements in each row. The bond between two atoms can be considered intermediate between purely ionic and purely covalent, the amount of ionic character depending on the electronegativity difference between the two atoms. Thus for the fluorides of the second row of the periodic table, NaF has the most ionic bonds, ClF the least ionic and most covalent. The amount of ionic character decreases regularly along the row, and no sudden change in bond type is implied by the sudden change in properties from high melting solids (NaF, CaF_2, AlF_3) to the gases (SiF_4, PF_5, SF_6, ClF).

As was discussed in the section on Group III elements, this change in properties represents a change in co-ordination number due to the decreasing size of the central ion, so that the last four substances exist as discrete molecules in the solid state, whereas the first three form continuous crystals without separate molecule units.

The halogens beyond fluorine can share their unpaired p electron with oxygen to give the $1+$ oxidation state, characterized by the hypohalites: hypochlorous acid (HClO), hypobromous acid (HBrO) and hypoiodous acid (HIO). These are weak acids and are formed by disproportionation (autooxidation and reduction) of the halogens in water by reactions such as:

$$Cl_2 + H_2O \rightarrow HClO + H^+ + Cl^-$$

The hypohalites themselves are unstable and disproportionate slowly to give halides and halates. The hypohalites are rapid, powerful oxidizing agents.

The $3+$ oxidation state is known in the compounds ClF_3, BrF_3 and ICl_3 but the corresponding oxy-acid is known only for chlorine; *i.e.*, chlorous acid ($HClO_2$). Chlorous acid, a weak acid,

is a strong oxidizing agent and decomposes readily to chlorine and chlorine dioxide (ClO_2).

Oxidation of halogens leads to halates: chlorate (ClO_3^-), bromate (BrO_3^-) and iodate (IO_3^-), where the halogen is in the 5+ oxidation state. The halic acids are strong acids and powerful oxidizing agents.

The highest state of oxidation for this group is 7+, found in the compounds iodine heptafluoride (IF_7), perchloric acid ($HClO_4$) and periodic acid (H_5IO_6 and HIO_4). Perchloric acid is a strong acid and thermodynamically a strong oxidizing agent. With most reducing agents, however, its rate of reaction is low, so that perchlorates remain unchanged in the presence of many powerful reducing agents. The perchlorate ion also has the property of being the poorest anion in forming co-ordination complexes with cations. (*See* HALOGENS.)

9. Group VIII, the Inert Gases.—These remarkable elements (helium, neon, argon. krypton, xenon and ruthenium) have almost no chemistry. Their electronic configurations are: for helium $1s^2$, for the others s^2p^6, which constitutes a filled shell. That is, there are no empty orbitals available in the atom of low enough energy to be used in chemical binding. The energy needed to remove an electron from the outer shell is much greater than that available in ordinary chemical reactions, so that no ions such as Ne^+ are formed. The inert gas atoms have no affinity for electrons to form negative ions such as Ne^-. No more electrons can be accommodated in the filled shell, so that no covalent bonds can be formed.

These elements are all monatomic gases at room temperature, differing in their melting and boiling points and in the extent to which they can be adsorbed on surfaces. Helium atoms have so little attraction for one another that helium does not solidify even at the absolute zero of temperature.

10. The Transition Metals.—The 30 transition metals include scandium, titanium, vanadium, chromium, manganese, iron, cobalt, nickel. copper, zinc and the corresponding series of the second and third long periods. They have many similarities in properties because of their similar valence electron configuration. With minor exceptions for chromium and copper, each atom has two electrons in the outer valence shell, in an s orbital (in the first transition series, the 4s orbital). Members of the series differ in the number of electrons in an inner subshell, the 3d orbitals. There are five of these orbitals, each of which can accommodate two electrons, thus accounting for the 10 members of the series. Scandium has an outer electron configuration $3d^14s^2$, titanium $3d^24s^2$, vanadium $3d^34s^2$, etc., until the 3d level is filled at zinc.

All the transition metals, except scandium, form stable compounds in the 2+ oxidation state by loss of the pair of 4s electrons. The 2+ cations formed differ only slightly from one another in size, the trend being toward smaller ions as more d electrons are added. Because there is no variation in charge, and little variation in size of these cations, their chemical properties are very similar. All form insoluble hydroxides and sulfides, soluble halides and sulfates, and crystals in which other transition metal ions can be substituted to form extensive solid solutions.

Most of the transition metals are also known in the 3+ oxidation state, forming another set of similar ions. An important property of the transition metals, particularly in the 2+ and 3+ oxidation states, is their ability to form co-ordination compounds. These are molecules or ions in which a transition metal ion is surrounded by several other atoms, molecules or ions known as ligands. The ligands are arranged in a simple geometrical manner around the central atom. For example, six ligands usually form a regular octahedron, and four ligands form either a tetrahedron or a plane square. Compounds of this sort exist also for nontransition metal ions, such as $Ca(H_2O)_6^{2+}$, the calcium ion in aqueous solution, but the presence of d electrons in the transition metals makes their complex ions more stable and often more inert to chemical reaction. Typical transition metal complexes are: $Fe(CN)_6^{3-}$, hexacyanoferrate (III); $Co(NH_3)_6^{3+}$, hexaammine cobalt (III); $Mn(H_2O)_6^{2+}$, hexaaquomanganese (II); $Cu(NH_3)_4^{2+}$, tetraammine copper (II). (*See* CO-ORDINATION COMPOUNDS: Some *Important* Types of Co-ordination Compounds.)

All reactions of the transition metal ions in solution should be considered as reactions involving co-ordination complexes. The solid compounds of these elements are best described as complex ions linked together through sharing ligands. For instance, in solid CrF_2, the chromium ion is at the centre of an octahedron of fluoride ions, very similar to its environment in solution.

Lower valence states are also able to form co-ordination complexes with certain ligands, giving compounds such as $Ni(CO_4)$, tetracarbonyl nickel (0), and $Pd(PF_3)_3$, tris-trifluorophosphine palladium (0).

In their highest oxidation states, some of the transition metals form acid oxides and anions. Vanadium can share its three d electrons and two s electrons with oxygen to give vanadates containing the ion VO_4^{3-} or VO_3^- (compare with phosphate). Similarly, chromium in the 6+ oxidation state gives chromic acid and chromates (such as K_2CrO_4). Manganese is known in the 6+ state as the manganate ion MnO_4^{2-} and in the 7+ state as the permanganate ion MnO_4^-.

In the second transition series (yttrium through cadmium) and the third series (lanthanum, hafnium, tantalum, etc., to mercury), higher oxidation states tend to be more stable, and lower oxidation states less stable than in the first transition series. Compounds of the 2+ oxidation state are rare, and compounds of the maximum oxidation state reached by sharing all the d and s electrons are common. This can be illustrated by considering examples of elements of the same outer electron configuration from the three transition periods.

Vanadium, Niobium, Tantalum.—Vanadium exists as V^{2+}, V^{3+} and VO^{2+} in aqueous solution, the 2+ ion being readily oxidized to the 3+ state. In the 5+ state, vanadic acid is a good oxidizing agent. Niobium forms a trichloride, $NbCl_3$, but the 3+ state in aqueous solution is a strong reducing agent, being oxidized to the 5+ state. The only compounds of tantalum stable in aqueous solution are tantalates, involving the 5+ oxidation state.

Iron, Ruthenium, Osmium.—The common stable oxidation states of iron are 2+ and 3+. By electrolytic oxidation in strongly basic solution, iron may be oxidized to the ferrate (VI) ion, FeO_4^{2-}, which is a powerful oxidizing agent (better than permanganate). Ruthenium forms stable solutions containing complex ions of the 3+ and 4+ oxidation states. Also known are the ruthenate (VI) ion, RuO_4^{2-}, and the ruthenate (VII) ion, RuO_4^-. Continued oxidation produces a volatile compound, RuO_4, ruthenium tetroxide, in the 8+ oxidation state. The chemistry of osmium is similar to that of ruthenium, with the higher oxidation states being still more stable.

The stabilization of higher oxidation states in the second and third transition series decreases as the d shell fills up, so that there is not much difference in stability of the corresponding oxidation states of nickel, palladium and platinum.

Copper, Silver and Gold.—In this group only the 1+, 2+ and 3+ states are stable. For copper, Cu^{2+} is stable in most environments and the 3+ state, as in the cuprate (III) ion, CuO_2^-, is a strong oxidizing agent. Both the 2+ and 3+ states of silver are powerful oxidizing agents. Complex ions involving gold (III) are only moderate oxidizing agents. Both the 1+ and 2+ states are unstable with respect to disproportionation to gold (0) and gold (III). No compounds of gold (II) are known.

Zinc, *Cadmium* and Mercury.—In these elements the 3d subshell is full and only the two electrons in the 4s subshell are involved in chemical binding. The commonest oxidation states are 2+, but compounds of mercury (I), which contain the ion Hg_2^{2+}, are also known.

It is interesting to compare the chemistry of zinc, cadmium and mercury with that of magnesium, calcium and strontium of the alkaline earths. All give ions with a charge 2+ by loss of a pair of outer s electrons. The sizes of corresponding pairs of ions are comparable: the ionic radii are Zn^{2+}, 0.72 A; Mg^{2+}, 0.66 A; Cd^{2+}, 0.96 Å; Ca^{2+}, 0.99 Å; Hg^{2+}, 1.10 Å; Sr^{2+}, 1.15 A. (The symbol A is for angstrom unit, which equals 10^{-8} cm.) In all these cases the ions are spherical and differ therefore only in that those of the zinc group have a filled d subshell as their outermost electrons, whereas those of the alkaline earth group have a

filled p subshell. For purely ionic chemical binding, the binding energy of a compound decreases as the separation between the centres of the ions increases, so that the binding energy of a series of ionic compounds of the alkaline earth elements decreases from magnesium to calcium to strontium. For example, the heats of hydration of these ions are as follows: Mg^{2+}, 464 kg.cal./mol.; Ca^{2+}, 382 kg.cal./mol.; Sr^{2+}, 350 kg.cal./mol. For purely ionic bonds, the heat of hydration of an ion of the zinc group should be very similar to that of the corresponding alkaline earth ion of the same size, since the charges and radii are alike. The observed values are Zn^{2+}, 492 kg.cal./mol.; Cd^{2+}, 437 kg.cal./mol.; Hg^{2+}, 441 kg.cal./mol. It is observed that the second group has larger binding energies and that these decrease much less for the heavier members. This is accounted for by an increase in the covalent nature of the bonds for ions with an 18-electron outer shell, such as the zinc group. The increase in amount of covalent character is the result of the poorer shielding of the nuclear charge provided by outer d electrons than by outer p electrons.

Because 18-electron shell ions form bonds that have considerable covalent character, structures of their compounds are generally more complicated than those of ions that have the electronic configuration of an inert gas. In the latter case, crystal structures are determined primarily by the efficiency of packing of spherical ions. In the former case, directed valence bonds are present, which lead to crystal structures other than the simple closest-packed structures. For example, magnesium oxide has a cubic structure of the sodium chloride type, but zinc oxide has a hexagonal structure of the wurtzite (a zinc sulfide ore) type in which each zinc ion is tetrahedrally surrounded by four oxygen atoms.

11. Rare-Earth or Lanthanide Elements. — These 14 elements, which have remarkably similar chemical properties, include cerium, praseodymium, neodymium, promethium, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium and lutetium. In their electronic structures, they have the following in common: filled shells up to the 5s and 5p levels to give an electron core of the same configuration as the inert gas xenon, usually empty 5d orbitals (these become filled in the third transition series described above) and a pair of 6s electrons. The electronic structures of the rare earths differ from one another only in the number of electrons in the 4f subshell, ranging from 2 for cerium up to 14 for lutetium. The orbitals of the 4f electrons are buried so far inside the electron cloud of these atoms that they have very little influence on the chemical properties.

The characteristic oxidation state of the rare earths in aqueous solution is 3+. Besides this state, a few elements with electronic configurations near f^0, f^7 and f^{14} are found in 2+ or 4+ states, such as Ce (IV), Eu (11), Tb (IV).

The chemistry of the rare-earth elements is similar to that of the alkaline earth metals. The elements are metallic, dissolve readily in acids and react with hot water to form the hydroxides and liberate hydrogen. The oxides M_2O_3 are basic, and salts of M^{3+} cations with strong acids are only slightly hydrolyzed. The halides (except fluoride), nitrates and perchlorates are quite soluble in water, whereas the oxides, hydroxides, sulfates, phosphates and fluorides are insoluble. Because of their large ionic radii, the rare earths form very few complex ions.

Because of their strong similarities in properties, the rare-earth elements are not easily separated from one another by the classical chemical techniques of precipitation or extraction. Since differences in solubility of different rare-earth compounds are very slight, many tedious fractional crystallizations are necessary in the use of such techniques. However, the adaptation of ion exchange (*q.v.*) procedures on a large scale has made possible the preparation of large quantities of very pure rare earth compounds. (See RARE EARTHS.)

12. Actinide Elements. — These 14 elements form a series, analogous to the lanthanide series, in which the 5f subshell is being filled. Members of the actinide series include thorium, protactinium, uranium, neptunium, plutonium, americum, curium, berkelium, californium, einsteinium, ferium, mendelevium, nobelium and lawrencium. In the first members of the series, thorium, protactinium and uranium, there is little energy difference between the 5f electrons and the 6d electrons so that these elements resemble in some ways the elements hafnium, tantalum and tungsten more than the first elements of the lanthanide series. For instance, the most stable oxidation states in aqueous solution are Th (IV), Pa (V) and U (VI). With increasing atomic number, the actinide elements resemble more closely the lanthanides, and the 3+ oxidation state is the most stable for the elements after plutonium.

All the actinide elements are radioactive, and beyond uranium are necessarily man-made since they are not found on the earth (see TRANSURANIUM ELEMENTS). For the higher atomic numbers, most of the isotopes have short half-lives and therefore high specific activities, so that it is not feasible to study their chemistry on large amounts of material. Special carrier techniques are used to study the properties of these elements. (See RADIOACTIVITY, ARTIFICIAL: Methods of *Chemical* Identification and Concentration.)

The metallic element actinium is sometimes regarded as the prototype of the actinide series and when it is considered part of this group the series is called the actinium series. The chemical properties of actinium, however, resemble those of the rare-earth (lanthanide) elements. (See ACTINIUM.)

C. Experimental Procedures in Inorganic Chemistry

1. Structural Chemistry. — In order to understand the properties and reactions of any compound it is necessary to know the structure of its molecular or crystal units. This requires a knowledge first of the spatial arrangement of the constituent atoms in terms of distances between atoms (bond lengths) and angles between bonds. It also requires information on the distribution of electrons in the compound so that distinction can be made between single and multiple bonds, between more ionic and more covalent bonds, etc.

Several experimental methods are used in determining molecular structures, and these tend to complement one another. The most widely used technique is the determination of the structures of crystals by X-ray diffraction (see CRYSTALLOGRAPHY: Diffraction by Crystals). In this way, a three-dimensional map of the molecule can be obtained, with the locations of each atom known to an accuracy of about .01 A. The structures of gaseous molecules can be studied by means of electron diffraction (*q.v.*), a technique in which a beam of electrons is scattered by the molecules of the gas. The dimensions of simple molecules can be measured with great accuracy (to .001 A) by determining the rotational energy levels of a molecule in the gas phase. The experimental method used is absorption spectroscopy in the infrared and microwave regions. (See SPECTROSCOPY: Applications; SPECTROCHEMICAL ANALYSIS.)

The procedures listed above are used to determine the positions of the atoms in a molecule and do not directly give much information on the electronic configuration. However, relationships are known between structural properties and electronic properties. For example, it is known that a double bond between two atoms is shorter than a single bond between the same two atoms, so that the measured bond length gives information on the electronic distribution in that bond. Further information on the electronic structure is given by measurement of the electric dipole moment of the molecule. (See DIPOLE MOMENTS.)

The magnetic properties of a molecule depend on its electronic configuration. Most molecules have their orbitals filled with electrons in pairs with spins opposed. Such substances, said to be diamagnetic, move away from a magnetic pole in a nonuniform field. Some molecules have one or more electrons that are not paired with electrons of opposite spin. These electrons behave as small magnets and can be lined up by an external magnetic field. Substances of this sort are described as paramagnetic and are attracted by a magnetic pole in a nonuniform field. Common examples of paramagnetic substances are: oxygen, nitric oxide, free radicals and most compounds of the transition metals and rare earths. A study of the magnetic properties of matter therefore gives information on the number of electrons with unpaired spins and on the distribution of electrons in the molecule. The experi-

mental techniques include measurement of the magnetic susceptibility and electron spin resonance.

2. Reaction Mechanisms. — In a chemical reaction, molecules of the reacting species are destroyed, and molecules of the products are formed. This requires breaking of some chemical bonds and formation of new bonds. Information can be derived from the details of this process in terms of the sequence of events, and the geometrical and electronic structure of intermediate and transitional molecular units. One approach to this problem is through the study of the rates of chemical reaction, and the dependence of these rates on the concentrations of the reacting substances (see REACTION KINETICS: "Order" of Reaction). By this means it was shown, for example, that the reaction between hydrogen gas and iodine gas to give hydrogen iodide

$$H_2 + I_2 \rightarrow 2HI$$

takes place by a simple collision of one hydrogen molecule with one iodine molecule. On the other hand, the similar reaction between hydrogen and bromine

$$H_2 + Br_2 \rightarrow 2HBr$$

proceeds primarily by a chain reaction mechanism, in which a bromine molecule is dissociated into two atoms, each of which then attacks a hydrogen molecule, producing HBr and a hydrogen atom. Each hydrogen atom then reacts with another bromine molecule to give HBr and a bromine atom. This whole process is repeated many times.

Another important method of studying mechanisms of reactions is with isotopic tracers. By substituting a radioactive isotope for a stable element in a particular atom of a molecule, the course of the reaction can be followed and the final position of the labeled atom determined. (See RADIOACTIVITY, ARTIFICIAL: Application to Chemistry and Medicine.)

3. Synthetic Inorganic Chemistry. — Besides the conventional studies of reactions and properties of substances in their pure states and in aqueous solutions, modern inorganic chemistry also deals with reactions and properties in unusual solvents and environments. Many interesting reactions that cannot be carried out in the presence of water can be observed in solvents such as liquid ammonia, liquid sulfur dioxide or liquid hydrogen fluoride. Also important are reactions in systems of molten salts. A large area of study is concerned with the behaviour of inorganic substances at very high pressures.

A large number of new co-ordination complexes were being made in aqueous solutions in the early 1960s, in many cases with organic ligands. Since complexes related to these are known in biological systems, this area is a link between inorganic chemistry and biochemistry. (R. N. CL.)

III. ORGANIC CHEMISTRY

A. Definition and Introduction

Although the term organic chemistry was introduced at the beginning of the 19th century, the development of the subject on a rational basis did not occur until about 1860. The decision to call a branch of chemistry organic chemistry was made because of the tendency of chemists to classify substances in terms of their origin. Thus organic chemical compounds were regarded as substances derivable either from plants or animals.

This led to the suggestion that there was some "vital force" associated with organic compounds and that this intrinsic quality made their synthesis in the laboratory impossible. It is now known, of course, that this was not correct, but during the initial development of organic chemistry this opinion was widely held.

Friedrich Wohler is usually given the credit for disposing of the vital force theory, although other researches in progress at that time caused some chemists to be rather skeptical about it. Wohler's classical experiment (1828) was the thermal conversion of ammonium cyanate into urea

$$NH_4 \cdot CNO \xrightarrow{heat} H_2N \cdot CO \cdot NH_2$$

From this experiment Wöhler concluded that heat had transformed ammonium cyanate, a typical inorganic compound, into the organic compound urea. His reaction to this result is shown by the following statement, which he made in a letter to Berzelius in 1828: "I must tell you that I can prepare urea without requiring a kidney of an animal, either man or dog."

This laboratory synthesis of an organic compound was not accepted by all chemists as proof that the vital force theory was incorrect. Some argued that because urea was isolated from urine it should be regarded as an end product of a metabolic process. The view was taken that as the formation of urea involved the degradation of a more complex organic precursor it was therefore not structurally characteristic of a synthetic process taking place in a living organism. The significance of the synthesis (1845) by (Adolph Wilhelm) Hermann Kolbe of acetic acid, CH_3CO_2H, was not universally accepted either, but it certainly helped to develop a climate of opinion among chemists that led them to reject the notion that a "vital force" was essential for the synthesis of an organic compound. The final blow to this theory was delivered (1860) by Berthelot in his famous treatise entitled La Chimie organique fondke sur la *synthèse;* the development of organic chemistry as a rational science proceeded from that date.

Even when it became evident that substances derived from plant or animal sources were not chemically distinguishable from inorganic compounds, it was still desirable to maintain this division into organic chemistry and inorganic chemistry.

Organic compounds contain carbon as a constituent element and organic chemistry may be briefly defined as the chemistry of compounds of carbon. There are some substances containing carbon that are nevertheless classified as inorganic because their behaviour is much more typical of inorganic substances. This is an artificial distinction that is acceptable because it is convenient. Substances that are usually considered to be inorganic include metal salts such as the carbonates, cyanides, carbides, cyanates and thiocyanates. It should be emphasized, however, that the border line between all branches of chemistry is diffuse.

At first sight it may cause surprise that the extent of the study of derivatives of a single element, carbon, should be sufficient to constitute a separate subject. However, the number of known derivatives of carbon that have been discovered as a result of researches in organic chemistry now far exceeds the total number of compounds derived from all the other elements. The total number of known organic compounds is not easily assessed, but it certainly exceeds 1,000,000. In 1880 the number was approximately 12,000; in 1910 it was 150,000; and in 1940 about 500,000.

It is also convenient to distinguish between organic and inorganic compounds because structurally related organic substances usually show very similar properties. A corresponding pattern of information also exists in inorganic chemistry and some of the aspects of behaviour that at one time were considered to be characteristic of organic chemistry are now known to have their counterparts in inorganic chemistry.

B. The Development of the Theory of Molecular Structure

1. The Early Theories of Chemical Combination. — The establishment of chemistry as a science has been achieved through the recognition and experimental verification of the following concepts: (1) the conservation of matter in most chemical reactions; (2) the existence of chemical elements; (3) the derivation of compounds from elements and the interpretation of this process at a molecular and atomic level; (4) the existence of stable molecules and ions and the relationship between their stability and atomic constituents; (5) the nature of the chemical bond and valency; and (6) the arrangement in space of the atoms in molecules and in ions. The evolution of these concepts was directly related to the experimental approach, which required: (1) the study of reactions between substances; (2) the characterization of pure elements and compounds; (3) the determination of the composition of compounds by qualitative and quantitative analytical processes; and (4) the recognition of mass relationships between atoms and molecules by the precise determination of their atomic and molecular weights. By these processes it was possible to determine the type and number of atoms in molecules. The next step was to find a

system of chemical notation. This nomenclature had to be acceptable for the description not only of molecular composition but also of chemical reactions. It will be appreciated that many chemists contributed to the solution of this problem, but the system of chemical notation that came to be generally adopted owes much to Berzelius.

Organic chemistry provided an important contribution to the development of chemical nomenclature and related structural theory. Lavoisier (1743–94), who emphasized the importance of the quantitative aspect of experimentation, showed that oxidative combustion of organic substances yielded carbon dioxide and water. In principle, Lavoisier's experiment could have established the composition of the organic substances that he investigated, but in fact they were impure; the ethyl alcohol that he isolated by distillation of wine certainly contained some water. Furthermore, the compositions of water and carbon dioxide were not known when these experiments were being carried out. However, in spite of the fact that Lavoisier's results were quantitatively in error, they were nevertheless extremely important in showing that organic substances were usually derived from carbon and hydrogen. The presence of other elements became clear from more accurate experimental study.

Louis Jaques Thénard and Gay-Lussac (1811), conducted some remarkably accurate investigations of the elementary composition of organic substances. If the primitive nature of the equipment that they used is taken into consideration, their approach must be ranked as a model of accurate experimentation. By examining a variety of organic compounds they were able to show a surprising relationship between oxygen content and the physical properties of substances of plant origin. Substances containing a high proportion of oxygen were often acidic whereas those containing a lower proportion of oxygen were frequently oily, resinous or alcohollike in behaviour. Some substances such as sugars, plant gums and starch were shown to contain hydrogen and oxygen in the same relative proportions as water. They were regarded as "hydrated carbon" and for this reason were later called carbohydrates.

At this time Berzelius was conducting his classical investigations of the composition of chemical substances by quantitative analytical methods. He was able to provide experimental verification (1818) of the laws of constant and multiple proportions, which Dalton (1766–1844) had deduced theoretically from his atomic theory. These studies at the beginning of the 19th century by Berzelius also included the analytical investigation of the composition of many organic compounds. He showed that many of these substances contained carbon, hydrogen, oxygen and nitrogen and in this respect corresponded with inorganic substances, but he was quite unable to produce evidence to support the "vital force" component of organic molecules; in spite of this, however, he still believed in its existence.

It is obvious that Wohler was excited by the prospect of structural investigation of organic substances but it was not immediately clear to him how (using the language of modern organic chemistry) the arrangement of atoms in molecules might be established. Wohler in a letter to Berzelius in 1835 said, "Organic chemistry just now is enough to drive one mad. It gives one an impression of a primeval tropical forest, full of the most remarkable things, a monstrous and boundless thicket, with no way of escape, into which one may well dread to enter."

2. The Radical Theory of Structure (Wöhler and Liebig).—At about this time (1820) the concept of radicals was beginning to be recognized, although this approach did not immediately find general favour among chemists and about 20 years elapsed before it was generally accepted. Lavoisier may be credited with the idea that certain types of compound were associated with particular types of radical and he published a list of radicals associated with acidic properties. In 1815 Gay-Lussac isolated cyanogen, which he believed to be the radical CN, corresponding to hydrogen cyanide, HCN. (It is now known that cyanogen is C_2N_2.) Berzelius called attention to the similarity between ammonium salts and alkali metal salts and interpreted this in terms of an ammonium radical. The relation of this proposal to the modern interpretation involving, for example, the ammonium cation, NH_4^+, and the sodium ion, Na^+, emphasizes the remarkable insight that Berzelius showed when considering these matters.

The next step forward was a consequence of the discovery of analytical methods by Liebig for the determination of carbon and hydrogen (1831), and by Jean Baptiste André Dumas for the direct determination of nitrogen (1833) (see *Analytical Chemistry* below). These methods provided precise information regarding the carbon, hydrogen and nitrogen content of organic molecules, and, when other elements were shown to be absent, the oxygen content could be determined by difference.

The determination of the elemental composition, coupled with early studies of organic chemical reactions, led to a resurgence of interest in the radical theory of structure and in 1832 Wohler and Liebig published their important paper on "the radical of benzoic acid." Because of the misunderstanding that existed at that time about atomic weights, they deduced that the benzoyl radical contained 14 carbon atoms, 10 hydrogen atoms and 2 oxygen atoms. Their view may now be reinterpreted in terms of the correct atomic weights and the benzoyl radical becomes C_7H_5O or, more specifically, C_6H_5CO. In organic chemistry, C_6H_5 is often written as Ph, and the benzoyl radical may be written PhCO.

It should be mentioned that this group is no longer referred to as a benzoyl radical in organic chemistry because the term radical is reserved for free radicals (*q.v.*). It is called a benzoyl group. Wohler and Liebig made the suggestion, which now forms one of the foundations of organic chemical theory, that the benzoyl group preserved its identity in a large number of reactions shown by derivatives of benzoic acid. If their proposals are interpreted in terms of current knowledge, the following molecular formulas may be given to these compounds:

Benzoic acid	$C_6H_5CO\cdot OH$	Benzoyl chloride	$C_6H_5CO\cdot Cl$
Benzaldehyde	$C_6H_5CO\cdot H$	Benzamide	$C_6H_5CO\cdot NH_2$
	Benzoic anhydride	$C_6H_5CO\cdot O\cdot CO\cdot C_6H_5$	

Benzoyl chloride reacts with ammonia to give benzamide

$$C_6H_5CO\cdot Cl + 2NH_3 \rightarrow C_6H_5CO\cdot NH_2 + NH_4Cl$$

This involves the replacement of the chlorine atom (Cl) in benzoyl chloride by an amino group (NH_2). Inspection of this reaction shows the importance of the proposals made by Wohler and Liebig. The benzoyl group was unchanged while the group to which it was attached was replaced by another.

A pattern was beginning to emerge that correlated the chemical behaviour of organic compounds. Organic chemists were also encouraged to make predictions of the way in which "radicals" would participate in chemical reactions. These predictions could be subjected to experimental scrutiny and it was this situation that stimulated considerable research. Several years after the first proposal was made regarding the nature of the benzoyl radical, Liebig (1834) published a memoir that became a point of departure toward the discovery of a modern organic structural theory and knowledge.

It is interesting to note that during 1837–43 Robert Wilhelm Bunsen carried out an elaborate investigation of various organoarsenic compounds as part of a study of the radical theory. This led to the recognition of the cacodyl radical, $(CH_3)_2As$—, which corresponds in some ways to the benzoyl radical PhCO—. It may be noted that this was the first investigation of organometallic compounds and it is only since about 1930 that there has been a tremendous renewal of interest in the chemistry of organometallic compounds—a field of research that lies on the border between inorganic and organic chemistry.

3. The Theory of Chemical Type and the Overthrow of the Electro-Dualistic Theory.—The revival and elaboration of the radical theory of structure was mainly because of Dumas, Auguste Laurent and Charles Frédéric Gerhardt. This development led eventually to the theory of chemical types (Dumas, 1840), which is best illustrated by an example. The hydroxyl (OH) group in benzoic acid ($C_6H_5CO\cdot OH$) may by suitable chemical reactions be replaced by various other groups as shown in the following compounds:

$C_6H_5CO\cdot Cl$	$C_6H_5CO\cdot Br$	$C_6H_5CO\cdot NH2$
Benzoyl chloride	Benzoyl bromide	Benzoyl amide

These compounds may be represented by the general formula $C_6H_5CO\cdot X$ where X = Cl, Br and NH_2 respectively. All three can be made to react with water to give benzoic acid as one of the products, and the three reactions are of exactly the same type. They may be represented by a single equation:

$$C_6H_5CO\cdot X + H_2O \rightarrow C_6H_5CO\cdot OH + HX$$

Dumas also detected what he called "the persistence of chemical type" in a large number of other compounds. This is illustrated by the following chlorine derivatives of acetaldehyde.

	Type Formula	Molecular Formula
Acetaldehyde	CH_3CHO	C_2H_4O
Monochloroacetaldehyde	$ClCH_2CHO$	C_2H_3OCl
Dichloroacetaldehyde	Cl_2CHCHO	$C_2H_2OCl_2$
Trichloroacetaldehyde	Cl_3CCHO	C_2HOCl_3

Comparison of the molecular formula of these four compounds showed that it was possible to replace only three of the four hydrogen atoms in acetaldehyde, indicating that one of the hydrogen atoms was unlike the other three. Dumas also noticed a preservation of the CO group in the members of this series and he associated the unique hydrogen atom with the CO group, as shown in the type formulas.

At this stage further development of organic structural theory was impossible because of an apparent conflict with the electro-dualistic theory of chemical combination proposed by Berzelius (1814). This conflict resulted from a more detailed consideration of the chemical properties of the chlorine derivatives of acetaldehyde listed above. Dumas argued that although comparison of the molecular formulas C_2H_4O, C_2H_3OCl, $C_2H_2OCl_2$ and C_2HOCl_3, suggested that the chlorine atoms were replacing the hydrogen atoms, they could not in fact be occupying the same position in the molecules. This conclusion, based on Dumas' belief that electropositive hydrogen could not be replaced by highly electronegative chlorine without causing a considerable alteration in the chemical behaviour of the substances, led directly from the electro-dualistic theory of chemical combination suggested by Davy in 1807. This theory involved the doctrine that some atoms (and radicals that behave like atoms in the preservation of their identity) are either positively or negatively electrically charged and Berzelius developed this by saying that only bodies of opposite electrical charge could exist in stable combination.

Laurent, however, was not concerned about the difficulty of reconciling the electro-dualistic theory with the consequences of an organic reaction involving the direct replacement of one atom by another. He regarded these organic substitution reactions as mechanical displacement processes and although initially Dumas accused Laurent of allowing his intuition to carry him beyond experimental fact, he was cater persuaded by the accumulating experimental evidence that Laurent was right: Dumas abandoned the Davy-Berzelius theory and became an ardent supporter of Laurent's theories.

Meanwhile Gerhardt was able to effect a synthesis of the substitution (Dumas-Laurent) theory and the chemical type (Dumas) theory. This was a direct consequence of the possibility of determining the molecular formulas of organic compounds using the hypotheses of Avogadro and André Marie Ampère.

Gerhardt regarded organic compounds as being derived structurally from either hydrogen (H—H), halogen acids (H—X), water (H—O—H) or ammonia (H—NH_2); his approach is illustrated by the following compounds, whose structures are depicted according to the "rational" chemical formulas suggested by Gerhardt to represent chemical compounds.

Derivatives of H—H		Derivatives of H—O—H	
Ethane	C_2H_5—H	Ethyl alcohol	C_2H_5—O—H
Acetaldehyde	CH_3CO—H	Acetic acid	CH_3CO—O—H
Benzaldehyde	C_6H_5CO—H	Benzoic acid	C_6H_5CO—O—H
Butane	C_2H_5—C_2H_5	Ethyl ether	C_2H_5—O—C_2H_5
Acetone	CH_3CO—CH_3	Methyl acetate	CH_3CO—O—CH_3

Corresponding formulations of ethylamine (C_2H_5—NH_2) as a derivative of arnmonia (H—NH_2) and ethyl bromide (C_2H_5—Br) as a derivative of hydrogen bromide (H—Br) are obviously possible.

It was clear that Gerhardt's theory was not applicable to all the evidence available within the scope of organic chemistry and the search for a more satisfactory unifying concept was continued.

It might be thought that the period from 1830 to 1850 was characterized by groping in semidarkness for theoretical interpretations, but nevertheless a considerable body of information was being accumulated by the study of the reactions of organic compounds. This not only directed attention toward the chemical type theory but also showed that some atoms or groups of atoms were equivalent.

4. The Structure of Organic Molecules (Kekulé-Couper).—In 1858 two of the most important contributions to the literature of organic chemistry were published by KekulC and Couper. Although Couper's paper was the first of the two to be submitted for publication, Kekulé's was the first to appear. From that time Couper's interest in chemistry lapsed and he took no further part in the development of his theories. Kekulé, however, continued to play a dominant role in the growth of his subject and he is now generally regarded as the founder of organic structural theory.

The 1858 papers of Kekulé and Couper may be regarded as two independent but complementary contributions. Couper rejected the type theory of chemical structure and replaced it by a thesis that molecular structure was a consequence of the valency of the component atoms. From this he was able to write structural formulas for organic molecules that indicated the way in which the constituent atoms were bonded together. If allowance is made for the misunderstanding about atomic and molecular weights then current. it is clear that Couper's formulas were much more closely related than Kekulé's to the structural formulas now used by organic chemists. Couper was the first to designate bonds in formulas by dashes.

Kekulé (1858) recognized that Gerhardt's classification was too restricting and showed that it was possible to combine some of the features of the chemical type theory with implications regarding chemical behaviour that were provided by the radical theory. He emphasized that as the behaviour of a compound was dependent upon the conditions of the reaction, it was possible for a compound to belong to more than one type in the Gerhardt classification. He also recognized the fundamental importance of the valency of the atoms in molecules and showed that atoms or groups were either monovalent, divalent, trivalent or tetravalent. Thus carbon, with its valency of four, provided CH_4, which could join NH_3, H_2O and H_2 in the Gerhardt classification.

Kekulé's ideas led eventually to the transformation of Gerhardt's type formulas into the structural formulas that are still widely and successfully used. The significance of the "revolution" in organic structural theory that was promoted by KekulC is obvious, but at the time he proposed his "rational formulas" he did not regard them as "representing the arrangement of groupings of atoms in existing compounds." Instead he thought of them as "expressions of certain relations in metamorphoses," that is, in chemical reactions. Some years elapsed before these formulas were considered to be structural formulas; in fact Adolf von Baeyer in 1890 said that the Kekulé molecular models were "even cleverer than their inventor." It is interesting to recall that KekulC started his studies as a student of architecture at the University of Giessen in 1847, and it was there as a result of his contact with Liebig, who was professor of chemistry, that he took an interest in chemistry. He obviously continued to use an architectural approach when considering the structure of molecules.

So, during a period of 15 years, the situation regarding molecular structure was completely transformed and Gerhardt's original opinion that formulas represented the way in which a molecule could react gave place to the concept of representing structures by graphic formulas. The idea of structural formulas still required development in a three-dimensional sense and also interpretation in terms of the electronic theory of atomic structure, but these further advances occurred much later.

Couper's 1858 paper contained analogous ideas about the tetravalency of carbon and the suggestion that chains of carbon atoms could exist in organic molecules. Seven years later Kekulé proposed a constitutional formula for benzene (C_6H_6) that contained a closed chain of six carbon atoms and in 1866 he suggested that the four valency bonds of carbon were tetrahedrally disposed. He made it clear that the tetrahedral model for carbon was not to be taken literally but subsequent developments in organic chemistry showed that this appreciation of the way in which a carbon atom could be joined to other atoms was remarkably close to reality.

5. Optical Activity and the Tetrahedral Carbon Atom. — The theories of Kekulé and Couper did not account for the fact that in some cases more compounds were known than could be expected when two-dimensional graphic formulas were used. In 1848 Pasteur was studying the optical activity of the tartaric acids and showed that there were dextrorotatory, levorotatory and optically inactive forms and he realized that this ability to rotate the plane of polarized light must be associated in some way with molecular structure. It is unquestionably the influence of Pasteur's work that led to the interpretation (van't Hoff and Le Bel, 1874) of optical activity in terms of the tetrahedral disposition of the four valencies around carbon. This provided a satisfactory interpretation of Pasteur's results and a basis for all subsequent development regarding the structure of molecules. Thus it became clear that there was a geometrical aspect associated with chemical binding that had not previously been appreciated *(see* also STEREOCHEMISTRY: *The Stereochemistry of Carbon).*

6. The Strain Theory (Baeyer) and Structure of Cyclic Molecules. — The geometry of organic molecules is a subject that has been investigated from various standpoints since the van't Hoff-Le Bel theory was first proposed. In particular, Baeyer (1885) proposed his famous strain theory, which related the ease of formation and reactivity of cyclic organic compounds to the number of atoms in the ring. This theory implied that five-membered rings with an intervalency angle of 108°, which is close to the tetrahedral angle of 109°28′, would be easily formed, whereas larger or smaller rings would be less stable. The studies by the younger Perkin of the synthesis and properties of small ring compounds coupled with later work on the many-membered (macrocyclic) ring compounds showed that Baeyer's original hypothesis was not entirely correct because he had assumed that cyclic compounds were planar. This difficulty was resolved by H. Sachse (1890) and his theory was considerably elaborated by Ernst Mohr about 30 years (1918) later. The Sachse-Mohr theory suggested that six- and larger-membered rings could have a puckered multiplanar arrangement and it was this idea that formed the basis of the theory of conformational analysis (Derek H. R. Barton, 1950). Conformational analysis (*q.v.*) is concerned with the modern stereochemical treatment of organic structure.

7. Developments Since 1900. — Many of the developments of organic structural theory that followed the Kekulé-Couper proposals were empirically based on information acquired by the study of the synthesis of organic molecules and the determination of their structure by degradation. Much of this work was stimulated by the determination of the structure of natural products, and this marked the beginning of the return of organic chemistry to its original objective — the study of compounds isolated from plants and animals. Outstanding among these were the important studies on alkaloids (the younger Perkin and Sir Robert Robinson), plant colouring matters (Richard Willstätter) and terpenes, amino acids and proteins (Emil Fischer). Work in the natural product chemistry field also includes the later studies of the structures of vitamins, hormones and antibiotics.

At the time of these discoveries, ideas were being developed regarding the electronic theory of chemical bonding, which had a considerable impact on organic chemistry. Organic chemists quickly realized the significance of the progress that was being made concurrently in physics and in physical chemistry. Following the elucidation of the structure of the atom by Rutherford (1911), theoriei regarding the electronic nature of the chemical bond were proposed (G. N. Lewis. 1916). These ideas were initially applied by Arthur Lapworth to describe chemical reactions as processes involving movement of electrons. This interpretation of the structure and reactions of organic molecules was considerably extended (1920–30) by Robinson and Ingold and eventually formed the basis of theoretical organic chemistry. This rapidly expanding branch of the subject attracted many investigators and it was possible by the 1950s to correlate and interpret in detail the mechanism of many organic reactions.

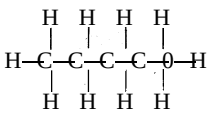
Another major 20th-century development was the application of quantum mechanics (Max Planck. 1900) to the description of the detailed structure of organic molecules. This provided a physical interpretation of covalent bonding and an understanding of the details of valency and stereochemistry. Pauling has reviewed (1938) in *The Nature of the Chemical Bond and the Structure of Molecules and Crystals* his mathematical interpretation of the structure of organic molecules that led to the proposal (1931–33) of the theory of resonance (*q.v.*) and the description of molecular structure by mathematical methods.

Although the early proposals regarding the structure of molecules were empirical, they later received dramatic support by completely independent physical methods. These methods, although of many different types, give results that agree with the three-dimensional structures deduced by using the "classical" methods of degradation and synthesis. The methods of X-ray crystallography and electron diffraction should be particularly mentioned. By X-ray crystallographic examination of crystals of organic substances it is often possible to determine the relative positions of the heavier atoms in the structure; the positions of hydrogen atoms are placed deductively. Electron diffraction by compounds in the vapour state provides similar information, and the confirmation of structures by these various physical techniques is convincing support for the methods and logic of organic chemistry.

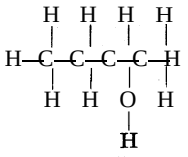
C. Representation of the Structure of Organic Compounds

It is clear from the above information that one of the important objectives in organic chemistry is to determine the structural formulas of organic compounds. It is possible to deduce from analytical data an empirical formula that shows the relative number of constituent atoms in a molecule, and then from a knowledge of the molecular weight to deduce the molecular formula of the compound. The molecular formula shows the numbers of each type of atom that are present in the molecule and the elucidation of the structural formula involves the determination of the positions of each of these atoms.

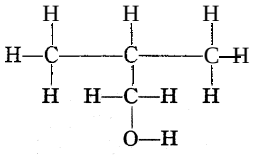
1. Aliphatic Compounds. — The methods used to represent the structure of aliphatic compounds are best illustrated by an example. Carbon and hydrogen analysis shows that a compound has the empirical formula $C_4H_{10}O$, and a vapour density determination corresponds with the molecular formula $C_4H_{10}O$ (calculated molecular weight $= 4 \times 12 + 10 \times 1 + 1 \times 16 = 74$). It is possible to write seven structural formulas corresponding with the molecular formula $C_4H_{10}O$, in which the normal valencies of the constituent atoms (carbon = 4, oxygen = 2, hydrogen = 1) are observed. These formulas are:



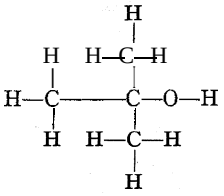
I



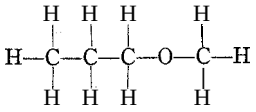
II



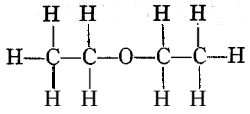
III



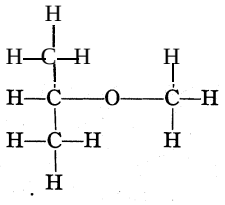
IV



V



VI

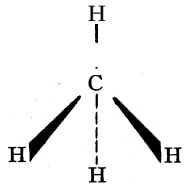


VII

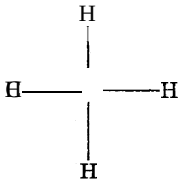
Thus there are seven possible ways of joining together four carbon atoms, ten hydrogen atoms and one oxygen atom when the conditions imposed by the valencies of these atoms are observed. It may be mentioned that, in fact, eight compounds can exist with the molecular formula $C_4H_{10}O$, and the reasons for this will become clear later.

The formulas I–VII are said to represent the structures of isomers, that is, substances with the same molecular formula, $C_4H_{10}O$, but with different structural formulas. These substances display different physical properties and different chemical reactions and it is these facts that permit the allocation of a particular structure to a compound (see ISOMERISM: Assignment of Structures to Isomers).

It should be emphasized that the formulas I–VII are only approximate, two-dimensional representations of structures that are in fact three-dimensional. This three-dimensional shape of the actual structure of the molecules is a consequence of the tetrahedral disposition of the four valencies around each carbon atom. Thus the molecule methane, CH_4, has a tetrahedral structure in which the intervalency angle between the C—H bonds is 109°28′. There are various ways of representing the three-dimensional structure of methane, but the perspective illustration VIIIa is probably the most easily understood.



VIIIa



VIIIb

In formula VIIIa, the continuous thin line represents a bond in the plane of the paper, the thickened lines represent bonds projecting toward the observer and the dotted line a bond directed away from the observer. It would, however, be very time-consuming always to use a formula such as VIIIa to represent organic structure, so unless it is necessary to emphasize a stereochemical situation a projection formula (VIIIb) is used. It must be realized that VIIIb is just a two-dimensional representation of a molecule that is in fact three-dimensional. Thus planar projection formulas must always be interpreted three-dimensionally.

The projection formulas I–VII are often abbreviated further as indicated in the formulas shown in Table I. Further abbreviation is also indicated in which a methyl (CH_3) group is replaced by the symbol Me, an ethyl (C_2H_5) group by Et, and so on. The valence bonds are indicated by dots.

The methods used for the representation of structural formulas indicated by the examples in Table I may be readily applied to more complex structures (see Table II). These examples include olefins, which contain double bonds (C=C); aldehydes and ketones, which contain carbonyl groups (CO); and acetylenes, which contain triple bonds (C≡C).

2. Aromatic Compounds. — The examples given in Tables I and II illustrate the structural formulas that may be drawn for aliphatic compounds. Structural formulas can also be written for aromatic compounds, which are most easily defined as derivatives of benzene. The problem presented by the structure of benzene is made clear if the structure of this molecule is considered.

TABLE I

Projection Formula	Abbreviated Projection Formula	
	$CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot OH$	$Me.(CH_2)_3 \cdot OH$
	$CH_3 \cdot CH_2 \cdot CH \cdot CH_3$ OH	$Et \cdot CH(OH) \cdot Me$
	$CH_3 \cdot CH \cdot CH_3$ CH_2 OH	$Me_2CH \cdot CH_2 \cdot OH$

TABLE II

Name	Molecular Formula	Structural Formula
1-Butene	C_4H_8	$CH_3 \cdot CH_2 \cdot CH=CH_2$
2-Butene	C_4H_8	$CH_3 \cdot CH=CH \cdot CH_3$
Allyl alcohol	C_3H_6O	$CH_2=CH-CH_2OH$
Acetaldehyde	C_2H_4O	Acetic acid	$C_2H_4O_2$	Acetone	C_3H_6O	Acetylene	C_2H_2	$HC \equiv CH$
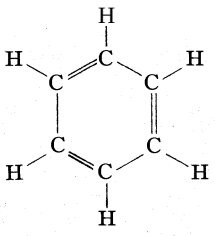
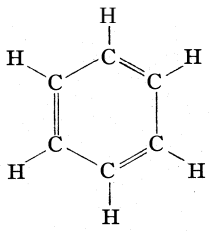
1-Butyne	C_4H_6	$CH_3 \cdot CH_2 \cdot C \equiv CH$
2-Butyne	C_4H_6	$CH_3 \cdot C \equiv C \cdot CH_3$

Kekulé (1865) suggested that benzene (C_6H_6) had a structural formula that oscillated between the structures IXa and IXb, but this suggestion, which involves a dynamic equilibrium between structures IXa and IXb, is not now considered correct. A more accurate description of the structure of benzene is given by the application of the theories of resonance (Pauling) or mesomerism (Ingold).



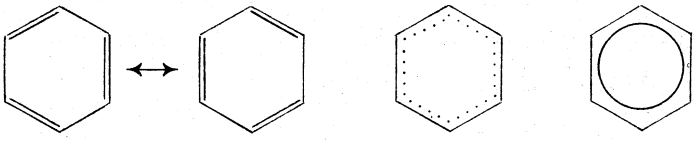
IXa



IXb

Ingold's view was that benzene had a mesomeric structure (mesomer ≡ "between state") intermediate between IXa and IXb. This idea, which was developed intuitively, was given a mathematical treatment by Pauling (1933), who showed that benzene had a resonance hybrid structure to which IXa and IXb were the major contributors; IXa and IXb are called contributing structures or canonical forms. Similar views regarding the structure of aromatic compounds were proposed by Robinson and were extended by him to include other organic compounds.

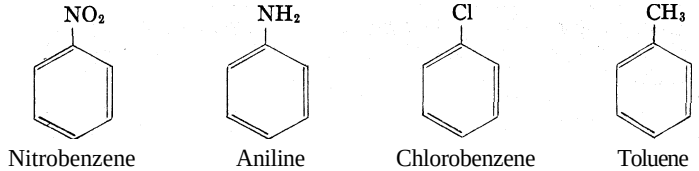
It would clearly be time-consuming to have to write a detailed structure (*e.g.*, IXa) for benzene, so neater methods of representation are usually employed. The resonance hybrid structure for benzene is represented by the X, and it is customary to select either one or the other of the Kekulé structures shown in X to represent benzene. Although these structures contain indicated double bonds, it is not implied that there is any degree of double-bond fixation in the structure. The use of a Kekulé structure to represent benzene is just a convenient symbol summarizing the situation shown in X.



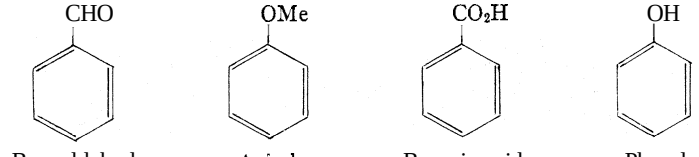
X XI XII

Because of the equivalence of the six carbon-carhon bonds in benzene, the suggestion has been made from time to time that the representation of benzene by a Kekulé structure is somewhat misleading. This is not true if the condition cited above is observed, but it is, nevertheless, the reason why alternative forms of representation for benzene have been proposed. These have included formula XI, which is a type of structural formula very similar to the formula proposed by Johannes Thiele for benzene in his theory of partial valencies (1899). The dotted line in XI represents partial bonding. The relationship of XI to the mathematical description of the structure of benzene using the molecular orbital theory is very close. The molecular orbital theory may be briefly (and somewhat inaccurately) described as follows. In benzene there are six normal covalent C—C bonds and six normal covalent C—H bonds. Of the valence electrons supplied by the constituent atoms this leaves six valence electrons that are not involved in normal covalent bonding. These are called π electrons and it may be shown that 6π electrons when associated with atoms in a cyclic system form a particularly stable electronic situation. This arrangement of 6π electrons is responsible for aromatic stability aqd the association of 6π electrons with aromatic stability was first recognized and elaborated by Robinson. Some chemists have suggested that this view of the structure of benzene is satisfactorily indicated by XII where the full circle represents 6π electrons. A Kekulé-type formula for benzene is still often used.

For monosubstituted benzenes it is customary to indicate only the substituents and not the hydrogen atoms attached to the aromatic nucleus. Typical formulas of various benzene derivatives are given below.

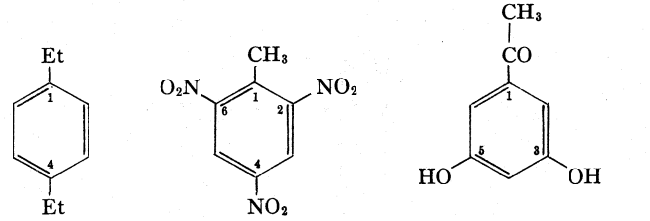


Nitrobenzene Aniline Chlorobenzene Toluene



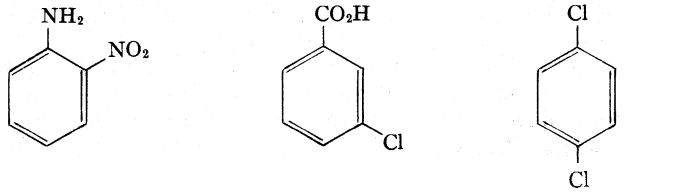
Benzaldehyde Anisole Benzoic acid Phenol

For polysubstituted benzenes it is necessary to indicate the relative positions of substituents by numbering the nuclear carbon atoms. One of the substituents is conventionally placed in position 1 and by selecting the appropriate numbers the positions of other substituents are determined. Examples of this method of naming compounds are shown below.



1,4-Diethylbenzene 2,4,6-Trinitrotoluene 3,5-Dihydroxyacetophenone

For disubstituted benzenes it should be noted that o- (*ortho*), *m*- (meta) and *p*- (para) may be used in place of 1,2-, 1,3- and 1,4- respectively.

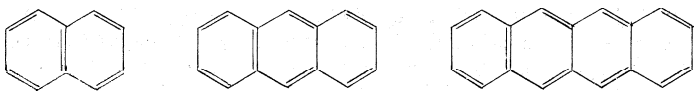


2-nitroaniline or o-nitroaniline

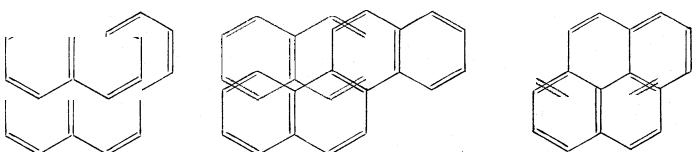
3-chlorobenzoic acid or m-chlorobenzoic acid

1,4-dichlorobenzene or *p*-dichlorobenzene

Large numbers of polycyclic compounds have been synthesized and the structural formulas of some of the better-known hydrocarbons are given below.



Naphthalene Anthracene Naphthacene



Phenanthrene Chrysene Pyrene

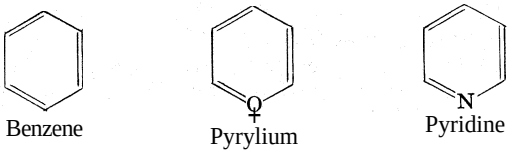
The names of many of these polycyclic hydrocarbons have not been determined by the nomenclature rules of organic chemistry. Derivatives of these more complex molecules are given names chosen according to rules that correspond to the rules for naming benzene derivatives.

3. Heterocyclic Compounds. — This is a vast field and it can only be surveyed rather superficially here. It will be clear from a valence standpoint that the following groups are equivalent

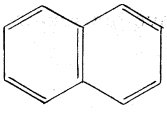
$$>CH_2 \equiv >O \equiv >NH \equiv >S$$

$$\gtrless CH \equiv N \equiv \gtrless O^+$$

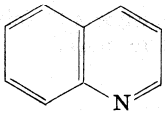
It is therefore possible in principle to replace $> CH_2$ or $\gtrless CH$ in a cyclic hydrocarbon structure with their structurally equivalent groups and so produce structures that have been shown to be those of the following heterocyclic compounds.



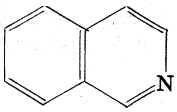
Benzene Pyrylium Pyridine



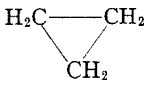
Naphthalene



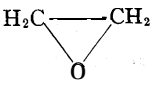
Quinoline



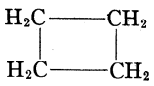
Isoquinoline



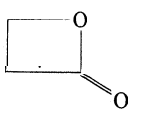
Cyclopropane



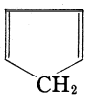
Ethylene oxide



Cyclobutane

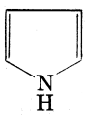


β-Propiolactone



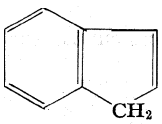
Cyclopentadiene

Furan

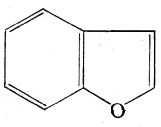


Pyrrole

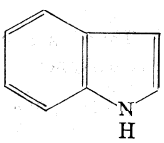
Thiophene



Indene

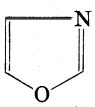


Benzfuran

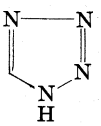


Indole

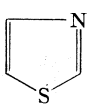
Heterocyclic compounds can also have more than one heteroatom, as shown below



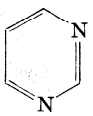
Oxazole



Tetrazole



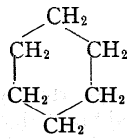
Thiazole

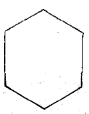


Pyrimidine

4. Representation of Complex Structures. — As has already been indicated, it is often customary not to indicate hydrogen atoms in organic structural formulas but it follows that it is imperative to indicate unsaturation as, for example, in C=C bonds. In the past there has been a tendency to represent benzene and cyclohexane by regular hexagons but it is important to differentiate between them by using appropriate structures, as in XIII and XIV.

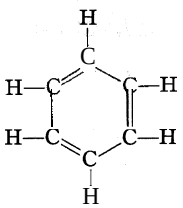
Cyclohexane (C_6H_{12})

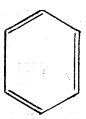




XIII

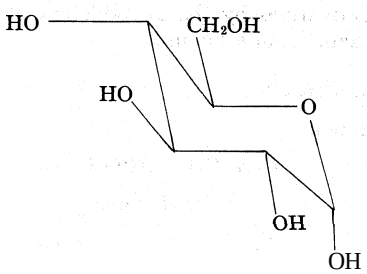
Benzene (C_6H_6)



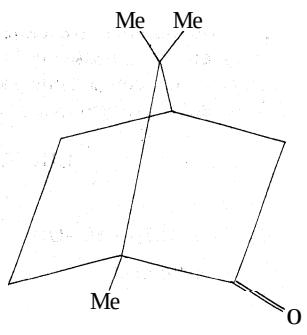


XIV

It is often customary not to designate carbon atoms by C in complicated organic structures. In many cases projection formulas do not show the detailed arrangements of the atoms in the molecules and in these cases formulas are used to indicate their three-dimensional structure. These formulas are sometimes called stereo formulas, and examples of these are provided by the structural formulas of glucose and camphor (XV and XVI).



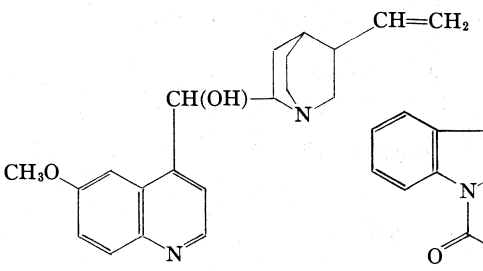
a-D-Glucopyranose
XV



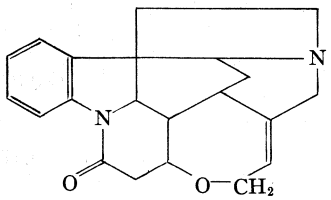
Camphor
XVI

Natural products are often characterized by quite complex arrangements of their component atoms and many of the triumphs of 20th-century organic chemistry have been concerned with their structural elucidation. A selection of illustrative examples is given and includes alkaloids (quinine, strychnine and morphine), vitamins (vitamin C and vitamin E), plant-colouring matters (chlorophyll a), hormones (cortisone), antibiotics (penicillin and oxytetracycline) and the important coenzyme adenosine triphosphate.

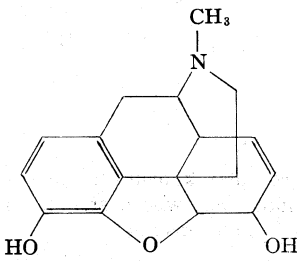
Even a cursory inspection of these structural formulas shows the complexity of molecular structure that can now be unraveled. In all the cases quoted above the substances were first obtained as natural products and were then, with the exception of oxytetracycline, synthesized in the laboratory.



