Over 30 private speeches are extant under Demosthenes' name, but many of these are spurious. Eight are concerned with a certain Apollodorus, son of the banker Pasion; not more than two of these can have been written by Demosthenes. The private speeches deal with a wide range of topics which include business contracts, bankers' loans, testamentary claims, and various points of civil law. Somewhat surprisingly Demosthenes continued to write speeches for private cases after he had become a leading politician.

Early Political Life, 355–352 B.C.—Demosthenes started his political career by writing speeches for the prosecution in important state trials. These trials were closely connected with the political life of Athens. In particular, indictment of an unconstitutional proposal (*graphe paranomon*) was an instrument often used to weaken or discredit political opponents. Demosthenes' public forensic speeches during this period were all concerned with such suits. The first of these trials was the prosecution of Androtion in 355 for illegally proposing the award of a golden crown to the outgoing council (*boule*). The plaintiffs were two comparatively obscure men, Euctemon and Diodorus; Demosthenes composed the speech *Against Androtion* for Diodorus. Apart from its personal attack on Androtion it was a scathing denunciation of Athenian financial policy.

In the following year he is said to have himself delivered the speech *Against the Law of Leptines* in a suit brought against Leptines who had introduced a law to abolish the hereditary exemption from taxation granted to public benefactors. In 352 Demosthenes again wrote a speech for Diodorus, *Against Timocrates,* in a sequel to the earlier action against Androtion. A group

of men which included Androtion had embezzled money belonging to the state. When Timocrates proposed that they should be allowed an extended period for repayment, he was prosecuted by Diodorus on the grounds that his proposal was unconstitutional.

In the meantime Demosthenes had started to take part in the deliberations of the assembly *(ecclesia)*. In 354 rumours were rife at Athens that Artaxerxes III of Persia was preparing to attack Greece, and the people were eager for war. In his speech *On the Symmories* (naval-taxation panels) Demosthenes belittled the immediate danger and deprecated any acts of provocation. To safeguard the future he urged that the efficiency of the fleet should be improved by reforming the system of taxation which provided funds for its upkeep. This policy of caution and moderation must have been influenced by his future opponent Eubulus (*q.v.*). In addressing the assembly two years later Demosthenes appears to have been acting more independently. In 352 Megalopolis, founded by Epaminondas of Thebes about 369 as the centre of the Arcadian league, was threatened by the Spartans, and appealed to Athens for help. Both sides sent embassies to put their case before the Athenian assembly. In his speech *For the Megalopolitans* Demosthenes supported the case for Megalopolis, although Athens was bound by treaty to Sparta. Probably during the same year in his speech *On the Freedom of the Rhodians* he supported a request by a deputation of exiled Rhodian democrats for assistance in making Rhodes independent of the dynasts of Caria. The cause he pleaded was unpopular at Athens because the Rhodians had been partly responsible for the break-up of the Athenian confederacy. In both these debates Demosthenes must have been opposing the noninterventionist policy of Eubulus. In neither case was his advice followed. About the same time he was concerned in a public trial which affected Athenian policy in northern Greece. A motion had been passed at the instigation of Aristocrates that special measures should be taken by Athens to ensure the personal security of Charidemus, a well-known mercenary leader and brother-in-law of the Thracian king Cersobleptes. *Against Aristocrates* was written by Demosthenes for Euthycles who prosecuted Aristocrates for the illegality of his proposal. Charidemus (*q.v.*) was an undesirable character who had served several powers, and Demosthenes made a strong case against him, but the wider political implications of this speech are not clear, and scholars differ widely in their attempts to assess them.

Too little is known about the intricacies of Athenian politics for Demosthenes' early political activity to be properly understood. but it is possible to see the main trends. He entered political life at an early age without wealth or influence. At first he appears to have supported Eubulus' policy of financial reform at home and nonintervention abroad. He soon rebelled against Eubulus' cautious moderation, and his speeches before the assembly in 352 show a growing independence.

Demosthenes and Philip II of Macedonia. — The Athenians had been half-heartedly at war with Philip since his seizure of Amphipolis in 357. By a series of rapid conquests Philip had deprived Athens of one ally after another. In 352 he advanced into southern Thessaly against Onomarchus of Phocis and threatened to pass through Thermopylae into central Greece. The Athenians, stirred to action, sent troops to Thermopylae to bar his advance. Philip thereupon overran Thrace and marched to Heraeum on or near the Propontis (Sea of Marmara), thus endangering Athenian interests at a vital point, as the Athenian corn supply came largely from the Black sea area. It is difficult to say at what point Demosthenes realized the seriousness of the Macedonian threat. Not until the *First Philippic* speech do we find Philip treated as the real enemy of Athens; henceforth Demosthenes' energies and oratory were passionately devoted to combating Philip. This speech is traditionally dated 352–351, immediately after Philip's advance into the Propontis, but many scholars now ascribe it to 349 because of an apparent reference to Philip's attack on Olynthus in that year. It is an eloquent appeal to the Athenians to rouse themselves from their lethargy and make vigorous preparations for war, and it gives detailed and practical advice on how this should be done.

The speech *On the New Order (peri syntaxeos)*, which proposes changes in financial and administrative organization, belongs roughly to this period. It was rejected as spurious by 19th-century scholars, but there is now a tendency to regard it as authentic. The three *Olynthiac* speeches were written in 349–348. Having recovered from an illness incurred while besieging Heraeum, Philip now threatened the Greek cities of Chalcidice, particularly Olynthus which appealed for help to Athens. In these speeches Demosthenes urged the Athenians to save Olynthus and advised them how Philip could most effectively be opposed. The Athenians did in fact send an expeditionary force, but it arrived too late to save Olynthus which was ruthlessly destroyed by Philip. The traditional order of the three speeches, which was disputed in the past, is now accepted by most scholars. It is however an open question whether they were ever delivered in anything like the form in which they have survived.

The bitter hostility which now existed between Demosthenes and Eubulus' peace party was reflected in an incident at the Dionysiac festival of 348. On this occasion Midias, a supporter of Eubulus, struck Demosthenes in the face. Demosthenes prepared to prosecute, and the speech *Against Midias,* which was written for the trial, survives. It was never delivered because a compromise was reached, presumably because the political parties realized the need for unity. The recent military efforts had exhausted the Athenians financially and the necessity for peace was generally recognized. A mission with this end in view, of which Demosthenes, Eubulus, and Aeschines were members, was sent to Philip in 346. The resulting peace of Philocrates was ratified later that year. Demosthenes condemned its terms, but in his speech *On the Peace* maintained that they must be observed.

The peace lasted nominally for six years during which Philip extended his influence to the west and north of Macedonia. In 344 Demosthenes led a mission to the Peloponnese to counter Macedonian intrigues there. Philip sent an embassy to Athens to protest against this misconstruction of his motives. Demosthenes used the occasion to deliver his *Second Philippic* speech in which he uncompromisingly attacked Philip as the enemy of Greece. In 343, when the war party dominated the assembly, Demosthenes brought an action against Aeschines, which had been pending for three years, for treacherous conduct in the negotiations which led to the peace of Philocrates. On *the False Embassy,* Demosthenes' long speech in prosecution, like Aeschines' speech in defense, reflects the wild passions and unscrupulous misrepresentations nhich characterized these public trials. Aeschines, supported by Eubulus, was acquitted by a narrow majority. *On Halonnesus* (342), which asserts Athenian rights over this small island south of Lemnos, held by Philip, is of doubtful authenticity. About 342 at Demosthenes' instigation the Athenians sent a force under Diopithes to the Thracian Chersonese (Gallipoli peninsula). Diopithes, using this peninsula as a base, attacked some of Philip's possessions in the area, thus violating the terms of the peace. When Philip remonstrated with the Athenians, the pro-Macedonian party wished to recall Diopithes. Demosthenes in the speech *On the Affairs in the Chersonese* (341) vigorously opposed his recall on the grounds that it would leave Athenian interests in this area at Philip's mercy. In the same year he delivered his famous *Third Philippic* speech. This is unquestionably the greatest of all his political orations. Speaking with burning passion in the name of the whole Greek world he called upon the Athenians as the hereditary champions of Greek liberty to prepare for war, send a force to the Chersonese, and unite the Greek states in the common cause. The speech has been preserved in a longer and a shorter form; the modern tendency is to regard both versions as the work of Demosthenes. The *Fourth Philippic* speech, which advises the Athenians to seek help from the king of Persia, is regarded by many as a later work of compilation and forgery. It has several imitations and repetitions of passages from Demosthenes' earlier speeches, particularly *On the Affairs in the Chersonese.* If the fourth is not genuine, the *Third Philippic* is Demosthenes' last recorded political speech.

Betaeen the time of its delivery and the defeat of Chaeronea were the great years of Demosthenes' political life. He was the leading politician at Athens and at last succeeded in infecting

his fellow-citizens with his own passionate zeal. Byzantium and Perinthus were won over and Philip's designs in this area were checked. Athenian influence was re-established in Euboea. Envoys were sent to various parts of Greece and a confederacy of Greek states formed. At home Demosthenes carried out two reforms which he had long cherished—a more equitable distribution of the taxes which paid for equipping the fleet and the diversion of the theoric fund, which provided free seats at public spectacles, to purposes of war. This revival of patriotic enthusiasm was not to succeed, however. Open war between the Athenians and Philip broke out in 340 over Philip's seizure of 230 Athenian cargo ships; in 338 Philip, taking advantage of the Amphictyonic War *(see* AMPHICTYONY) against the Locrians of Amphissa, pushed through Thermopylae and entered Elatea in Phocis on the road to Thebes and Athens. At this critical moment Demosthenes himself led a mission to Thebes and secured the alliance of this long-standing enemy. It was his last achievement against Philip. Later in the same year came the disaster at Chaeronea (*q.v.*).

After Chaeronea **(338 B.C.).**—It was a mark of the people's confidence in Demosthenes that he was chosen to deliver the official funeral oration for the Athenians who had fallen in the battle. The extant speech supposed to have been delivered by Demosthenes on this occasion is conventional and commonplace, and in no way characteristic of his oratory. Its authenticity was denied even in ancient times. Some modern scholars, however, are inclined to think it genuine on the grounds that ceremonial oratory necessarily differed from that of the assembly.

Demosthenes continued to serve Athens, even in an official capacity. In 337 he was a member of a commission appointed to repair the fortifications of Athens and about the same time he was entrusted with the administration of the theoric fund. In 336 Philip was murdered. Hopes for a Greek revival were soon dashed by the energy and brilliance of his son Alexander III (the Great). A speech ascribed to Demosthenes, *On the Treaty with Alexander,* is certainly spurious and is now generally assigned to an unknown political adherent of Demosthenes. In 336 Ctesiphon proposed that the state should award Demosthenes a golden crown. Aeschines, Demosthenes' bitter opponent, thereupon indicted Ctesiphon for making an illegal proposal. The trial did not take place until 330. Demosthenes' magnificent speech *On the Crown,* ostensibly delivered in defense of Ctesiphon, is in fact a vindication of his own political life. In it he views in retrospect the whole drama of his campaign against Philip. His eloquence won over the jury and Aeschines was overwhelmingly defeated.

The last phase of Demosthenes' life was overshadowed by an incident connected with Harpalus, Alexander's chief treasurer in Asia. This man, hearing a rumour that Alexander had died in India, fled to Athens in 324 taking with him a mercenary force and a large sum of money. When Alexander's representatives demanded his surrender, the Athenians temporized. On Demosthenes' proposal Harpalus was imprisoned and the money kept in trust for Alexander. Harpalus, however, escaped and it was discovered that about half the money had disappeared. At Demosthenes' instigation the council of the Areopagus was asked to inquire into the scandal. When its findings were published Demosthenes was himself declared guilty of having received 20 talents. We are ill informed about the political intrigues which formed the background to this affair. If, as seems likely, Demosthenes did take this money, he may reasonably be supposed to have done so from patriotic or party motives rather than for his personal gain. He was fined 50 talents and being unable to pay went into exile at Troezen and Aegina.

On Alexander's death in 323 Demosthenes used his eloquence to win support against Macedonia in the Peloponnese. He was recalled from exile and his fine was paid from public funds. Athens and other Greek states revolted from Macedonian rule. After some initial successes the Greek forces were defeated by Antipater at Crannon in Thessaly in 322. Under pressure from Antipater the Athenians condemned Demosthenes and others to death. He had already taken refuge in the temple of Poseidon on the island of Calauria (Poros, 7 mi. S. of Aegina). Pursued there by Antipater's agent he killed himself by taking poison.

Demosthenes' Statesmanship.—No statesman of ancient times has been so variously estimated by the modem world as Demosthenes. For the greater part of the 19th century, when interest and admiration were centred on the classical period of Greek history and its ideal of the small, independent city-state, Demosthenes was regarded as a far-sighted statesman who failed gloriously in a heroic effort to revive the spirit of 5th-century Athens. In the late 19th and the 20th century there was a tendency to view Greek history in a wider perspective, and admiration for Demosthenes waned. Many have seen him as a narrow nationalist who made a suicidal attempt to stem the natural evolution of the Greek peoples. Some have completely discredited his personal integrity. Unbiased judgment is probably impossible, but there can be no doubt about the sincerity and single-minded purpose of his resistance to Macedonia.

Demosthenes' Oratory.—Demosthenes' oratorical qualities can only be studied from the extant speeches which represent versions revised and edited for publication. It is impossible to say how far they differed from the spoken speeches, but scholars have shown that they contain several elements which must have been inserted after the occasion of the actual debate. He prepared his speeches with a care which was considered remarkable by his contemporaries, and he was criticized on this account. This did not, however, lessen the effectiveness of his oratory. In his two greatest speeches, the *Third Philippic* and *On the Crown,* he reaches heights of eloquence without parallel in the ancient world. Passionate conviction in the rightness of his cause finds a natural outlet of expression in the artistry of his oratory. With Demosthenes stylistic embellishment was never a superimposed adornment, as it was with Isocrates (*q.v.*). It was the instrument used to achieve the practical purpose of persuading his hearers. He was well aware of the limitations of his audience and did not hesitate to take advantage of their ignorance or weaknesses. He employed various devices to sustain their interest and attention; paradoxical arguments, dramatic outbursts, supposed objections sometimes expanded into a dialogue with an imaginary opponent, repetition of salient points, avoidance of complex reasoning all served this purpose. The wit which he used to discredit his opponents in public trials was bitter and, to modern taste, crude; of genuine humour there is no trace. The scurrility of his invective was extravagant even by Athenian standards.

His language is for the most part simple, sometimes even colloquial, although striking phrases and poetical words appear in an appropriate context. He occasionally used bold metaphors, but rarely the expanded simile. His sentence structure has an infinite variety. He shows the Greek love of antithesis, in his more elaborate passages even interlacing two or more pairs of antithetical phrases or clauses. The complex period is, however, used with restraint and varied with short, simple sentences. Beyond all other Greek orators he succeeded in adapting the rhetorical figures to suit his specific purpose or context. He evidently had a delicate ear for sound, but attempts at rhythmical analysis of his sentences have been inconclusive. All that can safely be deduced is a tendency to avoid hiatus and an apparent dislike of three or more consecutive short syllables. The speeches have a formal introduction and a peroration, but otherwise he disregarded structural conventions. In general he avoids long, unbroken narrative, preferring to intersperse narrative with argument.

Demosthenes' supremacy among the Greek orators was acknowledged in his own day and has never since been seriously challenged. Cicero, Dionysius of Halicarnassus, and the author of the essay *On the Sublime* (formerly attributed to Longinus) all give him superlative praise. For the Greek rhetoricians of the 2nd and 3rd centuries A.D. he was the one great master. Even in modern times, when many would discredit his statesmanship, the brilliance and power of his eloquence is universally admitted.

Works.—Of the 61 speeches attributed to Demosthenes, the following are usually considered genuine.

Private Speeches: Against Aphobus i and ii (363); *Reply to Aphobus* (362); *Against Onetor* i and ii (361); *On the Crown for Trierarchs (c.* 360); *For Phormio* (350/349); *Against Stephanus*

(*c.* 349); *Against Boeotus* (348); *Against Pantaenetus* (346); *Appeal against Eubulides* (345); *Against Nausimachus and Xenopithes; Against Spudias; Against Conon; Against Callicles* (all undated).

Public Speeches: Against Androtion (355); *On the Symmories* (354); *Against the Law of Leptines* (354); *Against Timocrates* (352); *For the Megalopolitans* (352); *On the Freedom of the Rhodians* (probably 352); *Against Aristocrates* (*c.* 352); *Philippics* i–iii (349 probably, 344, 341); *On the New Order* (*peri syntaxeos*) (*c.* 350); *Olynthiacs* i–iii (349/348); *Against Midias* (348/347); *On the Peace* (346); *On the False Embassy* (343); *On the Affairs in the Chersonese* (341); *On the Crown* (330).

Among the works wrongly ascribed to Demosthenes, the *Eroticus*, an encomium of a handsome boy, must almost certainly also be included. and all. or at any rate most. of the six *Letters*. The collection of *prooimia*, introductions to political speeches, appears to be a compilation, consisting partly of genuine passages from Demosthenes, partly of later imitations.

DEMOTIC LANGUAGE AND WRITING. The name demotic, "popular," is taken from Herodotus to denote the ordinary Egyptian handwriting of late times. The script first appeared on papyri and potsherds ("ostraca") of the early 7th century B.C., after the re-unification of Egypt under the Ethiopian 25th dynasty. It had probably developed from business hieratic in the ports and commercial cities of lower Egypt during the two previous centuries. With the establishment at Saïs in the delta of a native dynasty and a strong centralized administration by Psamtik (Psammetichos) I in 663 B.C., demotic began to displace the corrupted form of hieratic ("abnormal hieratic") still in use in upper Egypt. By the time of Darius I (522–486 B.C.), who apparently encouraged the reorganization of the writing schools, a neat demotic script was everywhere in use for business and literary purposes; classical hieratic continued to be employed for religious texts. Before the Macedonian conquest the cursive ligatures of the early demotic gave birth to new symbols which were carefully and distinctly formed. In the Ptolemaic period an epigraphic variety appeared, priestly decrees being engraved on stelae (such as the Rosetta stone) in triple hieroglyphic, demotic and Greek versions; under the Romans, while religious texts continued to be written in hieratic, literary texts were in demotic. but Greek was almost universal for business documents. The use of demotic went out with or shortly before paganism, but priests of Isis continued to use it in their graffiti at Philae as late as A.D. 452.

Demotic is written from right to left in horizontal lines; the signs comprise phonograms, word signs and determinatives, and a single demotic sign is often in origin a ligature of several hieroglyphic signs. It is difficult to transcribe with precision into hieroglyphic, and the result of such a transcription looks absurd because of the unetymological spellings and the number of otiose signs included in the ligatures. The language of demotic may represent approximately the speech of the 26th dynasty; it approximates to Coptic (*q.v.*), but employs fewer auxiliaries and periphrastic forms, and even in its latest stages its loans from Greek are confined to a few technical words which do not affect the grammar. In the Ptolemaic age it first distinguished *l* from *r*, and in very late texts vocalization may be indicated to some extent.

The great bulk of extant demotic papyri and ostraca are legal documents. Outstanding among these are the long petition of Peteese (in the time of Darius) recounting the alleged wrongs done to his family by the priests of El Hibeh over a period of more than a century and a half, and the record of a trial before the native court at Syut (upper Egypt) in 170 B.C. Accounts, letters and other ephemera also abound. The chief literary compositions in demotic are stories (*The Stories of Sethon Khamois, The Romance of King Petubastis, The Myth of the Eye of Re,* etc.); a prophetic work, the so-called *Demotic Chronicle;* and collections of apophthegms (*The Insinger Wisdom Book, The Instructions of Onchsheshonqy*). Scientific works include medico-magical compilations, astronomical texts and dream interpretations. In the Roman period a few ritual and funerary texts were written in demotic. *See* also EGYPTIAN LANGUAGE; HIEROGLYPHS.

(F. LL. G.; HE. S. S.)

DEMPSEY, JACK (WILLIAM HARRISON DEMPSEY) (1895–), world heavyweight boxing champion from 1919 to 1926, was born June 24, 1895, at Manassa. Colo. His second bout with Gene Tunney. known as "The Battle of the Long Count," was one of the most controversial in boxing history. Dempsey stood 6 ft. 1 in., weighed 189 lb. He started fighting in 1914 as Kid Blackie and took the championship from Jess Willard in 1919. His fight with Tom Gibbons, July 4. 1923, at Shelby, Mont., was the only one of his championship fights to go 15 rounds. Dempsey dropped the heavyweight title to Tunney in Philadelphia, Sept. 23, 1926, lost to the fighting marine again a year later at Chicago trying to win it back. This second match with Tunney drew a record gate of $2,658,660. Both matches were 10-round de-, cisions. At the outset of his career, Dempsey fought for purses as low as $2.50, going on to earn more than $5,000,000. and he was the first fighter to draw a million-dollar gate, a figure he exceeded five times. He continued to appear in exhibitions as a referee until 1940 when he retired from the ring and became a successful New York restaurateur. *See* also BOXING. (J. D. McC.)

DEMPSTER, ARTHUR JEFFREY (1886–1950), Canadian-U.S. physicist, devoted his time almost exclusively to a single task—the discovery of stable isotopes of the chemical elements and the measurement of their relative abundances. He was born in Toronto, Ont., on Aug. 14, 1886, and attended the University of Toronto, obtaining his A.B. in 1909 and M.A. in 1910. He then studied in Germany, at the universities of Munich, Gottingen and Würzburg. Forced by World War I to leave Germany in 1914, he continued his work in physics at The University of Chicago, where he obtained his doctorate in 1916. His scientific career extended from 1911 (the date of his first paper) to almost the day of his death, March 11, 1950. He discovered a greater number of stable isotopes than anyone else except F. W. Aston, who opened this particular field of research. At the time of his death Dempster was professor of physics at The University of Chicago and director of the Argonne National laboratory's division of mass spectroscopy and crystallography. (S. K. A.)

DEMUTH, CHARLES (1883–1935), U.S. painter, a major influence in channeling modern European movements into American art, was born at Lancaster, Pa. His early training was under Thomas Anshutz and W. M. Chase at the Pennsylvania Academy of the Fine Arts, Philadelphia. Between 1907 and 1913 Demuth made several trips to Europe to study. In Paris he was attracted by the work of Marcel Duchamp and the Cubists, an influence which lasted throughout his career. After returning to the U.S. he illustrated works of several of his favourite authors, among them Henry James (*The Turn of the Screw, The Beast in the Jungle*), Émile Zola (*Nana, L'Assommoir*) and Edgar Allan Poe (*Masque of the Red Death*). Moving gradually away from illustrative art, he next executed a series of water colours of actors and actresses. These were characterized by the use of a graceful. fluid line and showed the influences of Aubrey Beardsley and Henri de Toulouse-Lautrec. Demuth's fame, however, lies more probably in the delicate still lifes of his late period. His careful use of

line and colour placed him in the first rank of water colourists of his period. He died on Oct. 23, 1935, in Lancaster, Pa.

DENAIN, a mining and industrial town in the Nord *département* of France, is situated on the Nord coal field near the Belgian frontier, 12.8 km. (8 mi.) S.W. of Valenciennes. The development of mining and iron smelting caused its rapid growth from a mere village in the early 19th century to a town of 26,914 inhabitants in 1954. Besides large iron- and steelworks, it has important locomotive works and other engineering establishments. It is served by the Scheldt canal. Nearby is the site of the battle of 1712, when marshal de Villars defeated Prince Eugbne.

(AR. E. S.)

DENBIGH, EARLS OF, an English title which has been held in the Feilding family since 1622. WILLIAM FEILDING (c. 1582–1643), 1st earl, was educated at Emmanuel college. Cambridge, and knighted in 1607. He was created baron of Newnham Paddockes and Viscount Feilding in 1620, and earl of Denbigh in 1622. He attended Prince Charles (afterward Charles I) in Spain (1623), served as admiral in the unsuccessful expedition to Cadiz in 1625 and commanded the disastrous attempt upon La Rochelle in 1628. In the Civil War he served under Prince Rupert. On April 3, 1643, during Rupert's attack on Birmingham, he was wounded, and died on April 8.

William's eldest son, BASIL (c. 1608–75), 2nd earl, was sent in 1634 by Charles I as ambassador to Venice, where he remained until the spring of 1638. During the Civil War Feilding supported the parliamentarians, led a regiment of horse at Edgehill, and having become earl of Denbigh on his father's death in April 1643, was made major general commanding the parliamentary forces in the midlands and lord lieutenant of Warwickshire. He resigned his command after the passing of the Self-Denying ordinance in April 1645. At Uxbridge (1645) and at Carisbrooke (1647) Denbigh was one of the commissioners appointed to treat with the king. He supported the army in its dispute with the parliament, but he would take no part in the trial of Charles I. Under the Commonwealth Denbigh was a member of the council of state (1649–51), but later he came to be regarded as a royalist and, as he concurred in the Restoration. was created Baron St. Liz in 1665. He died at Dunstable without issue on Nov. 28, 1675.

The 2nd earl's titles devolved on his nephew WILLIAM FEILDING (1640–85), son and heir of his brother George who had been created Baron Feilding of Lecaghe and Viscount Callan by the influence of the duke of Buckingham in 1622, and earl of Desmond in 1628. These titles continued to be held with the earldom of Denbigh, descending in direct line to WILLIAM RUDOLPH (1912–), 10th earl of Denbigh.

DENBIGH (DINBYCH), a municipal borough, the county town of Denbighshire, Wales, and the thief market town of the fertile Vale of Clwyd, lies 28 mi. W. of Chester. Pop. (1961) 8,044. Area 14.2 sq.mi. After the Norman Conquest Denbigh was a border town and the site of a Welsh fort. When Edward I conquered north Wales it became the centre of the lordship of Denbigh bestowed upon Henry de Lacy, 3rd earl of Lincoln (d. 1311), who built a massive castle which was completed in 1322 by Thomas. earl of Lancaster. De Lacy gave the town its first charter in 1284. The lordship was subsequently bestowed on other barons, the last being the earl of Leicester, the favourite of Elizabeth I; after his death it reverted to the crown.

Denbigh castle withstood a siege during the wars of Owen Glendower (Owain Glyndwr) who burned the town in 1402. During the Wars of the Roses it was taken and retaken by Yorkists and Lancastrians. In the Civil War it was held for the king by William Salisbury and Charles I spent a night there after his defeat at Rowton Heath in Sept. 1645. The castle was surrendered in Oct. 1646 to the parliamentarians. It was afterward razed. In 1920 the ruins were transferred to the ministry of works which also maintained the ruined friary of the White Carmelites, established in the 14th century. In the yard of the Hawk and Buckle inn there is a cockpit with a thatched roof dating from the 17th century. The earl of Leicester built the county hall and began the building of a very large church designed to replace the cathedral of St. Asaph. The Denbigh Grammar school was founded in 1727 and Howell's school, a boarding school for girls, in 1859.

Denbigh before the Industrial Revolution had many thriving industries; in the 1960s it was a busy agricultural centre with big fairs and markets and a few factories. Among the well-known men born in the town were Richard Clough (d. 1570) who suggested the building of the Royal Exchange, London; Sir Hugh Myddelton (1560–1621) who constructed the New River Head reservoir to bring the first water supply to London; Sir Henry Morton Stanley (1841–1904) the explorer; and Thomas Gee (1815–98) the Welsh Radical leader. (W. A. Ev.)

DENBIGHSHIRE (SIR DDINBYCH), a county of northern Wales, is bounded on the north by the Irish sea, on the west by Caernarvonshire, on the south by Merioneth and Montgomeryshire, and on the east by Shropshire, Cheshire and Flintshire. Area 668.9 sq.mi.

Physical Features. — The Conway (or Conwy) river forms most of the western boundary of the county. Much of the north-eastern boundary is marked by the Clwydian range, of which Moel Famma ("hill of mothers," 1,820 ft.) is the highest point, and most of the eastern boundary is formed by the Dee river. Broadly speaking, the boundaries coincide with the ancient ones of Gwynedd-is-Conwy and Powys Fadog. Apart from the vales of Conway and Clwyd (*q.v.*), the coastal plain and the Vale of Maelor in the east. Denbighshire is mountainous, with Mynydd Hiraethog forming the central mass of the plateau country. In the east and southeast a line of hills is formed by the Clwydian range, Cyrnybrian and the Berwyn range, of which the highest point is Moel Sych (2,713 ft.) at the meetingpoint of Denbighshire, Merioneth and Montgomeryshire. The Ceiriog, Rhayadr and Tanat rivers drain the southeast of the county, and the other main rivers are the Clwyd, Alwen and Dee, the last-named running through the deep and narrow incised meanders of the Vale of Llangollen, famous for its scenic beauty.

Geologically, the northwestern and southwestern regions of the county are divided by the dissected plateau of Silurian rocks north of Llangollen. The southeastern region includes the basin of the Ceiriog and its mountainous frame of the Berwyn ridge, of Ordovician rock with volcanic elements. This region also includes Ruabon and Wrexham and their Coal Measures on the borders of Cheshire. A narrow broken band of Old Red Sandstone, or what may be a conglomeratic basement bed of the Carboniferous Limestone series, crops up along the Vale of Clwyd and in Eglwyseg rocks. Resting upon this, the Carboniferous Limestone extends from Llanymynech, Shropshire, in the south, to the Cyrnybrian fault, and there forks into two divisions that terminate respectively in Great Orme's head, Caernarvonshire, and Talargoch, Flintshire, and are separated from each other by the denuded shales of the Clwydian range.

The Vale of Clwyd is sharply defined on its eastern margin by the great fault-line scarp which rises to the Clwydian range. Massive downfaulting to the west of this axis has led to the preservation of New Red Sandstone in the floor of the vale, where it overlies the limestone. In the eastern division it is itself overlaid by the Millstone Grit of Ruabon and Minera, and by a long reach of the Coal Measures which, near Wrexham, are $4\frac{1}{2}$ mi. in breadth. Eastward of these a broad strip of the red marly bed succeeds, and between this and the Dee the ground is again occupied by New Red rocks. The red sandstone areas form the best agricultural land. The eastern flank of the county (less sharp than on the west) grades down to the coal field west of the Dee, and, from the limestone below, lead and silver and zinc ores have been obtained. Valuable fire clays and terra-cotta marls are also taken near Wrexham. The whole of the lower ground in the county is covered more or less thickly with glacial drift. On the western side of the Vale of Clwyd, at Cefn and Plâs Heaton, there are caves which have yielded the remains of rhinoceros, mammoth, hippopotamus and other mammals now extinct in Britain.

In the lower parts the climate is mild, but it is bleak in the highlands. The region of heaviest rainfall is the highlands with

more than 70 in. annually, but the rainfall tends to decrease eastward, and parts of the Vale of Clwyd have less than 27 in. Vegetation includes a considerable amount of rye-grass in the valley pastures, white clover and fescue in the higher pastures and much stunted heather in the highlands. Part of Denbighshire is included in the Snowdonia National park. The National trust owns the well-known gardens at Bodnant Hall, near Conway, as well as such beauty spots as Tir Ifan, southeast of Llanrwst.

History.— The period of earliest occupation by man is doubtful. The high ground is dotted with tumuli. Finds of gold and socketed axes dating from the Later Bronze Age indicate that the upper Dee valley and the Vale of Clwyd had become important lines of movement by that time. Native hill fortresses such as Dinorben, and Roman statues of later times, show the importance of the north Wales coastal route. One Roman road ran from Chester to Caernarvon (Segontium) through the north of Denbighshire, while another ran through the south of the county. To the Roman period belong the inscribed stones at Gwytherin and Pentre Voelas. Eliseg's pillar, near Llangollen, tells of the struggle at Chester between the Britons and Aethelfrith's invading Northumbrians (*c.* 613). In the southeast is a section of Offa's dike as well as part of the smaller and parallel Watt's dike. Among the ancient monuments of Denbighshire are the burial chamber at Capel Garmon and the beautiful, ruined Cistercian abbey Valle Crucis (founded *c.* 1200), near Llangollen.

After the conquest of north wales-by Edward I Denbigh castle was built by Henry de Lacy, 3rd earl of Lincoln, and Ruthin castle probably by Hugh of Avranches, earl of Chester. The rolls of the court of Ruthin are complete from 1294 and are now in the National Library of Wales, Aberystwyth. Owen Glendower failed to take Ruthin in 1400. In the southeast Chirk castle was completed by Roger de Mortimer in the early 14th century. The county was formed by an act of Henry VIII out of the lordships of Denbigh, Ruthin, Rhos and Rhyfoniog, which were roughly the Perfeddwlad (midland) between the Conway and the Clwyd, and the lordships of Bromfield, Yale and Chirkland, the old possessions of Gruffydd ap Madoc, *arglwydd* (lord) of Dinas Brbn. Charles I took refuge in the county in 1645, and Denbigh castle was one of the last Welsh strongholds to surrender to the parliamentarians, who "slighted" (razed) both Denbigh and Ruthin castles. Near Ruabon is Wynnstay, formerly the seat of the old Watkin Williams-Wynn family of landowners. The fine church (1470) of Wrexham shows that this part of the county between the Welsh plateau and the English border had developed considerably during the middle ages. Royalist and Jacobite sympathies and continued adherence to the Roman Catholic Church on the part of some of the great families were features of the county, which developed greatly under the Nonconformist influences of the 18th century.

Oak wood lofts and screens are to be found in the churches at Llanrwst, Gresford and Derwen. Gresford has beautiful 15th-century stained glass, including the Te Deum east window, and in Llanrhaiadr church is a magnificent 16th-century Jesse window.

Population and Administration.— The population of the county in 1961 was 173.843. The chief towns are: Colwyn Bay (pop. 23,090), Denbigh (8,044), Ruthin (3,502) and Wrexham (35,427), all municipal boroughs; and the urban districts of Abergele (7,982), Llangollen (3,050) and Llanrwst (2,571). There are 5 rural districts and 72 parishes, of which Rhos Llanerchrugog, near Wrexham, has a population of more than 10,000. The county has two parliamentary divisions, Denbigh and Wrexham. Denbighshire is in the north Wales circuit, assizes being held at Ruthin, which is also the administrative centre of the county. Denbigh, the county town, and Wrexham have separate commissions of the peace, but no separate quarter-session courts. There are ten petty sessional divisions. The county is in the diocese of St. Asaph.

Agriculture and Industry.— Agriculture is one of the chief industries of the county, with milk production and the rearing of sheep as the predominant enterprises. The breeding of pigs and poultry is increasing. The chief markets are at Abergele, chiefly for fat sheep and lambs, Llanrwst, for fat sheep, lambs and store cattle (*i.e.,* cattle kept for fattening), and Wrexham, for store sheep and cattle, fat stock and dairy cattle. In the lowlands oats and mixed corn are grown and wheat to a lesser extent. Much heath and moorland was reclaimed after 1945. Forestry and its associated industries have also developed in recent years. Holt is a noted market garden centre.

Coal mining is an important industry in the southeast, the chief centres being Chirk, Ruabon, Wrexham, Gresford and Llay. High-quality steel is manufactured at Brymbo. Bricks are made, chiefly the famous red Ruabon bricks, fire-bricks and silica bricks for use in building blast furnaces. There are modern trading estates at Wrexham and Marchwiel, with such industries as light engineering and the manufacture of furniture and clothing.

The tourist industry is considerable, particularly along the coast and in the Dee valley. The International Musical Eisteddfod has been held annually at Llangollen since 1947. The Holyhead road to London, once a famous coaching route, traverses the Vale of Llangollen, and another main road runs along the north coast. A well-known road is the Horseshoe pass between Llangollen and Ruthin. The Holyhead railway line follows the coast in the north, and the Birkenhead-Shrewsbury line passes through Wrexham and Ruabon in the east. Of the canals built in the 18th and 19th centuries, only a six-mile feeder canal near Llangollen is still navigable, and there horse-drawn boats provide entertainment for thousands of holiday-makers.

DENDERA: see DANDARAH.

DENDROCHRONOLOGY is the study of the chronological sequence of annual rings in trees and aged wood. The first observations on tree rings were probably made several millenniums ago, but the earliest known writings on the subject were those of Leonardo da Vinci late in the 15th century. During the next three centuries the study was expanded by European botanists, and several European universities were teaching courses on tree growth and climate early in the 19th century. The field spread to the new world with the immigration to the United States of German foresters. A. E. Douglass, an astronomer in Arizona. independently revived and developed the study early in the 20th century, and the field as it is practised today is primarily based on principles that he set forth. Douglass was engaged in the study of sunspot activity and its relation to climate, and the rings in northern Arizona trees were found to exhibit the effect of certain sunspot activities.

Tree-ring studies are possible because certain species produce growth rings during annual growing seasons. The width of the ring (the amount of growth) for each year is determined by certain internal (genetic, physiologic and metabolic) and external (edaphic, biotic and climatic) factors acting on the tree's metabolism. Under normal conditions the internal factors and most of the external ones remain constant, year after year. In widespread geographic areas where there is uniform variation in growth activity resulting in uniform variance in ring widths, the cause of this uniformity is some widespread climatic factor which affects all trees in a similar fashion. In the United States southwest, for example, tree growth is a reflection of the amount of rainfall. Trees growing in well-drained soils rely solely on precipitation for soil moisture, and in these locations, the quantity of soil moisture is a result of how quickly the rains fall and of the amount of water lost through runoff and evaporation. A soil-moisture history can thus be compiled by studying the relative ring widths in any given tree growing in such a location. The growth rings in trees whose roots tap a permanent supply of soil moisture are too complacent for such an analysis.

In the southwest, wood specimens from old Indian villages and archaeological sites have been dated back to about 60 B.C., thus extending the ring series beyond the reach of living trees and adding many years to the local tree-ring record. The long-lived sequoia and bristlecone pine trees of California have also been systematically studied. Sequoias have been dated back more

than 3,000 years and bristlecone pines over 4,000 years, but by the early 1960s it had not been possible to use this evidence for the dating of prehistoric objects in North America.

Studies in dendrochronology are applied in the fields of botany. climatology, ecology, geochronology, geology, forestry and silvaculture. The studies are best known, however, in the field of geochronology (*q.v.*), where they are used to interpret the temporal placement of some prehistoric item or event through the study of wood contained in the archaeologic or geologic site. See also ARCHAEOLOGY: *The Materials of Archaeology.*

DENGUE, also called breakbone fever or dandy fever, is an acute. infectious, mosquito-borne fever that temporarily is completely incapacitating but is almost never fatal. Besides fever, the disease, caused by a virus, is characterized by an extreme pain in and stiffness of the joints (hence the name "breakbone fever") that often induces a dandified gait in the victim (hence the Spanish derived name "dengue" and the English "dandy fever"). It may occur in any country where the mosquito vectors breed. although it is endemic only among inhabitants of warm climates. The disease was first accurately described by Benjamin Rush in 1780, during an epidemic outbreak in Philadelphia, Pa., and the causative organism was first demonstrated by P. M. Ashburn and C. F. Craig in 1907 in the Philippine Islands.

The vector incriminated throughout most endemic areas is the yellon-fever mosquito. *Aedes aegypti,* but in the western Pacific regions *A. albopictus* and several other *Aedes* species and *Armigeres obturbans* are implicated; in Hawaii *A. albopictus* was responsible for an epidemic in 1944. The mosquito becomes infected only if it bites an infected individual (man and perhaps certain species of monkey) during the first three days of the victim's illness and then requires 8 to 11 days to incubate the virus before it is able to transmit the disease to another individual. Thereafter the mosquito remains infected for life. The virus is injected into the skin of the victim in minute droplets of saliva as the mosquito prepares to feed.

On introduction into the victim's body the virus multiplies and. during the incubation period of four to ten days, penetrates all the tissues, but particularly attacks the lining of the smallest blood vessels and the softer tissues. The toxic by-products of the virus produce the symptoms. The acute stage is usually ushered in by a sudden onset with chills; excruciating pain in the joints, loins, epigastric region and behind the eyeballs; a reddened, puffy appearance of the face; a fever rising to 103°–104° F.. and lasting from four to seven days; rapid pulse; and frequently extreme prostration. Thereafter there are characteristically a sudden drop in temperature, profuse sweating, loose stools and at times bleeding from the lips and nose. Although the patient is greatly weakened at this stage, he experiences profound relief. However. in approximately two-thirds of dengue patients the fever soon returns, the victim becomes exhausted and depressed and breaks out with a rash that rapidly progresses from the tips of the fingers and toes up the extremities to the trunk. In two or three days the rash recedes and is followed by a characteristic itching and a branlike sloughing oi the skin. During the progress of the disease there is marked reduction in certain white cells (neutrophils) of the blood as a result oi the death of the more mature cells of this type.

Convalescence is slow, and for many months there may be evidence of lassitude, nervousness and irritability, insomnia, a slow pulse and rheumatic pains. Recovery confers considerable immunity to the comparable strains of the virus. At times, however, dengue may be so mild as to produce no noteworthy symptoms.

Diagnosis is made on clinical findings; namely. sudden onset, moderately high fever, excruciating joint pains, intense pain behind the eyes, a second rise in temperature following the brief remission and particularly the type of rash and decided reduction in neutrophilic white blood cells. The disease must be differentiated from sandfly fever (*q.v.*), yellow fever (*q.v.*), typhus fever, Rocky mountain spotted fever, malaria, Weil's disease, relapsing fever, measles and scarlet fever.

There is no specific therapy; therefore attention is concentrated on relieving the symptoms. Temporary preventive measures must be directed to screening suspected as well as diagnosed cases during their first three days of illness and, by screens and repellents, to keeping mosquitoes from biting well persons.

Fundamental in the control of the disease is the use of DDT and other insecticidal sprays around human habitations and the destruction of breeding places of the mosquito vectors. In temperate climates mosquito breeding ceases with the first freeze and dengue is terminated until the next warm season; but in the moist tropics the disease is perpetual, and control must be both effective and prolonged to keep mosquito breeding below the disease transmission level.

DENGYO DAISHI: *see* SAICHO.

DENHAM, DIXON (1786–1828). English explorer in west Africa in the first half of the 19th century, was born in London, on Jan. 1, 1786 He joined the army and served in the Peninsula and Waterloo campaigns. In 1821 he volunteered to accompany Walter Oudney and Hugh Clapperton (*q.v*) on a government expedition across the Sahara to Bornu. He joined them at Murzuch and they eventually reached Bornu in Feb. 1823. There Denham accompanied a Bornu slave-raiding expedition to the Mandara highlands. This was routed and he barely escaped with his life. In Dec. 1823 Clapperton and Oudney set out on a journey westward leaving Denham to explore the western, southern and southeastern shores of Lake Chad and the lower courses of the rivers Waubé, Logone and Chari. He was later rejoined by Clapperton, Oudney having died, and they returned across the Sahara to England in June 1825. Denham returned to west Africa, to Freetown, in Jan. 1827. as superintendent of liberated slaves on the west coast. In the following year he was appointed governor of Sierra Leone but died almost immediately of fever at Freetown on May 8, 1828.

See *Narratioe of Travels and Discoveries in Mortherrt and Central Africa in the Years 1822–24* (1826), the greater part of which is written by Denham. (R. M. P.)

DENHAM, SIR JOHN (1615–1669), English poet, forerunner of the Augustan writers. Born in Dublin in 1615 and educated at Oxford, he was admitted to the bar in 1639 but he was already active in literature. He had earlier translated Books I–VI of Vergil's *Aeneid,* parts of which were later printed, but he made his reputation with *The Sophy,* a blank-verse play acted in 1641, and *Cooper's Hill,* a poem published in 1642. Throughout the Civil War, although not a major figure, he was actively engaged in England and abroad in the king's cause. After the Restoration. partly for these services, and partly because he had been an amusing companion to Charles II, he was made a knight of the Bath and appointed surveyor general of the works (official architect), a post for which he had no qualification. He nas elected to the Royal society, and served for some years as a member of parliament. He was possibly the first to praise Milton's *Paradise Lost* in public: he brought an unbound sheet of the first edition "wet from the press" into the house of commons saying that it was "part of the noblest poem that ever mas wrote in sny language, in any age." At his death in London on March 10, 1669, he was buried in the Poets' corner of Westminster abbey

Denham's poetry is essentially didactic. His strength lies in his thought, in his neatly turned expressions of ethical and moral truisms; and his reputation rested chiefly on his style. Restoration and 18th-century poets and critics praised him as being responsible, together with Edmund Waller, for the development of the closed heroic couplet. Denham knew Waller personally, and his poetry shows Waller's influence. Dryden says, "Even after Chaucer there was a Spencer, a Harrington, a Fairfax, before Waller and Denham were in being; and our numbers were in their

nonage till these last appeared," while Pope speaks of "Denham's strength" and of "majestic Denham." Denham was not the first to write closed couplets, but he certainly had great influence in increasing their popularity, mainly because of *Cooper's Hill,* in which the couplets show a marked tendency toward Augustan conciseness. In this poem he originated a genre described by Dr. Johnson as "local poetry, of which the fundamental subject is some particular landscape, to be poetically described, with the additions of such embellishments as may be supplied by historical retrospection, or incidental meditation." *Cooper's Hill* is Denham's chief title to fame. His play and his occasional poetry are of no permanent value; his translations are of significance only because they served as models for Dryden and Pope. But in writing *Cooper's Hill* he established a new and long-popular type of descriptive poetry in which he surpassed all his imitators, except Pope. and established himself for more than 100 years as one of the most famous English poets. *The Poetical Works of Denham* were edited by T. H. Banks (1928). (T. H. Bs.)

DENHARDT, CLEMENS ANDREAS (1852–1929) and **GUSTAV** (1856–1917), German explorers and colonial pioneers who were brothers and collaborators. After two expeditions into the Tana regions (1876–77, 1878–79) Clemens was able to negotiate a friendly treaty with the sultan of Witu (Kenya). The territory was subsequently sold to the Deutsche Witugesellschaft but in 1890, according to the British-German convention concerning Zanzibar, it was given to Great Britain in exchange for Heligoland. Since the private rights of the two brothers had not been safeguarded. this brought them great financial losses. During the subsequent decades they were successfully engaged in the former German East Africa but in 1919 Clemens Denhardt once more lost his possessions through expropriation. (K. A. S.)

DENIFLE, HEINRICH SEUSE (baptized JOSEPH) (1844–1905), Austrian historian and Dominican priest, who made available for the first time a mass of medieval documents and based major reinterpretations upon them. He was born Jan. 16. 1844, at Imst, Tyrol. entered the Dominican order in 1861 and was ordained priest in 1866. From 1870 he taught theology and philosophy at Graz and began publication of his important work on the mystics with *Das geistliche Leben. Eine Blumenlese aus den deutschen Mystikern des XIV. Jahrhunderts* (1873). He was called to Rome in 1880 to undertake preparation of a new edition of the works of Aquinas. In 1883 he became subarchivist of the Vatican, a great opportunity which contributed to his production of revolutionary work on medieval universities in *Die Universitäten des Mittelalters bis 1400* (1885) and, with É. Chbtelain, in *Chartularium Universitatis Parisiensis,* 4 vol. (1889–97), with two volumes of other documents. This latter work led him to undertake further French studies, culminating in *La Désolation des églises, monastères et hôpitaux en France pendant la guerre de cent ans,* 2 vol. (1897–99). At the same time. as cofounder with F. Ehrle, he was contributing to the invaluable *Archiv fur Literatur und Kirchengeschichte des Mittelalters* (1885–). His last major work was *Luther und Lutherthum* (1904–09), a wholly unsympathetic but brilliant, well-documented and seminal reinterpretation which was fundamental to all subsequent Luther studies. Denifle died in Munich, June 10, 1905.

DENIKIN, ANTON IVANOVICH (1872–1947). Russian general and leader of "White" forces in the civil war, was born near Warsaw on Dec. 16 (new style; 4, old style), 1872. The son of a former serf, he entered the army, where his capacity for leadership earned him rapid promotion. He fought in the Russo-Japanese War and in 1914–16 distinguished himself as a divisional and corps commander on the German and Austro-Hungarian fronts. After the Revolution of March 1917 he became chief of staff to the new commander in chief, Gen. M. V. Alekseev. A professional soldier without political experience, Denikin accepted the revolution but strongly resented the resulting breakdown of army discipline, for which he held the provisional government chiefly responsible. In July he was dismissed on political grounds and appointed commander of the western front. in which capacity he lent enthusiastic support to Gen. L. G. Kornilov in his bid for power. Imprisoned for three months, he escaped, with Kornilov and other officers, and rejoined Alekseev on the Don, where an anti-Bolshevik volunteer army was being formed.

On Kornilov's death (March 1918) Denikin became supreme commander of the "White" forces in southern Russia. By the beginning of 1919 he had won mastery of the northern Caucasus, and in May, rejecting Gen. P. N. Wrangel's plan to strike northeastward. chose to advance on a broad front through the Ukraine, with Moscow as his goal. By October he had reached Orel. 250 mi. from the capital. But his communications were dangerously overextended; the population resented his military dictatorship, which tolerated looting and other excesses. and peasant risings broke out in his rear; his pronounced Great Russian nationalism, shared by his predominantly upper-class officers, hampered collaboration with minority and autonomist groups, particularly the Cossacks; and the Allies failed to provide effective military support. The tide rapidly turned against Denikin; his army melted away, and in March 1920 the demoralized remnants were evacuated from Novorossisk to the Crimea. Appointing Wrangel as his successor (April), he left Russia to spend the remainder of his life as an *émigré,* first in western Europe, and from 1945 in the United States. He died at Ann Arbor. Mich., on Aug. 8, 1947.

See his memoirs. *Ocherki russkoi smuty,* 5 vol. (1923–27), and *Put russkogo ofitsera* (1953). (J. L. H. K.)

DENIM, a durable fabric used principally for work clothing, the name of which is said to have originated in the French *serge de Nîmes.* Yarn dyed, twill-woven and mill finished, denim is characteristically all cotton, although considerable quantities are of a cotton-nylon mixture. The material is mainly indigo or vat-dyed blue, but some is produced in other colours, as well as in stripes and various patterns. Traditionally used for ranch, farm, work and sea-going attire, denim became an important children's wear item and is used for casual wear for both sexes of all ages. (R. M. ST.)

DENIS (DIONYSIUS or DENYS), **SAINT,** first bishop of Paris and patron saint of France. According to Gregory of Tours' *Historia Francorum,* he was one of seven bishops sent to Gaul to convert the people at the time of the emperor Decius. Little is known of his life except that he became bishop of Paris and later suffered martyrdom. In 626 his relics were translated to the recently founded Benedictine abbey at St. Denis, near Paris. In the 8th century a passage in Gregory of Tours' work was wrongly interpreted as stating that he had been sent to France by Clement of Rome about A.D. 90. In the 9th century, Hilduin, abbot of St. Denis, in his life of Denis further identified him with Dionysius the Areopagite (*q.v.*). According to the legend, after being decapitated at the age of over 100, Denis walked a considerable distance holding his head in his hands. Hence he is generally thus represented in art. He is one of the 14 auxiliary saints, or holy helpers. His feast day is Oct. 9 in the Western, Oct. 3 in the Eastern church.

See H. Thurston and D. Attwater (eds.), ***Butler's Lives*** of ***the*** *Saints,* vol. iv, pp. 67–68 (1956). (H. C. G.)

DENIS, MAURICE (1870–1943), French painter, lithographer, designer and writer on art subjects, one of the leading artists and theoreticians of the Symbolist movement, was born at Granville, on Nov. 25, 1870.

Denis studied at the Académie Julian (1888) under Jules Lefebvre and at the École des Beaux-Arts. Probably the greatest influence in his early development was the work of Gauguin, whose style was also much admired by Denis's fellow students Paul Serusier, Edouard Vuillard, Pierre Bonnard and Ker Xavier Roussel, whom Denis joined in the Symbolist movement and later in the Nabis movement. In 1890 Denis expressed the underlying principle of much modern painting in the following often quoted words: "It should be remembered that a picture—before being a warhorse, a nude or an anecdote of some sort—is essentially a flat surface covered with colours assembled in a certain order." Denis was also influenced by the colour theories of Seurat, and by the works of the great Italian fresco painters of the 14th and 15th centuries. such as Giotto. Fra Angelico and Piero della Francesco, whose paintings he admired during his visits in Italy between 1895 and 1904. Denis's monumental mural decorations are to be seen in

many French churches as well as on the ceiling of the Champs Élysées theatre in Paris. In 1919 he founded the Studios of Sacred Art, along with Georges Devallières. His work was one of the chief forces in the revival of religious art in France.

Denis illustrated numerous books, and created designs for stained-glass windows, wallpaper, tapestries, mosaics, bas-reliefs and statues, and, in addition, published several books and numerous articles on art. He died at Paris on Nov. 13, 1943.

DENIS, (JOHANN NEPOMUK COSMAS) MICHAEL (1729–1800), Austrian poet who used the pseudonym of Sined the Bard and is best remembered for his German translation of *Ossian* in hexameters (1768–69). He was born at Scharding on the Inn, Sept. 27, 1729. Brought up by Jesuits he entered their order. As a bardic poet he was a follower of Klopstock and he published his own poems, with his translation of *Ossian,* as *Ossians und Sineds Lieder* (6 vol., 1791–92). His anthology *Sammlung kurzerer Gedichte aus den neuern Dichtern Deutschlands* (3 vol., 1762–76) introduced North German literature to Austrian readers. Denis died in Vienna, Sept. 29, 1800.

BIBLIOGRAPHY.—A selection of his poetry ed. by R. Hamel was published in vol. 48 of J. Kiirschner's *Deutsche National-literatur* (1884). His *Literarischer Nachlass* was published by J. F. von Retzer in 2 vol. (1801–02). *See* also P. von Hofmann-Wellenhof, *Michael Denis* (1881); *R.* Tombo, *Ossian in Germany* (1901).

DENISON, a city of Texas, U.S.: *see* SHERMAN-DENISON.

DENIZLI (anc. LAODICEA AD LYCUM), chief town of an *il* (province) of the same name in southwestern Turkey. It is picturesquely situated at an altitude of 1,167 ft. at the foot of Baba Dag (Mt. Salbacus), on a tributary of the Çuruksu (Lycus), 115 mi. E.S.E. of Izmir. Pop. (1960) 49,042. Denizli is connected by a branch line with the Goncali station on the Izmir-Dinar railway. It took the place of Laodicea (*q.v.*) after that town had been deserted during the wars between the Byzantines and Seljuk Turks, probably between 1158 and 1174. It had become an important Muslim city in the 14th century, and was then called Ladik, being famous for its woven and embroidered products. The delightful gardens of Denizli earned it the name of the "Damascus of Anatolia."

The *il* of DENIZLI (pop [1960] 425,672; area 4,596 sq.mi.) includes the eastern part of the fertile valley of the Büyükmenderes (Great Maeander) river and the mountainous areas surrounding it. The highest mountains of the *il* are Honaz Dagi (8,435 ft.) and Baba Dag (7,572 ft.). The climate is healthy with dry, warm summers, while the winters are relatively mild and rainy. The chief crops are cotton, cereals, grapes, figs and tobacco. Animal husbandry becomes increasingly important to the east. About 15 mi. N. of Denizli town is the famous Pamukkale (anc. Hierapolis), where limestone travertine deposited by hot springs forms wonderful cascades and basins. (N. TU.; S. ER.; E. Tu.)

DENMAN, THOMAS DENMAN, 1ST BARON (1779–1854), English judge remembered for his knowledge and interpretation of the law of privilege, was born in London on Feb. 23, 1779. The son of the well-known obstetrician Thomas Denman, he was educated at Eton and St. John's college, Cambridge, where he graduated in 1800. In 1806 he was called to the bar at Lincoln's Inn. He first distinguished himself by his eloquent defense in 1816 of the Luddites; but his most brilliant appearance, in 1820, was as one of the counsel for Queen Caroline, for whom he made a great speech before the lords which gained him the enmity of the king and retarded his career. In 1818 he became Whig M.P. for Wareham, Dorset, and from 1820 represented Nottingham until his elevation to the bench in 1832.

In 1830 he was made attorney general under Lord Grey's administration and two years later lord chief justice. In 1834 he was raised to the peerage. As a judge he is most celebrated for his decision in the important privilege case of *Stockdale* v. *Hansard (9* Ad. and El. i), but he was never ranked as a profound lawyer. In 1850 he resigned his chief justiceship. He died at Stoke Albany, Northamptonshire, on Sept. 22, 1854.

See Sir Joseph Arnould, *Memoir of Thomas, First Lord Denman* (1873); *E.* Manson. *Builders of Our Law* (1895; 2nd ed. 1904).

DENMARK (DANMARK), the smallest in area of the three Scandinavian kingdoms, comprises the northern part of the low peninsula of Jutland (Jylland) and two groups of islands. To the east, between the Skagerrak and the Baltic, lies the main archipelago of 482 islands with lonely Bornholm 88 mi. farther east. The second archipelago, that of the rocky Faeroe Islands (*q.v.;* Faeroerne), lies 700 mi. away in the Atlantic on the shortest route to Iceland (united with Denmark until 1941) and thence to Greenland (*q.v.;* 840,000 sq.mi.), a Danish colony until 1953 and since then an integral part of Denmark. Of the total area (17,159 sq mi.) of the kingdom, Jutland covers 11,441 sq.mi., the main archipelago 5,178 sq.mi., and the Faeroe Islands 540 sq.mi. Zealand (Sjaelland), the largest island of Denmark proper, covers 2,710 sq.mi. and is separated from south Sweden (Skaane) by the Sound (Oresund) only 2 mi. wide in its narrowest part. Fyn, the second largest island, is separated from Zealand by the Great Belt (Store Baelt) and from Jutland by the Little Belt (Lille Baelt). Denmark's frontier with Germany extends across the Jutland peninsula from Flensborg fjord (Flensburger förde) to a point between the islands of Romo and Sylt.

This article contains the following sections and subsections:

I. PHYSICAL GEOGRAPHY

1. Geology.— The Danish peninsula and archipelago are largely a product of the Quaternary Ice Age, solid rock being generally masked by thick deposits of glacial drift deposited by ice sheets that advanced south from Norway and Sweden and west from the Baltic. Beneath this mantle lies a basal platform of Cretaceous rocks, mainly chalk, whose saucerlike rim can be traced in an arc extending from the beak of Jutland southeast through the islands

of Laeso and Anholt to east Zealand, Moen, Falster and Lolland. Senonian chalk is exposed at the base of the impressive cliffs (Stevns Klint) in southeast Zealand and again at Mons Klint, while younger Danian limestone is extensively quarried at places such as Bolsdal and Fakse in southeast Zealand. The remainder of the preglacial floor consists of Tertiary sands, marls and clays with some lignite beds in Miocene deposits. In Bornholm the solid rock is markedly different, revealing close affinities with south Sweden. Exposures of Pre-Cambrian granites cover extensive areas in the northern half of the island, being overlaid to the south by Cambrian sandstones and shales with Triassic, Jurassic and Cretaceous deposits in the extreme southwest. Denmark was affected by three glacial periods of which the last (correlating with the Würm) was of paramount importance in determining the present surface features.

2. Physiography. — Although the whole of Denmark is relatively low-lying, a remarkable scenic boundary (A-B on fig. 1) can be traced from Nissum fjord on the west coast of Jutland eastward toward Viborg, thence swinging sharply south down the spine of the peninsula toward Aabenraa and the German city of Flensburg. Two major physiographical regions are distinguishable — the moraine lands and the outwash plains.

The Moraine Lands. — To the north and east of the boundary just described, which represents the maximum extent of Scandinavian and Baltic ice during the last glaciation, both the insular and peninsular areas are covered with a thick mantle of boulder clay giving rise to undulating country of fertile clay loams becoming markedly more sandy westward toward the ice front. This young moraine landscape attains its greatest elevation between Horsens and Silkeborg where lies Denmark's highest point, Yding Skovhoj (568 ft.). The sinuous, eastward-flowing streams, with their broad, flat-floored valleys, enter the Kattegat in long, shallow inlets. Although the latter are called fjords, they cannot be compared in character or origin with those of Norway. Denmark's longest stream, the Gudenaa, rises in east central Jutland and flows 98 mi. to its mouth in Randers fjord. Lakes are numerous in depressions on the hummocky moraine, often giving rise to peat bogs where infilling has occurred.

Z'he *Outwash* Plains. — West of the old ice front the landscape changes dramatically. There, it comprises a series of low plateaus, or "hill-islands" about 50–60 ft., representing morainic remnants dating from the second glacial period. These are wrapped around by extensive, level, outwash plains composed of sands and gravels strewn by the meltwaters that poured west from the shrinking ice sheet. The small, misfit streams with their broad, shallow, steep-sided valleys reach the North sea through a narrow belt of coastal dunes; in places large lagoons have been formed, *e.g.*, Ringkobing and Nissum fjords, Soils on the hill-islands are fairly fertile, though heavily leached, whereas the outwash sands and gravels generally bear hungry, acid soils.

Oscillations of land and sea level in the closing phases of the Pleistocene glaciation have also left their impress on the seaboard landscapes. Following the deposition of marine clays during the Late Glacial submergence associated with the Yoldia sea, land level rose in boreal times and forests of birch: pine and hazel slowly colonized the land. Uplift continued until Zealand was joined to south Sweden, and the Baltic became a fresh-water lake (Ancylus lake j. This was followed by the Littorina submergence (which allowed the sea to flow into the Baltic) when milder Atlantic climatic conditions prevailed and mixed oak forest spread over the land areas during early Neolithic times. The limits of the Littorina submergence are clearly visible today in lines of inland cliffs and raised beaches. The beech, the national tree of Denmark, continued to increase throughout the Bronze Age and occupied extensive areas by the Early Iron Age. The reconstruction of these climatic and vegetational changes owes much to the pollen analysis of the plentiful peat deposits. (See also BALTIC SEA.)

Denmark's coast line is 4,622 mi. long and varies considerably in character. The smooth west coast of the peninsula, a product of tidal deposition as seen clearly in the long spit of Skagen. is remote from the main economic hub of Denmark centred on Copenhagen. Apart from a few small fishing harbours, Esbjerg is the sole important port on this exposed coast and its development dates only from 1860. Esbjerg has the advantage of protection by the island of Fanö, one of a long string of sandy islands extending south to the German border and beyond that to the Netherlands. On the landward side of the islands, coastal reclamation in areas of tidal and fluvial deposition is providing year by year more land for farming. Port facilities in the sheltered Kattegat and Baltic are much better, but in a very cold winter the busy Sound, as well as Great and Little Belt, may be impeded by ice.

3. Climate — Lying on the eastern borders of the North sea, Denmark has a moist climate transitional between the oceanic conditions of western Europe and the continental conditions of central and eastern Europe. Although cool maritime influences generally prevail, especially in west Jutland, cold anticyclonic conditions may spread westward in winter, causing ice to form on the Baltic, whereas in summer continental heat may be experienced. Toward the east temperatures decline in winter and increase in summer. The mean annual temperature is 46° F., the average for January and February being 32° and that for July, the hottest month, 61°. Between October and April western coastal areas in Jutland have frost on about 75 days, but in Zealand this increases to 110. Temperatures down to −13° F. have been recorded in the east. The average annual precipitation of about 24 in. is fairly evenly distributed throughout the year but is heaviest from July to December. Thunderstorms are common in summer, particularly in August, the wettest month. Precipitation is least in February. Mean annual rainfall decreases eastward, the heaviest amount falling in south central Jutland. Snow falls on between 20 and 40 days depending on situation. Winds vary in direction according to the prevailing pressure conditions; thus southwest and west winds are common in January, east winds in April, and west and northwest winds in July. The strong winds of the west coast of Jutland caused dunes to migrate inland until a stabilization policy was introduced in the late 19th century. Similarly, when cultivation began on reclaimed heath land, belts of trees were planted on the outwash plains to shelter fields from the blast.

4. Vegetation and Animal Life. — Pollen analysis of ancient peat deposits reveals that in Neolithic times mixed oak forest covered most of Denmark, both the moraine lands and the outwash plains, with beech increasing from Bronze Age times. Deforestation by herdsmen, cultivators: woodcutters and charcoal burners not only removed great tracts of woodland but on the outwash plains abandoned clearings were colonized by a poor secondary vegetation of heath. So extensive did the latter become that by 1800 heath occupied about 40% of Jutland, especially in the west and north, but vigorous reclamation had reduced this to less than 9% by the 1960s. Reafforestatjon, including the provision of shelter belts, has reintroduced trees, especially conifers, to most Danish parishes (see Forestry, *Mining* und Fisheries, below).