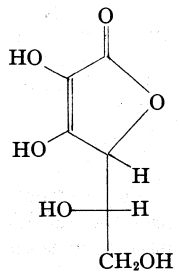
Quinine



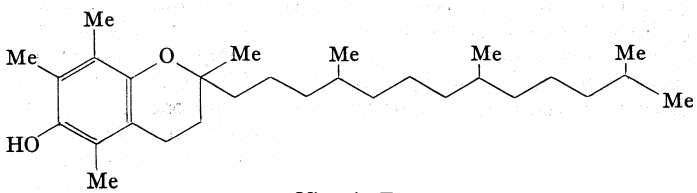
Strychnine



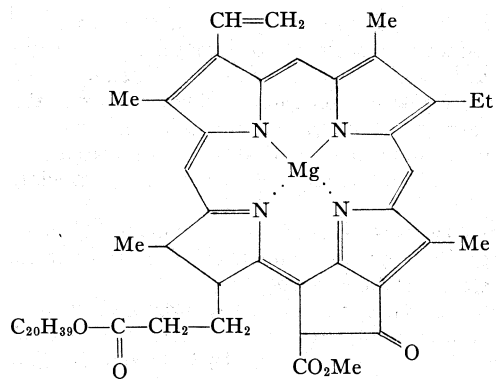
Morphine



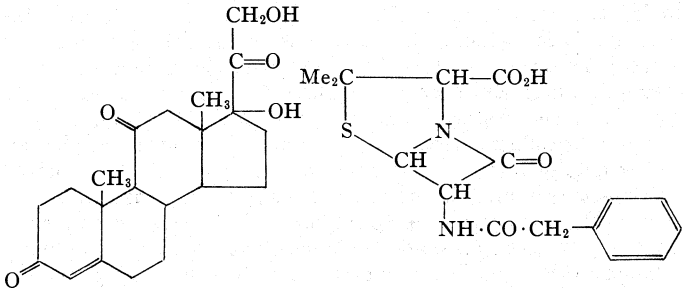
Vitamin C
(L-ascorbic acid)



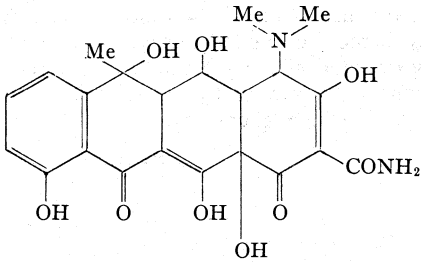
Vitamin E



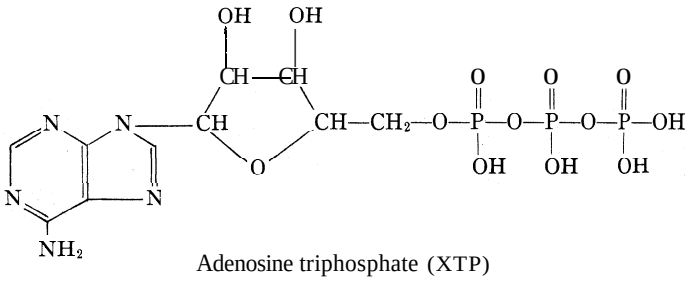
Chlorophyll a



Cortisone Penicillin



Oxytetracycline



Adenosine triphosphate (XTP)

These structures are not the most complex known and recent examples of highly complex organic molecules whose structures have been determined include vitamin B_{12} and insulin.

D. Classification of Organic Compounds

The variety of structures reviewed above indicates that any classification of the 1,000,000 or so known organic compounds will have to be somewhat arbitrary. Clearly any separation into categories in terms of molecular formulas is of practically no value and it is now customary to divide organic compounds into various types depending upon their structure. This is a fairly simple process for those compounds that contain only one or two functional groups (*e.g.,* alcohols or carboxylic acids), but when a number of different functional groups exist in the same molecule then the decision to classify in terms of one of the functional groups has to be made.

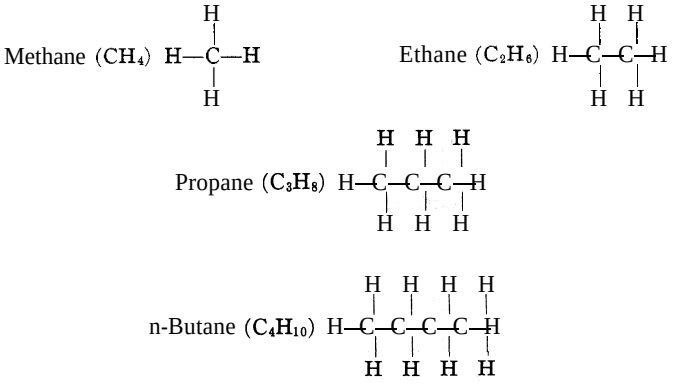
This problem of classification is also made extremely complicated by the tremendous variety of structures that exists among natural products. Consider, for example, the classification of alkaloids; although many of them can be placed in various families of structurally related compounds, there are some that are not easily accommodated in any general scheme.

It is not possible here to deal with the classification of organic compounds in detail, but the broader principles will be indicated.

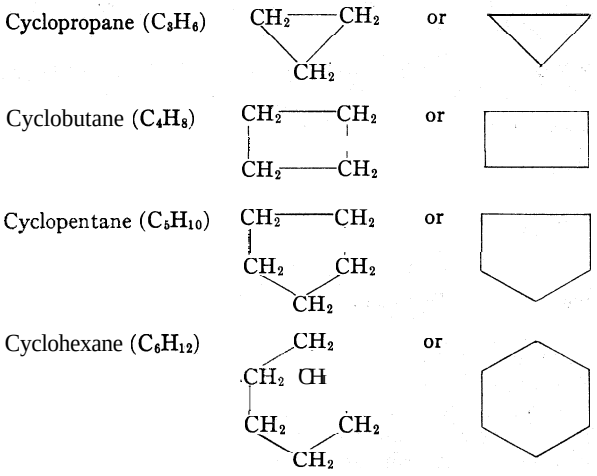
1. Main Divisions. — There are three main divisions of organic compounds: (1) aliphatic compounds; (2) aromatic compounds; and (3) heterocyclic compounds.

The term aliphatic was originally proposed to describe substances that were of a fatty nature, but later it was shown that many such substances were in fact derived from the alkanes, which are also known as paraffin hydrocarbons (*q.v.*).

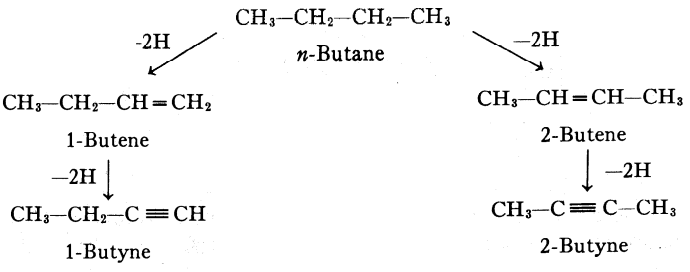
The alkanes form a homologous series with the general formula C_nH_{2n+2} and the lower members of this series have the following names and structural formulas.



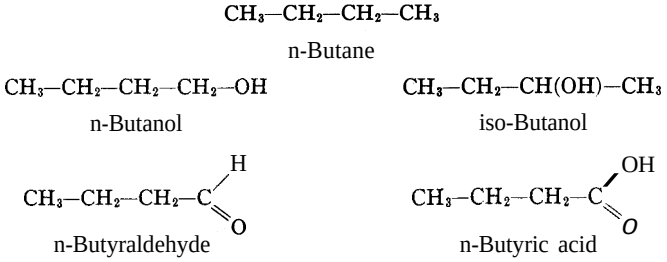
There is a corresponding series of alicyclic compounds, the cycloalkanes.



Aliphatic compounds may be regarded as derivatives of these compounds; the processes involved are either removal of hydrogen. leading to unsaturated compounds, or the replacement of hydrogen atoms by various functional groups. The first process is illustrated by the formation of the hydrocarbons derived from n-butane (the prefix *n* is an abbreviation for normal, meaning that the carbon atoms are in a straight chain).



The two butenes are called alkenes or olefins (*q.v.*) and the butynes are called alkynes or acetylenes. It is also possible to consider other compounds as derivatives by the introduction of various functional groups; for example, in n-butane.



$CH_3—CH_2—CO—CH_3$

Ethylmethyl ketone

$CH_3—CH_2—O—CH_3$

Ethylmethyl ether

$HO—\overset{\beta}{C}H_2—CH_2—CO—CH_3$

(β-Hydroxyethyl)-methyl ketone

$HO_2C—CH_2—CH_2—CO_2H$

Succinic acid

$CH_3—CH_2—NH—CH_3$

Ethylmethylamine

$CH_3—CH_2—CH_2—CH_2—Br$

n-Butyl bromide

These derivatives of n-butane can be related to other compounds that contain the same functional groups. The alcohols, for example, form a homologous series that is analogous to the homologous series formed by the alkanes; *n*-butanol is a member of the series that includes methanol ($CH_3·OH$), ethanol (CH, CH_2OH), n-propanol ($CH_3CH_2CH_2OH$), n-butanol ($CH_3·CH_2·CH_2CH_2OH$), *n*-pentanol ($CH_3·CH_2·CH_2CH_2CH$, OH) and so on. The aldehydes also form a homologous series: formaldehyde (HCHO), acetaldehyde (CH_3CHO), propionaldehyde ($CH_3·CH_2·CHO$), n-butyraldehyde ($CH_3CH_2CH_2CHO$), etc.

It will be clear that more than one functional group may be present in a molecule as in (β-hydroxyethyl)-methyl ketone, where there are alcoholic (OH) and ketonic (C=O) functional groups. Succinic acid contains two carboxyl (CO_2H) groups.

From these considerations it follows that many compounds in the aliphatic group can be classified into various families or types. The more important classes with their type formula are listed below. The general representation of an alkyl group such as methyl or ethyl is R.

Hydrocarbons	R·H
Alcohols	R·OH
Esters	$R.CO_2R'$
Ethers	R·O R'
Aldehydes	R.CHO
Ketones	R·CO·R
Carboxylic acids	$R·CO_2H$; Acid chloride R·CO·Cl; [Acid] Amide $R.CO·NH_2$
Amines	$R·NH_2$, R_2NH, R_3N
Alkyl halides	R·X (X = Cl, Br, I, F)

The term aromatic, which has been discussed above in Aromatic Compounds, is usually used to describe derivatives of benzene or polynuclear aromatic hydrocarbons such as naphthalene, anthracene, phenanthrene, etc. The more important types of aromatic compounds are listed below; the indicated functional group is attached directly to the benzene ring or aromatic system.

Nitro compounds (—NO_2)
Sulfonic acids (—SO_3H)
Aromatic amines (—NH_2)
Phenols (—OH)
Aromatic aldehydes (—CHO)
Aromatic ketones (—COR)
Aromatic carboxylic acids (—CO_2H)
Aromatic halides (—F, —Cl, —Br, —I)

It is also customary to regard quinones as aromatic compounds. There are two types of quinone, represented by *p*-benzoquinone (XVII) and o-benzoquinone (XVIII). Quinones are characterized by their striking colours: for example, *p*-benzoquinone is yellow and o-benzoquinone is red.

The derivation of heterocyclic structures and their relationship to alicyclic or aromatic structures are discussed under Heterocyclic Compounds above.

2. Classification by Functional Groups. — The classification of aliphatic and aromatic compounds is mainly based upon the functional groups that are present, but in some cases there are considerable differences in the reactions shown by aliphatic and aromatic compounds containing the same functional group. This is particularly striking in the case of substances that contain the hydroxyl (OH) group; alcohols and phenols show important differences in many of their reactions. There are also important differences in the chemical behaviour of primary aliphatic and aromatic amines.

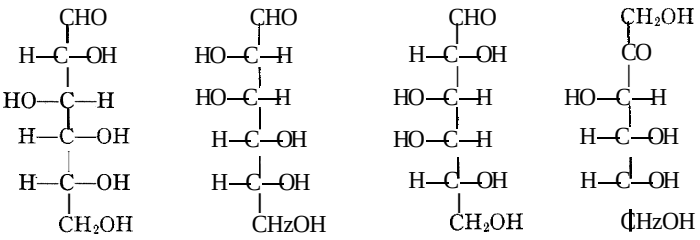
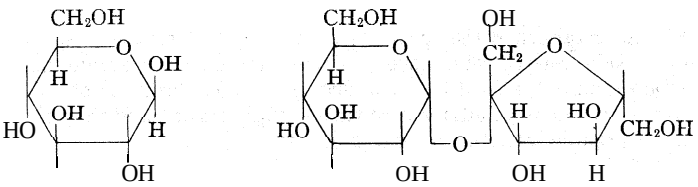
3. Natural Product Types.--Some classes of natural products such as carbohydrates, terpenes, steroids, fats, waxes, amino acids and proteins show a remarkable similarity of structure between the members of each class. This is illustrated by the structures of some representatives of carbohydrates.



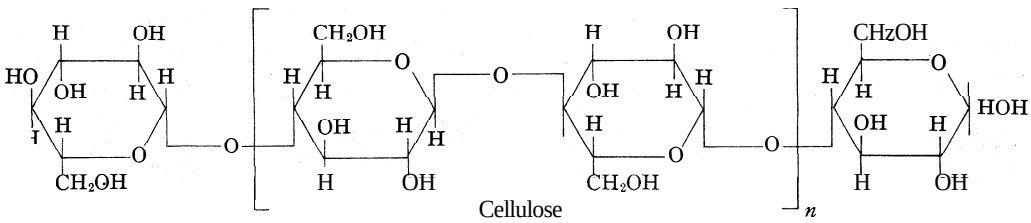
D-Glucose D-Mannose D-Galactose D-Fructose

Carbohydrates. — These sugars have been represented by open-chain structures, but in many natural products they exist in a cyclic form. Comparison of the cyclic structure of D-glucose with that of sucrose (the name usually used by organic chemists for cane sugar) shows their relation. Sucrose contains a glucose and a fructose unit.

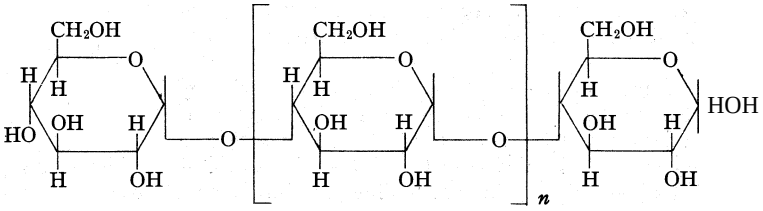


D-Glucose Sucrose

D-glucose is called a monosaccharide and sucrose, since it contains two sugar residues, is called a disaccharide. Their relation to two well-known and important polysaccharides, starch and cellulose, is shown by the following structural formulas. The glucose unit is repeated many times in both starch and cellulose.

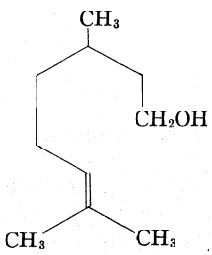


Cellulose

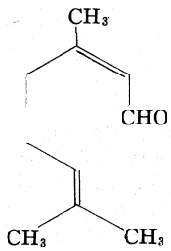


Starch (simplified structure)

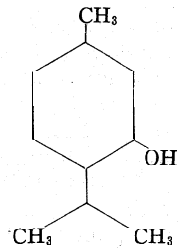
The structural formulas of carbohydrates show a remarkable variety of structure, but there is nevertheless a degree of similarity among them that makes it very desirable to classify them in one class. The study of this relationship between the structures of the sugars was initiated by Fischer and is one of the high lights of scientific research. Carbohydrate chemistry now forms one of the more important branches of organic chemistry (see CARBOHYDRATES).



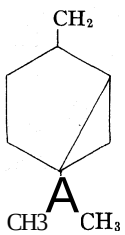
Citronellol



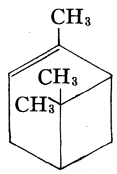
Citral



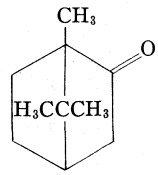
Menthol



Sabinene



α-Pinene



Camphor

Terpenes.—It will be noticed that all these compounds contain identical C_{10} skeletons that are folded in various ways. The close relationship between their structures is a good reason for placing them in the same group. They are called monoterpenes.

Similar structural features can be detected in the higher terpenes, which include the sesquiterpenes (C_{15} skeleton), diterpenes (C_{20} skeleton), triterpenes (C_{30} skeleton) and tetraterpenes (C_{40} skeleton).

a-Amino Acids and Proteins.—The classical investigations by Fischer established that proteins on acid hydrolysis give mixtures of closely related substances. These are called a-amino acids (the a symbol is used to show that the $—NH_2$ group is attached to the carbon atom adjacent to the $—CO_2H$ group) and they show a remarkable variety of structure.

Glycine	$CH_2(NH_2)CO_2H$
Alanine	$CH_3CH(NH_2)CO_2H$
Valine	$(CH_3)_2CHCH(NH_2)CO_2H$
Serine	$HOCH_2CH(NH_2)CO_2H$
Cysteine	$HSCH_2CH(NH_2)CO_2H$
Glutamic acid	$HO_2CCH_2CH_2CH(NH_2)CO_2H$
Arginine	$H_2NC(=NH)NHCH_2CH_2CH_2CH(NH_2)CO_2H$
Phenylalanine	 $CH_2CH(NH_2)CO_2H$
Histidine	 $CH_2CH(NH_2)CO_2H$

However, in spite of this variation, the natural amino acids do have a common type of structure represented by the type formula $RCH(NH_2)CO_2H$. The group R may represent an aliphatic, aromatic (as in phenylalanine) or heterocyclic (as in histidine) residue.

The proteins are macromolecules derived from a-amino acids by a process equivalent to dehydration between the $—NH_2$ group of one amino acid and the $—CO_2H$ group of another. This leads to a structure of the type . . . NH—CHR′—CO—NH—CHR″—CO—NH—CHR″—CHR‴—CO . . . in which different amino acid residues are repeated many times. Thus, from about 20 different amino acids, the colossal array of different proteins required by different forms of life is constructed.

The determination of the sequence of amino acids in proteins has represented a major challenge to the ingenuity and technical skill of organic chemists since the polypeptide nature of proteins was first recognized. Tremendous progress was made in this field during 1955–60; the complete structure of insulin was elucidated and considerable progress made toward the determination of the complete structure of other important hormones such as the corticotrophins and enzymes such as ribonuclease.

Vitamins.—There is a close relationship between the representatives of terpenes, carbohydrates and amino acids, and it is therefore logical to classify them together. This is not true of all natural products; for example, the vitamins are classified together because they have the same type of activity. Vitamins are essential constituents of food and their absence from animal diet causes disease. For example, lack of vitamin C causes scurvy.

Since the vitamins exist in natural substances in very low concentration, their isolation and identification of structure presented a formidable task. The structure of vitamin C was the first to be determined (1933) and since that time many others have been characterized. As might be expected, the vitamins show a wide variety of structure. (See VITAMINS.)

Antibiotics.—Like the vitamins, there is very little similarity between the structures of the many known antibiotics. (*See* ANTIBIOTICS.)

E. Reactions of Organic Compounds

This subject may be considered from two points of view: (1) the reactions of particular functional groups and the way in which these reactions are modified by interaction between the groups when they are present in the same molecule, and (2) the interpretation of reactions of organic compounds in terms of reaction mechanism.

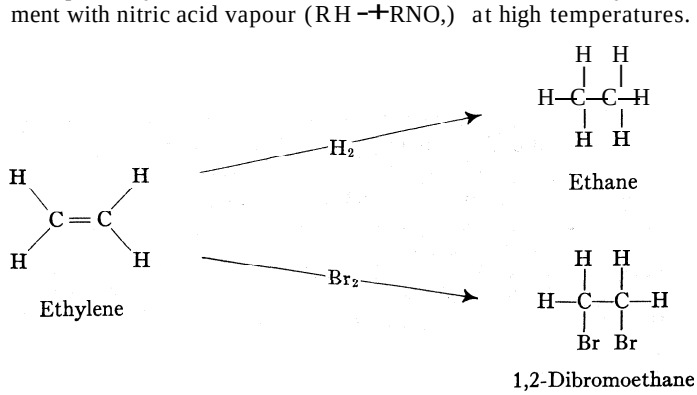
1. Functional **Group** Chemistry.—Although the aliphatic hydrocarbons (alkanes) are usually considered to have no functional groups, it is customary to begin discussions of organic functional group chemistry with a discussion of the alkanes.

Hydrocarbons.—The alkanes, which contain only carbon and hydrogen atoms, have the general formula C_nH_{2n+2}, in which all the valencies of the constituent atoms are satisfied. The characteristic reactions are therefore substitution reactions in which hydrogen atoms are replaced by other atoms or groups.

A typical substitution reaction of alkanes is the reaction with chlorine to give alkyl chlorides. Further replacement of hydrogen by chlorine leads to polychloro derivatives. The products obtained by the light-induced chlorination of methane are given below.

$$CH_4 \xrightarrow[\text{light}]{Cl_2} \underset{\text{Methyl chloride}}{CH_3Cl} + \underset{\text{Methylene chloride}}{CH_2Cl_2} + \underset{\text{Chloroform}}{CHCl_3} + \underset{\text{Carbon tetrachloride}}{CCl_4}$$

Aliphatic hydrocarbons undergo a substitution reaction by treatment with nitric acid vapour ($RH \rightarrow RNO_2$) at high temperatures.



The olefins (alkenes) contain a carbon-carbon double bond as a functional group and this results in addition rather than substitution reactions. Thus ethylene may be catalytically hydrogenated

to ethane and it can be made to undergo an addition reaction with bromine, giving 1,2-dibromoethane.

The transformation of alkanes into alkenes is a very important industrial process because alkenes show a much greater number of reactions as a consequence of their carbon-carbon double bond. Alkenes are extremely versatile in their reactions and may be used as starting materials in a large number of industrial processes. The cracking of saturated hydrocarbons is achieved thermally, often with catalysts. The pyrolysis products from the simpler hydrocarbons illustrate the various products that are obtainable.

$$CH_3{-}CH_3 \longrightarrow CH_2{=}CH_2 + H_2$$

$$CH_3{-}CH_2{-}CH_3 \longrightarrow \begin{cases} CH_3{-}CH{=}CH_2 + H_2 \\ CH2{=}CH_2 + CH_4 \end{cases}$$

$$CH_3{-}CH_2{-}CH_2{-}CH_3 \longrightarrow \begin{cases} CH_3{-}CH_2{-}CH{=}CH_2 + \\ CH_3{-}CH{=}CH{-}CH_3 + H_2 \\ CH_3{-}CH{=}CH_2 + CH_4 \\ CH_2{=}CH_2 + C_2H_6 \end{cases}$$

"Isooctane" (2,2,4-trimethylpentane) is an important constituent of high-quality gasoline; its industrial synthesis from 2-methylpropene (isobutene), a product from the cracking process, illustrates the acid-catalyzed dimerization (combining of two molecules) of alkenes, which is one of their characteristic reactions. (See GASOLINE.)

$$2\ Me_2C{=}CH_2 \xrightarrow{\text{acid}}$$

2-methylpropene (isobutene)

$$Me_3C{-}CH_2{-}\underset{\displaystyle Me}{\underset{|}{C}}{=}CH_2 \xrightarrow{H_2} Me_3C{-}CH_2{-}CHMe_2$$

"Isooctane" (2,2,4-trimethylpentane)

Hydration of ethylene ($C_2H_4 + H_2O \rightarrow C_2H_5OH$) is acid-catalyzed and is one of the methods used in industry to prepare ethanol.

Acetylene ($H{-}C{\equiv}C{-}H$) contains a triple bond. It shows many reactions characteristic of this type of unsaturation and such reactions are used widely for the industrial synthesis of a large range of compounds. Hydration of acetylene to acetaldehyde ($C_2H_2 + H_2O \cdot + CH_3CHO$) is easily achieved with dilute sulfuric acid and mercuric sulfate as catalysts. The acetaldehyde so produced is used in vast quantities for the industrial preparation of acetic acid. The addition reaction between acetic acid and acetylene gives vinyl acetate, which on polymerization by various catalysts gives the polymer polyvinyl acetate (PVA).

$$CH{\equiv}CH + CH_3{-}CO_2H \longrightarrow H_2C{=}\underset{\displaystyle H}{\underset{|}{C}}{-}O{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}CH_3$$

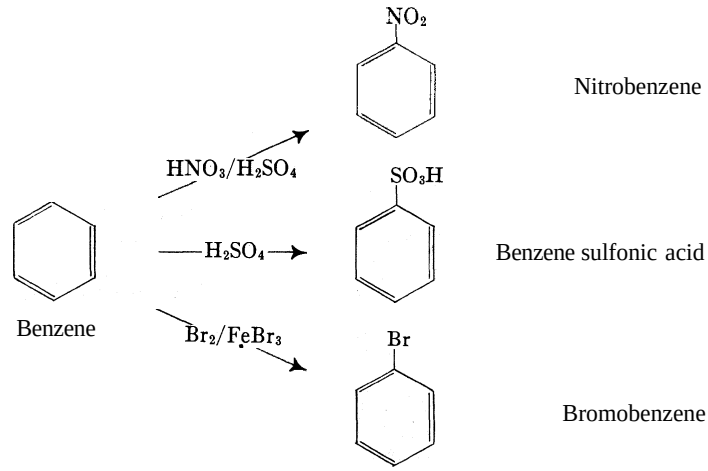
acetylene + acetic acid → Vinyl acetate

$$\ldots\left[\begin{array}{l} OCOCH_3\ \ OCOCH_3\ \ OCOCH_3\ \ OCOCH_3 \\ CH{-}CH_2{-}CH{-}CH_2{-}CH{-}CH_2{-}CH{-}CH_2 \end{array}\right]_n \ldots$$

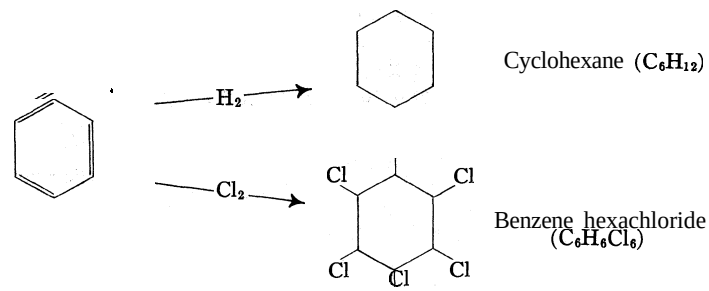
Polyvinyl acetate

The molecular formula of benzene (C_6H_6) is such that it would be expected to behave as an unsaturated compound, but in fact in many of its reactions it shows substitution rather than addition reactions. Substitution reactions of benzene include nitration, giving nitrobenzene; sulfonation, giving benzene sulfonic acid; and halogenation.

Benzene also shows reactions of the addition type. These include the formation of cyclohexane by catalytic reduction and the light-induced reaction with chlorine that yields benzene hexachloride.



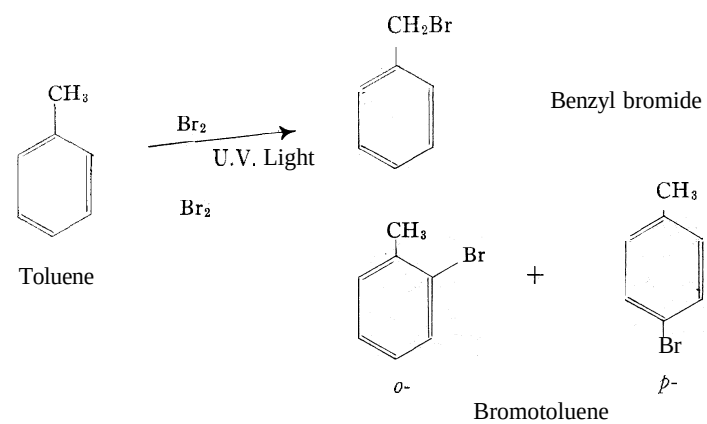
Substitution reactions of benzene



Addition reactions of benzene

This duality of reaction type shown by benzene is compatible with its aromatic structure. The unsaturation indicated by the molecular formula explains the addition reactions, and the substitution reactions are in accord with the stability characteristic of aromatic systems. The polynuclear aromatic hydrocarbons such as naphthalene and anthracene also show substitution and addition reactions.

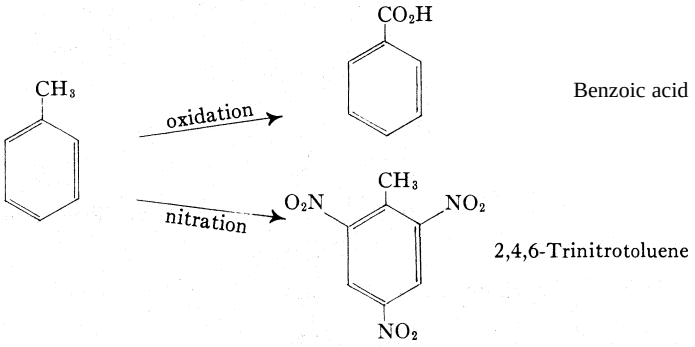
The alkylbenzenes (*e.g.*, toluene and the xylenes) contain alkyl and aryl groups and, as might be expected, show properties characteristic of both groups. Thus, bromination of toluene in the presence of ultraviolet light gives benzyl bromide, but in the presence of aluminum bromide nuclear bromination occurs, giving a mixture containing o-bromotoluene and *p*-bromotoluene as the main constituents.



Bromotoluene

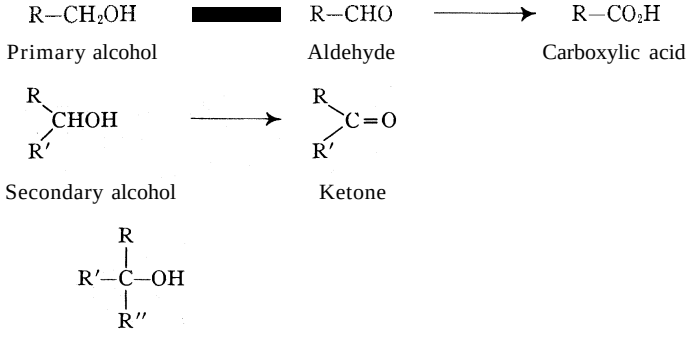
An interesting feature of the reactions of alkylbenzenes is that both the methyl and the phenyl groups show a higher degree of reactivity than is shown by methane or benzene. For example, oxidation of toluene by potassium permanganate gives benzoic acid, whereas methane is unaffected under these conditions. Thus one group activates the other. Nitration of toluene, to cite another example, gives 2,4,6-trinitrotoluene (TNT) whereas the nitration

of benzene yields only a dinitro derivative (1,3-dinitrobenzene).

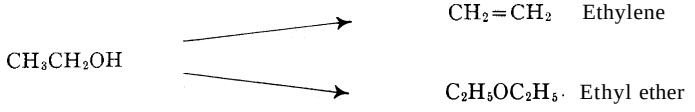


Hydroxy Compounds.—Two important types of organic compound contain hydroxyl groups. They are the alcohol (*q.v.*) type, where the hydroxyl group is bonded to a saturated carbon, and the phenols (*q.v.*), in which the hydroxyl group is attached directly to a benzene ring or aromatic system. The latter are called phenols after the parent of the series, phenol (C_6H_5OH).

The three kinds of alcohols may be represented by the type formulas shown below. They differ in their reaction toward oxidizing agents (*e.g.*, potassium chromate in dilute sulfuric acid).

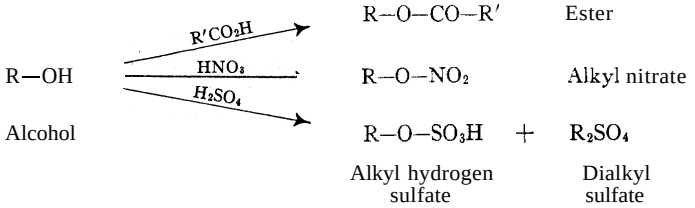


Mild oxidation of ethanol (C_2H_5OH), for example, gives acetaldehyde (CH_3CHO) and more vigorous oxidation gives acetic acid (CH_3CO_2H). Oxidation of isopropanol [$(CH_3)_2CHOH$] gives the ketone, acetone (CH_3COCH_3). Oxidation of a tertiary alcohol. such as t-butyl alcohol, either produces no change or results in oxidative degradation. Dehydration of alcohols may give either olefins (alkenes) or ethers. depending on the structure of the molecule and the conditions of the reaction.



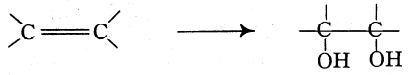
Ethyl ether (ethoxyethane), the ether often used as an anesthetic, is prepared by the dehydration of ethyl alcohol.

Alkyl halides may be prepared from alcohols ($ROH \rightarrow RX$, where X = Cl, Br, I) by reaction with phosphorus halides, thionyl chloride (giving RCl) or halogen acids. This is a particularly valuable reaction synthetically because the alkyl halides show a large number of different reactions. When alcohols are treated with sodium metal, the corresponding alkoxide is formed (*e.g.*, $C_2H_5OH \xrightarrow{Na} C_2H_5ONa$). This shows the weakly acidic character of the hydrogen atom in an alcoholic hydroxyl group.

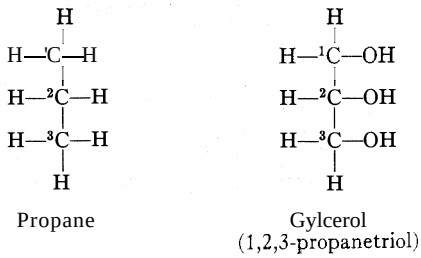


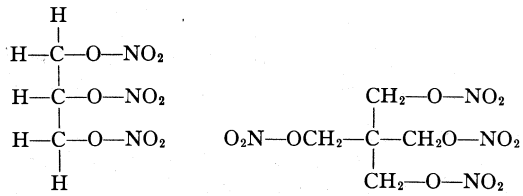
A reaction that is characteristic of alcohols is the formation of esters. Reaction between alcohols and carboxylic acids gives organic esters; and inorganic acids, such as nitric or sulfuric acids, give inorganic esters when they react with alcohols.

The preparation and reactions of polyhydroxy compounds (*i.e.*, compounds containing more than one hydroxyl group) are of interest. The 1,2-diols, which contain the part structure —C(OH)—C(OH)—, may be prepared by oxidation of alkenes with alkaline permanganate or osmium tetroxide. The general reaction may be represented as follows:



Glycerol, which is often produced by the alkaline hydrolysis (saponification) of animal oils and fats, contains three hydroxyl groups in each molecule. It is called 1,2,3-propanetriol or trihydroxypropane. It is so named because glycerol is a derivative of propane in which hydrogen atoms attached to the carbon atoms numbered 1, 2 and 3 are replaced by hydroxyl groups.





Treatment of glycerol with a mixture of concentrated nitric and sulfuric acids gives the powerful explosive nitroglycerine, which, when absorbed on kieselguhr (diatomaceous earth), is used as dynamite. A related explosive is pentaerythritol tetranitrate (PETS), which is prepared from the tetrahydroxy compound pentaerythritol [$C(CH_2OH)_4$].

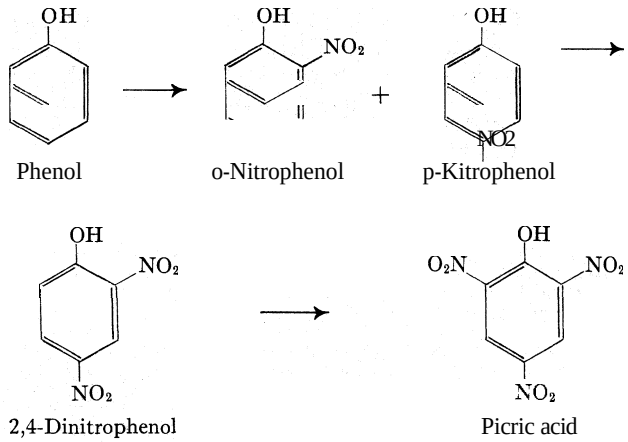
The phenols are aromatic hydroxy compounds. They show some reactions that correspond to reactions of alcohols (*e.g.*, formation of esters and others). but most of their more interesting reactions are associated with the aromatic nucleus, to which the hydroxyl group is bonded. Phenols undergo aromatic substitution reactions such as nitration, sulfonation and halogenation much more easily than do the corresponding aromatic hydrocarbons because of the activating influence of the phenolic hydroxyl group.

Nitration of phenol gives various products depending upon the conditions and the nitrating agent.

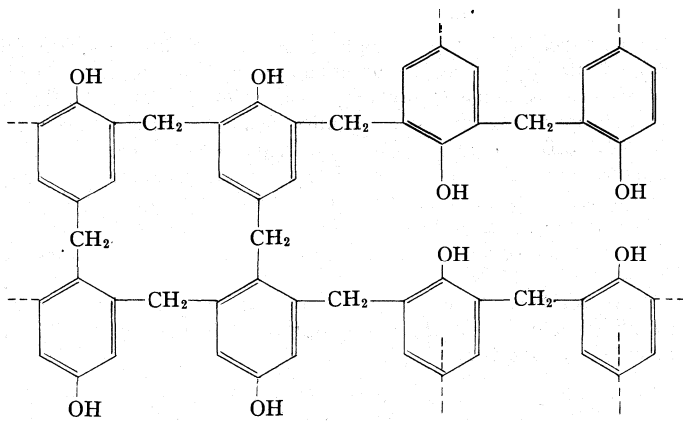
In these substitution reactions the substituent is located either ortho or para to the phenolic group. The phenolic group is said to be an ortho-para directing group since it activates the ortho and para positions.

Phenols are more strongly acidic than alcohols and are soluble in sodium hydroxide because the phenolate anion is more stable than an alkoxide anion.

Phenols react with aldehydes to give condensation products, a reaction that is employed in the technical preparation of the phenol-formaldehyde resins, which are plastics of the thermosetting type. The industrial process was discovered by Leo Hendrik Baekeland and the plastics are called Bakelite. The structure of



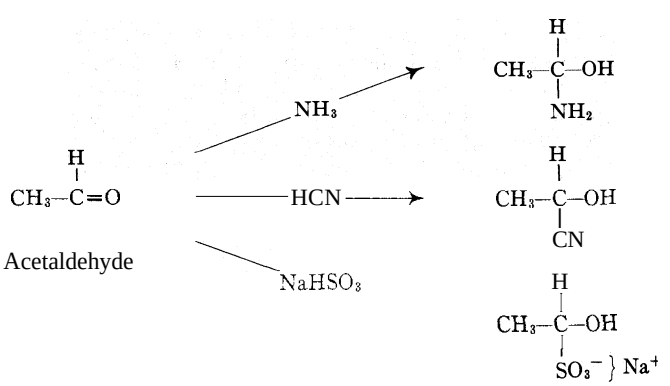
the bakelite-type resins produced from phenol and formaldehyde is macromolecular and contains phenol residues cross-linked via methylene groups supplied by the formaldehyde precursor. Examination of the part structure shown below indicates how the cross-linkages involve the ortho and para positions of the phenolic residues.



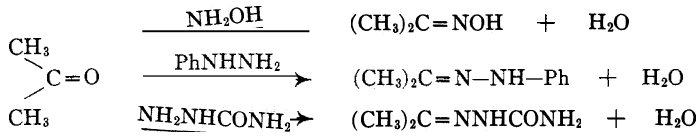
Many substances that occur naturally are phenolic. Lignin, for example, a major constituent of wood, has a macromolecular structure containing phenolic residues, but its detailed structure was not known in the early 1960s.

Aldehydes and Ketones.—These are compounds represented by the type formulas, R—CHO (aldehydes) and R—CO—R' (ketones). They contain a carbonyl (>C=O) group; the chemical reactions that they show may be associated either with the >C=O group directly or with the way in which the >C=O group modifies the groups to which it is attached.

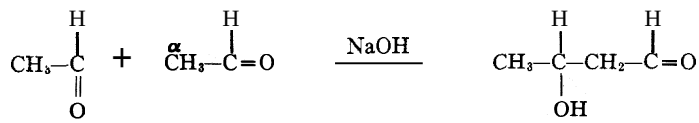
The >C=O group is unsaturated like the >C=C< group and, as could be expected, aldehydes and ketones (*q.v.*) show addition reactions. The reactions of acetaldehyde, as shown below, are typical; they include additions with ammonia, hydrogen cyanide and sodium bisulfite.



Aldehydes and ketones also react with a variety of reagents in addition reactions, in the elimination of water. The reactions of the ketone acetone with hydroxylamine, phenylhydrazine and semicarbazide, giving acetoxime, acetone phenylhydrazone and acetone semicarbazone respectively.



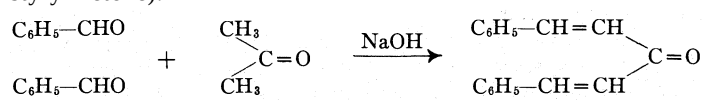
When acetaldehyde is treated with a small quantity of sodium hydroxide it iorms aldol; this reaction may be regarded as involving the addition of one molecule of acetaldehyde to the carbonyl group of another.



Aldol

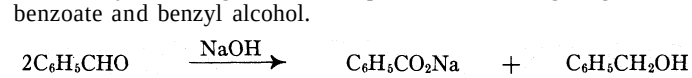
The methyl group designated as α in the above equation is said to be activated by the adjacent carbonyl group, with the result that it may undergo addition to another carbonyl group.

Aldol is dehydrated to give crotonaldehyde ($CH_3—CH=CH—CHO$) by heating, and this reaction takes place particularly easily in the presence of acid. In some reactions the intermediate of the aldol type, although it is certainly formed, is not isolated. In these cases a condensation product is obtained directly; thus benzaldehyde and acetone in the presence of aqueous sodium hydroxide give dibenzylidene-acetone (dibenzalacetone, or styryl ketone).



Benzaldehyde Acetone Dibenzylidene-acetone

The reaction of aliphatic aldehydes with bases differs from that of aromatic aldehydes. Acetaldehyde yields aldol, whereas benzaldehyde undergoes an unexpected reaction, giving sodium benzoate and benzyl alcohol.



Benzaldehyde Sodium benzoate Benzyl alcohol

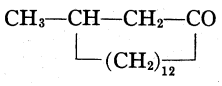
This reaction was discovered by Cannizzaro (1853) and is called the Cannizzaro reaction. It may be regarded as an internal oxidation-reduction reaction.

It is possible to differentiate between aldehydes and ketones by using tests that depend upon the ability of aldehydes to act as reducing agents. They are easily oxidized to carboxylic acids and it is this property that is involved in the silver mirror test and in Fehling's test for aldehydes.

Carboxylic Acids and Their Derivatives.—Most of the properties of carboxylic acids are attributable to reactions involving the carboxyl (—CO_2H) group. Carboxylic acids are acidic, though usually less so than most inorganic acids. The carboxylic acids are represented by the type formula R—CO_2H; decarboxylation by heating with soda lime gives the alkane (R—H). Electrolysis of aqueous solutions of sodium salts (R—CO_2Na) gives alkanes (R—H), a reaction (discovered by Kolbe) that involves fret radical intermediates. When the calcium salts of carboxylic acids are heated they yield ketones (*e.g.*, calcium acetate gives acetone).

This reaction formed the basis of Leopold Ruzicka's classical studies (1934) on the synthesis of ketones with large-membered rings. By heating the thorium salts of dicarboxylic acids he showed that it was possible to obtain cyclic ketones with

structures similar to muscone, the odiferous principle of musk perfume.



Muscone

By suitable reactions it is possible to change the carboxyl group of carboxylic acids ($R—CO_2H$) into various groups that lead to derivatives such as esters ($R—CO_2R'$), acid chlorides ($R—COCl$), acid amides ($R—CONH_2$) and acid anhydrides ($R—CO—O—COR$). These derivatives are important as intermediates in synthetic organic chemistry.

Amines.—Amines (*q.v.*) are of three types: primary amines ($R—NH_2$), secondary amines ($R—NHR'$) and tertiary amines ($R—NR'R''$). When the NH_2 group is attached to an aromatic ring the compounds often show different properties than do aliphatic primary amines.

Amines are basic compounds, as shown by their reaction with acids to form salts and by the formation of quaternary ammonium salts when they are treated with alkyl halides.

$$MeNH_2 + HCl \rightarrow [MeNH_3^+]Cl^-$$

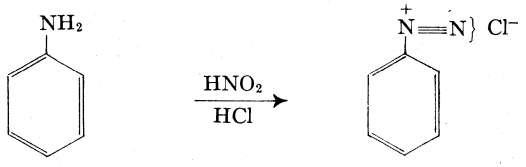
Methylammonium chloride

$$Me_3N + MeCl \rightarrow [Me_4N^+]Cl^-$$

Tetramethylammonium chloride

The reaction of aliphatic amines with nitrous acid may be used to differentiate between primary, secondary and tertiary amines. Primary amines often give the alcohol and nitrogen ($R—NH_2 + HNO, \rightarrow R—OH + N_2 + H_2O$), secondary amines give nitrosamines ($RR'NH + HNO_2 \rightarrow RR'N—NO + H_2O$) and tertiary amines form only a nitrite salt.

In this respect primary aliphatic amines differ from primary aromatic amines, since the latter react with nitrous acid under controlled conditions to give diazonium salts. For example, aniline and sodium nitrite in aqueous hydrochloric acid at 0°–5° C. give benzenediazonium chloride.



Aniline

Benzenediazonium chloride

The diazonium salts show a remarkable variety of reactions and may be transformed into phenols, aryl halides (Sandmeyer reaction), aryl hydrazines and azo compounds by coupling with phenols or aromatic amines. The coupling reaction of diazonium salts was discovered by Johann Peter Griess (1858) while he was working in Kolbe's laboratory, and this observation led to the large industry now associated with the manufacture of azo dyes.

2. Mechanisms of Organic Reactions. — During the 1920s the first attempts were made by organic chemists to describe the reactions of organic compounds in terms of the electronic theory of atomic structure. It had already been recognized that single covalent bonds involved the interaction between two electrons (Lewis, 1916) and it was reasonable to expect that chemical reactions, which involve the formation and cleavage of chemical bonds, might be treated as processes involving the movement of electrons. These newer electronic concepts were successfully applied to organic phenomena by several organic chemists including Lapworth, Robinson and Ingold. Their approach developed into a branch of the subject that is termed theoretical organic chemistry and made it possible to provide rationalizations for many organic reactions and to detect many subtle similarities in the behaviour of organic compounds. The theory of reaction mechanisms is now so well based that it is frequently possible to make predictions about the course of chemical reactions.

Two main types of reaction may be recognized—ionic reactions and free radical reactions. Ionic reactions are those in which electrically charged intermediates (ions) are involved; this type of reaction intermediate can be produced by the heterolytic cleavage of covalent bonds. Homolytic cleavage reactions give intermediates of the free radical type.

Ionic reaction (Heterolytic)	$A:B \longrightarrow A^+ + B:^-$
Free radical reaction (Homolytic)	$A:B \longrightarrow A\cdot + B\cdot$

Each dot in equations of this kind represents one electron.

Since free radicals (*q.v.*) are dealt with elsewhere, this section will be concerned primarily with ionic reactions. The heterolytic cleavage of the covalent bond in A–B is often represented by a curved arrow, which symbolizes the movement of two electrons. Thus the ionic reaction show above can also be represented in the following way:

$$A \overset{\frown}{—} B \rightarrow A^+ + B^-$$

Electrophilic and Nucleophilic Reagents. — Reagents can be divided into at least two types. electrophilic (cationoid. or electron-accepting) and nucleophilic (anionoid, or electron-donating). During a reaction an electrophilic reagent seeks a negatively charged site in a molecule, or an anion, and it therefore often provides a less stable (more reactive) cation A^+ on heterolysis. Thus bromine is an electrophilic reagent since heterolysis ($Br—Br \rightarrow Br^+ + Br^-$) gives the reactive Br^+ cation. The bromide anion, Br^-, is stable. Similarly, a nucleophilic reagent seeks a positively charged site in a molecule since heterolysis provides a relatively more reactive anion. The equivalent process is possible in molecules containing atoms that have lone pairs of electrons (*e.g.*, $R_3N:$).

Some simple examples of electrophilic and nucleophilic reagents are given below and, where appropriate, the reactive entity is indicated in parentheses:

Electrophilic reagents	Acids (H^+); halogens (X^+); nitrating acid (NO_2^+);
Nucleophilic reagents	Hydroxides (OH^-); cyanides (CN^-); alkoxides (OR^-); enolate anions; amines ($R_3N:$)

Reactions are classified according to the types of reagent involved. The alkaline hydrolysis of an alkyl halide giving an alcohol ($R—Br + OH^- \rightarrow R—OH + Br^-$) is described as a nucleophilic substitution since it is a substitution reaction involving a nucleophilic reagent that provides OH^-. The addition of halogen acid to an olefin (*e.g.*, $CH_3—CH=CH_2 + HBr \rightarrow CH_3CHBrCH_3$) is an electrophilic addition since it involves an attack by H^+ and Br^- upon the $>C=C<$ double bond.

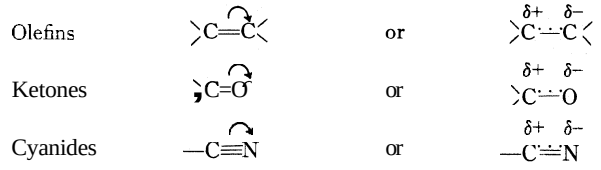
Structure of *Molecules.*—Although it is usual to represent molecules as not containing atoms bearing formal positive or negative charges, electron displacements can occur within molecules by the operation of inductive (electrostatic) and electromeric (tautomeric, mesomeric or resonance) effects.

The inductive effect is the polarization of single bonds connecting atoms of different electronegativities. Thus methyl chloride (CH_3Cl) contains a C—Cl bond and because the chlorine atom is more electronegative than carbon, the C—Cl bond is polarized. The carbon atom bears a fractional positive charge and the chlorine atom a fractional negative charge. These charges are presented by δ^+ and δ^-. There are two ways of indicating the inductive effect in the formula of methyl chloride:

$$H_3C \rightarrow — Cl \qquad \overset{\delta^+}{H_3C} — \overset{\delta^-}{Cl}$$

The electromeric effect is a consequence of the charge displacement that can occur in unsaturated systems (*e.g.*, $>c{-}{-}C<$; $>C=O$; $-C\equiv N$). It is not, unlike the inductive effect, neces-

sarily an intrinsic property of the molecule, but it may be brought about only by the presence of an attacking reagent. The polarization can be represented in two ways as in, for example, the olefins, ketones and cyanides.



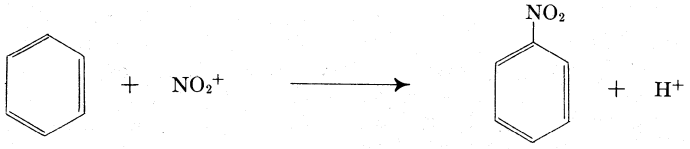
These charge displacements can, so to speak. encourage reactions with either electrophilic or nucleophilic reagents.

Organic Reaction *Mechanisms.*—In a brief account it is not possible to survey all aspects of organic reaction mechanisms. In some cases a simplified treatment is given, but no reference is made to the detailed approach to the subject that is now possible when use is made of the principles of modern physical chemistry. (See Physical Chemistry below; see also REACTION KINETICS: *Reaction Mechanism.*)

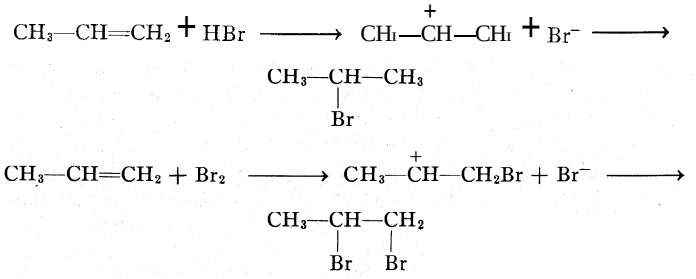
Reactions in organic chemistry may be classified into four main groups: substitution; addition; elimination; and rearrangement reactions.

1. Substitution reactions may be represented by the general expression ($X + A{-}B \rightarrow X{-}A + B$) in which the group X is replacing the group B. A typical reaction is the alkaline hydrolysis of an alkyl bromide ($OH^- + R{-}Br \rightarrow HO{-}R + Br^-$). This reaction is called a nucleophilic aliphatic substitution reaction; reactions of this type were closely examined by Ingold.

Aromatic substitution reactions are often reactions of the electrophilic type as exemplified by the nitration of benzene to nitrobenzene. It has been shown that the active entity in this process is the nitronium cation (NO_2^+), which displaces the hydrogen as H^+.

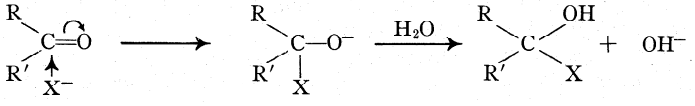


2. Addition reactions can also involve electrophilic or nucleophilic reagents. The addition reactions of olefins involve the former type of reagent. The similarity between the addition of hydrogen bromide and bromine to an olefinic group is indicated in the following addition reactions of propene.

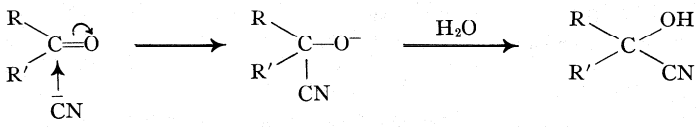


The cations ($CH_3\overset{+}{C}HCH_3$ and $CH_3\overset{+}{C}HCH_2Br$), represented as intermediates in these reactions. are called carbonium ions. Many aspects of the behaviour of carbonium ions were investigated by the American chemists Frank C. Whitmore and Saul Winstein.

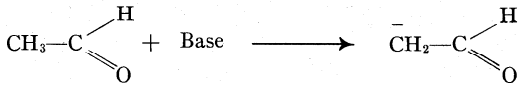
The electromeric effect in the carbonyl group ($>C{=}O$) of aldehydes and ketones is responsible for the electrophilic addition reactions shown by them. These reactions can be represented generally by

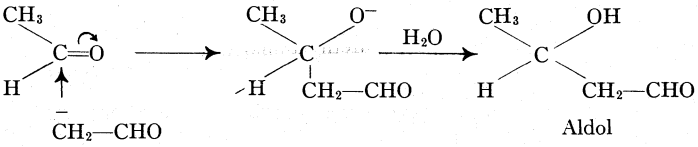


The addition reactions of ketones with hydrogen cyanide, sodium bisulfite and ammonia may be represented mechanistically in this way. The hydrogen cyanide reaction, for example, may be shown as follows:

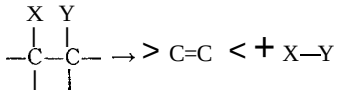


It is also possible to represent related reactions by similar mechanisms. Thus the base-catalyzed formation of aldol involves the addition of the anion derived from acetaldehyde to the carbonyl group of another acetaldehyde molecule.

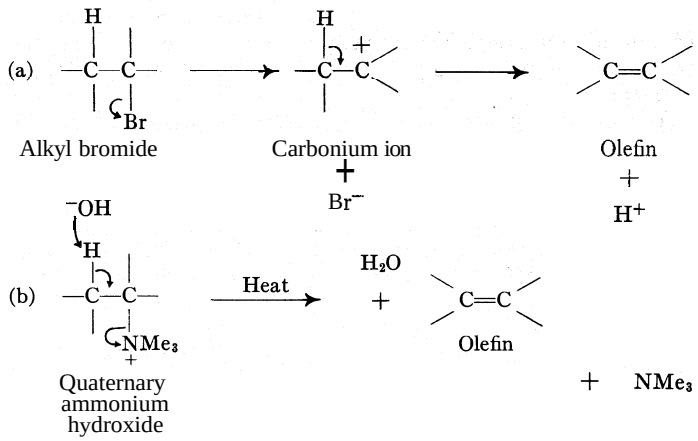




3. Elimination reactions are of various types; olefin formation may be represented by the general expression



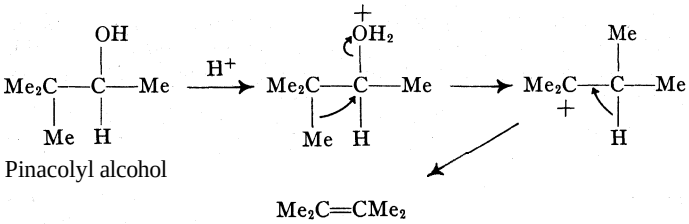
The two reactions that are often used for the preparation of olefins are (a) the reaction of alkyl halides with strong alkali and (b) the Hofmann degradation, uhich is achieved by the pyrolysis of quaternary ammonium hydroxides. The mechanisms of these reactions may be represented as follows:



The diagrams shown above for reactions (a) and (b) illustrate the symbols that are used by organic chemists to indicate the mechanisms of the reactions. Partial structures are used to indicate the generality of the reactions and the curved arrows are used to indicate the shift of two electrons (*i.e.*, the shift of one bond).

4. Molecular rearrangements (*q.v.*) are those reactions that are associated with an alteration in the relative positions of the skeletal atoms of a molecule. Numerous reactions of this type are known; they can be illustrated by (1) the Wagner-Meerwein rearrangement; and (2) the Beckmann rearrangement. Examples of these rearrangements are given below:

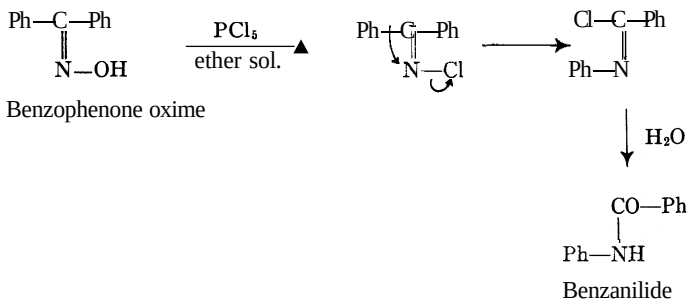
(1) Acid-catalyzed dehydration of pinacolyl alcohol gives tetramethylethylene by the following mechanism



Pinacolyl alcohol

Tetramethylethylene

(2) Benzophenone oxime and phosphorus pentachloride in an ether solution give benzanilide by the Beckmann rearrangement.



Benzophenone oxime

Benzanilide

The Beckmann reaction involves a migration of a phenyl group from carbon to nitrogen.

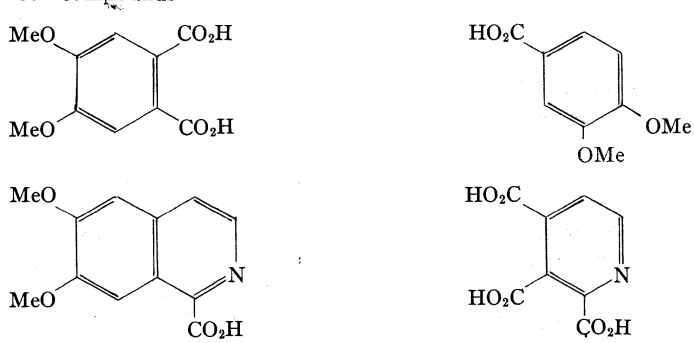
F. Proof of Structure

One of the major activities of organic chemists has been the determination of the structures of organic compounds. Natural products and also products of unexpected constitution resulting from synthetic reactions have been examined.

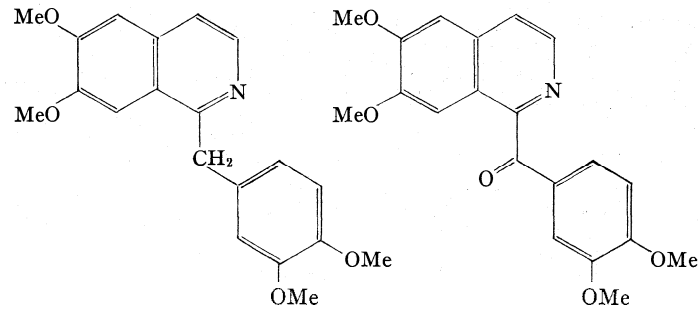
The classical methods for the establishment of structure involve elucidation by degradation followed by confirmation of the structural proposal by a rational synthesis. In determining the structure by degradation a study is made of the reactions of the compound with various reagents, including acids, bases, oxidizing agents and reducing agents. This eventually leads to the recognition of functional groups.

Successful degradation reactions also provide simpler products of known structure and from these it is possible to determine the structural formula of the molecule from which they could be derived.