Wild animals and birds are those of central Europe generally, deer, foxes and hares still being numerous while rabbits are largely confined to the island of Fanö. Fresh-water fish and eels flourish in many rivers and lakes, with salmon in west Jutland and around Bornholm. Lim fjord is the centre of a prosperous oyster and mussel fishery. Sea fishing in the North sea, Skagerrak and Kattegat makes an important contribution to the national income and is the principal occupation of the Faeroe Islands. **(HA. T.)**

II. THE PEOPLE

The Danish people belong to the Nordic race but to a less pure strain than that to be found in the more northern parts of Scandinavia. The anthropological finds prove that the modern Danes are descended from the first invaders who came into the country from the south shortly after the last Ice Age. They are mostly tall and strongly built with blond hair, blue or gray eyes and a mesocephalic skull.

The language is Nordic, forming a subdivision of the Germanic group. It is closely related to but iess melodious than Norwegian and Swedish. On account of the frequent stressing of syllables Danish may sound rather guttural. As Denmark, apart from the peninsula of Jutland, consists of nearly 500 islands of varying size, numerous dialects are to be found, but the differences between

them are gradually being lessened. (See DANISH LANGUAGE; for literary history see DANISH LITERATURE.)

The constitution provides for religious freedom. Most of the people belong to the Lutheran Church (Folke Kirken), the established Church of Denmark, which is administered by the ministry of ecclesiastical affairs. The largest non-Lutheran community is the Roman Catholic Church. The religious festivals, Christmas, Easter and Whitsun, are kept according to old traditions, but there is a tendency to abolish old customs, even in the rural districts where they used to be particularly observed.

National costumes are still worn by women in the islands of Fanö and Romo in the southwest of Jutland. The national flag is greatly revered; flagpoles are to be found in most private gardens and there are many official flag days during the year. A special custom is observed on Good Friday when the flag is flown at half-mast. The Danish people have a great sense of humour; the Copenhageners especially excel in ready wit while the humour of the Jutlanders is sterner. Danish wit was an active weapon against the Herrenvolk during the German occupation of Denmark in World War II. The Danes take a keen interest in their food and their cooking is excellent; the Danish "open sandwiches" (*smör*-rebrod) are well known. (E. M. E. B.)

III. HISTORY

The first trustworthy written evidence of a kingdom of Denmark belongs to the early Viking period. Roman knowledge of this remote country was fragmentary and unreliable, and the traditional accounts in *Widsith* and *Beowulf* and by later Scandinavian writers, notably Saxo Grammaticus (*q.v.*), are too mythological and legendary to serve as history. Archaeology and the study of place names, however, provide some information about the earliest settlements.

After the first nomadic hunters, before 10000 B.C., a Stone-Age culture developed which culminated in the megalithic culture c. 2000 B.C. There followed a break so violent as to suggest that the settled agriculturalists were displaced by newcomers, that is by the Separate-Grave people who eventually took possession of central Denmark. Apart from minor later immigrations the country seems to have received its permanent population at this time, though not to have been finally settled. The refined culture of the ruling class in the Bronze Age (c. 1500–400 B.C.) and the poor peasant culture of the earliest Iron Age were developed mainly in the old settlements, but in the centuries around the beginning of the Christian era it seems to have been completely reorganized. The old habitations round the small primitive field systems (dikes) were abandoned for the earliest of existing villages with the characteristic place name endings *inge*, Lose, sted and *um*.

The open-field system with its long ridged strips was probably introduced at the same time or later. The period of the great migrations. the dimmest in Danish history, was one of war and unrest; probably at this time the whole country was conquered by Danish tribes from the east. There are glimpses of a tribal organization associated with local things (arbitrating assemblies), but no trace of comprehensive government. Place names indicate belief in the pagan gods; *e.g.*, Njord and Frey, Tyr and Odin.

1. *Viking Period,* 800–1050.—The northward extension of Charlemagne's empire brought Denmark into close connection with the rest of Europe. The Frankish conquests were halted by the Danish king Godfred or Gudfred (d. 810), and under his successor Hemming (d. 812) a solemn treaty on the Eider in 811 made this river the frontier, which it remained until 1864. Godfred may have ruled over all Denmark, but the centre of gravity was in the extreme south of the Jutland peninsula: there Hedeby, on the Schlei, became an important station on the new Frankish trade route to the Muslim states of the east via the Baltic sea and the Russian rivers. To protect this vital borderland a great rampart, the Dannevirke (Danewerk), was erected, but it failed to prevent temporary Swedish and German conquests. The Danes took an active part in the new trade together with the Frisians. At the same time Danish and other Scandinavian Vikings began the expeditions of plunder and conquest (see VIKING) which resulted in the Viking kingdoms in Friesland, England, France and Russia. After Hemming's death the kingdom was dissolved. Various dynasties contended for power and appealed to the Frankish rulers, who sought to promote Frankish infiltration into Scandinavia by missionaries—notably Ansgar (*q.v.*), "the apostle of the North"—though this was without lasting result.

In the 10th century a new royal line, centred at Jelling (north Jutland), succeeded at last in uniting the kingdom. The name of the kingdom occurs for the first time on Danish soil in runic inscriptions on the Jelling stones. The self-glorifying phrase "Denmark's salvation" (Danmarks bod) used of himself by King Gorm may refer to the reconquest of the Hedeby region; his son Harald Bluetooth (Harald Blaatand) boasted of completing the country's unification, converting the Danes to Christianity and conquering Norway.

After Harald's baptism (c. 960) his father's pagan tomb was transformed into a Christian place of worship with a church between two great mounds, and the newly appointed Jutland bishops, under the archbishop of Hamburg, organized the country's conversion. The expansion begun by Harald in Norway was continued by his son Sweyn I (*q.v.*; d. 1014). who conquered England in 1013. Under Sweyn's son Canute (*q.v.*) there grew up a great Anglo-Scandinavian kingdom that included parts of Sweden.

Numerous runic inscriptions show that. over the broad peasant population, there was a class of warlike chieftains (thegner and drenge), of great wealth and power; the circular encampments of Trelleborg, Aggersborg and Fyrkat (excavated from 1934), astonishing in size and mathematical construction, testify to a technically advanced and highly organized society. (See also SCANDINAVIAN CNILIZATION.)

2. ***Kingdom of the Valdemars,*** 1050–1241.—Shortly after the death of Canute (1035) his great kingdom was dissolved. Denmark again became a purely Scandinavian power, for a time under Norwegian rule, until Canute's nephew Sweyn II (*q.v.*) founded a new Danish kingdom on western European lines and in close association with the Roman Church. He was succeeded by his five sons in turn (1074–1134), several of whom accepted a weak form of monarchy and worked in sympathy with the aristocracy; others, opposing the aristocracy but in close association with the church, sought to create a powerful and centralized monarchy. The church, nhich for a period had been under strong Anglo-Saxon influence, now passed once more under the leadership of Hamburg. In the end it became (c. 1104) a separate national church with an archbishopric at Lund in Skaane. Canon law made slow progress and never became absolute in Danish ecclesiastical law, but kings and nobles and villagers vied with each other in building Romanesque stone churches in nearly every parish, some of them new ones and some replacements of wooden buildings.

The reigns of Sweyn's sons were followed by disintegration and internal strife among their many heirs. For a time the country was split up into minor kingdoms. weak kings took their land in fief from the Holy Roman emperor, and the new Scandinavian church was reverting to the primacy of Hamburg. But unity and independence were restored, first in the church under Archbishop Eskil, a great founder of monasteries and persistent champion of Gregorian ideas of reform. and later (1157) in the nation, when Valdemar I (*q.v.*) had defeated his rivals. In close association with Absalon (*q.v.*; bishop of Roskilde, 1158), who was inspired by French monarchical ideas, King Valdemar built up a powerful monarchy. Archbishop Eskil, seeing a threat to the church's freedom, went into exile; but later, after an agreement with the king, he inaugurated in a double celebration at Ringsted in 1170 the theocratic and hereditary monarchy of the Valdemars. canonizing the king's father, the duke Canute Lavard, and crowning and anointing the king's young son Canute. In 1177, Eskil yielded the archbishopric to Absalon. Regardless of the oath of fealty to the emperor the country's military power was reorganized and in rivalry with the Germans the Danes began, after their conquest of Rügen (1169), to dominate the Slav countries of the Baltic.

After Valdemar's death (1182) Absalon rejected by force of arms the German demand for supremacy and consolidated the monarchy internally and externally. Under Valdemar II (1202–41) Baltic expansion gained impetus, and in 1214 the emperor ac-

knowledged Danish suzerainty over the German-Slav lands north of the Elbe and the Elde. Estonia was conquered in 1219. Thus culminated Danish dominion of the Baltic: soon after, the king having been taken prisoner by one of his German vassals. it collapsed. An attempt at reconquest of the German Baltic lands failed when the Danish army that had invaded Holstein was defeated at Bornhoved in 1227. Only Riigen and Estonia were left.

The successful establishment of a great Danish kingdom was due in part to German weakness, in part, however, to internal reasons. A rapid growth in population since the Viking period had led to intensive settlement within Denmark itself; new villages and towns had grown up and rising exports of agricultural goods and herring from Skaane gave increased prosperity. The Valdemars gained the allegiance of the clergy and of the class of the powerful landed lords (herremaend) that had arisen by a fusion of the king's retainers (*hird*) with the old nobility. From this were recruited the court officials who, together with the greatly expanded chancellery, were responsible for the central government, and the local officials (ombudsmaend), who also administered the royal demesnes. The landed nobility formed a new and better-equipped regular army, which increasingly took the place of the old peasant levies (leding). In return, the people's military obligations and services for maintaining the king were converted into fixed property taxes. Intellectual life flourished through a clergy educated at French and Italian schools. Denmark was drawing abreast of the civilized nations of Europe.

3. **Dissolution and Consolidation, 1241–1375.**—The policy of conquest had overstrained the country's resources, and when the population ceased to grow the resources were lacking to colonize what had been conquered. The breakdown of the expansionist policy was therefore inevitable. Moreover the powerful monarchy had sown the seed of internal disruption and national dismemberment. Valdemar II had distributed large areas of the royal patrimony as feudal appanages to his younger and illegitimate sons, and the extensive privileges which the autocratic monarchy had paid for the loyal support of the clerical and lay nobility had created a huge aristocracy that soon became a danger to the throne. Valdemar's eldest son, Eric IV Plovpenning (Ploughpenny), crowned as co-regent in 1232 and king from 1241, was soon in dispute with the church and with his brothers about royal prerogatives. His brother, Duke Abel of Schleswig, proclaimed himself king and had Eric murdered (1250). He was then elected king, but when he fell fighting against rebel Frisians (1252) his sons were passed over and his brother was elected as Christopher I. Thus not only was the hereditary principle broken, but the older Abel line, which continued to hold the duchy of Schleswig (Slesvig), became a permanent source of unrest and, by its close association with Holstein, began the germanization of Schleswig. In Denmark itself a number of prelates, notably the archbishops Jacob Erlandsen and Jens Grand, persisted in the church's struggle against the crown. In this nationally destructive contest the king held the upper hand. He had been forced, however, to accede to the constitutional demands of the aristocracy. In the 1250s an aristocratic national assembly (Lat. *parlamentum,* Dan. hof) was formed, which imposed legal limits to the arbitrary rule of the monarchy. After a long constitutional struggle in which the king turned for support to a narrow privy council and to some extent to German princes and mercenaries, Eric V Glipping (*q.v.;* 1259–86) was forced to yield. The first charter (haandfaestning) of 1282 legalized the assembly's authority and limited the king's powers; during the next few years the nobles carried out a policy of radical reforms and reorganization. When Eric V was murdered in mysterious circumstances, the royalists seized the opportunity to regain control and had the leaders of the reform party convicted of the murder and exiled.

Eric VI Menved (*q.v.;* 1286–1319) tried to restore the power of the throne and revive expansion into German territories. Government finances broke down, and the kingdom began to disintegrate, especially when large territories were mortgaged to raise capital.

At subsequent royal elections the discontented nobles tried to control the monarchy by strict charters; but the result was more mortgages and increasing disintegration. From the death of Eric VI's brother Christopher II (1332) to 1340 the country was without a king. Holsteiner counts ruled over and impoverished Jutland and the islands as mortgagees. while Skaane subjected itself to the Swedish king. From 1241 the tendency had been for officials and nobles to separate themselves from government control while many free peasants abandoned their property rights to seek protection from the strong, which seemed to them more effective than the weak legal safeguards afforded by the monarchy.

Through the mediation of German princes and Hanseatic towns Valdemar IV (*q.v.;* 1340–75) reached a settlement with the Holsteiner mortgagees and obtained recognition as king. He gradually reunited the country, by redemption or by force of arms, and reconquered Skaane in 1360. Laying great stress on national unity and fellowship, he built up a strong central authority. He established a national army in which burghers and peasants gained a place beside the nobles. However, his military power rested chiefly on a chain of castles; under strict supervision, their wardens (lensmaend) became the leaders of local administration. The crown's finances were firmly restored: the old land taxes were given a fixed money value, and new taxes and labour services mere levied; meanwhile the nucleus formed by the royal demesnes was continually increased. as a royal court of law (retterting) awarded to the crown all lands lost during the period of dissolution. A national assembly at Kalundborg in 1360 closed with a "national peace," a two-sided, legally inspired contract fixing the king's and the people's rights and duties. The reorganization of the kingdom made great demands on all classes, especially since it was carried out at a time of agrarian crises with falling prices, derelict farms and abandoned villages. Discontent smoldered, particularly among the formerly independent nobles, who rebelled repeatedly. A rash assault on Visby in 1361 led to a dangerous coalition of the great Hanseatic league, Sweden, the Holsteiners and the Jutland nobles. Pressed on all sides, the king left the country; the privy council then assumed control and, in 1370, concluded the peace of Stralsund, which granted the Hanseatic towns great commercial privileges but left the kingdom intact. Reluctantly Valdemar acquiesced in the treaty as a condition of his return to the throne.

4. Scandinavian Union, 1375–1523.—The male line of the dynasty having died out with Valdemar IV, the privy council took control and elected as king Olaf (1375–87), the young son of Valdemar's daughter Margaret by her marriage with King Haakon VI of Norway and heir also to the succession of Sweden (where Albert of Mecklenburg, Haakon VI's cousin, was at that time reigning). The power of the throne was limited by charter; but the real ruler was Margaret who, when first her husband and then her son died, was acknowledged in 1387 as sovereign by Denmark and Norway. With wisdom and moderation she gained control over the privy council (which had taken over the authority of the *parlamentum*) and ruled with the aid of private court officials. She kept a close watch over the conduct of her stewards and zealously carried out the legal restitution of the lost demesnes.

Called in by discontented Swedish nobles, Margaret expelled the Mecklenburgers from Sweden in 1389 and thus became the actual ruler of all Scandinavia (see MARGARET, queen of Denmark, Norway and Sweden). Everywhere she enforced allegiance to her elder sister's grandson, Eric, duke of Pomerania, who was crowned king of all three countries in a solemn joint act at Kalmar in 1397. At this assembly, attempts were made to set up a more permanent connection between the several countries, but as there was disagreement over the question whether the government of the union should be aristocratic and constitutional or strictly monarchical the meeting seems to have ended without result. The famous charter of the union of Kalmar was probably never adopted; the aristocratic constitution at least never became effective. The monarchy remained powerful and was strengthened after Margaret's death in 1412. Being childless, Eric of Pomerania (Eric VII of Denmark) arranged for a Pomeranian cousin to be designated his successor and gained acceptance of the principle that the royal castles after his death should pass to his successor directly, not via the privy council. In foreign policy Eric evidently planned to create a great Baltic state of the Scandinavian kingdoms and Pomerania, but despite the best intentions he lacked the ability to accomplish even

limited tasks within Denmark. He wanted to recover for the crown the duchy of Schleswig, which after the expiry of the male line of the Abel dynasty had in 1386 been enfeoffed to the counts of Holstein; and he sought to weaken the commercial power of the Hanseatic league by such means as encouraging a Danish urban middle class—a policy that found expression in his edict of 1422, which reserved trades and crafts for Danish citizens. This caused the Hanseatic league to ally itself with the Holsteiners and, although the Danish navy defeated the league repeatedly in the Sound (where from c. 1429 Denmark exacted tolls), Denmark was inferior on land. The burdens of war converted Swedish discontent with royal rule into open revolt, and the Danish privy council enforced a tolerable peace with the Hanseatic league and the Holsteiners in 1435 in order to apply every energy to perpetuating the union. But at a meeting at Kalmar in 1436 the Danish councilors deserted the king's union policy and supported the constitutional program of the Swedish nobles, disavowing the Pomeranian succession; the result was an open breach. Eric withdrew to Gotland. and the nobles established a federative union in 1438. In 1439 Eric was also deposed in Denmark in favour of his sister's son, Christopher of Bavaria.

During Christopher III's brief reign (1439–48) the privy council predominated and the three Scandinavian countries remained united. After his death the union was dissolved. The Swedes elected the former regent, Karl Knutsson, king as Charles VIII; Denmark and later Norway took a descendant of the royal house, Count Christian of Oldenburg, founder of the Oldenburg dynasty (1448–1863) who became king as Christian I (d. 1481). Thereafter it was only for brief periods that the Oldenburgs reigned even nominally over Sweden. Christian I was more successful in his policy toward Schleswig: when the ducal line died out (1459) he managed—despite his confirmation in 1448 of the provision in the Constitutio *Waldemariana* of 1326 that Schleswig and Denmark must not be united under the same ruler—to become both duke of Schleswig and count of Holstein. He had himself elected, in 1460, by the combined Schleswig-Holstein knighthood, but only on severe economic terms and on condition that the two lands remain "for ever undivided."

5. The 15th-Century State.—In the 15th century the dualism that was to characterize Danish politics for two centuries mas already clearly discernible. The rigsraad, comprising the country's 7 bishops and about 20 noble landowners whom the king chose from the leading families, possessed in theory the highest constitutional powers. It elected the king, who from 1481 had to sign a pre-election charter drawn up by its members, embodying the constitution of the country and asserting that the king should conduct no important state affairs without its sanction. Yet, except by open revolt, the rigsraad possessed in reality only limited means of compelling the king, once elected, to observe the rules laid down in this charter; and further, the king and his chancery naturally retained control of the day-to-day administration of the country. Only in matters of local government was the king virtually obliged to make use of the nobles, who, insisting on their right to be appointed lords-lieutenant, were in charge of the local administration in the 200 *herreder* (hundreds) of the provinces which were governed from the king's castles.

The people now became divided more sharply into estates. Denmark's principal industry, then as at all times, was agriculture; the cultivated soil, apart from about 1,000 manorial estates, consisted of about 80,000 farms, clustered together in groups of 5–20 as villages. Each of these villages was administered by the peasant farmers in common, whether these owned their farms themselves or were tenants paying a yearly rent (landgilde). In the year 1500 there were about 12,000 Danish peasants who owned farms, about 18,000 faestebonder or leasehold tenants of crown lands, and about 30,000 leasehold tenants of the church estates or of the estates belonging to the nobles. These last were numerous, because such properties were free from the old land taxes due to the state. In one or two respects, however, this tax exemption had other results. Thus the leasehold tenant on a manorial estate was liable to certain terms of forced labour and feudal duties, and when, as a result of the agrarian crisis in the 14th century, many leasehold farms became vacant, a law was introduced by the lords of the manor, especially in Sjaelland, that the next heir to any leasehold tenant must take over his farm. This was in fact a form of serfdom which meant that a farmer's sons who had become artisans or tradesmen in a to n could be forced to abandon their occupations in order to continue the cultivation of their father's farm.

The Danish Church at this period, with its 7 bishoprics and more than 70 monasteries, was immensely rich. It derived a huge income from its estates and leasehold farms, which were exempt from the old land taxes and on which extraordinary taxes could be levied only with its consent. It drew still greater revenues from the tithes on the entire grain production of the country. one-third of such tithes going to the bishops, one-third to the parish churches and one-third to the parish priests. The pope, since the Council of Basel. had assumed the right to make all ecclesiastical appointments in Denmark, though he allowed certain nominations by the king. The Danish nobles, however, tried to reserve ecclesiastical appointments for their younger sons, who were too poor to buy estates, and in 1523 King Frederick issued a decree that to become a bishop a man must be a Danish noble; for an important prelacy he must be either a noble or else a doctor of theology. This was one cause of the decline of religion in Denmark during the 15th century: people turned away from a church most of whose leaders did little but enjoy the material rewards of their high offices. Still, with the setting up of a university and school of theology in Copenhagen in 1479, a more serious study of the principles of Christianity began. Paul Helgesen, who became *lektor* in 1519, vigorously attacked the malpractices in the church, especially in the matter of the sale of indulgences; but Martin Luther's break with Rome in 1521 changed Helgesen into one of the last great champions of the Catholic Church in Denmark.

The 15th century marks a turning point in the history of the Danish nobility. Until then any Dane could become a noble by presenting himself, in time of war, well-equipped for military service at his own expense. In return for this he was exempted from all taxes on his entire estate. But from the 15th century the nobility became an estate apart: to belong to it a man had to show that his forefathers had enjoyed tax exemption for at least three generations.

The nobles thus stopped new families from entering their ranks. The king sought to assume the right to issue titles of nobility, but despite this the Danish nobility in the 15th century developed the characteristics of a caste. From 264 families known during the years 1400–50, the number sank from 230 families in 1500 to 140 (including at most 3.000 persons) in 1650. Of the noble families in the 15th century the Gyldenstjerne and the Rosenkrans (whose names are commemorated in Shakespeare's Hamlet) were among the most important.

The Danish landowning nobility of the 15th century acquired estates in great numbers, were capable agriculturists and witnessed Denmark's increased exports of farm produce. The country had a long-standing market for its horses; now stall-fed bullocks were added and the landowners had to find sales not only for their own produce but also for that levied by them as rent from their leasehold tenants. In this way the estate owners, lay and clerical, also became merchants, many of them having their own ships.

(A. E. CN.)

6. The First Oldenburgs and the Estates.—The three first Oldenburgs, Christian I (reigned 1448–81), John (Hans; 1481–1513) and Christian II (1513–23), tried to foster the economies of the Danish towns while curbing the direct trade of German Hanseatic merchants with the peasants. By the 1422 ordinance of Eric of Pomerania, reissued and extended in 1475, the peasants had to sell their produce in the towns and make their purchases there, while the Hanse merchants were confined to trading with burghers. Hanseatic merchants and other foreign traders therefore settled permanently in Danish towns. The Danish nobility and prelates now had their medieval trading rights restricted to agricultural produce and household goods. The king favoured the towns partly to counterbalance the power of the nobility. The bishops in the rigsraad, with few exceptions, were clerics of noble

parentage, and the council acted in unison even though its lay members were nominated by the king. Christian I and John tried to balance the *rigsraad's* power by calling in an assembly of estates. John also employed commoners in the central administration and as bailiffs on the royal manors. This irked the leading nobles, who had derived much of their income as administrators of royal demesnes held in farm. The king's income from these had become negligible: to pay for the royal household he had to rely on the royal manors and the income from customs such as the Sound tolls. Occasionally the *rigsraad* or an assembly of estates grudgingly voted taxes — usually to support the king's wars with the Hanseatic league or with Sweden. Christian II, the son of John, was early known to share his father's views. As regent in Norway he had shown his taste for democracy, so that the majority in the *rigsraad,* distrusting him, tried to safeguard themselves by a stringent charter which Christian was forced to issue before his accession in 1513. In it he conceded all the traditional privileges of the nobility and recognized the constitutional power of the *rigsraad.* However, he soon broke these terms, especially after 1517. Although not completely disregarding the *rigsraad,* he used commoners as his advisers, giving them the rank of councilors. The two most prominent were Hans Mikkelsen, the burgomaster of Malmö, and Sigbrit Villoms, the wife of a Dutch burgher. Her daughter Dyveke had become Christian's mistress during his stay in Norway. and the king brought Sigbrit and Dyveke to Denmark in 1513. Dyveke's death in 1517 left her mother's influence over the king unimpaired, and during the later years of Christian's reign she virtually controlled Danish finances. Her power provoked much hatred and ill-feeling. The influence of both Sigbrit and Mikkelsen shows in the reformed legal codes, *Lundloven* and *Byloven.* These two codes presupposed increasing central control and inspection and therefore remained at best a program of reform adding to the widespread discontent, as also did the desperate means (including debasement of the coinage) used to meet the heavy costs of the Hanseatic wars and revolts in Sweden (reconquered in 1520 and finally independent in 1523). Members of the Jutish nobility, who had suffered from Christian's drastic changes in local administration and feared worse, turned to Christian's paternal uncle, Frederick, duke of Schleswig and Holstein, and offered to support his claim to the throne. When he accepted they renounced their allegiance to Christian. In April 1523 Christian left Denmark with his queen (sister to the emperor Charles V), Sigbrit and Hans Mikkelsen. From his exile in the Netherlands he made several attempts to reconquer Denmark and Norway, but these ended in disaster in 1531 when an attempted invasion of w a y failed. In the spring of 1532 Christian II signed a truce and sailed to Copenhagen on a Danish ship. Though he was not a prisoner the Danes, fearing new troubles if he returned into exile, confined him first at Sonderborg castle and later at Kalundborg castle. (*See* also CHRISTIAN II.)

7. Frederick I, 1523–33. — The charter which Frederick I issued before his accession was no less rigorous than that agreed to by Christian II. The privileges of the nobility were enlarged and their freedom to trade specifically mentioned. Frederick I adhered to the charter hut under protest. He refused to settle in Denmark, claiming that his Danish revenues were inadequate, and stayed mostly at the castle of Gottorp. From 1525, when he visited Denmark, it became evident that Frederick adhered to Lutheranism, as did prominent members of the *rigsruad.* With the king's sanction the Franciscans were expelled from their houses, while Lutheran preachers received freedom to preach in several towns.

8. Civil War and the Lutheran Reformation. — After the death of Frederick I in April 1533 the Catholic and conservative majority of the *rigsraad* once more triumphed. They postponed the election of a new king, fearing that the obvious candidate Prince Christian (later King Christian III; *q.v.*), if elected, would immediately introduce Lutheranism. Unsuccessfully they tried to sponsor his younger brother Hans. In the civil war that followed (1534–36), the burgomasters of Malmö and Copenhagen accepted an offer of help from the democratic burgomaster of Liibeck. The Liibeckers, on the pretext of restoring Christian II, hoped to regain their mercantile supremacy and control of the Sound. The landing of Lubeck. troops in Sjaelland in the early summer of 1534 roused the Jutish nobility. Now even the Catholic bishops rallied to support Prince Christian. Count Christopher of Oldenburg was leader of the forces of Liibeck, while Christian's general was the Holstein noble Johan Rantzau, who was also a Lutheran. Rantzau subdued a revolt of the Jutish peasants and then won the rest of Denmark for Christian. The civil war ended with the surrender of Copenhagen in the summer of 1536. Shortly thereafter, the Catholic bishops were put into custody and their property confiscated; the monasteries were dissolved and vast estates came to the crown. In Oct. 1536 the estates sanctioned a Danish Lutheran Church. The year 1537 saw the appointment of new bishops, several of them former Lutheran preachers and all of burgher descent. They could not, however. claim political influence, as bishops no longer sat in the *rigsraad.* The church organization was finally established in 1539. The purged *rigsraad* which emerged after 1536 was soon able to assert itself. The charter which Christian III issued differed only slightly from former charters on the subject of the privileges of the nobility and the constitutional power of the *rigsmad.* The king's attempt to make the throne hereditary did not quite succeed. The *rigsraad* named Prince Frederick as the successor of his father and the king's charter provided that a Danish prince should always be elected, but this was omitted in Frederick II's charter in 1559. The *rigsraad* thus suffered no permanent loss of elective power.

9. Reorganization, Stability and Prosperity. — During the first years of Christian III's reign the Holstein nobility exercised a powerful influence. Denmark was impoverished; the situation improved only when the chancellor Johan Friis (*q.v.*) arranged a settlement and division of the war debts and the nobility offered substantial loans. From 1539 Christian took up residence in Denmark. In 1534 Schleswig and Holstein were equally divided between Christian and two of his younger brothers. By several statutes and with the assent of the *rigsraad* much of the reform program sketched in Christian II's two laws was given new life. Johan Friis likewise modernized the central and local administration, in which the younger members of the nobility became increasingly important. The most able began in the chancery or obtained responsible posts in the local administration, usually ending their careers with royal nomination to the *rigsraad.* The exchequer, too, came to be partly staffed by chancery clerks Not until 1660 did commoners again hold responsible government posts. As Christian's coronation charter required sanction by the *rigsraad* for any ne ennoblement it maintained the castelike nature of the nobility. The few exceptions had no political significance. Some of the king's German favourites or councilors serving in the *Tyske Kancelli* (German Chancery) and the diplomatic service were admitted to the full privileges of the Danish nobility, but they usually belonged to the nobility of .their home country.

During the second half of the 16th century the nobles had considerable wealth. The price revolution in the century showed a steeper rise in food prices, which favoured Denmark, whose chief exports were grain and livestock. The nobility reaped most of the benefit. Living was easy and luxuries became everyday habits. The astronomer Tycho Brahe (*q.v.*) illustrates the high standing of the nobility. The royal justiciar Arild Huitfeldt wrote the comprehensive chronicle *Danmarks Riges Krönicke.* Enterprising burghers developed a remunerative export and import business. The nobility gave up trade with German merchants and entrusted their affairs to Danes, who also succeeded in becoming providers to the court. It seems that the peasants during the 16th century did not fare too badly either. Nearly all of them were copyholders but by statute it was forbidden to raise their rent. During the later decades of the century few taxes were imposed. Cattle raising must have given the farmer a reasonable surplus.

10. The First Swedish Wars. — Christian III tried to avoid war but in 1542 was forced into conflict with the emperor Charles V who supported his nieces in their claims on the Danish throne. A lasting peace was, however, achieved by the*treaty of Speyer (1544). Under Christian III of Denmark and Gustavus I Vasa of Sweden the two Scandinavian kingdoms remained at peace.

With the accession, however, of the young warrior kings, Frederick II of Denmark (1559) and Eric XIV of Sweden (1560), war became inevitable. The Seven Years' War of the North (1563–70) sprang mainly from their rivalries, though the Baltic provinces were also at issue. The Danish crown still had many outlying possessions both in the Baltic (Gotland) and in the North sea and the Atlantic (Norway, the Faeroe Islands, Iceland). Moreover, Skaane was still a Danish province. Denmark thus controlled the entrance to the Baltic and so could claim *dominium maris* Baltici (dominion of the Baltic sea). The Danes soon raised similar claims for the waters surrounding their other possessions, but with less success. The war with Sweden produced only financial exhaustion, though a new Sound toll (lastetold), originally imposed during the war, gave the king an additional source of income. After 1570 Frederick concentrated on maintaining peace and building castles; above all, Kronborg castle at Elsinore. Peace lasted during the minority (1588–96) of Frederick's son and successor Christian IV (*q.v.*). Not until 1611, when Christian threatened to declare war as duke of Holstein, was the rigsraad compelled to sanction plans for war against Sweden. In the Kalmar War which followed (1611–13) the Swedish army consisted of trained peasant soldiers, whereas the Danes had mostly to rely on mercenaries. Nevertheless since Gustavus II Adolphus was engaged elsewhere, the Danes were able to seize and hold Elfsborg (Älvsborg) against the payment of ransom.

11. Christian **IV's** Achievements.— After this fruitless war Christian IV concentrated on the economic development of his kingdoms, especially the towns. Copenhagen prospered; he adorned it with buildings and erected an exchange. However, his attempt to organize a textile industry failed, and his trading companies did not survive his reign. His outlay on the fleet was more effective. The royal shipyards were enlarged and a protective harbour built at Copenhagen. Christian founded new towns both for economic and defense purposes. Gliickstadt in Holstein was planned as a rival to Hamburg, and a chain of fortresses was begun on the Swedish frontier, though Christian had no desire to resume war with Sweden. He built two royal palaces: the magnificent Frederiksborg at Hillerod and the small castle of Rosenborg at Copenhagen.