The use of degradative methods to elucidate structure may be illustrated by brief reference to G. Goldschmiedt's studies on papaverine, an alkaloid isolated from the poppy. Papaverine was shown to have the molecular formula $C_{20}H_{21}NO_4$ with the four oxygen atoms accommodated in four methoxy (OMe) groups. Mild oxidation gave papaveraldine, $C_{20}H_{19}NO_5$, corresponding to the change $>CH_2 \rightarrow CO$, and more vigorous oxidation gave the four compounds:



By comparing these structures it is possible to deduce which carbon atoms are common to the degradation products; from this deduction follows the proposed structure for papaverine. Its relationship to papaveraldine, as indicated by their structural formulas, is acceptable.



Papaverine

Papaveraldine

This argument illustrates the approach used by organic chemists in tackling structural problems. Experiments are carried out and a structure is eventually proposed that is compatible with the degradative evidence. It should be pointed out, however, that the determination of the structure of papaverine was fairly straightforward; other determinations have required very lengthy study for their solution. It will be clear from the discussion in earlier sections that many structural problems presented by molecules of great complexity were soluble by the early 1960s. The remarkable progress that was made in this field during the 1950s was to some extent due to the wide use of physical methods by organic chemists; these methods include ultraviolet, infrared and nuclear magnetic resonance spectroscopy.

G. Synthesis of Organic Compounds

A great deal of effort has been devoted to the synthesis of organic compounds. This has included, for example, the synthesis of natural products in order to make them artificially and to verify the structure that had previously been established by degradation. Other studies have been motivated by the desire to discover or exploit new organic reactions, to synthesize new compounds in order to study their reactions and to test theoretical proposals. Since about 1900 tremendous activity has also been directed toward the synthesis of new organic compounds that may be valuable as pharmaceuticals (chemotherapy), synthetic substitutes (fibres, plastics and resins), dyes, insecticides. anesthetics and hormones. This list is by no means complete, but it does show the wide range of substances that fall within the province of synthetic organic chemistry.

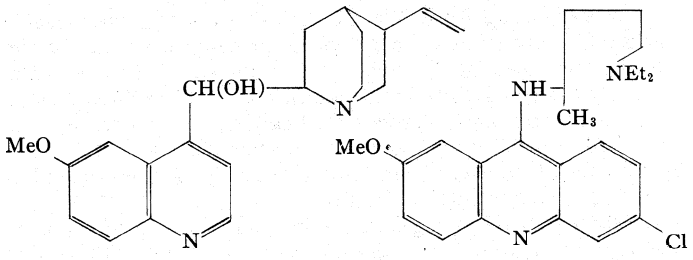
1. Synthesis of Natural Products. — Many of the milestones in the history of organic chemistry have been provided by the synthesis of natural products. Important achievements include the syntheses of urea (Wohler, 1828), acetic acid (Kolbe, 1845), alizarin (Carl Graebe and Carl Liebermann, 1868), coniine (Albert Ladenburg. 1886). glucose (Fischer, 1890), camphor (Gustav Komppa, 1903), tropinone (Robinson, 1917), anthocyanins (Robinson. 1931) and vitamin C (Walter N. Haworth, Edmund L. Hirst and Tadeus Reichstein, 1933).

Between 1950 and 1960 the power of modern synthetic methods was demonstrated by the syntheses of complex alkaloids (Robert B. Woodward), steroids (Robinson, Woodward et al.), polypeptides (Vincent du Vigneaud), nucleotides and coenzymes (Alexander R. Todd).

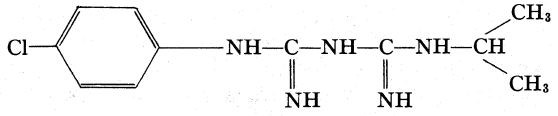
2. Synthetic Pharmaceuticals and Chemotherapy. — The synthesis of molecules that are structurally related to natural products and have pharmaceutical activity has led to extensive inquiry. A good example of this approach is the search for synthetic antimalarials (as substitutes for quinine) that led to the discovery of quinacrine hydrochloride (Atabrine; Atebrine) (W. Kikuth, H. Mauss and F. Mietzsch, 1930). (See Quinine.)

Comparison of the structure of quinacrine hydrochloride with that of quinine indicates relationships between molecular structure and biological activity. However, the effective antimalarial chlorguanide hydrochloride (Paludrine), which was discovered during World War II, is rather remote structurally from both quinine and quinacrine hydrochloride.

Chlorguanide hydrochloride is in many respects superior to quinine for the treatment of malaria. Discoveries such as those



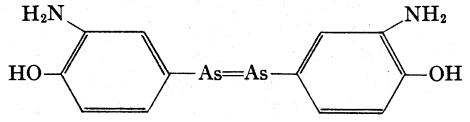
Quinine Quinacrine (Atabrine)



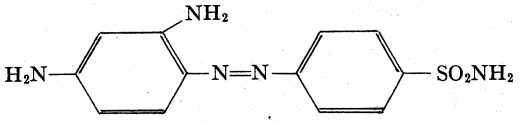
Chlorguanide (Paludrine)

of chlorguanide hydrochloride are made only as a result of research on a very broad front; during World War II more than 14.000 compounds were screened in the United States, Great Britain and Canada as possible antimalarials.

Interest in chemotherapy was stimulated by the remarkable researches carried out by Paul Ehrlich in his search for chemical agents that might selectively destroy pathogenic organisms without seriously damaging the host. In 1909 Ehrlich discovered that arsphenamine (Salvarsan) had an ameliorative effect upon syphilis; he also discovered that various dyes had certain curative effects on other diseases. Many dyes were examined and in 1935 Gerhard Domagk discovered that the dye Prontosil, the first sulfonamide drug, was spectacularly effective against certain streptococcal infections.

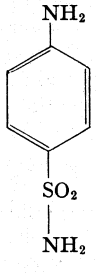


Arsphenarnine (Salvarsan)

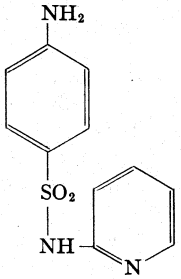


4′-Sulfamyl-2,4-diaminoazobenzene (Prontosil)

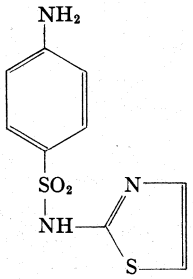
In 1936 J. Tréfoël discovered that Prontosil is transformed in *vivo* into *p*-aminobenzenesulfonamide (sulfanilamide) and this led to the synthesis and examination of a large number of derivatives of sulfanilamide, and to the discovery of the important group of chemotherapeutic agents called the sulfonamides, which are compounds of the following type:



Sulfanilamide



Sulfapyridine



Sulfathiazole

The discovery of antibiotics had a tremendous impact on methods of treatment of disease, but it has not reduced the effort devoted to the synthesis and examination of organic compounds as possible pharmaceuticals (see also PHARMACOLOGY).

3. Man-made Fibres, Plastics and Resins.—Many types of organic chemicals of high molecular weight are synthesized on a large scale for use as fibres and plastics. These include substances such as nylon, Dacron (Terylene), polyethylene and polyvinyl chloride; their production forms a very important part of the chemical industry. Synthetic polymers are structurally related to various natural products such as cotton or rubber and in some cases the qualities of the synthetic products are superior to those of the substances they are designed to replace. See SYNTHETIC FIBRES; PLASTICS; RESINS. (W. D. Os.)

IV. PHYSICAL CHEMISTRY

The easiest definition of physical chemistry is that which describes it as the borderline subject between physics and chemistry, but this definition is not necessarily the most accurate. No greater clarity results by adopting the name "chemical physics." In fact, physical chemistry, since the first issue of the *Zeitschrift für physikalische Chemie* appeared in 1887, can claim to be a science in its own right. It certainly covers the ill-defined territory between physics and chemistry, as biochemistry does between chemistry and biology, and mathematical physics between mathematics and physics, but it can also stake a claim to quite a sizable piece of land. as extensive and as cultivated as the regions conventionally allocated to the so-called pure sciences of physics and chemistry. A definition of physical chemistry is difficult to formulate because, properly regarded, it is less a circumscription of subject matter than a method of approach. applicable equally to the problems of physics, chemistry and biology. There can be no harm, however, in attempting to describe the physical chemist: he is a man who observes natural phenomena and records his observations but maintains a judicious balance between the material changes themselves, the physical effects that accompany them and the mathematical machinery by which the whole can be most compactly condensed.

The three ordinary states of matter—solid, liquid and gaseous—fall within the province of physical chemistry, as do the metallic state, the interfacial state, the colloidal state and, most important of all, the dissolved state of matter. The influence of heat, light and mechanical and electrical forces on the various states of matter forms the subjects of thermochemistry, photochemistry, piezochemistry and electrochemistry, which rank among the most important subdivisions of physical chemistry. In this article various problems that have been solved, particularly during the 20th century, or are still being investigated will be discussed.

1. Adsorption.—When ethylene gas at atmospheric pressure is sealed in a vessel containing copper turnings, the pressure within the vessel gradually diminishes until it reaches a constant value. Similarly, when a solution of iodine is kept in contact with charcoal, the concentration of iodine diminishes until it reaches a constant value. Gas molecules in the first case and solute molecules in the second case have adhered to the surface of the solid. The phenomenon is known as adsorption and occurs in varying degrees for all solutes and all gases kept in contact with the surface of solids. Argon gas, for example, is adsorbed on the surface of potassium chloride crystals, and enzymes are adsorbed on diatomite (kieselguhr). The extent of adsorption depends on specific properties of the adsorbed and the adsorbing molecules, on the temperature and on the concentration or pressure. The familiar facts have been utilized practically without being understood theoretically. The fairly general adsorbing power of charcoal. for example, explains its use in decolorizing solutions in the course of organic preparations, in protection against toxic vapours and in the treatment of digestive ailments. The reverse process, desorption, has been utilized in the isolation of pure enzymes. While attempts were being made to understand the mechanism of adsorption, many empirical relations appeared connecting the amount adsorbed with temperature and concentration, the principal variables. Curves showing fractional adsorption as a function of the concentration at constant temperature are termed adsorption isotherms, and the empirical formulas advanced to account for these were numerous but unenlightening.

In 1916 Langmuir proposed a theory of adsorption that was not only sufficient to explain the phenomenon but also had extensive applications in other fields, including statistical physics. His the-

ory was simple. The surface of the solid, of area O cm.^{2}, is likened to a chess board, on which solute or gas molecules impinge. Some adhere to the unitary areas; others fly back to the bulk of the solution or the gas phase. When equilibrium is attained, a certain fraction, θ_s, of the area of the solid remains covered with adsorbed molecules. The fraction of free surface is then $(1 - \theta_s)$. In deriving the theoretical expression for the adsorption isotherm, the terminology of solutions will be used though the formulas are applicable, with certain changes, to gaseous systems. Let the total number of sites per unit area of surface, on which solute molecules can be adsorbed, be n_0 and the probability per second that an adsorbed molecule may become desorbed be v_s. Then the total number of molecules escaping per second from a surface of area, O cm^2, is $On_s v_s\theta_s$. The total number of solute molecules reaching the surface from the solution in one second is proportional to the surface area, O, and to the concentration, n_s, of solute molecules. Denoting the proportionality factor by k_s, the number is thus $k_s On_s$ molecules per second. But only those that hit vacant sites are adsorbed. Hence the rate of adsorption is $k_s On_s(1 - \theta_s)$. At equilibrium, the rates of adsorption and desorption are equal. On solving for θ, it is found that $\theta_s = k_s n_s/(k_s n_s + v_s n_0)$, which is Langmuir's adsorption isotherm. From the form of this equation, it will be noted that at low concentrations the fraction of the surface that is covered is proportional to the concentration of the supernatant solution, and is, in fact, $(k_s/v_s n_0)n_s$. At high concentrations, θ, tends toward unity. The whole surface is then covered with adsorbed molecules, and the extent of adsorption becomes independent of the concentration. It is generally possible, by quite simple experiments, to measure the concentration, n_0^*, which corresponds to a surface that is only one-half covered. This concentration, from the isotherm equation, is seen to be $v_s n_0 k_s$.

Among the many applications of Langmuir's theory is the experimental determination of the number of catalytically active sites on the surface of a single enzyme. It has been shown that $n_s = k_s n_s^*/v_s$. The proportionality factor, k_s, is given by classical theory in terms of the mass, m, of the solute molecule, the absolute temperature, T, and Boltzmann's constant, k, which is numerically 1.38044×10^{-16} erg/degree: $k_s = (kT/2\pi m)^{\frac{1}{2}}$. The probability per second, v_s, that an adsorbed molecule will escape is given by quantal theory in terms of the energy, E, of adsorption, and Planck's constant, h, which is numerically 6.62517×10^{-27} erg-second: $v_s = (kT/h)e^{-E/kT}$. Thus $n_0 = hn_s^*(2\pi mkT)^{-\frac{1}{2}} e^{-E/kT}$. The application of this formula to experimental results on the inversion of cane sugar by invertase shows that there are only a few active sites, probably eight, on the not inconsiderable surface of one enzyme.

Systems of greater complexity and interest are those in which the surface can simultaneously adsorb more than one kind of solute. Let the second solute be denoted by the subscript I. The fraction of the surface that, under equilibrium conditions, is covered by solute molecules of the first type is now $\theta_s = k_s n_s/[k_s n_s + v_s n_0 + k_I n_I(v_s/v_I)]$. This formula, as Langmuir showed, can explain a number of the idiosyncrasies of catalyzed reactions in solution. Inhibition of chemical reactions and the poisoning of catalysts by substances such as mercuric chloride are readily understood as a preferential adsorption of these compounds and a consequent exclusion of the reactants from the active centres. Similarly, many reactions proceed at rates that are inversely proportional to the concentration of products. These rates were discovered by Emil Schuetz in 1900 and include the digestion of proteins; they indicate that the greater the extent of reaction, the smaller the rate of the persisting reaction. Clearly, in such cases, the products are more firmly adsorbed than the reactants. There can be little doubt that the condition of satiety finds its mechanistic basis here; so also does the protective effect so often exerted by the products of hydrolysis on the enzyme responsible for their appearance.

The energy that an adsorbed molecule must acquire before it can become dislodged must, in general, depend on how many of its neighbouring sites are occupied. The experimental dependence of the heat of adsorption on the extent of adsorption was established experimentally by J. K. Roberts a few years before his untimely death during World War II. It ranks as the greatest single extension of Langmuir's theory and is proving to be one of the most fruitful fields for the investigation of surface catalysis. The discovery has had far-reaching applications in theoretical physics, which, in attempting to derive statistical laws for condensed systems, had previously been at a loss to know how to make allowance for the dependence of the molecular energy on the probability of occupation of neighbouring sites.

2. Diffusion. — The sugar at the bottom of a cup of tea soon dissolves into a sirup, but, if the tea were not stirred, considerably more time would be required for the sugar to distribute itself throughout the whole volume of the beverage. The process whereby a quiescent solute at a high concentration moves isothermally to a region of low concentration is known as diffusion. It is analogous to thermal conduction and viscous flow, and differs from them only in that matter is transported in diffusion, whereas energy and momentum, respectively, are transported in the others. The exact mathematical theory of all three phenomena is difficult, but new laws of great beauty and simplicity were, nevertheless, discovered by Einstein during the first decade of the 20th century and have had much to do with elucidating the nature of diffusion. They have been applied to determine the Avogadro number; *i.e.*, the number of molecules in one gram-molecule, to estimate the size of colloid particles, to evaluate the time taken by a given molecule in the gas phase or in solution to reach the walls of its container and to develop the modem theory of liquids.

The number, dN, of molecules transported in a time interval, dt, across an area, O, is, according to Fick's law, proportional to both dt and O, and to the concentration gradient, dn/dx, at the plane crossed: $dN = -DO(dn/dx)dt$. The proportionality factor. D, is termed the coefficient of diffusion. Molecules are transported in the direction of increasing x only when the concentration gradient in that direction is negative. By subtracting from dN_1, the number of molecules crossing a given plane, the number dN_2 crossing a neighbouring and parallel plane at a distance. dx, from it, the net transport is obtained. Since dN/Odx is the increase in concentration between the planes, it may be denoted by dn, so that $dn/dt = D(d^2n/dx^2)$, which is a more general expression for the coefficient, D, of diffusion. When molecules at a concentration, n, move with an average velocity, v, the number that in one second cross unit area of a plane at right angles to the direction of motion is nv. The rate of transport of molecules across an area O cm.^{2} is thus $dN/dt = Onv$. Comparison with Fick's law indicates that the coefficient of diffusion is $D = -nv/(dn/dx)$. According to van't Hoff's laws, the osmotic pressure, π, of a solution containing n molecules per cubic centimetre is $a = kTn$. Any isothermal change in the osmotic pressure must therefore be the result of a change in the concentration, so that $d\pi = kTdn$. The additional force exerted in the direction of increasing x on an area, O, caused by a difference in concentration is thus $-Od\pi = -OkTdn$. The number of molecules exerting the force is the number contained in the volume element, Odx, which is $nOdx$. Hence the force exerted by each molecule is, on an average, $X = -(kT/n)(dn/dx)$. The uniform velocity, v, is the ratio of this force to the resistance factor, s. Thus $v = X/s$. Sir George G. Stokes's expression for the resistance factor in the case of a spherical molecule of radius, r, moving in a medium of viscosity, η, is $6\pi\eta r$. Hence $vn/(dn/dx) = -kT/6\pi\eta r$. According to the previous equation, the expression on the left side is simply the coefficient of diffusion with the sign reversed. It follows that $D = kT/6\pi\eta r$, which is Einstein's equation. The coefficients of diffusion and viscosity are not difficult to measure at a constant temperature, T, and the radii of particles diffusing in solution thus become directly measurable.

Diffusion has hitherto been regarded as a property of molecules in systems of uneven concentration and as the mechanism whereby uniformity of concentration is established. The process, however, must persist, though without a net transfer of matter, even in systems of uniform molecular concentration. The laws of diffusion can be applied, for example, to determine the fate of an arbitrarily selected group of molecules from one part of an equilibrated system to another. By solving the differential form of Fick's equation in the case of linear motion, it can readily be shown that the

uniform velocity at the distance x is $v = D/x$. But $v = dx/dt$; hence $dx/dt = D/x$, which gives on integration: $x^2/2 = Dt +$ a constant. The system of reference chosen for the selected migrating molecules was that corresponding to $x = 0$ when $t = 0$, so that the square of the net displacement suffered by the selected molecules in time t, and measured along the x axis, is $x^2 = 2Dt$, which is the second of Einstein's diffusion laws. This law was verified by Jean Perrin in a series of experiments in which he used colloidal particles that were made visible in the ultramicroscope and were followed at time intervals of a few seconds. It is to be noted that, because the motion is a random one, the average distance traversed (or, more precisely, the square root of the average of the square of the distance) is proportional, not to the time, but to the square root of the time.

Einstein's treatment of diffusion did much to stimulate work in the physical chemistry of solutions. In particular, attempts have been made to extend the treatment to the movement of molecules under the influences of forces other than the thermal and viscous forces to which the early work was restricted. Only partial success has been achieved and that has been recorded in cases where the additional force is of a simple and well-known form. There is, however, no reason why the method should not ultimately prove helpful in the recognition of the type of force actually at work.

Perrin's experimental verification of Einstein's second law of diffusion afforded one of the most accurate estimates of the Avogadro number. It is 6.0248×10^{23} molecules per gram-mole. This fundamentally important constant has also been measured. with confirmatory results, in many other ways. It enables the physical chemists to compute, in all systems of interest, the actual number of molecules present. One drop of water, weighing 5 milligrams, is thus found to contain 167.2 million million million molecules.

3. Coagulation.—Colloid particles may be prepared, either in the gaseous phase or in solution, by a variety of methods. Aerosols, for example, may be made by mixing the vapour of the substance to be dispersed with a blast of air at a lower temperature, or by suddenly bursting a sample of liquid at great pressure into air at ordinary pressure. Liquid sols may be made by slow chemical reaction in dilute solution or, in the case of metals, by G. Bredig's method of sparking between electrodes immersed in the solvent. The chief characteristic of the dispersed phase in either system is its instability. The dispersed particles, when initially generated, are relatively small, but, with the passage of time, they become coarser, until they are large enough to come under the influence of gravity. The process of coarsening is termed coagulation, and it has been extensively studied. Experiment shows that the instantaneous rate at which the number of particles diminishes is proportional to the square of the concentration, n, of particles present at that instant. Therefore $-dn/dt = k_2n^2$, where k_2 is the coefficient of coagulation. On integrating—and noting that the initial condition of $t = 0$ corresponds to the initial concentration of $n = n_0$—we have $k_2 = (1/t) \times (1/n - 1/n_0)$. If we denote by $t_{\frac{1}{2}}$ the time required for the number of particles to be reduced to one-half of their original number, then clearly $k_2 = 1/t_{\frac{1}{2}}n_0$. These formulas are characteristic of bimolecular processes. The latter simply states that the product of the half life and the initial concentration for such processes is a constant, and that it is equal to the reciprocal of the bimolecular velocity coefficient. The formulas have been abundantly verified for the process of coagulation in solution and in the gaseous phase. When the latter equation is rearranged in logarithmic form, it becomes $\log_{10}t_{\frac{1}{2}} = -\log_{10}k_2 - \log_{10}n_0$. A plot of the logarithm of the half life against the logarithm of the initial concentration should thus be a linear one, with a gradient of -1, and it should intercept the abscissa at a concentration numerically equal to the reciprocal of the bimolecular velocity coefficient. These generalities are illustrated in fig. 1, which has been drawn from P. Tuorila's data on the rate of coagulation of colloidal gold in water at 20" C. It will be noted that the initial concentration has been varied by a factor of more than 10,000, and that k_2 becomes 6.8 X 10^{-12} ml./particle-second, which has a constant value over the whole range of concentrations. There can be no doubt that the coagulation of sols in aqueous solution takes place, as R. Zsigmondy first showed, as a result of binary encounters.

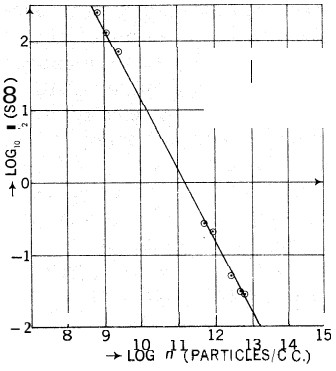


FIG. 1.—THE BIMOLECULARITY OF THE COAGULATION OF COLLOIDAL GOLD

Inquiry is next made, following M. von Smoluchowski, into the theoretical interpretation of the coefficient, k_2, and for this purpose the frequency of binary collisions must be determined. The number of molecules of type A that, in one second, cross a spherical surface of radius, r, surrounding a molecule of type B is the product of the concentration of the A molecules by their velocity and by the spherical area. It has been shown that the velocity is D/r, and, since the area is $4\pi r^2$, the number crossing per second is $4\pi Drn_A$. This equals the number of collisions, when r becomes the sum of the radii $(r_A + r_B)$ of the colliding partners. Hence ${}_1Z_A = 4\pi D(r_A + r_B)n_A$. The total number, ${}_AZ_B$, of collisions in unit volume is n_B times as great. Viewing the problem from the complementary angle of a stationary A molecule surrounded by approaching B molecules, and taking the mean, we obtain, for the number of binary collisions in unit volume and in unit time: ${}_AZ_B = 2\pi(D_A + D_B)(r_A + r_B)n_An_B$. If use is made of Einstein's first diffusion formula, this expression may be rewritten in terms of the viscosity, thus obtaining ${}_AZ_B = (kT/3\eta)(r_A + r_B)^2\ n_An_B/r_Ar_B$, which, for particles of equal radii, reduces to $(4kT/3\eta)n^2$. Now if a collision between two particles is a sufficient condition for their coalescence. the coagulation coefficient, k_2, should equal $4kT/3\eta$. Since the viscosity of water at 20° C. is 0.01005 gram/cm.-second, the theoretical estimate of k_2 is seen to be 5.33×10^{-12} ml. per particle-second, which is in good agreement with the experimental findings of Zsigmondy and of Tuorila. Moreover, the temperature dependence of the bimolecular velocity constant is correctly reflected by the ratio T/η. Smoluchowski's theory thus provides a fairly complete account of the kinetics of coagulation in solution and establishes the fact that the rate of this process is simply the rate at which particles collide with one another. Points of refinement deal with the uneven distribution of particle size and are relatively unimportant. There is also the possibility of preferential dissolution from the surface of the smaller particles.

Air at 20° C. is about 55 times less viscous than water at the same temperature. If, therefore, colloidal particles in air coagulate according to the same mechanism as colloidal particles in solution. the coagulation coefficient should be greater by about this factor, and should therefore be about 3×10^{-10} ml. per particle-second. Smokes made from a variety of substances, such as magnesium oxide, cadmium oxide, long-chain fatty acids and resinous materials, were examined by R. Whytlaw-Gray and H. S. Patterson. who found that k_2, though not exactly 3×10^{-10}, seldom varies beyond the limits of 5 and 8 in the same units. Vaporization from the particulate surface and the possible inadequacy of Stokes's expression for the frictional resistance factor are among the explanations offered for the slight discrepancy. Apart from points of detail, however, Smoluchowski's theory is as applicable to aerosols as to liquid sols. The point is an important one, as the work in the two phases has been carried out by different investigators in different countries and without liaison or much knowledge of one another's activities.

It is, perhaps, one of the most attractive features of 20th-century physical chemistry that theories, like that of Smoluchowski, sometimes emerge that, on being extensively applied, bring coherence to sets of phenomena that have been traditionally regarded as unrelated.

4. The Quenching of Resonance Radiation.— A substance that, while absorbing radiation of a given wave length, simultaneously emits radiation of a longer wave length, is said to flouresce. Aqueous solutions of chlorophyll, fluorescein, uranine and quinine

bisulfate are familiar examples. The phenomenon of fluorescence was interpreted at the end of the 19th century in terms of ionization; not until the advent of the quantum theory was the correct interpretation provided by O. Stern and M. Volmer and by O. Klein and S. Rosseland, who postulated the theory that electronically excited molecules or ions could loose their electronic energy either by spontaneous emission of radiation, as envisaged by Einstein in his theory of the distribution of thermal radiation. or in radiationless transfers of energy during collision. The theory was amply verified for the quenching of resonance radiation of thallium, mercury, sodium and cadmium atoms in the gas phase by Guenther Cario and J. Franck, and for the quenching of the fluorescence of numerous solutes in aqueous solution by S. J. Wawilow and by R. H. Mueller, E. R. Jette and W. West. Perrin, E. Gaviola and others employed the theory to determine the average lifetime of electronically excited structures. The theory can best be formulated in terms of a general procedure devised by J. A. Christiansen and H. A. Mramers and generally referred to as the stationary state procedure.

It is assumed that the electronically excited molecules are produced at a rate that is proportional to the concentration of normal molecules, say, n_A per ml. The rate of production may then be given as $k_3 n_A$, where the proportionality constant, k_3, depends in magnitude on the nature and intensity of the exciting radiation and on the dimensions and design of the reaction vessel. A threefold fate awaits these excited structures. They may, in the first place, emit radiation spontaneously, at a rate that is proportional to the concentration, a, of the excited structures. Let this rate of emission be denoted by $k_1 a$, where k_1 is the decay constant. or the reciprocal of the mean life. They may, in the second place, be robbed of energy in collisions with normal molecules of their own kind: this rate is a bimolecular one and may be denoted by $k_4 n_A a$. Finally, the excited molecules, atoms or ions may loose energy by transfer during collisions with molecules of another kind, nhich, let it be supposed, are present at a concentration n_B molecules per ml.: this rate again is a bimolecular one and may be expressed as $k_2 n_A a$. When a stationary concentration of excited molecules has been reached, the rate of production by absorption of light equals the sum of the three rates of destruction. We can thus solve for a, the concentration of excited molecules. But the rate of emission is known to be $k_1 a$. After a is eliminated from these two expressions, the rate. I, of emission becomes $k_1 k_3 n_A/(k, + k_2 n_B + k_4 n_A)$. Maximum emission, I_o, coincides with absence of the quenching molecules and is clearly $k_1 k_3 n_A/(k_1 + k_4 n_A)$. The ratio of the intensity of fluorescence in the absence of a quenching material to that in the presence of a quencher is $I_o/I = 1 + \frac{(k_2)}{(k_1 + k_4 n_A)} n_B$. If self-quenching is insignificant, the term $k_4 n_A$ can be ignored; the ratio I_o/I is then a linear function of the concentration of quenching molecules, and the gradient $d(I_o I)/dn_B$ is the ratio of two velocity coefficients, k_2/k_1. The decay constant, k_1, is known from other sources. and the velocity coefficient that governs the bimolecular process whereby excited molecules are deprived of their energy can thus be determined. When the magnitude of the velocity coefficient is compared with the number of collisions, as given by the formula in the section on coagulation. varying results are obtained. according to the quenching molecule. Collisions between electronically excited quinine ion and normal iodide ion in water almost invariably lead to a radiationless transfer of energy. Collisions of the same organic ions with other inorganic quenchers are never quite so efficient. Inorganic ions, in fact, range themselves in an order of quenching efficiency that is the same as the order of electronic polarizability, coagulation power and lyophilic activity. The constant k_2 for gaseous processes. such as the damping of resonance radiation of sodium atoms by nitrogen molecules, is usually greater than the number of collisions occurring per milliliter per second. This result has generally been interpreted as indicating that the electronically excited atom has a larger radius than the normal atom.

Perhaps the chief theoretical interest attaching to work on the quenching of resonance radiation in gases and of fluorescence in solution is that it brings to the fore the mechanism according to which, during collisions, energy of one kind is converted into energy of another kind. The present examples are confined to the conversion of electronic energy into some other form; *e.g.*, into kinetic energy, but the problem posed is a much more general one. When, for example, an atom of argon collides with a molecule of nitrogen, does the kinetic energy of the atom become exchanged for the kinetic energy of the molecule? Or does the atom during collision transmit its energy into vibrational energy of the molecule? In principle, these are questions that the quantum theory is able to answer but, in practice, little has yet been done in deriving the mathematical solution. A difficulty in the way is that complete information is required of the forces at work, and this is not always available. Assumptions as to the form of forces acting at short distances were made, for example, by C. Zener, who consequently arrived at a partial solution of the problem of conversion of energy from the kinetic to the vibrational kind. Arnold Eucken and his collaborators pursued the same problem experimentally, using acoustical methods. The limit of accumulation of vibrational energy in a diatomic molecule corresponds to its dissociation into atoms, a process that is known to happen in certain cases of resonance quenching. Moreover. the most efficient quenchers are diatomic molecules whose energy of dissociation lies near to the quantum of energy emitted by the electronically excited atom. The theory of energy transfer during collisions was, in the early 1960s, in its infancy, and many more experimental guides such as those enumerated here will probably have to be discovered before any considerable growth can ensue.

5. Spectroscopy. — Studies made after 1930 of the radiation absorbed and emitted by chemical compounds in the gaseous and dissolved states of matter have given the physical chemist a more penetrating insight into the structure of molecules than would have been thought possible at the beginning of the 20th century. The key to the interpretation of the multitudinous spectra exhibited was provided by Rutherford and Niels Bohr in their treatment of the spectrum of the hydrogen atom. According to their theory, the hydrogen atom can exist only in definite energy states; all conceivable energy states lying between these so-called "quantized" states are excluded from the realm of possibility. The energy levels are related to one another in the ratio of the inverse square of the integral ordinal numbers. To adopt an analogy effectively used by Bertrand Russell. it is as if the citizens of some fictitious town were allowed to possess curious sums of money, such as £100, £25 and £11 2s. 23 d., but not sums intermediate betneen these. All transactions would then be in terms of equally curious sums, such as £75, £13 17s. 9⅓d., but not in intervening quantities. Analysis of the spectra of molecules shows that molecular electronic levels resemble atomic electronic levels. Vibrational energies in molecules are. however, almost directly proportional to integral ordinal numbers, and rotational energies are approximately proportional to the squares of integral numbers. If the translational energy is excluded, the total energy of molecules may be considered as made up of three components, *viz.*, the electronic energy, E_e, the vibrational energy, E_v, and the rotational energy, E_r. Then $E = E_e + E, + E_r$. The difference between two neighbouring electronic energy levels in molecules is usually commensurable with the difference in the electronic levels in atoms. For every electronic energy level there exists a number of vibrational levels, which lie relatively near to one another. Associated. in turn, with each vibrational energy level are many rotational levels, which, generally, lie still nearer together. The rotational energy, E_r, of a molecule in any given state depends not only on the rotational quantum number, J, but also on the vibrational quantum number, v, as well as on the electronic quantum number necessary to define completely a given molecular state. The vibrational level is also to some extent dependent on E_e, but the latter is independent of either J or v. The transition of a molecule from a state with energy E to one with a higher energy, E^1, is accompanied by the absorption of a quantum of radiation hv, where h is Planck's constant and v is the frequency of the radiation absorbed. The frequency $v = (E' - E)h =$

$$\frac{E'_e + E'_v + E'_r}{h} - \frac{E_e + E_v + E_r}{h} = \frac{E'_e - E_e}{h} + \frac{E'_v - E_v}{h} + \frac{E'_r - E_r}{h} = \nu_e + \nu_v + \nu_r.$$

When both ν_e and v, are zero, all the absorption lines in the spectrum are the result of transitions between two states of the molecule with fixed electronic and vibrational quantum numbers; the lines of absorption are said to constitute a pure rotation band, and, since they occur between energy levels that lie very close together, the frequencies of the absorbed radiation are low, and therefore the wave lengths of the absorption lines are large. They are found in the infrared region of the spectrum. When only $\nu_e = 0$, the lines may be caused by transitions between molecular states differing in both their vibrational and rotational quantum numbers; the lines constitute vibration-rotation bands and often appear in the visible region of the spectrum. When v,, ν_v and ν_r all have positive values, the lines of absorption or emission correspond to transitions between molecules that have different electronic, vibrational and rotational energies. The whole band system may then extend right across from the far infrared to the far ultraviolet regions. Because of the inequality $\nu_e > \nu_v > \nu_r$, it follows that the general position of a nonelectronic band is governed by the vibrational quantum number, while the structure of the various bands is determined by the rotational quantum numbers.

Special apparatuses and techniques pertain to the various spectra, and, although many physical chemists have devoted their time to the investigation of molecular spectra, the subject is so vast and the experimental intricacies attached to the various spectral regions so specific, that few investigators, if any, can claim to be directly acquainted with more than one technique. Experimentally, the investigators are grouped as infrared, visible region and ultraviolet spectroscopists, and, as will be shown in the next section, as Raman spectroscopists. Details of the investigations will not be discussed here. It is. however, necessary to outline the theoretical sections of the quantum theory that have been advanced by spectroscopic knowledge and to indicate briefly what information of value to the physical chemist has emerged in very simple cases.

According to the quantum theory, the rotational energy of a diatomic molecule, with a moment of inertia, I, is E, = J(J + 1) $\times \frac{h^2}{8\pi^2 I}$ where $J = 0, 1, 2, 3 \ldots$. The difference in energy between two neighbouring states is thus J(J + 1)(h^2/4n^{2}1). The greater the rotational quantum number, the farther apart are the energies of any two neighbouring states. The emission frequencies that form given states to those immediately below them are, by the Bohr frequency law, (J + 1)$(h/4\pi^2 I)$. Transitions between systems performing simple harmonic motions, of which free rotation is an example, can take place only with unit change in the quantum number. The frequencies of the radiation absorbed or emitted by diatomic molecules in the infrared region of the spectrum should therefore be $\frac{h}{4n^2 1}$, $2\frac{h}{4\pi^2 I}$, $3\frac{h}{4\pi^2 I}$, etc. Except for a small correction, this conclusion has been verified in the case of the hydrogen halides. Karl Czerny found that the pure rotational frequencies (in reciprocal seconds) of hydrogen chloride and hydrogen bromide are, respectively, $6.034 \times 10^{11} \times M$ and $5.002 \times 10^{11} \times M$, where M is 1, 2, 3, 4, ... Now the moment of inertia is the product of the reduced mass of the rotator and the square of the distance apart of the nuclei. In this way it is possible to determine accurately the internuclear distances in simple molecules. The results for hydrogen fluoride, hydrogen chloride, hydrogen bromide and hydrogen iodide are, in angstrom units, 0.923, 1.281, 1.421 and 1.617 respectively.

A more detailed analysis takes into account the fact that ordinary hydrogen chloride, for example, is a mixture of two kinds of molecules, one of which contains the chlorine atom of atomic weight 35, and the other the chlorine atom of atomic weight 37. The internuclear distance is found to be the same for the two molecules.

If the nuclei in a diatomic molecule were to vibrate harmonically with a frequency v, the total vibrational energy of the molecule characterized by a quantum number, v, would be $E_v = (v + \frac{1}{2})h\nu$, and. by the Bohr frequency relationship, the frequency of the radiation absorbed or emitted would be $\nu_v = v$. But, since transitions between harmonically vibrating systems must coincide with unit changes in the quantum number, there should be only one absorption or emission line, and its frequency should be identical with the vibration frequency of the molecule. H. Deslandres showed that the vibrational energy levels are more satisfactorily reproduced by the equation, $E_v = (v + \frac{1}{2})h\nu - x(v + \frac{1}{2})^2 h\nu$, in which the empirical factor, x, though numerically small, is never zero. It can be shown to be approximately equal to $h\nu/4D$, where D is the energy necessary to dissociate the molecule into atoms. The analysis of the vibrational spectra of simple molecules thus yields information on two important properties—the frequency of internuclear vibration, and the energy of dissociation. The vibration frequencies of the halogen molecules, in units of 10^{12} reciprocal seconds, are thus found to be 16.03 (Cl_2), 9.712 (Br_2) and 6.424 (I,). The dissociation energies of the alkali metal diatoms, expressed in units of kilocalories per gram-molecule, are, by the same method, found to be 23.7 (Li_2), 16.8 (Na_2) and 11.85 (K_2).

The absorption or emission lines in the electronic spectra of simple molecules can be represented semiempirically by equations of the Ritz-Rydberg form, which include terms inversely dependent on the square of an integral number. The constant term in the formula affords an analytical means of estimating the limit of absorption of electronic energy, and thus of the energy required to eject the least firmly bound electron. Ionization potentials of simple molecules and electron affinities of simple ions thus come within the reach of experiment. Both are of fundamental importance in the description of the electronic structure of molecules, a subject that, from the purely theoretical aspect, is fraught with complications.

From these elementary beginnings, modern physicochemical spectroscopy bifurcates. One branch seeks, with only qualified success, to extend to more complicated molecules the dynamic principles on which the spectra of diatomic molecules have been interpreted. The more complicated the molecule, the greater is the number of electrons and nuclei contained in it, and the more numerous, for that reason, are the ionization potentials and the internuclear frequencies. The other branch is directed to the applications of the spectra to the problems of chemical analysis and has progressed further. Spectroscopic methods are now familiar not only for detecting impurities in suspect samples but also for estimating the composition of mixtures that could not be analyzed by ordinary physicochemical methods. The preparation of vitamins from fish oils and the rectification of high-grade aviation fuels from petroleum are but two of the important industrial spheres in which spectroscopic analyses have proved to be supreme.

6. The Raman Effect.—In absorption spectra, atoms and molecules assimilate only those quanta of radiation to which they are constitutionally adapted. In Raman absorption, incident light of an arbitrary frequency is used. Moreover, the experimental technique is relatively simple. Raman instruments now take their place among the most useful tools of the physicochemical workshop.

It has been known since John Tyndall's time that a faint blue colour becomes visible from all directions when a beam of white light is passed through a pure transparent medium. Light of short wave length is more readily scattered than light of long wave length, as Rayleigh emphasized in his explanation of the blueness of the sky. When, instead of white light, a beam of monochromatic radiation is allowed to pass through a homogeneous specimen of matter, light detected in a direction perpendicular to that of the incident beam is found to contain, in addition to the original radiation, light of other frequencies in numbers and intensities that depend on the scattering medium. The displaced lines, on analysis after resolution in the detecting spectroscope, are found to be much fainter than the line resulting from the original

light; exposures of several days are often necessary for the measurement of their position and intensity. The scattering of homogeneous radiation by chemical compounds is termed the Raman efiect (*q.v.*). It was experimentally established by Sir C. V. Raman and K. S. Krishnan in 1928, though its occurrence had been theoretically foreshadoued by A. Smekal in 1923. Since its discovery. tens of thousands of compounds have been investigated by its means, with important consequences.

Consider a head-on collision between a quantum, $h\nu_1$, of incident light and an atom or molecule of mass, m, which is supposed to be moving with velocity v_1 and to possess an internal energy. E_1, in addition to its kinetic energy, $\frac{1}{2}mv_1^2$. The energy of the incident photon is $h\nu_1$, and. according to an important quantal law discovered by Louis Broglie, its momentum is $h\nu_1/c$, where c is the velocity of light. The laws of the conservation of energy and momentum then give the relations $h\nu_1 + E_1 + \frac{1}{2}mv_1^2 = h\nu_2 + E_2 + \frac{1}{2}mv_2^2$ and $(h\nu_1/c) + mv_1 = (h\nu_2/c) + mv^2$. The maximum energy exchange clearly occurs when $v_1 = 0$ and $v_2 = 0$, *i.e.*, when the kinetic energy of the incident photon is completely converted into kinetic energy of the atom or molecule that was initially at rest. Only head-on collisions have been considered here, but it can be shown by classical dynamics that the conclusion is a true one in general. It follows that the maximum gain in kinetic energy is $\frac{1}{2}\ mv_2^2 = \frac{1}{2m}(mv_2)^2 = \frac{1}{2m}\left(\frac{h\nu_1}{c}\right)^2$. Under the most favourable conditions, therefore, the fraction of the incident energy, $h\nu_1$, that is convertible is $h\nu_1/2mc^2$. This is of a very small order of magnitude. When, for example, the 4358 Å line of the mercury spectrum is used as incident radiation, and carbon tetrachloride as the scattering medium, the fraction proves to be less than 10^{-11}. Any change in the frequency of the light caused by its passage through the medium must accordingly be the result of a change in the internal energy of the molecule. The first of Smekal's equations now becomes, effectively, $\nu_1 - \nu_2 = (E_2 - E_1)/h$. The difference between the frequencies of the incident and emergent radiation is termed the Raman frequency: it could with more logic be termed the Raman shift. We have, then, the relation $\nu_R = \nu_1 - \nu_2$ nhere ν, can be greater than, equal to or less than zero, according to whether the light is displaced toward the red end of the spectrum. is unaffected or is displaced toward the ultraviolet end of the spectrum. The responsible collisions are said to be, respectively. inelastic, elastic or superelastic. The extent of the displacement in the two directions is the same, so that lines in the scattered radiation appear in pairs, equidistantly draping the undisplaced line. The intensities of the two displaced lines are, however, very different, and, by measuring the way in which the ratio of the two intensities varies with respect to the temperature, it has been possible to ascribe a numerical value to Planck's constant, h.

Although the occurrence of the Raman effect becomes intelligible in terms of Smekal's hypothesis, its true origin is to be traced to the fact that, on account of the vibratory motion executed by the atoms within a molecule, the molecular polarizability varies with the phase of intramolecular motion. The interplay between the variable internal field thus set up and the harmonic field caused by the electrical component of light results in the generation of three electromagnetic vibrations, of frequencies ν,, $\nu_L + \nu_R$ and $\nu_L - \nu$, where ν_L is the frequency of the incident light and ν_R is the Raman frequency.

The commonest source of light used is that given by the mercury-vapour discharge tube, which emits strong radiation of wave lengths 5460.74, 4358.34 and 4046.56 angstrom units. These correspond to the reversal of the electronically excited mercury atom from the 2s state to the three 2p states. Two of these radiations may be cut out by suitable filters (such as quinine sulfate to eject the 4047 line), and as intense a beam of the monochromatic 4358 line as possible is used to irradiate the medium — generally in the pure liquid phase. The total light emitted is recorded on a photographic plate after the light is passed through a prism.

Experiment shows that the Raman shift, *i.e.*, the difference between the frequencies (or wave numbers) of the incident and scattered radiation, is (1) independent of the frequency of the incident light; and (2) to a first approximation is independent of the state of the scattering substance. By virtue of Smekal's equations, the quantum $h\nu_R$ equals the difference between two stationary energy levels of the scattering molecule. The Raman wave numbers, in reciprocal centimetres, of the chloride, bromide and iodide of hydrogen in the gaseous phase are, respectively, 2880, 2558 and 2233. Very often the evidence afforded by Raman spectroscopy is complementary to that given by infrared absorption spectroscopy, as lines missing in one may appear in the other. In the case of the three heteronuclear diatomic molecules mentioned here, the missing null lines in the infrared spectra of the gases have the wave numbers 2887, 2559 and 2240, respectively. Experiments show that the Raman wave numbers of these three compounds in the liquid state are about 80 less, and in the solid state about 130 less. than in the gaseous phase.

The Raman spectra of polyatomic molecules are naturally more complicated. An important guiding principle revealed by extensive experiments is that a given bond in a complicated molecule often gives rise to a Raman frequency that is but slightly affected by variations in the structure of the remaining portions of the molecule. All incompletely substituted aliphatic compounds, for example, exhibit a Raman shift in the neighbourhood of 2934 cm.$^{-1}$. A line near 1700 cm.$^{-1}$ is invariably found in the Raman spectra of carboxylic acids, aldehydes, ketones, acid chlorides and esters, and is naturally attributed to the presence of the carbonyl group. $=C=O$. The exact value found for the methyl, ethyl, propyl, butyl and amyl esters of formic acid is 1718 ± 3, and for the corresponding values for the esters of chloroformic and acetic acids the values are. respectively, 1775 ± 5 and 1738 1 2 reciprocal centimetres. These variations, though genuine, are not great enough to invalidate, as a guiding rule, the principle of a virtual independence of group frequencies. In this way, characteristic Raman shifts may be allotted to atom pairs in polyatomic molecules. such as the wave number 3050 for the —C—H pair in aromatic hydrocarbons and that of 2924 for the same pair in aliphatic hydrocarbons. The spectra of amines, alcohols and mercaptans similarly yield 3370 for the —N—H group. 3650 for the —0—H group and 2572 for the —S—H group.

Higher values of the Raman frequencies are obtained when the two atoms are joined by divalent bonds, and still higher values when the same two atoms are united by the tervalent bond. Thus, when the carbon-carbon, the carbon-nitrogen and the carbon-oxygen bonds are examined, each in the three valency states. the ratio of the Raman shifts are 1:1.63:2.10. Now it can readily be shown that the average restoring force of a linear harmonic oscillator is proportional to the vibration frequency raised to the power of 3/2, and is in fact equal to $\pi(h\mu\nu^3)^{\frac{1}{2}}$, nhere μ is the reduced mass. It is thus shown, as 4. Dadieu and F. W. G. Kohlrausch first pointed out, that, for univalent. divalent and tervalent bonds between the same pair of atoms, the average restoring forces stand in the ratio of 1 to 2.08 and 3.05. The classical theory of valency is thus quantitatively vindicated by the study of the Raman effect. It is, thus, a natural result to find that the average restoring force exerted in the carbon-nitrogen bond contained in oximes, ketimines and isocyanates is intermediate in strength between the average forces exerted, on the one hand, in amines, amides and pyrroles, and, on the other hand, in nitriles, ferrocyanides and cyanamides.

Only a few instances can be cited of the further application of the Raman technique to physicochemical problems. In the familiar conversion of the keto to the enol modification suffered by ketonic compounds, the characteristic ethylenic lines at 1632 and 1725 cm.$^{-1}$, which are present in the spectrum of ethyl acetoacetate (the ethyl ester of acetoacetic acid) are found to be absent from the spectrum of ethyl dimethyl acetoacetate, which shows, however, a doublet at 1707 and 1738, which is typical of the carbonpl group. In the polymerization of methyl methacrylate, the Raman line resulting from the C=C bond gradually vanishes and is almost completely absent from the final polymer formed, which indicates that the double bond is obliterated during the linking up. The great similarity between the Raman spectra of the tertiary butane molecule and the tetra methyl-ammonium

ion establishes a regular tetrahedral configuration for the latter. Finally, promising attempts have been made at computing, from a knowledge of the Raman frequencies, the specific heat of certain liquids and the latent heats of fusion of certain solids.

7. The **Kinetic** Theory of Gases.—With the exception of the atomic theory of matter, no theory has so powerfully influenced chemistry as the kinetic theory of gases. Its origin may be traced, through Gassendi in the 17th century, to the early speculations of the Greek philosophers. but its formulation as we now know it is due in equal measure to the German scientist Boltzmann and the British scientist hiaxwell; their classical theorems on the distribution of energy and velocity appeared in 1859. It is worthy of note that many of the ideas essential to the theory, though inaccurately formulated, were expressed in 1845 by J. J. Waterston, whose celebrated communication was not published until 1892. The original postulates are that the molecules constituting a gas are hard, perfectly elastic spheres, endowed with incessant translatory motion, and occupy a volume that is negligible compared with the total volume of the gas. The velocities, momenta, energies and directions of motion are not the same for all the molecules in any specimen of gas but are distributed among them according to the formal laws of probability.

Few of the postulates underlying the original theory are now regarded as valid, but enormous advances have been made by accepting them as working propositions, and by inventing additional postulates to explain divergences between theory and practice.

The kinetic theory of gases gives a logical meaning to the well-known laws of Robert Boyle. J. A. C. Charles and Avogadro. Thomas Graham (1829) showed that the velocity of effusion of gases at a constant temperature should be independent of the pressure and inversely proportional to the square root of the molecular weight. He verified this theoretical deduction by measuring the rates of effusion of nitrogen and ethylene, which were found to be nearly equal, and the relative rates of effusion of hydrogen and oxygen, which were found to be 3.815.1.000, as compared aith the anticipated value of 3.985. Atmolysis. the separation of gases by diffusion, was used by Sir William Ramsay and M. Travers to isolate helium from other gases. and by Rayleigh and Ramsay to effect a partial separation of argon from nitrogen with the aid of the celebrated churchwarden pipe technique. In this experiment, a mixture of gases of unequal molecular weight is made to flow through a tube that bifurcates into one tube of glass and one formed of two churchwarden pipes joined together. The lighter gas diffuses through the clay walls more readily than the heavier one, and partial separation can be effected. The formula (O_3) of ozone was first established as a result of diffusion experiments.

According to the kinetic theory, the specific heat of gases. and the ratio (γ) of the specific heat at constant pressure to that at constant volume, should be independent of the temperature and determined by the number of atoms in the molecule. The first of these conclusions has proved to be untrue, and the real effect, which is an increase in the specific heat with a rise in temperature, has been understood, in terms of the quantum theory, only comparatively recently. The second conclusion, though limited in validity, has been of direct value to chemistry in allowing an experimental determination of the number of atoms in molecules. Rayleigh and Ramsay (1894) found γ, from the velocity of sound in the gas, to be nearly 1.67 in the case of argon, and concluded that this molecule was therefore monatomic.

Ramsay (1879) gave the first kinetic interpretation of the Brownian movement as the motion of small particles resulting from molecular impacts with molecules of the surrounding medium. This interpretation led later (1905) to the kinetic theories of the effect by Einstein and by Smoluchowski (1906), and to the first reliable experimental value of the Avogadro number by Perrin (1909). The Brownian movement of smoke particles studied by E. N. da C. Andrade and R. C. Parker (1937) offers direct visual evidence of the effects of collisions by gas molecules on the movements of small particles of suspensoid.

The coefficients of viscosity, diffusion and thermal conduction are given by the kinetic theory in terms of the molecular diameters (P. G. Tait, 1886–92). The three methods afforded early values of molecular radii, which agree among themselves and with those obtained by numerous other methods, of which only two—both devised by Rayleigh—need be mentioned here. The first (1871) depends on the refraction of light by particles of molecular dimensions, and the second (1905) is based on the computed minimum thickness of an oil layer found necessary to stop the Brownian movement of camphor particles in the water-air interface. The value estimated by Rayleigh by the second method was 16×10^{-8} cm. His kinetic treatment of the effect forms the basis of the Langmuir-Adam-Rideal (Langmuir, N. K. Adam and E. K. Rideal) trough techniques for examining surface films.

The kinetic theory in its original form accounts only for the kinetic pressure exerted by a gas and ignores intermolecular cohesion. The second factor is necessary to explain the condensation of gases into liquids, a process that was investigated experimentally by T. Andrews (1862) in his work on critical phenomena and theoretically by James Thomson (1871) and van der Waals (1871) in their theories of the continuity of states. The existence of cohesive forces between molecules is manifested by the cooling that ordinarily occurs when a gas expands. By developing the porous plug experiment of J. P. Joule and James Thomson. both Sir James Dewar (1900) and M. W. Travers (1900) succeeded in liquefying hydrogen, which is one of the two gases that Michael Faraday was unable to liquefy by other means. It is the liquefaction of gases, and of helium in particular, that has enabled all the recent work to be done on physical and chemical properties of matter at low temperatures.

The classical work of Sir Joseph John Thomson on the conduction of electricity through gases followed the observation of Sir William Crookes (1881) that the viscosity of gases at low pressures is less than that predicted by the kinetic theory.

The fundamental ideas of the kinetic theory of gases have been extensively applied to systems other than the gaseous system. In particular, they have greatly influenced the development of the theories of solution. which stimulated the precise experimental work of E. G. J. Hartley and Lord Berkeley, and led to van't Hoff's hypothesis of osmosis.

The kinetic theory in its primitive form affords expressions for the number of collisions taking place in unit time between gas molecules and unit area of a surface and between gas molecules themselves in unit volume. The former of these expressions was compared by Rayleigh with the rate of reduction of solid silver oxide by gaseous ozone (1912), and the latter was compared by Trautz (1916) and Lewis (1918) with the rate of decomposition of gaseous hydrogen iodide. The collision hypothesis, supplemented by the fundamental conception of a random distribution of energy, has since dominated the field of chemical kinetics and surface catalysis.

Extensions of the kinetic theory of gases to cover the repulsive and attractive forces exerted between the molecules were made by A. W. Chapman (1915) and by Sir John Lennard-Jones (1924). The theory has also been extended to the kinetics of solutions (1933).

To the experimental chemist, the kinetic theory has given a picture of how molecules behave and has made it possible for him to construct in his imagination the types of molecular interactions that constitute chemical change. It has given him a lively and interesting method of approach to many of his problems, a method that is neither as formal as that of thermodynamics nor as difficult as that of statistical mechanics.

8. The Maxwell-Boltzmann Law.—Reference has already been made to the theorems of Maxwell and of Boltzmann on the distribution, respectively, of momenta and energies among gaseous molecules. Boltzmann proved that the fractional number of molecules retained in a system at constant volume and temperature that possess an energy, E, per molecule, is proportional to the term $e^{-E/kT}$, where e is the base of the natural logarithms, T the temperature on the Kelvin scale and k a constant that is independent of the system; k is now recognized universally as Boltzmann's constant. As E increases, the Boltzmann factor $e^{-E/kT}$ decreases. Hence, the number of molecules that are

energetically well-endowed is relatively small, while the number of molecules with lower energies is large. Energy among molecules is thus like money among men; the poor are numerous, the rich few. This law has proved to be one of the securest possessions of natural science and has survived the storms of quanta1 mechanics that overthrew so many of the stately edifices constructed in the placid days of classical mechanics. Salvador de Madariaga held that the derivation of the Maxwell-Boltzmann lam offered the best example of pure logical deduction evinced since the middle of the 19th century. Its derivation will not be discussed here. but some indication must be given of its far-reaching effects on the development of many physicochemical themes.

When a liquid is kept in a closed vessel, like wine in a bottle, the molecules in the closed system distribute themselves between the condensed and vaporous phases in such a way that (except at the critical temperature) the molecular concentration in the vapour is considerably less than that in the liquid. The explanation, according to the Maxwell-Boltzmann law, is that only those molecules of the liquid that possess an energy L can vaporize. L is the latent heat of vaporization and is usually large; hence the number of liquid molecules that have sufficient energy to detach themselves from their neighbours in the condensed state is relatively small.

A very similar state of affairs prevails in the case of electrons in metals. It is known that the atmosphere above the surface of a cold metal is electrically neutral. At high temperatures, honever, all metals emit a stream of electrons that constitutes the so-called "thermionic current" so extensively utilized in the construction of electronic tubes. O W Richardson discovered that the logarithm of the current is proportional to the reciprocal of the absolute temperature In other words, the current itself has a strength that is proportional to $e^{-W/kT}$, where W is positive. In terms of the Maxwell-Boltzmann law, W can be identified as the nork that must be expended to remove an electron from inside the metal It is known as the thermionic work term and was shonn hy Einstein to be equal to the quantum. $h\nu$, of light necessary at the threshold frequency to emit electrons in the photoelectric effect.

It is well known that high-altitude aviators must carry their own supply of oxygen with them, because the concentration of this vital gas at great heights is too attenuated to support life. The distribution of concentration with height is again governed by the Maxwell-Boltzmann law. The concentration, n_1, at a height H_1, is proportional to $e^{-mgH_1/kT}$, where m is the mass of one molecule and g the gravitational constant. At the same temperature but at another height, H_2, the concentration, n_2, is proportional to $e^{-mgH_2/kT}$. The ratio of the concentrations at two heights differing by H is thus $n_1/n_2 = e^{mgH/kT}$. The earth's atmosphere is not the most suitable medium for testing this equation because the molecules are invisible. and because of the overwhelming complications due to meteorological factors. In work with colloid particles suspended in water at a constant temperature, however, the numbers may be counted by visible means and the difference in height measured microscopically. This Perrin did in his researches that both verified the lam and afforded an experimental determination of the Boltzmann constant, k.

The Maxwell-Boltzmann law forms the basis of the modern theories of electrolytic solutions, which were first proposed by S. R Milner in *1913* and were improved by P. Debye ten years later. The electrolyte is regarded as dissociated completely or partially into ions, in a medium of uniform dielectric capacity. The random distribution of ions in solution differs from the random distribution of molecules in a gas, because of the strong Coulombic forces exerted between them. When the Boltzmann law is applied to a determination of the ionic concentration in the neighbourhood of any selected ion, the selected ion will be surrounded by a relatively high concentration of ions of the opposite sign and by a relatively low concentration of ions of the same sign as its onn This uneven distribution of electrical charges leads to the formation, around each ion, of a cloud of ions whose net charge is opposite that of the ion. The total electrostatic energy of ionic solutions is thus diminished and is less than the electrostatic energy of the same number of ions in an infinitely dilute solution. In extremely dilute solutions of electrolytes of low valency type, the Milner-Debye theory has been corroborated in various ways; for example, by measuring cryoscopically the activity coefficients of electrolytes. by determining the ionic mobility in electrical fields and by estimating the effect of dilution on the heat of dissolution. The assumption that the Maxwell-Boltzmann law applies to electrolytic solutions is one of its least debatable ones and is certainly less dubious than the law of the invariance of the dielectric capacity of the medium.

The intensity of a line in the Raman spectrum is proportional to the stationary concentration of excited molecules in that state; transition from that state causes the emission. If I, and I_r stand, respectively, for the intensities of the lines displaced toward the blue and red ends of the spectrum from the central position of the undisplaced line, then the following expression holds, according to the Boltzmann law for the ratio of the intensities: $R = I_b/I_r = e^{-Eq/kT}/e^{-Ep/kT}$. But, from the discussion of the Raman effect, it is known that $E_p - E_q = 2h\nu_R$; hence $R = e^{2h\nu_R/kT}$. As the temperature rises, the ratio approaches unity. By plotting $\log_{10}R$ against $1/T$, this relation was verified independently by P. Daure and by L. S. Ornstein and J. Rekveld. The gradient determined from experiment yields the value of 4.79×10^{-11} degree-seconds for h/k. If k is taken as 1.372×10^{-16} erg per degree, h thus becomes 6.56×10^{-27} erg-second; this result satisfactorily confirms the more accurate estimates based on the photoelectric effect and the spectrum of atomic hydrogen.

Finally, it was shown by J. J. Hood *(1878)* and by Arrhenius *(1889)* that the logarithm of the velocity coefficient of a chemical reaction is linearly related to the reciprocal of the absolute temperature. The velocity itself is thus proportional to $e^{-E/kT}$, where E is termed the energy of activation. This relationship is the foundation of chemical dynamics.