12. Decline and **Wars.**—From 1620 it became obvious that Christian aspired to meddle in international politics. He had his younger sons chosen as coadjutors in secularized bishoprics in northwestern Germany. Soon he was involved, and not unwillingly, in the Thirty Years' War (*q.v.*). The Protestant cause in northern Germany was endangered. While Gustavus II Adolphus of Sweden had rejected the English subsidies for his intervention as insufficient, Christian accepted and began operations in 1625. His adversaries were experienced and famous generals. His defeat was complete. During the following years Jutland was invaded and plundered. Christian's humiliation was the greater as a fairly favourable peace treaty was partly due to the intervention and support of Gustavus. Christian had to abandon the German bishoprics and to renounce further intervention in the German war. Gustavus Adolphus continued the war, nor did his premature death in 1632 stop Swedish operations in Germany. Christian, however, thought he could now act as mediator. He tried to strengthen the army and increased his income by raising the Sound tolls, but his policies made him generally distrusted. In 1643 the Swedes invaded Jutland; the Danes were again defeated. By the treaty of Christianopel (1645) Denmark ceded Jamtland and Harjedalen (Norway), Halland (Denmark) and the islands of Gotland and Ösel to Sweden. The rigsraad held Christian responsible, but he relied on his sons-in-law for support. When he died in 1648 the *rigsraad* forced on his son and successor Frederick III a charter binding him to co-operate in all matters of state and to seek approval when nominating new members. But as prices for agricultural produce slackened, Denmark suffered an economic decline, while the government, now somewhat outmoded, found its task increasingly difficult. Many nobles had become indebted to the merchants, who were however not entitled to acquire landed property in payment. In 1657 when Charles X of Sweden was at war with Poland, Frederick felt he might regain the lost provinces. But Denmark was ill-prepared and Charles X roundly defeated the Danes by a lightning attack from the south of Jutland. The severe winter had frozen the Danish Belts, permitting Charles to march his troops across against Sjaelland. In Jan. 1658 he prepared a siege of Copenhagen Ensuing negotiations led to the peace of Roskilde in Feb. 1658. Denmark ceded the Skaane provinces, the island of Bornholm, and Trondheim and Bohus in Norway.

Soon Charles wished that he had completely conquered Denmark. He resumed war, but now Frederick (aided by the Dutch who were opposed to Swedish control of both sides of the Sound) and the population of Copenhagen were determined not to yield. In Feb. 1659 a Swedish attack on Copenhagen's fortifications was repelled. Trondheim was reconquered and the inhabitants of Bornholm shook off Swedish rule. Early in 1660 Charles suddenly died, and the Swedes had to end the war. The treaty of Copenhagen (May 1660) confirmed that of Roskilde in several points, but Trondheim and the island of Bornholm were regained.

13. Constitutional Revolution of 1660.—The estates met in Copenhagen in Sept. 1660. Heavy debts contracted during the wars required immediate measures, and an excise duty was proposed. The nobility was for the most part unwilling to forgo its exemption from taxes. But the clergy, headed by bishop Hans Svane, and the townsmen, led by the burgomaster of Copenhagen Hans Nansen, jointly forced the *rigsraad* and nobility to relinquish their fiscal privilege and to negotiate with the king for a change in the constitution. Svane and Nansen, acting for their estates, offered to confer hereditary succession on Frederick III and his descendants. The rigsraad ultimately yielded under pressure on Oct. 13. when all three estates made the same offer to the king. Frederick was absolved from his coronation charter and on Oct. 18 was acclaimed as hereditary sovereign. In Jan. 1661 the government sent out an instrument or pragmatic sanction, to be signed by all the more prominent citizens, landowners, bishops, professors, magistrates, etc.; by this the king conferred on himself not merely the succession but also absolute power.

The constitution which Frederick had promised was signed on Nov. 14, 1665. The King's law or *Kongeloven* made the Danish sovereign absolute; it charged him with keeping the kingdom undivided and maintaining the Christian religion in accordance with the Confession of Augsburg and settled the succession on Frederick's heirs. An absolute monarchy was essential to deprive the nobility of its political power. Henceforth distinctions of rank were minimized: all citizens, the peasants excepted, were to be on a level under the absolute rule of the king.

14. Absolutism and Reorganization.— The central administration, not divided into departments as in other European states, had now to be completely overhauled. The chancery continued to be the most important department of state dealing with home affairs, but burghers were now able to serve as much as aristocrats. Alongside the admiralty, a new war office was created. The exchequer was reorganized. For a short while the noble Hannibal Sehested (*q.v.*) was lord high treasurer (rigesskatmester), but the aristocracy soon lost its lead; the burghers came to the fore, as did representatives of the Holstein aristocracy and Germans of varied descent. All these departments of state, as well as the department for foreign affairs and the Schleswig-Holstein duchies and the supreme court, were organized as administrative boards (kollegieordningen). Proposals from the several boards were debated in the king's presence by the privy council, whose members, selected chiefly from the heads of the boards, were nominated by the king. In the local administration civil servants or former members of the royal household were now appointed as *amtmaend,* acting as the king's representatives in the provinces, but they no longer administered the rapidly declining royal estates. The greater part was sold to the creditors of the state. Landed property thus passed into burgher hands. Often the new owners found their land a burden, as grain prices were falling and livestock became less profitable. Under the outdated agricultural system the peasants were worse off than ever. not to mention the increasing pressure of taxation. The towns fared better, especially Copenhagen. With government support new trading com-

panies were launched, while the Asiatic company, founded under Christian IV, was revived. The carrying trade prospered during the European wars.

The most brilliant figure of the new bureaucracy was Peder Schumacher, later Count Griffenfeld (*q.v.*). A member of a rich and respected Copenhagen family, he became librarian to Frederick III. The king died in 1670, and in the first years of Christian V's reign Schumacher's rise was rapid In 1674 he became *rigskansler,* having been created a count and a knight of the Elephant. However, his independent line on foreign policy, his distaste for Christian's ambitions to reconquer Skaane and the enmity of rivals led to his fall in March 1676. The so-called Skaane War (1675–79) failed to win back the lost provinces. For the following 20 years peace reigned. In 1683 a joint code of laws for the whole kingdom was issued. Christian *V's* Danske Lov. This and subsequent legislation showed that in spite of poverty Denmark was developing on the lines of the more advanced European states.

(As. F.)

15. Frederick **IV's** Wars and **Holstein-Gottorp.**—Twenty years after the failure of Christian V's Skaane War, his successor Frederick IV (1699–1730) decided to resume the struggle against Sweden. In 1700 and from 1709 to 1720. Denmark participated in the Great Northern War, which entailed terrible sacrifices. Though Skaane was not recovered, Frederick's victories over Sweden's allies, the dukes of Holstein-Gottorp, enabled him to annex the ducal part of Schleswig to the royal part

The resentment of the house of Holstein-Gottorp was to threaten Frederick's successors for the next 50 years, especially after the adoption of Peter of Holstein-Gottorp by the Russian empress Elizabeth (1741) and the election of Adolphus Frederick as heir to the Swedish throne (1743). On Peter's accession to the Russian throne as Peter III (1762), war seemed inevitable and Denmark had to arm, but the tension was diminished after his assassination. when his consort took his place as Catherine II. Denmark's foreign policy, controlled since 1751 by J. H. E. Bernstorff (*q.v.*), now took on the new aim of inducing the empress to exchange the Gottorp portion of Holstein for Oldenburg (which Griffenfeld had assured to Denmark by a treaty of 1671). This aim was achieved in 1773; the Danish king once again held both dukedoms, Schleswig as a Danish and Holstein as a German fief.

16. The 18th-Century State.—Taxation lay heavy on the people. Danish agriculture long remained stagnant. Grain, the chief export to Norway, fell in price during 1720–40, though it began to recover by 1750. Trade in bullocks to the Netherlands declined when the Dutch imposed a heavy duty in 1718; the North German market took some of these exports instead. Cattle plague inflicted great losses after 1745. To pay for the war with Sweden, the crown, after 1660, had to sell much of its property. Gifts from the king to ministers and favourites, and continual sales steadily raised the landowner's share of the soil. In order to collect taxes from the peasants the crown had to make the landowners responsible for levies due from their leasehold tenants. In return the owners were granted exemption for their principal estates; thus privilege was restored, though on a new basis of law. This applied also to the new nobility of counts and barons who acquired all the rights formerly enjoyed by the old Danish nobility, including the right to leave their estates in entail to the eldest son, though as a fief which on extinction of the direct line should revert to the crown. The harder the times the more the crown had to accede to the landowners' demands for the right to compel occupation of their leasehold estates and obtain free labour from their tenants. One of the first acts of Christian VI (1730-36) had been the abolition of the national militia, but in 1733 it was reintroduced, in combination with the so-called stavnsbaand, which provided that all Danish farmers' sons from their 14th to their 36th year should be bound as villeins to the estates on which they were born. In 1746 it was further decreed that even soldiers who had served their time were bound to return to the same estate and to take up tenant farms. As grain prices began to rise about 1750, landowners, bent on greater production. extorted more work from their tenants, either by force or by contracts often open to abuse.

The mid-18th century, however, brought economic advance when, mainly through French enterprise, colonial goods from the West Indies (especially sugar, coffee and tobacco) began to find a European market. Denmark acquired three West Indian islands, of which the most important were St. Croix and St. Thomas. The eastern Asiatic trade also began to flourish under the leadership of England. Danish trade expanded and the new Asiatic and West Indian companies both prospered. A Danish bank of issue, founded in 1736, supported these ventures. When the great colonial war broke out between France and England the neutral trade of Denmark soared. A. G. Moltke (*q.v.*), the favourite of Frederick V (1746–66) and a great landowner, was the first to realize that this might also expand Danish agriculture, but the landowners were too conservative to consider the economic freedom of the peasants. However their rule was overthrown in 1770 by Struensee (*q.v.*), an accomplished physician and a man of great gifts, who secured power through his liaison with Caroline Matilda, sister of King George III of Great Britain, who had been unhappily married with the degenerate and morbid Christian VII (1766–1808). Struensee carried through a number of reforms, including some reduction of villeinage, but conservatism again revived under Ove Hoegh-Guldberg. who declared that the "yoke of the peasants could not be removed without Denmark's shaking and quivering to its foundation."

Agricultural reforms were imminent, however, and when in 1784 the crown prince Frederick had acquired power by a coup d'ktat, he found a brilliant spokesman in a landowner of old Danish stock, Christian Ditlev Reventlow (*q.v.*), who had studied agriculture in England. Reventlow became the life and soul of a commission which freed the Danish peasant. The stavnsbaand was ended on June 20, 1788; villeinage mas either clearly defined or commuted, compensation in money being given; the old agricultural associations were abolished, and the peasant was allotted his own plot of land. Many at once left the villages for the country. This thorough and successful land reform ultimately aimed at freehold ownership. Danish agriculture and trade now took great strides. Commerce was facilitated by the toll law of 1797 which extended the principle of free trade. Wealthy businesses grew up in Copenhagen, and the bank of issue granted ever-increasing credit. After 1757 the bank was exempted from having to meet its notes with silver; after it was taken over by the state in 1773, the note issue had to cover both the needs of business and the state's financial demands.

17. Napoleonic Wars.—In the late 18th century England had become a grain-importing country. The prices of grain and agricultural products rose steadily during the French Revolution and the Napoleonic Wars. In this favourable period, which continued until 1807, nearly half the Danish peasants became freeholders.

Danish trade also prospered while the foreign minister, Andreas Peter Bernstorff, like his uncle J. H. E. Bernstorff before him, succeeded in keeping Denmark out of war. After his death in 1797 there came a clash with England. In Dec. 1800 Denmark joined the second armed league of neutrality of the Baltic powers, set up to protect the rights of neutral shipping by convoy in time of war. In 1801 an English fleet was dispatched to Copenhagen under Sir Hyde Parker, with Nelson his second-in-command, to compel Denmark's withdrawal. The Danish government refused to be coerced, but in the battle of Copenhagen in April, the Danish fleet was largely destroyed and Denmark had to agree to the English terms. (For an account of the battle see COPENHAGEN.)

In 1807 the British asked the neutral Danes to give up their navy lest Napoleon use it against England. The Danes yielded, but not before a British squadron of ships of the line with troop transports had laid large portions of Copenhagen in ruins. In anger over this, Frederick VI (1808–39) thenceforth backed Napoleon. In the seven burdensome war years that followed, relations between Denmark and Norway were completely broken off and Danish trade was brought to a standstill. With Napoleon's defeat Denmark had to conclude a peace at Kiel in 1814, losing Noruay to Sweden and Heligoland to England. but acquiring Lauenburg. Since neither taxes nor loans could be raised to meet the immense war costs, the state bank issued notes without limit;

in 1813 it went bankrupt and a new national bank was founded, which became private in 1818. The failure of the bank, the destruction of Danish trade and the fall of grain prices, especially between 1818 and 1824, caused a period of poverty and stagnation during which the land reforms came to a standstill.

18. The Liberal Constitution, 1849.—This naturally provoked criticism of Frederick's absolute government. Under the influence of the July revolution of 1830 in France, Frederick in 1834 set up four consultative provincial assemblies. These marked the beginning of parliamentary life and encouraged public discussion of political questions. A Liberal party came into existence, basing itself on the principles of constitutional and representative government. Not even Christian VIII (1839–48), who as king of Norway in 1814 had co-operated in framing Norway's free constitution, seemed disposed to perform the same service for Denmark. Immediately after his death on Jan. 20, 1848, came the February revolution in France and the short-lived victory of liberalism. In Copenhagen there was a public procession on March 21 to the new king demanding a liberal constitution. Frederick VII (1848–63) thereupon announced he would renounce absolute rule and had already planned a representative government. This was appointed next day with A. W. Moltke (*q.v.*) as prime minister; among the ministers were leading National Liberals like D. G. Monrad and Orla Lehmann; A. F. Tscherning, leader of the Bondevenner, or Friends of the Peasants, was more radical. On Oct. 23 a national assembly met; on the basis of a draft submitted by Monrad, it prepared the Danish constitution of June 5, 1849. The legislature became a *rigsdag,* with specified powers, consisting of a *landsting* and a *folketing*; the members of the former were to be elected for eight years by indirect vote and the latter for three years by direct vote.

19. The Schleswig-Holstein Question.—The question of the new constitution was, however, overshadowed by the widening differences between Germans and Danes. The Napoleonic Wars had awakened German national feeling, and the political bonds which had existed between Schleswig and Holstein ever since the election of Christian I as their joint ruler in 1460 suggested that these two regions should form a single country within a united Germany. A countermovement developed among the Danish population in North Schleswig and from 1838 in Denmark itself, where, from 1842, the Liberals were insisting that Schleswig had belonged to Denmark for centuries and that the frontier between Germany and Denmark must in the future as in the past be the Eider. (*See* SCHLESWIG-HOLSTEIN QUESTION.) This difference between Eiderdanism, as it came to be called, and Schleswig-Holsteinism led in March 1848 to an open Schleswig-Holstein revolution, helped by the armed intervention of Prussia. The outcome of this was a three years' war (1848–50) which ended in a victory for Denmark. Great Britain, France, Russia and Norway-Sweden in 1850 recognized the integrity of the Danish monarchy and, in the London convention of 1852, together with Austria and Prussia acknowledged Prince Christian of Glücksburg as heir to the whole monarchy after the death of the childless Frederick VII. In the agreement with Prussia, however, the Danish government by a protocol of 1852 undertook not to tie Schleswig more closely to Denmark than to Holstein. That this condition was impracticable soon emerged.

In the Danish *rigsdag* three parties had been formed: the Conservatives, comprising most of the landowners and all opponents of the free constitution; the National Liberal Burgher party, which had carried through the June constitution; and the left, including the Peasants and the Friends of the Peasants, whose chief aim was continued land reform. The Conservatives were in favour of restricting the June constitution as much as possible, being ready to fulfill the guarantee to Prussia by creating a conservative joint constitution for the whole kingdom, with a joint *rigsraad* in which the Holstein landowners should also be represented. Such a constitution came into existence in 1855, but the Holsteiners promptly refused to meet in a joint *rigsraad.* After 1857 the National Liberals returned to power with Carl Christian Hall (*q.v.*) as prime minister. He abolished the joint constitution for Holstein and on Nov. 18, 1863, prevailed on the new king, Christian IX (1863–1906), to sign a new joint constitution for Denmark and Schleswig. Prussia and Austria were now able to intervene as the upholders of the 1852 protocol. In 1864, Danish military resistance was crushed in two brief campaigns, and by the treaty of Vienna in October Christian IX surrendered his claims in Schleswig, Holstein, Lauenburg and Danish North Schleswig to the emperor of Austria and the king of Prussia. In 1866 after the Austro-Prussian War these territories became part of Prussia. The treaty of Prague (1866) provided that North Schleswig should be reunited with Denmark should the majority of the population by a free vote so desire; but in 1878 Prussia and Austria agreed to cancel the article.

20. The 1866 Constitution.—The National Liberal Eider-Danish policy had brought about Denmark's defeat. The Conservatives took office and carried through the new constitution of July 28, 1866, which was considerably more conservative than that of June 1849: the general suffrage was retained for the *folketing,* but in the composition of the *landsting* the landowners and the most highly taxed people were given an overwhelming influence. This resulted in the two chambers entering into a state of permanent opposition to each other. In 1870 the left severed their alliance with the Conservatives, who soon combined with the National Liberals to form a right. This right leaned on the *landsting* and maintained the king's privilege of selecting his ministers without regard to the majority in the *folketing.*

In 1872 the left secured a majority in the *folketing* and insisted that the king must choose his ministers from the majority party. The struggle persisted from 1875, when J. B. S. Estrup (*q.v.*), the leader of the right, became prime minister. The contest was bitter, for throughout all this period the left had a growing majority in the *folketing.* The election of 1884 gave them more than 80 seats, of which 2 were held by the first Social Democrats ever elected to the chamber. The right demanded large appropriations for defense, in particular for the fortifications around Copenhagen; the left, especially Viggo Hörup, who after the 1870s stood for a foreign policy of neutrality and disarmament, refused to admit this. Under the leadership of Christen Berg the *folketing* went so far as to reject the budget in 1877 and again in 1885. But Estrup did not shrink from letting the king declare a "provisional budget," and by this means the right were able to maintain themselves in power. In 1894 a group of Moderates came to an agreement with the Conservatives about defense policy, and Estrup now resigned as prime minister. Only when the election of 1901 had reduced the government's strength in the second chamber to 8 members of the right and 16 of the so-called Moderates, as against 76 of the left and 14 Social Democrats, did King Christian IX request J. H. Deuntzer to form the first left ministry, of which Jens C. Christensen, Hörup and Christopher Hage became members.

21. Economic Progress.—Since prices went on rising, land reform could be resumed, as the Friends of the Peasants and the left desired. The National Liberal government supported these moves with Monrad's law of 1861 changing the leasehold tenancies into freehold land. Thus 87% of the farms were freehold by 1873 and 95% by 1905. The increasing exports of grain from America and Russia between 1873 and 1895 undermined Danish agriculture, but the farmers now developed the export of butter and bacon and through a system of co-operative dairies and slaughterhouses established a strong position in the English market. Later there came co-operative export associations.

The port of Esbjerg, established in 1868, became an important centre for the English export trade. C. F. Tietgen founded the United Steamship Co. (whose Esbjerg-Harwich line took over the export to England) and the great Northern Telegraph Co., which acquired its greatest importance through its relations with China and Japan. New banks were founded, including the Landmandsbank (Agriculturists' bank) in 1871 and the Handelsbank (Trade bank) in 1873. The towns grew; during the 1870s Frederick III's old ramparts round Copenhagen were pulled down and new quarters arose on their site. A wage-earning class arose and was soon identified with the Social Democrats. A labour conflict in 1899 led to the establishment of an arbitration court for settling labour

disputes (the June constitution had already acknowledged the full right of association). In 1891 there was introduced an old-age pension law, in 1892 a health insurance law, in 1899 an important law for the establishment of small farms with state help.

22. Ministries of the **Left.**—As a ministerial party, the left had great difficulties to overcome. It had to try to introduce universal suffrage in the election of parish councils *(sogneraad)*, of county councils *(amtsraad)* and even of the lower chamber itself, for which a new fundamental law was required; it had to proceed with social legislation; it had to change taxes such as the tithe into taxes on the incomes and property of the citizens; it had to introduce regular budgets. The Deuntzer ministry carried through a tax reform in 1903; two years later Jens C. Christensen became prime minister. He was anxious to demonstrate that the left could rule, even with a hostile upper chamber, but he believed that to do this the left should break with the Social Democrats and declare itself willing to carry through measures of defense adequate to the country's needs, even if defense expenditure could not be reduced. A small section of the left which would not admit these two measures set up as an independent party, the Radical party, under the leadership of Carl Theodor Zahle. In the following year the military problem became the dominant issue; the prime minister tried to solve it in conjunction with the Moderates, whose leaders were Klaus Berntsen and Niels Neergaard. But in 1908 the ministry was severely shaken when the minister of justice, A. Alberti, was forced to resign and subsequently confessed himself guilty of fraud. The Christensen cabinet had to resign in Oct. 1908. Three short-lived cabinets followed (Neergaard, Count Holstein-Ledreborg, Zahle), and finally, in June 1910, Klaus Berntsen formed a cabinet of the left, including the Moderates, which lasted until 1913. King Frederick VIII, who had succeeded in 1906, died in 1912.

In 1910 the left had begun to agitate for a democratic amendment to the constitution. The right, strong in the *landsting*, opposed this, and no solution had been reached when the elections were held in May 1913. The Radicals and Socialists now held 63 seats out of the 114 in the *folketing* and united to force the reform under a new Zahle cabinet containing Erik Scavenius (foreign affairs), Edvard Brandes (finance). Ove Rode (interior) and Peter Munch (defense). The right answered by obstruction in the *landsting*, which the government then dissolved. The new *landsting* contained 38 supporters and 28 opponents of the constitutional amendment.

23. World War I.—During the crisis of July 1914 the Danish government remained cautious. When war broke out on Aug. 1 it forthwith proclaimed its neutrality and mobilized an emergency force.

On the night of Aug. 4–5 Germany began mining southern Danish waters and next morning the German minister asked if Denmark would lay mines in the Great Belt. Fearing that the Germans would otherwise lay the mines themselves and build fortifications on the coast to protect them, the Danes gave an affirmative answer, King Christian X (1912–47) having informed his cousin the king of England, who agreed. All Danish waters were mined.

During this crisis the Zahle government proposed a coalition of all four parties, but discussions between them failed. The *rigsdag* passed several emergency laws, primarily economic. Germany could stop Danish exports to England, and England strangle imports of supplies needed for Danish agriculture and industries. Arrangements acceptable to all interests were concluded, and in November the Scandinavian countries declared that they intended to follow a uniform trade policy. In December a meeting of the three Scandinavian kings, prime ministers and foreign ministers took place at Malmö.

As the war progressed the restrictions on imports, imposed by England, became more severe. The German U-boat warfare was expanded from Jan. 31, 1917, and Danish shipping suffered increasing losses. When the United States entered the war difficulties increased, because of U.S. restrictions on trade with Germany. Gradually the consequences of war were felt on the domestic scene. Agreements with the belligerents made restrictions on business necessary and were received with resentment. To combat inflation, prices on domestic products were fixed; but legislation requiring the farmers to deliver certain amounts of grain met with opposition. From April 1, 1917, rationing mas gradually imposed on several goods. Salaries did not rise and shortages in raw materials created unemployment. Rising governmental expenditure made higher taxes and loans necessary.

When the first anxiety over the war had died down the question of a new constitution was taken up again. The right mas now interested in an agreement, and on June 5, 1915, the king signed the new constitution. This provided a two-chamber parliament with equal suffrage for men and women. The privileged suffrage for the landlords and the wealthier classes electing the upper chamber came to an end. The voting age for the upper chamber (the *landsting)* was 35 and for the lower chamber (the *folketing)* the age was to be lowered successively from 30 to 25. The *landsting* had 72 members. 18 of whom were elected by the outgoing chamber. the remainder by indirect elections. The *folketing* had 140 members; of these 93 were elected in individual districts and 24 in Copenhagen according to proportional representation. The additional 23 seats were distributed according to each party's percentage of the total vote. Any amendment to the constitution had to pass the two chambers of parliament. according to specific rules, and to be approved by 45% of the eligible voters in a referendum.

With the adoption of the new constitution the right accepted parliamentary government, and important legislation was passed during the following years without much opposition. This included a reform of the administration of justice (April 1916), which separated the administrative and judicial systems and introduced oral proceedings and publicity and trial by jury in criminal and political cases. The privileged suffrage for county councils *(anztsraad)* was finally abolished in 1916. The land reform of 1919 resulted in the division of many large estates and church lands into small holdings. A law of 1916 required all employers to insure their employees against accidents. A law regulating limited companies was passed in 1917 and the first regulatory bank law was passed in 1919.

When in Aug. 1916 the government concluded a treaty ceding the Danish West Indies (the Virgin Islands) to the United States for $25,000,000 a political conflict arose. The Conservative and Liberal parties were originally opposed to the sale of the islands, but a coalition government was formed and a plebiscite was held on Dec. 14, which agreed to the ratification of the treaty.

The first election of the *rigsdag* in accordance with the new constitution was held in April 1918. Already in January the coalition had been dissolved, but the Zahle government was upheld by the Radical Liberal and Social Democratic parties. The election issues were the government's economic policies, as many groups were tired of the restrictions and rationings imposed during the war. The government parties won a narrow victory in the *folketing*, but the opposition parties were in a majority in the *landsting*.

24. The **Schleswig** Question, 1918–24.—After the armistice on Nov. 11, 1918, the emergency army was quickly demobilized, the wartime military regulations abolished and the land defenses of Copenhagen destroyed. Germany's defeat now made possible the return of a part at least of Schleswig. The Danish population's representative in the German parliament, the Schleswiger H. P. Hanssen, and the Zahle government wanted only those parts where the majority of the population was indisputably Danish to return to Denmark and suggested a plebiscite in the northern zone of Schleswig; but a growing body of Danish opinion wanted the city of Flensburg too, or the whole province of Schleswig.

Hanssen had already raised the question of self-determination for the Danes in Schleswig in the German *Reichstag* in Oct. 1918. The Danish government on Nov. 28 turned to the victorious Allied powers and suggested a plebiscite in two zones: the first zone should vote as an entity, while in the second, which should include Flensburg, votes should be counted community by community. The Versailles treaty contained these provisions. Voting took place on Feb. 10, 1920, in zone 1, where approximately 75,000

votes were cast for Denmark and 25,000 for Germany, and on March 14 in zone 2, where there were 52,000 for Germany and 13,000 for Denmark, only three small communities voting for the latter. The frontier was thus drawn as close to the nationality line as possible. In June the necessary amendment of the constitution was passed, and North Schleswig was incorporated into Denmark.

Disagreement over the Schleswig question and other political controversies had resulted in the "Easter crisis" of 1920. Although the Zahle government had a slight majority in the *folketing,* the king felt that the people were on the whcle against the government's Schleswig policy and dismissed the ministry on March 29. The Social Democrats considered this move unconstitutional and threatened a general strike, but in a few days a ministry of nonpoliticians was formed with the task of framing an electoral law and holding elections. The election took place on April 26, 1920, when the Radical Liberals lost nearly 50% of their seats. The Liberal Neergaard then formed a new ministry.

The immediate postwar period was one of economic and social crisis. Trade was declining, unemployment growing, prices rising and the krone depreciating. This led to inflation, unrest among the workers and numerous strikes; and in April 1920 the employers threatened a general lockout.

The Neergaard government (1920–24) slowly reconciled the conflicting interests. Its program was to abolish what remained of the economic control introduced during the war. This it gradually did. and the latter part of 1920 saw an economic boom. But the fall of world prices in 1921 produced a severe crisis. Counting on new markets in eastern Europe, many firms had overstocked, and when their expectations proved wrong they found themselves in difficulties. Home industries that had grown up during the war were now hit by foreign competition, and in 1921–22 unemployment rose to 19.3%. The industries called for protection, but the government stuck to the free-trade policy. Many bankruptcies ensued and several banks closed. In March 1922 the Copenhagen Landmandsbank was saved only by government intervention. Losses amounted to 500,000,000 Kr. Several of the leading bankers were convicted of fraud.

From 1923 the business cycle turned, exports rose and unemployment fell; but the value of the krone continued to fall. In the elections for the *folketing* held in April 1924 the Neergaard government was defeated and the Social Democrats became the largest party in the lower house. Important legislation during the Neergaard period had included a new defense law in 1922, reducing expenditure on defense to 44,000,000 Kr.; an extension of land possibilities for smallholders; and several laws concerning the church, such as one that admitted laymen to the pulpit and one that permitted free choice of civil or ecclesiastical marriage.

25. **Social Democratic Government, 1924–26.**—After the election in 1924 the Neergaard government resigned and Thorvaid Stauning formed the first Social Democratic government in Denmark. Together with the Radical Liberals the Social Democrats had a majority of 2 in the *folketing,* while the opposition had a majority of 10 in the *landsting.* This forced the government to restrict legislation to the fields where an agreement with the opposition was possible.

On the advice of a committee the government in December introduced a law bringing the value of the krone gradually up to par; and in 1926 the gold standard was reintroduced. This deflationary policy led to a new crisis, marked by a heavy fall in agricultural prices, industrial difficulties and unemployment. There were labour disputes from March to June in 1925 and wages rose slightly. Bad economic conditions continued through 1926, unemployment figures reaching 29.8%. A poor harvest and German tariff on agricultural products increased the difficulties. In October the government introduced extensive legislation to combat the crisis, but the Radical Liberals voted against it. The ensuing election in December resulted in a narrow defeat for rhe government. A new party, the Retsforbund, won only 2 seats.

26. **The Madsen Mygdal Government,** 1926–29.—The Liberal leader T. Madsen Mygdal, an estate owner, became prime minister. In February Madsen Mygdal introduced a budget cutting governmental expenditure by 60,000,000 Kr. through reduction in civil service salaries, social legislation and military appropriations; but this did not solve the problems arising from unemployment and agricultural distress. In 1928–29 economic prospects seemed brighter, but a bank crisis in Sept. 1928 indicated further worries ahead. The government's continued deflationary policy, together with a law restricting the activities of trade unions, raised bitter opposition among labour groups. Then a conflict with the Conservative party on military appropriations forced the Madsen Mygdal government to dissolve the *folketing.* In the election of April 1929 the Social Democrats regained their position as the largest single party in the lower house.

27. **The Stauning-Munch Government,** 1929-40.—The new government was a coalition of the Social Democrats and the Radical Liberals, with Stauning as prime minister and the Radical Liberal leader Munch as minister of foreign affairs; its program included disarmament, reform of the social legislation and the abolition of the *landsting.*

Denmark, being highly dependent on foreign trade (especially with England and Germany), soon felt the effects of the great depression which now broke on the world. At the end of 1930 there was a steep decline in agricultural prices. The crisis spread to industry and to the building trades, and unemployment rose. In 1932 one-third of registered labour was unemployed, and in the winter of 1932–33 economic collapse seemed imminent. A return to prewar economy was thus impossible, and many forms of state planning were introduced. But strained economy and social unrest gave extreme parties a chance. During the early 1930s dissatisfied farmers formed a party and the Communists won seats in the *rigsdag.* A small group had adhered to Fascism in the 1920s and a Nazi party was also formed in the 1930s. Neither Fascists nor Nazis gained any substantial following, however. and their activities were curtailed by the law of April 1933, which forbade the civilian use of uniforms in public (except for Boy Scouts).

When Great Britain left the gold standard in Sept. 1931 Denmark followed suit. In Jan. 1932 the government assumed central control over trade in foreign currency and imposed import restrictions which enabled it to stabilize the krone. After the Ottawa agreements an Anglo-Danish trade agreement was concluded in April 1933, increasing imports from England. Bilateral trade agreements with Germany and other countries followed. The economic crisis required much domestic legislation and brought about co-operation between the coalition parties and the opposition. In Oct. 1931 the first "crisis agreement" was concluded with the Conservative party, providing relief for the unemployed and help to farmers, financed by increased taxation. In 1932 a new agreement was concluded, with all four parties co-operating.

In Nov. 1932 the *folketing* was dissolved. In the new elections the government parties won, but for the first time the Communists were represented in parliament. In Jan. 1933 a compromise was concluded *(Kanslergadejorliget)* by which the agreements on wages were prolonged, the value of the krone reduced and the farmers guaranteed better prices on the most important products. Earlier social legislation was co-ordinated and expanded into the *Socialreform,* which made Denmark one of the most progressive "welfare states" of western Europe. A new criminal code was passed and several public-works projects begun; *e.g.,* the building of bridges connecting the islands.

In the autumn of 1935 the government again dissolved the *folketing,* and the Social Democratic party won a great victory. At the elections for the *landsting* next year the government coalition also won a majority. After long negotiations the government parties and a majority of the Conservatives, led by G. L. J. Christmas Moller, agreed on a constitutional reform designed to combine in a new *rigsdag* the advantages of the two-chamber and single-chamber systems. In May 1939 the measure was passed by the *rzgsdag* but failed to secure sufficient votes in a plebiscite. After this defeat the government declared that the constitutional question would rest. A few months later World War II began.