In these instances of the application of the Maxwell-Boltzmann law, care has been taken to emphasize the proportionality between, rather than the identity of, the fractional number of energized molecules and the factor $e^{-E/kT}$. The ratio of the number of active molecules to the total number is equal to the exponential term only when the energy concerned can be expressed as the sum of two quadratic terms. A generalized form of the law was derived by *A.* Berthoud *(1911)*.

9. Chemical Kinetics. — Instructions for the preparation of chemical compounds frequently contain such phrases as "heat substance 4 with substance B for two hours." The time element is important in the process; its inclusion aims at the most abundant yield of the desired commodity. The process of preparing chemical compounds is, of course, one of the principal activities of the chemist. Physical chemists have two guides to help them. One is thermodynamics, which can, in principle. tell them how far any reaction can go. given all the relevant thermal data; the other is chemical kinetics, which can, in most cases. tell them how fast the reactions can go. Chemical kinetics, since its inception by Wilhelmy in *1850,* has proved to be one of the most popular branches of physical chemistry, and one which has shown the most consistent and continuous growth. It introduces time as an essential variable in chemical systems. The laws of chemical kinetics, rigidly formulated. all contain time as a factor, and reduce, when the time is extended to infinity, to the equilibrium laws of chemical thermodynamics. The formal side of chemical kinetics deals nith the velocity of chemical change in all systems. In its development, however, a machinery has been created for handling a variety of problems outside its formal sphere and for solving problems that have proved too difficult for chemical thermodynamics or statistical physics. Adsorption, discussed in the first section of this article, provides a good example. Other problems that have been successfully approached by the method of chemical kinetics are the standard electrode process, overpotential, the conduction of electricity through gases, vaporization, enzyme structure. dissolution, the persistence of clouds and the disorderliness of simple binary systems in the condensed phases.

Clearly one condition that must be fulfilled before molecules

can react is that they should meet. If an encounter between two molecules is a sufficient condition for reaction, the rate of chemical change should be equal to the rate of collisions. Two physical changes have already been discussed from this point of view, and it has been shown that the rate at which colloid particles in the gas phase and in solution coagulate and the rate at which electronically excited molecules in both systems are deprived of their energy are equal to the rate at which the molecules meet. Binary collisions are thus a necessary but not always a sufficient condition for the occurrence of these physical changes. When, however, the rate of chemical processes is examined in the light of the collision hypothesis, a wide disparity is found. Experiment shows that only a very small fraction of the total number of collisions is fruitful. Trautz, in 1916, and Lewis independently in 1918, argued that, since only molecules possessing exceptional energies can undergo chemical change, the rate of reaction should be compared not with the total rate of collisions but with the rate of activating collisions, which, according to the Maxwell-Boltzmann law, is less by the factor $e^{-E/RT}$, where E is the energy of activation. Experiment shows that the energies of activation for the decomposition of ozone into oxygen, of hydrogen iodide into hydrogen and iodine and of nitrous oxide into nitrogen and oxygen are, respectively, 26,365, 47,275 and 61,550 cal. per gram-mole. The Boltzmann factors are thus extremely small. Nevertheless, when multiplied by the total collision rate, they yield products that are experimentally indistinguishable from the rates of chemical reaction. This conclusion forms the basis of the collision theory of chemical change.

An application of the same reasoning by Christiansen in 1924 to reactions in solution met with less success, in that a considerable discrepancy appeared between the observed rates and those computed on the basis of the collision theory. It was, therefore, maintained for some years that the theory, though apparently applicable to gases, was not, without drastic modifications, applicable to solutions. In 1932, however, it was revealed that hundreds of reactions in solution, some of which had been examined with great accuracy during the 19th century, fitted in perfectly with the predictions of the collision theory. Thousands more have since been discovered, and there now remains no doubt that the theory of activating collisions, sometimes in revised forms, is fundamentally sound. Among these numerous reactions are to be found the etherifications of alkyl halides by organic bases such as sodium methoxide, potassium phenoxide and alkali β-naphthoxides, the replacements of halogen and hydroxyl from aliphatic compounds by anions in various solvents, the union of ethyl bromide with ethyl sulfide in hydrolytic media, and the formation of the bicarbonate ion from carbon dioxide and the hydroxyl ion in aqueous solution.

Occasionally when two chemical compounds interact, only one of them suffers chemical change, while the other, which is termed a catalyst, emerges from the reaction unchanged. These catalytic reactions are essentially bimolecular, and their rates, with few exceptions, are also in agreement with the prediction of the collision theory. The catalytic mutarotation of the reducing sugars by hydrogen ions, the catalytic decomposition of ethylene iodide by iodine atoms, the catalytic mutarotation of beryllium benzoylcamphor by cresol, the catalytic conversion of the picryl ethers of benzophenone oximes by acetone and nitromethane are all processes whose rates are given by the expression: number of molecules reacting in unit volume in one second equals the number of collisions between catalyst and reactant in unit volume in one second multiplied by $e^{-E/RT}$.

If only those molecules that possess considerable energies in excess of the average can react, on what is this energy expended? The answer was first given by W. Heitler and F. London in 1927. Chemical change involves first the loosening and finally the breaking of a chemical bond and usually the simultaneous formation of a new bond. To break a bond requires energy; and this, duly compensated by energy liberated in the formation of another bond, constitutes the energy of activation. Heitler and London showed how the energy of activation could be calculated from first principles for very simple chemical changes, such as the following reaction between an atom, *A*, and a diatomic molecule, *BC*; $A + B - C \rightarrow A \cdot B + C$. The initial system corresponds to a free atom, *A*, at an infinite distance from the stable molecule, *BC*, the atoms in which are at their normal, or equilibrium, distance apart. This state of affairs may be described by saying that r_{AB} is infinite, and $r_{BC} = r^{\circ}_{BC}$. The final state, after the completion of reaction, corresponds to a free atom, *C*, at an infinite distance from the stable molecule, *AB*. This state of affairs may be summarized by saying that $r_{AB} = r^{\circ}_{AB}$, and that r_{BC} is infinite. Between these stages, the internuclear distances, r_{AB} and r_{BC}, must have had comparable magnitudes, and this very nearly corresponds to the activated state, as D. S. Villars (1930) independently concluded. The difference between the energy of the complex $A \ldots B \ldots C$ in the activated state and the energy of the initial system is the energy of activation. The solution of the dynamic problem is somewhat tortuous and demands an exact knowledge of the forces exerted between the various atoms. The results of calculations on the energy of activation of the reaction between the bromine atom and the hydrogen molecule ($Br + H - H \rightarrow Br - H + H$) are shown graphically in fig. 2. From the energy contours, which are given in kilocalories per gram-mole, it is seen that the easiest of an infinite number of passages from the initial atomic configuration (top left-hand corner) to the final atomic configuration (bottom right-hand corner) requires an ascent of 22,000 cal., and that the two internuclear distances at this pass height are equal to 1.43×10^{-8} cm. The former value is in agreement, though not directly comparable, with the experimental values obtained by Max Bodenstein and H. Luetkemeyer, and later by F. Bach, K. F. Bonhoeffer and E. A. Moelwyn-Hughes, using both ordinary hydrogen and its heavy isotope.

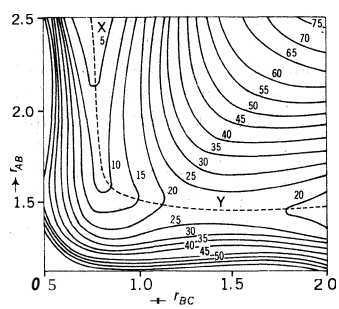

FIG. 2.— POTENTIALENERGY CURVES FOR THE SYSTEM BR . . . H . . . H

The first calculations of the energy of activation of triatomic reactions according to the Heitler-London method were made by Henry Eyring and Michael Polanyi on the ortho-para conversion of hydrogen, which, as Adalbert Farkas and Bonhoeffer have shown, proceeds by the same mechanism as that previously established for the hydrogen-bromine reaction. Attempts at computing the energies of activation of more complicated reactions have also been made.

If all chemical reactions conformed to the collision theory, chemical changes would proceed with wide ranges of velocities, from the fast reactions that require little energy to the slow reactions that require much, but the changes would, as a rule, be orderly, and would never get out of hand. It is well known that many chemical reactions run riot; they proceed with accelerative rates and lead to explosions. The explanation of the occurrence of thermal explosions and of numerous phenomena with which they are akin was given, principally by Bodenstein, R. Willstatter, Fritz Haber, Christiansen, Kramers and N. Semenoff, in terms of the chain theory of chemical change. The primary notion is one of "hot" molecules; *i.e.*, of chemically reactive molecules produced during the activation process and capable of retaining their energy until an opportunity affords of passing it on to fresh reactant molecules, which in turn become activated. One initial activation can thus lead to the conversion of many molecules. The average number so destroyed per unit activation is termed the chain length. This may amount to many thousands of molecules not only in gases but also in solution, where deactivations by solvent molecules, though possibly not entirely absent, are by no means as probable as they mere at one time thought to be. It can readily be shown that, if, in a system containing n molecules per ml., the decomposition occurs by the mechanism under discussion, the rate of reaction becomes $-\frac{dn}{dt} = \frac{k_1 n^2}{(k_4/k_3)n + (1-\alpha)}$, where k_1 governs the rate of formation of active reactants by collisions between normal molecules, k_4 governs the rate of de-

struction of active reactants in deactivating collisions with normal molecules, and k_3 is the unimolecular constant for the spontaneous decomposition of active reactants. The important term a takes account of the fact that not all of the collisions between normal molecules and active products that lead to deactivation are effective in regenerating active molecules of reactants. In all thermal, or "quiet" reactions, a is zero. Chain reactions are characterized by real values of a. In simple cases, the chain length is simply the reciprocal of $(1 - a)$, which may be very large when α approaches unity. Branching chains are characterized by values of a exceeding unity, in which case the denominator in the general rate equation may become zero, and the rate itself may become infinite. This is what is generally meant by an explosion.

The chain theory has been employed to interpret numerous phenomena in the kinetics of chemical changes in gaseous and liquid systems. It can successfully account for the apparently unimolecular behaviour of molecules decomposing in systems of high concentration, though the rate of production of active molecules itself is a bimolecular process, and is therefore dependent on the square of the concentration, and for the distinction between the mechanism of hydrolytic and oxidative enzymic reactions.

The extensions of chemical kinetics resulting from the quantum theory are concerned with the more exact determination of the energy of activation, and with the possibility (precluded according to the classical theory) of the transit of a molecule over a potential barrier while not possessing sufficient energy to surmount it. The latter phenomenon is known as the tunnel effect, and is relevant only for light molecules that penetrate barriers at low temperatures.

10. Intermolecular Energy. — When molecules come near enough to influence one another, at least two forces are brought into play: one of attraction, and one of repulsion. If molecules did not exert forces of attraction, they would not cohere, as they manifestly do in the liquid and crystalline state. Were there no forces of repulsion, the forces of attraction would be supreme, and nothing would prevent molecules from annihilating one another. Much as human conduct is determined by a conflict of loyalties, molecular behaviour is, to a large extent, determined by the balance struck betneen the forces that tend to pull molecules together and those that tend to push them apart. The detection of the kind of intermolecular force at work in particular systems has been an important new feature of the physical chemistry of the 20th century.

More is generally known about attractive than about repulsive forces. When, for example, two ions, of valencies z_A and z_B, are held at a distance, a, apart, there exists between them, in *vacuo* an energy that C. A. de Coulomb showed experimentally to be inversely proportional to their separation. In fact, the energy is $u = z_A z_B \epsilon^2/a$, where ϵ is the electronic charge (4.802×10^{-10} electrostatic units). The force, X, is given by the general equation $X = -\frac{du}{da}$, which, in the present example, becomes $z_A z_B \epsilon^2/a^2$. Thus, when both ions have charges of the same sign, their mutual energy and the force acting between them are positive, denoting repulsion. When the ions have charges of opposite signs, their mutual energy and the force acting between them are negative, indicating attraction. It is this Coulombic force that, as Rutherford and Bohr first showed, accounts for the tenacity with which electrons in atoms are held to the positively charged nuclei. In crystalline salts, the units are positive and negative ions, such as the sodium and chlorine ions in common salt; and here also. the binding force is almost entirely due to the Coulombic attraction between the ions. It is thus easy to understand why the lattice energy (*i.e.*, the energy required to transform the crystalline salt into gaseous ions) is four times as great for a bi-bivalent salt as it is for a uni-univalent salt of the same molar volume. The Coulombic energy of a pair of ions separated by a medium of dielectric constant, D, is less than that in *vacuo* at the same separation by the ratio D:1. The dielectric constant of water at ordinary temperatures is about 80; hence the force attracting cations to anions in aqueous solution is relatively small and can be effectively combated by the kinetic energy that results from their motion.

The energy of interaction of an ion of charge $z_A\epsilon$ and a dipole of moment μ_B that is inclined at an angle of 6 to the line joining their centres is given approximately by the equation $z_A\epsilon\mu_B \cos\theta/a^2$. The mutual energy may now be positive or negative even for a system containing the same ion, because cos θ can be positive or negative. It is this term that explains the comparative stability of inorganic ions in solvents of high dielectric constant, such as water. alcohol and nitromethane. In solution, each ion attracts the solvent molecules and forms a shell around itself, with each solvent molecule oriented in the position of minimum energy. The exact number of solvent molecules that forms the first sheath had not been established in the early 1960s, although the co-ordination number of many ions in crystals of hydrated salts was known. When chemical reaction takes place between an ion and a polar molecule. the approach of the ion to the molecule is influenced by the position and magnitude of the dipolar groups that the latter contains. The interaction of the ion with all the dipoles constitutes an important component of the energy of activation and thus modifies the velocity of reaction. In the light of these considerations. it is now, for the first time, becoming clear why the substitution of a given group in the benzene ring may hasten or retard chemical reaction according to the position, relative to the point of attack, that it occupies.

When two dipoles interact, four angles, in addition to the distance apart of their centres, are required in order to express their mutual energy, which now varies inversely as the third power of the distance, as may easily be derived by applying Coulomb's law to the interaction due to each pole, or by carrying out experiments with bar magnets, which are the macroscopic and magnetic analogues of the microscopic and electric moments in molecules. The interaction of permanent dipoles probably explains most of the anomalous properties of binary liquid mixtures, such as those of acetone and chloroform.

The next force of physicochemical interest is that which comes into play when an ion approaches a nonpolar molecule. The field generated by the ion induces an electric moment in the molecule, and the net interaction energy that results is readily shown to be directly proportional to the square of the ionic charge and to the polarizability of the molecule, and inversely proportional to the fourth power of their distances apart. An example is afforded by the attraction of the highly polarizable iodine molecule for the iodide ion; iodine is very sparingly soluble in water but is readily soluble in aqueous iodides.

Many forces vary inversely as the seventh pomer of the intermolecular distance. The most important is the so-called "dispersion force," which London (1930) showed to be related to the frequency of vibration of the electrons in the molecules. This is the force that accounts for the cohesion of nonpolar molecules in the condensed state. In the case of the inert elements, and of symmetrical molecules such as chlorine, carbon tetrachloride and benzene, the dispersion force is the only attractive one; it also comes into play even in polar cases, where it is often dominant. Deviations of the behaviour of real gases from that of ideal gases are in large measure caused by the presence of London forces.

As stated above, rather less is known of the repulsion forces. These may, it is thought, be exponentially related to the intermolecular distance, or they map vary inversely with respect to the distance raised to some pomer that must be higher than the power governing the attractive forces. If the latter supposition is provisionally adopted, the total interaction energy of a molecular pair, at a distance a apart, may be expressed as the sum of the repulsive and the attractive energies: $u = Aa^{-n} - Ba^{-m}$, where n is greater than m. This relationship was applied by Gustav Mie in 1903 to a variety of chemical and physical problems. He showed how this equation, which represents the interaction energy of an isolated pair of molecules, can be extended to the evaluation of the interaction energy of a large number, mutually influencing one another, and derived, in terms of the constants, A, B, and the integers, m, n, illuminating expressions for the isotherms, the compressibilities and the expansivities of condensed systems. Mie's equation

was later applied by Max Born to the study of solids and by Lennard-Jones to the study of gases.

Other types of forces that are only partially electrostatic in origin are exerted between the atoms in a molecule and give rise to the variety of chemical bonds. It has already been shown that the average interatomic force between two atoms varies linearly with respect to their valencies. How the interatomic forces vary with the distance apart of the nuclei is a problem that is, as yet, only dimly understood. Progress is being made on empirical lines. There is, however, no obscurity about certain conditions that experiment imposes on the general nature of the force laws. It is certain, for example, that the force tending to restore the atoms to their equilibrium positions after they have been slightly displaced therefrom must increase'in proportion to the displacement, and thus obey Hooke's law. Only in terms of such an elastic force can the essential harmonicity of the interatomic vibrations, which is proved alike by infrared and Raman spectroscopy, be understood. If, however, only elastic forces were at work, the more the atoms were drawn apart the stronger would be the forces of restitution, and the less would be the likelihood of bond cleavage. Experiment shows that, with increasing separation, the atoms come under the influence of a very ueak force, uhich eventually vanishes as the interatomic distance reaches infinity. Finally, the interatomic forces must be consistent with the thermal and spectroscopic evidence on the energy of dissociation, as well as on the known values of the equilibrium separation and the fundamental vibration frequencies. These guides suffice to indicate the general way in which the force varies with the distance, and several empirical expressions embodying these essential features have been advanced. The most widely used is one given by Philip M. Morse in 1929.

Rather special assumptions have to be made concerning the forces responsible for the properties of metals—their hardness, stability, lustre and high powers of conducting both heat and electricity. The essential features of the elementary model of metals are that the framework is provided by the nuclei, and that the whole of the volume of the metal is accessible to the valency electrons. High electrical conductivity is thus intelligible. The attractive energy is provided by the Coulomb forces between the cations and the mobile electrons, and the repulsive energy is provided by the kinetic energy of the electrons. The latter, according to the quantum theory, is much greater than would be expected on classical arguments. and was evaluated by Enrico Fermi. The energy required to expel an electron from a metal, which can be measured photoelectrically or thermionically, thus equals in magnitude the difference between the Fermi and Coulomb energies. Such a simple model of metals. is. however, deficient in many ways. It cannot, for example. give an explanation of the elastic constants, such as the compressibility and the fundamental vibration frequency. that is consistent with the specific heat. Other forces must come into play in metallic cohesion, and research on their nature was being actively carried out in the early 1960s by many investigators.

11. The Liquid State.—The liquid state has consistently been the most neglected of the various states of matter. Attention has been paid almost exclusively to the gaseous and crystalline states. Classical kinetic theory has been progressively applied for 100 years to the study of the gaseous state. and the quantum theory has been vigorously used for more than 50 years in the study of solids. It is only since the 1920s that either theory has been applied to liquids, except by a very small number of investigators, of whom Mie is the foremost. Two reasons may be advanced to explain the neglect. In the first place, the liquid state is the intermediate state of matter—the state that matter naturally assumes in passing from the solid to the vapour—and its properties are not so pronounced or sharp-edged as those of the extremes that flank it. In the second place, the classical theory appeared adequate to the knowledge of gases, and the quantum theory to the knowledge of solids Neither suffices to explain what is known of liquids. The elucidation of their nature requires the full resources of both classical and quantal theories.

Solids are characterized by low potential energies that result from powerful cohesive forces and tie the molecules together, usually in an orderly pattern. and prohibit motion except an oscillation of small amplitude about the mean position of equilibrium. Gases are characterized by high potential energies, resulting from weak cohesive forces, that allow free motion and a completely random molecular distribution. A liquid, with its intermediate potential energies and moderate cohesive forces, has neither the orderliness of a crystal nor the randomness of a gas. Its molecules, though not constrained to vibrate about fixed positions in space, are, at the same time, not capable of unrestricted motion throughout the total volume.

The mean free path of a molecule in a crystal is less than, and of a molecule in a gas is greater than, the linear extension of the molecule. In a liquid, the mean free path is, under ordinary conditions, commensurate with the molecular dimensions. W. T. Kelvin once used a telling analogy of molecules with ships. In gases, the molecules are like ships on the high seas. which only seldom come within reach of one another; in solids, the molecules are like ships under construction in the dry docks of the building yard; in liquids, the molecules are like ships on a navigable river or in a busy harbour.

Largely because of the prominence given in classical physical chemistry to the idea of a continuity of state, the liquid state has usually been approached from the vapour end; textbooks almost invariably introduce it as the highly compressed fluid. There has been a tendency during recent years to approach the liquid state from the solid end, and, in fact, the results of experiments on the scattering of X-rays and the diffraction of electrons by liquids have indicated a striking similarity between the molecular arrangements in solids and liquids at low temperatures. There is at present some danger of overemphasizing the crystallike features of liquids and of regarding them as slightly released solids. How the right balance is to be struck is decided by temperature within the relatively narrow region—bounded by the triple and critical points—of the liquid's natural existence in equilibrium with its vapour. At the triple point, a liquid demonstrably retains many of the characteristics of a solid, while acquiring to some extent the characteristics of a gas. The former are not completely lost nor the latter fully developed until the critical point is reached.

The simplest liquids to examine are those formed of nonpolar molecules, because the potential energy is then dependent only on the distances apart, and not on any angular function. Molten metals and salts should also be treated as specialized liquids, or, perhaps more logically, as solutions rather than as pure liquids. Even in the interpretation of the facts established concerning simple, nonpolar liquids, there has appeared a great variety of theories, of which but a few can be mentioned here.

It has long been suspected that many of the properties of liquids are more closely related to their free volumes than to their actual volumes. In the theory of van der Waals, the free space in a gas consisting of noncompressible spheres is taken as the difference between the actual volume and a forbidden volume, the latter being identical with four times the sum of the volumes of the incompressible spheres. Coupled with a not unreasonable postulate concerning the attractive forces. this idea leads to the conclusion that the free space per molecule at the critical point is two-thirds of the critical molecular volume. An alternative assumption concerning the interaction energy led C. Dieterici to identify the forbidden volume with one-half the critical volume. Although neither conclusion can now be sustained, they both bring home the essential truth that the free volume in liquids increases as the temperature is raised. G. Jaeger's important extension of the free space theory is to allow for the possibility that the free space is a function not only of the total volume and the total number of molecules but of the temperature also. The extended theory is more consistent with the isotherms of the vapours and the internal pressures of the liquids. Although it is not always easy to evaluate the free volume in liquids, there is no difficulty in obtaining, at any temperature. the ratio of the free volume in the saturated vapour phase to the free volume in the liquid. Dieterici (1898) showed by the method of chemical kinetics and Lewis (1912) by the method of thermodynamics that this ratio is simply the inverse

of the Boltzmann factor, with the internal heat of vaporization as the energy term. At relatively low temperatures, the saturated vapour has a volume that is virtually identical with the free volume; under these conditions, the absolute free volume per molecule of liquid and the vapour pressure of the liquid in terms of its volume are readily obtained. The molecular free volume of water at 25° C., for example, is found to be 1.27×10^{-26} ml.

In these early forms of the free space theory of liquids, the total free volume is assumed to be evenly distributed throughout the liquid. each molecule claiming. as it were its own *Lebensraum.* The randomness of molecular distribution and energies envisaged in the kinetic theory suggest that the free space may be unevenly distributed. There can be, in other words, more free space in one region than in another. This argument leads naturally to the conception of holes in the liquid. Many versions of the theory of holes have been advanced during the 20th century (e g., by H. Eyring and by M. Fuerth). It is an attractive theory, capable of explaining phenomena not readily understood by other means, and one that is developing harmoniously with the theories of the solid state. The expansion of volume that most liquids enjoy on fusion can be attributed to the creation of holes; diffusion in liquids becomes readily intelligible; viscosity can be treated not as the passage of molecules in the direction of viscous flow but as the movement of holes in the opposite direction; liquids may be regarded as solutions of holes in matter, and vapours as solutions of matter in free space; the diminution of liquid density with an increase in temperature may be attributed to an increase in the solubility of holes.

The cluster theory of fluids, developed by M. Reinganum in 1901, was revived in 1923 by Raman, who applied it to the problem of the temperature dependence of the viscosity of liquids. The governing notion is one of localized molecular order; it does not extend to great distances. The representative molecule in a liquid is regarded as capable of maintaining order among the small number of members forming the family circle. while lacking control of those placed farther afield. Molecules in the orderly groups form clusters exothermally and therefore in concentrations that diminish as the temperature is raised. The transport of momentum through the liquid is due not solely to the translation of molecules but partly to the transmission of elastic waves through the groups of relatively stationary molecules. The cluster theory thus explains why the viscosity decreases somewhat rapidly with a rise in temperature. Direct experimental evidence for localized molecular order in certain liquids has been afforded by experiments on the scattering of X-rays, which present a novel and fascinating method for tackling the long-neglected problem of the physical chemistry of liquids.

V. ANALYTICAL CHEMISTRY

Analytical chemistry may be defined as the science of determining the composition of substances in terms of the elements or compounds that they contain. Thus at the molecular level analysis is concerned with the determination of the number and types of atoms present in molecules, whereas the analysis of mixtures is concerned with the determination of the chemical elements or compounds that are present. Qualitative analysis is the identification of constituents and quantitative analysis is the precise determination of their relative amounts.

The early history of methods of analysis shows how analytical chemistry developed from iatrochemistry (1500–1700). Curiosity about the behaviour of chemical substances led Libavius (1540–1616) to originate tests for identifying metal salts in aqueous solution. In the 17th century Boyle coined the term analysis and referred to various tests that could be used for qualitative identification. He showed. for example, that plant extracts such as litmus could be used to differentiate between acids and bases.

During the 18th century, the time of the phlogiston theory, contributions to analytical methods mere made by Friedrich Hoffmann. Andreas Marggraf. Karl Scheele and Torbern Bergman. They devised methods whereby metal salts could be separated into groups by reactions in solution. In mineralogy, the blowpipe technique for analyzing ores was being developed by A. F. Cronstedt; the general application of the blowpipe technique as a method of qualitative analysis was due to Berzelius and Johann Hausmann. Flame tests carried out by examination of the colour imparted to flames when they were brought into contact with volatile metal salts were known to Marggraf and were used by him to identify salts of sodium and potassium. Flame tests were shown to be of much greater value by Bunsen and Gustav Kirchhoff, who demonstrated that the spectra produced in flames were extremely characteristic of the metal.

Analytical investigations during the phlogistic period were mainly of a qualitative nature and it mas not until the time of Lavoisier that the quantitative method was widely used. He emphasized the importance of discovering the composition by weight of chemical compounds; because of his systematic use of the balance he must be regarded as the founder of methods of quantitative analysis. This technique nas of great value to Jeremias Richter (1762–1807) and Joseph Louis Proust (1755–1826) in their studies leading to the recognition of the law of constant proportions. which states that chemical combination occurs only in definite proportions by weight. The experimental inquiry initiated by the atomic theory (1808) proposed by Dalton also required precise measurement and gave further impetus to the development of quantitative analysis, which was placed on a firm foundation by Berzelius, whose laborious investigations may be said to have inaugurated the quantitative era in chemistry and whose studies certainly provided experimental support for Dalton's atomic theory.

Gravimetric analysis involves the transformation of a known weight of a mixture into a weight of a particular compound; this procedure formed the basis of most early analytical methods. This method. honever. is extremely time-consuming and the search for alternative methods continued.

Volumetric analysis consists of careful measurement of the volume of a solution of known concentration that reacts quantitatively with a volume of a solution of the substance to be determined. This method has many advantages over gravimetric analysis, particularly in the analytical control of technical processes. The volumetric technique was developed by Gay-Lussac. who also developed the methods of acidimetry and alkalimetry and the method for the chlorimetric determination of silver (1832). The advantages of volumetric methods were not, however, generally appreciated until potassium permanganate mas used for the determination of ferrous iron by F. Margueritte (1846) and Bunsen showed that copper could be determined by titration with iodine. Significant contributions nere made later by K. F. Mohr and Jacob Volhard. and by the end of the 19th century many gravimetric analytical processes had been superseded by volumetric methods.

Since 1900 the use of instrumental methods has been increasing in analytical chemistry. The most striking developments up until the early 1960s were concerned with electroanalytical procedures including potentiometry. polarography, voltammetry, conductometry and coulometry. (*See* TITRATION: *Electrometric Titrations;* POLAROGRAPHY.) Advent of the manufacture of spectrometers covering the ultraviolet. visible and infrared ranges promoted the use of spectroscopic methods in analytical chemistry. Spectrographic methods. which depend upon the measurement of the wave length and intensity of light emitted by an element in a flame or electric arc, have extensively replaced some conventional methods of qualitative analysis. They are also extremely useful for the quantitative determination of trace substances that are present as minor constituents. (See SPECTROSCOPY: *Spectrochemical* Analysis; SPECTROCHEMICAL ANALYSIS; SPECTROPHOTOMETRY.) Another new technique, chromatography (*q.v.*), which was widely

used after 1950, completely altered the approach to problems associated with the separation and analysis of mixtures of inorganic and organic compounds. Chromatography includes techniques such as absorption, partition, ion exchange and vapour phase (gas) chromatography. Radiochemical methods of analysis with radioactive tracers were used widely after radioactive isotopes became available. (See RADIOACTIVITY, ARTIFICIAL: *Application* to *Chemistry* and Medicine.)

The elemental analysis of organic compounds has remained almost unchanged since the description by Fritz Pregl of his quantitative microanalytical techniques (1917). Any alterations made between 1917 and the early 1960s were concerned mainly with refinements in the design of apparatus and only to a much smaller extent were the reagents or procedures changed. By the application of microchemical methods, samples weighing only a few milligrams can be analyzed with great accuracy and this has had a profound influence on the rate of progress in organic chemistry. Methods were available in the early 1960s for the determination of most elements that occur in organic compounds; the direct determination of oxygen became possible in 1947.

A. Qualitative Inorganic Analysis

A large number of methods has been described for the qualitative analysis of an inorganic salt or of a mixture of inorganic salts; and, although there are differences between them, these methods all conform to a general pattern. In this section it is not appropriate to discuss the theoretical principles involved in the separation and identification of cations (bases) and anions (acid radicals). The analysis may be carried out on a normal (macro) scale, but since about 1940, particularly in the teaching of chemistry, there has been an emphasis upon small-scale techniques that use quantities of reagents intermediate between the macro and micro scales. In macroanalysis the weights and volumes of solutions are approximately 1 g. and 10 ml., while the corresponding quantities in microanalysis are 5 mg. and 0.1 ml. Spot tests may be used for the identification of individual anions and cations; the limit of identification is the smallest amount that can be recognized. It is expressed in micrograms (μg.) or gamma (γ). The relationship betneen these quantities is: $1\ \mu g = 1\ \gamma = \frac{1}{1,000}$ mg. $= 10^{-6}$ g.

Qualitative inorganic analysis employs either dry tests, which are carried out on the solid, or wet tests. which are used in solution (almost invariably in aqueous solution). The systematic analysis of a mixture may be divided into various parts: (1) preliminary dry tests; (2) tests for anions; (3) confirmatory tests for anions; (4) separation of cations into groups; and (5) identification of cations. In some cases the analysis may be considerably shortened by the use of specific spot tests.

1. Systematic Analysis.—Systems for the complete qualitative analysis of a material in the wet way are based on the principle of treating a solution of the material with a succession of reagents so that each reagent separates a group of constituents. The groups are then treated successively with reagents that divide a large group into subgroups or separate the constituents singly. When a constituent has been separated it may be further examined to confirm its presence and to establish the amount present. Portions of the material are dissolved separately and different procedures are used for each to detect the cationic and anionic constituents. (W. D. Os.)

Preliminary Dry Tests.—1. Effect of heat: The substance when heated in a hard glass tube may char, become tarry or smoke; these actions indicate the presence of organic matter. Since many organic compounds interfere with the wet method of analysis, organic matter should be eliminated by preliminary treatment with nitric acid added to sulfuric or perchloric acid. A test for organic matter can be made in a wet way by heating the substance with concentrated sulfuric acid and noting if charring occurs.

If the substance contains water an aqueous deposit will form on the cooler part of the tube. A white sublimate is given by ammonium halide salts, mercurous chloride and bromide, and oxides of arsenic; a yellow sublimate may consist of sulfur (reddish-brown when molten), arsenic sulfide and mercuric iodide (turning red on rubbing). A blackish deposit results from the condensation of violet iodine vapour or of mercuric sulfide, while most mercury compounds other than those mentioned give a gray deposit. Metallic mercury and arsenic appear as minute globules and a gray mirror.

Oxygen results from the decomposition of peroxides. chlorates, nitrates, iodates and similar oxygenated compounds, and also from oxides of the noble metals; carbon dioxide is produced from carbonates and organic substances, usually accompanied in the latter case by charring; sulfur dioxide is obtained from many sulfides and thiosulfates. Chlorine, bromine and iodine are evolved from certain halide salts, particularly in the presence of oxidizing agents, and oxides of nitrogen are evolved from nitrates. Some cyanides evolve cyanogen or hydrocyanic acid and possibly ammonia in the presence of water. All fluosilicates (silicofluorides) decompose on heating and evolve silicon tetrafluoride.

2. Flame tests. When volatilized in a nonluminous flame, the compounds of certain elements cause characteristic colours. This test is carried out by introducing a portion of the substance into the flame; the test material is placed on a platinum wire and is moistened with hydrochloric acid; the acid forms chlorides, which are comparatively volatile salts. Sodium gives an intense yellow coloration; potassium, violet; rubidium and cesium, bluish-violet (the latter blue when pure); calcium, red; strontium and lithium, crimson; barium. yellowish-green; and copper, bright green; while lead, arsenic and antimony (which should not be tested on platinum) give a grayish-blue coloration. By observing the flame through a spectroscope much more definite decisions can be made. Of the rarer metals that give flame colours, indium (blue), thallium (green), cesium and rubidium (violet) were discovered by means of the spectroscope.

3. Blowpipe and bead tests: The substance is placed in a depression on a charcoal block and heated in the reducing flame of a blowpipe. From the changes that occur and the residue that remains, information may be obtained as to the general nature of the material. Specific information as to certain eiements may be obtained by treating the residue with certain reagents, such as cobalt nitrate or sodium carbonate, and again heating. The colourless beads obtained by fusing borax (sodium tetraborate) or microcosmic salt (sodium ammonium phosphate) on a small loop of platinum wire are capable of dissolving many metallic oxides or salts, often mith the production of characteristic colours; the colour may differ according to whether the bead is heated in an oxidizing or reducing flame. These tests are of uncertain value when applied to complex mixtures and have been largely replaced for practical use by spectrographic methods or in some cases by wet tests that employ organic reagents for the identification of specific elements by the formation of coloured precipitates or soluble compounds.

Preparation of Solution for Wet Tests.—Different procedures are used for dissolving the material for subsequent analysis according to whether the material is to be analyzed for only the common cations or for the rarer elements as well. The solution for the analysis of the common cations is prepared by first treating the material successively with water, dilute nitric or hydrochloric acids, or a mixture of these concentrated acids. Any residue is usually treated separately with hydrofluoric acid in conjunction with fuming perchloric acid or sulfuric acid in order to eliminate silica. A refractory residue is then fused with sodium carbonate, with or without the addition of potassium nitrate. The fusion mass is treated with water, whereby the acidic constituents are extracted, and the carbonate-oxide residue is then dissolved in acid.

Test for Anions.—The analysis for anions presents a more difficult problem and is of necessity less systematic than is that for cations. This is so because it is necessary not only to detect certain acidic elements but also to establish their oxidation state and association with oxygen or other elements. For example, if sulfur is present the analysis should not only detect it but also should determine whether it is present as elementary sulfur, sulfide, sulfite, sulfate, the numerous other sulfur oxygen acids, or in combination with other elements, as in thiocyanate. In addition, many of the anions are stable only in alkaline solutions or may react with each other upon acidification. Because of these facts appro-

priate tests are made in order to determine if certain groups of anions are present or absent.

The preliminary tests include those for anions that (1) act as oxidizing agents or reducing agents; (2) form precipitates with silver ion in neutral acid solutions; (3) form precipitates with barium ion in neutral or acid solutions; and (4) form precipitates with calcium ion in ammoniacal solutions.

The solution for the analysis for the anions is usually prepared by treating the material with sodium carbonate solution. This reagent removes most of the heavy metals as carbonates or oxides; otherwise they mould interfere with the subsequent analysis. In the systematic analysis a portion of the sodium carbonate solution is acidified with acetic acid; sulfide and cyanide are then volatilized as hydrogen sulfide and hydrogen cyanide and are collected in an alkaline solution. Addition of perchloric acid causes the volatilization of sulfite as sulfur dioxide. Addition of cadmium nitrate causes precipitation of cadmium ferrocyanide and ferricyanide. Addition of silver nitrate to the filtrate precipitates silver iodate, iodide, thiocyanate, bromide and chloride; the iodate is separated and the last four anions constitute the so-called halide group. In those cases where oxidizing agents were detected by the preliminary tests, sodium nitrite is added to the filtrate; this causes chlorate and bromate to be reduced to chloride and bromide and to precipitate as the silver halides. Any iodate previously precipitated is reduced and precipitated as silver iodide. The filtrate is neutralized and then made slightly acid with acetic acid; silver phosphate, arsenate, arsenite and oxalate are precipitated (the phosphate group). From the filtrate, sulfate is precipitated as barium sulfate and oxalate as calcium oxalate.

Tests are made on separate portions of the sodium carbonate solution for acetate, perchlorate, nitrate, nitrite, borate, peroxysulfate and periodate. The sodium carbonate treatment of the material may leave certain acidic constituents in the residue as insoluble compounds; therefore, this residue is decomposed with zinc and sulfuric acid and additional tests made for sulfide, cyanide, phosphate, arsenate, borate and the halides. **A** separate portion of the material is tested for carbonate.

Confirmatory Tests for Anions.—The tests given above will indicate the presence of certain anions, but this presence must be confirmed by tests that are reasonably specific. Thus, nitrate may be detected by the "brown ring test" with concentrated nitric acid and ferrous sulfate, cyanide by the prussian blue test, and acetate by the formation of ethyl acetate on treatment with ethyl alcohol and sulfuric acid. These tests illustrate the type of confirmatory evidence that is frequently used, but it is often necessary to devise special tests when there are mixtures containing a number of anions. For example, nitrite can be easily detected in the presence of nitrate by the starch-iodide reaction, but the identification of nitrate in the presence of nitrite is difficult because both give a positive "brown ring test." In this case it is necessary to remove the nitrite by treatment with urea or sulfamic acid before carrying out the usual tests for nitrate.

In the analysis for anions many difficult problems may arise when several anions are present; some of these problems may be easily solved by using paper chromatography.

Separation of Cations Into Groups.—Most of the various systems that have been developed employ essentially the same reagents for the major group separations. A typical analytical scheme is summarized below. Minor modifications exist in some cases where the system is designed for a semimicro scale of operation or for elementary instruction.

The ammonium cation may be considered as a constituent of group V but a separate sample must be used for its detection since it is introduced in the course of the analysis. When the analysis is made on a macro scale, the precipitates obtained are usually separated by filtration; centrifugation is more extensively used if the analysis is made on a semimicro scale.

2. Identification of Cations.—The next step, after the cations are separated into groups, is the identification of the individual cations in each group. Innumerable procedures have been suggested for the separation and identification of the individual cations. The methods given below are those that have been used extensively and are representative of the general principles involved.

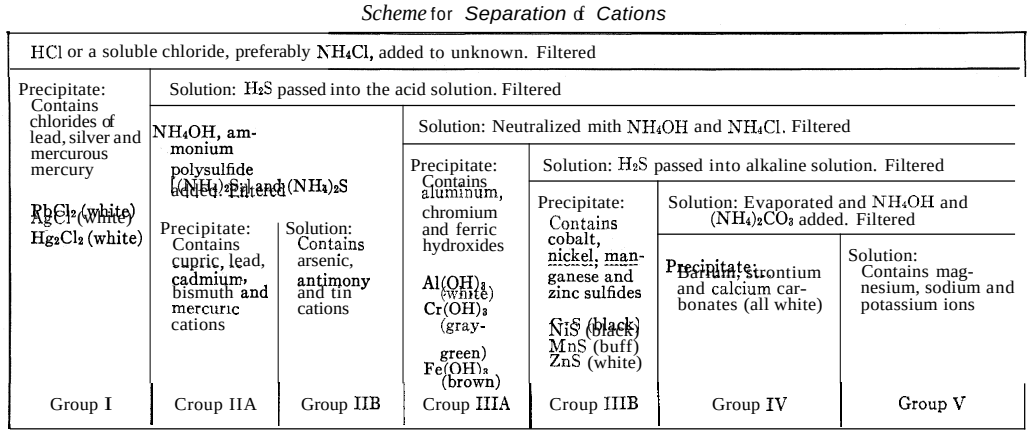
The Silver Group (*Group* I).—The group precipitate is leached with hot water to remove the lead chloride; the formation of yellow lead chromate when acetic acid and a soluble chromate are added to the solution identifies lead. The residue is leached with ammonia. Mercurous chloride is converted into a black residue of mercury and mercuric aminochloride; silver chloride dissolves and is reprecipitated by acidifying the ammonia solution.

The Copper Group (Group *IIA*).—The sulfide precipitate is dissolved in nitric acid (if mercuric sulfide is present it remains as a residue) and sulfuric acid is added; the solution is evaporated until it fumes and is then diluted; this procedure precipitates lead sulfate. The precipitate is dissolved in ammonium acetate and yellow lead chromate is precipitated by addition of a soluble chromate. Addition to the sulfuric acid filtrate of an excess of ammonia precipitates white bismuth hydroxide; treatment of the precipitate with an alkaline sodium stannite solution reduces the bismuth to the black metal. If copper is present the ammoniacal filtrate is blue because of the formation of the cupric tetrammine complex; when copper is present, cyanide is added to form the colourless cuprous tricyano-complex and the solution is treated with hydrogen sulfide to precipitate yellow cadmium sulfide.

The Arsenic *Group* (*Group IIB*).—The alkaline sulfide solution is acidified to reprecipitate the sulfides. After this precipitate is treated with potassium hydroxide and peroxide, only mercuric sulfide is left as a residue. The residue is dissolved in hydrochloric acid; first sodium chlorate and then an excess of stannous chloride are added; the stannous chloride precipitates white mercurous chloride, which becomes gray as it is reduced to mercury. Arsenic, antimony and tin are again precipitated as sulfides and the precipitate is treated with hot concentrated hydrochloric acid; as a result, the residue contains only arsenic sulfide. This is dissolved by means of sodium hydroxide and peroxide and the arsenic reprecipitated as magnesium ammonium arsenate. The concentrated hydrochloric acid solution is diluted sixfold, oxalic acid is added and the reddish-orange antimony sulfide is precipitated by hydrogen sulfide. The oxalic and hydrochloric acids are removed from the filtrate by adding sulfuric acid and evaporating to fuming; the solution is diluted and then treated with hydrogen sulfide to precipitate yellow tin sulfide.

The Iron Group (Group *IIIA*).—The precipitate may contain the hydroxides of iron, chromium and aluminum, but before the precipitate is examined phosphate must be removed by forming, for example, the rather insoluble zirconium hydrogen phosphate.

Scheme for *Separation* of *Cations*



The reprecipitated hydroxides are then treated with sodium hydroxide and hydrogen peroxide. An insoluble residue indicates the presence of ferric hydroxide and this is confirmed by dissolving the residue in hydrochloric acid and adding potassium thiocyanate. The original sodium hydroxide solution is divided into two parts. Ammonia is added to one part and a white flocculent precipitate of aluminum hydroxide indicates aluminum. The other part of the solution is acidified (acetic acid), lead acetate is added and a yellow precipitate of lead chromate establishes that chromium is present.

The Zinc Group (Group *IIIB*).—The precipitated sulfides are treated with very dilute cold hydrochloric acid The residue may contain either cobalt or nickel sulfide; cobalt may be recognized by a borax bead test. The rest of the insoluble residue is treated with ammonium chloride and ammonium hydroxide until it is alkaline; then dimethylglyoxime is added. A red precipitate indicates that nickel is present. The hydrochloric acid solution may contain manganous chloride or zinc chloride. It is boiled to remove hydrogen sulfide, made alkaline with sodium hydroxide and heated further. A dark-coloured precipitate indicates manganese and this is confirmed by formation of purple permanganic acid on oxidation with nitric acid and lead peroxide. The sodium hydroxide solution may contain sodium hydrogen zincate; if zinc is present, hydrogen sulfide gives a cream-coloured precipitate of zinc sulfide.

The Calcium Group (Group *IV*).—The precipitate produced by ammonium carbonate is dissolved in acetic acid and then potassium chromate is added; yellow barium chromate precipitates. When the solution is neutralized and alcohol is added, yellow strontium chromate is precipitated. Addition of ammonium oxalate to the filtrate precipitates white calcium oxalate. Magnesium, when present in this group, is precipitated as magnesium ammonium phosphate.

The Alkali Group (Group *V*).—The filtrate from the ammonium sulfide precipitation is evaporated to dryness and then is heated until ammonium salts are volatilized to prevent them from interfering with the test for potassium. The residue is dissolved in water and the solution is divided into two portions. To one is added sodium nitrocobaltate III (sodium cobaltinitrite), which causes the precipitation of yellow potassium sodium nitrocobaltate III (potassium sodium cobaltinitrite); to the other is added magnesium uranyl acetate, which causes pale yellowish sodium magnesium uranyl acetate to precipitate.. A separate portion of the original material to be analyzed is tested for ammonium cation by heating it with sodium hydroxide; ammonia is evolved and may be detected by its odour or by its alkaline effect on litmus paper.

Spot Tests.—A large number of so-called tests for individual cations and anions have been developed, especially by Fritz Feigl. The material to be tested is dissolved. a drop of the solution is placed in an indentation on a white tile (spot plate), a drop of reagent solution is added and the mixture is examined for a characteristic precipitate or coloration; as a modification the solution may be tested by being applied to a strip of paper impregnated with reagent or by being drawn into a capillary tube that contains the reagent. The reagent frequently contains an organic compound capable of forming intensely coloured compounds with certain elements or radicals. When applied to complex mixtures these tests are limited in value because several constituents may give similar reactions. and other constituents may mask or cause the test to fail.

3. *Qualitative Analysis for Some of the Rarer Elements.* —The analytical schemes that have been described have been concerned with analytical procedures for use when only the commoner salts are present. With the development of modern industrial techniques for the isolation of metals, many metals that once were considered rare are now used widely. The designation "rare element" is retained in analytical chemistry, however, to classify metals such as tungsten, titanium, beryllium, uranium and thallium.

The first system designed to cope with the rarer elements was designed by Arthur A. Noyes and William Crowell Bray (1927). Other systems have been devised, including the one by Arthur I. Vogel (1954). Many of the analytical methods used in the control of industrial processes that involve the more unusual metals are specially devised. They are, therefore, not discussed in detail. The system of Noyes and Bray is mainly of historical interest, but when it was published it employed several novel techniques. Their system is characterized by the separation of groups during the preparation of the solution of the material being analyzed and by the use of separations depending upon the volatility or extractability by immiscible solvents of the compounds of certain elements. The complete analysis is too extended to be given and only the principal separations are outlined below.

The *Selenium* Group.—The material is distilled with concentrated hydrobromic acid; selenium, arsenic and germanium are volatilized as the bromides.

Silicon, *Osmium* and Ruthenium.—Any solid residue is treated with hydrofluoric acid to eliminate silica as the volatile silicon tetrafluoride; the solution is then distilled with perchloric acid to volatilize osmium tetroxide; addition of concentrated nitric acid to the perchloric acid and repetition of the distillation volatilizes ruthenium tetroxide.

The Tungsten, Tantalum and Gold *Groups*.—The residual solution from the ruthenium distillation is diluted, formic acid is added and the mixture is heated. The resulting precipitate contains: the oxides of tungsten, molybdenum, antimony and tin, which form the tungsten group; the oxides of tantalum. columbium and titanium (in part), the tantalum group; also metallic gold, mercury, platinum and palladium, the gold group. The tungsten and tantalum group elements are dissolved by treating the residue with hydrofluoric acid; the solution is fumed with sulfuric acid to eliminate the hydrofluoric acid and then an excess of ammonia and ammonium sulfide is added. By this treatment the tantalum group elements are reprecipitated as oxides and the tungsten group elements are dissolved as sulfoanions.

The *Thallium* Group.—Hydrobromic acid is added to the formic acid filtrate, thus precipitating the bromides of silver, thallium (ous) and lead (incompletely).

The Hydrogen *Sulfide Group*.—The hydrogen ion concentration is adjusted to three-tenths molar and the solution is treated nith hydrogen sulfide to precipitate the sulfides of tellurium, molybdenum, iridium and rhodium (the tellurium group) and lead. bismuth, copper and cadmium (the copper group). The tellurium and molybdenum are removed separately; then the copper group elements are precipitated as hydroxides.

The Ammonium Sulfide Group.—Small portions of the filtrate from the hydrogen sulfide group precipitation are tested for iron and phosphate. Additional iron is added to the main filtrate and a basic acetate precipitation is made by adding ammonium acetate and boiling the solution. This process causes the precipitation of chromium, aluminum, indium, zirconium. titanium, gallium and vanadium together with the iron as hydrous oxides, basic acetates, phosphates or vanadates; the precipitation of gallium and vanadium is complete only when iron is present.

The precipitate is dissolved in hydrochloric acid and the iron and gallium extracted with ether. The hydrochloric acid solution is made alkaline and excess sodium peroxide added; indium, zirconium and thorium hydroxides are precipitated; these elements constitute the zirconium group.

The filtrate from the basic acetate precipitation is made alkaline with ammonia and then ammonium sulfide is added. Beryllium and the rare-earth elements are precipitated as hydroxides and manganese, zinc, cobalt, nickel and uranium as sulfides. The precipitate is dissolved in acid; excess sodium hydroxide and peroxide are added and manganese, cobalt and nickel (the nickel group) and the rare-earth elements (the rare-earth group) are precipitated as oxides or hydroxides. The two sodium hydroxide filtrates are united.

The elements present are aluminum, chromium, vanadium, beryllium and zinc (the aluminum group).

The Alkaline Earth Group.—This group is precipitated and separated as described above in The *Calcium Group* (Group *IV*).

The Alkali Group.—The final filtrate is analyzed for lithium, rubidium and cesium in addition to sodium and potassium.

No provision is made in the system for the radioactive elements (other than uranium and thorium), rhenium, the inert gases, nor for any elements with atomic numbers greater than 92.

(E. H. St.; W. D. Os.)

B. Quantitative Inorganic Analysis

The branch of chemistry that deals with the determination of the amount or percentage of one or more constituents of a sample is known as quantitative analysis. This field is important because of its widespread use both in research and in industrial processes; whenever chemicals are used quantitative analyses are needed. Consequently every chemist is trained in analytical methods and in their applications and limitations.

A variety of methods is utilized for quantitative analyses; in fact, almost every property of matter can be made the basis for some analytical process. For convenience these methods may be broadly classified as chemical or physical, depending upon which properties are utilized. Chemical methods are those that depend upon reactions such as precipitation, neutralization, oxidation or, in general, the formation of a new compound. Physical methods are those that involve the measurement of some physical property such as density, refractive index, absorption or polarization of light. electromotive force. production of spectra, magnetic susceptibility and numerous others. Frequently an analysis will involve a combination of chemical and physical methods, the former for separating desired constituents from a sample and the latter for measuring the amounts present.

The basic tool in all quantitative analyses is the analytical balance, which is used for the accurate weighing of samples and precipitates. The balance operates on the principle of levers; the weight of an object is determined by finding the sum of the weights of known mass that are required to balance the object. For usual analytical work the balance should be sensitive to and able to determine differences in mass of 0.1 mg. (about ,000003 oz.).

In microanalyses the balance is about 1,000 times more sensitive and for special work balances of even higher sensitivity have been constructed. (See Balance: *Ultramicrobalance.*)

1. Chemical Methods (Gravimetric and Volumetric).— The major types of strictly chemical methods are known respectively as gravimetric and volumetric (or titrimetric) analysis. As the names imply, the former is based upon a measurement of the weight of a sample constituent and the latter upon the measurement of a volume of solution required to react mith the sample. Application of these tno methods may be illustrated by procedures that are used for the determination of chloride. In a gravimetric analysis the sample is treated nith an excess of silver nitrate solution, nhich precipitates the chloride as silver chloride. The amount present is determined from the weight of silver chloride obtained In a volumetric analysis the sample is treated with a solution of silver nitrate of known concentration and the volume of solution required to react with all the chloride present is measured From this volume and the knoan concentration of the solution, the amount of chloride in the sample is computed.

The choice of method, gravimetric or volumetric, depends upon the conditions of the analysis. The two methods are about equal in accuracy. Usually a volumetric analysis is far more rapid than a gravimetric after the necessary standard solutions are prepared. Consequently, whenever many samples are to be analyzed a volumetric method is chosen when one is available. But if only a few samples are analyzed it may be more convenient to use a gravimetric method than to prepare and standardize the solutions needed for the volumetric method.

Gravimetric.—In a gravimetric analysis the constituent sought is converted into a substance of definite composition. as expressed by a chemical formula, in 100% yield. All operations in gravimetric analyses are directed toward the objectives of purity and yield. The following operations are common: (1) preparing a solution containing a knonn weight of the sample; (2) separating the desired constituent in a pure condition of known composition; (3) neighing the isolated constituent; and (4) computing from the observed weight the amount of the particular'constituent in the sample.

There are many methods for isolating the desired constituent from a solution of a sample. The commonest is precipitation. A reagent is added that will form an insoluble compound with the desired constituent but will not precipitate other constituents of the sample. The precipitate obtained is separated by filtration, mashed free of soluble impurities, dried or ignited to remove water and weighed. Volatilization is used to separate a substance that can be converted readily into a gaseous compound. An example is the determination of carbonate in a mineral analysis. The sample is treated with an acid and carbon dioxide is evolved as a gas. The gas is absorbed in a weighed portion of an alkaline reagent and the amnunt of carbon dioxide is determined from the gain in weight of the absorbent. Electrodeposition is used to separate certain metals that can be plated out by passing an electric current through a solution. Copper in alloys is frequently determined by this method when interfering metals are not present in the sample. (See Electrochemistry.)

The general methods of precipitation analyses are much like those of qualitative analyses (see Qualitative *Inorganic* Analysis above). If the sample is complex, *i* e., contains many constituents, it is necessary to separate the constituents into groups by successive addition of various reagents. Many of the reagents used for group separations are the same as those employed in qualitative analyses. After the groups are separated, each is redissolved and treated nith specific reagents to precipitate the constituents separately. The complete gravimetric analysis of a complex mineral may require several days, even with highly skilled operators.

If errors are made in gravimetric analyses they usually relate to the purity of the isolated constituent. In general the compounds precipitated are very insoluble and there is little error due to incompleteness of precipitation. It is a difficult matter. however, to obtain a precipitate that is 100% pure and exactly of the composition represented by a chemical formula. All gravimetric methods are subject to some degree of error because of this.

Volumetric.—In a volumetric analysis a solution of known concentration of the reagent is added to a solution of the substance to be determined until the quantity of the reagent is equivalent to the quantity of substance being analyzed. (An equivalent amount is that which reacts exactly with another substance. See Equivalent.) All volumetric operations are directed toward measuring the amount of reagent equivalent to the constituent sought in the analysis. Not every chemical reaction can be utilized for volumetric procedures. The following conditions are necessary: (1) the reagent must react with only one constituent of the sample; (2) reaction must be rapid, so that each portion of reagent reacts as rapidly as added; (3) there must be some change in properties of the solution when the equivalence point is reached (usually a sudden change in concentration of ions present); and (4) an indicator (see Indicator, Chemical) must be available to show the point at which equivalence is reached.

The steps in volumetric analysis are: (1) preparation of sample solution; (2) titration of sample solution with standard solution that contains a known concentration of the reagent chemical; and (3) computation of the amount of constituent in the sample from the volume and concentration of reagent solution used. Titration, which is the name for the process of determining the amount of reagent equivalent to the sample, is performed by adding the reagent slowly from a burette until the indicator shows a colour change. Ordinarily a 50-ml. burette is used and the analyst chooses conditions so that 30 to 40 ml. of reagent are required. In microchemistry the burette may have a capacity of one millilitre or sometimes even less. Chemical indicators generally are used in titrations but various physical methods can also be used in special cases to show the equivalence point. A chemical indicator is a highly coloured substance that reacts with one of the components of the system and shows by a colour change when a component disappears or appears A nell-known example is starch, which gives an intense blue colour with iodine. If an iodine solution is being titrated the end point is marked by the disappearance of colour or. conversely, if iodine is the titration reagent the presence of an excess of iodine when the equivalence point is passed is marked by the appearance of blue colour.

All volumetric analyses must be preceded by standardization of the reagent solution. This is usually done by comparing the solution uith a aeighed sample of known purity. An acid solution, for example. is standardized by titration of a known weight of some pure basic substance such as sodium carbonate.

The determination of the amount of acid or base in a sample by titration with a standard solution of base or acid is known as neutralization. This type of volumetric analysis is widely used. Examples are the determination of the amount of free acid in vinegar or the amount of free base in lye. A variety of acid-base indicators is knonn. Among the most frequently used are phenolphthalein. methyl red and bromothymol blue. These differ from each other by showing colour changes at different hydrogen ion concentrations. In an acid-base titration it is important to select an indicator ahose colour chdnge corresponds to the hydrogen ion concentration of the equivalence point; use of the wrong indicator might lead to erroneous results.

Many volumetric methods are based upon oxidation-reduction reactions in uhich there is a change in valence of some ion. A familiar example is the determination of iron by titration with permanganate or ceric sulfate solution Before this determination is started all iron must be reduced to the ferrous (Fe^{2+}) condition and all other reducing agents that might react uith the standard solution of oxidizing agent must be removed. In the titration iron is oxidized to the ierric condition (Fe^{3+}). The amount present is computed from the volume of oxidizing agent required to react nith the iron. If the standard solution used is potassium permanganate no indicator is required for the titration. Permanganate ion is so highly coloured that uhen the equivalence point is passed a drop or two of solution in excess will impart colour to the solution, thereby giving the end point. Oxidation indicators also can be used. These are substances that are less readily oxidized than ferrous ion and consequently are not affected until the equivalence point is reached and all the ferrous ion has been oxidized. At this point the indicator is oxidized and shows by a colour change that the end point is reached.

The most widely used standard oxidizing agents are potassium perrnanganate and ceric sulfate. Both are strong oxidizers and can be used to titrate numerous reducing agents, such as iron, titanium, vanadium, uranium. sulfides, nitrites. sulfites, oxalates, hydrogen peroxide. arsenic, antimony, molybdenum and many others; the material to be titrated must be in its lower valence state.

Another important class of oxidation-reduction (frequently called redox) determinations involves iodine. When potassium iodide is treated with any strong oxidizing agent iodine is liberated in equivalent amount. Titration of the liberated iodine gives an indirect measure of the amount of oxidizing agent that reacted with the potassium iodide. Thus this method can be used to analyze any oxidizing agent that liberates iodine from potassium iodide. The standard solution used to titrate the iodine may be either sodium thiosulfate or arsenic trioxide.

Precipitation reactions can often be used for volumetric analyses when an indicator is available to shon when the equivalence point is reached. A common example is the determination of chloride by titration with silver nitrate solution.

Good volumetric methods are lacking for numerous substances. Among these substances are ions that are not readily oxidized or reduced and do not give precipitates that are suitable for use in volumetric analyses; examples are sodium, potassium, calcium and aluminum. For some of these it is possible to devise an indirect method of volumetric analysis. Calcium, for example. can be determined volumetrically by first precipitating it as calcium oxalate, then dissolving the precipitate in sulfuric acid and determining oxalate by titration with potassium permanganate.

Since the amounts of calcium and oxalate in the precipitate are equivalent, the titration gives the equivalents of calcium in the sample.

2. Other Chemical Methods. — Several chemical and physicochemical methods used less frequently than gravimetric and volumetric analyses are listed below:

Colorimetric analyses are based upon the absorption of light by coloured substances in solution. They can be used when the constituent sought can be converted by chemical reaction into a coloured compound without creating other coloured compounds in the solution.

Nephelometric analyses are based upon the amount of turbidity in a solution and the effect of this turbidity upon the transmission oi light. This method can be applied only to the determination of small amounts of substances that yield a precipitate when treated with certain reagents.

Gas analysis depends upon selective absorption of constituents in a gaseous mixture and measurement of the changes in volume that occur when absorption has taken place.

Fire assay is used to determine the amounts of precious metals in ores. The ore samples are heated with a flux and the metals are reduced to the free state. The free metals are then extracted from the flux by molten lead. which on cooling retains the precious metals as an alloy. The amounts of precious metals are determined by dissolving (parting) the lead button in acids and then performing a chemical analysis on the solution or on the metals that do not dissolve.

3. Computation of Chemical Analyses. — The basis for all quantitative computations is the weight relations expressed by a chemical equation. For example, the equation:

$$2NaOH + H_2SO_4 \rightarrow Na_2SO_4 + 2H_2O$$

shows that two molecules of sodium hydroxide react with one molecule of suliuric acid to give one molecule of sodium suliate and two molecules of water. Since a molecule of sodium hydroxide weighs 40.00 atomic weight units (the sum of the atomic weights of Na, O and H) and a molecule of sulfuric acid 98.08 units then 2×40.00 units of NaOH react with 98.08 units of H_2SO_4. The ratio of weights of NaOH and H_2SO_4 reacting are the same regardless of the units employed, whether these are grams, ounces, tons, etc.

In gravimetric analysis the weight of the constituent sought is computed from the weight of a precipitate by using a factor based upon the atomic aeights. Thus, from the weight of AgCl precipitate the weight of Cl is computed by the relation

$$\text{Weight Cl} = \text{Weight AgCl} \times \frac{\text{Atomic weight Cl}}{\text{sum of atomic weights of Ag and Cl}}$$

and

$$\% \text{ Cl} = \frac{\text{Weight of Ag Cl X 24.74}}{\text{Weight of sample}}$$

In volumetric analyses the computations involve the volume and concentration of the reagent solution. The unit of concentration usually chosen is the equivalent weight (see EQUIVALENT); a solution that contains one equivalent weight of solute per litre is known as a 1 normal (1N) solution. Since titrations are made to the point that the equivalents of reagent equal the equivalents of sample, it follows from the definitions that the product (volume of reagent in litres times the normality of the reagent) is the total equivalents of reagent and therefore the total equivalents of the sought constituent in the sample. Multiplying this value by the weight of one equivalent gives the weight of the sample constituent in grams. For example, if titration of a Cl sample requires 40.00 ml. of 0.1N $AgNO_3$ solution, the weight of Cl in the sample is

$$\underset{\text{(vol. in litres)}}{40.00/1{,}000} \times \underset{\text{(normality)}}{0.1} \times \underset{\text{(eq. wt. Cl)}}{35.46} = \text{grams Cl}$$

(W. C. P.; W. D. Os.)

4. Physical Methods. — Progress in the field of chemical analysis has been concerned mainly with the discovery of instrumental methods based upon physical properties. Practically all these processes have been developed since 1930 and most of them rely upon spectroscopic, optical or electrochemical phenomena. By the use of modern electronic apparatus it is possible for the analytical results to be displayed by pen-recording devices, and it is also possible for the analysis to be carried out completely automatically and to effectdirect control of the technical process. (See SPECTROCHEMICAL ANALYSIS.)

Absorption Spectroscopy.—By the 1960s, colorimetric analysis had been in use for many years as an analytical technique. It is an application of the fact that the intensity of colour varies with the concentration of a coloured component. Thus, by matching a coloured solution with a series of solutions of the same substance of known concentration, it is possible to determine the unknown concentration. This method of analysis depends on comparisons at one wave length. With recording spectrometers that can determine absorption characteristics in the ultraviolet. visible and infrared parts of the spectrum, these methods can be used for the analysis of colourless compounds and are of tremendous power and value.

Emission Spectroscopy.—The work of Bunsen and Kirchhoff (1860) showed that many metals, when suitably excited, emit radiation of characteristic wave lengths. These emission spectra have long been used in the qualitative identification of metals. as in the flame tests for alkali metals and the alkaline earth metals. Quantitative emission spectroscopy or flame spectrometry has become increasingly important as an analytical tool, and by employing more powerful excitation by means of electric arcs the method can be extended to include many nonmetallic elements. The emission spectrum can be observed visually with a spectroscope or it may be recorded photographically with a spectrograph. From the intensity of the lines of the spectrum produced under standard conditions, the nature and the quantity of various elements present can be determined. Elements such as barium, calcium, cesium, copper, gallium, indium, palladium, rhodium and vanadium are detectable in amounts less than one part per million (1 p.p.m.).

The application of emission spectroscopy to quantitative analyses is now so well established that in many control laboratories it has supplanted chemical analyses for numerous constituents. This is particularly true in the analysis of alloys for minor constituents. The basis for the method is the fact that the intensity of spectral lines can be related to the concentration of the emitting element in the sample (see SPECTROSCOPY: *Observations* and Measurements.) Requirements are a spectroscope of sufficient dispersion in both the visible and the ultraviolet regions and a microphotometer for measuring the blackness or density of the spectral line.

Before a spectrochemical method can be used it is necessary to work out curves relating line densities to concentrations, based upon samples of the general composition of those to be analyzed. This preliminary preparation of the working curve is based upon chemical analyses of the standard samples. Weeks of careful work may be required to standardize conditions and develop the working curve for a given analysis. Consequently the spectrochemical method is not well suited to the analysis of occasional samples but is well suited for routine analyses where large numbers of samples must be processed. Once methods are developed the spectrographic procedure is very rapid and accurate. It is possible to take molten metal samples from a furnace and obtain an analysis for several constituents within minutes after the sample is withdrawn.

Polarimetry and Optical Rotatory Dispersion.—Polarimetry (*q.v.*), or the measurement of the rotation of the plane of polarized light by solutions of optically active substances, has been used for many years as an analytical procedure. One application is the analysis of sugar solutions (saccharimetry). The concentration of sugar solutions can be determined directly by using a suitably graduated polarimeter.

Since 1955, mainly because of the studies of Carl Djerassi, it has become possible to make routine measurements of the optical rotation of optically active substances at various wave lengths throughout the ultraviolet and visible parts of the spectrum. The rotations recorded in the ultraviolet are much higher than in the visible regions and may be used for analytical purposes.

Refractivity.—The refractive index (a measure of the bending of light when it crosses the boundary between two media of different optical density) is often used to identify organic compounds and to measure the concentration of solutions. A useful application is in the determination of the alcoholic content of beverages. Alcohol is distilled from the sample and collected in a measured volume of water. From the refractive index of the resulting solution the alcoholic content of the original sample is readily computed. (See LIGHT: Refraction and *Double* Refraction.)

Potentiometry.—There are two ways in which potentiometric methods are used in analytical chemistry: (1) the potential of a cell is measured and is used to calculate the concentration of one constituent (this is an application of the Nernst equation, which states the simple relation between the relative potential of an electrode and the concentration of the corresponding ionic species in solution); and (2) the variation of potential during a titration is used to determine the end point.

Ordinary volumetric methods are subject to personal error; potentiometric titration has two important advantages: the end point may be detected even with highly coloured solutions and the method is very accurate even with small amounts (0.2–2.0 mg.) of material.

A great many titrations can be followed potentiometrically by choosing suitable electrodes. Acid-base titrations can be followed with a glass electrode and a calomel reference electrode; oxidation-reduction reactions can be studied with a platinum electrode.

One analysis that is very frequently carried out potentiometrically is the determination of hydrogen-ion concentration (pH). Some potentiometers are calibrated to give the pH value directly. The continuous and accurate determination of hydrogen-ion concentrations is important in many manufacturing processes. To facilitate this determination, many types of pH meters have been constructed in which the hydrogen-ion concentration is related to the voltage reading of the meter. By a slight modification these instruments can be used to detect potentiometrically the end point in oxidation-reduction and in certain precipitation titrations. (See HYDROGEN IONS: *Glass* Electrode [Cell With Glass Membrane].)

Conductometry.—The conductivity of a solution depends upon the nature and concentration of the ions present in the solution. Thus, by measuring the conductivity with inert electrodes it is possible to determine ionic concentration.

Polarography.—In this method the timed relationship between voltage and current is determined for t o electrodes in a solution. The reference electrode is nonpolarizable (usually saturated calomel) and the polarized electrode is the dropping mercury electrode. The general process that uses other polarizable electrodes is called voltammetry. Instruments are available for recording the voltage-current curves directly; the position of the curve on the voltage axis is characteristic of the substance. The amplitude of the curve is proportional to the concentration. Polarography can therefore be used both for the qualitative and quantitative analyses of inorganic or organic substances and it can be used for mixtures and in trace analysis for concentrations as low as 10^{-5} or 10^{-7} molar. The volume of the solution may be of the order of 0.3 ml.

Polarography is a most important analytical technique. Jaroslav Heyrovsky was awarded the 1959 Nobel prize for chemistry for originating and developing polarography.

Coulometry.—This analytical technique is based on Faraday's law of electrolysis. In direct determination, the quantity of charge required to bring about electrolytic deposition or solution is measured, but this technique has serious limitations because it is essentially a gravimetric method. The indirect methods of coulometry do not have this disadvantage; they usually require the determination of the amount of charge necessary to produce a substance that will react stoichiometrically with the substance to be determined. Such methods can be controlled automatically and have been used, for example, in the continuous determination of sulfur compounds in coal gas.

The movement of the recording pen is a measure of the amount of charge required to maintain a small excess of oxidizing agent (bromine) in the electrolyte. This is an analytical method that can be applied widely in the automatic analytical control of technical processes.

X-ray *Diffraction.*—The characteristic X-ray diffraction pattern given by crystalline substances can be made the basis for quali-

tative and quantitative analyses where other methods are not suitable. A beam of monochromatic X-rays is passed through a small tube of the powdered sample and the diffracted lines detected by their effect upon a photographic plate or film. The position of the lines serves to identify the crystalline species present; quantitative measurements of amounts present can be made by measuring the intensity of the lines. (*See* SPECTROSCOPY, X-RAY.)

Mass Spectrometry. — By using high resolution mass spectrometers it is possible to carry out remarkably accurate analyses on even microgram quantities of volatile materials (see MASS SPECTROSCOPY). Identification may be made with certainty by comparison of cracking patterns.

Countercurrent Distribution. — The physical principle on which this method is based is that of partition. Countercurrent distribution involves a multiple, consecutive extraction process in which a sample is distributed between two immiscible liquid phases. Since it is a repetitive process, mixtures of substances with only very slightly differing partition coefficients are easily separated. It is a powerful method for the analysis of complex mixtures of organic substances of biochemical origin.

5. Analysis With Radioactive Substances. — The ability to produce radioactive forms of many elements and compounds has opened up a field of analytical chemistry in which very accurate measurement of ionizing radiation is possible. Techniques such as activation analysis, isotope dilution and radiometric analysis make use of this high-precision technique. Neutron activation analysis involves irradiation of the substance in a nuclear reactor where, as a result of neutron bombardment, radioactivity may be induced in the elements present. The sample is then removed and the change of activity with time is plotted, giving a decay curve. From the shape of this curve the elements may be identified by their characteristic half-lives, and from their relative activities the amounts present may be calculated.

Isotope Dilution. — This method permits the quantitative determination of an element or substance in a mixture. A compound containing a radio-labeled atom or atoms of the element or substance is added to the mixture and a pure sample of the element or substance is isolated from the mixture by any suitable process. The radioactivity of the pure isolate is determined and, since the radioactivity and amount of labeled material first added is known, the amount of unlabeled material originally present is easily calculated. (*See* ISOTOPE: *Uses* of Isotopes.)

Radiometric analysis is a powerful method of analysis in which a radioactive substance is used indirectly. For example, chloride ion can be easily determined by adding radioactive silver (Ag^{110}) nitrate and determining the activity of the precipitated silver chloride. (W. D. Os.)

C. ORGANIC ANALYSIS

The number of elements (carbon, hydrogen, oxygen, nitrogen, sulfur, the halogens and occasionally phosphorus and some metals) usually present in organic compounds is limited. All these elements can be estimated quantitatively. Although oxygen is usually determined by difference, it can be determined directly.

1. Qualitative Tests for the **Elements.**—*Carbon* and *Hydrogen.* — The organic nature of a compound is generally indicated by its behaviour on being heated in air; solids usually melt, then burn with a more or less smoky flame, leaving a black residue of carbon. To test directly for carbon and hydrogen, a small quantity of the material intimately mixed with about 20 times its bulk of dry copper oxide powder is heated in a dry test tube closed by a cork carrying a delivery tube that dips into a solution of limewater. The copper oxide is reduced, the hydrogen is converted to water, which condenses on the cool part of the tube, and the carbon is oxidized to carbon dioxide, which with limewater yields a precipitate of calcium carbonate.

Nitrogen, Halogens, Sulfur. — When organic compounds containing any or all of these elements are heated strongly with metallic sodium, they decompose and form sodium cyanide, halide and sulfide, respectively (Lassaigne's test). To test for these elements, a small quantity (1 mg.) of the substance and a small pellet of sodium (or potassium) are heated in a narrow test tube, gently at first and afterward more strongly, until the glass softens; the hot tube is shattered by plunging it into water, thereby converting any residual sodium into sodium hydroxide and yielding an alkaline solution of the sodium salts; the solution is boiled and filtered, and the filtrate is used in the following tests:

1. Nitrogen. — A portion of the filtrate is mixed with a ferrous sulfate solution that contains a small quantity of the ferric salt and the mixture is boiled, thereby converting any sodium cyanide present to ferrocyanide, which gives a bluish-green solution and a precipitate of prussian blue when hydrochloric acid is added.

2. Halogens. — A second portion of the alkaline filtrate is acidified with nitric acid, and silver nitrate is added; any precipitate of chloride, bromide or iodide, or a mixture of these. is examined in the usual manner. If the original substance also contains nitrogen or sulfur, the acid solution must be boiled to expel the hydrogen cyanide or hydrogen sulfide before the silver nitrate is added.

3. Sulfur. — A third portion of the alkaline filtrate is tested for sodium sulfide: its presence is indicated (1) by the formation of a deep violet colour when the filtrate is treated with a few drops of a freshly prepared solution of sodium nitroprusside; (2) by the evolution of hydrogen sulfide when the filtrate is acidified — this is readily detected by its odour and also by lead acetate test paper.

Phosphorus. — A small portion of the organic compound is intimately mixed with about ten times its bulk of a mixture of sodium carbonate and sodium peroxide (2:3) and heated to fusion in a nickel crucible. The cold water extract of the melt is filtered. acidified with nitric acid and tested for phosphoric acid with ammonium molybdate.

Metals. — They are detected in organic compounds by using the standard methods mentioned in Qualitative Inorganic Analysis above.

2. Quantitative Analysis of Organic **Compounds.**—*Estimation* of Carbon and Hydrogen. — The carbon and hydrogen in an organic compound are estimated by completely oxidizing a weighed quantity of the substance and weighing the carbon dioxide and water thus formed. The simple method devised by Liebig in 1831 for carrying out this operation mas in all essential principles the one still employed in the early 1960s. A weighed quantity of the substance is heated in a tube filled with dry copper oxide, and the water and carbon dioxide are absorbed in weighed tubes filled with dried calcium chloride and potassium hydroxide solution or soda lime respectively. A current of dry air or oxygen is passed through the tube to sweep the products of combustion into the absorption apparatus.

In the absorption apparatus, water is collected in a glass-stoppered U-tube that is filled with calcium chloride (carefully freed from lime). Carbon dioxide is absorbed by the soda lime contained in a connected pair of U-tubes; the second limb of each tube contains a short filling of calcium chloride. The two soda lime tubes may be replaced by an apparatus in which the bulbs are charged with concentrated potassium hydroxide solution and the side tube filled with soda lime and calcium chloride. An apparatus for purifying the current of air or oxygen is connected with the anterior end of the tube; it consists of a series of washing cylinders charged with potassium hydroxide or sulfuric acid and tubes filled with soda lime or calcium chloride to remove moisture and carbon dioxide from the incoming gas. This apparatus is arranged in duplicate, one for the air and one for the oxygen supply. The copper oxide tube map be heated electrically or by any simple form of gas furnace.

The combustion tube and its copper oxide charge are thoroughly dried while the compound to be analyzed, its container (a platinum or porcelain "boat") and the collecting tubes are weighed. The fore part of the tube containing the oxidized spiral and the first six inches of copper oxide is cooled and the boat and its contents are then introduced into the anterior end of the combustion tube. A slow current of air is passed through the tube, and the burners under the oxidized spiral in the rear of the boat are lighted. The heating is gradually extended toward the boat, the object being to distill the contents of the boat, or the volatile products of decomposition, on to the cold copper oxide. where the combustion is completed. This most critical part of the operation must be car-

ried out very slowly and is finally completed in a current of oxygen that burns any residue of carbon left in the boat and reoxidizes the reduced copper oxide. After the oxygen in the apparatus is displaced by air, the absorption tubes are removed. closed, cleaned and allowed to cool in the balance room before being reweighed. From the weight of carbon dioxide and water yielded by the known weight of the compound, the percentages of carbon and hydrogen in the compound may be calculated.

The simple method described above applies to compounds containing carbon, hydrogen and oxygen only; if elements other than these are present the filling of the tube must be modified as follows: (1) Nitrogen present. The copper oxide spiral is replaced by a similar spiral of freshly reduced copper to reduce any oxides of nitrogen that may form during the combustion. The reduced copper is introduced into the previously cooled end of the tube before the absorption apparatus is attached. (2) Halogens, *sulfur* or arsenic present. The first six inches of copper oxide after the boat are replaced by a lead chromate cartridge. The container becomes oxidized in the preliminary heating of the tube; nonvolatile lead compounds are formed with the sulfur or arsenic in the compound, and sparingly volatile compounds are formed with the halogens. A short spiral of silver gauze should, therefore, be introduced at the posterior end of the tube when the compound contains halogens.

Estimation of Nitrogen.—The two methods used for the estimation of nitrogen are (1) the absolute method (Dumas), in which the nitrogen in a known weight of the compound is converted to the elemental form and determined directly; and (2) the Kjeldahl method, in which the nitrogen in a known weight of the material is reduced to ammonia and estimated volumetrically by titration.

The Dumas method consists of completely oxidizing a known weight of the compound by heating it with copper oxide in a tube in a current of carbon dioxide, passing the gaseous products of combustion over a heated copper spiral and collecting the nitrogen in a gas burette over strong potassium hydroxide solution. The amount of the substance used in an analysis should be sufficient to give about 20 ml. of nitrogen. The charged tube is placed in the furnace and connected with an apparatus for generating carbon dioxide and with a Schiff's nitrometer filled with a concentrated solution of potassium hydroxide. While the air in the apparatus is being displaced by carbon dioxide, the part of the tube containing the coarse copper oxide and reduced spiral is heated to dull redness. When no insoluble gas collects in the charged nitrometer, the current of carbon dioxide is stopped and the nitrometer is filled with the potassium hydroxide solution, which is allowed to overflow into the thistle funnel seal attached to the end of the capillary transferring tube. The burners under the copper oxide spiral are then lighted, and when this part of the tube is at a dull red heat, the heating is extended toward the mixture of the substance with copper oxide and so regulated that not more than three bubbles of gas are ascending the nitrometer tube at the same time. Finally, when all the burners are lighted, the tube has attained a uniform dull red heat and there is no further evolution of gas, a slow current of carbon dioxide is again passed through the tube to sweep out the remainder of the nitrogen. The nitrometer is then removed and the gas reduced to atmospheric pressure. The nitrometer tube itself may be calibrated; or after about 15 minutes the nitrogen is transferred to a eudiometer tube over boiled-out water; the eudiometer tube is then completely immersed in a tall glass cylinder that contains water and a thermometer. After about ten minutes the volume of the nitrogen (v), the temperature (t) and the barometer (p) are read. If p' is the tension of aqueous vapour under these conditions and w denotes the weight of substance taken, the weight of nitrogen in the compound is given by the expression

$$N = \frac{v}{w} \times \frac{273 \times (p - p') \times 0.12507}{(273 + t) \times 760}$$

The Kjeldahl method is used for the estimation of nitrogen in foodstuffs, therapeutic substances, fertilizers or other materials in which the amount of nitrogen is small and under circumstances in which many determinations must be carried out simultaneously and rapidly. The method consists of decomposing the organic material by heating it with concentrated sulfuric acid; the carbon is oxidized and the nitrogen converted to ammonium sulfate. which is afterward estimated in the usual manner by distillation (see AMMONIA: Detection and Estimation). A weighed quantity of the material (0.5 to 5.0. g.) is placed in a long-necked, pear-shaped flask of 500 ml. capacity, 20 ml. of concentrated sulfuric acid are added, the flask is clamped in an inclined position and the contents are heated gradually to avoid frothing. After the acid has been boiling for about 15 minutes, 10 g. of potassium sulfate are added and the heating is continued until the contents of the flask become clear and faintly straw coloured. Small quantities of certain metallic salts such as copper or mercuric sulfate or mercurous iodide may be added when materials that are not easily oxidized are being analyzed. Finally the cold acid liquid is transferred, with the washings of the flask, into the distilling flask of an ammonia distillation apparatus; after the contents of the flask have been made alkaline, the ammonia is distilled into a measured volume of standard sulfuric acid and is estimated by titrating the excess of acid.

The Kjeldahl method can also be applied to the analysis of pure organic compounds, provided those compounds that contain nitrogen combined directly with oxygen or with nitrogen, as in nitro-, nitroso-, azo- or diazo-compounds or hydrazines, are first reduced by a pretreatment with hydrogen iodide (hydriodic acid).

Estimation of Halogens.—The estimation of halogens involves the complete decomposition of the compound with the conversion of the halogen element into the halogen acid or one of its salts, which is subsequently precipitated and estimated as the silver salt. (1) Liebig's is the oldest method and the one that can be applied to the largest number of organic compounds. It consists of decomposing a weighed quantity of the compound by heating it to redness with a large excess of pure lime in a glass tube sealed at one end, plunging the hot tube into cold water, dissolving the lime and calcium halide in cold dilute nitric acid, filtering and estimating the halogen acid in the filtrate in the usual manner. (2) Stepanoff's method, as modified by Bacon, is applicable to compounds in which the halogen is readily eliminated as halogen acid by hydrolysis or by reduction. It consists of heating a weighed quantity of the compound with sodium and alcohol, and estimating the sodium halide in the resulting solution. (3) The method of Carius, as modified by Kuster, is the one most generally employed; it consists of the destructive oxidation of a weighed quantity of the compound (about 0.2 g.) by means of fuming nitric acid (2 ml.) in the presence of silver nitrate in a sealed tube at a temperature of 250°–270° C. The halogen is converted into the silver salt and is weighed as such.

Estimation of Sulfur.—The estimation of sulfur in organic compounds involves the destructive oxidation of the substance; the sulfur is converted to sulfuric acid and then is determined as barium sulfate. The two methods in general use are: (1) The method of Carius. in which the operation is carried out as for halogen; no silver nitrate is required but, since the oxidation is facilitated by the presence of a small quantity of bromine. a crystal of potassium bromide is placed in the tube containing the compound. The contents of the tube are diluted with water, the nitric acid is removed by evaporation and the sulfur is determined as barium sulfate precipitate. (2) The method of Asboth. in which the oxidizing agent employed is a mixture of sodium peroxide (three parts) and sodium carbonate (two parts). A weighed quantity of the substance (0.2 to 0.5 g.) is mixed with about 15 g. of the oxidizing mixture in a nickel crucible, which is then carefully heated until the contents become liquid. When cold, the melt is extracted with water and the soluble sulfate is estimated as barium sulfate.

Estimation of Phosphorus.—Organic compounds containing phosphorus are oxidized by fuming nitric acid, by concentrated nitric acid and potassium permanganate, or by chromic and sulfuric acids. The resulting phosphoric acid is precipitated as ammonium phosphomolybdate and subsequently weighed as magnesium pyrophosphate.

Estimation of Metals in the Salts of Organic Acids and Bases.—These may be determined by using the standard methods of quantitative inorganic analysis (see above).

The methods of quantitative organic analysis just described have now frequently been replaced by semimicro or micro methods except in certain industrial processes. In some cases they have been retained because the organic material to be examined is rather heterogeneous and a representative sample is difficult to obtain. They are still used, for example, in the analysis of some solid and liquid fuels, creosote and some plastic materials.

(M. A. W.; W. D. Os.)

D. Microanalysis

Chemical analysis becomes chemical microanalysis when the quantities of substance examined are in the 1–5 mg. range. It is customary to use the terms semimicro, micro or ultramicro with reference to the following amounts of material: semimicro (20–50 mg.), micro (1–5 mg.). Ultramicro refers to trace analysis on the microgram (gamma) scale.

The emergence of microchemistry and microanalysis as a separate discipline was the result of the teachings of Friedrich Emich who, about 1893, started a systematical development of micromethods of chemistry by embarking on a study of all kinds of chemical experimentation on an ever-smaller scale. He showed that only the techniques of handling, observing and measuring must be changed when extremely small quantities are being used. Emich developed micromethods of chemistry not only for qualitative and quantitative analysis but also for preparatory work, physicochemical studies and lecture demonstration.

Since most information regarding matter is derived from visual impressions, the microscope must be employed whenever the amounts of material become very small. The microchemical balance by W. H. Kuhlmann in Hamburg, Ger., was adopted for service in microanalysis because of its comparatively large carrying capacity of 20 g., which is required for the weighing of absorption tubes or organic combustion analysis. A variety of microbalances with beams of vitreous silica and using different principles for weighing (elasticity and torsion forces, buoyant effect, electromagnetic attraction) have been designed. (See Physical Methods above.)

Microanalytical analysis by spectroscopy, spectrophotometry, colorimetry, fluorimetry, nephelometry, polarography, radioactivity, chromatography and microbiological assay possess in certain instances high specificity and extraordinary sensitivity that give these methods a supreme position for the determination of trace constituents. Application of the methods on a small scale further increases their efficiency, and truly amazing limits may be obtained. Spectrophotometric measurements have yielded a sensitivity of 0.1 milligamma (nanogram), or 10^{-10} g. A. E. Mirsky and A. W. Pollister have performed colorimetric measurements on the microscopic image of tissue-thin sections, and they were able to measure as little as 0.0001 milligamma of tyrosine. Small-scale application of microbiological assay allows accurate estimations of quantity with less than 1 milligamma of certain substances.

1. Qualitative Microanalysis.—Modern inorganic qualitative analysis is frequently done on a semimicro (centigram) scale; results are confirmed by spot tests. In at least one instance the milligram scale has been adopted and the confirmatory tests are observed under the microscope. Schemes of analysis, including those for rare elements, are available on the semimicro as well as on the milligram scale. A technique for efficient work on the microgram scale, with sensitivities from 1 to 10 milligammas for the confirmatory tests, was developed during the 1930s. Most operations are performed under the low-power stage of the microscope with simple manipulators having rack-and-pinion motions. The microgram technique is, of course, applicable to general chemical experimentation, and it has been used in the study of the chemistry of small quantities of elements produced synthetically or obtained as a consequence of nuclear fission processes. Since most of the work is done by remote control, the technique is especially attractive for work with highly radioactive material.

Since each element produces its own characteristic emission spectrum, an examination of the spectrum of a substance reveals the identities of the elements present. The delicacy of the method transcends that of most sensitive chemical reactions. The presence of $\frac{1}{100,000}$ part of a milligram of lithium may be revealed in this way; or $\frac{5}{100,000}$ of a milligram of the rare gas neon, which is present in the atmosphere, may be detected. The metallic elements, gallium, rubidium, indium, cesium and thallium were discovered with this technique. The absorption spectra of many inorganic and organic substances are also characteristic and are widely used for the identification of small amounts of material. (See Spectrochemical Analysis: *Emission* Spectrochemical Analysis; Spectroscopy: Emission Spectra.)

Spot tests are widely employed. They are purely chemical methods that depend upon the production, when reagents are added to the sample or to its solution, of (1) colorations or colour changes; (2) precipitates having characteristic odour, colour or crystalline form; or (3) gases or liquids that can be distilled and identified. These tests, many of which are very delicate, may be specific for particular compounds, radicals or elements, or for groups of these. Thus, the presence of 1 part of copper in 100,000,000 parts of water is shown by the blue colour produced on the successive addition of alcoholic hydrogen peroxide and guaiacum resin in pyridine. The presence of 1 part of gold in 20,000,000 parts of solution is revealed by the yellow coloration given with *o*-tolidine. Prussic acid (1 part in 2,000,000 of air) may be detected by the blue colour it gives on a test paper moistened with a solution containing o-tolidine, acetic acid and copper acetate. There are many hundreds of such tests, some of which are also quantitative.

Schemes of organic qualitative analysis may be carried out on a centigram or milligram scale with microtechniques developed mostly by Emich and his co-workers and spot tests devised by Feigl.

2. Quantitative Microanalysis of Organic Compounds.—The milligram procedures for organic analysis (determination of carbon, hydrogen, nitrogen, oxygen, sulfur, halide, phosphorus and metallic constituents) have almost displaced the old macromethods, and the same may be said of the micromethods for the determination of the functional groups in the molecule. Economy with regard to the material under investigation has become progressively more important as organic chemistry has turned to the study of biochemical problems. The superior reliability and general efficiency of the micromethods were no longer questioned in the early 1960s. The original methods of Pregl are still widely used with and without modifications. There is a trend toward mechanizing organic analysis with the use of automatic furnaces.

A brief outline of one of the more important microanalytical procedures is given below:

Determination of Carbon and Hydrogen.—A weighed quantity (three to five milligrams) of the substance, placed in a small platinum boat, is burned in a current of dried oxygen in a hard-glass combustion tube. The tube is 40 cm. in length and contains a filling of chemicals designed to arrest the escape of nitrogen, sulfur, halogens and other products that might vitiate the analysis. The remaining gaseous products of the combustion, water and carbon dioxide, are swept over with air and are retained in separate water-absorbing and carbon dioxide-absorbing tubes that are weighed before and after the experiment. From the gains in weight of these tubes, the amounts of hydrogen and carbon in the original material are calculated. The gas pressures at different points of the apparatus are carefully regulated, and the temperature of lead dioxide placed at the exit of the combustion tube to insure maximum combustion is maintained at 180° C. by an external heating device. Practically all classes of organic substances may be analyzed for carbon and hydrogen with great accuracy in this type of apparatus.

3. Microanalytical Apparatus and **Micromethods.**—Complicated separations involving rare elements followed by the determination of the isolated constituents have been carried out on the milligram scale. The most flexible technique of filtration is provided by the use of Emich's filterstick, an immersion filter

consisting essentially of a tube with a filter mat near its lower (immersed) opening. The foundation for gravimetric work on a microgram scale has been laid by Emich's systematic investigations on highly sensitive microbalances with beams of vitreous silica. Little progress had been made in the early 1960s beyond the performance of simple residue determinations and electrolytic precipitations.

A systematic investigation of titrimetry, predominantly on the milligram scale, was carried out by J. Mika. Titrimetric and colorimetric methods are, however, widely used on the microgram scale. Various burettes have been developed for the purpose; some use the principle of the injection syringe and others rely on the surface tension force originating in the fine tip to take the place of the stopcock of the customary burette. With the latter type it is possible to dispense and measure volumes of standard solutions down to 0.0000002 ml. by adopting the injection technique of the microbiologist and performing the titration in the field of a microscope.

Micromethods for the determination of density, some based on the use of pycnometers and some based on the principles of the floating and falling drop methods, have been applied to the determination of heavy water and to various biochemical studies. Of the gas volumetric and manometric procedures, the very sensitive technique of D. D. van Slyke demonstrated its great versatility. An ingenious adaptation of the principle of the Cartesian diver for gas volumetric determinations on a microgram scale was made by K. Linderstrom-Lang.

Micromethods for the analysis of small samples of gases. originally introduced by C. Timiriazeff and A. Krogh, have been variously modified and refined for use in connection with chemical, industrial. biological and medical work.

4. **Chromatographic** Analysis. — Chromatography, which is widely used in microanalysis, is the general term for several related techniques that are used for separating the components of a mixture by a process involving differential migration. The discovery of partition and paper chromatography was one of the major advances in technique made in chemistry, biochemistry and allied subjects. An equally important development was the introduction of gas chromatography. These are discussed in detail elsewhere (see CHROMATOGRAPHY). (A. A. B.-P.; W. D. Os.)

E. Gas Analysis

The field of gas analysis in a broad sense embraces the sampling and determining of all types of gaseous substances. The applications of such analyses are many and varied. The following are a few typical examples: (1) evaluation of toxicity hazard of a particular gas in a specific place, such as carbon monoxide in a vehicular tunnel; (2) determination of the composition of fuel gases to ascertain heating value or for control of plant operations, flue gases to evaluate efficiency of combustion, exhaust gases from internal-combustion engines to establish proper carburetor adjustment for maximum efficiency and mine gases to evaluate explosion hazard and quality of air; and (3) determination of products of combustion of various types of materials to ascertain toxic constituents formed.

Gas analysis is treated as a special branch of analytical chemistry because the manipulation of gases involves the use of specialized apparatus. The methods are of two main types: those that depend upon volumetric determination of the components of a mixture; and those that rely upon physical methods such as infrared spectroscopy and mass spectrometry for their qualitative and quantitative determination. Outstanding developments have taken place in the application of physical methods to gas analysis and this, coupled with the discovery of gas (vapour phase) chromatography, has provided a challenge to the older methods of gas analysis. However, many of the older volumetric methods were still used in the early 1960s because they do not require the use of expensive electronic equipment.

The classical methods of gas volumetric analysis such as those using the Orsat apparatus or the Bone and Wheeler apparatus depend upon the selective removal of the constituents by suitable absorption reagents. In the Orsat method, the composition of the sample can be determined from the known original volume of the gas sample and the known volume of each constituent measured under standard conditions of temperature and pressure. In the Bone and Wheeler method, the volume is kept constant and changes in pressure associated with the removal of each constituent by absorption are determined. The latter method is more accurate.

The applicability of these methods of volumetric gas analysis depends upon the availability of suitably selective absorbents. In some cases, as with the saturated gaseous hydrocarbons (*e.g.*, methane or ethane) and with hydrogen, methods dependent upon absorption cannot be used directly and in these cases the change in volume associated with oxidation and absorption of the oxidation products is used to determine these gases. With mixtures of saturated hydrocarbons, analysis by combustion methods is not very satisfactory and physical methods are often employed.

Methods of gas analysis have also been designed in which the amount of absorbed gas is determined by: (1) titration (*q.v.*) of the absorbed gas with a suitable reagent as in acidimetric or iodimetric titration; (2) colorimetric methods (see COLORIMETRY); and (3) gravimetric methods as in the determination of carbon dioxide by its conversion to barium carbonate.

This discussion is limited to some typical gas analysis methods and does not include descriptions of specialized techniques such as that of Van Slyke for the determination of gases in biological fluids or Warburg's apparatus for studying the production or absorption of gases in biochemical reactions.

Sampling.—It is often extremely difficult to secure a representative sample of a gaseous mixture; various methods have been devised to reduce this potential source of error. These include the snap collection of samples in evacuated tubes or the displacement of air or a liquid such as mercury, water or brine from a vessel. When gas samples are collected it is particularly important to avoid contamination with air; errors due to solubility are possible with methods that involve liquid displacement with liquids such as water.

1. Gas Volumetric Analysis. — These methods usually require the use of solutions that specifically absorb certain constituents. Such absorbents include aqueous sodium hydroxide or potassium hydroxide for carbon dioxide, fuming sulfuric acid or bromine water for unsaturated hydrocarbons, alkaline pyrogallol for oxygen and chromous chloride for carbon monoxide. Hydrogen is removed by oxidation to water by using heated copper oxide at 270°–280° C. Saturated hydrocarbons are oxidized by copper oxide-iron oxide at 580°–600° C. to carbon dioxide and water.

Tno basic procedures are used to absorb the gases; in one the absorbent is confined in a vessel or pipette into which the gas is passed for absorption, and in the other the absorbent is added to the gas in the burette or auxiliary vessel. The absorbent in the pipette is used to analyze a number of samples, whereas when the absorbent is added to the burette or auxiliary vessel it is used only once.

The Hempel, Orsat and Haldane apparatus are examples of the former. and the Elliott and Morehead are examples of the latter. In the Hempel apparatus the burette and pipette are separate. The appropriate pipette is connected to the burette for each specific constituent.

In the Orsat and Haldane apparatus a series of pipettes is securely attached to the burette through a manifold to make an integral unit.

As a discussion of all types and modifications of apparatus that utilize these principles would be too extensive, only typical examples are described.

2. Orsat Type of Gas Analysis Apparatus. — The Orsat type of gas analysis apparatus is designed for various applications that range from small compact portable types with only one or two pipettes to large laboratory models having a half dozen or more pipettes.

The Orsat type of gas analysis apparatus consists essentially of: (1) burette. (2) pipettes, (3) copper oxide tube, (4) confining liquid, (5) compensator tube and (6) a water jacket for the burette and compensator tube. The burette is a cylindrical glass

tube of 100 ml. capacity with carefully calibrated graduation marks to permit reading of gas volumes to a fraction of a millilitre. The burette is closed at the top with a stopcock, and the bottom is connected by a rubber hose to a reservoir for the confining liquid. The confining liquid may be water, a salt solution or mercury. As gases may dissolve in water or aqueous solutions, mercury is preferred and usually is employed in laboratory apparatus. Acid water or salt solutions are usually employed in portable units. The number and type of pipettes depend on the type of work to be done, but laboratory models usually have pipettes for the removal of carbon dioxide, illuminants, oxygen, carbon monoxide and for slow combustion of methane and ethane. The copper oxide tube is for the oxidation of carbon monoxide and hydrogen. The confining liquid not only confines the gas in the burette but also draws the sample into the burette and forces it into the pipettes or copper oxide tube as required. Since the results of the analyses are based on change in volume due to absorption or combustion, it is essential that the volume of the sample is not changed because of changes in temperature, atmospheric pressure or water vapour. The water jacket surrounding the burette and compensator tube serves to control the temperature. Changes in pressure and water-vapour content due to slight changes in temperature are controlled by the compensator and by having a small amount of water on the mercury in the burette and in the compensator tube.

3. Analysis of Fuel Gas.—The use of the Orsat type of gas analysis apparatus for the analysis of a fuel gas offers a typical example of the application and technique of gas analysis. The analysis of a fuel gas may require determination of the following constituents: carbon dioxide, illuminants, oxygen, carbon monoxide, hydrogen, methane, ethane and inert gases, mainly nitrogen. Illuminants include a number of unsaturated hydrocarbons, such as ethylene, propylene, butylene, benzene, toluene and acetylene.

Since the constituents are removed one at a time it is necessary that the absorbent used for the first constituent does not remove any of the other components. In other words, the order of removal of constituents is important and is fixed by the reagents used.

The following is the order in which the gases are usually determined and the reagents or reactions that are commonly used for the determination of the various gases:

(1) Carbon dioxide	Absorbed with potassium hydroxide
(2) Unsaturated hydrocarbons	Absorbed with fuming sulfuric acid
(3) Oxygen	Absorbed with alkaline pyrogallol
(4) Carbon monoxide	Absorbed with acid or ammoniacal cuprous chloride and 2-naphthol-cuprous sulfate. Also determined by oxidation with heated copper oxide or by slow combustion with heated platinum spiral
(5) Hydrogen	Determined by oxidation with heated copper oxide or by slow combustion with oxygen
(6) Methane	Determined by slow combustion with oxygen
(7) Ethane	Determined by slow combustion with oxygen
(8) Nitrogen and other inert gases	Estimated by difference. Not determined directly

The potassium hydroxide solution is prepared by dissolving 30 g. of KOH in 100 ml. of distilled water. Sodium hydroxide also may be used; but it has the disadvantages of greater chemical action on the glass, and it forms a bicarbonate precipitate more readily than potassium hydroxide. The fuming sulfuric acid when fresh should contain 20% to 25% free sulfur trioxide. Bromine water (prepared by dissolving bromine in water until an excess of liquid bromine remains in the bottom of the pipette) also may be used to absorb unsaturated hydrocarbons but should not be used when mercury is used as the confining liquid. Alkaline pyrogallol is prepared by dissolving 50 g. of pure pyrogallol in 150 ml. of distilled water, and mixing with a solution containing 1,200 g. of potassium hydroxide in 800 ml. of water. The mixture should be immediately protected from the air. Oxygen may be absorbed by other reagents such as white phosphorus, chromous chloride or acetate, and sodium hydrosulfite. There are objections to the use of these reagents and therefore alkaline pyrogallol is usually employed. For the absorption of carbon monoxide, acid cuprous chloride (450 g. of chemically pure cuprous chloride dissolved in 2,500 ml. of concentrated C.P. hydrochloric acid) is frequently used, but 2-naphthol-cuprous sulfate is also used. The latter is prepared from cuprous oxide, 20 parts; sulfuric acid, 200 parts; water, 25 parts; and 2-naphthol, 25 parts.

4. Analytical Procedure.—Before an analysis is started, the apparatus should be checked to be sure that it is in proper operating condition. It should be tested for leaks to assure that the sample is not lost or diluted with air. A small amount of water should be placed in the burette and in the compensator tube. The air in the compensator tube should be adjusted to atmospheric pressure. The capillary tubes of the manifold through which the sample is passed to the pipettes and copper oxide tube should be swept free of air by drawing a sample of air into the burette, absorbing the oxygen in the alkaline pyrogallol solution and then passing the residual inert gas through the apparatus.

To obtain a sample for analysis, the mercury reservoir or leveling bulb is raised to free the burette of air. The burette is then connected to the gas sample container with capillary tubing and the leveling bulb lowered to draw the sample into the burette. The stopcock at the top of the burette is closed and the volume of gas in the burette is read at atmospheric pressure by adjusting the mercury in the leveling bulb and burette to the same level. The analyst is now ready to proceed with the analysis.

Carbon Dioxide.—The stopcocks are aligned so that the sample can be forced, by raising the leveling bulb, from the burette into the pipette that contains the potassium hydroxide. The leveling bulb is alternately lowered and raised in order to pass the sample back and forth from the burette to the pipette. This procedure facilitates absorption of the carbon dioxide, which should be completely removed after four or five passes into the pipette. The leveling bulb is finally lowered until the potassium hydroxide reaches a mark on the capillary at the top of the pipette. The stopcock to the pipette is then closed and the volume of gas in the burette read as previously described. The decrease in volume is due to removal of carbon dioxide since the other constituents are not absorbed. If the original volume of the sample was 100 ml., and after removal of carbon dioxide the volume was 98 ml., then the amount of carbon dioxide present in the sample was 2 ml. or 2 parts in 100, that is, 2% by volume.

Unsaturated Hydrocarbons.—The stopcocks are now aligned so that the sample can be passed into the pipette containing the fuming sulfuric acid. The sample is passed into the pipette three or four times as described for carbon dioxide. However, before the volume is read, the sample is passed once or twice into the potassium hydroxide pipette to remove any sulfur trioxide vapours removed from the fuming sulfuric acid. The volume of the residual gas is then read on the burette. If the reading is 95 ml., then 3 ml. (98 minus 95) or 3% unsaturated hydrocarbons are present.

Oxygen.—The procedure described for carbon dioxide and unsaturated hydrocarbons is repeated; the sample is passed into the pipette containing the alkaline pyrogallol 6 to 12 times, depending on the concentration of oxygen in the sample. If the burette reading has decreased from 95 to 94 ml., then the sample contains 1 ml. or 1% oxygen.

Carbon *Monoxide*.—The procedure used for the previous constituents can be used for determining carbon monoxide by passing

Typical Values for Individual Constituents of Several Kinds of Fuel Gas

Kind of gas	Carbon dioxide	Unsaturated	Oxygen	Carbon monoxide	Hydrogen	Methane	Ethane	Nitrogen
Natural	..	..	..	..	..	85.5	13.5	1.0
Blast furnace	10.8	..	..	28.2	0.8	..	..	60.2
Producer	5.6	..	0.4	25.4	15.2	1.4	..	53.0
Coal	2.1	3.3	0.4	8.2	50.5	28.6	..	6.9
Water (blue)	5.2	..	0.6	41.5	48.7	1.4	..	3.6
Carburetted water	2.7	9.2	0.1	33.6	35.2	12.4	..	6.2
Coke oven	1.9	3.5	0.3	6.4	52.5	30.6	..	4.8

Information on the composition of a fuel gas can be used in various ways; for example, by calculating the heating value and specific gravity of the gas, data that are essential for the safe and efficient utilization of gaseous fuels

the sample five or six times into a pipette containing one of the absorbents for carbon monoxide. The percentage present is calculated in the same way as for carbon dioxide.

Carbon monoxide also may be determined by oxidation with copper oxide as described below.

Hydrogen and Carbon *Monoxide.*—The stopcocks are aligned so that the residual sample can be passed through the copper oxide tube, which is heated by means of a small furnace to from 290° to 310° C. The sample is passed through the copper oxide tube slowly (about 10 ml. per minute) and returned to the burette. This operation is repeated and the contraction in volume noted. The carbon dioxide produced by the oxidation of carbon monoxide is then determined as prescribed previously for carbon dioxide. The reactions that take place are as follows:

$$\mathrm{Ha} + \mathrm{CuO} \rightarrow \mathrm{H_2O} + \mathrm{Cu}$$
$$\mathrm{CO} + \mathrm{CuO} \rightarrow \mathrm{CO_2} + \mathrm{Cu}$$

Thus for hydrogen there is a decrease in volume equal to the amount of hydrogen in the sample since the water formed condenses and occupies a negligible space. The carbon monoxide produces an equal volume of carbon dioxide and therefore no change in volume. The volume of hydrogen in the sample equals the contraction of the sample after oxidation and the volume of carbon monoxide is equal to the volume of carbon dioxide produced.

Methane and Ethane. — At this stage in the analysis the residual gas may consist of methane, ethane and inert gases, mainly nitrogen. Since methane and ethane require oxygen for combustion, it is necessary to add oxygen. The residual gas is stored in the potassium hydroxide pipette and an excess of oxygen necessary for combustion of the methane and ethane is carefully measured in the burette. The oxygen is passed into the combustion pipette and the residual gas returned to the burette. The platinum spiral at the top of the combustion pipette is heated electrically to a bright yellow and the residual gas passed slowly (about 10 ml. per minute) into the combustion pipette, Methane and ethane are oxidized to carbon dioxide and water according to the following equations:

$$\mathrm{CH_4} + 2\mathrm{O2} \rightarrow \mathrm{CO_2} + 2\mathrm{H_2O}$$
$$2\mathrm{C_2H_6} + 7\mathrm{O_2} \rightarrow 4\mathrm{CO_2} + 6\mathrm{H_2O}$$

On the basis of these reactions, the percentages of methane and ethane can be calculated as follows:

$$\% \text{ ethane} = \frac{(2 \times \text{carbon dioxide} - \text{contraction}) \times 100}{1.5 \times \text{ml. sample taken}}$$

$$\% \text{ methane} = \frac{(\text{carbon dioxide} - 2 \times \text{ethane}) \times 100}{\text{ml. sample taken}}$$

The sum of the percentages of all the constituents determined is then subtracted from 100 and the remainder is the percentage of nitrogen or inert gas in the sample.

In presenting the analytical procedure, only the basic steps have been described and no attempt has been made to incorporate numerous minor steps that are necessary to obtain accurate results.

5. Haldane Apparatus. — Another gas volumetric apparatus widely used for the analysis of mine atmospheres and samples that contain small quantities of carbon dioxide, combustible gases and oxygen. with an accuracy greater than that obtainable with the apparatus of the type previously described, is known as the Haldane apparatus. The basic principles of the apparatus and procedures are the same as for those of other gas volumetric methods of analysis. The conventional apparatus consists of a water-jacketed burette and compensator, with two absorption and one combustion pipettes. The burette consists of an ungraduated bulb at the top having a volume of 15 ml. and a stem with a volume of 6 ml. graduated to 0.01 ml. Samples to be analyzed must not contain an explosive mixture of combustible gases. and there must be sufficient oxygen in the sample to burn completely all the combustible gases. Carbon dioxide is removed first. then the combustibles (methane, hydrogen and carbon monoxide) and finally oxygen. The oxygen determined is that remaining after combustion, and therefore it is necessary to add the amount consumed by the combustion. Calculation of results is essentially the same as for the Orsat type of apparatus.

6. Bone and Wheeler Method. — This method of constant volume gas analysis. devised by W. A. Bone and R. V. Wheeler (1908). is based on selective absorption in a single vessel. The reagent for a single constituent is added to the vessel, the constituent is removed and the change in pressure at constant volume is measured. The reagent for that constituent is removed and the process is repeated with a reagent for another constituent. The method is still used for gas analysis although it has been modified a number of times. The most important modifications were made by W. J. Gooderham (1938) and include an alteration to the absorption pipette and the use of better absorption reagents. Gooderham also described (1957) a constant volume gas analysis apparatus that includes further modifications.

7. Gooderham's Method. — In this method, a stream of gas is bubbled through a series of absorbent solutions. Between each absorbent is a device for measuring the reduction in volume resulting from the selective removal of each constituent. The device is a flowmeter and is essentially a glass tube along which a soap film travels: by measuring the change in the rate of movement of the soap film it is possible to calculate the reduction in volume. The analysis of coal gas by this method can be completed in 10 minutes with a high degree of accuracy (error less than 0.1%).

8. Thermal Conductivity Method. — This method, which may be used to analyze simple mixtures. depends upon the fact that the rate of loss of heat from an electrically heated wire is dependent upon the nature of the gaseous medium surrounding the wire. Changes in the temperature of the wire will produce changes in electrical resistance that can be determined by a Wheatstone bridge arrangement. The instrument is empirically calibrated beforehand by standard mixtures and can then be used for quantitative analysis.

9. Low-Temperature Distillation Method. — In this method the components of a mixture that are gaseous at normal temperatures are separated by fractional distillation. Distillation is achieved by cooling to low temperatures with refrigerants such as liquid air; with this method it is possible to separate mixtures of gases with boiling points in the range −190° C. to +40° C. and to operate in "closed" high-vacuum pas analysis equipment. Quantitative measurements are made with a McLeod gauge and gases, are circulated and collected by pumps.

10. Mass Spectrometry and Infrared Spectroscopy. — These methods are extensively used in gas analysis. particularly for the analysis of hydrocarbon mixtures. They are important for the control of processes in the petroleum cracking industry.

11. Gas Chromatography. — The usual arrangement for analytical gas chromatography is a column filled with a porous granular solid, the pores of which contain an organic liquid with a high boiling point. The column is enclosed in a box equipped with a thermostat and an inert carrier such as helium or argon is passed through the column. The sample is injected and is transmitted by the carrier gas through the column by a process involving partition between the stationary liquid phase and the moving gas phase. The constituents of the sample as they emerge are detected by a suitable physical method such as their effect upon thermal conductivity. Qualitative identification is achieved by comparison with known compounds; quantitative estimations of the material present also can be made.

CHEMISTRY, SOCIETIES OF. Chemical organizations are among the most active agencies for promoting the increase and diffusion of chemical knowledge. At first the chemists functioned purely within such general scientific bodies as the Royal Society of London. In the closing decades of the 18th century, however. a few chemical societies sprang up in England, Scotland and the United States. Some doubt exists as to the order of priority in which these societies were formed but the most likely sequence seems to be: a London chemical society (1782); a chemical society at the University of Edinburgh (1785) composed of the students of Joseph Black; a chemical society at the University of Glasgow (1786); a chemical society in Manchester (prior to 1787); the Chemical Society of Philadelphia, founded by James Woodhouse (1792); another chemical society in Glasgow (1798); and a chemical society in Edinburgh (1800).

In the more industrialized areas in Europe, South Africa and the United States, permanent chemical societies developed before 1900 to provide a means for exchange of practical and theoretical knowledge All these organizations have similar origin. and all foster original research and dissemination of new knowledge through publications, meetings, lectures, grants for research and medals for meritorious work. In 1841, 25 men. among them Sir William Robert Grove and Lyon Playfair, met in London to promote a chemical society. Robert Warrington was a moving spirit and Thomas Graham the first president. A royal charter was granted in 1848 to this group, to be known as "The Chemical Society for the advancement of Chemical Science as intimately connected with the prosperity of the manufactures of the Cnited Kingdom, many of which depend upon the application of chemical principles and discoveries for their beneficial development and . . . economical application of the industrial resources and sanitary condition of the community." Its principal publications are the *Memoirs, Quarterly,* and *Journal of the Chemical Society* and *British Abstracts.* The society has one of the largest chemical libraries in the world, including the Roscoe collection of alchemical and early chemical works. The Royal Institute of Chemistry was founded in 1877 with high membership standards to promote efficiency among its members and interest throughout the country.

In 1857, with the British society as a model, three lecture demonstrators invited seven men to study means of communication between the foreign chemistry students in the Paris laboratories. This endeavour grew into the unification of all chemists in France in the Société Chimique de France. By Dec. 1858 the membership was extended to older men and an illustrious group was elected as officers. J. B. Dumas was president, Louis Pasteur and A. Cahours vice-presidents, C. A. Wurtz secretary and F. S. Cloez the treasurer. The official organ is the *Bulletin de la société chimique de France.*

One hundred persons attended the organization meeting of Der Deutschen Chernischen Gesellschaft in Nov 1867. This was called by a provisional committee. The speaker, Adolph Baeyer, regarded the time propitious for a union of Berlin chemists August Hofmann, who was familiar with the British society. was temporary president. He recommended an alliance between theorists and industrial chemists who welcomed scientific assistance. In full session in Jan. 1868, Robert Wilhelm von Bunsen, Justus von Liebig and Friedrich Wohler. who lent their ponerful support. were elected honorary members. The society. reorganized as Gesellschaft Deutscher Chemiker in 1946, publishes *Angewandte Chemie* and sponsors *Chemisches Zentralblatt* and Beilstein's *Handbuch der organischen Chemie.* Its journal is *Chemische Berzchte* (known prior to 1947 as *Berichte der deutschen chemzschen Gesellscha jt).*

In the United States, the short-lived Columbian Society of Philadelphia, founded in 1811, antedated the American Chemical society. To celebrate the 100th anniversary of the discovery of oxygen by Joseph Priestley, a pilgrimage to his home in Northumberland, Pa.. was made by 77 chemists in 1874. Friendly relations then stimulated a group of New York chemists to found the society two years later under the presidency of J. W. Draper. The society's principal journals and their founding dates are *Journal of the American Chemical Society* (1876), *Chemical Abstracts* (1907), *Chemical and Engineering News* (1923), *Industrial and Engineering Chemzstry* (1909), *Analytical Chemistry* (1929), and *Journal of Agricultural and Food Chemistry* (1953). The society also publishes the *Journal of Physical Chemistry* and the *Journal of Organic Chemistry.*

There are separate societies for industrial chemistry. chemical engineering, electrochemistry and other specialized fields. An International Congress of Pure and Applied Chemistry was organ-

ized in Brussels in 1894. The present International Chemical Union of Pure and Applied Chemistry was started in 1919.

CHEMNITZ (KEMNITZ), **MARTIN** (1522–1586), the leading German Lutheran theologian of the late 16th century, known (with reference to Martin Luther) as "the second Martin," was born at Treuenbrietzen, Brandenburg, Nov. 9, 1522. He attended the universities of Frankfurt an der Oder (1543) and If'ittenberg (1545), where he became a protégé of Philipp Melanchthon and studied chiefly mathematics, branching out into the then respectable field of astrology. He took his master's degree at Konigsberg (Kaliningrad), where a subsequent appointment as ducal librarian (1550) gave him the opportunity for theological studies. Back at Wittenberg (1553), he began to lecture on Melanchthon's *Loci communes.* In 1554 he received holy orders in order to become co-adjutor to Joachim Mörlin, whom he succeeded (1567) as superintendent of the churches of Brunswick, the post that he held the rest of his life. In 1568 he took a doctorate in theology at Rostock and with Jakob Andrea began the Reformation of the duchy of Brunswick-Wolfenbüttel. For another decade the two worked together for the reunion of the Lutheran Church; the document that achieved this end, the *Formula of Concord* (1577), is chiefly their work. Ill-health forced Chemnitz to retire in 1584; he died April 8, 1586.

Chemnitz' importance may be measured by his Roman Catholic opponents' epigram: *Si Martinus non fuisset, Martinus* vix *stetisset* ("If Martin [Chemnitz] had not come along, Martin [Luther] would hardly have survived"). His great contribution was the building of a bridge between Luther's and Melanchthon's theologies. His main works are: a defense of the Lutheran doctrine of the real presence of Christ's body and blood in the Eucharist (1561); a systematization of the biblical and patristic data on the relation of the divine and human natures in the single person of Christ (1570); *Examen Concilii Tridentini* (1565–73), the classic Lutheran analysis of the doctrinal decisions of the Council of Trent (1545–63); and an extended but incomplete presentation of his theology in the form of a commentary on Melanchthon's *Loci* (edited in 1591, after his death).

CHEMNITZ: *see* KARL-MARX-STADT.

CHEMOTHERAPY is the treatment of infectious or parasitic diseases by chemical compounds. The word was coined by Paul Ehrlich (*q.v.*) in Germany, and it provided a distinction from the treatment of such diseases with serums and vaccines. It is generally used in this sense, though there is a tendency to broaden its scope to include the chemical treatment of nonparasitic diseases.

Until the end of the 19th century, most drugs were derived either from minerals or from plants. The researches of Louis Pasteur in France and Robert Koch in Germany laid the foundations of bacteriology, which found its first practical application in medicine when Joseph Lister (later Lord Lister) at Glasgow in 1865 introduced antiseptic surgery, using phenol (carbolic acid) as the disinfectant. It was Ehrlich; however, who made the greatest contribution to the science he named. The problem was to produce a disinfectant which would destroy parasites within a living animal without serious damage to the host.

William H. Perkin, in England, made the first aniline dye as a result of abortive attempts to synthesize quinine, the sole antimalarial drug available at that time (1856). About 30 years later, by a curious paradox of history, Ehrlich found that a synthetic dye, methylene blue, has antimalarial properties. He had been led to this by a study of the specific staining of organs of an animal or of a parasite following the injection of a synthetic dye. From these studies there emerged in 1901–04 Ehrlich's well-known "side-chain" theory, in which he sought for the first time to correlate the chemical structure of a synthetic drug with its biological effects. In 1903 Ehrlich invented a dye, trypan red, which was the first drug to show activity against trypanosomal infections in mice. Ehrlich's greatest triumph; however, was the discovery of the organic arsenical drug salvarsan, which proved to be effective in the treatment of syphilis (1910). Largely as a result of the energetic pursuit of chemotherapy by German industrial concerns, other important chemotherapeutic agents followed, and it is perhaps not surprising, historically, that these were mainly remedies for tropical diseases. Of great importance among these was Atabrine (mepacrine), which was widely used during World War II as an antimalarial agent but which was largely superseded later by drugs such as proguanil (Paludrine) and chloroquine. Chemical compounds of varying types also were developed for the treatment of trypanosomiasis (African sleeping sickness).

For many years the search for an antibacterial chemotherapeutic agent proved elusive, but authoritative pronouncements on the improbability of this ever being achieved were confounded by the discovery of Prontosil in Germany in the early 1930s. This was the forerunner of the sulfonamide drugs, which came to be widely used for the treatment of bacterial infections in man and domestic animals (*see* SULFONAMIDES). Other important synthetic drugs used in the treatment of bacterial infections are p-aminosalicylic acid and isonicotinic hydrazide, both employed in the treatment of tuberculosis.

The discovery of penicillin (*q.v.*) by Sir Alexander Fleming in England in 1928, and its practical development by Sir Howard Florey and his associates at Oxford (1940), marked another important advance in bacterial chemotherapy. Penicillin was the first of the so-called antibiotics, which are chemical products of fermentations, and it was followed by other important antibiotics such as streptomycin, the tetracyclines and the macrolides. Research in this field is intense and the production of antibiotics is a large industry. (*See* also ANTIBIOTICS.)

Apart from the antiprotozoal and antibacterial drugs, there are synthetic chemotherapeutic agents to combat other types of parasitic diseases, such as those caused by worms in domestic animals and man. The outstanding problem awaiting solution at the beginning of the 1960s was the chemotherapy of virus infections, though diseases caused by certain of the larger viruses had already shown themselves amenable to chemotherapy. The treatment of parasitic diseases of plants by means of chemicals remained mainly in the disinfectant stage. After World War II, however, there were attempts to develop plant chemotherapy, whereby chemicals which are poisonous to insects or fungi (but not to the plants themselves) are absorbed and translocated within the plants. *See* also PHARMACOLOGY.