28. **Denmark and Iceland,** 1918.—From the beginning of the 20th century public opinion in Iceland had turned more and more toward independence, and in 1918 the constitutional link between Iceland and Denmark was amended. According to the new Danish-

Icelandic treaty of union the two countries were independent sovereign states, united through the king. The treaty contained provisions for common citizenship and stipulated that the Danish foreign service should represent Iceland in foreign countries; that Danish naval ships should take care of the inspection of fisheries in Icelandic waters; that a Danish-Icelandic council, meeting alternately in the two countries, should give advice on questions of common interest; and finally that amendments or a declaration of complete Icelandic independence could take place in 1943. *(See* ICELAND: *History.)*

29. Foreign Relations, 1918–40.—Already before the end of World War I a Danish committee had worked on a charter for an international organization. In March 1919 a delegation participated in forming the covenant of the League of Nations. and in Jan. 1920 Denmark accepted the invitation to join the new organization. The parliamentary resolution authorizing this stated that the charter did not bind the small nations to participate in military sanctions or restrict their freedom to reduce armaments. Denmark took part wholeheartedly in the activities of the league in the following years and had a nonpermanent seat in the council in 1933 to 1936. It concluded arbitration treaties with several countries in the 1920s and signed the Kellogg-Briand pact in 1928.

In 1931 a conflict with Norway arose over Greenland. When the Norwegian-Danish union was dissolved in 1814 this island had remained with Denmark. The Danish trading system had been extended to the western coast during the 19th century, and the United States had acknowledged Danish sovereignty over the whole island in connection with the sale of the Danish West Indies. In 1921, Denmark's sovereignty over all Greenland was acknowledged, but the Norwegian government maintained that East Greenland, apart from one Danish settlement, was no man's land. In 1931 the country between the 71st and the 75th parallel and in 1932 the district between the 60th and the 63rd were occupied by Norwegian expeditions and proclaimed to be Norwegian sovereignty. Denmark appealed to the Permanent Court of International Justice, which decided on April 5, 1933, in favour of Danish sovereignty over the whole of Greenland. Excitement over this conflict soon subsided in both Norway and Denmark, and Scandinavian co-operation in foreign affairs increased in the late 1930s; meetings of the Scandinavian foreign ministers had been taking place since World War I. A common attitude was discernible in the League of Nations, and as the European and international atmosphere grew tense in the 1930s understanding between the Scandinavian states, now joined by Iceland and Finland, became closer. Denmark joined Finland. Norway, Sweden, Belgium and the Netherlands in the "Oslo group" created in 1930 for co-operation in tariff questions, and these states tried also to form a political partnership. But as the influence of the League of Nations declined the Oslo group at a meeting in Copenhagen in July 1938 declared that members of the league were no longer bound to participate in applying sanctions.

As the power of Adolf Hitler's Germany grew, so did Danish apprehensions; it was feared that Germany would raise the question of North Schleswig. Early in the 1930s the German minority in this province had become restless, and its representative in the *folketing* raised the question of reunion with Germany. The government in many ways tried to satisfy the German-speaking citizens. When in May 1939 Germany proposed a nonaggression treaty, Scandinavian co-operation broke down: Denmark accepted the German offer, Sweden and Norway rejected it. The treaty, valid for ten years, was signed on May 31 in Berlin. The two countries pledged themselves not to go to war against each other or give help to belligerents against the other; normal trade should be allowed during a conflict between one of the powers and a third country.

30. **German Occupation,** 1940–45.—In 1933 and 1937 new defense laws had been passed, but when war broke out in Sept. 1939 Denmark was badly prepared to withstand an attack. The government at once proclaimed Danish neutrality and, as in 1914. parliament passed laws adapting the economy to the new situation. The Stauning-Munch government suggested a coalition backed by the so-called "old parties," but the Liberals rejected the offer.

On Sept. 4, 1939, British aircraft bombed the city of Esbjerg by mistake, causing material damage. The Danish ship "Vendila" was sunk in the North sea and 33 ships were lost by April 1940. King Christian X conferred with the other Scandinavian kings and with the president of Finland in Stockholm. When the U.S.S.R. attacked Finland, Denmark's sympathy was all uith the latter: Danish volunteers participated in the war, and medical and other supplies were sent It was hoped that Denmark would be able to stay neutral, as in World War I. Precautions were taken to prevent violations of Danish waters by U-boats, and in Jan. 1940 the government declared that Denmark would fight if attacked.

Although Germany at the end of Aug. 1939 had declared that Danish neutrality would be respected. in Jan. 1940 Hitler gave orders to make plans for the occupation of Norway. with Denmark included as the vital passage. Herluf Zahle, the Danish minister in Berlin, reported rumours of German concentrations in Baltic harbours on April 4. and the departure of transport ships from Stettin on April 7. England and France on April 7 and 8 mined Norwegian waters and at the same time German troops were reported on the move between Rendsburg and Flensburg. The German minister Cecil von Renthe-Fink warned Munch against any measures that might provoke Berlin to retaliation. After consultations with the leaders of the parties the government therefore decided not to mobilize the emergency army, but an order of readiness was issued to the navy. On the same day a German fleet went through the Great Belt. Two of the ships went north of Sjaelland, then turned south and sailed through the Sound.

The attack began as planned, at 4 o'clock on April 9. At that time Renthe-Fink presented Munch with a memorandum (the 13 points) stating that Great Britain planned to occupy Denmark, that Germany therefore must protect Danish territory but would respect Denmark's integrity and political independence. German troops crossed the border with some fighting and landed at several points on the islands. They also entered Denmark's only naval harbour, Copenhagen. Ice had prevented the necessary patrolling and confusion in one of the forts at the harbour entrance allowed two German ships to enter without a shot being fired. Troops landed, occupied the citadel and moved toward the Amalienborg palace, where fighting with the royal guards began. The king and several of the ministers were discussing the ultimatum while German bombers were circling over the city. As help from Great Britain or France could not be expected, it was decided to accept occupation under protest. The people felt dismayed and humiliated, but obeyed the king's proclamation to maintain order and avoid conflict with the German troops. Normal life was gradually resumed. The Danish people. generally pro-British and for historical reasons antagonistic toward Germany, at first adopted an attitude of "wait and see" in view of the correct behaviour of the Germans. But the ostensible willingness to co-operate turned into passive resistance when the Germans broke their promise not to interfere in Danish affairs.

A coalition government was formed on April 10, with Stauning as prime minister, and the democratic parties in parliament formed a co-operation committee which established the unavoidable collaboration with the Germans. The necessary economic provisions were passed by parliament. Imports from the west were stopped, and despite agricultural production stocks of food ran low. The requirements of the Germans led to severe shortages and strict rationing became necessary. Inflation was, however, kept under control.

On April 9 the connection between Denmark and Iceland mas broken, and on April 10 the Icelandic ministry took over the functions of the king. The Faeroe Islands were occupied by British troops on April 12, and the Danish minister in Washington, D.C.. Henrik Kauffmann, laid the foundation for the U.S. occupation and protection of Greenland.

The government was reconstructed in July: Erik Scavenius, accused by many of a pro-German attitude as foreign minister during World War I, took over the portfolio of foreign affairs, and the industrialist Gunnar Larsen was appointed minister of transport. On July 8 Scavenius issued a declaration promising co-operation with the Germans. Negotiations on a customs and cur-

rency union began, but the German proposals invariably involved Danish subservience to the German economy, and in August the government succeeded in postponing the negotiations indefinitely.

Passive resistance soon increased. The king's 70th birthday in September was made the occasion for loyal demonstrations. The minister of trade, Christmas Moller, leader of the Conservative party, was one of the first politicians to express Danish antagonism toward the conqueror. During the negotiations on the customs and currency union the first underground newspaper was printed.

In the autumn a Nazi-infiltrated farmers' group and a group of industrialists and rightists attempted unsuccessfully to force a change of government. In November the Nazi party, under the leadership of F. Clausen, tried a coup that ended in utter failure. Around the New Year, *1941,* the Germans tried in vain to have Stauning dismissed. However, they succeeded in forcing two leading Social Democrats to resign from their party posts and used the ensuing conflict to press the government into delivering a number of destroyers to the German marine.

From the beginning of *1941* the Germans increased their efforts to absorb Denmark into "the new Europe." A crisis arose in April, when Henrik Kauffmann, who from the beginning of the occupation had detached himself from the government, concluded the Greenland treaty with the United States: the government repudiated this step and dismissed him from office. In May, Iceland declared that the union of *1918* would not be renewed when it came up for review in *1943.*

The Communists had taken a benevolent attitude toward the occupation, but after the German attack on the U.S.S.R. they were arrested and interned, the Communist party being made illegal. In July, with Scavenius' official approval, Danish volunteers joined "Frikorps Danmark" to participate in the war on the eastern front. Along with other tensions in the ministry, this led to a crisis in July, when Scavenius threatened to resign. In the autumn the Germans forced the government to sign the anti-Comintern pact, which provoked the first serious anti-German demonstrations in Copenhagen. In April *1942* Christmas Möller and others, interested in active resistance against the Germans, founded the underground paper *Frit Danmark.* Christmas Moller fled to England in May and was elected chairman of the Danish council in London. His broadcasts strengthened the will to resistance, and the first saboteurs, trained in England, were parachuted into Denmark and established contact with the resistance movement.

In September, when Frikorps Danmark returned home on leave, clashes between citizens and soldiers broke out because the population generally considered them traitors. The Germans, angered at the flight of Christmas Moller, accused the Conservatives of duplicity. Patriots spoke and lectured. Attempts to curb them by prison sentences only produced more and bolder harangues. As sabotage consequently increased the Germans' anger grew.

Hitler, offended by the king's curt reply to a birthday telegram, now had his excuse for an ultimatum (the so-called Telegram crisis, Nov. *1942).* The German minister was recalled, the Danish minister in Berlin was handed his passport and the Germans demanded the resignation of the Social Democratic prime minister Vilhelm Buhl (who had taken office on Stauning's death in May *1942)* and the formation of a ministry that would actively collaborate with them. Scavenius, though he despised German and Danish Nazis, nevertheless was convinced of Germany's strength: he accepted the prime-ministership, but was received with resentment both among the people and in parliament.

The new German representative, Werner Best, reputed as an intelligent Nazi, wanted to restore quiet in Denmark to exhibit the country as a "model protectorate." The Germans, in March *1943,* therefore permitted an election for the *folketing.* The democratic parties fought the campaign on a closed front, there was an enormous poll and the result was a resounding defeat for Danish Naziism. But Best could interpret the result as a victory for the government and his appeasement policy. During the summer of *1943* sabotage increased regardless of warnings from the king and from the prime minister. After the fall of Italy, general unrest prevailed. In August violent riots broke out in several cities, followed by waves of sabotage. On Aug. *28* Best delivered an ultimatum demanding proclamation of martial law and death sentences for acts of sabotage. This was rejected the same day. Next morning the German army assumed control and their commander in chief, Gen. Hermann von Hanneken, declared martial law. Simultaneously, fearing that it would help the Allies in the event of invasion, the Germans attacked the Danish army at several places. A great part of the navy was scuttled to prevent its falling into German hands. The king was provisionally interned. Peaceful co-operation had ended. In September the Liberty council *(Frihedsruadet)* was formed by representatives of all groups participating in active resistance. Until the liberation it was Denmark's unofficial government. In October the Germans began arresting Jews; some were sent to a German concentration camp, but most escaped to Sweden. The first patriots were shot for sabotage. From then onward resistance increased rapidly: armed groups were trained and contact was established between the Liberty council and the political parties. Civil servants stayed at their posts in order to maintain as far as possible an orderly administration.

The Germans, assisted by Danish traitors, formed terror groups (*Schalburgkorps*), arranged countersabotage and murdered patriots, the so-called "clearing murders." In June *1944* the population of Copenhagen revolted and called a general strike (*folkestrejken*). For several days the situation was tense but finally the Germans accepted a compromise, by which the strike was called off and the German troops moved away from the city.

In September the Danish police, rightly suspected of helping the resistance, were arrested and sent to concentration camps. From then on lawlessness and terror reigned. Several leaders of the resistance, who had been interned by the Gestapo in the Shell building in Copenhagen, escaped when the building was destroyed by the Royal Air Force (March *21, 1945);* and the Gestapo's archives disappeared in the flames. The Gestapo headquarters in Aarhus and Odense were also bombed.

From Feb. *1945,* with the defeat of Germany in sight, thousands of German civilian refugees began to arrive in Denmark. On May *4, 1945,* German forces in northern Germany, the Netherlands and Denmark capitulated, and the next day British troops moved over the Danish frontier. While the main part of Denmark was liberated by British units, Soviet troops moved into Bornholm, where on May 7 several places were bombed as the Germans refused to surrender.

31. Post-World War II Developments. — A government under Buhl, which included members from the political parties and from the resistance movement, was appointed on May 5. During the summer parliament repealed all legislation enacted under German pressure and passed laws for the prosecution of collaborators and war criminals. After an election held on Oct. *30,* the Buhl ministry resigned and the Liberals formed a minority government under Knud Kristensen, with the diplomat Gustav Rasmussen as foreign minister.

During *1945–46* there were frequent strikes, partly over wages and partly over the conduct of the prosecution of collaborators and war criminals. Another question that gradually brought the government into conflict with the majority in parliament was that of South Schleswig. After the liberation the government had declared that it would not seek immediate revision of the frontier and that it favoured self-determination for the Danish population of South Schleswig. But as pro-Danish sympathies manifested themselves there, groups in Denmark came to press for the recovery of South Schleswig, and the prime minister's speeches indicated his agreement with this policy. On Oct. *28, 1947,* the *folketing* was dissolved. In the ensuing election both the Social Democrats and the Liberals gained seats, the Communists lost heavily but the Retsforbund increased its representation. Knud Kristensen resigned, and the Social Democratic leader Hans Hedtoft formed a new minority government. King Christian X died and was succeeded by his son Frederick IX in April *1947.*

After *1945* the government's major problems were economic. New investment was necessary to bring production back to prewar levels, and occupation costs had to be liquidated. The *200,000* German refugees who stayed in the country until *1949* increased

the difficulties. The Marshall plan therefore afforded decisive help. From mid-1948 economic prospects improved; production reached prewar levels and rationing was abolished for most goods. The postwar period brought vigorous economic activity. Increases in incomes in conjunction with a weak foreign exchange position several times created difficulties calling for drastic government action.

Immediately after the war a delegation went to San Francisco to participate in the United Nations conference. During 1945 and 1946 the South Schleswig question loomed large in foreign relations, but from the beginning of 1948 defense and potential alliances began to overshadow all other issues. The Communist coup in Czechoslovakia changed public opinion, and during the second half of 1948 Denmark, Norway and Sweden began negotiations for a defensive alliance. In Jan. 1949, however, these negotiations broke down. The Hedtoft government suggested a Swedish-Danish defense arrangement, but this was rejected by the Swedes. Thereupon Denmark in April 1949 accepted the invitation to join the North Atlantic Treaty organization (NATO). This complete break with the traditional policy of neutrality was accepted by the majority of the people but was opposed by the Communists and, because of their belief in neutrality, by the Radical Liberals.

An election in Sept. 1950 did not decisively alter the strength of the parties in the *folketing,* but shortly afterward the Hedtoft government was replaced by a coalition of Liberals and Conservatives under Erik Eriksen. Economic troubles continued and rearmament contributed to the growing deficit. The government introduced several measures to combat inflation and to limit imports, and early in 1952 there was some indication that the situation was beginning to improve.

The question of constitutional reform was taken up again and agreement mas reached among the five main parties. The new constitution which was adopted in May 1953 and signed by the king on June 5 introduced a single chamber system, the *landsting* being abolished. The *folketing* had 179 seats, of which two were for the Faeroe Islands and two for Greenland. The voting age became 23; new rules governing plebiscites were introduced and parliamentary rule. practised in Danish politics since 1901, was now embodied in the constitution. Female succession to the throne was provided for, so that Frederick ~ X ' selder daughter, Princess Margrethe, now became heir apparent.

The first election under the new constitution took place in Sept. 1953 and was won by the Social Democrats. Erik Eriksen retired, and Hans Hedtoft again formed a government: H. C. Hansen became foreign minister and, after Hedtoft's death in Jan. 1955, prime minister. As a rule the government had the support of the Radical Liberals in contending with the country's economic difficulties. An increasing exchange deficit made it necessary to increase taxation and restrict state expenditure on building. In 1956 Hansen was obliged to intervene in an industrial dispute and to impose arbitration. The Communists, Liberals and Conservatives attacked the government, and in the election of May 1957 the Social Democrats lost some ground. Nevertheless the crisis resulted in Hansen's forming a coalition government together with the Radicals and the Retsforbund; together the three parties had a majority in the *folketing.* During the following years the exchange vosition improved. agricultural and industrial production increased and unemployment practically disappeared. Prices for agricultural products were however relativelv low and the opposition demanded tax reliefs, while the government's taxation policy was intended to limit the increase of consumption. Social legislation was extended, a new education act was passed and a defense policy carried through by agreement among all the Danish parties of the *rigsdag* except the Communists. Hansen died in Feb. 1960. Viggo Kampmann, finance minister since 1953, now became prime minister. In the election of Nov. 1960 the Social Democrats gained 6 seats now holding a total of 76 seats. Viggo Kampmann's new cabinet consisted of Social Democrats and Radicals; it included a minister for Greenland.

Denmark had joined the Council of Europe but rejected, together with the other Scandinavian states and Great Britain, the continental European policy in this body. Although Scandinavian defense plans had broken down, Denmark still tried to develop Nordic co-operation. Negotiations for a customs union came to nothing, but in 1953 the Scandinavian council (Nordisk Raad), a consultative body of parliamentary and ministerial representatives of Denmark, Norway, Sweden and Iceland, mas inaugurated.

The Scandinavian council had held 9 sessions up to Feb. 1961 and achieved results in common Scandinavian legislation on juridical, social, political and cultural matters. Economic co-operation did not lead to a Nordic common market, but in 1960 Denmark, with Norway and Sweden, joined the European Free Trade association (E.F.T.A.). However, the export interests of Danish agriculture, in particular, caused Denmark to maintain a preference for a broad, European solution of trade problems.

(E. Ap.; S. Hn.; F. Sk.)

IV. POPULATION

The total population in 1960 was 4,585,256 (*cf.* 3,844,312 in 1940) with an average density of 275.9 per sq.mi. During World War II the annual increase averaged 1.11%; from 1950 to 1955 it was 0.78%, roughly the prewar average. The rapid population growth during World War II was caused by an increase in the rate of births from 18.3 per 1,000 inhabitants in 1940 to 23.5 in 1945, the death rate in the same years being 10.4 and 10.5. In 1955 the birth rate was 17.3 and the death rate 8.7.

The density of the population in the islands is nearly twice that in the peninsula. Copenhagen (*q.v.*), the capital, had 721,-381 inhabitants in 1960 (700,465 in 1940); the capital area, including Frederiksberg and Gentofte (*qq.v.*), however, totaled 923,-974 (890.130 in 1940). With the suburbs included, "Greater Copenhagen" numbers more than one quarter of the total population. The next largest town, Aarhus (*q.v.*), had 119,568 inhabitants in 1960 (99,881 in 1940), Odense (*q.v.*) 111,145 (87,521), Aalborg 85,000 (55,652) and Esbjerg 55,171 (33,155). The urban population in 1960 amounted to 2,166,421.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government. — Denmark is a constitutional monarchy. Legislative authority, based on the 1953 constitution, rests jointly mith the crown and the parliament, which consists of one chamber, the *folketing,* with 179 members (including two from the Faeroe Islands and two from Greenland), elected for four years. The franchise is held by all persons over 23 years of age. The *folketing* is in session throughout the year. No minister can continue in officeif the *folketing* passes a vote of no confidence in him; and if a vote of no confidence is directed against the prime minister the government must either resign or demand a new election.

The executive power is vested in the monarch who exercises it through the *Statsraad* (state council) which is made up of 15

ministers, headed by the prime minister. The country is divided into 89 urban and about 1,300 rural municipalities, each having a municipal council, elected every four years. The ministry of the interior has the superintendence of the cities and towns, and the governors of 22 counties (*amter*) have the superintendence of the rural municipalities. (See History above for constitutional development.)

2. Taxation. — Land taxes, taxes on buildings and a special tax on increase of land value contribute to the revenues of both the state and the municipalities. Income taxes and taxes on companies also contribute, whereas customs and excise duties are paid only to the state. The taxation of individuals is combined with a system of deductions and a progressive rate of taxation, and excise duties are to some degree placed on luxury articles so that the total taxation tends to level differences between individual incomes.

3. Living Conditions. — The standard of living has kept pace with 20th-century development. Unemployment, a big social problem in the 1920s and the 1930s, diminished steadily, and by the early 1960s Denmark had full employment. Most workers are members of trade unions, the bulk of which are affiliated to the Central Organization of Danish Trade Unions. Employers are represented by the Danish Employer's Confederation. Wage agreements are concluded every three years and real wages have been raised. The working hours were reduced to 48 a week in 1919 and to 45 in 1958; a two weeks' vacation is given to every worker who is employed throughout the year. Housing conditions have been improved by the state loans and guarantees, and the trend toward one-family houses has been strong since World War II.

4. Welfare Services. — Denmark has an old-age pension system for all persons over 67 and also a disability pension system. These pensions are financed wholly through taxation whereas health insurance, open to everyone regardless of age or condition of health, is subsidized by the state to the extent of 25% of total compensation. State or municipal hospitals are open to everyone at 10% to 15% of the real costs, and as this charge is usually paid by the health insurance, hospitalization is practically free of charge. Unemployment insurance is voluntary but widespread; worker and employer pay the insurance but get state repayment if unemployment rises or becomes protracted. Children's allowances are paid until the age of 16. Widows get a pension from the age of 55. Every child is medically examined, free of charge, at regular intervals from birth and throughout the school years.

5. Justice. — The administration of justice is exercised by 99 lower courts, 2 appeal courts (one in Jutland and one for the islands) and a supreme court in Copenhagen. At the appeal courts cases may be tried by juries, and at the lower courts the judge may be assisted by two jurymen. The police are organized on a national basis under the control of the chief of the state police; there are 69 police districts, each headed by a chief constable.

6. Education. — Illiteracy is practically unknown. Education is compulsory in elementary schools for children between 7 and 14 years. Secondary schools give instruction to those between 14 and 19 years. Both elementary and secondary education is free. In the early 1960s more than 3,260 schools were maintained locally; in addition there were about 360 private, 40 government institutions and 25 teacher-training colleges. In secondary schools there is a choice between practical, classical, modern language and scientific courses, terminated by a state examination after three or five years. Youth schools are free to those who do not attend the secondary schools. There are more than 60 popular high schools for adults, all private but assisted by the state. For specialized study there are a number of agricultural colleges, domestic science colleges and dairy schools; also more than 200 commercial schools and about 300 technical schools as well as institutions for dentistry, pharmacy, music and art. Copenhagen university was founded in 1479 and has about 5,500 students. Aarhus university, founded in 1928, and the Technical university in Copenhagen each has about 2,000 students. About 1,000 students attend the Veterinary and Agricultural university in Copenhagen. There are 1,400 public libraries.

7. Defense. — National defense policy is based on collective defense attendant on membership of NATO. Recruits to the armed forces are enrolled at 17 and receive instruction from 10 to 14 months between the ages of 19 and 25. Liability to call-up extends over 16 years, in two classes. The principle of national conscription has been maintained since 1849. However, the armed forces have a growing number of volunteers. Service in the home guard and the civil defense corps is voluntary. The navy comprises small vessels for coastal defense, motor torpedo boats, mine layers and mine sweepers, escort vessels and submarines; the air force is limited to squadrons of fighters.

8. Political Parties. — The Socialdemokratiske parti (Social Democratic party), mainly representing the workers, is the biggest of the political parties (76 seats at the 1960 election). The Radikale Venstre parti (Social Liberal party; 11 seats), mainly representing smallholders, handicraftsmen and salaried smployees, has on several occasions formed coalition governments with the Social Democrats. The Venstre parti (Moderate Liberal or Agrarian party), mainly representing the farmers, is the second biggest (38 seats); it formed an Agrarian-Conservative coalition government in 1950–53 and has since then co-operated with the Konservative folke-parti (Conservative party; 32 seats) which especially represents the more prosperous section of the urban population. The Retsforbund (no seats) is the Single Tax party. The Communist party (6 seats in the 1957 election but none in 1960) was split in 1958 when a smaller group formed the Socialist People's party (11 seats at the 1960 election). The Schleswig party, representing the German minority in North Schleswig, had one seat in 1960.

VI. THE ECONOMY

Denmark has always been famous for high quality agricultural produce and one of the most significant facts of its economy is the high ratio of productivity of the land: 90% is productive and 75% actually farmed. Long stretches of the coast are protected against erosion by breakwaters, especially along the North sea; elsewhere low-lying stretches have been protected by dikes, while considerable areas have been reclaimed by damming. Despite the lack of raw materials industrialization has been growing rapidly, especially since World War II, and industry now occupies more people than agriculture.

1. Agriculture. — Denmark possesses an unusually large number of freehold farms — 95% as against 5% rented, which is the result of an attempt by the government to subdivide large farms and to establish agricultural workers on independent holdings. Co-operatives help to make small-farm operation profitable, and animal husbandry, a prominent feature of their activity, also lends itself to small individual enterprise.

The Small Holdings acts of 1899, 1919 and 1949 and the agricultural expansion of the country resulted in the subdivision of large estates, the parceling out of glebe land and the abolition of leasehold. Tiny parcels were added to other small holdings or enlarged by land from bigger farms. Thousands of small holdings have been established since 1899 and small- and medium-sized farms (between 10 and 60 hectares) now comprise the majority of the nearly 200,000 holdings. Purchasers under the acts of 1919 of glebe land, fiefs or estates pay no purchase sum but only an annual rent to the government. In effect these holders become owners.

Production and Marketing. — From 1875 Danish agricultural production increased rapidly, though there was a temporary decline during World Wars I and II and the agricultural depression in the early 1930s. Between 1880 and 1954 the crop yield increased 300%, mainly through the purposeful application of science in the breeding of plants, a more enlightened use of manure and fertilizers and mechanization, apart from expansion of the cultivated area. Crops include grain, hay, potatoes, fodder beet, sugar beet, chicory roots and green fodder. Barley and oats account for 85% of the grain crop, fodder beet for 85% of the root crops.

The increase of crop yield (doubled since 1900) together with the importation of feeding stuffs made the Danish specialization in animal husbandry possible. The rise in the livestock production, which began in the 1880s, must also be attributed to the ap-

ADAPTED FROM AAGE H. KAMPP

THE CROP REGIONS OF DENMARK

plication of science in breeding, to improved methods in feeding and care and to versatility in farm management and marketing. Its progress is shown in Table II. World Wars I and II seriously injured the industrialized agricultural economy. The stocks of horses and cattle of course fluctuate less widely than those of pigs and poultry, which can be adjusted very quickly to changing conditions.

In the early 1960s the aggregate production of animal husbandry in metric tons was as follows (in parentheses the annual average for 1935–39): milk 5,400,000 (5,270,000); butter 166,000 (180,000); cheese 114,000 (33,000); beef and veal 254,000 (176,000); bacon, pork fillets, etc. 652.000 (329,000); eggs 138,000 (120,000).

Co-operatives.—Associational promotion began with the founding of the Royal Agricultural Society of Denmark (1769), and both it and numerous special societies stimulate breeding and other improvements. The National Federation of Farmers' associations established in 1919 a joint organization with the Federation of Danish Co-operative societies known as the Agricultural council (Landbrugsraadet). This council and the National Federation of Smallholders' societies represent agriculture in dealings with the government and with industry and in foreign trade. Numerous co-operative societies flourish, and in the important dairy and bacon business they dominate the scene. In the early 1960s there were more than 1,400 dairies, most of which were co-operative societies, and about 60 co-operative bacon factories. About 30% of the egg production is co-operatively organized. The extraordinary success of the Danish farmers in managing their co-operative societies, following the establishment of the first dairy co-operative society in 1882, resulted largely from the spread of adult education and especially the folk high schools.

Financial Returns.—After the long period of depression, at the close of the 19th century prices improved, and the relatively few accounts available for the years 1910–13 show an average yield of interest on capital invested in well-managed farms of about 4%–5%. During the first years of World War I the prices of grain and seed, and later of eggs, bacon and dairy products, rose so that the average yield of interest increased to 8.3% in 1918–19. In the following ten years the average yield of interest was from 1.1 to 6.4. The international agricultural depression brought an average loss of 0.4% on agricultural produce in 1931–32; when the depression was overcome, the average yield of interest rose to 3.8% in 1939–40. Rising prices during World War II increased the interest to 6.6% in 1943–44; but much of this increase was also caused by reduction of livestock (see Table II). When the reduction was stopped after the war and prices were reduced, the average yield of interest dropped to 2.3% in 1945–46. As the result of very good harvests, increased prices and a considerable rise in livestock, the interest rose to 6.5% in 1948–49. It was 4.6% in 1958–59 and 3.8% in 1960–61.

*Including south Jutland.

2. Forestry, Mining and Fisheries.—Forests and plantations cover about 10% of the country. About half of this area is covered with conifers, the rest being under broadleaf trees, mainly beech, and mixed growth.

Though coal is found in Bornholm, neither coal nor metals can be profitably mined anywhere. Lignite was mined in Jutland and peat mas cut in many places during World War II. Bog iron ores in Jutland are used for purifying purposes in gasworks. The newer chalk is utilized in lime burning and in the important cement industry. Bornholm supplies granite for building and paving, and kaolin for the china and paper manufactures. Salt is mined in western Jutland as a basis for chemical industries. About 0.4% of the Danish people are directly engaged in fishing and many others are dependent on it, such as workers in herring-oil factories, merchants, netmakers, boatbuilders and motor makers (most of the motors and gear are manufactured in Denmark). The catches consist largely of fish for industry with flatfish, cod, herring, mackerel and eel following in order of importance. The fishermen have marketing and purchasing co-operatives, though not on the same scale as the farmers' societies.

3. Power and Industries.—Power plants are owned by co-operatives or municipal authorities and mainly use coal, lignite or oil as fuel. In Jutland there is a small hydroelectric plant but most of the plants in use are the bigger ones. Some power is imported from Swedish hydroelectric plants.

Before 1870 Danish industry was unimportant. In the 1870s the

Industrial Revolution reached Denmark and by 1900 the former cottage industries at the farms, such as spinning, weaving, brewing, baking and sewing, had been supplanted by factories which produced primarily for home consumption. Between the two world wars, and especially after World War II, industrial production increased rapidly and came to account for as big a share of the national income as agriculture. The iron and metal industries provide more than half the total value of the expanding industrial exports and their chief products are diesel motors, steamships and motor vessels, dairy and agricultural machines. refrigerators, cement machines, electrical equipment and automobiles. The chemical industry (vegetable and animal oils, fish meal, oil cakes, pharmaceutical products, etc.) comes next in importance in value of exports while other exports include portland cement, beers, china, furniture, sugar and textiles, the latter having been produced only for the home market until 1950.

The metal industries employ the most workmen, followed by food processing, earthworks and building, textile, footwear and clothing industries, woodworking and chemicals. About a quarter of the total number of industrial workers are women.

4. Trade and Finance.—The per capita rate of Denmark's foreign commerce is exceptionally high, about 4,000 Kr. per inhabitant. In the first three decades of the 20th century this commerce depended especially on the United Kingdom to which Denmark sent about 60% of its exports. The depression caused a decline in the 1930s and World War II put an end to the British trade. After the war this trade was resumed, comprising by the early 1960s about 25% of total Danish exports and 20% of imports. Other principal trade partners were the Federal Republic of Germany, Sweden and the U.S. (see Table IV). In 1960 Denmark joined the European Free Trade association, although its trade with the six countries of the European Economic Community (the Common Market), remained considerable.

The Danmarks Nationalbanken is the only bank of issue and is controlled by a board of 25 governors, who are chosen by the government, the folketing, the ministry of trade and the board itself. In the early 1960s there were three large private banks and about 150 smaller ones, the three large ones doing about half the total business. Savings banks numbered about 500. The stock exchange is in Copenhagen. Insurance companies, several dating from the 1700s. do a large business abroad and at home.

The monetary unit is the krone. (One U.S. dollar is equivalent to 6.91 Kr.) In the early 1960s current revenue and current expenditure each exceeded 6,000,000,000 Kr. and the national debt amounted to more than 9,000,000,000 Kr.

5. Transport and Communications.—Motor transport is highly developed. The total length of the principal roads is 8,398 km. (5,218 mi.) of which 2,270 km. (1,379 mi.) are main highways; byroads total 46,196 km. (28,705 mi.). The state runs 2,555 km. (1,588 mi.) of railways, and 1,787 km. (1,110 mi.) are run by private lines in which the state and the larger towns hold nearly all the shares. There are highly organized train-ferry and motorcar-ferry schemes for communication between Zealand and Fyn and between Zealand and Jutland. A bridge (875 yd.) connects Fyn and Jutland, and another bridge (3,499 yd.) connects Zealand and Falster. The main land route is the railway and the highway from Copenhagen to Esbjerg, from where there is regular connection with England by sea to Harwich. On this main route Fredericia in Jutland is a junction from where railways and highways go south to Hamburg via Padborg and north to Frederikshavn which has a ferry service to Norway (Oslo and Larvik) and Sweden (Goteborg). Another main railway and a main highway go from Copenhagen north to Elsinore (ferry to Sweden), and south to Gedser from where ferries serve Warnemiinde (German Democratic Republic) and Grossenbrode (Federal Republic of Germany).

Denmark is in a favourable position for shipping with numerous ports, small harbours and quays. It has a large merchant fleet in proportion to its population. The country was a leader in the modern transition to motor ships; its biggest diesel works are in Copenhagen. Danish vessels carry about two-fifths of the national sea-borne trade and do a large foreign business.

Copenhagen with Kastrup airport serves inland routes to Jutland and Bornholm and is a centre of international traffic. S.A.S. (Scandinavian Airlines system, a joint Danish, Norwegian, Swedish enterprise) serves European and intercontinental lines.

The state runs the postal, telegraph, cable, radio and television services, whereas the telephone is owned by the state and the municipalities jointly.

(Ha. T.; E. Ap.; S. Hn.; F. Sk.; H. Ln.)

DENNIS, JOHN (1657–1734), English critic and dramatist whose insistence upon the importance of passion in poetry led to his long quarrel with Pope, was born in London in 1657. Educated at Harrow and Cambridge, he traveled on the continent before settling in London where he mixed with leading literary figures. At first he wrote Pindaric odes and plays, but, although a prolific dramatist, he was never very successful. He produced, among other plays, *A Plot and No Plot* (1697), a satire on the Jacobites; *Rinaldo and Armida* (1699) from Tasso's *Gerusalemme Liberata; Iphigenia* (1700); and *Liberty Asserted* (1704), which attacked the French and was something of a success.

The most important of Dennis' critical works are *The Advancement and Reformation oj Modern Poetry* (1701), *The Grounds of Criticism in Poetry* (1704), *The Usefulness of the Stage* (1698) and *An Essay on the Genius and Writings of Shakespear* (1712). His basic contention is that literature, and especially drama, is comparable to religion in that its effect is to move men's minds by means of the emotions. What he looks for primarily in a work of art is passion and elevation rather than decorum and polish. "Poetry," he says, "is Poetry because it is more Passionate and Sensual than Prose . . . where-ever a Discourse is not Pathetick, there it is Prosaick." His idol among the moderns is therefore Milton. Fundamentally this bias probably explains Dennis' antipathy toward Pope and accounts for the hostility between them. Pope included an adverse allusion to Dennis in his *Essay on Criticism*:

> But Appius reddens at each word you speak,
> And stares, tremendous, with a threat'ning eye,
> Like some fierce Tyrant in old tapestry . . .

Dennis replied with *Reflections Critical and Satyrical, Upon a Late Rhapsody, Call'd, An Essay Upon Criticism* (1711) which mixed criticism of the poem with a vicious personal attack upon Pope as "a hunch-back'd toad" whose deformed body mirrored a deformed mind. Despite a temporary reconciliation the quarrel continued sporadically until Dennis' death, Jan. 6, 1734, in London.

Dennis defended the drama against Jeremy Collier's *A Short View of the Immorality and Profaneness of the English Stage* (1698). He argued that plays were of value in discouraging disaffection by spreading pleasure and in providing exercise for the passions. His central practical doctrine is the necessity of observing strict poetic justice, because through poetic justice the writer instructs his audience by anticipating the divine rewards and penalties normally postponed until a future life. In this way the stage becomes "useful to the Advancement of Religion."

Dennis believed passionately in the arguments that he propounded. and his prose is often hectoring, always forceful, with the conviction of a man who believes that "Poetry has been thought . . . by God himself . . . to be the fittest Method for the enforcing Religion upon the Minds of Men," and who feels it his business to set this idea clearly before the writers and readers of his day.

See *The Critical Works oj John Dennis,* ed. by E. N. Hooker, 2 vol. (1939–43). (Jn. C.)

DENNISON, AARON LUFKIN (1812–1895), U.S. watch manufacturer who was among the first to adapt the technique of interchangeable parts to the production of pocket watches and is generally credited with being the "father of American watchmaking." Dennison was born March 6, 1812, in Freeport, Me., and at the age of 18 was apprenticed to a watchmaker in Brunswick, where he learned the prevailing manual methods of watchmaking.

Later he went to Boston, where he set up his own business and then studied mass-production techniques employed at the Springfield arsenal. Surmounting the technical difficulties of machine production of very small parts Dennison in 1850 set up a factory and began to supply the market with the first inexpensive, factory-made watches. This shop was the forerunner of the Waltham Watch company. Another by-product of Dennison's inventive genius was the Dennison Manufacturing company, which grew out of Dennison's successful efforts to employ machinery in the manufacture of paper boxes and, later, a wide variety of paper products. He died Jan. 9, 1895.

See E. P. Hayes and Charlotte Heath, *History of the Dennison Manufacturing Conzpany* (1929); Charles W. Moore, *Timing a Century, History of the Waltham Watch Conzpany* (1945). (G. S. Gb.)

DENOMINATIONAL SCHOOLS: *see* PAROCHIAL SCHOOLS.

DENON, DOMINIQUE VIVANT, BARON (1747–1825), French artist! archaeologist and museum official whose connoisseurship was instrumental in the development of the Louvre collection, was born at Chalon-sur-Saône on Jan. 4, 1747. He studied law in Paris, and in his 23rd year wrote a well-received comedy. Denon then took up drawing with Noel Hall6 and did some painting. Louis XV commissioned him to arrange a cabinet of carved gems inherited'from Madame de Pompadour. Between 1772 and 1787 Denon was entrusted with several diplomatic missions which brought him to St. Petersburg, Naples and Switzerland. In 177j he visited Voltaire in Ferney and drew his portrait. Much to the discontent of the writer, Denon had the drawing engraved. During his stay in Naples, he engraved the majority of his reproductions after old masters, collected works of art and etched small portraits of members of society. In 1757 he became a member of the Académie de Peinture as *artiste de genre.*

During the Revolution he returned to Paris, where he was protected by his friend, the painter David. At Bonaparte's invitation he joined the expedition to Egypt, and there made numerous sketches of the monuments of ancient art, sometimes under the very fire of the enemy. The results were published in his *Voyage dans la basse et la haute Égypte* (1802). From 1804 to 1815 he was director-general of museums. He accompanied Napoleon in his expeditions to Austria, Spain and Poland, advising the conqueror in his choice of spoils of art from the various countries pillaged. After Denon had become acquainted with the work of Aloys Senefelder, the inventor of lithography, he was one of the first artists to introduce lithography into France. His first lithograph is dated Sept. 15, 1809. Denon died in Paris on April 27, 182j. He left unfinished a history of ancient and modern art, with admirable engravings, which was published posthumously, with an explanatory text by Amaury Duval, under the title *Monuments des arts du dessin chez les peuples tant anciens que modernes* (4 vol., 1829). (Hs. H.)

DENOTATION. A *name* is said to *denote* that thing or those things of which it is a name, or to which, in other words, we intend to *refer* when we use the name. The threatened circularity of this definition (the three italicized words are not easily defined except by means of one another) suggests that we are here dealing with a basic concept, for which an axiomatic treatment may be more appropriate than definition. And though, for a fixed formalized language a definition of *denotation* of names in that language is possible, there is no definition available for *denotation* in general except by semantical terms closely related to it *(see* SEMANTICS IN LOGIC). *See* the article NAME (IN LOGIC), where the denotation of names in natural language is discussed more fully. And for the distinction of denotation and connotation, *see* CONNOTATION.

(Ao. C.)

DENSITY, or mass per unit volume, is an important and easily measurable property of matter in all its states. The inert elements were discovered by tracing the difference in the densities of samples of nitrogen prepared from ammonium nitrite and extracted from the air. Later experiments on the density of gases have yielded information on the nature and magnitude of the forces exerted between molecules; and the densities of decomposing gases or vapours have been used to extend knowledge of the forces which hold atoms together within the molecule. Measurements of the density of liquids serve as a convenient adjunct to

their analysis, and are frequently used in the control of industrial operations. The degree of proof of spirituous liquors and the gravity of beer are determined densimetrically. The density of a solid is intimately related to its structure and to the distance apart of the neighbouring ions, atoms or molecules which constitute it. The difference between soot and diamond is due, as W. H. and W. L. Bragg have shown, to the arrangement of the identical carbon atoms from which both are built, and is reflected in the difference in their densities.

FIG. 1.—A SIMPLE PYC-

In scientific work, density is expressed in grams per cubic centimetre (c.c.) or in grams per millilitre (ml.). The difference between the two units, though small, is not insignificant: 1 ml. = 1.000028 c.c. Each density datum should be accompanied by a specification of the temperature and pressure to which it refers. When the pressure is not specified. that of one atmosphere is implied. Specific gravity is the ratio of the density of a substance to that of water at the same temperature.

Matter in the solid state is denser than in the liquid state under identical conditions; water and gallium are exceptions. Pure liquids

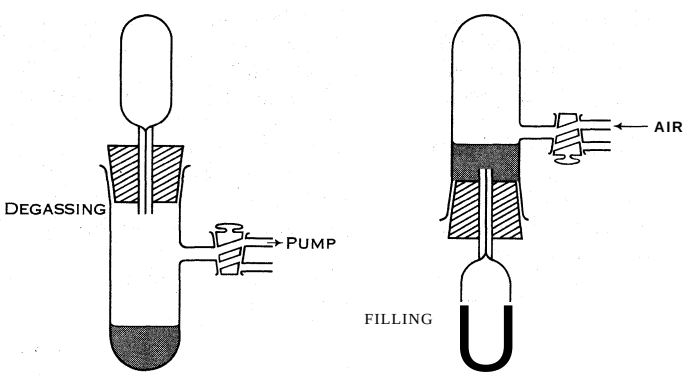

FIG. 2.— DEGASSING AND FILLING A PYCNOMETER

are denser, except at the critical point, than the vapours with which they are in equilibrium. An increase in pressure at a constant temperature and a decrease in temperature at a constant pressure generally lead to an increase in density. The densest matter is found in the interiors of the stars, and the most attenuated in interstellar space.

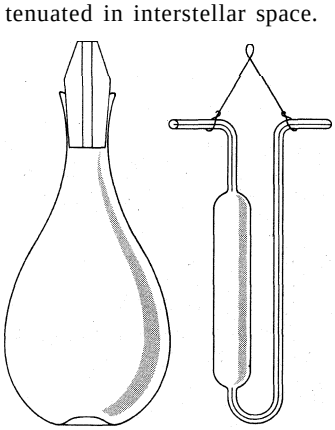

FIG 3.—OTHER TYPES OF PYCNOMETERS

The Pycnometric Determination of Density.—Of the pycnometers in use for measuring the densities of liquids, one of the simplest consists of a glass tube of about 10 c.c. capacity, to which has been sealed a length of about 4 cm. of 0.5-mm. bore capillary (fig. 1). After cleansing successively with chromic acid, nitric acid. hot water, absolute alcohol and dry acetone, the vessel, supported by wire, is weighed empty (apparent weight w_1), full of water (apparent weight w_2) and finally full of the liquid which is being examined (apparent weight w_3). A simple device for degassing the liquid and for completely filling the pycnometer is shown in fig. 2. Each weighing refers to a sample which has attained a known constant temperature. Then if W_1, W_2 and W_3 be the corrected weights in *vacuo* of the pycnometer alone and of the pycnometer filled respectively with water and the liquid at a temperature t, the specific gravity of the liquid is, by definition,

$$s_t^t = \frac{W_3 - W_1}{W_2 - W_1}$$

and the density is

$$\rho_4^t = \frac{W_3 - W_1}{W_2 - W_1} \cdot D_4^t$$

where D_4^t is the density of water at $t°$ C., relative to its value of unity at 3.98° C.

The real weights are related as follows to the apparent weights:

$$W_1 = w_1\left(1 + \frac{\rho_a}{\rho_g} - \frac{\rho_a}{\rho_b}\right)$$

$$W_2 = w_2\left(1 + \frac{\rho_a}{\rho_g + \rho_w} - \frac{\rho_a}{\rho_b}\right)$$

$$W_3 = w_3\left(1 + \frac{\rho_g}{\rho_g + \rho_l} - \frac{\rho_a}{\rho_b}\right)$$

The subscripts to the density term, p, refer to air (a), brass weights (b), water (w), liquid (l) and glass (g). Approximately, $\rho_a = 0.012$, $\rho_b = 8.5$ and $\rho_g = 2.3$ gm./c.c. Finally

$$\rho_{g+w} = w_2 \Big/ \left(\frac{w_l}{\rho_g} + w_2 - w_1\right)$$

and

$$\rho_{g+l} = w_3 \Big/ \left(\frac{w_l}{\rho_g} + w_2 - w_1\right)$$

More familiar types of pycnometers, of which there are many modifications, are shown in fig. 3 and 4. With any of these, densities can be readily measured with an accuracy of 0.0001 gm./c.c.

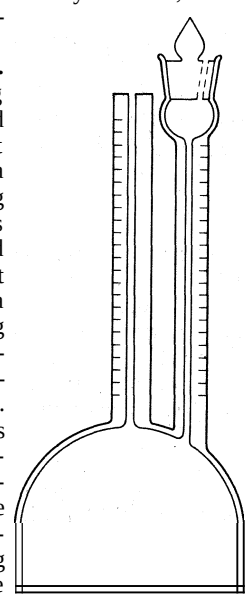

FIG. 4 —WHITING'S PYCNOMETER

The Electromagnetic Float Method.—The buoyancy method of determining density is convenient with toxic liquids and with systems which for other reasons must be sealed off. The float consists of a soda-glass vessel. F (fig. j), containing in its narrow end some soft iron turnings or a small coil of steel. A perforated plunger, P, may be used to keep the float submerged. To counteract its buoyancy, a magnetic field is produced by sending through an electromagnet, M, placed beneath the thermostat. a current of just sufficient strength, i, to pull down the float. The magnetic force acting on the float is ki^2. where k is a constant. The gravitational force acting on it in the same direction is $V\rho_o g$, where V is the volume of the float, ρ_o is its density and g is the gravitational constant. The upthrust. according to Archimedes' law, is I'pg, where p is the density of the liquid. When the current has reached the critical value, i, which is just sufficient to release the float and start it on its downward journey we have the equality

$$V\rho g = V\rho_o g + ki^2$$

or

$$\rho = \rho_o + (k/Vg)i^2$$

For a given float, V is constant; hence

$$\rho = \rho_o + Ki^2$$

The density, ρ_o, of the float, and the apparatus constant K are best measured by working with a series of liquids of known densities, such as aqueous solutions of sucrose or mixtures of di-(n-butyl)-phthalate and β-bromonaphthalene.

Binary liquid mixtures of benzene and methylene di-iodide at ordinary temperatures provide a nearly fourfold range in density. When the known liquid densities are plotted as a function of the square of the critical current, the intercept corresponding to zero current gives ρ_o and the gradient is K. The sensitivity of the method is limited only by the precision with which the current strength can be measured.

The Variation of the Density of Liquids With Respect to

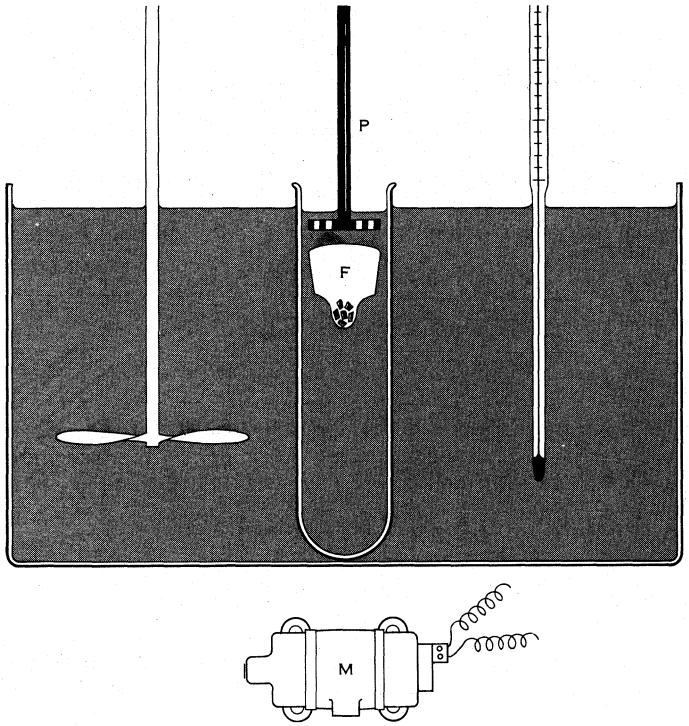

FIG. 5.— ELECTROMAGNETIC FLOAT

Temperature.— The variation with respect to temperature of the density of liquids at atmospheric pressure can be expressed in terms of the temperature, T, and of three empirical constants by means of the equation

$$\rho=\rho_o-K_1T-K_2T^2$$

The first term here denotes the density which the liquid would have if it could be subcooled to the absolute zero of temperature. Water, which has a maximum density when T is 277.14° K., is an exception. The constant K_1 is positive for all liquids, and the constant K_2 is positive for most. Among those liquids for which K_2 is negative are mercury, hydrogen fluoride and carbon tetrachloride. The coefficient of cubical expansion is defined as follows:

$$\alpha=\frac{1}{V}\left(\frac{dV}{dT}\right)_P=-\frac{1}{\rho}\left(\frac{d\rho}{dT}\right)_P$$

At atmospheric pressure, therefore, the coefficient of expansion of those liquids which obey this equation is

$$\alpha=\frac{K_1+2K_2T}{\rho_o-K_1T-K_2T^2}$$

Subcooled liquids, therefore, retain at the absolute zero of temperature a real coefficient of expansion, which is $\alpha_o=K_1/\rho_o$. This property is to be contrasted with that of solids. It is reasonably certain that α, for solid metals is zero, as it is also for molecular solids like carbon dioxide, the intermolecular separation of which varies as the square of the absolute temperature.

Empirical equations like the one discussed here are useful in predicting many properties of liquids. For example, the variation, with respect to pressure, of the heat capacity at constant pressure is given thermodynamically as follows:

$$\left(\frac{dC_P}{dP}\right)_T=-T\left(\frac{d^2V}{dT^2}\right)_\rho$$

Hence

$$\left(\frac{dC_P}{dP}\right)_T=-\frac{2MT}{\rho_2}\left[K_2+(K_1+2K_2T)^2/\rho\right]$$

We would therefore expect the heat capacity of liquids at atmospheric pressure to decrease as the pressure is increased, and this is in fact what P. W. Bridgman found (1931).

The Variation of the Density of Liquids With Respect to Pressure.— The density of liquids, as of all pure substances, increases as the pressure is increased. The relative increase in density caused by unit increase in pressure is termed the compressibility, or the coefficient of isothermal compression. This is defined in terms of the volume, V, or the density, ρ, as follows:

$$\beta=-\frac{1}{V}\left(\frac{dV}{dP}\right)_T=\frac{1}{\rho}\left(\frac{d\rho}{dP}\right)_T$$

The compressibility can be measured by observing the decrease in volume caused by sudden compression, or the increase in volume caused by sudden expansion, or by taking account of the fact that the velocity of sound is proportional to the square root of the compressibility. These methods yield an adiabatic compressibility, β^*, to which the isothermal compressibility is related by the thermodynamic equation

$$\beta=\beta^*+\alpha^2VT/C_P$$

where C_P is the molar heat capacity and V the molar volume. Accurate values of the compressibilities of all the elements and of a variety of compounds in the gaseous, liquid and solid states have been obtained by G. H. J. A. Tammann and P. W. Bridgman. The isothermal compressibility is not constant but decreases with increasing pressure; *i.e.*, substances become less compressible the more they are compressed.

Whether liquids become incompressible under enormous pressures cannot be experimentally decided. Tammann believed that liquids under very high pressures reached a limiting volume, which was independent of temperature. Bridgman, who worked with pressures exceeding 10,000 atm., showed that liquids can be compressed, at ordinary temperatures, to volumes which are smaller than those they possess at the absolute zero of temperature. Moreover, as liquids are still compressible at the highest pressures used, it seems reasonable to conclude that they could be still further compressed under still higher pressures. These points are of theoretical as well as practical importance, and have led M. Polanyi and others to speculate as to whether a pure substance can have zero entropy at real temperatures.

P. G. Tait (1888) found that the compression of water up to 500 atm. could be represented by the equation

$$\frac{dV}{dP}=\frac{A'}{B+P}$$

where A and B are constants. The former has the dimensions of a volume and is negative in sign. If we replace it by $A=-A'/V^o$, where V^o is the volume at some reference pressure, P^o, we obtain the following isotherm

$$\frac{V}{V^o}=\frac{\rho^o}{\rho}=\left[1-A\ln_e\left(\frac{B+P}{B+P^o}\right)\right]$$

Another isotherm takes the form

$$\frac{\rho}{\rho^e}=\left[1+C\beta^o(P-P^o)\right]^{1/C}$$

where the symbols bearing the superscripts refer to the density, compressibility and pressure of the liquid in some reference state (say at atmospheric pressure), and the constant C is related as follows to certain integers, n and m,

$$C=\tfrac{1}{3}(n+m+6)$$

These integers (n and m) are those required to express the potential energy, ϕ, of an isolated pair of molecules at a distance, a, apart, according to the equation of Gustav Mie:

$$\phi=Aa^{-n}-Ba^{-m}$$

The Law of Rectilinear Diameters.— The density of a saturated vapour increases with a rise in temperature. That of a liquid, as we have seen. decreases. The mean of the two decreases linearly with respect to the absolute temperature (L. P. Cailletet and E. Mathias, 1887), so that

$$\frac{d}{dT}\left[\tfrac{1}{2}(\rho_L+\rho_V)\right]=-C$$

where C is a positive constant, and the subscripts L and V refer

to the liquid and saturated vapour respectively. On integrating between the absolute zero, when ρ_V vanishes, and the critical temperature, T_c, when it is equal to p_c, we may rewrite the equation in the form

$$\rho_L+\rho_V=\rho_o-(\rho_o-2\rho_c)\ (T/T_c)$$

By plotting the sum of the densities of the liquid and its saturated vapour as a function of the reduced temperature TIT,, it is thus possible to determine the limiting density ρ_o and the critical density ρ_c. Their ratio is nearly 4 for all liquids except helium, for which it is approximately 2.

The Density of Liquid Solutions. — Let us first consider one mole of a solution to be formed at constant temperature and pressure from two components which mix without a change in volume. Then if V_i denotes the molar volume of the pure components, we have

$$V_i=x_1V_1^o+x_2V_2^o$$

where x is the molar fraction. Since the total mass of the solution is $x_1M_1+x_2M_2$ and the densities of the pure components are M_1/V_1^o and M_2/V_2^o, it follows that the density of the solution is

$$\rho_i=\rho_1^o+(\rho_2^o-\rho_1^o)\theta_2$$

where θ_2 is the volume fraction of the second component. The same result can be written in the form

$$\rho_i=\rho_1^o+(1-\frac{\rho_1^o}{\rho_2^o})c_2$$

where c_2 is the weight of the second component in 1 c.c. of solution. The coefficient of c_2 in this equation has been termed the density increment by G. S. Adair. The density of solutions of this kind thus varies linearly with respect to the concentration, expressed in grams per cubic centimetre of solution.

Most binary solutions are formed with a change in volume. Thus. for example. if we were to add successive amounts of methyl iodide at 25° C. to chloroform, so as to make one mole of mixture, we would find at first a contraction; with a mole fraction of 0.3 of methyl iodide there would be no volume change; at higher compositions, there would result an expansion. Even in simpler solutions showing only a single maximum or minimum when the molar volume is plotted as a function of the molar fraction, the results are extremely difficult to understand or even to represent analytically.

Densimetric Determination of Isotopic Composition. — Because the forces exerted by isotopic atoms are identical, their contribution to volume is also identical in all the states of matter. Hence, if ρ_1 be the density of an element or compound, and ρ_2 that of its isotope, the density of a binary solution containing a volume fraction θ_2 of the isotope is given rigorously by the linear equation

$$\rho=\rho_1+(\rho_2-\rho_1)\theta_2$$

But, because the atomic volumes, or the molar volumes, of the two components are equal, M_1/ρ_1 is equal to M_2/ρ_2, and volume fractions are identical with molar fractions. Hence the molar fraction of the second component is seen to be

$$x_2=\left(\frac{\rho-\rho_1}{\rho_1}\right)\left(\frac{M_1}{M_2-M_1}\right)$$

Most of the many investigators who have worked with heavy water have used this equation to determine the molar fraction of deuterium (heavy hydrogen) in solution.

Measurement of the Density of Gases and **Vapours.**—The density of a gas is more sensitive to changes in pressure and temperature than are the densities of liquids or solids. With ideal gases, the density, p, at a constant temperature is directly proportional to the pressure. P, and the density at constant pressure is inversely proportional to the absolute temperature, T, for we have

$$\rho=(M/RT)P$$

where M is the molar weight ($O_2=32$) and R is the universal gas constant (8.3144×10^7 ergs/mole-degree$=0.082052$ litre-atmosphere/mole-degree). This law applies also to real gases in regions of high dilution, and the limiting values of ρ/P consequently give reliable molar weights.

The principle of the methods used for measuring the density of a gas or vapour is the same as that used with liquids: a vessel of known volume is weighed empty, full of gas or vapour, and full of a liquid of known density (*e.g.*, water or mercury). In Viktor Meyer's apparatus for measuring the density of vapours (fig. 6), the liquid in A is heated until air ceases to issue from the tube B. The calibrated tube C, filled with water, is placed over B, and a weighted sample of liquid is introduced into D in a small glass phial with a glass stopper. The temperature of the jacket A is usually kept well above the boiling point of the liquid, so that, as soon as the phial is let into D, the stopper is blown off, and the liquid vaporizes. The air displaced by the vapour is collected and measured in C, at a known temperature and pressure. Its volume is equal to that of the vapour at the same temperature, and its pressure can be found in terms of the barometric reading, the height of the water left in C, the saturation pressure of water and the solubility of the vapour in it.

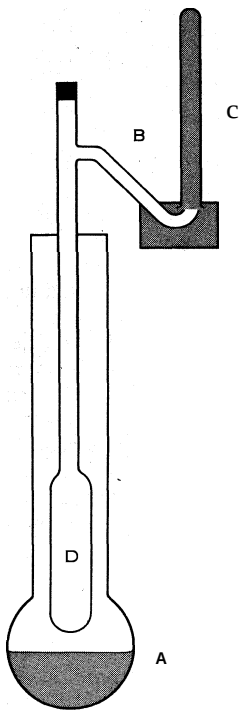

FIG. 6.—MEYER'S APPARATUS

In precise work, the pressure of the gas is measured directly, and its volume is found by weighing mercury which the sample of gas has displaced. The principle of the apparatus used by A. Michels, B. Blaisse and C. Michels (1937) for determining the densities of gases at high pressures is shown in fig. 7. Initially, the vessel A and the bell jar B are filled, and the vessel D partially filled, with mercury. A known weight of gas is introduced into B, and the mercury which it displaces is caught and weighed in the vessel D. The weight of mercury gained by D gives an accurate measure of the volume of the gas, and its pressure is measured at F. The weight of the gas is known from the volume which has been admitted, at low pressures, into B.

Isotherms of Gases. — Any relationship between the pressure and volume of a system at a constant temperature is termed an isotherm. Results obtained at the Reichsanstalt, Berlin, are given in the form

$$PV=A+BP+CP^2+DP^4+\ldots$$

where P is the pressure of the gas, and B, C, . . . are constants at a constant temperature. Results of the Dutch chemists working at Leyden are given in terms of the density of the gas:

$$PV=A+Bp+Cp^2+\ \ldots$$

The constant B is known as the second virial coefficient, C as the third, and so on. Each is a function of the temperature. The product PV, being an extensive property of the system, depends in magnitude on the amount of substance in it. The Leyden convention is to take as unit quantity of gas that amount which will make

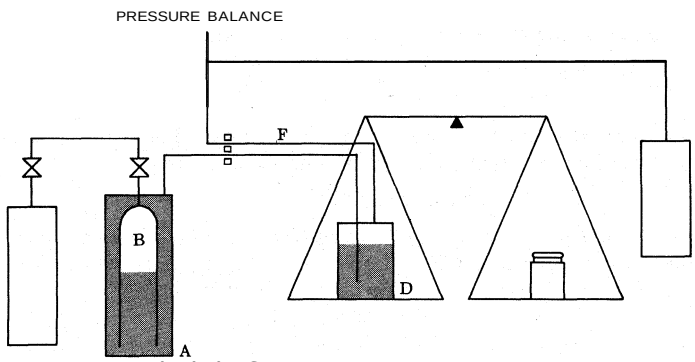

FIG. 7.—APPARATUS OF MICHELS. BLAISSE AND MICHELS

A exactly unity at 0° C. and at atmospheric pressure. If under these conditions the gas obeyed the ideal laws, the amount concerned would be $PV/RT = 1/0.082054 \times 273.16 = 0.044613$ gram-mole in one litre.

Real gases are not quite ideal under the conditions stipulated, and the amount of gas to which V refers differs slightly from gas to gas. Thus, for example, the Amagat unit of density for carbon monoxide is 0.044643 moles per litre, and for ethane is 0.045064. PV values are often given correctly to *1* part in 10^5, and densities to *1* part in 10^6. From sets of such isotherms obtained by Michels and his collaborators in the van der Waals laboratory, he derived accurate values of the changes in entropy, heat capacity and other thermodynamic properties of several pure gases and gas mixtures under varying conditions. Starting from the Leyden isotherm in the form $P = RT\rho + Bp^2 + C\rho^3$ and neglecting higher terms, the heat capacity at constant volume is found to be given by the equation

$$C_V = C_V^0 - (\rho - 1)T\frac{d^2B}{dT^2} - (1/2)(\rho^2 - 1)T\frac{d^2C}{dT^2}$$

In this way A. Michels and J. Strijland (1952) have shown that the heat capacity of carbon dioxide, at temperatures in the neighbourhood of the critical temperature, at first increases with an increase in density, and then rises to a sharp maximum at the critical density.

The virial coefficients can be interpreted in terms of intermolecular forces, as was shown by Lord Rayleigh. If, for example, the second virial coefficient alone is considered, and the isotherm is expressed in terms of the molecular concentration, n*, in molecules per cubic centimetre, $PV/NkT = 1 + Bn^*$, where N is the total number of molecules in the volume V, and k is Boltzmann's constant. The approximate theoretical interpretation of B for symmetrical molecules is

$$B = \frac{2\pi\sigma^3}{3}\left[1 - \frac{3\left(\frac{n^n}{m^m}\right)\frac{1}{n-m}}{(n-3)(m-3)} \cdot \frac{De}{kT}\right]$$

where σ is the distance to which the centres of two isolated molecules come when their interaction energy is zero, D_e is the energy required to dissociate an isolated pair of molecules from its most stable state, and n and m are integers. By plotting the experimental values of B as a function of $1/T$, both constants can be evaluated. They enable us to calculate the interaction energy, ϕ, of an isolated pair of molecules at any separation, a, using the equation of Gustav Mie:

$$\phi = \frac{D_e}{n-m}\left(\frac{n^n}{m^m}\right)^{1/(n-m)}\left[\left(\frac{\sigma}{a}\right)^n - \left(\frac{\sigma}{a}\right)^m\right]$$

The integer m is less than n and is generally known, being 6 for nonpolar molecules, according to the dispersion theory of F. London (1931).