CHEMULPO (INCH 'ŏN), seaport and industrial centre in central Korea, near the mouth of the Han river, is 25 mi, W.S.W. of Seoul. Connected with Seoul by rail lines: it serves as the city's chief seaport.

Formerly a small fishing village, it became one of three treaty ports opened in 1883. During Japanese occupation (1910–45) modern industries and port facilities were developed and tidal basins constructed to overcome 33-ft. differences in tide levels. Successful UN landings at Inch'on crippled the North Korean invasion in mid-September 1950 (see KOREAN WAR). After the Korean war. a plate glass factory, an iron and steel plant, and new docks. constructed with U.S. and UN economic aid, increased the yearly port capacity to 2,300,000 tons. Other industries are chemicals, lumber and rice cleaning. Pop. (1960) 302.009. (S. McC.)

CHEMURGY is the application of the sciences, particularly chemistry, to the industrial utilization of farm products. The name, coined in 1935, is derived from two Greek words that may be freely translated as chemistry at work. The term farm chemurgy is frequently used.

The farm chemurgic movement rose in the United States because of t e distress caused by the enormous crop surpluses blocking the farmers' market in the late 1920s and middle 1930s. It was started in 1935 by a group of industrialists and agriculturists, who proposed to meet this problem in three ways: (1) by discovering new uses for established farm crops; (2) by developing new crops for acreage devoted to surplus crops; and (3) by more profitable use of farm wastes; better described as farm residues.

In a broad sense, most farm crops go into industry, but in a manner based largely on the old uses. food, clothing and shelter. These uses have not changed essentially since the middle of the 19th century. They have only been made more complex by the coming of the industrial age and the departure of most agricultural industry from the farm. The substitution of the power loom for farm weaving and the replacement of the home container by the tin can do not mean that more wool, cotton or farm produce are consumed than previously but merely that they are used elsewhere and travel farther than they did in the days when wool moved almost directly from the back of the sheep to the back of its owner.

Many factors contributed to build up the burdensome crop surpluses of the 1920s and 1930s. The advent of automobiles and tractors and the departure of the horse left available for other crops the approximately 30,000,000 ac. formerly devoted to forage crops in the United States, while the markets for nonforage crops remained about the same. The development of high-yielding crop varieties, the extensive use of fertilizers and the application of other improvements resulting from research led to greater farm productivity. Thus the farmers' productivity increased while the traditional uses for their products were about stationary or even diminishing.

At the beginning of the 20th century, the industrial utilization of agricultural raw materials for purposes other than foods and feeds began to receive the attention of many organizations in the United States. notably the U.S. department of agriculture. Much work was done on the manufacture of alcohol from starchy crops; on new crops for fibres, alcohol and oil; and on the production of paper and furfural from cornstalks, wheat straw, corncobs and other agricultural residues. Many of these investigations were completed on a laboratory and a pilot-plant scale.

At this point the farm chemurgic movement was started. A committee of those interested in improving the situation of the farmer—businessmen, agriculturists and scientists—mailed invitations for a conference. The first meeting, held at Dearborn, Mich., in 1933. resulted in the formation of the National Farm Chemurgic council (later called the Council for Agricultural and Chemurgic Research!, the central organization of the chemurgic movement in the United States.

The council's chief function is to encourage the advancement of chemurgic objectives. The council sponsors local and regional conferences at which representatives of agriculture, science and business discuss the chemurgic possibilities of the particular area. The discussions cover many fields, including industrial developments. new research achievements and suggestions for new crops. These activities have contributed to state, industry and government accomplishments in chemurgy. In fact, it can be said that the chemurgic movement is largely responsible for the biggest government venture in this field—the establishment of the four large regional research laboratories of the U.S. department of agriculture.

Leading to the establishment of the four laboratories nas the 1933 Bankhead-Jones bill, nhich provided funds for additional research in the department of agriculture and the state agricultural experiment stations.

The U.S. Regional Soybean Industrial Products laboratory, set up under the provisions of this bill in 1936. was a chemurgic laboratory devoted primarily to finding new industrial uses for the soybean. Its success in making paints, varnishes. plastics and fibres from soybeans led to a flood of other bills in congress proposing the establishment of similar laboratories to expand the industrial utilization of other crops.

These activities culminated in an amendment to the Agricultural Adjustment act of 1938 which authorized the establishment of the four regional research laboratories to study new uses for agricultural raw materials. These laboratories, sometimes known as the chemurgic laboratories. were designed according to the latest construction developments, including ample provisions for work on a semi-industrial scale. They cost. fully equipped, around $2,000,000 each. Accommodations were planned for approximately 400 scientists and auxiliary workers in each laboratory. The sites chosen were at Peoria, Ill.; New Orleans. La.; Philadelphia, Pa.; and Albany, Calif. The laboratories were appropriately named for the four points of the compass.

The commodities to be studied, chosen primarily from those in surplus. included: Northern laboratory: cereal crops. oilseeds of the region, agricultural residues; Southern laboratory: cotton, cottonseed, peanuts. sweet potatoes; Eastern laboratory: dairy products. tobacco, apples. White potatoes. vegetables. animal fats. hides. skins, tanning materials; Western laboratory: fruits, vegetables. alfalfa, wheat, poultry products.

The research of these four laboratories and their associated units. done co-operatively with industrial and many other organizations. has led to the creation of vast new wealth and benefits for agriculture. industry, national defense and consumers. The value of the commercial processes, machinery and products stemming from—or significantly aided by—their work amounted to billions of dollars.

Contributions included penicillin and other antibiotics; dextran. a blood plasma extender; the drugs rutin and quercetin; surgical sponge from starch; elastic bandage from cotton; certain vitamins; fibres from corn. peanuts and milk; new products from feathers; improved dried-egg products; new cotton-processing machinery; chemical fibres from cotton having new properties for specific end uses; improved wool products; synthetic rubbers and rubber chemicals; improved methods for making rubber from guayule; frozen citrus concentrates; fruit juice powders and new types of dehydrated foods; methods for recovering fruit essences; improved processes for tanning leather; apple sirup as a humectant for tobacco; new coatings from vegetable oils and pine gum, and industrial products from animal fats: detergents; antioxidants; synthetic lubricants; wax and chemicals from sugar cane; newsprint and paperboard from agricultural residues; and improved methods for processing oilseeds, pine gum and other crops.

While the direct. visible benefits of this work are certainly great. the indirect benefits—resulting primarily from the publication of several thousand scientific papers—are in all probability even greater.

Chemurgic research in other organizations, *e.g.*, state experiment stations. schools and industry, also has proved highly profitable. Important achievements resulting from this work include nylon from the chemical furfural, which is manufactured from oat hulls and corncobs; paper, newsprint and plastics from sugar cane bagasse; plastics and protective coatings from cotton linters; chemicals from corn; cortisone and related drugs; the chemical sorbitol and detergents from sugar; synthetic rubber from alcohol; chemicals for making rubber and resins from naval stores; fibres. protective coatings and plastics from castor oil; and chemicals from tall oil.

Favourable to the progress of chemurgy are the establishment

of new industries and the expansion of old ones that represent outlets for chemurgic products. For example. the chemical industry expanded about threefold during the first 15 years' existence of the four regional laboratories. This advantage is counterbalanced to some extent by the fact that competition from petroleum, natural gas and other raw materials is becoming stronger. The volume of research to make new and better products from these ran· materials is many times greater than that devoted to expanding and improving the utilization of farm crops.

Chemurgy, already successful, will continue to aid agriculture and improve living standards for all. Being based on the use of annually renewable raw materials, chemurgy will also enable nations to conserve their other resources.

See Wheeler McMillen, *New Riches From the Soil* (1946); *U.S.* Department of Agriculture, *Crops* in *Peace and War, Yearbook of Agriculture, 1950–1951* (1951). (C. H. FR.)

CHENAB (Sanskrit ASIKNI, Greek ACESINES), one of the "five rivers" of the Punjab. Its headwaters are the Chandra and the Bhaga, which rise southeast and northwest respectively of the Bara Lacha pass (16,047 ft.) in the Himalayas in India. The two unite at Tandi (7,500 ft.) as the Chandra-Bhaga or Chenab. The joint stream flows northwestward for 100 mi. in the trough formed by the Great Himalayan and Pir Panjal ranges. It then turns southward about Kishtwar in Kashmir and crosses the Pir Panjal by a gorge, leaving the mountains at Akhnur. From the Bara Lacha pass to Akhnur the length of the Chenab is 378 mi. and the total fall 15,500 ft. It enters Punjab (Pakistan) at Khairi Rihal in Sialkot district. Its catchment area above the 1.000-ft. contour is 10.588 sq.mi., including 1,475 sq.mi. under glaciers. Mean annual rainfall in the catchment is 47.24 in.

The Upper Chenab irrigation canal is taken off at Marala 8 mi. from the Kashmir border, and the Lower Chenab canal at Khanki, 35 mi. farther downstream. Thence the Chenab flows on. greatly diminished, dividing the Chaj doab in the northwest from the Kechna doab in the southeast. The Jhelum joins it at Trimmu and the Ravi near Sidhu. after which it is called Trimab. The Sutlej, already united with the Beas river, joins it at Madwala. The united stream flows on as Panjnad ("five streams") to join the Indus. The general set of the stream is to the west. There is evidence that as late as A.D. 1245 it flowed east of Multan and by 1397 had shifted its course to the west of that city. The total length of the Chenab, excluding the Panjnad, is 599 mi. The river begins to rise in March and attains its maximum level in July and August, after which it gradually falls. It is at its lowest from November to February. Its height has a range of about 15 ft.

The annual inundation affects generally only a narrow fringe along the river ranging in width from 2 to 6 mi., but because of the loose. sandy nature of its banks, the moisture percolates far inland and benefits much land not actually covered by floods. The deposits left by the annual flood are very sandy and much inferior to the rich silt laid down by the Jhelum and other Punjab rivers. (R. S. AD.)

CHEN-CHIANG, one-time treaty port on the south bank of the Yangtze river in Kiangsu province, China, 160 mi. above Shanghai and 43 mi, below Nanking, on the railway. Pop. (1953) 201,400. It lies where the north-south route of the Grand canal from Hangchow to Peking crosses the east-west route of the Yangtze and three miles upstream from a barrier of forts commanding the one-mile river width. So long as the Grand canal remained an arterial line of communication, Chen-chiang retained its significance. But after 1850 traffic on the Grand canal declined. moving instead by coastal steamships and the Tientsin —P'u-k'ou railway which meets the Yangtze opposite Nanking, itself the terminus of a railway from Shanghai. Channel silting has also been reducing the port's usefulness.

As a local centre, Chen-chiang is well-known and was the provincial capital (1928–49). Streets were widened beginning in 1934 when the walls were leveled. Riangsu Medical college is located there. Three of its local products are much prized by consumers in east China: lacquerware inlaid with mother-of-pearl: thin natural coloured silk for summer clothing, and its famous vinegar. There is also some brocade weaving from thrown silk as part of the larger production in the Yanking area. (TE. H.)

CHENCHU, a people of southern India, about 11,000 in number, residing mainly in the districts of Kurnool, Guntur and Mahbubnagar in the state of Andhra Pradesh. The Chenchu speak variants of Telugu (*q.v.*), the regional language. They have medium stature, brown skin, wavy brown or black hair and varied facial features similar to those found among the Andhra peasantry. Their round houses of wattle and thatch are not unlike those used by peasants of the region, while their costume is distinguished mainly by its brevity. They follow Telugu kinship patterns generally.

An older seminomadic way of life and one of the simplest technologies known to aboriginal India are practised by a few hundred Chenchu who dwell in the wooded hills of the Amrabad plateau in Mahbubnagar. Those Chenchu gain nine-tenths of their food supply by hunting and by collecting the edible products of the jungle, particularly tubers. The bow and arrow, a metal-tipped digging stick, an ax and a simple knife are the only essential tools. There most families leave their fixed homes and wander for weeks on collecting tours of their large village territories, especially during the hot dry season. Such hill Chenchu are of a markedly individualistic disposition. Baskets. honey and herbs are increasingly exchanged with plains people for iron, cloth and grain, but the hill Chenchu remain among those aboriginal peoples of India who are most removed from the dominant Hindu civilization. Rituals are few and simple; religious and political specialization is slight. Small conjugal families predominate, women taking equal rank with men and marrying in maturity.

Most Chenchu, however. have been pressed by the expanding peasantry into agricultural and forest labour and out of their wandering, collecting life. Most have taken on Hindu gods and customs to a greater extent and have been accorded a relatively high caste status.

See Christoph von Fürer-Haimendorf, *Aboriginal Tribes of Hyderabad,* vol. i, *The Chenchus* (1943). (M. Ma.)

CHENEY, CHARLES EDWARD (1836–1916), U.S. clergyman, one of the founders of the Reformed Episcopal Church, was born in Canandaigua, N.Y., on Feb. 12, 1836. He graduated from Hobart college, Geneva, N.Y., in 1857 and spent a year at Virginia Theological seminary, Alexandria, Va. He was ordained deacon in the Protestant Episcopal Church on Nov. 21, 1858, and priest on March 4, 1860. After serving briefly as assistant minister in St. Luke's church, Rochester, N.Y., and minister-in-charge of St. Paul's church, Havana, N.Y., he became rector of Christ church, Chicago, in 1860. A pronounced evangelical, Cheney soon became deeply involved in the bitter ecclesiastical controversies of the period. He was one of the signers of the "Chicago protest" against "unprotestantizing" tendencies in the church, issued on Feb. 18, 1869. On June 21, 1869, he was brought to trial'before an ecclesiastical court for omitting the words "regeneration" and "regenerate" from the baptismal office of the Book of Common Prayer. He was convicted and suspended. After a second trial he was deposed for continuing to officiate when under suspension, but a civil court overruled the deposition. His parish followed him when he united with the Reformed Episcopal Church on its organization in 1873. He was elected missionary bishop of the northwest and consecrated on Dec. 14, 1873, his title being changed to bishop of the synod of Chicago in 1878. He continued to serve as rector of Christ church as well as bishop until his death on Nov. 15, 1916. (W. W. Ms.)

CHENGCHOW (CHENG-CHOU), the provincial capital of Honan province. China. Pop. (1953) 594,700. Located at the western edge of the north China plain, where the Yellow river enters the plain. Chengchow has long been an important trade centre. Its modern importance is derived from its position at the junction of the east-west Lunghai railway with the north-south Ping-Han railway, and it has become the dominant urban trade centre of Honan. Manufacturing was confined to agricultural processing and handicrafts until 1952, when the Communist government began the development of modern industry. Between 1955 and 1958 a new thermal power plant, rail yards, textile mills, new agricultural processing plants! textile and heavy machinery

1917 Lord and Lady Lee changed their tenancy into a freehold, and created a trust, which, on their deaths should make the house an adequate seat where the prime ministers could entertain guests. The original draft for the Chequers Trust declared that:—"The main features of the scheme are, therefore, designed not merely to make Chequers available as the official country residence of the prime minister of the day, but to tempt him to visit it regularly, and to make it possible for him to live there, even if his income should be limited to his salary." With this object an endowment was provided to cover the cost of a small, permanent domestic staff, of keeping up the gardens and grounds, of maintenance and repairs and other necessary expenses. There is also a residential allowance for the official occupant calculated in a fashion deliberately designed to encourage regular weekend visits. The draft, however, insisted upon the unaltered preservation of both house and contents. Parliamentary approval of the gift was formally declared by the Chequers Estate act. 1917.

In 1920 Lord and Lady Lee resolved that this scheme should not await their death but should take immediate effect. All the preparations for establishing and working the trust having been completed, the prime minister, David Lloyd George, held his housewarming on Jan. 8, 1921. His successors have spent part of their time there during their terms of office and ministerial week ends at Chequers court are a part of British political life.

CHER, a de'partement of central France, formed from the eastern part of the ancient province of Berry, together with parts of Bourbonnais, Nivernais and Orléanais. It is bounded on the north by Loiret, west by Loir-et-Cher and Indre, south by Allier and Creuse and east by Nièvre. Area 2.820 sq.mi. Pop. (1954) 284,376. The capital is at Bourges (*q.v.*).

From the crystalline rocks of the Massif Central that form the highest ground in the extreme south, the *département* extends northward across the belt of Jurassic rocks to the chalk of the Sancerrois hills and the margins of the lake-studded Tertiary country of the Sologne. within the great arc of the river Loire. The Cher and its tributaries, flowing north, cross the rich pastures of the clay vale that fringes the Massif Central and then traverse the limestone platform of Berry where there are great stretches of hedgeless arable fields. The broken chalk escarpment that forms the hills of Sancerrois east of the river Cher is less prominent farther west. Its south- and southeast-facing slopes formerly were covered with vineyards, but most of these have not been re-established since the phylloxera plague at the end of the 19th century. The area under vineyards is now small, but the dry. white wines are of high repute. To the north and west the chalk plateau is usually coated with clay with flints, giving heavy soils (pays fort) that still carry a considerable amount of woodland. The valley of the Loire in the extreme east is especially fertile, and is cultivated in small holdings with a variety of crops among which fruits are especially important. The de'partement is profoundly agricultural, and, although iron ore was formerly worked and stone is quarried, there is little industry except at Bourges and the railway junction of Vierzon where there are engineering and ordnance works.

The chief rivers. besides the Cher and its tributaries, are the Grande Sauldre and the Petite Sauldre on the north, but the Loire. which forms the eastern boundary, and the Allier, though not falling within the de'partement, drain the eastern districts, and are navigable. The Cher itself becomes navigable when it receives the Arnon and Yèvre. The Berry canal connecting the Cher with the Loire is no longer important. but the Loire lateral canal, which follows the left bank of the river in this de'partement, is still used and is connected from Briare with the Seine and Paris.

The *département* is divided into the two arrondissements of Bourges and St. Amand-Mont-Rond. Bourges is the seat of an archbishop and has a court of appeal, but the *département* belongs to the educational division (acade'mie) of Paris.

For the history of the region, see articles on the ancient provinces mentioned above. (AR. E S)

CHER, a river of central France. tributary to the Loire, rises in the north of the Massif Central and flows northward across the Combrailles uplands past Montluçon. Leaving the crystalline rocks, it traverses the rich pastures of the clay vale fringing the massif and crosses the limestone platform of Berry in a trenchlike valley. Farther north, the Cher receives the Yèvre at Vierzon and the Arnon a little farther downstream. Between these valleys the limestone of Berry presents tracts of dry, hedgeless cornfields and sheep pastures. Swinging west below Vierzon the Cher opens out; farther west it receives the Sauldre, from the marshland of Sologne. In its lower course the silt-laden Cher flows in a wide valley with rich meadows, vineyards and numerous cave dwellings cut in the chalk. The valley converges with that of the Loire, but the Cher passes south of Tours to join the Loire farther west at Cinq-Mars-la-Pile. Except for the industrialized area of Montluçon and industrial development at Bourges and Vierzon the Cher basin is rural. The Berry canal, which parallels stretches of the Cher above Noyers, is disused. (AR. E. S.)

CHERBOURG, a naval station. fortified town and seaport of northwestern France, in the de'partement of Manche, is on the English channel. 348 km. (216 mi.) W.N.W. of Paris by road. Pop. (1954) 35,246. Cherbourg is situated at the mouth of the Divette river, on the north shore of the Cotentin peninsula, overlooked by the steep Montagne du Roule.

The Cherbourg naval harbour, with an area of 55 ac., consists of three main basins cut out of the rock. The minimum depth of water is 30 ft. Connected with the harbour are dry docks, shipbuilding yards and a large naval hospital. The commercial harbour, at the mouth of the Divette, has an outer tidal harbour of $17\frac{1}{2}$ ac. and an inner basin of 15 ac.. with a depth of 25 ft. Outside these harbours is the triangular bay that forms the roadstead of Cherbourg. The bay is naturally sheltered on every side but the north, where lies the huge breakwater (begun by Louis XVI). $2\frac{1}{4}$ mi. in length, 650 ft. wide at its base and 30 ft. at its summit. The breakwater, protected by forts, leaves passages for vessels at both sides.

Near the roadstead is the church of La Trinité (1423–1504), a good example of the flamboyant style and one of the few historic buildings of Cherbourg. A rich collection of paintings is housed in the *hôtel* de *ville,* and a statue of the painter Jean François Millet. born near the town, stands in the public garden. The city is the home of a naval school. It is the terminus of a main railway line from Paris, and in the summer air services operate from Maupertus airfield (12 km. [7 mi.] E.) to Southampton, Eng., and the Channel Islands.

The main economic activities of the town spring directly from its position as a seaport. The naval port is a supply station and a base for small units, and its dockyards specialize in repair work and shipbuilding. Cherbourg is also a major port of call for transatlantic liners. The commercial harbour proper has a varied trade, importing coal, timber, fuel, tar, wine and various manufactured goods, and exporting iron ore. The fishing port is developing rapidly, and the yachting station, much visited by English yachtsmen, is the French winning post for many English sailing races. Cherbourg is to some extent an industrial city (boatyards, agricultural machinery), and it is an important market town. Early vegetables are one of the principal agricultural products of the region. The picturesque regions of La Hague cape (29 km. [18 mi.] W. of Cherbourg), with its wild, rocky cliffs, and the Saire valley (villages of Barfleur and Saint-Vaast-la-Hougue, 29 km. [18 mi.] E. of Cherbourg) rank among the town's tourist attractions.

Cherbourg is supposed to occupy the site of the Roman station of Coriallum. The peninsula, reaching toward the Isle of Wight, seems to have been used by Bronze Age traders as a starting place for the British Isles. William the Conqueror provided the settlement with a hospital and a church. Under Philip Augustus it became of military importance; in 1295 it was pillaged by an English fleet from Yarmouth. and in the wars of the 14th century it suffered frequently. Captured by the English in 1418 after a four months' siege. it was recovered by Charles VII of France in 1450. Harbour works were begun under Louis XVI and continued by Napoleon I, but it was left to Louis Philippe and Napoleon III to complete them. In World War II Cherbourg was occupied by the Germans in June 1940. They destroyed most of the harbour

installations and the arsenal before evacuating the town, which was taken by the U.S. 7th corps in June 1944. By October the port was handling 200 tons of war material daily. The maritime station was reopened in 1952. (RA. H.; AN. J. R.)

CHEREMIS, the name applied in the west, as it was in pre-Soviet Russia, to a people, now totaling about 500.000, who speak a language of the Finno-Ugric family. The people, however, refer to themselves as Mari, a term which has been adopted by the Soviet Russians and incorporated in the name of the Mari Autonomous Soviet Socialist Republic. Created on Dec. 5, 1936, this republic, with a Cheremis population in excess of 51%, is located in the upper Volga basin; there are also some Cheremis in adjacent regions, as well as nearly 100,000 in the Bashkir A.S.S.R.

The Cheremis language contains more than 1,000 Turkic loanwords, borrowed from two languages: Volga-Bulgar and Tatar. About half of them—the earlier layer—come from the language of the forefathers of the present-day Chuvash. The Cheremis and Chuvash have lived in a quasi-symbiotic relationship from about A.D. 700 to this day, although the period of most intense influence ended in 1236, when Tatar contacts became pressing. Tatar loans date from 1236 to 1552; then Kazan fell and the area came increasingly under the influence of Moscow. The process of Cheremis assimilation to Russian civilization accelerated during the 17th century, and the ever mounting symptoms of social and economic change may be traced in many forms, including strong nativistic movements.

The local group among the contemporary Cheremis is the cooperative village or *kolkhoz;* the principal source of subsistence is agriculture combined with animal husbandry. Yoshkas-Ola, the Mari capital, boasts of training schools in subjects such as animal husbandry, forestry, optics and papermaking, as well as factories and department stores.

See Thomas *A.* Sebeok, *The Cheremis* (1955); Thomas **A.** Sebeok and Frances J. Ingemann, *Studies* in *Cheremis: the Supernatural (1956).* (*T. A.* SB.)

CHEREMKHOVO, a town of Irkutsk *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Trans-Siberian railway, about 80 mi. N.W. of Irkutsk. Pop. (1959) 123.000. A branch line links Cheremkhovo to Svirsk on the Angara river. The town is also on the Irkutsk-Krasnoyarsk motor road. Founded in 1772 as a station on the Siberian Post road, the town has developed as the chief mining centre of the Cheremkhovo coal field, which is the largest' in eastern Siberia, and extends for about 150 mi. along the Trans-Siberian railway. There are also heavy engineering and timberworking industries. (R. A. F.)

CHEREPOVETS, a town of Vologda *oblast* in the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the right bank of the Sheksna river (70 mi. W. of Vologda), where it flows into the vast Rybinsk reservoir of the Volga. Pop. (1959) 92,000. The Sheksna is linked by the Mariinsk waterway system to Lake Onega and thus to the Baltic-White sea waterway, while Cherepovets lies also on the Leningrad-Vologda railway. These excellent communications led to the establishment there in 1955 of a large integrated iron and steel works, using iron ore from the Kola peninsula and coal from Vorkuta. The slag from the works is used to make thermo-insulating sheeting. Shipbuilding and repair and timberworking, especially the production of veneer, are also carried on. (R. A. F.)

CHERIBON (TJIREBON) is a city and residency of northeast West Java province on the Java sea, Indon. Pop. (1957 est.) 2,917,009. Although some Javanese live in the north, Cheribon is Sundanese country, its eastern boundary dividing the Sundanese from the Javanese territory of central Java. It has been for centuries the centre of Islam in'west Java, for it is there that the Muslim power was strongly established as early as 1526, under Gunung Djati, and much of the opposition to Dutch rule at a later date came from this district. The northern half of the residency is flat and marshy in places, while the southern half is mountainous. Southwest of the city stands the huge volcano Tjaremai, clad with virgin forest and plantations, and surrounded at its foot by rice fields.

Sulfur and salt springs occur on the slopes of Tjaremai and near Pallmanan, where a cavernous hole exhales carbonic acid gas.

The principal products of cultivation are tea, rice, tobacco, essential oils, sugar, cinchona, cassava, peanuts and pulses. Cheribon city and seaport has a good open roadstead and quay and warehouse accommodation for lighters. It was formerly the residence of the powerful sultans of Cheribon. Indramaju is another principal town, and Kuningan, famous for a breed of horses, is a hill resort (2,200 ft.). The residency was occupied by the Japanese from 1942 to 1945.

On Nov. 15, 1946, the Dutch-Indonesian pact (the Cheribon, or Linggadjati, agreement) recognizing the Republic of Indonesia was drafted at Linggadjati, a resort village 13 mi. S. of Cheribon port. See JAVA: *History.*

CHERIMOYA (CHERIMOYER or CHIRIMOYA), the fruit of *Annona cherimola,* a medium-sized tree of the family Annonaceae, originally from the Andes of southern Ecuador and northern Peru, now cultivated commercially, on a small scale, in California, Mexico, Chile, Argentina, southern Spain, Queensland and several other regions. Throughout the highlands of tropical America it is a favourite dooryard tree and the fruit is often seen in local markets.

Its abundance of large, ovate, rich green leaves makes the tree a handsome one, while the fruit, which matures from September to January in the northern hemisphere, was termed by Mark Twain "deliciousness itself." It is oval to round in form, sometimes weighing 2 to 3 lb. though usually less, pale-green in colour with a thin skin enclosing creamy white flesh in which numerous seeds the size of beans are embedded. The texture of the flesh is like that of firm ice cream, the flavour delicately subacid. It has been compared to a combination of pineapple and banana.

Though geographically tropical in origin, the cherimoya does not attain perfection in the tropical lowlands. Its culture is limited to elevations of 3,000 to 7,500 ft. in the tropics, and to mild-wintered subtropical regions. Its climatic requirements are, in fact, quite specialized; it will grow satisfactorily in many regions, but in some of these, little fruit will be produced and may be of unsatisfactory quality. Successful efforts to increase production have been made in California and elsewhere by hand pollinating the flowers.

Propagation is commonly by means of seeds, but the cherimoya lends itself readily to grafting, and superior varieties are perpetuated in this way. The method commonly used is the one employed with citrus fruits, *i.e.,* shield budding. Trees are planted in orchard form, spaced about 25 ft. apart; they are given much the same cultural attention as oranges. They come into commercial production at three to five years of age.

To this same family, Annonaceae, belong several other tropical American fruit trees. The best of these is probably the guanábana or soursop *(Annona muricata);* its large fruits are used to make ice creams and refreshing drinks, popular in Cuba. Another species, *A. squamosa,* usually known in English as sugar apple, is commonly grown in drier parts of the American tropics as well as in India and elsewhere. A hybrid between this and the cherimoya is cultivated commercially on a small scale in Israel. Another species, *A. reticulata,* known as custard apple, produces a fruit of mediocre quality; this tends to confuse it with the cherimoya to which the same name is sometimes applied in English-speaking regions. Annonas in general require care in handling and transportation. Harvested at an appropriate stage of maturity and carefully packed, however, they will remain in good condition for a week or so without refrigeration. (W. Po.)

CHERKASSY, an *oblast* (administrative division) and a town and administrative centre in the Ukrainian Soviet Socialist Republic of the U.S.S.R. Pop. of *oblast* (1959) 1,470,214. Area 7,992 sq.mi. By far the greater part of the *oblast,* which was formed in 1954, lies in the Dnieper right bank area. A small part, of low-lying flood plain, lies on the left (eastern) bank around Zolotonosha. The right bank consists of rolling hills of the Dnieper uplands, much cut up by the valleys of small streams flowing to the Dnieper and by the headwaters of the Sinyukha, flowing south to the Southern Bug river. The area is covered by

loess, overlying an ancient granite platform, which occasionally outcrops in the valleys. The loess is easily eroded and the formation of gullies is widespread. On the loess are developed the fertile black earth soils (chernozem), but little survives of the natural steppe vegetation of feather grasses and fescues. There are intermittent small groves of oak.

In 1959 about 23% of the population were urban. The towns are mostly small and the more important are Cherkassy, Smela, Uman and Zvenigorodka. Population density (184 per square mile) is above average for the Soviet Union. Agriculture takes first place in the economy, the main crops being sugar beet and winter wheat. Part of the chief sugar beet area of the U.S.S.R., the oblast has a number of sugar refineries. Barley. maize (corn), sunflowers, tobacco and hemp are also grown, while livestock. particularly dairy cattle and pigs, is important. Industry is largely concerned with processing agricultural products, sugar refining. flour milling and fruit and vegetable canning. Some lignite is mined near Zvenigorodka. Smela and Uman have light engineering. The oblast is traversed by the Moscow-Odessa railway, from which lines branch off at Smela to Belaya Tserkov and the western Ukraine.

CHERKASSY, administrative centre of the oblast, stands on the high right bank of the Dnieper, on the shores of the reservoir formed by the Kremenchug hydroelectric station 95 mi. S.E. of Kiev. Pop. (1959) 83,000. Founded in the 15th century in the Polish Ukraine, the town was annexed by Russia in 1795. It began to acquire importance in the late 19th century, as the point where the direct Moscow-Odessa railway bridged the navigable Dnieper. Cherkassy was occupied (1941–43) by the Germans in World War II. Industries include light engineering (producing machinery for the food industry), food processing, textiles and timberworking. A pedagogical institute is located there. (R. A. F.)

CHERKESSIA (CIRCASSIA) is a historical region (part of Ciscaucasia) of the Union of Soviet Socialist Republics between the western end of the Greater Caucasus range and the Kuban river. and now the area comprising Krasnodar Krai (*q.v.*) of the Russian Soviet Federated Socialist Republic. Cherkessia derives its name from the Cherkess people (Circassian; *q.v.*), one of the main ethnic groups of the Western Caucasus, who are still found in the Karachai-Cherkess autonomous oblast, the Kabardino-Balkar Autonomous Soviet Socialist Republic, U.S.S.R., and the Adygei autonomous oblast (*qq.v.*), the Kabardinians and Adygei being branches of the Cherkess. After resisting Russian expansion into the Caucasus, the Cherkessians were eventually subjugated by 1864. A mass emigration movement into Turkey followed. The related Abkhaz of the Abkhaz Autonomous Soviet Socialist Republic, U.S.S.R. (*q.v.*), are also sometimes referred to as Circassians. See also CAUCASUS. (R. A. F.)

CHERNIGOV, an oblast (administrative division formed in 1932) and a town and an oblast centre in the Ukrainian Soviet Socialist Republic in the U.S.S.R., lying in north central Ukraine, east of the Dnieper river, which in part forms its western boundary. Pop. (1959) 1,553,773 (oblast). Area 12,162 sq.mi. Mostly in the basin of the Desna. a major tributary of the Dnieper the oblast is a low-lying plain, three-quarters covered by damp or swampy areas and mixed forest of oak, pine, hornbeam, maple and other trees. In the south, around Priluki, it is drier and more open, with rich black earth soils (chernozem) developed on loess subsoils, where groves of oak alternate with open steppes, now almost wholly under the plow. Less than a quarter of the population are urban. Apart from Chernigov, towns are small, the most important being Priluki and Nezhin. The economy is mainly agricultural. although less than half the area is under crops. The drier forest steppe is most important, with grain, sugar beet, tobacco and maize (corn). Grain crops occupy two-thirds of the arable land. In the damp north drainage operations were undertaken and flax and hemp are widely grown, together with rye, oats. potatoes and vegetables. The Nezhin area is noted for its cucumbers and onions. Pigs are important and there are large herds of beef and dairy cattle, especially on the meadows of the north. Industry is mostly concerned with processing agricultural products. Enterprises are usually small and scattered through the rural areas. In the towns, light engineering, textile and footwear manufacture and timberworking predominate. The industries in Priluki include furniture, plastics and loading machinery.

CHERNIGOV, town and oblast centre, lies on the right bank of the Desna 80 mi. N.N.E. of Kiev. Pop. (1959) 89,000. First mentioned in 907, it was one of the chief towns of Kievan Russia, but after the Tatar invasion (1239) it lost its importance. Its Spasski cathedral dates from 1024. In 1797 it became the provincial centre. It is now an important communications focus, on the navigable Desna. with railways north to Gomel. west to the Polish frontier and south to Cherkassy and Odessa. Industries include boot and shoemaking, leatherworking, textiles, timberworking, musical instrument making and food processing. Chernigov is the seat of a university (1875) and has a pedagogical institute. In World War II the town was occupied (1941–43) by the Germans. (R. A. F.)

CHERNIKHOVSKI, SAUL GUTMANOVICH (1875–1943). Hebrew poet, was a leading representative of the "classical" or "Odessa" period of the modern Hebrew revival. Born in the Crimea on Aug. 20, 1875. he lived at Odessa during 1890–99, after which he studied medicine at Heidelberg and Lausanne until 1907. During World War I he served in the Russian army as a surgeon. In 1922 he left Russia and, after wanderings which took him to the United States in 1928–29, he settled in Palestine in 1931 and became a school physician at Tel Aviv. His poetic production, from the age of 14 until a month before his death. was immense, and included sonnet cycles, idylls of Jewish village life in Russia, and translations of the Iliad, the Odyssey, *Gilgamesh,* Shakespeare, Molière and Longfellow. He also wrote short stories. When nearly 60 years old he changed the rhythm of his poetry from the eastern European to the Palestinian pronunciation. Chernikhovski's poetry is deeply romantic and suffused with a love of Greek culture; the conflict between this and Judaism gave rise to some of his finest nork.

Chernikhovski died at Jerusalem on Oct. 13, 1943.

CHERNIKOVSK: see **UFA.**

CHERNOV, VIKTOR MIKHAILOVICH (VIKTOR OLIENIN) (1876–1952), one of the foremost leaders of the Russian Social Revolutionary party. Engaged in revolutionary activity from 1893, he shared in the foundation of the party in 1902 and became a member of its central committee and editor of its periodical *Revolyutsionnaya* Rossiya. At the Zimmerwald conference of 1915 (see INTERNATIONAL, THE). during World War I. he supported the "defeatist" resolution of the party's left wing condemning the "imperialist war." After the revolution of March 1917 he returned to Russia and changed to a "defender" of his country against the German imperialist war.

Chernov edited the journal Delo *Naroda* and opposed the left wing of his party and the Bolsheviks. He became minister of agriculture in the provisional coalition governments of May, July and August 1917 and drew up a radical project of agrarian reform, but resigned in September after the anarchist peasant movement had seized lands from their owners. He was elected president of the constituent assembly which opened in Petrograd on Jan. 18, 1918. and was dispersed next day by the Bolsheviks. During the civil war he fought against the Reds on the Volga. Emigrating in 1920, he devoted himself to literary work after the failure of the Kronstadt rising of 1921, living in Paris until the outbreak of World War II, when he went to the United States. There he contributed to anti-Communist periodicals. He died in New York city on April 15, 1952.

CHERNOVTSY, an oblast (administrative division) of the Ukrainian Soviet Socialist Republic. U.S.S.R. Pop. (1959) 774,-121. Area 3,127 sq.mi. It is roughly triangular, with the apex on the crest of the Carpathian mountains and extending down over the foothills and the Seret and Prut valleys to a base line on the Dniester. Most of the Carpathians are thickly forested, mainly

with beech, but the highest areas are open Alpine meadows, known as *poloniny*.

Formerly the northern part of Bukovina (*q.v.*), the *oblast* was formed in 1940, when this area, together with Bessarabia, was ceded to the U.S.S.R. by Rumania. In 1959, 212,838 (27%) of the population were urban. Chernovtsy, the *oblast* centre, and Khotin are the only notable towns. In general there is a great deal of dispersed settlement. Over-all population density (248 per square mile) is one of the highest in the U.S.S.R., but it is far higher in the valleys, where most of the population lives.

The complex political history of this area has led to a very mixed population. As well as Ukrainians. who form about three-quarters of the total, there are Russians. Poles, Jews, Hungarians, Rumanians and Moldavians. Arable land is confined to the valleys of the Dniester and Prut, while pasturage predominates in the mountains. Timberworking and food processing are the main industries. (R. A. F.)

CHERNOVTSY (Ger. CZERNOWITZ; Rum. CERNĂUTI), a town and *oblast* (administrative) centre of the Ukrainian Soviet Socialist Republic in the U.S.S.R., stands on the high right bank of the Prut river in the Carpathian foothills. Pop. (1959) 145,000. An ancient town of Kievan Russia, once the capital of Bukovina (*q.v.*) Chernovtsy has known Polish, Austro-Hungarian and Rumanian rule. It was finally secured from Rumania by the U.S.S.R. in 1947. Industries include woolen and cotton textiles and stockings, light engineering, timberworking, chemical production and food processing. The town has excellent rail connections to Lvov (140 mi. S.E.) and Ternopol in the Ukraine, to the Moldavian Soviet Socialist Republic and to Rumania. There is a university, founded in 1875, and a medical institute. (R. A. F.)

CHERNYAEV, MIKHAIL GRIGORIEVICH (1828–1898), Russian general distinguished for his Pan-Slav activities. He first made a name for himself with the Russian forces in central Asia, where his conquest of Tashkent in 1865, contrary to instructions from St. Petersburg, made him a controversial figure. Enthusiastic in his support of the Balkan Slavs, Chernyaev dreamed of leading them in a war of liberation against Turkey. In 1867 he offered his services to Prince Michael of Serbia. The Russian war minister, D. A. Milyutin, already angry with him over the Tashkent episode, promptly placed him on the army's retired list, but Chernyaev through intrigue got himself reinstated and then served in the Russian army in Poland.

Early in 1875 Chernyaev left the army to become editor of the nationalist St. Petersburg newspaper, *Russki Mir*. When the Hercegovina revolt broke out in July, his newspaper aroused Russian sympathies for the rebels. Chernyaev sought to raise a detachment of volunteers to fight the Turks but could not obtain sufficient funds from the Moscow Slav committee.

Early in 1876 Chernyaev, through the committee, again offered his services to the Serbian government. Somewhat reluctantly the Serbs invited him to Belgrade. Contrary to the emperor Alexander II's wishes, he journeyed clandestinely to Serbia in April, accepted Serbian citizenship and was named commander in chief of the armed forces by Prince Milan. Believing that Russia would back up Chernyaev, Milan declared war on Turkey in June. Chernyaev persuaded the Serbs to launch an offensive into Bulgaria expecting that the Balkan Slavs would rise against the Turks. Tremendous enthusiasm was stirred up in Russia by exaggerated reports of his early successes and several thousand Russian volunteers joined his army. He was widely regarded in Russia as the hero of the hour.

Despite generous aid from the Slav committees, Chernyaev's poorly trained forces met defeat in Oct. 1876 and were saved from annihilation only by a Russian ultimation to Turkey. His faulty strategy and lack of political acumen played a major part in Serbia's defeat. Russian public opinion shifted strongly against him. Discredited by defeat, he was relegated to a staff post in the Caucasus during the Russo-Turkish war (1877–78). Under Alexander III he emerged briefly as governor-general of Turkestan (1882–84). He died at his country seat at Tybushki, in the Mogilev district, on hug. 17, 1898.

See B. Sumner, *Russia and the Balkans* (1937). (D. MACK.)

CHERNYAKHOVSK, a town of Kaliningrad *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., until 1945 the German Insterburg in East Prussia, stands on the Pregolya (Pregel) river, at the head of navigation 50 mi. E. of Kaliningrad city. Pop. (1959) 30,000. It is an important railway junction on the Kaliningrad-Kaunas line, with a line north to Klaipeda (Memel) and Riga and lines southwest and southeast into Poland. There are light industries, of which the most important is the preparation of foodstuffs. The town was founded by the Teutonic knights as a stronghold in the 14th century. It was occupied by the Russians in 1914 and again in Jan. 1945. At the Potsdam conference (1945) it was awarded to the Russians, who renamed it after the Soviet general who led the forces that captured it during World War II. (R. A. F.)

CHERNYSHEVSKI, NIKOLAI GAVRILOVICH (1828–1889), Russian radical journalist and author, who greatly influenced the young Russian intelligentsia of the 1860s. was born on July 1, 1828, in Saratov, where his father was a poor priest. In 1854 he joined the staff of the review *Sovremennik* ("Contemporary"), whose readers were swayed by the burning sincerity, practical bent and clear, responsible tone of his articles. Though he focused attention on social and economic evils and expounded predictable laws of economic change, he followed V. G. Belinsky (*q.v.*) and the English utilitarians in preaching a highly purified egoism as the most natural and desirable mainspring of human conduct. Landowners accused him of stirring up class hatred and of creating distrust of the government committees which were then drafting the emancipation edicts of 1861. The extent to which he was actively subversive is a matter of controversy, but in 1862 he was arrested and. after two years' imprisonment, was exiled to Siberia, where he remained until 1883. While in prison he wrote his didactic novel *Shto Delat'?* (1863; Eng. trans. *A Vital Question* or *What Is* To *Be Done?* 1866). Chernyshevski always remained a westernizer who opposed the nationalist Slavophils. In the U.S.S.R. he is interpreted as a forerunner of Lenin. He died in Saratov on Oct. 29, 1889.

CHEROKEE, an important Indian tribe of the United States, of Iroquoian lineage, originally located in eastern Tennessee and western North and South Carolina. Within this area they possessed approximately 200 settlements or towns. In 1650 their population was about 22,000, after a smallpox epidemic had reduced their number by nearly one-half.

Cherokee life and culture greatly resembled that of the Creek and other southeastern tribes (*see* MUSKOGIAN INDIANS). The Cherokee nation was composed of a confederacy of red and white towns, otherwise known as war and peace towns. The chiefs of the red towns were subordinated to a supreme war chief of the entire tribe, while the officials of the white towns were under the supreme peace chief of the tribe. The white towns were regarded as places of sanctuary, as in the ancient Hebrew cities of refuge where those who fled from blood avengers might find asylum.

When first encountered by Europeans, the Cherokee possessed a variety of stone implements including knives, axes and celts. Skills such as basket weaving and pottery making were known, and the characteristic Amerindian plants (maize, beans and squash) were cultivated. The art of hunting was well developed, and deer, bear and elk furnished meat and clothing. As with other tribes of the southeast, a simple shelter was derived from a framework of poles with coverings of bark and cane. James Adair, William Bartram and Henry Timberlake have given first-hand observations on the Cherokee of the 18th century.

The Cherokee first came to notice in 1730 when Sir Alexander Cuming, an emissary of King George II, conferred the title of emperor on Chief Moytoy at Tellico, Tenn. In 1740 a party of Cherokee under Chief Kalanu, the Raven, took part in Gen. James Oglethorpe's expedition against the Spaniards of St. Augustine, Fla. During the French and Indian War, Col. George Washington complained of the unseasonable delay in obtaining aid from the

Cherokee, noting that their friendship and assistance were well worth cultivating. In 1761 Outacity, a Cherokee warrior, visited London with a delegation of fellow tribesmen and received an audience with George III. A subsequent visit by a Cherokee delegation to London in 1765 resulted in the arrival among the Cherokee of John Hammerer, the first white teacher.

During the American Revolution the attitude of the Cherokee was a matter of great concern. Although opinion was divided. the tribe tended to favour the king against the colonists. This attitude persisted even after the conclusion of peace, and in the treaty of 1793 between Spain and the southern Indians the Cherokee nation requested the Spanish king to admit it under his immediate protection, as the Chickasaw, Alibamu and Choctaw had been previously admitted. In a speech made on Aug. 29, 1796, President Washington informed the Cherokee that they would be used as an experiment in Indian education and that the future of all other Indian tribes and their dealings with the federal government would depend on their example. In accordance with this policy, Dartmouth college set up loans in 1799 to educate Cherokee youth.

During the first three decades of the 19th century, progress of the Cherokee in the arts of civilization was both rapid and revolutionary. Georgia was the principal seat of the reorganized Cherokee nation. and forms of republican government accompanied adoption of the white man's agriculture, animal husbandry. log cabin homes and weaving. Perhaps the most remarkable development of all was the invention of a native system of writing the Cherokee language by Sequoyah, or George Guess, about 1820. This syllabary was so successful that almost the entire tribe became literate within a short time. It was now possible for Cherokees to communicate with their brethren who had migrated westward and to develop the first Indian press north of the Rio Grande. A written constitution was adopted by the tribe, and religious literature flourished, including translations from the Christian scriptures. An Indian newspaper, the *Cherokee Phoenix,* the first of its kind, appeared Feb. 21, 1828.

Despite valuable aid rendered by the Cherokee under Chief Junaluska to Andrew Jackson against the Creek in the battle of Horse-shoe Bend, pressure on the Cherokee in Georgia from advancing white settlers grew rapidly in the early 19th century. At the treaty of New Echota, Dec. 29, 1835, the Cherokee signers agreed to move west of the Mississippi in the neighbourhood of the Arkansas river. The agitation connected with removal led to the compilation of the John Howard Payne manuscripts on Cherokee life and customs about 1836. The authors of these papers, Daniel Sabin Butrick and others, believed that the Cherokee were descended from the Ten Lost Tribes of Israel and advanced extensive reasons for this hypothesis. John Haywood, in his *Natural and Aboriginal History of Tennessee* (1823), advanced the idea that the Cherokee were compounded of tribes from India and Scythia.

Opposition to forced removal of the Cherokee westward was voiced by many prominent Americans of the time, both in the north and south, but their protests were in vain. Pres. Andrew Jackson took personal direction of the situation and in 1838 ordered Gen. Winfield Scott to enforce the provisions of the treaty of New Echota. The removal, consummated in the winter of 1838–39, was a calamity. The tribe lost nearly 25% of its number as casualties mounted from disease and exposure. Even when the main body had finally reached its new home in what is now northeastern Oklahoma, they were faced by controversies with the old settlers who had preceded them in the west. Feuds and murders rent the tribe as reprisals were made on those Cherokee who had signed the treaty of New Echota. With the advent of the Civil War 20 years later. the tribe was rent again by new partisan groups and military devastation.

The fate of the western Cherokee has been traced by Morris Wardell in his *Political History of the Cherokee Nation, 1838–1907* (1938). The capital of the nation was at Tahlequah. and the old council house still stands in that city. Many thousand Cherokee still reside in northeastern Oklahoma. The tribal government was abolished in 1906 during the procedures leading to the establishment of the state of Oklahoma.

At the time of the removal a few hundred Cherokee escaped to the mountains and furnished the nucleus for the 3.000 Cherokee of western North Carolina. The construction of modern highways through the area beginning in 1931 led to economic development, historical museums, a summer-long pageant of Cherokee history entitled "Unto These Hills" and Oconaluftee village, a replica of a Cherokee settlement of 1750.

CHERKAPUNJI, a village in the United Khasi and Jaintia Hills district of Assam. India. about 32 mi. S. of Shillong, capital of Assam. It is situated on the southern margin of Shillong plateau. a detached block of the Rajmahal hills, of Archaean origin, and is inhabited by Khasi tribes, a proto-Australoid group having a matriarchal social system. Pop. (1951) 1,962. Cherrapunji is notable for its heavy rainfall. The annual average is 428 in., which varies greatly; 905 in. was recorded in 1861 with a maximum precipitation in July of 366 in. The heaviest rainfall in the world is recorded in the nearby village of Mawsynram, with an annual average of 550 in. The excessive rainfall is due to the situation on an amphitheatre relief and on the windward side of the monsoon. The Chera coal mine is important. Among the tribal groups *jhum* (shifting cultivation) and terrace cultivation is common. and rice is the staple crop. Common fruits include the banana, plum, citrus fruits and pineapple. (M. BA.)

CHERRY, a widely grown fruit of the temperate zone; also the name given to many trees belonging to various species of *Prunus* that produce cherrylike fruits. Cherries belong to the great group of stone fruits characterized by having a single seed enclosed in a hard covering or "stone." The stone is enclosed in a fleshy tissue which, in most species of *Prunus,* is edible. The stones are nearly round and are relatively smooth. These characteristics distinguish cherries from the other important kinds of stone fruits.

There is a large number of species of cherry, mostly native to the northern hemisphere. Some 10 to 12 species are recognized in North America and a similar number in Europe. The greatest concentration of species, however, appears to be in eastern Asia. These native species vary in size from bushes to trees 40 to 50 ft. in height.

The native habitat of the species from which the cultivated cherries came is believed to be western Asia and eastern Europe from the Caspian sea to the Balkans. Cherries had spread throughout Europe, however. before agricultural history was recorded. Greek and Roman ariters before the time of Christ described various kinds of the fruit. Cherries were taken to America by the earliest European settlers.

Cherry Fruit. — Three types are mainly grown for their fruit. These are the sweet cherries, *P. avium,* the sour cherries, *P. cerasus,* and. grown to a much smaller extent, the dukes, which are crosses of sweet and sour cherries. The sweet cherry trees are large and rather upright, attaining heights up to 35 ft. The fruit is generally heart-shaped to nearly globular, about one inch in diameter and varies in color from yellow to red to nearly black. The acid content of the fruit is low so the fruits taste sweet. Sour cherry trees are smaller, rarely over 15 ft. in height. The fruit is round to oblate in shape, generally dark red in color and has so much acid that it is not appealing for eating fresh. The duke cherries are intermediate in both tree and fruit characters.

Regions of Cherry Production. — Cherries are grown in all areas of the world where winter temperatures are not too severe and where there is sufficient winter cold to break the rest period

of the trees. Sweet varieties will withstand winter temperatures down to about −15° F. (−26° C.) without injury. Sour types will generally withstand temperatures down to −25° F. (−31° C.). The trees bloom quite early in the spring, just after peaches and earlier than apples, and crops are often lost or damaged by spring frosts unless they are planted on the most frost-free sites. The cultivated cherry is not adapted to tropical countries as the trees require a period of winter cold to break the rest period and start them into uniform and vigorous spring growth. Cherries do not thrive well where summer temperatures are extremely hot or humid. Sweet cherries particularly tend to crack open if rain occurs when the fruit is nearly ripe. Therefore they are grown mainly in areas where summer rainfall is low.

Production. — The United States is the leading country in production with an annual crop of about 225,000 tons. In all of the European countries, however, cherries are a major crop and total production in western Europe is about 600,000 tons annually. Western Germany, Italy and Switzerland lead in production in Europe. Turkey, Japan, Argentina. Chile, Australia and Canada all produce substantial quantities.

In the United States over half of the production is sour cherries, with major-producing areas adjacent to the Great Lakes in Michigan, New York and Wisconsin. Most of the sweet types are produced in the Pacific coast states of California, Washington and Oregon. Sour cherries are utilized largely for processing, about half of the crop being frozen and half canned. Sweet cherries, in season, are consumed fresh, widely canned and are the principal source of maraschino cherries. In Europe, the fruit is used fresh, canned or made into wine.

Hardy bush cherries of north Asian origin were introduced into northern plains areas of the United States, southern Canada and the colder sections of Europe. Some of them produce quite good fruit somewhat resembling the commercial sour cherries.

In the orient, particularly Japan, cherries have been selected for the beauty of their flowers. Most of these do not set fruit but are beautiful ornamentals and are featured in many gardens. Mainly after 1900, these became widely disseminated throughout the moderate temperature areas of North America and Europe. The famous flowering cherries of Washington, D.C., are introductions from Japan.

Diseases and Insect Pests. — Cherries, wherever grown, are subject to attack by diseases and insect pests. Some viral diseases kill the trees, others affect them only mildly. No cure exists for the virus diseases, and severely affected trees should be destroyed. The brown rot fungus that causes fruit rot and leaf attacking fungi that cause leaf drop are serious in humid climates. Important insect pests include scales, fruit flies and mites. Several sprays per season of suitable insecticide and fungicide materials are required in most areas to produce high quality fruit. Ripening cherries are a favourite food of birds, and bird feeding causes severe losses, especially in small, isolated plantings.

The wood of a number of the cherry species is close-grained, dark red in colour and especially esteemed for the manufacture of fine furniture. (J. R. MAG.)

CHERRY VALLEY, a village of Otsego county, in east central New York, U.S., 54 mi. W. of Albany, scene of the Cherry Valley massacre, was founded in 1741 chiefly by Scotch-Irish settlers from New England.

During the American Revolution it was a fortified frontier town exposed to enemy attack. On Nov. 11, 1778, about 800 Indians and Tories under Capt. Walter Butler and Joseph Brant, the Iroquois chief, surprised the village and destroyed it. Fourteen soldiers were killed; 30 settlers, including women and children, were massacred. Many survivors were made prisoner but most were released the next day.

Incorporated in 1812, Cherry Valley became for a time a thriving transportation centre on the Great Western turnpike. Bypassed by railroads and major highways, it is a charming rural community surrounded by dairy farms; population is about 700. (J. A. FR.)

CHERSONESE (CHERSONESUS or CHERRONESUS), in ancient geography a word equivalent to "peninsula" (Gr. chersos, "dry," and nesos, "island"). In ancient times the Chersonesus Thracica, Chersonesus Taurica or Scythica and Chersonesus Cimbrica correspond to the Gallipoli peninsula, the Crimea and Jutland (see CHERSONESE, TAURIC; CHERSONESE, THRACIAN); the Chersonesus Aurea or Golden Chersonese is usually identified with the Malay peninsula. The Tauric Chersonese was further characterized as "the Great." in contrast with the Heracleotic or Little Chersonese at its southwestern corner (where Sevastopol now stands) which was part of it.

CHERSONESE, TAURIC, in ancient geography, denotes the Crimea. The Greek word chersonesos ("peninsula") was used to indicate both cities and regions in a peninsular situation. Tauric Chersonese is therefore descriptive not merely of the city of Chersonesus, situated on a peninsula 3 mi. W. of the modern Sevastopol, but also the Crimea as a whole (see CRIMEA; BOSPORUS, KINGDOM OF THE). This article deals with the history of the city and its inland territory.

The city of Tauric (or Heracleotic) Chersonese was founded by Ionian Greeks in the 6th century B.C., perhaps as a trading factory rather than a city. In the 5th century it was refounded by Megarian 'Greeks from Heraclea Pontica on the southern side of the Black sea and became a purely Dorian city. Its history is obscure until the 4th century B.C. when it appears to have entered a fairly long period of prosperity coinciding with that of the kingdom of the Bosporus to the east. Although differing from the Bosporan state in that it maintained a free constitution of the Greek type. it had similar problems in its external relations; both had to contend with the power of the Scythians who occupied southern Russia and the northern Crimea, and both had to secure satisfactory markets for their natural produce in other parts of the Greek world. Additional problems for the Chersonesites were the tasks of defending their lands against the native Tauri, who inhabited the mountains of the southern Crimea, and of maintaining their independence against the imperialist ambitions of the Bosporan kings.

The Heracleotic peninsula on which the city stood was divided into individual allotments for the citizens, and vineyards were planted which proved extremely productive. Large areas of land in the western Crimea grew wheat and a large surplus was exported. In the early period commercial relations existed with Athens and the cities of the coast of Pontus; later, in the Hellenistic age, there was trade with Delos, Rhodes and Delphi.

About 110 B.C. the citizens turned to Pontus for protection against the Scythians, who were then pressing heavily upon the Crimean Greeks, with the result that Chersonese, together with the Bosporan state, was incorporated in the empire of the Pontic king Mithradates VI (*q.v.*). Under the Roman empire Chersonese was treated as a free city protected by the client-king of the Bosporan state. The export trade in grain was of considerable importance in the imperial economy: to safeguard the traffic a Roman military station was established at Chersonese. In the 1st and 2nd centuries A.D. the city flourished, as in the early Hellenistic age. Later it became increasingly exposed to barbarian attacks from the peoples of the interior. During the period of the Byzantine empire prosperity returned.

The city's remains occupy a space about two-thirds of a mile long by half a mile broad, enclosed by a Byzantine wall. Remains of an earlier wall going back to the 4th century B.C. have been found beneath this in the eastern or original part of the site. Many Byzantine churches have been excavated. Uninhabited since the 14th century, the site is important for our knowledge of Byzantine life.

See E. H. Minns, ***Scythians and Greeks*** (1913); *M.* Rostovtzeff, ***Iranians and Greeks in South Russia*** (1922). *(R. H* SI.)

CHERSONESE, THRACIAN, in ancient geography corresponds to the modern Gallipoli peninsula. Situated on the Hellespont (Dardanelles), and therefore on the main route between Europe and Asia, it was important to the Athenians for the corn trade from the Euxine (Black sea).

In the 7th century the Thracian Chersonese was colonized by Aeolian settlers from Leshos and by Ionian Greeks from Miletus and other towns. Xenophon states that it contained 11 or 12

Greek cities. The local inhabitants, the Thracian Dolonci, appealed to the Athenians about 560 B.C. for help against the neighbouring Apsinthii. Miltiades, sent by Pisistratus, founded an Athenian colony and built a defensive wall across the isthmus from Cardia to Pactya. Chosen by the Dolonci as king, Miltiades became tyrant of the Greek cities and founded a dynasty. His nephew Miltiades abandoned the Chersonese to Darius I of Persia about 492. After the Persian wars, the Athenians controlled the Chersonese by enrolling its cities in the Confederacy of Delos, and colonies were established about 450. At the end of the Peloponnesian War the Chersonese was taken by the Spartans (405). In the 4th century, however, Athenian sea power revived and Athenian settlers were sent out in 353. It remained in Athenian possession until 338, when it was ceded to Philip II of Macedonia after the battle of Chaeronea. Part of the Seleucid empire. the Chersonese was given to Eumenes II of Pergamum at the peace of Apamea (188) between the Romans and the Seleucid king Antiochus III. In 133 Attalus III of Pergamum bequeathed his kingdom to the Romans and most of the Chersonese became ager *publicus* (state-owned land). Under the emperor Augustus it was imperial property, governed by a procurator.

CHERT AND FLINT. Chert is a rock composed essentially of very fine-grained quartz (silica) with minor impurities. Chert forms by the chemical precipitation of silica, hence is distinguished from sandstone in which quartz particles are deposited mechanically.

Varieties.—Several varieties are included under the general term chert: flint, which with common chert is discussed in this article, and jasper, chalcedony, agate and novaculite (*qq.v.*). Flint is gray to black and nearly opaque because of included carbonaceous matter (translucent brown in thin splinters). Jasper is opaque and red or green as a result of abundant inclusions of iron oxide, chlorite or clay minerals. Chalcedony is translucent gray to white with waxy lustre. Agate is banded with various colours and novaculite is opaque white chert of homogeneous texture. Opaque, dull whitish to pale brown or gray specimens are simply called chert. The light colour and opacity of common chert are caused by abundant, extremely minute inclusions of water or air.