The Density of Solids.—Many different methods are again available, based on the same principles. One consists of weighing the solid, of volume, V, and density ρ_s, first in air of density ρ_a and then in a liquid of density ρ_l. In the first case, the force acting downward on the left pan of the balance is

$$V(\rho_s - \rho_a)g = W\left(1 - \frac{\rho_a}{\rho_s}\right)g$$

where W is the real mass of the solid in *vacuo*. The force on the right pan is

$$w_1\left(1 - \frac{\rho_a}{\rho_b}\right)g$$

where w_1 denotes the observed brass weights. These forces are equal, so that the real mass of the solid in *vacuo* is

$$W = w_1[1 - (\rho_a/\rho_b)]/[1 - (\rho_a/\rho_s)]$$

If w_2 denotes the brass weights necessary to obtain a balance when the solid is suspended in a liquid of density ρ_l, in which it is completely submerged, we now have the equality

$$V(\rho_s - \rho_l) = w_2[1 - (\rho_a/\rho_b)]$$

On dividing one expression by the other and rearranging the terms, remembering that $\rho_s = W/V$, we obtain the following expression for the density of the solid:

$$\rho_s = \frac{W_1\rho_l - W_2\rho_a}{W_1 - W_2}$$

A slight correction is necessary to allow for the interfacial tension exerted between the liquid and the fine wire used for suspending the solid in it. It will be seen that, if W_2 were zero, ρ_s would equal ρ_l. This leads us to another method of finding the density of a solid. It is to place it successively in a series of liquids of varying densities, in some of which it rises and in some of which it sinks, until a liquid is found of such a density that the solid neither rises nor sinks in it. This method has been successfully used in an accurate determination of the density of hemoglobin in aqueous solution.

Nicholson's hydrometer (fig. 8, after J. Reilly and W. N. Rae, *Physico-Chemical Methods*, 4th ed. [1943]) provides an interesting. though not accurate, method of measuring the density of a solid without using a balance. Weights are first added to the top pan until a mark on the hydrometer stem is in the liquid surface. Different weights are required to bring the hydrometer to the same position when the solid is placed. secondly. in the top pan and, finally, in the bottom pan. From these three weights, the density of the solid is readily estimated.

In principle, the determination of internuclear distances in crystals by the methods of X-ray reflection and electron diffraction offers a highly accurate means of determining their densities, but a difficulty has arisen which until recently was unexpected. If molecules in a crystal are symmetrically arranged, and the distance between the centres of neighbouring molecules is a, the volume of a specimen of crystal containing N molecules must be $V = \kappa Na^3$, where κ is a structural constant, of order of magnitude unity. In a body-centred cubic arrangement, for example, κ is $4/3\sqrt{3}$, and in a face-centred cubic lattice, κ is $1/\sqrt{2}$. The molar volume is $V_m = \kappa N_o a^3$, where N_o is Avogadro's number which is known from a variety of experimental sources to be 6.024×10^{23}. Since V_m is also M/ρ, we see that the density of the crystal should be $\rho = M/\kappa N_o a^3$.

FIG. 8—NICHOLSON'S HYDROMETER

Densities of solids computed in this way. however, prove to be in many instances somewhat greater than the observed densities, and the differenceis not thought to be due to imperfections in the crystal lattice. Some of the molecules apparently leave their proper sites, and occupy abnormal interstitial positions, or there may happen to be at ordinary temperatures a few holes in the crystal. There is evidence that the diamond lattice attains perfection, and that the quartz and calcite lattices are not greatly lacking in it.

Crystalline alkali chlorides prepared from melts are less perfect than those which crystallize from solution. Defects in chemically pure crystals at temperatures far below the melting points are relatively few, so that, under these conditions, the intermolecular-distance method of determining the density of solids is reliable.

DENTAL AUXILIARIES are persons qualified by training and experience to perform dental work under the direction and supervision of the dentist. Some of these auxiliary persons work directly for the dentist in his own office; others work in a separate office or laboratory, in which case they perform services to the dentist on the basis of work authorizations or prescriptions. There are three principal dental auxiliary groups: the dental hygienist, the dental laboratory technician and the dental assistant. The great majority of dental auxiliary persons are women, who

serve either as hygienists or as assistants; a high percentage of laboratory technicians are male. Very few hygienists or assistants make a lifetime career of these vocations, and they remain in active practice on an average of only five or six years. The laboratory technician stays in the laboratory industry longer than this as a rule, but in the United States, though not in Great Britain, there is a very high turnover of persons entering and leaving this craft each year. Since all dental schools instruct students in the effective use of dental auxiliary personnel, demand by dentists for the services of hygienists, laboratory technicians and assistants is expected to increase substantially over the next 10 to 15 years.

Dental Hygienist. — The hygienist, working under the direction of a licensed dentist, cleans and polishes the patient's teeth and gives advice on the care of teeth. If she works for a dentist in private practice, she may also take and develop X-ray pictures of the teeth, mix filling compounds and otherwise assist the dentist in his work with the patient. In the United States hygienists are also employed by public-school systems to visit schools, examine the teeth of the children periodically and refer to the dentist cases in which more extensive dental health treatment is indicated. Some hygienists are employed in hospitals and public health clinics; in the hospitals they may be called upon to work with bed and ambulatory patients who require limited prophylactic treatment. In some dental offices, dental hygienists are permitted to apply fluorides to the teeth of the patient.

The profession of dental hygiene got its start largely through the efforts of Alfred Fones, and the first school was established in 1913 by Fones in his home. Of the dental auxiliaries in the U.S., the hygienist is the only one who must obtain a licence to practise and also is the only one permitted to work in the mouth of the patient. Her responsibilities are specified in the dental practice acts, as are the responsibilities of the dentist. The Council on Dental Education of the American Dental association (A.D.A.) accredits dental hygiene schools, of which there are more than 30; approximately two-thirds are associated with the dental programs of universities, the others with colleges or universities that do not have dental schools. The dental hygienist student may elect to take either a four-year college course leading to a bachelor's degree or a two-year college-level course for which she receives a certificate or diploma in dental hygiene. The four-year degree program includes two years of regular college training and a two-year specialized course in dental hygiene; the two-year program includes only the specialized dental hygiene course. Whether the dental hygiene student takes the two- or the four-year training program, she must obtain a licence from a licensing board in the state in which she wishes to practise. Upon passing the licensing examination, the hygienist becomes a registered dental hygienist (R.D.H.) and is then permitted to practise under a licensed dentist within the jurisdiction of the licensing agency.

Dental Laboratory Technician. — The second major auxiliary group of the dental profession is composed of laboratory technicians. Most technicians in the United States are employed by or own commercial laboratories. Of the remainder (approximately one-seventh of the total), most work for dentists in the dental office, although a few are employed by schools as teachers and by dental manufacturers and dental supply houses. A dental laboratory technician, through a prescription or work authorization form received from a licensed dentist, fabricates various appliances that the dentist uses in making restorations for the patient. The dental practice acts of the various states and territories and the District of Columbia do not permit the laboratory technician to serve the public directly. Instead, on receipt of the work order or prescription from the dentist, he fabricates full and partial dentures, crowns and bridges and other prosthetic devices needed by the dentist for the patient. The laboratory technician is not permitted to fit into the patient's mouth the appliances that he fabricates, nor is he permitted to take the impressions of the patient's tooth and jaw structures from which the dentures and other devices are fabricated.

Most technicians in the United States have been trained by the laboratories or the dentists in various types of on-the-job training programs; however, a few formal two-year training programs, developed by the American Dental association in co-operation with the National Association of Dental Laboratories and accredited after 1948 by the Council on Dental Education of the American Dental association, are in operation, and it is expected that larger numbers of laboratory technicians will be trained in the formal training programs. Requirements were established and approved by the American Dental association in the latter part of 1957. The training program extends over a period of two years and is divided into two parts of one year each. The first year, for which a high-school diploma or its equivalent is a requirement, may be offered by public-school systems as vocational or technical post-graduate training programs, or by junior colleges, technical institutes or dental schools. The second year is designed as an experience program and in most cases is conducted in commercial dental laboratories that have been approved for such purposes by the Council on Dental Education of the A.D.A. The second year is intended to give the student practical experience in all phases of dental laboratory technology and permits him to earn and learn simultaneously.

In 1958 the National Association of Dental Laboratories established the National Board for Certification, an agency empowered to grant certificates to certain laboratory technicians who can demonstrate exceptional knowledge and skill in the technology of the craft. These technicians, to be eligible for certification by the National Board for Certification, after Jan. 1, 1963, must have successfully completed the two-year formal educational program and give evidence of having an additional three years of experience in the craft, either in general technology or in one of the recognized special fields of technology. A certificate is awarded to dental laboratory technicians who have fulfilled these requirements and who have passed examinations prepared by the certification board to evaluate the level of the applicant's knowledge and skill. Although the certificate is in no sense a licence, it attests to the high standards of performance, skill and knowledge that the holder has achieved.

Dental Assistant. — About 65% of all the dental auxiliaries are dental assistants, and most of these are women; male dental assistants are used by the armed forces, but few, if any, continue in this vocation as civilians. The duties of a dental assistant vary extensively according to the degree to which the dentist elects to delegate the duties of his practice that do not require professional knowledge. In general, however, the assistant is expected to receive and prepare patients for dental treatment; to prepare materials and equipment for use by the dentist, including sterilizing and laying out instruments; to know instrument and equipment nomenclature; to keep records of appointments, examination, treatments and supplies. A growing number of assistants are being trained to assist the dentist at the chair in restorative dentistry, in surgical operations and in prosthetic dentistry; many also are being trained to perform dental X-ray work. Regardless of specific assignments in the dental office, all assistants need to have the ability to work in a clinical atmosphere, to follow written and oral instructions and to handle delicate instruments and materials without damaging them; all should be able to demonstrate tact, courtesy and understanding in dealing with the dental patient.

Many dentists train assistants in their own offices, but increasing numbers who enter this field do so through formal educational programs. These formal courses vary, in the United States, from about six months in length to two or more years of college work; there is no well-defined curriculum for the dental assistant. A large number of dental assistants take a short, 104-hour extension study course (frequently given as a night school study program) to prepare ior examinations leading to a certificate in dental assisting. Dental assistants may be certified by the Certification board of the American Dental Assistants association. The certificate demonstrates that the assistant has attained the requisite amount of education and experience and has a high standard of knowledge and skill; it is in no sense a licence, but it recognizes proved accomplishment. (SR. PN.)

Great Britain. — In Great Britain, taking the conditions described that apply to the United States as a basis, the dental

hygienist, the dental laboratory technician and the dental assistant are the classes of assistants who help the dentist. The term dental auxiliary is used separately for a fourth class of assistant who is an ancillary worker, for whom an experimental scheme was begun in Great Britain under the Dentists act, 1957. The dental auxiliary was to be permitted to carry out certain types of dental treatment under the supervision of a dentist in the local education and health authority dental services. In most countries with an efficient dental service, there has been much opposition to this category of dental auxiliary, though, because of the shortage of dentists, it was introduced in New Zealand in 1921 under the title of dental nurse. British dental auxiliaries can carry out the same dental work as dental hygienists, but, in addition, they are permitted to extract deciduous teeth under local anesthesia and to undertake simple dental fillings likely to be required up to the time of leaving school. The course should extend over two years, and be followed by an examination.

Courses of training in dental hygiene and the use of dental hygienists were started first in the Royal Air Force in 1943. After World War II training was also given under the auspices of the ministry of health, after which the hygienists were employed in hospitals under a registered dentist. Following the Dentists act, 1957, the course of instruction given by training bodies should extend over not less than nine months, and be followed by an examination. The great majority of hygienists are women, and the types of dental work that they are permitted to carry out are similar to those outlined above; they do not visit schools for the purpose of examining children and referring those requiring treatment to a dentist, but they might visit to give advice on matters relating to oral hygiene. They are permitted to work under the direction of a dentist in his practice.

Dental laboratory technicians are mostly trained and perform duties as in the United States; they are chiefly men and serve an apprenticeship, usually for five years. Few have taken a recognized technical examination. The City and Guilds of London have organized a schedule of instruction in a wide range of subjects to be given in local polytechnical schools, and also grant a certificate to candidates who have been successful in passing the test examination Dental technicians carry out the mechanical procedures that have already been described. and it is illegal for them to undertake any work in a patient's mouth, such as taking impressions or fitting dentures.

Dental chairside assistants are practically always women, and the duties are similar to those of assistants in the U.S. Most of them receive their training from dentists. but formal courses of instruction are available in some dental hospitals. The length varies from six months to two years, and is followed by an examination by the training body. There is also a certificate examination, available equally to those trained in private practice and hospitals. This examination is organized by the Dental Nurses and Assistants' society.

DENTATUS, MANIUS CURIUS (3rd century B.C.), Roman general, conqueror of the Samnites and of Pyrrhus, king of Epirus, was born of humble parents, and was possibly of Sabine origin. In 290 B C.. when consul with P Cornelius Rufinus. he gained a decisive victory over the Samnites. which ended a war that had lasted 50 years. He also reduced to submission the Sabines, who were in revolt, and who subsequently were incorporated into the Roman state and received Roman citizenship without the right of voting. With the proceeds of the spoils Dentatus cut a channel to carry off the waters of Lake Velinus. so as to drain the valley in which the town of Reate (modern Rieti) lay. In 284 he was elected to take the place of the consul L. Metellus Denter, killed by the invading Senones. and defeated them. He also defeated the Lucanians. In 275, after Pyrrhus had returned from Sicily to Italy, Dentatus (again consul) took the field against him and defeated him finally near Beneventum (Benevento) Dentatus was consul for the last time in 274. As censor in 272 he began to build an aqueduct to carry the waters of the Anio river into the city, but died (270) before its completion. Dentatus was idealized as a model of old Roman simplicity and frugality by later writers

DENTIL, in architecture, a small, rectangular block, used in a row as a decoration for the bed molding of a cornice. It was undoubtedly a decorative interpretation in stone of projecting beam ends in earlier wooden construction, and many of the famous rock cut tombs of Lycia, in Asia Minor, which represent wooden structures, show similar forms. Moreover, the tomb of Darius at Nakshi Rustan (c. 486 B.C.), which represents the entire front of a Persian palace, plainly shows the beam ends appearing as a dentil band. In ordinary classic usage the dentil decorates the cornices of the Ionic and Corinthian orders (see ORDER). The Attic custom, followed generally by the Romans and the Renaissance architects, kept the dentil relatively small, and spaced the dentils with an interspace of about half the width of the block itself. Occasionally, as in the Pantheon at Rome (c. 120), an unbroken band, known as a dentil band, replaced the separate dentils.

In the Hellenistic temples of Asia Minor, such as the great temple of Athena Polias at Priene (c. 334 B.C.), the archaic type heavy Ionic entablature was used, in which the dentils were much enlarged, more widely spaced and resembled brackets. The Byzantine dentil was a specific type of band ornament, possibly with little relation to the classic dentil, and was used especially as a border for panels. It consisted of an alternation of projecting blocks with splayed faces between, usually arranged in a double band, with the blocks on one side of the centre, in every case opposite the splays on the other. It is so found bordering the marble panels of Hagia Sophia at Constantinople (6th century), and became a favourite ornament in Venice, where it was used as a panel mold, as a horizontal band and around arches.

DENTISTRY is the healing art concerned with the health of the mouth, especially the teeth. It is also the profession practising this art.

Of the many conditions of the mouth treated by the dentist, the three that occupied most of the profession's attention throughout its history are dental caries (or decay of the teeth) and its consequences, disease of the supporting and investing structures of the teeth (periodontitis, commonly called pyorrhea) and irregularities (malpositions) of the teeth.

Caries. the principal problem of dentistry, is produced by acid dissolution of the calcium salts which constitute most of the tooth. W. D. Miller showed, 1880–90, that microorganisms participate in the formation of the acid. Destruction begins in spots on the surface where the microorganisms are undisturbed; and the action is believed to occur within a few minutes after carbohydrate foods, especially sugars, are taken into the mouth. In saliva, these are transformed, through products of the microorganisms, into lactic acid or other organic acids. Caries, from its inception, is a liability of the tooth, because it may lead, successively, to loss of part or all of the crown, involvement of the dental pulp, infection of the structures about the end of the root, loss of the entire tooth, or impairment of health by dissemination of the infectious influence through the circulation. Dentistry may prevent or remedy, by treatment, all of these conditions. Preventive measures, although logically the first step in combating caries, were largely neglected until the early years of the 20th century. The historical order in which measures were taken against the destruction of caries was probably: (1) use of medicinal applications to the teeth when toothache was present; (2) removal of affected teeth after the inefficacy of medicinal remedies became generally apparent, and the substitution of artificial teeth; (3) removal of the decay and restoration artificially of the lost part—the means most largely employed after the early 19th century; and (4) steps to prevent the disease or arrest it at an early stage.

Operative Dentistry.—This phase of dentistry aims to conserve the tooth and restore it, when carious, before the crown is lost. The first step in filling is preparation of the cavity. Before 1800 the preparation was limited to gaining access to the cavity and to removing the decay. From 1800 to 1860 attention was given to modifying the cavity so that the filling would not be displaced. From 1891 to 1900, largely through G. V. Black. cavity

preparation was systematized and modification of the cavity outline, called extension for prevention. was introduced to prevent recurrence of decay. After 1907, slight modifications were made for the cast-gold inlay.

The earliest fillings known, placed during the middle ages, were resins, waxes and gums. In the late middle ages leaf metals—particularly lead and gold—were employed. Gold was used as early as 1450. In 1855 Robert Arthur introduced the technique of cohesive gold foil, in which the foil was heated to render the surface pure, and cold welded in the cavity under pressure of hand instruments. When the cohesive property was understood and a control of saliva was found in the rubber dam (invented by S. C. Barnum in 1864), cohesive gold became, by 1875, the preferred filling, since by it alone the form of the tooth could be restored. Cohesive gold serves perfectly as a preserver of the tooth, but because of the tediousness, for patient and dentist, of placing it, it was partly superseded, after about 1910, by silver amalgam and the cast-gold inlay. Amalgam was introduced by 1828. It consists of silver or some of its alloys combined with mercury to make a plastic mass that can be adapted to the cavity and will harden within a reasonable time. Because of leaky margins of fillings and the unfounded belief that the contained mercury could affect the patient's health, amalgams were not altogether in good repute until after 1895. Then the experimental work of G. V. Black placed them upon a scientific basis. In posterior teeth, amalgams are satisfactory fillings and are the most frequently placed.

In 1907 William H. Taggart introduced a practical method of making cast-gold inlays. An impression of the cavity is taken in wax; after this has been invested with an artificial stone material to form a mold, and the wax burned out, molten gold is forced into the mold. The resulting casting is cemented into the cavity. Methods of compensating for the shrinkage of gold upon solidifying made the gold inlay a satisfactorily fitting restoration, and the advantage of restoring the anatomical contours of the tooth often gives it preference. The gold inlay largely restricted the use of gold foil. An ideal filling material unites durability with appropriate colour. The durable materials, mentioned above, are all lacking in tooth colour; the materials with aesthetic properties lack durability. Baked porcelain inlays (c. 1889) and silicious cement (1904), improperly called synthetic porcelain, have been extensively employed. About 1938 inlays and fillings of synthetic resins began to be tried. These restorations have high aesthetic properties but lack hardness comparable with tooth structure. Other materials—oxychloride of zinc cement (1860), zinc phosphate cement (1878) and gutta-percha (1848)—have been used for temporary or special purposes.

Endodontics.—When caries penetrates to the pulp, toothache usually occurs, and the actual or potential diseased condition of the pulp must be considered in the treatment. In children's teeth, where the root end is not completed, sometimes capping of the pulp with filling material has been resorted to. In other cases, ordinarily, the pulp is removed if the tooth is retained. Until about 1880, extirpation of the pulp was regarded as out of harmony with current pathological principles; nevertheless. after 1836. with the introduction of arsenic by J. R. Spooner to destroy the pulp, the practice of pulp removal increased greatly because the operation became almost painless. Recognition, after 1880, that microorganisms are responsible for pulp disease was thought justification for pulp extirpation on theoretical grounds; and for the next 30 years, drastic germicidal methods were employed to sterilize root canals. About 1910 dentists began to realize that these methods often lead to injury of the structures about the root end, with the result that this region becomes vulnerable to further infection. which may be extended to other parts of the body.

An address by William Hunter criticizing dental practices, especially in croun and bridgework, and disregard for dangerous septic conditions prevailing in the mouths of patients greatly influenced dentists and physicians to consider general health in relation to conditions of the teeth. X-rays played an important part in the discovery of these conditions. As a result, some dentists advocated extraction of all teeth with involved pulps. Others resorted to more conservative measures of pulp removal, using milder antiseptics; and in general substituting an aseptic technique for more drastic antiseptic measures. In place of arsenic, cocaine (1890) and procaine (1906) were employed for anesthetizing the pulp for removal. When the pulp is removed the root canal should be completely filled to the apex of the tooth, and for this purpose gutta-percha was generally employed after about 1870.

Prosthetics.— This is the substitution of artificial replacements for lost natural parts. Strictly speaking, a filling is a prosthesis but, conventionally, prosthetic dentistry is confined to the restoration of whole crowns and lost teeth.

Removal of Teeth.— Extraction was practised in ancient Greece, for it was recommended in the Hippocratic literature (5th century B.C.). Until about A.D. 1400, surgeons believed in extracting only loose teeth, and relied on crude prying instruments and ill-adapted forceps. During the period 1400–1750 new and powerful instruments—such as the "pelican" and the "turnkey"—made possible the removal of firm teeth quickly, but not always without injury to the jaw or other teeth. From 1830 to 1840 improved forceps designed for the various types of teeth ensured more scientific extractions. The introduction of general anesthesia. after 1844, made possible the painless and careful removal of teeth in accordance with surgical principles known, but inapplicable, in antiquity. The use of local anesthetics after 1905 still further facilitated extraction. X-rays aided proper extraction of the teeth by revealing the shape and condition of the root to be removed. Because extraction of septic teeth may have serious complications, some oral surgeons, about 1915, recommended alveolectomy, or surgical extraction; *i.e.,* removing surgically the bone overlying the root, and lifting the tooth from its socket, instead of the usual forceps removal.

Preventive Dentistry.— Preventive dentistry aims to anticipate and control all forms of dental trouble. It was given attention in 1743 by Robert Bunon, but was not stressed until after 1910. The commonest preventive measures, practised from early times, are oral hygiene such as toothbrushing by the patient and prophylaxis, or cleaning of the teeth, by the dentist. These measures are helpful in preventing caries and periodontitis, but have not proved sufficient. Operative measures were also employed; *i.e.,* permanent separation of the teeth by filing away their contacts (1800–80), Black's extension for prevention, and the cutting out and filling of fissures of the enamel on the chewing surfaces. After 1846 silver nitrate was applied to tooth surfaces to immunize them temporarily against caries. In 1936 efforts began to combat caries by the use of chemical substances. These were intended either to interfere with the chain of reactions which caused acid to be formed on the teeth. or to make the teeth less soluble to acid, or to reduce the number of microorganisms involved in the production of acid. The chief substances that have been used are fluorides, ammonium compounds, penicillin and so-called antienzymes. These substances have been added to some dentifrices. Sodium fluoride has been added to the drinking water of many communities to raise the fluoride concentration to about 1 part per 1,000,000. This measure has reduced the incidence of caries by as much as 60%. Fluoride solution has also been applied topically to the teeth. Reduction of sugar consumption has been recommended as a means of reducing incidence of caries.

Public Health Dentistry.— This is concerned with the provision of dental service to groups of persons through agencies other than private practice. About 1910 began an increased tendency to regard dentistry from the viewpoint of prevention and public health. Oral disease prevalent throughout the world had not received adequate care. and the supply of dentists was insufficient to furnish the care needed. In some countries, as Sweden, the state undertook to provide dental service to persons unable to pay the charges of dentists. In England, beginning in July 1948, the government, under the National Health act. provided from the public funds complete dental service to all applicants. In the United States many different agencies began to furnish dentistry to groups, but no large integrated system was instituted. The emphasis was placed upon limited dental service to children. A. C.

Fones, in Bridgeport, Conn., between the years 1914 and 1924, was responsible for the maintenance of dental service for the school children of that city. This project resulted in important decrease of dental disease and in reduction of the number of children failing in school. Fones inaugurated the education and employment of dental hygienists to inspect and clean teeth and instruct in the schools. Dental hygienists have been employed throughout the United States, and many states have given them a legal status.

Privately endowed clinics were established in several localities. Among these were the Forsyth dental infirmary (1915) in Boston; the Walter G. Zoller Memorial dental clinic (1936), Chicago; the Rochester dental clinic, endowed by George Eastman (1915); various other dental clinics in large European cities, also endowed by Eastman; the Guggenheim dental clinic in New York city; etc. Other private organizations and funds—such as the W. K. Kellogg foundation (1930) and the Children's Fund of Michigan, created by James Couzens (1929)—supported dental public health work. Large industries began to give employees dental service. City and state governments, the United States public health service and the children's bureau (under the Social Security act of 1935) also instituted or supported public health dentistry. The nature and extent of the service is extremely variable. Educational work and dental inspections are common in public schools; prophylaxis is sometimes included; fillings and extractions are less commonly provided. Buenos Aires Arg.. established (1934) municipal clinics furnishing all services. including orthodontics.

Professional Development.— Dentistry as a vocation existed in ancient Roman times: Martial mentions one Cascellius who "removes or restores a bad tooth." Dentistry received some recognition as a profession in France during the 18th century, but institutions characteristic of a profession did not appear until 1840. Previously, dental education was secured largely through apprenticeship to dentists and technical craftsmen. In 1839–40, in the United States, the first regular dental school (the Baltimore College of Dental Surgery), the first dental journal (the *American Journal of Dental Science)* and the first national dental organization (the American Society of Dental Surgeons) were established. Similar developments took place a few years later in England, Germany and France. Considerably later, effective measures for licensing dentists by government agencies were instituted. Technical literature on dentistry began with Pierre Fauchard's *Chirurgien Dentiste,* in 1728. It was followed by a continuous issue of professional books in France, England, Germany and other countries. The earliest notable work in the United States was Chapin A. Harris' *Dental Art* (1839). In England the outstanding work was John Tomes' *Dental Physiology and Surgery* (1848). Periodical publication increased enormously throughout the world during the 19th century.

Dental education in the United States is carried on independently of medicine and surgery. From a few months, the dental course was gradually lengthened until, by 1940, it consisted of two years' predental study in college and four years in dental school. The course covers basic sciences, medical sciences and technical training, as well as clinical practice. In England the first licences were issued by the Royal College of Surgeons in 1859, and the dental profession remained largely under medical control. Two views of dentistry competed for supremacy throughout its history, especially in Europe—that of the stomatologists, who consider dentistry as a specialty of medical practice, and that of the odontologists, who hold that dentistry is a distinct practice. Dentistry is completely organized in professional societies in most countries of the world. In the United States, the American Dental association is the national organization. In England, the British Dental association is the official society.

Specialization.— Specialization in the practice of dentistry developed largely in the 20th century. The specialties recognized by the American Dental association are: (1) orthodontics; (2) oral surgery; (3) periodontics (care of the supporting tissue of the teeth); (4) pedodontics (children's dentistry): (5) prosthodontics (denture work); (6) public health dentrstry; (7) oral pathology. Other services which are sometimes supplied as exclusively restricted practices are radiodontics (X-ray diagnosis), crown and bridge work, implant dentistry. dental ceramics (porcelain work), and exodontics (extraction of teeth).

The technical and scientific progress of dentistry closely paralleled the progress of science and technology generally throughout the 19th and 20th centuries. The inventions and discoveries in physical, biological and medical sciences particularly pertaining to dentistry have been, in the main, the work of dentists or persons closely associated with that profession. *See* DENTAL AUXILIARIES; ENDODONTICS; ORAL SURGERY; ORTHODONTICS; PEDODONTICS; PERIODONTAL DISEASES; PROSTHODONTICS; TEETH; TEETH, ARTIFICIAL. *See* also references under "Dentistry" in the Index volume.

DENTON, an urban district of Lancashire, Eng., comprising the townships of Denton and Haughton, lies in the extreme southeastern corner of Lancashire, 5½ mi. E.S.E. of Manchester. The river Tame, a tributary of the Mersey, forms the southerly and easterly boundaries of the district. Pop. (1961) 31,086. Records of Denton date back to the 13th century, but of the three ancient halls—Denton, Hyde and Haughton—only Hyde hall, former house of the Hydes of Denton, remains. It is a black-and-white half-timbered house dating from the 15th century. The main industry, from the 17th century, has been the manufacture of felt hats; others include the making of plastics, storage batteries, rubber, leather and cotton. Denton contains reservoirs of the Manchester water system.

DENTON, a city and seat of Denton county, Tex., U.S., is located at the northern apex of the Dallas-Fort Worth metropolitan area, about 30 mi. from each city. Denton county was created in 1846 from Fannin county and named for John B. Denton, early Texas frontiersman, Indian fighter and aide to Gen. Edward H. Tarrant. The town was settled in 1857 and incorporated in 1866.

The economy of the county is changing from agriculture to industrial urbanization. Industries include flour mills, concrete, clothing, brick, furniture and beverages. However, the city, home of Texas Women's university (1901), North Texas State college (1890) and the Denton State school, is predominantly an educational and cultural centre. The scholastic population has consistently maintained a ratio of approximately one to three of the city total. The educational, cultural and recreational advantages, together with the city's proximity to Dallas and Fort Worth, attract many middle-income home owners. Two artificial lakes, Garza-Little Elm, 10 mi. E., and Grapevine reservoir, 10 mi. S. of the city, provide water and recreational facilities. Denton has an annual agricultural fair and a rodeo.

For comparative population figures *see* table in TEXAS: *Population.* (S. B. McA.)

D'ENTRECASTEAUX ISLANDS, a group of three large islands off the eastern tip of New Guinea. are administratively part of the Milne bay territory of Papua. Pop. (1954) about 29,785. Area 1.213 sq.mi. Discovered and named by the French navigator, Bruni d'Entrecasteaux during his search for J. F. La Pérouse in 1793, they were more accurately charted and individually named (Normanby, Ferpusson, Goodenough) by John Moresby in 1873. The islands are volcanic. mountainous (5.000–8.350 ft.), and forest-clad. Indigenous and plantation copra is produced in fertile coastal patches, and numbers of the natives are employed as contract labourers in the New Guinea goldfields. Like the Trobriands, and other adjacent islands, the D'Entrecasteaux have attracted anthropological attention.

DENVER, capital of Colorado. U.S., the seat of Denver county. and the largest North American city between the Missouri river and the Pacific states, is located at the western edge of the Great Plains and is the commercial, financial and transportation centre for much of this area. The altitude of Denver is one mile above sea level, and the favourable climate is one of the city's

distinctive characteristics. Humidity is low, averaging 52%; average annual precipitation is 14.2 in. with 249 days of sunshine yearly.

West of Denver, a 150-mi. panorama of the Rocky mountains extends from Pikes peak on the south to beyond Longs peak on the north. many of the peaks retaining areas of snow cover through the summer. This combination of climate and nearby mountains has made tourism a major industry.

History. — Denver was founded in what was called the "Pikes peak or bust!" gold rush of 1859. The site had been a stopping place for Indians, fur trappers, traders and explorers. The first gold was discovered as early as 1807, and additional traces were found in the early 1850s. Reports of these finds, greatly magnified, led to serious prospecting in 1858. Rumours of success, again much exaggerated, resulted in the rush of 1859–60, in which 150,000 persons crossed the plains. The first settlements in 1858 were called Placer Camp and Montana. These gave way to rival towns straddling Cherry creek: Auraria on the southwest and St. Charles on the northeast. St. Charles, which was in the western reaches of Kansas territory, was renamed Denver City for James W. Denver, then governor of the territory. Auraria and Denver consolidated in 1860. Colorado became a federal territory in 1861, and Denver was designated the permanent capital in 1867.

The first newspaper, the *Rocky Mountain News*, was founded April 23, 1859, and was published continuously thereafter. The *News* received word of the election of Lincoln by pony express from St. Joseph, Mo., 660 mi. away, in four days. Telegraph lines reached Denver in 1863, but Indians, buffalo and storms frequently severed the wires.