All chert varieties are harder than steel or glass, thus a knife blade leaves a silvery streak across the surface. Chert is usually nonporous and brittle with a smooth, splintery or conchoidal fracture. When shattered, it breaks into extremely sharp slivers like glass. Because of the minutely granular structure, chert has a waxy or dull lustre; upon weathering, flint develops a light gray, dull patina a few millimetres thick. Most chert has a density of about 2.65 and consists of 95% to 99.5% silica (SiO_2). Slowly soluble in strong alkalies and hydrofluoric acid, it is inert to other common reagents. Mineralogically chert consists of exceedingly fine-grained quartz mixed with a small and variable amount of free water occupying discrete, usually spherical cavities 0.00005 to 0.002 mm. in diameter. This included water lowers the refractive index and density of chert relative to pure quartz, and is responsible for the brownish appearance of much chert under the microscope.

Fine-grained quartz assumes two forms in chert and flint. Greatly preponderant is microcrystalline quartz, consisting of irregular, subequant polyhedral grains 0.001 to 0.010 mm. in diameter; under the polarizing microscope, this type appears as minute, pinpoint grains. Secondly, chalcedonic quartz under polarized light appears as spherulites or bundles of radiating fibres 0.02 mm. to several millimetres long, often concentrically banded with water bubbles; this variety occurs in small amounts and usually fills cavities or replaces fossils. Along with chalcedonic and microcrystalline quartz and a trace to several per cent of free water, some chert contains more coarsely crystalline quartz, opal and other impurities such as organic matter, calcite, dolomite, pyrite, iron oxides, clay minerals and sand or silt grains.

Occurrence and Origin.—Chert and flint occur as individual nodules or layers of nodules in limestone or dolomite; they are common in rocks of all ages (notably Cretaceous chalk of England). Nodules range from an inch to several feet across, and are smoothly ellipsoidal, tabular, bulbous or irregular tuberous. Masses generally lie parallel with bedding of the enclosing strata, but some cut across bedding or follow inclined veins. Hard and chemically resistant, the nodules become concentrated in residual soils as the surrounding carbonate rock weathers away. In places chert forms massive beds several hundred feet thick which extend laterally hundreds of miles. Chert also occurs as a fine powder disseminated throughout carbonate rock, impregnates shale and rarely forms cement in sandstone. It also develops in the vicinity of some metalliferous veins, precipitated by hot ore-depositing solutions. Erosion of chert beds or chert-bearing limestone produces chert pebbles, which are abundant in river and beach gravel. The origin of chert has been a subject of much controversy. At first it was assumed that chert nodules formed by coagulation of silica gel directly from sea water, to form a spheroidal mass resting on the sea bottom. Perhaps some chert may have formed in this way, but microscopic study shows conclusively that most chert and flint has formed by replacement of the enclosing carbonate sediment after burial beneath the sea floor. This replacement origin (similar to the petrifaction of wood) is substantiated by preservation in chert of the minute textural details of the enclosing carbonate rocks. Beds of oolite, fossils, carbonate pebbles, bedding planes and colour bands are faithfully duplicated and can be traced from the carbonate rock directly through chert. Irregular shapes attained by some chert masses and embedded patches of unreplaced limestone can only be explained by replacement. Probably chert is precipitated in place of limestone as limestone simultaneously dissolves, the two substances remaining always in immediate contact in order to preserve the textures. Analogously, one might imagine a wall of red bricks set in complex designs; one could then replace the wall by placing a white brick in the position of each red one as it was removed, and the pattern of the wall would be perfectly preserved. Replacement usually occurred while the surrounding carbonate sediment was still a soft, plastic material buried perhaps a few feet beneath the sea floor. Some chert masses have been bent or even torn apart when the surrounding soft carbonate sediment deformed plastically during mudflows or submarine landslides, and cracks in chert nodules are frequently invaded by unconsolidated lime mud. Nevertheless, some nodules may have formed much later upon deep burial of the rocks, and other chert masses have formed upon weathering in surface outcrops. Bedded chert presents a different problem; it is not usually associated with carbonate beds and shows little evidence of replaced carbonate rock structure. This evidence, albeit largely negative, indicates that perhaps bedded cherts were precipitated directly from sea water. Most silica required to form chert is evidently derived from normal weathering processes on land, which contribute dissolved SiO_2 to the sea in entirely adequate amounts. Organisms often acted as intermediate agents; some chert nodules have obtained their silica by solution and redeposition of siliceous (opaline) sponge spicules, radiolarians and diatoms. Many cherts contain abundant remains of these organisms. Locally, volcanic ash falls or submarine eruptions have contributed much silica in solution.

Uses.—Flint and chert provided the main source of tools and weapons for Stone Age man. The uniform fine grain, brittleness and conchoidal fracture made it easy to shape arrowheads by spalling or flaking off chips, and the edges produced were quite sharp. Quarrying and manufacture of flint weapons were among mankind's earliest business ventures, and it is sometimes possible to trace ancient trade routes by knowing where a particular type of flint was obtained (see FLINTS). From the 17th through the early 19th centuries. flints again found extensive military use in flintlock rifles, gunpowder being ignited by sparks produced when flint struck steel. Flint is used as an important ingredient in pottery. Several thousand tons of flint pebbles are used yearly in mills which grind raw materials for ceramic and paint industries. The use of flint pebbles (instead of steel balls) as a grinding agent is desirable in order to avoid contaminating the product with iron. Considerable chert finds use in road construction and concrete aggregate, although some types of chert are objectionable because they react with cement and may crack the structure. Novaculite

is used for whetstones; buhrstone (a porous chert) for grindstones; basanite (a velvety black flint) to estimate purity of alloys by observing the colour of the metallic streak. Some chert, agate and jasper take an excellent polish and serve as semiprecious jewelry. *See* also SILICA. (R. L. FK.)

CHERTSEY, an urban district of Surrey, Eng., 21 mi. S.W. of London by road. Pop. (1961) 40.376. Area 15.6 sq mi. It lies on the right bank of the Thames. which is crossed by a bridge of seven arches built of Purbeck stone in 1785. The first religious settlement in Surrey, a Benedictine abbey, was founded in 666 at Chertsey (Cerotaesei, Certesy). Little remains of the abbey buildings, but the ground plan can be traced and the fish ponds are complete. In the reign of Edward the Confessor, Chertsey was a large village and became the head of Godley hundred As the centre of an agricultural district, its markets were important and are still held. Fairs were granted to the abbots in 1129 and 1282, and a market on Mondays was obtained in the latter year—this market is now held on Saturdays. From Michaelmas to Lady day the curfew bell of St. Peter's parish church, founded in 1310, is still rung nightly. The poet Abraham Cowley died in Chertsey. Charles James Fox, the statesman, lived at St. Anne's Hill. Apart from the historic township of Chertsey, the urban district includes areas of modern development such as New Haw and Addlestone. Among the industries. engineering of varying types predominates balanced by agriculture and market gardening.

CHERUBIM, in the Old Testament, are hybrid creatures, with wings of birds, human or animal faces, regarded as attendants upon the divine throne or guardians of specially sacred places. Similar creatures are found in other oriental religions. In Jewish literature the cherubim appear as a class of angels, and in patristic times they were counted as one of the nine choirs of angels. *See* ANGEL.

CHERUBINI, (MARIA) LUIGI (CARLO ZENOBIO SALVATORE) (1760–1842), Italian composer who was one of the principal figures in the development of French opera during and after the Revolution. Born in Florence on Sept. 8, 1760, he received musical training from his father and from other teachers, among them Giuseppe Sarti, in the basic traditions of Italian music: first, the religious unity of Palestrinian counterpoint, then the vocal lyricism of 18th-century *opera seria—a* convention that embodied, almost ritualistically, the values of an aristocratic world that nas in the process of disintegration. He composed quantities of church music but then turned to opera, completing 13 by 1788. He was appointed composer to the king, George III, in 1785 for a year during his visit to London and in the following year he settled more or less permanently in Paris. In 1805 he visited Vienna, where his operas *Lodozska* and *Fanzska* were produced. In 1822 he was appointed director of the newly founded Paris conservatory, nhose reputation his strict rule did much to establish. Cherubini died in Paris on March 15, 1842.

Cherubini's career offers the paradox of an innate conservative who lived through, and was in some ways representative of, a revolutionary era. Though the operas he wrote from the time he settled in Paris (1786) do not relinquish heroic and aristocratic grandeur, they followed Gluck in seeking themes that were morally relevant to a changing world. The new heroism was centred not in titular rank but within the spirit of the men and women who were creating the future. This is why Cherubini, like Gluck (and Mozart). reconciled the objective splendour of classical lyricism with the internal drama of sonata style. He carried the Horror and Escape and Rescue opera into a realm of inner experience that could appeal to Beethoven. who studied the score of *Les Deux Journées* before writing *Fidelio.* Yet along with this Beethovenian drama Cherubini preserved a classical purity of line that suggests Berlioz—especially the superb vision of the world remade in *Les Troyens.* What is missing from Cherubini's music is. on the one hand, the dramatic cogency, the inner incandescence, that informs Beethoven's *Fidelio* as it informs his purely instrumental movements; or. on the other hand. the enormous melodic span and lyrical subtlety that are the essence of Berlioz. It is not Cherubini's fault that, after *Fzdelio* and *Les Troyens,* his operas seem unnecessary; and it is the misfortune of present-day audiences that they find it difficult to respond to what operas such as *Lodoïska* (1791), *Medée* (1797) and *Les Deux Journées* (1800) have to offer intrinsically. Though their virtues have been obliterated by the genius of greater men, they are real virtues, powerfully embodying the experience of the Tory democrat. It is not an accident that their force should be dependent on their classical restraint.

This vital conservatism is found also in Cherubini's nontheatrical music. The best of his string quartets (1814–37) have not the disturbing vehemence or wit of Beethoven's early and middle period works in this medium. let alone the (to Cherubini) utterly baffling and original profundity of Beethoven's last quartets. But their classical sobriety is not merely academic. and the drama within their lyricism is not the less trenchant for being operatically conceived.

Cherubini was. however, essentially a vocal composer; and when in later life he devoted less time to opera composition he turned not to instrumental music but to music for the church. This somewhat surprising development was precipitated by an invitation he received 'in the summer of 1808 to write a mass for the consecration of a church on the country estate of the prince de Chimay. Despite his early training in Roman liturgical style. the mature Cherubini. as a man of the Revolution, was not mystically inclined. But his operas, insofar as they were concerned with human potentiality and the creation of a new world, implied a belief in something outside himself; and the relationship between his liturgical and operatic manners exactly parallels the relationship between the ecclesiastical and secular styles of Berlioz. Their church music is a vision of a world of re-created grandeur aware of. yet triumphant over. human fallibility and chaos. Cherubini's two Requiems (especially the one in D minor, for male voices) are impressive and personal works. It is irrelevant to complain that thepressure of experience behind their ordered lucidity seems slight when they are compared with Berlioz's tremendous *Requiem* or that they do not scale the purgatorial heights and depths of Beethoven's Mass in D.

Cherubini's conservatism assumed a more damaging form in his celebrated *Cours de contrepoint et de la fugue* (1835) written nith the help of his pupil Jacques François Fromental Halévy, for in this work he tends to allow reverence for the past to destroy his awareness of the creative life of musical structures, his own included. This may have been part of the basic fear of life that made him shy away from men like Beethoven and Berlioz, who seemed so close to him yet were so irrevocably distant. This treatise has its value, hornever, for from it generations of composers have learned facility in their craft. The pity is that Cherubini's criteria of academic correctness should have subconsciously influenced the response of later generations to his own music. which, though not of Beethovenian or Berliozian vitality, was modern in its own day and became truly creative again in its influence in the 20th centurv.

See R. Hohenemser, *L. Cherubini: sein Leben und seine Werke* (1913). (W. H. M.)

CHÉRUEL, (PIERRE) ADOLPHE (1809–1891), French historian, revered for pioneer work on the reign of Louis XIV, was born in Rouen on Jan. 17, 1809. He pursued an academic career and rose to the highest posts. His early work was concerned with Norman history or with the general history of France; but an epoch-making edition of the *Mémoires* of the duc de Saint-Simon (20 vol.. 1856–58) was followed by editions of older memoirs and diaries and by the publication of Cardinal Mazarin's letters (6 vol.. 1872–91; completed with 3 vol. ed. by G. d'Avenel, 1891–1906), which transformed the historiography of the *Fuonde.*

In his most important original works, *Histoiue de France pendant la minorité de Louis XIV (4* vol., 1879–80) and *Histoire de France sous le ministère de Mazarin,* 1651–1661 (3 vol , 1882), Chéruel took full advantage of his long researches. He died in Paris on May 1, 1891.

CHERUSCI, an ancient German tribe living on both sides of the middle Visurgis (Weser) river, extending eastward to the Xlbis (Elbe) river, whose prince Arminius (*q.v.*) inflicted a severe

defeat on the Roman general P. Quinctilius Varus in A.D. 9. They appear at that time to have been the leading tribe of northern Germany, but after Arminius' death they were weakened by repeated wars with the Chatti (*q.v.*). The Romans gave them a king in A.D. 47 and supplied them with financial aid against the Chatti (c. 85) in Domitian's reign.

See Tacitus, *Annals*, i, ii, xi, 16 and xii, 28; *Germania*, 36.

(*G.* E. F. C.)

CHESAPEAKE BAY, the largest inlet (180 mi. long and 3 to 27 mi. wide) in the Atlantic coastal plain of the U.S., created by the submergence of the lower courses of the Susquehanna river and its tributaries. The southern part of the bay is bordered by Virginia, its northern part by Maryland; its entrance is flanked by Cape Charles in the north and Cape Henry in the south. Besides the Susquehanna, major rivers emptying into the bay include the James, York, Rappahannock, Potomac and Patuxent from the west, and the Wicomico, Nanticoke, Choptank and Chester from the east. Most of the irregular eastern shore of the bay is low and marshy; the straighter western shore consists, for long distances, of cliffs. The first European settlement in the bay area, Jamestown (*q.v.*), was founded in 1607. One year later Capt. John Smith explored and mapped the bay and its estuaries, and soon afterward, settlers came to the bay's easily accessible, well protected shores.

Baltimore, Md., the chief port on the upper bay, handles a great variety of cargoes. The Chesapeake and Delaware canal connecting the head of the bay with the Delaware river estuary shortens the sea routes to Baltimore from the north and from Europe. The port group of Norfolk, Va., at the mouth of the James river! exports coal and tobacco. Norfolk is also an important naval base. Oysters: crabs and many species of fish in the bay form the basis for commercial fishing from many small ports. The bay also has attracted recreational activities.

Since 1952 a 4.2-mi. long highway bridge has spanned the bay near Annapolis. Md. (F. O. A.)

CHESELDEN, WILLIAM (1688–1752), English surgeon, one of the most famous and rapid operators in the preanesthetic period, was born at Somerby, Leicestershire, on Oct. 19, 1688. He studied anatomy in London under William Cowper (1666–1709), and in 1713 published his *Anatomy of the Human Body*. He became surgeon at St. Thomas' and St. George's hospitals, London. Cheselden is famous for his "lateral operation for the stone," which he first performed in 1727.

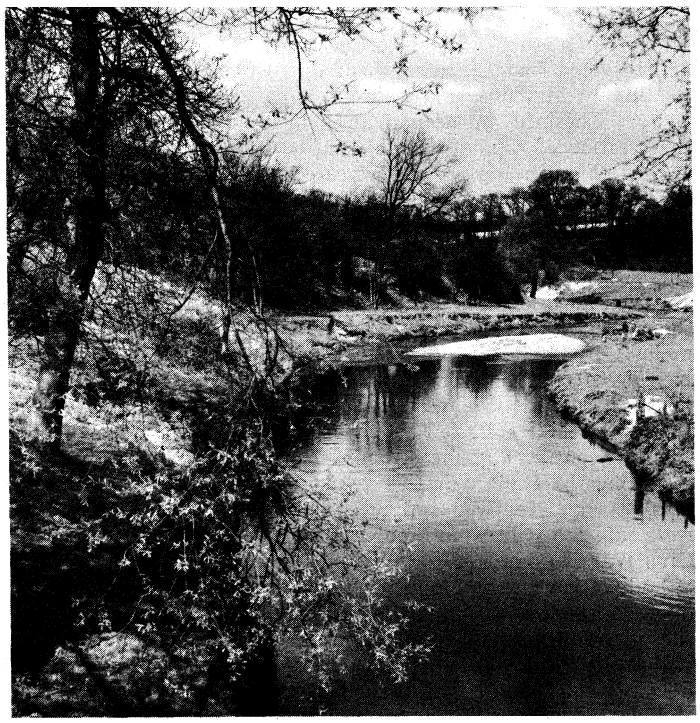
He also effected a great advance in ophthalmic surgery by his operation for the treatment of certain forms of blindness by the production of an "artificial pupil." He attended Sir Isaac Newton in his last illness, and was a friend of Alexander Pope and of Sir Hans Sloane. He died at Bath on April 10, 1752.

See F. H. Garrison, *Introduction to the History of Medicine*, p. 343 (1929).

CHESHIRE, a northwest maritime county of England bounded on the north by Lancashire and Yorkshire and the Irish sea, on the east by Derbyshire, on the south by Staffordshire, Shropshire and Flintshire and on the west by Denbighshire and Flintshire. Area (land and inland water) 1,015.2 sq.mi.

Physical Features. — Almost the whole of Cheshire forms part of the central lowland area of England, the only exception being a narrow strip along the eastern boundary of the county where the land rises to nearly 2,000 ft. to form part of the Pennines (*q.v.*). The low undulating Cheshire plain forms the southern and western parts of the county. It is bisected by the north-south hills of the mid-Cheshire ridge which in the Peckforton hills reaches 746 ft. The western portion of the plain is drained by the Dee, which forms the county boundary in the southwest, and the Gowy, a tributary of the Mersey (*q.v.*). East of the ridge the plain is drained by the Weaver, Dane and Bollin, all flowing into the Mersey which, for much of its length, forms the northern county boundary. The low plateau of Wirral forms a peninsula about 8 mi. wide between the estuaries of the Dee and Mersey.

With the exception of a small area of Lower Lias Slates near Audlem in the extreme south, the whole of the Cheshire plain is underlain by Triassic strata. The central ridge of hills is formed



J. ALLAN CASH

RIVER BOLLIN, NEAR WILMSLOW. CHESHIRE, ENG.

of Keuper Sandstone and this formation reappears in ridges northwest of Macclesfield and along the northern border of the county between Runcorn and Altrincham and in the Birkenhead area. West of the central ridge the predominant formation is Bunter Sandstone, while to the east and dominating the geological pattern of the county are the Keuper Marls extending to the Pennine foothills. There the Bunter Sandstone reappears soon to give way to rocks of the Carboniferous series of which the Pennines are formed. The predominant rock formation in this highland region is Millstone Grit, while a tongue of Coal Measures extends northward from Macclesfield, east of Stockport, to join the main body of the Lancashire coal field. Coal-bearing strata are also found at Neston in the Wirral, but, as in east Cheshire, the coal is no longer mined. By far the most important mineral deposits are the rock-salt beds which are present in the Keuper Marl strata of the east Cheshire plain. Apart from the central ridge and eastern hills, practically all the geological strata are overlain by drift deposits chiefly composed of glacial clays, sands and gravels which in places have a thickness of several hundred feet. Narrow strips along the banks of the major rivers are covered with alluvium and river gravel, while peat is present in isolated areas in the east Cheshire plain, and, in the north, in Delamere and along the lowlands of the Mersey between Runcorn and Ashton-upon-Mersey. Areas of blown sand occur in north Wirral and west of Sale. The glacial clays produce a heavy soil, difficult to plow, while the soils developed on sands and gravels are more amenable to cultivation. The intricate pattern of the sand and clay deposits has created a great variety of soil type throughout the county, which in general is extremely fertile. (AR. C. HE.)

History. — The first substantial settlements in Cheshire, the hill forts of Bronze and Iron Age near Helsby and at Eddisbury and Bickerton, were sited on the lightly wooded mid-Cheshire ridge. Cheshire came into prominence with the establishment (*c.* A.D. 71) of the Roman legionary fortress at Deva (Chester), designed as a base for the conquest of north Wales and the defense of the northwest. The departure of the legions left Cheshire remote and isolated. In 830 the Anglo-Saxons pushing northwestward defeated the Celts and brought Cheshire into the kingdom of Mercia. Cheshire first emerged as a distinctive administrative unit upon the subdivision of Mercia in the 10th century. During the 9th and 10th centuries Wirral was invaded by Norsemen whose settlements are recorded in the many Norse place names of the peninsula

(*e.g.*, Meols, Frankby, Thingwall and Thurstaston). The county established by the Normans was much larger than modern Cheshire and included Lancashire south of the Ribble and large parts of the present Flintshire and Denbighshire. By the end of the 13th century Cheshire had been reduced to its modern dimensions by the creation of separate administrations in Lancashire and north Wales. The Chester earldom, created in 1071 and given by William the Conquerer to Hugh of Xvranches, passed to the crown in 1241 and the county became a palatinate with control over its own administration, both legal and fiscal (see CHESTER, EARLS OF). In the reign of Henry VIII these privileges were progressively abridged until only the palatine courts still functioned and. with their disappearance in 1830, only the title of County Palatine remains. In 1403 Cheshire was the headquarters of Hotspur (Sir Henry Percy; *q.v.*), who roused the people by telling them that Richard II was still alive. At the beginning of the Wars of the Roses Margaret collected a body of supporters from among the Cheshire gentry, and Lancastrian uprisings occurred as late as 1464.

During the Civil War the county was divided, Chester being loyalist while Nantwich supported parliament. The king's forces were defeated at Rowton Moor outside Chester in 1646. After the Civil War Cheshire's history was one of steady economic progress in both agriculture and industry, punctuated by such events as the discovery of rock salt in 1670, and the introduction of cotton textiles in the 18th century and chemicals in the 19th. (E. S. SI.)

Population and Administration. — The population of Cheshire was 1,367,860 in 1961. It shows a high degree of concentration and two areas, the Wirral peninsula and the southern fringe of Manchester, account for nearly two-thirds of the total. In these areas Cheshire becomes part of the Merseyside and Southeast Lancashire conurbations respectively. In the remainder of the county the population is also largely urbanized and only 15% of the total lives in rural areas. The major towns are: Birkenhead; Stockport; Wallasey; Chester; Crewe; Bebington; Sale; Altrincham; Ellesmere Port; Macclesfield; Hyde; Stalybridge; Congleton (*qq.v.*); and Dukinfield.

Cheshire contains four county boroughs, Chester, which is the county town, Birkenhead, Wallasey and Stockport, which are responsible for all services normally provided by a local authority. The remainder of the county is administered by the county council whose area is subdivided into 10 noncounty boroughs. 22 urban districts and 10 rural districts. Many of the county council's powers are delegated to these district councils. Part of the administrative county (almost the whole of Tintwistle rural district and a considerable portion of Macclesfield rural district) is included in the area of the Peak District (*q.v.*) national park.

Cheshire is in the Wales and Chester circuit and the assizes are held at Chester. Its court of quarter sessions sits both at Chester and Knutsford. All the county boroughs, and also the boroughs of Crewe and Macclesfield, have separate commissions of the peace. Ecclesiastically, the county is almost entirely in the diocese of Chester, except for small parts in Manchester, St. Asaph and Lichfield. Sixteen members are returned to parliament, six for the boroughs and ten for county constituencies. (AR. C. HE.)

Industries and Communications. — The greater part of Cheshire supports a highly productive agriculture in which dairying is the dominant enterprise. Its largest centres of population and industry, in Wirral and to the south of Manchester, are peripheral rather than central to the county, their location furthering the impression of a rural shire.

Agriculture.—Farming can be grouped according to three major land categories: southern and western grassy plain, northern arable land and poorer eastern marginal farmland. Each has its own regional expression and all are concerned with dairying. Cheshire has a higher density of dairy cattle (27 per 100 ac.) than any other county. The most widespread type of farming is grassland dairying, practised in Wirral and the drift covered plains to the east and west of the central ridge. In these areas the predominance of heavy, water-retentive soils favours grassland more than arable, and Cheshire has been for centuries renowned for its grass. cattle and cheese. These areas with their small thorn-hedged fields support in summer large herds of dairy cattle, chiefly Friesians and Ayrshires. By the early 1960s more sown grasses and fodder crops were being grown than before World War II, though grassland still predominated. Amid pleasant green fields stand the scattered farmsteads, each of considerable size. The farmhouse, occasionally a half-timbered Elizabethan dwelling. sometimes a gracious Georgian house, more often a solid brick Victorian structure, is usually ranged with the stock buildings in an open square around a yard. The buildings are large and provide lying and shelter for considerable numbers of cattle for about five months of the year. Cheese making, once widespread, is practised on few farms today; instead, milk is collected daily to supply the Merseyside and Manchester conurbations and the Potteries.

The light and loamy soils of the drift-free Triassic sandstones and sandy drifts of north central Cheshire are extensively plowed for crops. However, this arable region is still concerned with dairying. Temporary grasses are commoner than permanent pasture, oats and roots are grown as feed for dairy cattle, and the sale of liquid milk is the main source of income. In addition the sale of potatoes and wheat provides the farmer with a further revenue, early potatoes being of particular importance on the light soils of the Delamere-Frodsham area.

In the east of the county, where the gritstones and shales of the Pennine slopes give rise to thin acid soils, the land is largely in grazing but is much inferior to that of the plain. Small dairy farms, which also raise sheep and beef cattle to diversify their economy. are the most characteristic. The area is one of poor marginal farms in contrast to the productive holdings of both the grassy plain and the northern arable region.

Industry. — Cheshire is by no means entirely concerned with farming, for the majority of its people live in industrial towns. In the northeast, towns such as Stockport, Hyde and Stalybridge are part of the textile province of Lancashire. The expanding conurbation of Manchester has leaped the Mersey and the Cheshire towns of Sale, Altrincham, Cheadle and Gatley (*qq.v.*) which function largely as satellite industrial centres and dormitory suburbs for Manchester. Further afield, Hazel Grove, Bramhall and Wilmslow also fall within the Manchester commuter network.

The towns of the Cheshire salt field exhibit a more autochthonous growth based on the exploitation of this mineral resource and its increasing use in heavy chemical industries. Northwich and Runcorn (*qq.v.*) are particularly important chemical towns, while Middlewich, Winsford and Sandbach are lesser centres also concerned with salt or chemicals. In the east of the county, and separate from the cotton manufacturing region peripheral to Manchester, the "isolated" industrial town of Macclesfield, with the lesser centre of Congleton, is important for silk textiles and textile machinery. Another "isolated" industrial town is the rail junction of Crewe. The advantages of its site in the south of the county are entirely man made; the establishment of locomotive works at the junction led to the growth of the town which, together with the transport facilities, attracted other manufactures, in particular those of motor vehicles and aircraft engines.

Along the Mersey shores of the Wirral peninsula is a further industrial region where two factors led to the growth and concentration of industry: the facilities of Birkenhead docks and the deep water sites afforded by the Manchester Ship canal. Industries such as flour milling, oil-seed crushing, soap (Port Sunlight) and margarine manufacture and oil refining (Stanlow) have developed along quayside sites. On the Mersey shore are also the great Birkenhead shipyards and chemical, paper and engineering works. The remaining gaps of open land are rapidly being built upon. one being earmarked as the site for a motor vehicle plant. In addition to housing workers in these industries, north Wirral is a dormitory suburb of the Merseyside conurbation.

Communications.—Eleven important national traffic routes cross Cheshire from north to south and east to west, and are interconnected by an extensive system of minor roads. Numerous road improvement schemes were undertaken. notably the building of a bridge across the Mersey at Runcorn (replacing the Edwardian Transporter bridge) and the construction of that part of the East of Birmingham-Preston motorway which passes from south to north through the county. Downstream in the narrows of the

Mersey, between Liverpool and Birkenhead, the Mersey tunnel (opened in 1934) carries heavy goods and passenger traffic.

Crewe, which is centrally situated in the county, is one of the most important railway junctions in England with repair shops. The major lines passing through it run north and south while rail communications between east and west are poor. Electrification of many of the major railways was carried after 1960 while a diesel service operated on others. The county is also served by a system of waterways, the most important being the Manchester Ship canal, which extends 36½ mi. from Manchester to Eastham along the south bank of the Mersey and is capable of handling ocean-going vessels up to 15,000 tons. Just inside the county is the largest municipally owned airport in England, which is operated by Manchester city council at Ringway. (E. S. Si.)

CHESHUNT, an urban district in the East Hertfordshire parliamentary division of Hertfordshire, Eng., in the Lea valley, 13 mi N. of London and 9 mi S.S E. of Hertford by road. Pop. (1961) 35,297. It contains Cheshunt, Waltham Cross and Goff's Oak. At Waltham Cross stands one of the three remaining crosses erected in memory of Queen Eleanor (d. 1290). Cardinal Wolsey once owned the Great house. In Cedars park, given to Cheshunt in 1921, stood Theobalds palace, where James I died in 1625. One of the entrances to Theobalds park, on the other side of the Great Cambridge road, is old Temple Bar, moved there from Fleet street, London, in 1878. The training college for the Countess of Huntingdon's Connexion (a nonconformist sect which came there from Trevecca, Brecknockshire, in 1792) was moved to Cambridge in 1904, where it is known as Cheshunt college (Congregational). Bishops' college in Cheshunt is administered by the Church of England. Cheshunt is a centre for market and greenhouse gardening; it has a horticultural research station.

CHESIL BANK (O E., *ceosol,* "pebble bank"), a remarkable beach of shingle on the coast of Dorsetshire, Eng. It is separated from the mainland for 8 mi. by an inlet called the Fleet, famous for its swannery, and continues in all for 18 mi. southeastward from near Abbotsbury, terminating at the Isle of Portland (q v). At the Portland end it is 35 ft. above spring-tide level, and 200 yd. wide, while at the landward end the width is 170 yd. and the pebbles are less in size. The beach was formed by general drift of shingle along this coast from west to east.

CHESNEY, FRANCIS RAWDON (1789–1872), British soldier, explorer and middle east traveler whose fame rests on his projects for the Suez canal and for an overland route to India by the Euphrates valley. The son of Capt. Alexander Chesney, who had served under Lord Rawdon (later marquis of Hastings) in the American Revolution, Francis Rawdon was born at Annalong, County Down, Ire., on March 16, 1789. After a cadetship at Woolwich he was gazetted to the royal artillery in 1805 and later rose to be a general. During a tour of military duty at Constantinople in 1829, he formulated plans for the Suez canal that were the basis of Ferdinand de Lesseps' undertaking completed in 1868.

After a daring journey from Anah on the Euphrates to the Persian gulf, Chesney in 1831 suggested the overland route to India and with the support of the East India company pressed the proposal on the British government. In 1835 he was sent in command of a small expedition to test the navigability of the Euphrates. In spite of much opposition from the Egyptian pasha, he transported two steamers in sections from the Mediterranean to the middle Euphrates, reaching Bushire on the Persian gulf in the summer of 1836. For this journey he received the Royal Geographical society's gold medal. Military duties in Hong Kong delayed publication of his book on the expedition until 1850. He retired from the army in 1847 and. though he went to the middle east again in 1856 and 1862, he made his home in Ireland until his death at Mourne on Jan. 30, 1872. His chief works are *The Expedition for the Survey of the Rivers Euphrates and Tigris* (1850), *Observations on . . . Firearms* (1852) and *The Russo-Turkish Campaigns of 1828 and 1829* (1854).

CHESS, a game for tuo players using a board and special pieces. From its pre-eminence among intellectual pastimes, it is called "the royal game." Probably originating in India during or before the 7th century (see *Origin of Chess,* below), chess spread to Persia, to Arabia and thence to western Europe. Its name and the term "checkmate" are sometimes said to derive from the Persian *shah,* "king," and *shah mat,* "the king is dead." The growth of an extensive occidental chess literature and the rise of international tournaments have standardized the game throughout Europe and America, but this has not affected the variants that have evolved in the countries east of India, as, for example, shogi (*q.v*) in Japan.

This article is divided into six main divisions dealing with the various aspects of chess, as follows:

I. THE GAME

1. The Board.—The chessboard comprises 64 squares, coloured alternately light and dark, in a large square. The players, designated White and Black, sit on opposite sides. In printed diagrams the Black side is by convention at the top. The board is placed so that each player finds a light square in the corner nearest his right hand. A row of eight squares parallel to the White and Black sides is called a rank; a row at right angles to the ranks is a file.

2. The Pieces.—Each player has 16 pieces, which are placed on the board at the beginning of a game as shown in fig. 1. The pieces are distinguished by their shapes into six kinds: king, queen, rook, bishop, knight, pawn. The king moves in any direction, one square at a time. The queen, rook and bishop are "long-range" pieces moving any distance along an unobstructed line. The rook moves only on the ranks and files, the bishop only on the diagonals. The queen combines the powers of rook and bishop and thus moves on any open line. The knight's move is made up of two different steps. It takes one step of one single square along the file or rank and then, still moving away from the square that it has left, takes one step along the diagonal (*see* fig. 4). This is not a line move, but a move from point to point, and therefore cannot be obstructed by any neighbouring

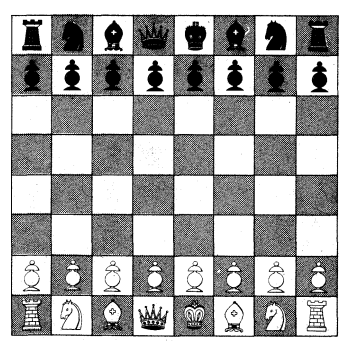

FIG. 1—DIAGRAM SHOWING POSITION OF CHESSMEN AT BEGINNING OF GAME

Queen's rook (QR); queen's knight (QKt); queen's bishop (QB); aueen (Q); king (K); king's bishop (KB); king's knight (KKt); king's rook (KR). The pieces in front of the principal pieces are the pawns (P)

pieces. The term "piece" is often used in a restricted sense to exclude panns Any piece not a pann captures in the same nay as it moves; that is it may capture an adverse man standing on a square to which it can legally move. The capturing piece replaces the captured on the same square, and the captured man is removed from the board

The pawn has several peculiarities. It moves only forward. and when not capturing advances only on the file. For the first advance from its initial square on the second rank the pawn has the option of moving one or two squares, but thereafter may move only one square at a time *(see* fig. 2). If it reaches the eighth rank, farthest from the owner, the pawn is immediately replaced by a queen. rook, bishop or knight of the same colour, at the option of the owner. This promotion is also called queening, since the usual choice is a queen, the most powerful piece. A pawn may promote even though the piece chosen to replace it has not previously disappeared from the board by capture; *e.g.,* a player may have two or more queens. The pawn alone captures differently from its noncapturing move. It captures to either square that is adjacent and diagonally forward. If a pawn makes the double advance for its first move. an adverse pawn that could have captured it, had the first pawn moved only one square, may capture it *en passant*, "in passing"; but this "e.p." capture may be made only on the immediate turn. not later.

Castling is a compound move of the king and one rook (formerly called "castle") that may be made, if at all, only once in a game. It is legal if neither the king nor the rook has yet moved; if all the squares between them on the rank are vacant and no adverse piece commands the two squares nearest the king on the side on which castling is to be carried out; and if the king is not in check. The move is executed by moving the king two squares toward the rook, and then placing the rook on the square passed over by the king *(see* fig. 3). Either the KR or the QR may be used in castling.

3. Notations. — In the descriptive notation *(see* fig. 5), each file is given the name of the piece originally posted on it. and the ranks are numbered from 1 to 8 away from the player. Each rank thus has a dual designation, according to the colour of the moving piece. A move is written in the form "P—QB4," the initial of the moving piece followed by the designation of the square moved to. The abbreviation "Kt" for knight is often replaced by "S" or "N." Indication of K-side or Q-side is omitted when no ambiguity would result; *e.g.*, "B—B4" when only one bishop can reach either of the B4 squares. The symbol "×" as in "P×P" indicates a capture and is read "takes." This notation was condensed in the middle of the 19th century from the earlier florid style; *e.g.,* "King's pawn to his fourth."

In the algebraic notation, the files are lettered A to H, from White's left to right. The ranks, from White to Black, are numbered 1 to 8. Each of the 64 squares thus has its own designation, a letter and a number. A move is written in the form "Pc2-c4," the initial of the moving piece followed by the square of departure and the square of arrival. The initial of the pawn, however: is usually omitted, as is also. in condensed style. the square of departure. The above move may be written as "c2 – c4" or even as "c4." Symbols used are as follows: (×) or (:) takes; (o-o) castles on K-side; (o-o-o) castles on Q-side; (†) or (+) check: (‡) or (#) checkmate; (!) best, or a good move; (?) questionable, or a poor move; (!?) is this best?

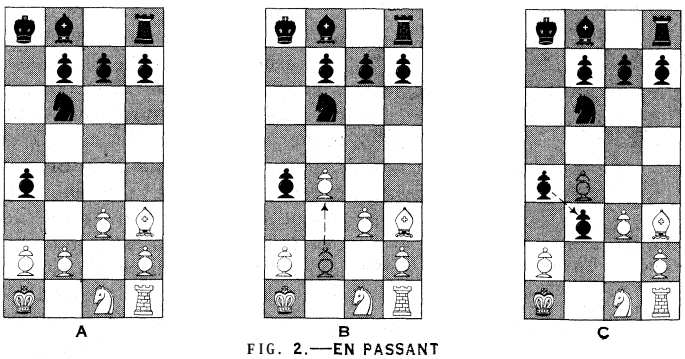

FIG. 2.—EN PASSANT

(A) Theoretical positions (right half of board). White's move. (B) White's pawn moves two squares (P—KB4). Dotted image indicates previous position. (C) Black captures White pawn *en passant* (P X P)

Game records are kept in columnar form. as below. White moves first after nhich the players alternate in making one move at a time. The moves are numbered serially, both a White move and a Black reply having the same number.

	Descriptive		Algebraic	
	White	Black	White	Black
1	P — K4	P — K4	e2 — e4	e7 — e5
2	Kt — KB3	Kt — QB3	Sg1 — f3	Sb8 — c6
3	B — B4	B — B4	Bf1 — c4	Bf8 — cj
4	P — B3	Kt — B3!	4 c2 — c3	Sg8 — f6!
5	P — Q4	P X P	5 d2 — d4	e5 — d4:
6	P × P	B — Kt5ch	6 c3 — d4:	Bc5 — b4†

In annotation, moves are written linearly, thus: (descriptive) 1 P—K4, P—K4; 2 Kt—KB3, Kt—QB3; 3 B—B4, B—B4; 4 P—QKt4, B×P; j P—B3; (algebraic) 1 e4, e5; 2 Sf3, Sc6; 3 Bc4, Bcj; 4 b4, Bb4:; 5 c3. Occasionally, the descriptive notation is nritten in fractional form, the White moves being above the line and the Black moves below, thus:

$$1\ \frac{P-K4}{P-K4}\quad 2\ \frac{Kt-KB3}{Kt-QB3}$$

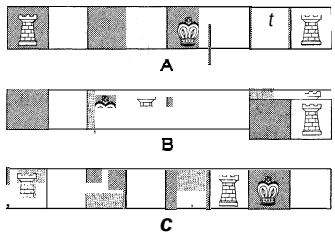

FIG. 3.— CASTLING

(A) Positions before castling; (B) castling with queen's rook: (C) castling with king's rook

In French and German, respectively. the names of the pieces are. king. *roi, König;* queen, *dame, Dame;* rook, *tour, Turm;* bishop *jou, Läufer;* knight. *cavalier, Springer;* pann. *pion, Bauer;* the game is chess, *les échecs, Schach*

4. Object of Play. — The game is won by capturing the adverse king. The capture is never consummated; when the king is attacked and cannot escape, he is said to be checkmated and the game ends forthwith. Many games end by resignation of a player who sees that he cannot escape eventual defeat.

A threat to capture the adverse king is a check; a check must of course be averted or the game forfeited. The only ways of meeting a check are to move the king. capture the attacker or interpose on the line of check given by a distant queen. rook or bishop.

Check by discovery may be given by a long-range piece. by removal of a piece standing on a line between it and the adverse king. A piece that cannot move without discovering check upon its own king is said to be pinned. Even if completely immobilized by pin, a piece may exert check on the adverse king. for if the captures were actually consummated. the pinned piece would capture the adverse king one move ahead of the loss of its own king.

5. Value of the **Pieces.**—With only the kings otherwise left on the board, checkmate can be forced by a single major piece. queen or rook, or by two bishops, or by a bishop and a knight. but not by two knights or any single hinor-piece. (But a king accompanied by "officious friends," pawns that block rather than protect him, is sometimes mated by a single knight or bishop.', A single pawn cannot give mate, but wins if it can be promoted. Two rooks normally draw against a queen. and may win. Two bishops can draw against a queen. But a queen wins against one rook or two minor pieces including a knight. One minor piece draws against a rook.

With additional pieces on the board, however, any material superiority, even one pawn, spells potential victory. The superior fighting power 'can usually increase its own margin of advantage. In terms of the pawn as 1, the fighting power of the pieces is approximately: knight 3, bishop 3, rook j. queen 9. This scale gives a measure of whether material equality is disturbed by an exchange of captures of unlike pieces. The phrase "winning the exchange" is applied particularly to winning a rook for a minor

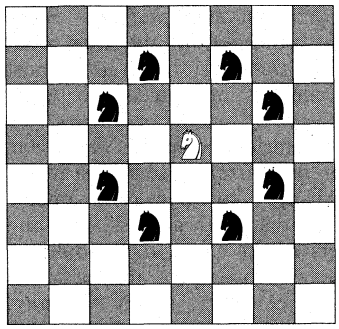

FIG. 4.—THE POSSIBLE MOVES OF A KNIGHT
The White knight may move onto any of the squares occupied by the Black knights

piece. Any such gain in relative power is potentially decisive. The more disparate the pieces exchanged. however, the more the outcome is affected by the particular position. For example, the merits of one rook v. five pawns cannot be stated in general, as there is no "general position." Positional considerations often override the abstract evaluations. Sacrifices of material are often made for positional advantage. The knight and bishop are rated equal. but a bishop is more favoured by the position than a knight, and two bishops are almost always stronger than two knights.

6. Drawn Games.—A game may be abandoned as drawn for any of the following reasons. Insufficient force: the pieces remaining on the board do not suffice to force checkmate. Stalemate: the player in turn to move has no legal move but is not in check. Perpetual check: a player demonstrates that he can check the adverse king without cessation. and declares that he will do so. Agreement: the players agree to abandon the game. Recurrence: if the same position of all forces recurs three times. with the same player to move on each occasion, that player may claim a draw. Fifty-move rule: when the player whose turn it is to move proves that at least 50 moves have been played by each side without a capture of a piece and without a pawn move's having been made. This number of 50 moves may be increased to an agreed total in certain positions provided that these have been laid down before the game (e g., it is possible to mate with two knights in 66 moves so long as the opponent has a pawn with which to avoid stalemate).

II. LAWS OF CHESS

All countries outside the orient follow the laws of chess as formulated by the World Chess federation (see *Fédération Internationale des Échecs*, below). These include not only the basic rules but the special regulations for official tournaments and matches. The more important of these regulations are as follows:

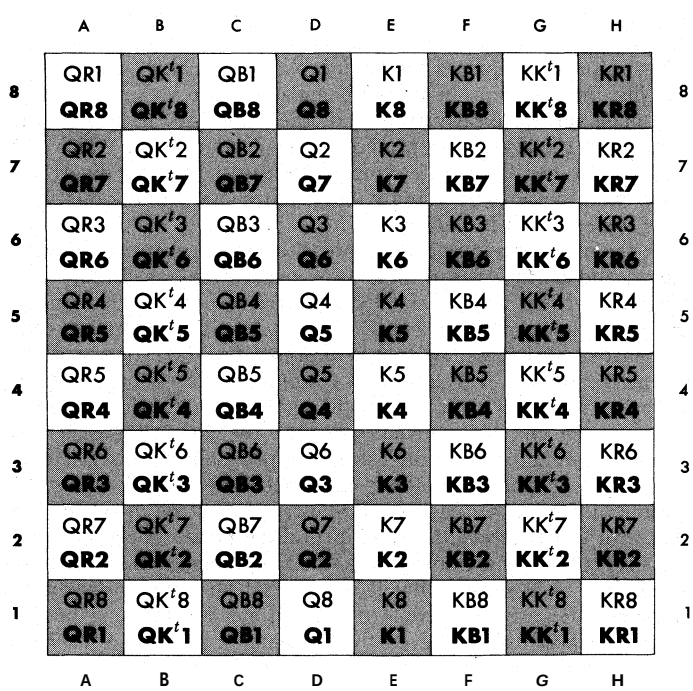

FIG. 5.— DESCRIPTIVEAND ALGEBRAIC SYSTEMS OF NOTATION
The descriptive system names the file after the piece on the first rank, as the "KR file" at the extreme right. The ranks are counted away from the player whose piece moves. in the algebraic system the files are lettered A to H, from White's left to right, and the ranks are numbered 1 to 8 from White to Biack. In diagrams the bottom edge is always the White side. Heavy type indicates system from White's side; lighter type is system as seen from Black's side

If he first warns his opponent, the player having the move is permitted to adjust one or more of the pieces. Except for this, if the player having the move touches one or more pieces, he must move or take the first piece he has touched which can be moved or taken. No penalty is entailed if the opponent makes no claim before himself touching a piece, or if none of the moves that are indicated above can legally be made.

A completed legal move may not be retracted. A move is completed: (1) in the case of transfer of a piece to a vacant square, when the player has taken his hand from the piece; (2) in the case of capture. when the captured piece has been removed from the chessboard and the player, having placed his own piece on its new square, has taken his hand from the piece: (3) in the case of castling. when the player, having moved the rook to the square crossed by the king. has taken his hand from the rook—when the player has taken his hand from the king. the move is not yet completed, but the player has lost the right to make any move other than castling; (4) in the case of promotion of a pawn, when the pawn has been removed from the chessboard and the player. having placed a new piece on the promotion square, has taken his hand from the piece—if the player has taken his hand from the pawn that has reached the promotion square, the move is not yet completed, but the player has lost the right of making a different move with the pawn.

If, during a game, it is found that an illegal move has been made, the position shall be restored to what it was before the illegal move was made; the game shall then continue, the player making a legal move with the piece that he touched when he made an illegal move. If it proves impossible to set up the correct position, the game shall be annulled and a fresh game played. If, in the course of a game. one or more of the pieces have been accidentally displaced and incorrectly replaced, the position shall be restored to what it was before the mistake and the game shall continue. If it proves impossible to set up the correct position, the game shall be annulled and a fresh game played.

If, in the course of a game, it is found that the initial position of the pieces was incorrect, the game shall be annulled. If, in the course of a game. it is found that the chessboard has been wrongly placed, the position that has been reached shall be transferred to a chessboard correctly placed and the game shall continue. If, after an adjournment (see below), the position has been set up incorrectly, it shall then be restored to what it was at adjournment and the game shall continue.

Each player must make a given number of moves in a given period of time; these two factors shall be specified in advance. Time is kept on each player by means of separate clocks. A player's clock is set going when it becomes his turn to move; he may stop it only after he has made his move. The White player's clock is started at the time scheduled for commencement of the game, regardless of whether both of the players are present.

If a game is not finished by the closing time for the session. it is adjourned. The player having the move takes what time he wishes for thought, writes his move on a slip of paper and seals it in an envelope which he hands to the referee; his clock is then stopped. At resumption of play. the referee adjusts the clocks, sets up the position as it was left at adjournment, opens the envelope, makes the indicated move and starts the opponent's clock.

A game is lost by a player who has not made the prescribed number of moves in the specified time: who arrives at the chessboard more than one hour late; who, after an adjournment, is found to have sealed an illegal move or a move so imprecise that it is impossible to establish its true meaning; or who, during the game, refuses to comply with the laws of chess. If both players arrive at the chessboard more than one hour late, or if both refuse to comply with the laws of chess, neither player shall receive any credit for this game; it shall be declared as lost by both of them.

III. HISTORY

1. Origin of Chess.—The invention of chess has been variously ascribed to the Greeks, Romans, Babylonians, Scythians, Egyp-

tians, Jews, Persians, Chinese, Hindus, Arabians, Araucanians, Castilians: Irish and Welsh. Some have even tried to fix upon particular individuals as the originators of the game; among others, upon Japheth. Shem, King Solomon, the wife of Ravan, king of Ceylon, Xerxes, Palamedes, Aristotle, Semiramis, Zenobia, Attalus (d. *c.* 200 B.C.), the mandarin Han-sing, the Brahman Sissa and Shatrenscha, stated to be a celebrated Persian astronomer. Many of these ascriptions are fabulous, others rest upon little authority, and some of them proceed from easily traceable errors, as where the Roman games of *ludus latrunculorum* and *ludus calculorum,* both board games played with pieces of different values, the Welsh recreation of *tawlbwrdd* (throw-board) and the ancient Irish pastime of *fithcheall* are assumed to be identical with chess; so far as the Romans and Welsh are concerned, the contrary can be proved, while from what little is known of the Irish game it appears not to have been a sedentary game at all.

N. Bland, in his *Persian Chess* (1850), endeavoured to prove that the Persians were the inventors of chess, maintaining that the game, born in Persia, found a home in India, whence after a series of ages it was brought back to its birthplace. The view which has obtained the most credence, however, is that which attributes the origin of chess to the Hindus. Thomas Hyde of Oxford. writing in 1694 (De *ludis orientalibus*), seems to have been the first to propound this theory, but he appears to have been ignorant of the game itself, and the Sanskrit records were not accessible in his time. About 1783–89 Sir William Jones, in an essay published in the second volume of *Asiatic Researches,* argued that Hindustan was the cradle of chess, the game having been known there from time immemorial by the name of *chaturanga,* that is. the four *angas,* or members of an army. which are said in the Xmara-kosha, a 4th-century vocabulary of Sanskrit roots, to be elephants. horses. chariots and foot soldiers. As applicable to real armies, the term *chaturanga* is frequently used by the epic poets of India. Sir William Jones's essay is substantially a translation of the Bhawishya purana, in which is given a description of a four-handed game of chess played with dice. A pundit named Rhadhakant informed him that this was mentioned in the oldest lawbooks, and also that it was invented by the wife of Ravan, king of Lanka (Ceylon). in the second age of the world in order to amuse that monarch while Rama was besieging his metropolis. This account claims for chess an existence of 4.000 or 5,000 years. Jones. however, grounded his opinions as to the Hindu origin of chess upon the testimony of the Persians and not upon the above manuscript, while he considered the game described therein to be more modern than the Persian game. Though sure that the latter came from India and was invented there. he admitted that he could not find any account of it in the classical writings of the Brahmans. He laid it down that chess, under the Sanskrit name *chaturanga,* was exported from India into Persia in the 6th century A.D.; that by a verbal corruption the old Persians changed the name into *chatrang,* but that when their country was soon afterward occupied by the Arabs. who had neither the initial nor final letter of the word in their alphabet, they altered it further into *shatranj,* which name found its way later into modern Persian and ultimately into the dialects of India.

H. J. R. Murray, in his monumental *History* of *Chess* (1913), came to the conclusion that chess is a descendant of an Indian game played in the 7th century.

Altogether, therefore. the best authorities agree that chess existed in India before it is known to have been played anywhere else. In this supposition they are strengthened by the names of the game and of some of the pieces. *Shatranj,* as the British orientalist Duncan Forbes, author of *The History* of *Chess* (1860), pointed out, is a foreign word among the Persians and Arabians, whereas its natural derivation from the term *chaturanga* is obvious. Again *al-fil,* the Arabic name of the bishop, means the elephant. otherwise *alephhind,* the Indian ox. The earliest authority on chess is Masudi, an Arabic author writing *c.* 950 who states that *shatranj* had existed long before his time.

2. Early and Medieval Times.—The dimness which shrouds the origin of chess naturally obscures also its early history. It has been seen that chess crossed over from India into Persia and became known in the latter country by the name of *shatranj.* Some have understood that word to mean "the play of the king"; but undoubtedly Sir William Jones's derivation carries with it the most plausibility. How and when the game was introduced into Persia there is no means of knowing.

The Persian poet Firdausi, in his historical poem the *Shahnama,* gives an account of the introduction of *shatranj* into Persia in the reign of Khosrau I Anushirvan (531–579), to whom came ambassadors from the sovereign of Hind (India) with a chessboard and men, asking him to solve the secrets of the game, if he could, or pay tribute. The king asked for seven days' grace, during which time the wise men vainly tried to discover the secret. Finally, the king's minister took the pieces home and discovered the secret in a day and a night. He then journeyed to India with a game of his own invention, *nard,* which the Indians could not reconstruct.

Other Persian and Arabian writers state that *shatranj* came into Persia from India, and there appears to be a consensus that may be considered to settle the question. Thus the game passed from the Hindus to the Persians and thence to the Arabs and from them, directly or indirectly, to various parts of Europe, at a time which cannot be definitely fixed, but which was either in or before the 10th century.

As to how chess was introduced into western and central Europe nothing is really known. The Spaniards very likely received it from their Muslim conquerors, the Italians not improbably from the Byzantines, and in either case it would pass northward to France, going on thence to Scandinavia and England. Some say that chess was introduced into Europe at the time of the crusades, the theory being that the Christian warriors learned to play it at Constantinople. This is negated by a curious epistle of St. Peter Damian (Pietro Damiani), cardinal bishop of Ostia, to Pope Alexander II written *c.* 1061, which, assuming its authenticity. shows that chess mas known in Italy before the date of the first crusade. The cardinal. as it seems, had imposed a penance upon a bishop whom he had found diverting himself at chess; and in his letter to the pope he repeats the language he had held to the erring prelate. viz., "Was it right, I say, and consistent with thy duty. to sport away thy evenings amidst the vanity of chess! and defile the hand which offers up the body of the Lord, and the tongue that mediates between God and man, with the pollution of a sacrilegious game?" Among those who took an unfavourable view of the game may be mentioned John Huss (1369–1415), who. when in prison, deplored his having played at chess, whereby he had lost time and run the risk of being subject to violent passions.

Among authentic early records of the game may be quoted the *Alexiad* of the Byzantine princess Anna Comnena, in which she relates how her father. the emperor Alexius, used to divert his mind from the cares of state by playing at chess with his relatives. This emperor died in 1118.

Concerning chess in England there is the usual confusion between legend and truth. Snorri Sturluson relates that as Canute was playing at chess with Earl Ulf, a quarrel arose. which resulted in the upsetting of the board by the latter, with the further consequence of his being murdered in church a few days afterward by Canute's orders. The Ramsey Chronicle relates how Bishop Ctheric, coming to Canute at night upon urgent business, found the monarch and his courtiers amusing themselves at dice and chess. There is nothing intrinsically improbable in this last narrative. except that the date is suspiciously early for chess, as Canute died in 1035. Moreover, allowance must be made for the ease with which chroniclers described other games as chess.

As regards the individual pieces, the king seems to have had the same move as at present, but it is said that he could formerly be captured. His castling privilege is a European invention; but he formerly leaped two and even three squares. and also to his Kt2. Castling dates no further back than the first half of the 16th century. The queen has suffered curious changes in name. sex and power. In *shatranj* the piece was called *farz* or *firz* (also *farzan, farzin* and *farzi*), signifying a "counselor." "minister" or "general." This was Latinized into *farzia* or *fercia.* The French slightly altered the latter form into *fierce, fierge* and, as some say, *vierge* ("virgin"), which, if true, might explain its becoming a

female. Another and much more probable account has it that whereas formerly a pawn on reaching an eighth square became a *farzin* and not any other piece, which promotion was of the same kind as at draughts (in French. *dames*), so she became a *dame* or queen as in the latter game, and thence *dama, donna,* etc. There are old Latin manuscripts in which the terms *ferzia* and *regina* are used indifferently.

The queen formerly moved only one square diagonally and was consequently the weakest piece on the board. The immense power now possessed by her seems to have been conferred as late as about the middle of the 15th century. Thus under the old system the queens could never meet each other: for they operated on diagonals of different colours. The bishop's scope of action was also formerly very limited; he could move only two squares diagonally and had no power over the intermediate square, which he could leap over whether it was occupied or not. This limitation of his powers prevailed in Europe until the 15th century. This piece, according to Forbes. was called among the Persians *pil,* "elephant," but the Arabs. not having the letter *p* in their alphabet, wrote it *fil,* or with their definite article *al-$1,* whence *alphilus, alfinus, alifiere,* the latter being the word used by the Italians. while the French perhaps get their *fol* and *fou* from the same source. The pawns formerly could move only one square at starting; their powers in this respect were increased about the early part of the 16th century. It was customary for them on arriving at an eighth square to be exchanged only for a *farzin* (queen) and no other piece; the rooks (so called from the Indian *rukh* and Persian *rokh,* meaning "a soldier") and the knights appear to have always had the same powers as at present. As to the chessboards. they were uncoloured, and it is not until the 13th century that we hear of checkered boards being used in Europe.

3. Development in Play. — The change of *shatranj* into modern chess took place most probably first in France. and thence made its way into Spain early in the 11th century, where the new game was called *Axedrez de la dama,* being also adopted by the Italians under the name of *scacci alla rabiosa.* The time of the first important writer on modern chess, the Spaniard Ruy Lopez de Sigura (1561), is also the period when the latest improvement, castling. was introduced, for his book, *Libro de la invencion liberal y arte del juego del Axedrez* ("Book of the Liberal Invention and Art of Playing Chess"), though treating of it as already in use, also gives the old mode of play, which allowed the king a leap of two or three squares. Shortly afterward the old *shatranj* disappeared altogether. López was the first who merits the name of chess analyst. At this time flourished the flower of the Spanish and Italian schools of chess — the former represented by Ruy Lopez, Alfonso Ceron, Santa Maria, Busnardo and Carlos Avalos, the latter by Giovanni Leonardo da Cutri (Il Puttino) and Paolo Boi (Il Syracusano). In the years 1562–75 both Italian masters visited Spain and defeated their Spanish antagonists. During the whole 17th century there was but one worthy to be mentioned, Gioachino Greco (Il Calabrese).

The middle of the 18th century inaugurated a new era in chess. The leading man of this time was Philidor (real name Francois André Danican; 1726–95). He was trained by M. de Kermar, sieur de Legal, the star of the Café de la Régence in Paris, which was the centre of French chess until early in the 20th century. In 1747 Philidor visited England and defeated the Arabian player, Phillip Stamma, by 8 games to 1 and 1 draw. In 1749 he published his *Analyze des échecs,* a book which went through more editions and x-as more translated than any other work upon the game. During more than half a century Philidor traveled much but never went to Italy. the only country where he could have found opponents of first-rate skill; for instance, Ercole del Rio. G. B. Lolli and D. L. Ponziani.

Blindfold chess play. already exhibited in the 11th century by Arabian and Persian experts, was taken up afresh by Philidor. who played on many occasions three games simultaneously aithout sight of board or men. These exhibitions were given in London. at the Chess club in St. James's street.

As eminent players of this period must be mentioned Count P. J. van Zuylen van Nyevelt (1743–1826) and the German player Johann Allgaier (1763–1823), after whom a well-known brilliant variation of the king's gambit is named. Philidor was succeeded by A. L. H. Lebreton Deschapelles (1780–1847), who was also a famous whist player. The only player who is known to have fought Deschapelles not unsuccessfully on even terms is John Cochrane. When he lost a match (1821) to William Lewis. Deschapelles had conceded the odds of "pax-n and move," the Englishman winning one and drawing the two others. Deschapelles's greatest pupil. and one of the strongest players France ever possessed, was L. C. Mahé de la Bourdonnais (1797–1840). His most memorable achievement was his contest with the English champion Alexander Macdonnell. the French player winning in the proportion of 3 to 2.

The English school of chess began about the beginning of the 19th century, and J. H. Sarratt was its first leader. He flourished until 1820 and was followed by his great pupil W. Lewis (1787–1870). Xfacdonnell (1798–1835) has been already mentioned. To the same period belong also Capt. W. D. Evans, the inventor in 1824 of the "Evans gambit" (White 4 P — QKt4 instead of P — B3 in the standard opening illustrated in *Notations,* above), who died at an advanced age in 1872; George Perigal (d. 1854), who played in the correspondence matches against Edinburgh and Paris; George \Talker (1803–79), chess editor of *Bell's Life* from 183j to 1873; and Cochrane (1798–1878), who met every strong player from Deschapelles down. In the same period Germany possessed but one good player. Julius Mendheim of Berlin.

The fifth decade of the 19th century is marked by the fact that the leadership passed from the French school to the English. After the death of La Bourdonnais, P. C. Fournié de Saint-Amant became the leading player in France; he visited England in the early part of 1843 and successfully met the best English players, including Howard Staunton; but the latter soon took his revenge, for in Nov. arid Dec. 1843 a great match between Staunton and Saint-Amant took place in Paris, the English champion winning by 11 games to 6 with 4 draws. During the succeeding eight years Staunton maintained his reputation by defeating H. W. Popert, Bernard Horwitz and D. Harrwitz. Staunton was defeated by Adolf Anderssen (1818–79) at the London tournament in 1851, and this concluded his career.

In the ten years 1830–40 a new school arose in Berlin, the seven leaders of which have been called "the Pleiades." These were Ludwig Bledow (1795–1846), P. R. von Bilguer (1815–40), W. Hanstein (1810–50), C. Mayet (1810–68), K. Schorn (1802–50), Horwitz (1809–85) and T. von Heydebrand und der Lasa, afterward Prussian (and later German) minister at Copenhagen. As belonging to the same period must be mentioned the three Hungarian players V. Grimm, J. Szen and J. Löwenthal.

Among the great masters since the middle of the 19th century. Paul Morphy (1837–84), an American, has seldom been surpassed as a chess player. His career was short but brilliant. Born in New Orleans. La., he was taught chess by his father when only ten years of age, and in two years' time became a strong player. When not quite 13 he played three games with Löwenthal and won two of them, the other being drawn. Competing in the New York city congress of 1857, he won the first prize. In 18j8 he visited England and there defeated S. S. Boden, G. W. Medley, A. Mongredien, the Rev. John Owen, H. E. Bird and others. He also beat Löwenthal by 9 games to 3 and 2 draws. In the same year he played a match at Paris with Harrwitz, winning by 5 to 2 and 1 drawn; later he obtained a victory over Anderssen. On two or three occasions he played blindfolded against eight strong players simultaneously, each time with great success. He returned to the U.S. in 1859 and continued to play, but with decreasing interest in the game, until 1866.

Wilhelm Steinitz (1836–1900) took the sixth prize at the London congress of 1862. He defeated J. H. Blackburne (1841–1924) in a match by 7 to 1 and 2 draws. In 1866 he beat Anderssen in a match by 8 games to 6. He carried off the first prize in the British Chess association handicap in 1868 and in the London grand tourney in 1872. also defeating J. H. Zukertort in a match by 7 games to 1 and 4 draws. In 1873 he carried off the first prize at the Vienna congress; and in 1876 he defeated Blackburne, winning seven games right off.

In Philidor's age it was considered almost incredible that he should be able to play three simultaneous games without seeing board or men, but Louis Paulsen, Blackburne and Zukertort often played 10 to 12 such games, while as many as 28 and 29 were so played by Alexander Alekhine (*q.v.*) and Richard Réti, respectively, in 1925. Again, Alekhine played 32 in 1933, and Georges Koltanowski played 34 in 1937. Then, in 1943, Miguel Najdorf exceeded all performances with 40 at Buenos Aires, and in 1947 he played 45 at São Paulo.

In 1876 England was in the van of the world's chess army. English-born players then were Boden, Amos Burn, Macdonnell, Bird, Blackburne and William Norwood Potter; while among naturalized English players were Lowenthal, Zukertort (who died in 1888), Horwitz and Steinitz (who in 1883 moved to the U.S. and became a citizen there). This predominance passed into the hands of the German chess masters toward the end of the century when such great figures as Emanuel Lasker, the world champion, and Siegbert Tarrasch, even greater as theorist than as player, were the world's leading exponents.

Germany and the central European countries held the leading place until the 1930s when this supremacy was challenged by the United States which, in the period 1931–37, won all four of the scheduled international team tournaments (see *Fédération Internationale* des *Échecs,* below). Meanwhile, the U.S.S.R., under the stimulus of powerful state aid, developed a vast quantity of outstanding players such as Mikhail Botvinnik, Vassily Smyslov, David Bronstein, Alexander Kotov and Isaac Boleslavsky. By 1945 the U.S.S.R. was clearly the strongest chess-playing country, and this was confirmed by its defeating the U.S. in a radio match by the overwhelming score of $15\frac{1}{2}$–$4\frac{1}{2}$. Following this, the U.S.S.R., with the addition of such players as E. Geller, T. Petrosian, M. Taimanov, B. Spassky and M. Tal, easily kept its predominance.

4. The World Championship. — The strongest players of their time, regarded therefore by later generations as "world champions," were: 1747–95, Philidor, France; 1815–20, Deschapelles, France; 1820–40, La Bourdonnais, France; 1843–51, Staunton, England; 1851–58, Anderssen, Germany; 1858–59, Morphy, United States; 1862–66, Anderssen, Germany. In 1866 Anderssen was defeated in a match by Steinitz of Austria, who then laid claim to the title "world champion" — rightly, for he was undoubtedly the strongest player of his day. Steinitz successfully defended his title in formal matches against Blackburne, Zukertort, M. I. Tchigorin (twice) and Isidor Gunsberg. His reign of 28 years was brought to a close in 1894, when he was defeated by a young German player, Emanuel Lasker.

Lasker held the title almost as long as Steinitz, whom he defeated again in a return match two years later. Other challengers who failed were Frank Marshall, Tarrasch, David Janowski and Carl Schlechter. Recognized as the logical challenger from *c.* 1914 on was José Raoul Capablanca of Cuba, but a match was not arranged until 1921. With Capablanca leading 4–0, and 10 draws, Lasker resigned the championship. Capablanca held the title for six years. In 1927 he lost it to Alekhine in a struggle lasting nearly three months, at Buenos Aires. The score was 6–3, with 25 draws, the longest title match up to that time.

Alekhine, a Russian who acquired French citizenship, was defeated in 1935 by Max Euwe of the Netherlands, by the score of 9–8 with 13 draws. Two years later he regained the title in a return match, winning 11–6 with 13 draws. Alekhine twice defeated Ewfim Bogoljubow in challenge matches, 1929 and 1934. The death of Alekhine in 1946 left the title vacant.

Then the World Chess federation (see below) took charge of affairs. It organized a match tournament between five contenders for the title out of which Botvinnik of the U.S.S.R. emerged as a decisive winner with 14 points. followed by Smyslov (U.S.S.R.) with 11. Samuel Reshevsky (U.S.A.) and Paul Keres (U.S.S.R.) with $10\frac{1}{2}$ each and Euwe (Netherlands) with 4.

Up to this period the world championship had been a somewhat haphazard contest in which the holder of the title was allowed to choose his own opponent and was as like as not to refuse playing the rightful contender. But the World Chess federation proceeded to hold a three-year cycle of tournaments in order to select the best candidate. In the first year zonal tournaments were held all over the world; in the next, an interzonal event including the leading players from the zonal tournaments; and in the third year a candidates' tournament the winner of which played a challenge match with the world champion for the title. In 1950 Bronstein won the candidates' tournament at Budapest, but Botvinnik successfully defended his title by drawing a match with his challenger in 1951 in Moscow. In 1953 Smyslov mas the winner of a candidates' tournament at Ziirich, and in the following year once again Botvinnik drew his match. In 1956 Smyslov won the tournament at Amsterdam and in 1957 also won the match with Botvinnik and became the new world champion. Botvinnik regained the championship in 1958, lost to Mikhail Tal, 23-year-old Latvian. in 1960 and again regained it in 1961. In 1958, 14-year-old Robert Fischer. U.S. open chess champion, won the U.S. national tourney, with Samuel Reshevsky runner-up.

Two other world championship events were organized by the World Chess federation — the women's world championship and the junior world championship (for players under 21). Vera Menchik had been the regular winner of the women's title before World War II but was killed in a bombing raid in England. After the war a cycle similar to that determining the male championship was organized and the two holders of the championship were both Russian: Ludmila Rudenko won the title in Jan. 1950 and lost it in a match to Elisaveta Bykova by the score of 6–8 in 1953. The first holder of the junior title was B. Ivkov (Yugoslavia) who won a tournament held at Birmingham in 1951. In 1953 the junior world champion was O. Panno (Argentina), in 1955 B. Spassky (U.S.S.R.), in 1957 W. Lombardy (U.S.) and in 1959 C. Bielicki (Argentina).

5. **Fédération** Internationale des **Echecs.**—The World Chess federation (or F.I.D.E. as it is usually known after the French initials) is an international chess organization to which all countries in Europe and nearly all countries in North and South America are affiliated. It controls all world chess events and is in charge of the enunciation and revision of the rules of the game.

Every year the federation holds a congress to discuss international affairs, at which a delegate from each affiliated country attends. Once every two years an international team tournament is held under F.I.D.E. auspices, with each country represented by a team of four players with two reserves. At the first tournament of this kind, held in London in 1927, the three leading teams were (1) Hungary, (2) Denmark and (3) Great Britain.

International Team Tournaments

Year	Where held	First	Second	Third
1927	London	Hungary	Denmark	Great Britain
	Hamburg	Poland	Hungary	Germany
	Prague	U.S.	Poland	Czechoslovakia
	Folkestone	U.S.	Czechoslovakia	Sweden
1933	Warsaw	U.S.	Sweden	Poland
1935	Stockholm	U.S.	Hungary	Poland
1937	Buenos Aires	Germany	Poland	Estonia
1939	Dubrovnik	Yugoslavia	Argentina	Germany
1950	Helsinki	U.S.S.R.	Yugoslavia	Yugoslavia
1952	Amsterdam	U.S.S.R.	Yugoslavia-Hungary (tied)	
1954	Moscow	U.S.S.R.	Yugoslavia	Argentina
1956	Munich	U.S.S.R.	U.S.	Yugoslavia
1958	Leipzig	U.S.S.R.		
1960				

International team tournaments were not held during World War II.

6. Literature. — The literature of chess is extensive; indeed, it has been calculated that the total number of books on chess exceeds that on all other games put together. Probably the systems of notation that enable one to record games accounts for this.

However, the most celebrated of the earlier works purporting to be about chess, that of the Dominican friar Jacobus de Cessolis (13th century), is really a moralization that uses chess for its argument. This was translated into English under the title of The *Game* and the Playe of Chesse and printed by William Caxton in 1474. Shortly afterward appeared the first important contribution to chess theory by Luis Ramirez de Lucena, a Spaniard whose work on the end game remains valid to this day. He was followed in the next century by Damiano (Damiano da Odemira), Ruy Lopez and G. C. Polerio, their chief contribution being to opening theory.

In the 17th century the books by Alessandro Salvio, Gustavus Selenus and Greco were the most popular, in particular the last named; and again the emphasis was on the openings. By the 18th

century the number of chess books was increasing considerably, and the names of Stamma, Carlo Cozio, Lolli and Ponziani all have an honoured place in the list. But the most important of all. possibly the most important of all time, was that of Philidor. whose influence on the theory of the game can hardly be overestimated. His *Analyze des échecs* (1749), and the numerous editions of the work that followed, contain truths that in some respects anticipated many modern discoveries.

The early decades of the 19th century were dominated first by such English writers as Sarratt and Lewis and then by the Germans Bilguer and Heydebrand und der Lasa. The works of Staunton, The *Chess Player's Handbook* (1847), *Tlze Chess Player's Companion* (1849) and *Chess Praxis* (1860), achieved great popularity and remained standard textbooks until the 20th century.

The advent of modern theory was marked by Steinitz' *Modern Chess Instructor,* 2 vol. (1889–95). Also important were a number of works by James Mason, notably *The Art of Clzess* (1895). The theories of Steinitz were further elucidated and popularized by Lasker (*Common Sense in Chess,* 1896) and by Tarrasch (*Dreihundert Schachpartieen,* 1895). The reaction to all this came in the writings of the school of the hypermoderns such as Réti, Aron Nimzowitsch and S. Tartakower in the early 20th century (see *Bibliography* below for specific instances). From the 1920s books on chess have appeared in ever-increasing profusion.

BIBLIOGRAPHY.—The most comprehensive introductions to chess are C. H. O'D. Alexander, *Chess* (1937); H. Golombek, *The Game of Chess* (1954); *M.* Hanauer, *Chess Made Simple* (1957). Also stimulating are G. Abrahams, *Teach Yourself Chess* (1948); *C.* Purdy, *Guide to Good Chess,* 5th ed. (1958).

History: the standard work is H. J. R. Murray, *A History of Chess* (1913). Also good is H. A. Davidson. *A Short History of Chess* (1949).

General treatises: J. R. Capablanca. *Chess Fundamentals* (1921); Edward Lasker. *Modern Chess Strategy,* new ed. (1956); Emanuel Lasker, *Manual of Chess* (1934); R. Rkti, *Modern Ideas in Chess* (1923); S. Tarrasch, *The Game of Clzess* (1935); S. Tartakower, *Die hypermoderne Sckacltpartie* (1924). The best of these is Tarrasch.

Openings, less advanced: R. Fine, *Ideas Behind the Chess Openings* (1943); E. A. Znosko-Borovskii, *How to Play the Chess Openings,* 6th ed. (1953). *More advanced:* R. Fine, *Practical Chess Openings* (1948); *P.* Keres, *Theorie der Schacheröffnung,* 2 vol. (1952–55); R. C. Griffith and J. H. White, *Modern Chess Openings,* 8th ed., ed. by W. Korn (1952); L. IV. THEORIES OF PLAY

One of Philidor's contributions was to draw attention to the importance of pawns as fighting units He formulated the classic pattern of attack against the castled king—the advance of pawns to break up the panns sheltering the enemy king and so open lines for the infiltration of pieces. The hundred years after the publication of his *Analyze des e'checs* saw the discovery of myriad permutations of the so-called "direct attack" and the rise of great masters of combination play. culminating in Anderssen. (See *Illustrative Game No 1.)* By "combination" is understood the calculation of specific variations of play, in search of a way to force a more or less immediate decision.

The characteristic of the games of this era was the sacrifice, and the dominating motive was the desire to attack as quickly as possible. The analysis of openings was largely concerned with gambits—sacrifices of pawns, sometimes of pieces, made to precipitate rapid contact with the enemy Some even held that the Evans gambit was the only debut worthy of a gentleman since this opening is particularly apt to lead to a slugging contest.

In 1858–59 Morphy created a sensation by trouncing all the masters nho would meet him His play introduced a new note. one that even todav is basic in the teaching of beginners. Although second to none in combinative skill. Morphy delayed attacking until he had completed his development. By simply bringing out his knights and bishops, posting the queen safe from harassment and castling. Morphy repeatedly achieved a won game after a dozen moves.

So effective was this procedure against the current fashion of attacking prematurely that it crystallized into a formula: move each centre pawn once. each bishop and knight once: get the queen off the back row, castle—before moving any piece a second time. The task of developing is not actually so easy: the opponent exerts threats that have to be parried. But it remains true that any relative loss of time in the opening can lead to a quick catastrophe. (See *Illustrative Game No. 2.*)

Rapid development, combinative attack—these principles seemed to be all-embracing and all-sufficient. Then came the pugnacious Austrian. Steinitz. whose play often violated classic principles. Yet with it he was able to win the world championship and to hold it longer than any other player. Steinitz lived to influence the theory of play more profoundly than any other player. His theories: at first seemingly antithetical to classic. principles, were presently seen to be supplementary.

Steinitz started from the premise that there is no combination without positional advantage. That is. a specific winning sequence of moves cannot be found if there is no superiority on which to base it. The player should therefore concern himself primarily with analyzing the position to detect its points of strength and weakness. On this score, Steinitz contributed a great deal of analysis on the nature of weaknesses and the specific meaning of permanent as opposed to transient weaknesses. The objective of play. he said, is to gain a decisive positional superiority by "the accumulation of small advantages." An adverse weakness must be "nursed" and magnified until it becomes fatal; then the combination will spring of itself from the position. (See *Illustrative Game No. 3.)*

In pursuit of local advantages. Steinitz often moved the same piece several times in the opening before completing his development. He demonstrated that the demands of the "close" game are somewhat different from those of the "open" game. It is indeed necessary to develop rapidly if centre pawns are exchanged early, opening lines of attack. But a slower development is feasible if the centre is kept closed: here it is often more important to get a single piece to its most effective post than to move all the pieces off the back row. Especially in his later years, Steinitz

preferred to maneuver behind the lines before breaking the centre. so as to gain the maximum advantage from the break when it came. (See *Illustrative Game* No. *4.)* This "hedgehog" policy forced upon him the necessity of defending accurately and economically against attack by a more developed opponent, and his games are instructive for the resources of defense. Steinitz was never so happy as when sustaining a furious onslaught upon his king; not fearing such attacks, he would accept all gambits. He said "When in doubt, take a pawn" and "A pawn is worth a little trouble."

The slow tempo of the Steinitz campaign was not for every taste, and it remained for Tarrasch to show how to quicken it and open lines for direct attack without relinquishing vital positional advantages. Tarrasch made great contributions to the theory. In play as well as in writings he showed how positional weaknesses may be forced upon a player if he commands less terrain than his opponent. He formulated the theory of the centre. The opening. he said, is to be understood as a fight for control of the squares d4, dj. e4, e5 (Q4, Q5, K4, Kj). A piece standing in the centre has its maximum range, and the centre is the vital avenue of communication between the wings of the army. At first the centre must be controlled by pawns, to prevent its occupation by adverse pieces. The player who controls the greater number or the more advanced of central squares has an advantage. (See *Illustrative Game* No. *6.)*

A consequence of the Steinitz-Tarrasch analysis was that the opening 1 P—K4 came to be played much less in master tournaments, in favour of 1 P—Q4. The latter is the more likely to lead to a close game. The growing body of knowledge of opening variations tends to indicate that White retains the advantage of the first move longer in a close than in an open game. The queen's gambit (sacrifice of a pawn for advantage of position) came to be a dreaded weapon. It was said, half-jocularly, that "After 1 P—Q4, Black's game is in its last throes." However, Black's prospects brightened in the 20th century with the discovery of several new defensive systems.

In 1913 a young Russian master, Nimzowitsch (1886–1935), published articles assailing some of the cardinal points of the Tarrasch creed. After World War I he published *Mein System* and other books expounding certain ideas, as "centralization," "overprotection," "the homeopathic process." In definition these ideas do not seem to be out of the Steinitz-Tarrasch tradition, but their realization sometimes involves moves condemned by it. Nevertheless, Nimzowitsch achieved some notable tournament successes and carried the Tarrasch principle of constraint to the extraordinary length of complete blockade. (See *Illustrative Game* No. *7.)* A curious conclusion is that, while the actual advance of a pawn wing may prove weakening. the mere inability to advance it at will is a positive weakness, often of decisive moment.

Nimzowitsch is credited with founding the self-styled hypermodern school. of which the avowed exponents were Tartakower, Réti and Bogoljubow. Réti (d. 1929) stated the principle of this school to be: "The golden rule is that there is no golden rule." Thus, any attempt to formulate its further principles is interdicted! In practice, the hypermoderns often go to great lengths to avoid releasing the tension in the centre, or even advancing the centre pawns at all, until pieces have been brought to bear upon it. This often involves the fianchetto (moving the pawn from Kt2 to open a path for the bishop) of one bishop or both. (See *Illustrative Game No. 8.)*

The hypermoderns claim Capablanca and Alekhine as exponents of hypermodern play, although both these world champions repudiated any conscious adherence. The Alekhine defense is cited as an example of relying on the evaluation of a particular position rather than upon general principles. After 1 P—K4, Kt—KB3; 2 P — K5, Kt — Q4; 3 P — QB4, Kt — Kt3: 4 P — Q4, White has three pawns in the centre, one being on the fifth rank: while Black has developed only a knight. By all classical precept. Black has wasted valuable time. Yet it has been abundantly demonstrated that. if White is not careful. his advance pawns will prove to be not an advantage but a liability.

While acknowledging the basic truths of the theory of the hypermodern school neither Capablanca nor Alekhine ever went so far as Nimzowitsch, Réti or Tartakower in their disavowal of the classical precepts of Tarrasch. In fact, these two great world champions pursued their own courses with a confidence in their genius that was fully justified by results. Capablanca was the more classically serene (see *Illustrative Game* So. *9),* while Alekhine's colourful imagination produced a bewildering number of masterpieces (see *Illustrative Game No. 10).*

By 1930 the theories of the hypermoderns had become commonly accepted by the average master, and for the next 20 years a style was developing that reflected Capablanca's influence in its striving after perfection in technique and Alekhine's in its openings. The Russian school tended to follow Alekhine, but some members of it also consciously strove after a return to the methods of the great Russian master of the 19th century, Tchigorin. Tchigorin's influence is clearly present in the games of Botvinnik; together with a marked depth of strategy that was that world champion's particular contribution to 20th-century style in chess. (See *Illustrative* Game *No. 11.)*

It should always be remembered that, while schools may pass and fashions come and go, fundamental positional truths remain the same throughout the centuries. (See *Illustrative Game* No. *12.)*

V. ILLUSTRATIVE GAMES

Illustrative Game No. 1.—Anderssen (1818–79) won first place in the first modern international tournament, London. 1851. His games are memorable for their slashing attacks and combinative brilliance. The famous game below was dubbed the "Immortal Partie."

	White Anderssen	Black Kieseritzki		White Anderssen	Black Kieseritzki
1	P — Kq	P — K4	13	P — Rj	Q — Kt4
2	P — KB4	P × P	14	Q — B3	Kt — Kt1 (c)
3	B — B4	P — QKt4	15	B × P	Q — B3
4	B × KtP	Q — R5ch	16	Kt — B3	B — B4 *(d)*
5	K — B1	Kt — KB3	17	Kt — Qj	Q × P *(e)*
6	Kt — KB3	Q — R3	18	B — Q6 *(f)*	B × R
7	P — Q3	Kt — R4 *(a)*	19	P — K5	Q X Rch
8	Kt — R4	P — QB3	20	K — Kz	KT — QR3 *(g)*
9	Kt — Bj	Q — Kt4	21	Kt × Pch	K — Q1
10	P — KKt4	Kt — B3	22	Q — B6ch	Kt X Q
11	R — Kt1 (b)	P × B	23	B — K7 mate	
12	P — KR4	Q — Kt3			

(a) Threatening Kt — Kt6ch. But this light-horse attack is backed by insufficient means. Black should have made a develcping move, as B — Ktz or even B — R3. (b) Commencing a combination based on the precarious position of the Black queen. *(c)* The only move to save the queen. *(d)* Perhaps better was B — Ktz to keep out the terrible knight. But there is no move to parry all of White's threats. *(e)* Staying on the diagonal to defend KKt2. *(f)* The key move of the combination. Now if 18 . . . Q × Rch; 19 K — K2, Q × R then 20 Kt × Pch, K — Q1; 21 B — B7 mate. Or if 18 . . . B × B; 19 Kt × Bch, K — Q1 then 20 Q × P and mate cannot be averted. *(g)* To prevent the mate given in note *(f).*

Illustrative Game No. 2.—When Morphy went to Europe in 1858 he met some unpleasant experiences with European masters jealous of their laurels. But Anderssen came out of retirement to play and lose a match to him in 1859 and was generous in praise of the American genius. The following game was the seventh of the match.

	White Morphy	Black Anderssen		White Morphy	Black Anderssen
1	P — K4	P — Q4	14	Q X Kt	Q × B
2	P × P	Q × P	15	B — Q3 *(f)*	B — Ktj
3	Kt — QB3	Q — QR4	16	Kt — Kt5 *(g)*	KR — Q1
4	P — Q4	P — K4	17	Q — Kt4 *(h)*	B — B1
5	P × P	Q × Pch	18	KR — K1	P — QR4
6	B — K2	B — QKt5	19	Q — K7	Q × Q
7	Kt — B3 *(a)*	B × Ktch	20	R X Q *(i)*	Kt — Q4
8	P × B	Q X Pch	21	B × Pch	K — R1 *(i)*
9	B — Q2	Q — B4 *(b)*	22	R × KBP	Kt — B6
10	R — QKt1 *(c)*	Kt — QB3	23	R — K1	Kt × P
11	Castles	Kt — B3	24	R — B4	R — R3
12	B — KB4	Castles *(d)*	25	B — Q3	Resigns
13	B X P *(e)*	Kt — Q5			

(a) He could save the pawn and also develop by B — Q2, but he is perfectly willing to let Black waste further time to win it *(b)* Black has won a pawn but lost the game. *(c)* Threatening B — Kt4 and

also holding back the Black QB. *(d)* Giving back the pawn in order to get his king to saiety. If 12 . . . Kt — Q4 then 13 R — Ktj wins a piece. *(e)* More than regaining his pawn, for now he threatens B — Q6. *(f)* White's advantage is greater than it may seem. He has the "good" bishop ior a K-side attack, while Black's "bad" bishop cannot even be moved out to release the QR. Black indeed tries to develop it, but the effort is quickly refuted. *(g)* Threatening 17 Kt × RP, Kt × Kt; 18 Q × B. *(h)* Maintaining the threat and also attacking the QKtP. To avoid immediate loss of a pawn Black is iorced to retreat his bishop. (i) The exchange of queens has brought Black no relief. Useless to defend the KBP is 20 . . . R — B1, ior then 22 Kt × BP, R × Kt; 23 B — B4 wins the exchange. *(j)* Forced, for if K — B1 then 22 R × Pch, K — K1; 23 R — K1ch leads to mate.

Illustrative Game No. 3.—In 1885 Zukertort and Steinitz met in the first official match for the world's championship. Since Steinitz had become a resident of the United States, the match was played in New York, St. Louis and New Orleans. Steinitz won it by a score of 10–5, with j draws.

	White Steinitz	Black Zukertort
1	P — K4	P — K4
2	Kt — KB3	Kt — QB3
3	B — Kt5	Kt — B3
4	Castles	Kt × P
5	R — K1	Kt — Q3
6	Kt × P	Kt × Kt
7	R × Ktch	B — K2
8	Kt — B3	Castles
9	B — Q3	B — B3

25	R — K3	Kt — K3 *(f)*
26	Q — KKt4	Kt — B1
27	Kt — Bj	B — B4
28	Kt — R6ch	K — Kt2
29	B × B *(g)*	Q × Q
30	Kt × Q	R × R
31	BP × R	Kt × B
32	Kt × P *(h)*	
	White won	

(a) According to Steinitz, the K-side pawns when under attack should not be moved unless there is no alternative. In his notes to this game he states that he considered this move a deliberate challenge to his theory. (b) Manifestly antipositional. The bishop is vitally needed at Kt2 to protect the holes in the pawn structure. (c) Nailing down the weakness of Black's KB3. *(d)* To force the following advance, which is a iurther weakening of the pawn wing. *(e)* An attacking move seen in many Steinitz games, made to loosen up the compromised pawns still iurther. *(f)* "From the 14th move until this moment Black, on the defense, has played good chess. Now White has no immediate threats and Black . . . is thrown on his own initiative . . . he has to originate a plan. But that is exactly what Zukertart did not understand . . . His right plan was to keep attention riveted on his weak points KB4, QB4 and KB3, and . . . work towards a draw by exchanging perilous pieces . . ." (Emanuel Lasker, *Manual of* Chess, new ed., David McKay Co., Inc., New York, 1947). *(g)* Actually, Steinitz checked with the knight several times, to gain time, before making this move. *(h)* "All" that Steinitz has to show for his exertions is the win of a pawn. But this is enough to win the ending.

Illustrative Game No. 4.—Before completing his development. Steinitz moves his QKt three times, only to exchange it a few moves later. His games are full of such long-winded maneuvers, in pursuit of modest but lasting positional advantages. Observe how carefully he refrains from P—Q4 until the move is decisive.

Havana, 1892

	White Steinitz	Black Tchigorin
1	P — K4	P — K4
2	Kt — KB3	Kt — QB3
3	B — Kt5	Kt — B3

26	B — R6ch	K — B3
27	Q — R4ch	K — K4
28	Q × Ktch	K — B4
29	Q — B4 mate	

(a) At variance irom the then iashionable practice of playing P — Q4 as soon as possible. *(b)* This pawn iormation was irequently adopted by Steinitz after 1 P — K4. Its object is only remotely to eniorce P — Q4; the primary purpose is to neutralize any effort by Black to break the centre. *(c)* The king's fianchetto was formerly much played against the Ruy Lopez, but it has dropped out of master practice as a result of Steinitz' victories against it. *(d)* Another of Steinitz' innovations was this maneuver B — Ktj — R4 — B2 to preserve the KB, "the thorn of the Ruy Lopez." *(e)* The virtue of this post is that it discourages 9 . . . P — B4, for after 10 P × P Black could not retake with the rook, and so keep the file open. *(f)* Again P — B4 would be premature; *e.g.*, 11 P × P, B × P; 12 Kt × B, R × Kt?; 13 P — Q4. (g) This typical Steinitz attack is the more powerful since he has delayed castling and still has his rook on the file. *(h)* "The logical reaction against a wing advance is a break in the centre." Black expects to profit from opening lines against his "undeveloped" opponent. (i) But it is White who profits. To avoid the opening of the diagonal upon his king, Black might have tried 13 . . . RP × P but then would have had to reckon with an attack on the open KR file. *(j)* Meeting the immediate threat of Kt — B5. But the move also has a subtle attacking purpose. *(k)* This long-delayed advance is now devastating. Black can scarcely avoid the exchanges that follow, because of the awkward situation of his queen, knight and QB. *(l)* An unpleasant surprise. After 24 B × Ktch, R — B3 Black could still put up a defense.

Illustrative Game No. 5.—Though Lasker was a follower of Steinitz, he regarded a chess game as being primarily a struggle. It has been said that he made moves which he knew to be inferior if they helped him to arrive at those tense and complicated positions in which he was supreme. He himself did not confirm this, but the will to win and the coolness and resourcefulness under fire which he showed in such games as the following tend to make this statement plausible.

Cambridge Springs, 1904

	White Lasker	Black Napier
1	P — K4	P — QB4
2	Kt — QB3	Kt — QB3
3	Kt — B3	P — KKt3
4	P — QA	P × P
5	Kt × P	B — Kt2
6	B — K3	P — Q3
7	P — KR3 (a)	Kt — B3
8	P — KKt4	Castles (b)
9	P — Kt5	Kt — K1
10	P — KR4	Kt — B2
11	P — B4	P — K4
12	Kt(4) — K2	P — Q4 *(c)*
13	KP × P	Kt — Q5
14	Kt × Kt	Kt × P *(d)*
15	Kt — B5 *(e)*	Kt × Kt
16	Q × Q	R X Q
17	Kt — K7ch	K — R1 *(f)*
18	P — R5 *(g)*	R — K1
19	B — B5	P X RP *(h)*
20	B — B4	P X P *(i)*
21	B × P	Kt — Kj
22	B X R	B X P
23	R — QKt1	B — B6ch
24	K — B1	B — KKt5 (
25	B × KRP (k)	B × B
26	R × B	Kt — Kt6ch
27	K — Kt2	Kt × R
28	R × P	P — R4
29	R — Kt3	B — Kt2
30	R — KR3	Kt — Kt6
31	K — B3	R — R3
32	K × P	Kt — K7ch
33	K — B5	Kt — B6
34	P — R3	Kt — R5
35	B — K3	Resigns

(a) The usual move is B — K2. The text move is the prelude to a pawn attack on the K-side. Now a flank attack when the centre is open is a violation oi the principles which Lasker himself has expounded. But, as opposed to this, it gives him the type of game that he desires. *(b)* Black's best plan is a counterattack in the centre. In preparation ior this, the king must first be removed irom the centre. It is thereiore proper to castle, in spite of the threatening attack. *(c)* This is attractive, but it would have been even stronger if Napier had delayed it, having first strengthened his game with B — Kt5. *(d)* An unpleasant surprise. After 15 Kt × Kt, Black plays P × Kt. *(e)* Lasker has foreseen this; he parries with his own surprise which seemingly wins a piece. Napier, in his turn, has foreseen this answer; he knows that he will not lose it. *(f)* Black's knight is saie; *e.g.*, 18 P × Kt, P × P; 19 B — Q4, B × B; 20 P × B, R — K1; and has the advantage. Ii 18 Kt × B, Kt — Q4; with the better game. *(g)* White continues with the attack on the K-side. The immediate threat is: 19 RP × P, P × P; 20 Kt × Pch, K — Kt1; 21 B — B4ch, Kt — Q4; 22 B × Ktch, R × B; 23 Kt — K7ch. *(h)* The knight is still invulnerable; *e.g.*, 20 P × Kt, B — B1; 21 B — Kt;, R × Kt; 22 B × R, B × B; with a favourable game despite the loss of the exchange. White returns to his K-side attack. *(i)* Passive measures are not adequate. Black, in his turn, goes back to his own attack. *(j)* White is now a rook ahead, but Black has iour immediate threats: R × B; Kt × B; Kt — Q7ch; Kt — Kt6ch. Besides this. White's king is in an exposed position. At this point, once again, he takes up his K-side attack. *(k)* With this move White surrenders all of his material advantage, but he sees that, if he does, his onslaught will, at last, be irresistible.

Illustrative Game No. 6.— Tarrasch was a prolific writer as well as a master player. He made large contributions to the Steinitz theory of positional play. Here he gives a classic demonstration of what ills may follow "surrender of the centre."

(a) Black can stop P — B5 by P — B4 or QKt — Q2 or Q — K2. Instead of this, he deliberately provokes it. (b) He has given White a phalanx of pawns on the Q-side in order to himself achieve the eventual control of the centre. (c) P — QR3 is better. Tarrasch now is able to concentrate on the QBP. (d) This prepares for P — K4, to drive back White's QB from the defense of the QBP. (e) New pressure on the QBP. The immediate threat is P × P followed by B × P. (f) Makes P — Kt6 possible. If 21 P — Kt6, Kt × KtP; 22 P × Kt, B × Q; and wins. (g) if 21 . . . P × P; 22 P — B6 wins. (h) Black prepares a new attack on the QBP. The queen will go to B1 while the knight on R3 will get to K3. (i) White seems to have no defense, but ingeniously finds a new resource. (j) The knights are pinned. If Black captures the QBP, he loses the exchange. But, as it happens, Tarrasch is prepared to do this. (k) As he has foreseen, he is the exchange down, but he has powerful pressure as well as the passed QBP. (l) White is helpless.

Illustrative Game No. 7.—The importance of maintaining sufficient space to maneuver is discussed by Nimzowitsch in his book *Die* Blockade (1925). He won several notable games by strangling the entire adverse army.

13 Kt × Kt	B × Kt	Resigns	

(a) The opening is all "book" so far. The natural move P — B4 has been shown to be somewhat hazardous. The object of P — B3 is to relieve the uncomfortable pin on the QB. Also played in this position is Q — B1. (b) In order to leave the Black QB locked behind its own centre pawns. (c) This post for the bishop is always dubious after its retreat to Kt3 has been blocked by the pawn advance. (d) The method of restraining the Black Q-side pawns here attempted by White is shown to be futile. Necessary was the mechanical blockade, P — QR3 and P — QKt4. (e) White is laboriously preparing a pawn advance, but the misplaced bishop allows Black to strike first. (f) Threatening after due preparation to move P — B5 and smash the compromised king position. White's unmoved KP is an obstacle to bringing the Q-side pieces over to the defense, hence White's ensuing plan to advance it. (g) Exacting heavy toll for White's failure to block the pawn, and his omission of moving the KP. The knight is forced back home, where it remains stalemated for the rest of the game. (h) At last White threatens to move P — K4, discovering attack on the knight by the queen. Black, having already won great superiority in space, ignores the threat. (i) "Two pawns. and a rook on the seventh rank. all for one knight!" remarks Nimzowitsch. (j) Shutting off access to the haven QKt3 and threatening R — K7. (k) "Announcing the *Zugzwang*." White has no moves left; *e.g.*, 26 B — QB1, B × Kt, or 26 K — R2, QR — B6, or 26 QR moves, R — K7. After exhausting his pawn moves, White will be forced to move a piece and commence losing material.

Illustrative Game No. 8.—At move **8,** Réti illustrates "the golden rule is that there is no golden rule" by switching from a "hypermodern" formation to a "classical."

New York city, 1924

13 B × P (f)	Q — B2 (g)		

(a) The opening moves of the so-called Réti system. (b) One idea of the system is to avoid blocking the diagonal of the QB, making the break in the centre by P — Q3 and P — K4. But Réti perceives that reversion to the "normal position" of the queen's gambit declined is strongest against the formation adopted by Black. (c) Forced in order to retreat B — B2 in case White plays P — B5. This advance is powerful when Black cannot counter with P — K4. If the bishop were forced to retreat to B1, White would have time for P — QKt4 and Kt — K5, with strangling effect. (d) Subsequent analysis indicates P — K4 to be Black's best move, but it is insufficient to overcome White's positional superiority. (e) White forces open the centre to capitalize the superior position of his pieces. (f) Of course not P × P, as the KP is to be used as a battering-ram. (g) One of Black's problems is to develop his QB. This move certainly seems to have better prospects than 13 . . . Kt × Kt; 14 P × Kt, B — B4ch; 15 K — Kt2, because White would then gain command of the open Q-file. (h) He must not allow P — K5, and P × P would leave his KP isolated. "Black appears to have surmounted the greater part of his early difficulty and it calls for exceptionally fine play on the part of White to make the hidden advantages of his position count so rapidly and convincingly." (A. Alekhine, "New York International Tournament, 1924," *American* Chess Bulletin, April 1, 1925.) (i) Guarding his QB5 to threaten P × QP, and also threatening P × KBP. If Black now plays P × KP then B × P and White wins either the KP or the KRP. (j) ,Indirectly guarding the QP; *e.g.*, 19B × QP, B × KBP. (k) Initiating a beautiful combination that won this game the first brilliancy prize. (l) No better is 23 . . . Q — K2; 24 B — B7ch, K — R1; 25 B — Qj, Q — B3; 26 Q — B8. (m) To avert mate he must give up at least the bishop.

Illustrative Game No. 9.—The classical serenity of Capablanca's style had a profound influence on the masters of succeeding generations, Traces of this are clearly discernible in the games of such great players as Keres, Smyslov and Laszlo Szabo. Unlike those of other titleholders. Capablanca's games give an impression of an almost effortless ease.

(a) Black has the open QR file. This is offset by the pawns on the QKt file; but he has a plan to make these weak pawns stronger. (*b*) After 10 . . . P — K3; 11 Kt — R4, thus obtaining the two bishops. The text not only makes 11 . . . P — K3 possible; it supports the advance of the QKtP. Black is planning. Kt — R4, P — QKt4, Kt — Bj. (c) Black's last more should have told him his intentions. B — Ktj, here or on the next few moves, would hamper the plan, but Janowski does not see this. (d) If 16 B × Kt, Black plays P × B; his double pawns are straightened out, and although he has lost his open R-file, he has the advantage oi two bishops. (e) White is hoping to get relief by P — K4. He is still averse to giving Black two bishops, but be keeps the knight in order to support the KP. (j) Black has kept the open R-file, the QBP is powerful and there is a latent threat in the remaining QKtP. (g) Janowski's last two moves really are not as strong as they seem. In fact, he has created a new target ior Black. When it is duly prepared, the KKtP will offer a threat that complements the one on the Q-side. Capablanca now will attack on one side and then on the other. (*h*) Back again to the Q-side, but the two wings of his attack now are so well co-ordinated that this move helps to bring the QB over to the K-side. (i) White cannot stop the bishop from reaching QB7; *e.g.,* 34 QR — B1, R × Pch wins. (*j*) Decisive; *e.g.,* 37 Kt — K3, P — Rj. If 37 Kt — R4, B × Kt; 38 B × B, R × Pch; 39 K — K3, R × R; 40 R — R7ch, K — Kt3; 41 K × R, R — Ktjch; and wins.

Illustrative Game No. 10.—No player in the long history of chess ever quite equaled Alekhine in imaginative richness and variety oi attack.

The following game is only one out of some hundreds of the same quality.

Semmering, 1926

17 Kt(3) — K2	P — Kt3	35 K — Kt2	Q × B
18 R — K1	Kt — Q2 (h)	and Black won	

(a) The usual move is 6 B — Q3. Black plays to take advantage of the queen going off the Q-file. (b) Black's position is commonly reached with the White queen on Q1 and QB on Ktj. Because of this difference Black now threatens to win a pawn; *e.g.,* 11 . . . P × P; 12 Kt × P, B × Pch; 13 K × B, Q — Q3ch. (c) In the light of older principles. (see *Illustrative* Ganze No. 6), one might suppose that White, having a centre pawn, has a superior game. This position, however, is an example of the hypermodern doctrine that an advanced pawn in the centre may also be.a disadvantage. It is important to have control oi the centre; it is not important to have mere physical possession. As Réti says, this particular pawn has no future. "White will never be able to move P — B4. Also, the KP can never serve here as a support for White's pieces, as this mill be made impossible by Black's pawns at QB3 and later at KKt3. Thus there remains of the centre pawn's properties only the undesirable one that it hinders the effectiveness of its own pieces." (R. Réti, *Masters* of the Chess Board, trans. by M. A. Schwendemann, new ed., G. Bell & Sons, Ltd., London, 1953.) (*d*) Two moves later the rook will go to K1, but this is no loss of tempo for the text induces White to weaken his K-position, the threat being 14 . . . B × Pch; 15 K × B, R × Kt; 16 R × R, Q — K4ch. (e) Threatens 15 . . . R × Kt; 16 R × R; Q — K4. This provokes 1j B — K3. At first glance this seems a good developing move; the bishop seems well placed; but Alekhine sets out to bring all oi White's pieces to the centre. He sees that in this position they will get in each other's way; they will also offer a number of targets for attack. (f) Brings another White piece to the centre. (g) Threatens Kt — Bj. When pawns are unequally distributed on both flanks, two bishops are a great advantage. *(h)* Threatens 19 . . . Kt — K4 and 20 . . . Kt × B. (i) He tries to keep the bishop; hemmed in by the pawn at Q4, the other bishop is less effective. (*j*) He also tries to keep the queen. After 21 Q × Q, Kt × Q: 22 Kt — B1, P — B3; 23 B — Q2, Kt × B; 24 Kt × Kt, Kt — Kt6; zj P — Kj. B — KB4 White mould stand at a decisive disadvantage. (k) But he must exchange the knights. He cannot allow 22 . . . Kt × Kt; 23 P × Kt, but any other way of avoiding this is immediately disastrous. (l) After 29 B × Kt, Black has a mate in three; *e.g.,* 29 . . . B — Kt6ch; 30 . . . Q — R7ch; to be followed by Q × BP mate. (*m*) Having the choice of bishops, he takes the more effective one.

Illustrative Game No. 11.—In his youth Botvinnik, too, was a follower of Capablanca, but his style became increasingly more complicated.

Primarily a positional player, Botvinnik will often accept a positional inferiority, as he does in the following game, in order to obtain a tactical initiative.

33 R X Qch	K X R		

(a) When Botvinnik is Black, he invariably plays 4 . . . B — Kt; after 3 Kt — QB3. When he is White, he plays 3 Kt — Q2, so as not to show his rivals how they ought to proceed against his favourite defense. (b) Black has an isolated QP; White's own pawns are connected; but he sees that. after this exchange of bishops, he will control his Q4 and QB5. (c) To obtain his objective, Botvinnik has connected Black's isolated QP and has given himseli an isolated KP. (*d*) Black can never get his pawn to QB4; he has the wrong-coloured bishop. White will bring his knights to magnificent posts at QB5 and Q4. *(e)* Getting rid oi his isolated KP; at the same time he increases his command oi the board and his rook pre-empts the K-file. (*f*) A tempting trap. 22 Q — KKt3 seems to win two pieces for a rook, but on 22 . . . P × P; 23 Kt(4) — Kt3, R — Q4; 24 Q × B, R × Kt; 25 Kt × R, Q × Ktch; 26 K — R1. Q × P; 27 QR — K1, P — B3, it is dubious ii White has any advantage; 24 QR — K1. R × Kt; 25 Kt × R, Q × Ktch; 26 K — R1, B — K3; 27 R × Kt. Q × P is no better. This time Botvinnik ignores the tactical and holds onto positional advantage. (*g*) He cannot take the queen; *e.g.,* 29 . . . R × Q; 30 Kt — Bjch. K — Kt1; 31 Kt × Q, R × Kt; 32 P — B4 and the passed pawns win easily. *(h)* Seeing a won ending, White continues to simplify. (i) He will force the Black king to the Q-side, after which he will induce a breach in the pawns on the K-side. (*j*) If 40 . . . R × P; 41 R × Rch. K × R; 42 K — B; and gets the pawns. (k) Freeing the rook to protect the K-side pawns. (l) Finally forcing a breach in the barrier. On 48 . . . P — Kt3; 49 R — Q7ch wins even more rapidly. (*m*) All "book." On 65 . . . R — B7ch; 66 K — Kt6, R — Kt7ch; 67 K — B6, R — B7ch; 68 K — Ktj, R — Kt7ch; 69 R — K4.

Illustrative Game No. 12.—No matter how much the technique of chess advances — and it has progressed a great deal as a result of the very large number of tournaments held since the beginning of the 20th century — the basic principles always remain the same.

In the following game Smyslov, twice Botvinnik's challenger for the world title and finally his conqueror, demonstrates the vital importance of control of the centre.

(a) Already Black has conceived the plan of attacking on Qj. How consistently he carries this out the course of the game will show. *(b)* Showing his hand rather too early. It mould be better to play first 7 B — Kz, and then 8 Castles. In so doing his game would have more elasticity. *(c)* This and his next move constitute a necessary transposition into a kind of queen's gambit. For if 7 . . . B — Kt2; 8 P — Q5, and White controls the centre. *(d)* After 11 Q — Kz, Kt — QKt5 the situation would be embarrassing for White. *(e)* The beginning of a fierce K-side attack that can be thwarted only by the utmost accuracy in defense and vigour in counterattack. (f) Putting his all into the attack; but if he retreats with 18 R — K1, then Black gains the upper hand by 18 . . . P × P; 19 R × P, B — Q4 *(g)* Though this move is most impressive it is not overwhelming in reality since Black need not accept the sacrifice. *(h)* Coolly and correctly played. Bad would be 19 . . . P × R; zo Q × P, R — K1; 21 P — R4, when White's attack cannot be met. (i) Black increases his control of the Q5 square; and with good reason since 21 . . . P × B leads to mate after 22 Q — R6, Q × P; 23 R — Kt7ch, B × R; 24 Q — R7. Now, however. Black has time to make a flight square for his king while further centralizing his pieces. (j) Nothing could be more pleasing in its harmonious logic than the manner in which Smyslov finishes off this game. Once more he emphasizes and utilizes his control of Q5. Why he encourages White, to advance his KBP soon becomes evident.

VI. CHESS PROBLEMS

Chess problems are artificial positions permitting mate in a specified number of moves against any defense, with play involving elements of strategy or beauty. .In no. 1, player and problemist alike mould see the need of advancing the White king to Kt6. The player would be satisfied to win easily in four moves by 1 K—Kt5. avoiding Black's promotion check; whereas the problemist would mate in three by 1 K—R5, leaving Kt5 open for the threat of 2 Kt—Q4ch and 3 Kt— Kt5 mate! while the seemingly powerful 1 . . . P— K8 (Q)ch is to be countered by the quiet 2 K— Kt6. with mate following on the next move even if Black continues checking.

The first recorded problems were Arabian *mansubat* (betting problems), the earliest known manuscript being a collection by al-Adli, c. A.D. 840. It was lost, but much of its contents was preserved in later collections, notably one compiled by someone who signed himself "Bonus Socius." The national library at Florence has a copy of his manuscript, believed to date from the late 13th century. containing 194 problems. The modern period, however, dates only from 1840 when the problems of an Englishman, the Rev. H. Bolton, a Belgian, A. d'Orville, and the German master player A. Anderssen heralded a great revival of interest. A collection published in Paris in 1846 by A. Alexandre contained 2.000 problems and seemed to leave little for the future to attempt. Yet at this very time. the establishment of many chess magazines and columns provided a sufficient stimulus to encourage the study of problems on unprecedented lines.

NO. 7.—MATE IN THREE NO. 8.— MATE IN THREE NO. 9.— MATE IN THREE

The years 1845–61 marked the discovery of many important themes. The Rev. H. A. Loveday, English chaplain at Delhi. published the historic Indian problem (no. 2) in 1845. The ambush 1 B— BI. 2 R— Q2, by which stalemate is avoided and mate attained. trite as it appears today, took the problem world by storm. (Originally published as a four-move problem, it had another Black pawn on QKt3, with very inaccurate play.) W. Grimshaw of England. A. Novotny of Austria and J. Plachutta of Germany experimented with the interference themes which bear their names, while F. Healey of England published his Bristol problem (no. 3) in 1861, with its surprising clearance key 1 R—KR1, preparing for 2 Q—Kt1 and 3 Q—KKt1 mate in certain contingencies.

In the U.S., Sam Loyd (1841–1911) composed a great number of celebrated problems such as no. 4 with its striking key Q—KB1, necessary so as to be able to occupy QKt1, Q3 or KB5 according to the Black bishop's moves. He discovered many new themes, as did his compatriots W. A. Shinkman and O. Wurzburg.

In three- and four-move problems Bohemian (Czech) composers long stood unrivaled in the blending of several lines of play, each terminating in a pure and economical mate (model). This doctrine of economy in the use of White force was first advocated about 1865 by A. Konig, the founder of the Bohemian school. His principles found ready acceptance in the work of J. Dobrusky and J. Pospisil and were carried farther by K. Traxler, L. Vetesnik, Z. Mach and others in Bohemia. The cult of the "model" mate spread all over Europe and composers of other schools made every effort to blend Bohemian principles with their own strategic ideas. Among the more successful were M. Feigl and K. Erlin (Austria), V. Marin (Spain), J. Fridlizius (Sweden), J. Scheel (Norway) and the great British composers G. Heathcote and P. F. Blake.

A school sprang up in Germany after the publication in 1903 of Das *Indische Problem* by J. Kohtz. He drew attention to the thematic problems of 1845–61 and encouraged fresh study of all the interference themes. This German problem renaissance had many distinguished members: W. von Holzhausen, F. Kohnlein, F. Sackmann and later A. Kraemer, F. Palatz and others. In no. j, the sacrifice key Kt— Q6 decoys the Black bishop so that it can no longer play to Kt4. When it now defends against 2 Q— Kz

NO. 15.— MATE IN TWO

by 2 . . . B—Bj, White is enabled to capture it. This decoy to a vulnerable point on a line Kohtz called the Roman theme.

No. 6 shows a famous Bohemian problem blending five model mates with two queen sacrifices: key R — K2, threat 2 Q X QPch. If P × R; 2 Kt—Kt6ch. If Kt—B4; 2 Q—Qjch. If R × P; 2 R—K4ch. The lightweight gem no. 7 has an unexpected key and four models, the first two lines leading to a beautiful "echo," or repeated mate: key Kt—R2, P × Kt; 2 Q—B2. If K—Q7; 2 K—B3. If K—K7; 2 Kt—Kt4. If K—Qj; 2 B—B2ch. No. 8 combines three elegant pin models: key R—Rj (threat 2 Kt X P [B5]ch). If B—Kt4; 2 R—Rqch. If B—K3; 2 Kt × P(B2)ch. If B — QB5; 2 Q — KKt7ch. No, 9, by a Russian composer, shows four popular queen sacrifices, each leading to a model mate: key Kt — R4, threat 2 Q — Bjch. If B — Kt5; 2 Q — Kqch. If Kt — K6; 2 Q × Pch. If R — K5; 2 Q — Kt5ch.

While of less depth than longer problems, two-movers enjoyed increasing popularity after the productions of T. Taverner appeared in England in the 1880s and 1890s. A. F. Mackenzie, the blind composer of Jamaica, gave two-move problems fresh vitality at the end of the century, drawing attention to the cross-check theme: where Black checks, such as those of the knight in no. 10 (key, B—K4), are countered without capture of the checking piece. Subsequently interferences and pinnings and unpinning~and then the changed mate, have provided the two-move problem with original materials. The establishment (1913–24) by J. F. Magee, Jr., of the Good Companion club of Philadelphia encouraged these two-move forms widely, calling into action many younger men, such as G. Guidelli and A. Mari of Italy, A. Ellerman of Argentina and C. Mansfield of England. Later, new paths were blazed by composers of the U.S.S.R., such as M. M. Barulin, L. I. Kubbel and L. I. Loshinsky. Ellerman's masterpiece, no. 11 (key, R—Q7), illustrates unpinning and other features. No.. 12 (key, R—QKt1) has three pairs of mutual interferences between Black rooks and bishops. One of the finest keys in a two-move problem (Q—B3) occurs in no. 13, by J. A. Schiffmann (Rumania).

After 1940 emphasis was often placed on defensive play. In no. 14, by a U.S. composer (key, Q—R6), an aimless move of the Black knight on K3 allows 2 Kt—QKt6 mate; but five moves of the knight can forestall this, forcing five new mates. Defensive play of another character is seen in no. 15 by a Dutch composer (key, B—QI, with eight mates accurately forced).

A large classified collection of more than 150,000 problems was initiated by Alain White, U.S. composer, who edited The *Christmas Series* of more than 30 books (1905 et seq.). His collection passed under the control of C. S. Kipping of England. Many national problem societies exist—the British Chess Problem Society (founded in 1919) has encouraged the study of problems by arranging tournaments for composers and solvers.

This article has not attempted to trace the story of problems other than direct mates. But the existence should not be overlooked of such important forms as the self-mate (in which the loser wins) or the many original "fairy" types invented and popularized by T. R. Dawson and others (often using freak pieces).

CHESS PIECE. More than 500 different patterns of chess pieces have been recorded. These, like the game itself, are probably derived from the "four arms" of the Indian army—*i.e.*, chariots, elephants, horses and infantry—although the stumpy. angular shapes of early pieces were variously misinterpreted in the game's long journey westward. The grading of pieces by modeling them into recognizable figures developed gradually in about the 11th century. Each chess-playing country produced its own designs and these were usually naturalistic, except where Muslim rule restricted them to symmetrical shapes that would avoid representation of man or animal, or where considerations of cost limited them to such simple wood turnings as could be sold in England for 8d. a set in the reign of Elizabeth I. The queen was a European interpretation of the raja's vizier, and the bishop of the English set (the original elephant) appeared in other European countries in entirely different guises, such as a jester in France.

Early European chess pieces at their finest were made in precious metals, jeweled and enameled, the kings and queens clad in royal regalia, the knights in armour and the pawns arrayed as foot soldiers. The cabinet pieces found today, however, derive mainly from the 18th and early 19th centuries. The ancient Hindu theme of martial strategy is evident in early 18th-century European sets, which have portrait busts of opposing leaders and their aides to commemorate military victories.

From the early 18th century until the 1830s the East India company imported lavishly carved chessmen in red and white ivory, the opposing sides being the company and Indians. Rajas and viziers were represented by laden elephants. those of the rajas bearing howdahs; company knights rode horses and the Indians vere mounted on dromedaries. During the second half of the 18th century the company's bishops and pawns in these sets sometimes wore top hats. The pieces were mounted on thin disks until the 1780s, when short turned pedestals became usual. In some sets the horses' heads of the knights suggested prancing animals, vith forelegs waving in the air.

The Chinese also exported chess pieces to western countries. In early sets each piece might be mounted on an openwork pedestal containing several loosely revolving concentric hollow fretted balls, the number varying with the importance of the piece: as many as seven were allowed for a king and three for a pawn. These balls supported a variety of figures, usually Chinese fighting men. The oriental faces and almond eyes distinguish them from similar sets. including the fretted balls, which were made in England during the mid-19th century. The Chinese themselves preferred draughtlike pieces inscribed with different marks.

As chess playing became more widespread from about 1820 there was a greater demand for less ornate pieces, the bodies of kings and queens being reduced to truncated cones, and during the 1830s cylindrical bodies with elaborately carved surfaces were usual. These continued until about 1860, when they were superseded by the Staunton chess pieces, the standard design of the 20th century, originated by Howard Staunton, who registered the pattern in 1849.

Chess pieces in ceramics date from 17j8, when Meissen introduced porcelain sets in which the castles were represented by elephants and the knights by riderless horses. From 1783 Wedgwood modeled sets in jasper from figures, designed by the sculptor J. Flaxman, of players in Shakespeare's *Macbeth* and these continue in production.

CHEST: *see* CABINET FCRNITURE.

CHESTER, EARLS OF. The English title of earl of Chester was first held by HUGH (c. 1047–1101), viscount of Avranches, to whom his kinsman William I entrusted the security of Cheshire in 1071. The Domesday survey shows that Earl Hugh ranked high among the greater landowners of Norman England. Within the county of Cheshire the earls came to enjoy semi-regal powers, which largely exempted it from the scope of the king's government, although not until after it had passed to the crown was Cheshire officially, but infrequently, termed a county palatine. The earls' immense influence, however, depended primarily on the great estates of the honour of Chester, which extended into more

than 20 shires, notably Lincolnshire and the midland counties. Earl Hugh, who founded Chester abbey, was followed by his son, RICHARD (d. 1120), and then by his nephew RANULF le Meschin (d. c. 1129), viscount of Bayeux, who had acquired the honour of Carlisle. His son, the proud and unscrupulous RANULF de Gernons (c. 1100–53) played a most important but wholly self-seeking part in the civil wars of Stephen's reign; the battle of Lincoln (1141) was almost a personal issue between the earl and the king. HUGH de Kevelioc (1147–81), son of Ranulf, joined the rebellion against Henry II in 1173. The peak of the family fortunes was reached under his son, RANULF de Blundeville (c. 1172–1232), who used the style of earl of Brittany and Richmond in right of his wife, Constance of Brittany. His loyalty to King John and the infant Henry III was richly rewarded with the earldom of Lincoln (1217) and the custody of the honours of Richmond. Leicester and Lancaster. He took the cross in 1218 and distinguished himself at the siege of Damietta; at his death his estates were divided among his four sisters or their heirs. Cheshire and the earldom passed to his nephew JOHN the Scot (c. 1207–37), earl of Huntingdon, and then. after long negotiations, were annexed to the crown by 1241. The Lord Edward (afterward Edward I) was created earl of Chester in 1254, and since 1301 the title has never been held by anyone other than the heir apparent of the monarch, and has regularly been one of the titles of successive princes of Wales.

Stewart-Brown "The End of the Norman Earldom of Chester" in *English Historical Review,* vol. xxxv (1920). (C. D. R.)

CHESTER, a city, county borough (1888), and the county town of Cheshire, Eng., and a county in itself, 18 mi. S.S.E. of Liverpool by road and the Mersey tunnel. Pop. (1961) 59,283. Chester, with a medieval aspect, lies in a bend of the Dee river on a small sandstone ridge, 6 mi. above the point at which the river opens out into a wide, shallow estuary. It is an important railway centre.

History.— Possibly Suetonius Paulinus built a small fort in this spot to defend the crossing of the Dee, when he advanced into north Wales in A.D. 61; and the force planted there may have remained. In about A.D. 78 the advance was renewed under Gnaeus Julius Agricola, and the 20th legion was stationed there to subdue the tribes of north Wales. From its key position in relation to the north Wales coastal route and to the defenses of the northern frontier, Chester, the Roman Deva or Castra Devana ("camp on the Dee") became the chief western legionary fortress. Many Roman inscriptions and remains were found, and the north and east walls stand in great part on Roman foundations. In 1929 a stone-built amphitheatre of the late 1st century A.D., the largest in England, was discovered outside the east wall. Deva was probably deserted in the second half of the 4th or beginning of the 5th century. In about 615 Aethelfrith, king of Northumbria, defeated a Welsh army there and apparently the fortress was then ruined.

In 907 Aethelflaed fortified the position as a Mercian defensive post and in the 10th century Chester (the Anglo-Saxon Legaceaster, abbreviated Ceaster, hence its modern name) became a place of importance, with its own mint. The Domesday Book account of the city includes a description of the Saxon laws under which it was governed in the time of Edward the Confessor.