Placer mining in the immediate vicinity never yielded gold in quantity. Many Pikes peakers went home as "gobacks," but just when it appeared that Denver would be depopulated by the reverse rush, rich strikes were made in the mountains in May 1859. The town was almost destroyed by fire in 1863, and a year later a flash flood in Cherry creek, which joins the South Platte river at Denver, swept away many buildings, including the city hall. Indian wars on the plains in the 1860s also were retarding factors in the city's growth and at times Denver was cut off from the nearest towns on the Missouri. Some felt Denver had been dealt a mortal blow when the transcontinental railway was built through Wyoming, but citizens organized their own railway to connect with the Cnion Pacific at Cheyenne. It was completed in June 1870, and shortly thereafter the Kansas Pacific also reached Denver. The coming of railways produced an immediate boom. In 1870 the population was 4,759; 20 years later it was 106.713.

During the 1870s and 1880s silver emerged as more important than gold. Rich mines poured wealth into Denver, mining kings were created almost overnight, and an opera house was built. This period of opulence ended with the 1893 silver panic. Banks failed, smelters shut down and silver kings became paupers. New gold discoveries helped prevent a major decline, and farming, cattle and sheep ranching and commerce began to provide a more stable economy.

The community chest plan for financing charities originated in Denver in 1887. and Denver's juvenile court, under Benjamin Barr Lindsey (*q.v.*), county judge 1901–27. was a pioneer in its field. Airplane service at Denver began in 1926. Fitzsimons army hospital was opened in 1918 and Lowry air force base in 1937. Other military installations include the U.S. Air Force academy (50 mi. S.), Rocky Mountain arsenal, Denver naval air station, the national air force finance centre, the Titan guided missile plant and Rocky Flats atomic energy project. The Denver branch of the U.S. mint produces approximately 75% of U.S. coinage and is the second largest U.S. gold depository.

Streets in the residential sections of Denver are tree lined and there is an extensive system of parkways and boulevards. Building regulations require that dwellings be set apart and back from streets, and as a result there are lawns and gardens around each home. Disastrous fires in the early days and the shortage of quality lumber led to other building regulations which make Denver a city of brick and stone construction. The state capitol (built 1887–95) and city and county building (1931–32) face each other across the 40-ac. Civic centre. The 272-ft. dome of the capitol is plated with gold leaf. Denver is youngest among the 25 largest U.S. cities and its appearance is new. The business-district skyline is relatively low. Principal features are a 330-ft. replica of Venice's campanile and several modern-style buildings of approximately the same height. Dominant structures in the skyline profile were built after 1950, the tallest being the First National bank of 28 stories (365 ft.), completed in 1958. (See also COLORADO: *History.*)

Administration and Finance. — Denver, with a land area of 66.8 sq.mi., has been a coextensive city and county since 1902. Government is by mayor and nine-member council. A commission government was in force briefly following 1912, but the mayor-council form was restored in 1916. The city is divided into councilmanic districts.

Commerce, Industry and Transportation. — The principal trade area embraces the Rocky mountain states and approximately 100 companies engage in foreign trade. Industry is light. The tno largest individual manufactories produce rubber goods and luggage. Denver Union stockyards is among the nine largest U.S. cattle markets and is the largest sheep market. Other major industries include food processing, milling, printing and publishing, steel processing and machinery manufacture. Administrative and service industries include insurance, beet sugar, oil exploration, coal. metal mining, wholesaling and automobile distribution; over 30 federal agencies have offices in Denver. The city is served by several railroads, and the municipal airport is one of the most active civilian airports in the U.S.

Education and Cultural Life. — The public-school system includes elementary, junior high and senior high schools, with an annual enrollment of about 85,000. Among institutions of higher learning are the University of Denver (Methodist, founded 1864), Regis college (Roman Catholic, founded 1888), Colorado Woman's college (American Baptist, established 1909), Iliff School of Theology (Methodist, founded 1892), Loretto Heights college (Roman Catholic, founded 1918), and the medical school and an extension centre of the University of Colorado. The Colorado School of Mines is 14 mi. away, at Golden.

The Denver Public library circulates 600.000 books and 300,000 documents. There are art, natural history and historical museums and a symphony orchestra and civic theatre are maintained.

Parks and Recreation. — There are almost 100 parks and more than 50 supervised playgrounds within the city limits and 28 mountain parks, aggregating approximately 13,500 ac. One of the mountain parks contains a natural amphitheatre seating 10,000 persons and is used for music festivals.

Population Characteristics. — The population enjoys income and educational levels above national medians. In the 1950s foreign-born residents constituted less than 6% and Negroes numbered about 15,000 or less than 4%. There was a considerable Spanish American population. Metropolitan area growth following World War II created a ring of satellite communities. Principal suburban entities. all primarily residential suburbs, were Arvada, Aurora, Brighton, Englewood, Golden, Hoffman Heights, Lakewood and Wheat Ridge. Denver experienced a marked growth following World War II, reflecting the westward shift of U.S. population. The city's population was 493,887 in 1960, with 923,161 persons in the standard metropolitan statistical area, comprising Denver, Adams, Arapahoe, Boulder and Jefferson counties. For comparative population figures *see* table in COLORADO: *Population.*

(RT. L. PN.)

DEODAND, a legal term formerly used to denote any item of personal property that had acted or had been used to cause the death of a human being. At common law in England such property was forfeited to the king in expiation for the soul of the person whose life was taken. The literal meaning of the term was "a thing given to God." A deodand might be animate or inanimate. Imputation of guilt to things incapable of reason was of ancient origin and can also be seen in the equally ancient custom of formal trials for animals accused of crime. The doctrine was a part both of the civil and criminal law.

Regardless of its pious origin, deodand became a mere forfeiture.

While originally the thing itself had to be handed over, later the forfeiture could be measured by the value of the thing as determined by a jury. By finding the value to be trifling, the jury could defeat inequitable forfeitures. Deodand came to involve many subtleties. If the thing that caused the death was in motion, its whole value was forfeited, whether the victim was an adult or an infant. If the thing was at rest and the victim an infant, there was no deodand. If the thing was not in motion and the victim an adult, the part that did the killing, like a falling cart wheel, was forfeited. Deodand could not arise at sea. Deodand as a legal concept is irreconcilable with principles of responsibility based on intent or negligence. It was never part of the law of the United States and was abolished in England in 1846. *See* also NEGLIGENCE. (G. M. Jo.)

DEODAR, or God tree (*Cedrus deodara*), is a species of coniferous evergreen tree closely allied to the cedar, its timber being of considerable value. It forms extensive forests in the Himalayas and is also found in Afghanistan and north Baluchistan. *See* CEDAR.

DEODORIZER, a substance that destroys, counteracts or masks an offensive odour, and which may or may not be a disinfectant or antiseptic. Unpleasant odours can largely be prevented by thorough cleanliness, proper refrigeration of foods, destruction of waste materials and the admission of fresh air and sunlight. However, owing to cooking, the use of tobacco, the presence of certain fabrics, pathological conditions, etc., absolute prevention is practically impossible, and substances to destroy, neutralize or mask obnoxious odours have been developed.

The glycols are chemical agents that act as solvents for many air-contained odorous substances. In spray form, minute glycol droplets dissolve or absorb the odorous molecules in the atmosphere. In vapour form, the glycols have a germicidal effect and can prevent development of odours caused by the action of microorganisms. Very low concentrations of glycols can kill air-borne bacteria.

Offensive gaseous and vaporous molecules can also be overcome by adsorption in certain solids, of which activated carbon is a versatile example. Within the carbon are innumerable cavities or capillaries that exert a powerful attraction on molecules of obnoxious substances in the atmosphere. Some other solids that have adsorptive power are silica gel, kieselguhr and fuller's earth.

The volatile molecules of such chemicals as formaldehyde or acetaldehyde in aqueous solution counteract the effect of a malodorous gas or vapour in the atmosphere, by physical attraction, molecule for molecule. When blended, the two substances lose their individual odours and produce a new odour complex. These chemicals tend to irritate the nasal membranes and have a narcotic effect on the olfactory nerve, so that an odour may be undetectable, although pungently present. In commercial preparations, however, the quantity of chemical present is too small to produce narcosis. Frequently, essential oils are added to the solution to lend their fragrance to the air. Perfumes and incense materials used alone serve only to mask the offensiveness of the atmosphere.

Disinfectants and antiseptics deodorize only by destructive contact with the microorganisms causing malodorous conditions. Some commonly known disinfectants and antiseptics are the coal-tar derivatives, cresol and phenol; such oxidizing agents as hydrogen peroxide and potassium permanganate; certain acids, of which boric acid and salicylic acid are familiar examples; the halogens, chlorine, bromine and iodine; and metallic salts, such as silver nitrate, mercuric chloride and potassium mercuric iodide. (E. L. *Y.*)

DEONTOLOGY is the title of a book by Jeremy Bentham (*q.v.*), who introduced the term to denote a utilitarian system of ethics. The name has since then come to be applied to a system of ethics in which prominence is given to ideas of duty rather than to those of right or goodness.

DEORIA, a town in Uttar Pradesh, India, is the headquarters of Deoria district. Pop. (1951) 20,156. It is connected by railways with Gorakhpur on the northwest, with Varanasi (Benares) on the southwest and with Bihar in the east. It is well served by roads which connect it with Gorakhpur, Varanasi, Fyzabad and Azamgarh.

DEORIA DISTRICT covers an area of 2,087 sq.mi. Pop. (1961) 2,372,088. The density of population (1,137 per square mile) is one of the highest in India. On the south it is bounded by the Rapti and Gogra rivers, on the west by the district of Gorakhpur and on the northeast by the Gandak river. It is in the Terai region and the whole area is a level plain gently sloping toward the southeast. (*See* TARAI). The northern tip has a monsoon type of forest, the soil is a fertile alluvium and the climate is of monsoon type (annual average rainfall 51 in.). About 86% of the population is engaged in agriculture, a large number of persons being employed in the 16 sugar-processing factories of the district. Other crops are rice, pulses and oilseeds. (M. N. K.)

DEPARTMENT, a division or part of a system; one of the branches of the administration in a state or municipality. In the United States many of the principal executive organs of government are known as departments; for example the department of state, the department of justice, etc. The subordinate components of the U.S. governmental departments are usually known as "bureaus." In Great Britain the term is commonly applied to the subordinate divisions of the chief executive offices of state. such as the savings bank or other department of the post office, the mines department of the board of trade.

In France the word is also used for a territorial division corresponding loosely to an English county. Previous to the French Revolution the local unit in France was the military *gouvernement*, roughly corresponding to the old provinces, such as Franche Comté. Provence, Bourgogne, Bretagne, etc. This division was too closely bound up with the administrative mismanagement of the old regime, however, and at the suggestion of Mirabeau, the "provinces" were divided into *dkpartements*, as nearly as possible equal to a certain average of size and population, and deriving their names principally from rivers, mountains or other prominent geographical features. In 1860 three new *départements* were created out of the newly annexed territory of Savoy and Nice. The three *départements* of Bas-Rhin, Haut-Rhin and Moselle, which were lost after the Franco-German War in 1871, were restored in 1919. Each *département* is presided over by an officer called a prefect and is subdivided into *arrondissements*, each in charge of a subprefect. *Arrondissements* are again subdivided into cantons and these into communes, somewhat equivalent to the English parish. *See* FRANCE: *Government, Politics and Law.*

DEPARTMENT STORE, a retail establishment which sells a wide variety of goods arranged in several departments. It features mainly shopping and specialty goods, including women's and misses' ready-to-wear accessories and apparel; men's and boys' ready-to-wear apparel and accessories; yard goods and household textiles; small household wares; furniture; and electrical appliances and accessories. Many department stores also have a food section and a restaurant. The organization of a department store is characterized by separation of merchandise assortments into divisions and departments supervised by individual divisional managers and department buyers; departmental divisions of merchandising, advertising, service, accounting and budgetary control functions; and varying degrees of integration with wholesaling and manufacturing establishments and functions.

The department store may be located in the business section of a large city or in a suburban one-stop shopping centre. . The distinction between the department store and the general merchandise or the dry-goods store, which is often organized on a departmental basis and renders similar service, is commonly understood as one of size.

In Great Britain, the board of trade defines a department store in wide and general terms. For the purpose of retail sales analysis, it regards as a department store any large shop actively engaged in the sale of a wide range of commodities, one of which must be clothing. Department stores usually sell women's clothing, household textiles, furniture and domestic hardware. They may also sell men's wear, food and other items. Going beyond this wide description was an attempt to define in terms of size. In 1950 the definition of size was on the basis of turnover, £100,000 being the

minimum. In 1957, the basis was altered to the number of employees engaged, and a shop with 25 or more employees would qualify as a department store provided that it satisfied the other criteria. The English approach in fact followed the pattern of the United States. In 1939 the bureau of the census had taken annual sales of $100,000 or more as the basis, but in 1948 had adopted as its definition of a department store the "normal employment" of 25 or more persons.

History.—The best authorities ascribe the beginnings of the department store to the Bon Marché in Paris, founded as a small shop in the early 19th century, which by the 1850s or early 1860s began to assume the proportions of a department store. In the 19th century many general merchandise stores, by broadening stocks and by setting up departments, converted to department stores. An example is A. T. Stewart's (now Wanamaker's) in New York city, started in 1826 by Stewart and later sold to John Wanamaker (*q.v.*). Lord and Taylor in New York also originated in 1826; among later stores were Macy's in New York (1858), Strawbridge and Clothier in Philadelphia (1868), Emery-Bird-Thayer in Kansas City (1863) and the store in Chicago organized in 1865 by Marshall Field (*q.v.*). Field's shortly became the largest department store in the world. Harry Gordon Selfridge, who started his career there, moved to London and in 1909 started Selfridge's, now as well known as Harrod's, an older English department store.

By 1900 the department store was fully established in the larger cities of the U.S., and its development was given impetus by the increasing growth of large population centres, better transportation and the harnessing of electricity for power and lighting. By 1929 the department store had reached the peak of its importance (about one-eighth to one-tenth of total retail sales, depending upon definition and data used); since that year, its importance in retail selling in the U.S. has been substantial but reduced below the 1929 level.

Up to 1920, the principal type of department store in the U.S. was the single-unit form with no branch store operations. But by 1924–25, the first chain department stores, intioduced by J. C. Penney company, were joined by Sears, Roebuck company, which began opening department or semidepartment stores in various cities (*see* CHAIN STORE). Beginning in 1929, and proceeding rapidly during the 1950s, many department stores opened branch stores t~ serve the growing suburban population. In addition, increasing numbers joined so-called "ownership groups" or buying groups, such as the Allied Merchandisers of Canada, in order to pool buying talent and financial resources. For such departments as millinery, foods and drugs, many department stores leased departments, owned by outside management but operated as though part of the department store.

Department stores or similar stores are found in almost all countries of the world, although their management and organization may differ somewhat. Moscow's famous GUM department store is entirely state controlled and therefore quite different. A distinctive feature of Canadian economy is the operation of a few department store chains, each of which has stores across the country. The T. Eaton company and Simpsons-Sears have outlets throughout Canada and do a large mail-order business as well. The Hudson's Bay company stores are mostly west of Winnipeg. In Great Britain, there is a growing tendency for department stores to be grouped. Thus Debenhams Ltd., The House of Frazer and Lewis's Investment Trust each control many department stores operating throughout the country. In all cases, general control has been centralized, but many of the stores exercise their own merchandising policy and maintain their own peculiarities and individuality.

Management.—*Competitive* Advantages.—The great appeal of the department store to customers derives from its use of the principles of functional specialization and product departmentization. Originally, central downtown locations offered accessibility to enough customer traffic to support the product assortments carried and to afford comparative shopping with other retail units. Another aspect was the offering of a wide range of "free" services such as deliveries, liberal credit arrangements, merchandise return privileges, nursery facilities and elaborate waiting rooms. Before the second half of the 20th century, considerable emphasis was placed upon introducing new types of merchandise and featuring products not traditionally handled by department stores. Such assortments were enhanced by modern building facilities, elaborate displays in windows and in departmental facilities and skilful advertising in newspapers, "shopping news" and other media.

Competitive Disadvantages.—Many of the competitive advantages outlined above have disappeared or have created offsetting disadvantages, which help account for reduction in importance of this kind of store in the U.S. after 1929. The so-called free services caused many department stores to be among the highest cost retailing institutions. Department stores have acted as a fertile training ground for management talent for competitors. The deterioration of rapid transit in cities and the congestion created by the increased use of the automobile have tended to penalize department stores located in the older business areas.

The large-scale organization also created several disadvantages. Turnover of sales personnel, caused in part by the high proportion of women employed and the continuous managerial pressure for sales volume, has led to some increasing impersonality of service to customers. With such impersonality of contacts, executives must depend on secondhand reports or upon impersonal statistical and accounting control devices.

Although department stores developed the use of newspapers as an advertising medium to a high degree, many stores did not develop skill in evaluating such advertising. The composition of the advertisements did not always compare favourably with the distinctive format of other specialty and shopping-goods stores. Nor were the department store prices always low enough.

Finally, the reduced importance of the department store may be reflected in the following difficult-to-measure but illustrative indicators: the relative competitive tactics taken by the most rapidly growing types of stores *v.* department stores; the increasing sameness among many department stores in their approach to organization, store layout and price policies; and the competitive impact of such basic trends as large shopping centre developments and discount house operations.

Department store management has taken many steps designed to improve its competitive position. Extensive modernization programs, branch store operations. improved training of sales personnel, application of self-service or partly self-service departmental layouts and more aggressive pricing have been used. Branch stores have been given more organizational autonomy. Chain department stores have expanded unit operations. Partial department store units have been used. Yet competing stores have cut into sales by expanded product assortments and by other tactics.

DEPEW, CHAUNCEY MITCHELL (1834–1928), U.S. railroad lawyer, orator and politician, was born in Peekskill, N.Y., on April 23, 1834. He graduated from Yale in 1856 and was admitted to the bar in 1858. He entered politics as a Republican, served as a member of the New York assembly (1861–62) and as secretary of state of New York (1864–65). In 1866 Depew became attorney for the New York and Harlem railway and in 1869 was appointed attorney of the newly consolidated New York Central and Hudson River railway, bf which he became a director and second vice-president. In 1875 he became general counsel for the entire Vanderbilt system. Depew became president of the New York Central and Hudson River railway in 1885, and in 1898,

chairman of the board of the Vanderbilt system. Depew joined the Liberal Republican movement in 1872 and ran for lieutenant governor of New York but was defeated. In 1899 Depew was elected to the U.S. senate and served until 1911. Depew's fame rests on his ability as an orator and after-dinner speaker. He died April 5, 1928. in New York city.

DEPORTATION AND EXILE. Both in the United States and the United Kingdom the term deportation is used to refer to the expulsion of an alien by an agency of the executive (in the U.S. by the immigration and naturalization service of the department of justice, in England by the home office) (see ALIEN; MIGRATION). Transportation refers to a system of punishment for crime involving the removal of the criminal to a penal settlement outside his own country. Exile is applied to prolonged absence from one's country either by authority of the sovereign or by voluntary action of the individual; the person who is outside his country under these circumstances is referred to as an exile. Deportation and exile are to be distinguished from exclusion and extradition. Exclusion is the process whereby the governing authority of a country refuses to admit an alien to its shores or rejects him. Extradition (*q.v.*) is the procedure which is invoked to secure the removal of a criminal to the state or country from which he has fled and which has jurisdiction over the crime committed by him.

Origins.— Exile or banishment may be traced from the biblical account of Adam and Eve's expulsion from the Garden of Eden to the punishment of tribal law declaring the tribal member an outcast and through the penal exile of the ancient Greeks and Romans. Thereafter came the outlawry for offensesin Anglo-Saxon law and the practices of many European countries of removal of criminals to penal settlements like the notorious Devil's Island and Siberia. In modern times, revolutions overthrowing dictatorships have added to the number of history's exiles.

The practice of exile and banishment probably originated as a primitive punishment of tribal law declaring an offending person an outcast and depriving him of the comfort and protection of his tribe. The Greek city-states borrowed banishment from their Ionian, Aeolian and Dorian ancestors. Among the ancient Greeks exile was chiefly known in connection with cases of homicide. The punishment of the murderer was originally the duty and the privilege of the relatives of the murdered man. Unless the relatives could be induced to accept a money payment as compensation, the criminal's only means of escaping punishment was flight and exile in a foreign land. If, during his self-imposed exile, the relatives agreed to accept the indemnity, he was at liberty to return and resume his position in society. Later, exile for life with confiscation of property was inflicted as a punishment for particular crimes. In time, exile came to be the established legal punishment for homicide in Greece and was imposed by the tribunal known as the ephetae. Under a law of Solon it was also the penalty meted out to those who remained neutral during a sedition. At times exile was a political measure adopted especially during civil disturbances, and a special form of banishment known as ostracism (*q.v.*) was sometimes imposed upon those considered dangerous to the welfare of the state. Greek citizens of Athens sometimes left the state for other reasons, such as debt or inability to pay a fine. Since extradition was utilized only for serious crimes, the fugitive was not troubled by the authorities and was free to return after a certain time had elapsed.

Originally there was no such thing as expulsion from Rome. A person, however, might be cut off or interdicted from fire and water (aquae et ignis interdictio), the symbols of civic communion and the necessities of everyday life. This, for all practical purposes, forced the individual to leave the country. The interdiction of fire and water was inflicted by the Roman assembly of the centuries (*comitia* centuriata) and later by a judicial commission appointed to try certain serious offenses such as treason, arson and poisoning. Exile in Rome was originally not a punishment but a means of escaping punishment. Before judgment had been finally pronounced, it was open to any Roman citizen condemned to death to escape the penalty by voluntary exile. If he broke the exile and returned anyone had the right to put him to death. Subsequently (probably at the time of the Gracchi) the interdiction of fire and water became a recognized legal penalty, practically the equivalent of exile, and took the place of capital punishment. The criminal was permitted to withdraw from the city after sentence was pronounced, and his withdrawal was sanctioned by a decree of the people which declared his exile permanent. Authorities are not agreed whether this exile by interdiction automatically involved loss of citizenship and all civil rights. It is, however. clear that only in rare cases mas it accompanied by confiscation of property.

Under the Roman empire, interdiction by fire and water was replaced by two types of banishment known as deportation (*deportatio*) and relegation (relegatio). Deportation consisted in transportation for life to an island (or someplace prescribed on the mainland, but not of Italy). Since deportation was generally to an island, the Romans came to refer to this type of banishment as deportatio in *insulam*. It was accompanied by loss of citizenship, loss of civil rights and confiscation of property. The most dreaded places of exile were the islands of Gyaros, Sardinia and an oasis in the desert of Libya; Crete, Cyprus and Rhodes were considered more tolerable. Expulsion of large groups of persons was accomplished by transportation to these places of exile. Thus. Tiberius sent about 4,000 freedmen to Sardinia for Jewish or Egyptian superstitious practices. Deportation was originally inflicted upon political criminals. In the course of time it became more particularly a means of removing those whose wealth and popularity rendered them objects of suspicion. Deportation was also a punishment for adultery, murder, poisoning, forgery, embezzlement, sacrilege and certain cases of immorality. Relegation was a milder form of punishment than deportation. It either excluded the person banished from one specified district (in imperial times the banishment would be from Rome) with permission to choose a residence elsewhere, or the place of exile was fixed. Relegation might be temporary or for life, but in either case it did not carry loss of citizenship or property, nor was the exile under military surveillance as in the case of deportation. Some Roman writers use the Latin equivalent of exile (exsilium) in the sense of all three of its Roman forms: interdiction of fire and water, deportation and relegation.

England.— According to Sir William Blackstone's Commentaries, exile and transportation were punishments unknown to the common law of England. However, even prior to the enactment of statutory law in England, the practice originated of granting an arrested man permission to abjure the realm. He would take an oath to depart and to never return. It is speculated that the origin of this practice may be traced to the Anglo-Saxon penalty of outlawry (*q.v.*). As in the days of the ancient Greeks and Romans, an Englishman might save himself from death by abjuring the realm. Transportation or exile was a conditional pardon and an alternative to execution. The English Vagrancy act of 1597 was the first statutory authorization in Great Britain to banish offenders and order them transported to assigned lands beyond the seas. It authorized banishment out of the realm of "such Rogues as shall not be thought fit not to be delivered." Toward the end of the 17th century transportation of criminals was used as a regular part of the English penal system and as a substitute for capital punishment. Its use in this way became more frequent as people realized that the criminal law was unduly severe. Pardons were frequently granted to capital offenders on condition that they consented to transportation. The Habeas Corpus act of 1679 recognized this procedure and provided that except in special cases persons could not be imprisoned beyond the seas. In 1717 the courts were authorized to order transportation as a direct punishment, and in 1768 the power of judges to reprieve capital convictions and to substitute transportation was confirmed by parliament and the procedure was simplified.

Large-scale transportation to the American colonies followed until 1776 and many of those transported were identured servants. After 1776 convicts ordered transported were for a time employed at hard labour at home or detained in prison ships. In 1779 trans-

portation was resumed to Africa but this was terminated because of climatic conditions. Beginning in 1787 the practice was established of sending English criminals to Australia, Tasmania and Norfolk Island. There, military control of the convicts was maintained, and they were put to work at heavy labour in penal colonies, building roads, bridges and other facilities. The early advances of Australia were in part attributable to their service to the young colony. After a time, with the influx of increasing numbers of convicts, a policy of "assignment" was adopted whereby convicts were freely loaned to anyone who would relieve the authorities of responsibility for them. This system developed abuses and there is a long story of failures, investigations and scandal. Because of the protests of the colonists themselves and of those opposed to the inhuman treatment of convicts sentenced to penal servitude abroad, the system of transportation was eventually abolished by the Penal Servitude acts of 1853 and 1857.

Continental Countries.— Spain and Portugal punished criminals by transportation to hard labour in mines and by imprisonment in military fortresses prior to the adoption of the practice in England. Portugal first sent criminals in 1415 to work on fortifications in north African posts taken from the Moors. Its policy of transporting criminals was continued throughout its colonial history and produced some of the earliest settlers of Brazil. In Spain during the reign of Ferdinand and Isabella convicts were punished by transportation to the mines of Hispaniola. Later, Spain also transported criminals to military fortifications in Africa.

France first adopted deportation of its criminals during the Revolutionary period. In 1797 a small group of political prisoners was deported to French Guiana, and in the following year 500 prisoners were sent there. However, this practice did not work out satisfactorily and the transportation of convicts to Guiana was condemned by publicists and the government. In 1854 it was reintroduced into the French penal code but again brought deplorable results. Nevertheless, deportation to Guiana was not entirely abandoned; instead of native-born Frenchmen, only convicts of subject people were sent there, but with no better success as regards colonization. New Caledonia, an island in the Pacific, was annexed by France in 1853 and ten years later became a new settlement for convict immigrants. However, in time it was feared that transportation to New Caledonia, with its fairly temperate climate and fertile soil, did not provide a sufficient deterrent against crime. The French administration, therefore, resumed the deportation of French-born persons to Guiana, which was notoriously unhealthy. Convicts who showed some promise of rehabilitation were still sent to New Caledonia, but those with the worst records were sent to the settlements on the equator. After 1897 no more convicts were transported to New Caledonia, though some were still transported to Guiana in the 20th century. Disclosures were made of the dreadful conditions on the islands near Cayenne where prisoners were held, particularly the notorious Devil's Island. In 1938 France abolished transportation, although persons already transported were still detained. The penal colonies in French Guiana were finally abolished by a decree of the Free French government during World War II.

Italy introduced deportation to various agricultural penal colonies around its coast. Under the Fascist regime. thousands of political prisoners were sent to the nonagricultural islands off the coast of Sicily.

Peter the Great of Russia ordered the first political prisoners to Siberia in 1710. From 1823 onward. Russia directed continuous streams of offenders to Siberia, and at one time the yearly average was 18,000. Transportation of Russian convicts to Turkistan and to the island of Sakhalin in the far east was also practised. Sakhalin, like Australia and New Caledonia. was hopefully intended as an outlet for released convicts. The result, however, was identical with the British and French experience, and before World War I it was recognized in Russia that transportation had failed. Gnder the Communist regime a special board attached to the people's commissariat for the interior and known as *osoboe soveshanie* is authorized to banish persons from localities, to impose banishment with settlement elsewhere, to confine in correctional settlements and to deport abroad. Exile can be imposed with or without confinement. According to H. E. Barnes and N. K. Teeters in *New Horizons in Criminology* (Prentice-Hall, Inc., New York, 1951), under the Communists "the Czarist system of sending prisoners to Siberia has been continued . . . on an ever greater scale, and, apparently with just as much brutality. There is, however, one difference. Under the Czars a large portion of those exiled were criminals in the conventional sense. Under the Soviet rule, most of those sent to Siberia have been political prisoners." In the view of these writers, "after making all qualifications necessary for the exaggeration of the bitterly anti-Soviet writers, it seems likely that the conditions in the Soviet labor camps in Siberia are as brutal and degrading as anything which was the rule under the Czars."

Other countries have adopted the practice of transportation of criminals. The Netherlands has had penal settlements in Batavia, the Moluccas and Penguin Islands; Denmark utilized Greenland for a brief period, and both Chile and Ecuador have had penal colonies on Pacific islands.

M. Griinhut observes in *Penal Reform* (Oxford University Press. Oxford, 1948) that the "tendency to get criminals out of sight goes back to primitive stages of criminal law." Transportation of convicts must be regarded as a most primitive solution to the problem of punishment and rehabilitation of criminals. Moreover, it is a solution likely to be accompanied by inhuman and deplorable conditions, as well as one most unlikely to succeed. Indeed, the general consensus is that it has proved a ghastly failure wherever it has been tried.

United States.— In the United States, transportation of criminals to penal settlements abroad has not been adopted either in practice or by statutory enactments. Deportation proceedings are considered civil in nature and, unlike the policies of most countries. this type of banishment can only be imposed upon aliens; *i.e.,* persons who are neither native-born or naturalized citizens of the U.S. Moreover, deportation is always to a foreign country, and the United States completely releases control over the individual once he has been transported abroad. An important distinction is to be made between aliens who are refused admission at the borders of the United States and those who have entered and are deported afterward. The former are excluded, while the latter are expelled or deported. The excluded alien can only be returned to the foreign country from which he came; the deported alien can be sent to any country willing to accept him. The grounds for the deportation of aliens is set forth in the Immigration and Nationality act of 1952, also known as the McCarran-Walter act. Provision is made for the deportation of aliens who entered illegally or without proper passports or visas, for those who became illegal residents by overstaying their temporary visits, for those who become public charges, commit crimes involving moral turpitude, engage in immoral conduct or who are considered subversives.

Aliens in the United States are entitled to full protection under the constitution and, in a deportation proceeding, enjoy the benefits of procedural due process. However, it has been said that the right of an alien to remain in the United States may be revoked by congress in its discretion *(Harisiades* v. *Shaughnessy,* 342 U.S. 580 [1952]). With rare exceptions, there are no limitations in point of time (statute of limitations) restricting the government's power to deport. Upon the ground that the deportation statute is considered a civil enactment, retroactive or ex post facto deportation legislation has been upheld against attack. Nevertheless, the supreme court has recognized that "deportation is a penalty—at times a most serious one" *(Bridges* v. *Wixon,* 326 U.S. 135 [1945]j and that deportation "can be the equivalent of banishment or exile" (*Delgadillo* v. *Carmichael,* 332 U.S. 388 [1947]). It has also been said that deportation is "a dreadful punishment abandoned by the common consent of all civilized peoples" (U.S. *ex rel Klonis* v. *Davis,* 13 F.2d 630 [C. A. 2, 1926]). Until a person has been admitted to citizenship. no matter how long he has been a resident of the United States and regardless of his family ties, he may be deported if he violates the deportation statute. In some cases where he has close family ties and can establish unusual hardship, the alien may be granted permanent residence despite

his deportation violation. The alien who becomes a naturalized citizen can be subjected to deportation if he loses his citizenship and commits a deportable offense. Aliens n-ho enter the United States unlawfully, surreptitiously or fraudulently. who enter as stowaways, who re-enter after deportation without permission, who unlawfully remain after entry as crewmen, or who willfully fail or refuse to depart from the United States after being ordered deported as criminals, subversives, narcotic violators or by reason of identification with prostitution are subject to prosecution for violating the criminal provisions of the laws of the United States.

DEPOSIT, CERTIFICATE OF, a written receipt from a bank acknowledging the deposit therein of a certain sum of money. Under such certificate, money may be deposited either on a demand basis or a time basis, hut in either case it cannot be drawn against by check. To withdraw funds deposited under a certificate of deposit it is necessary to present the certificate itself, properly endorsed. In the United States certificates of deposit are negotiable when properly endorsed and are usually acceptable as security for loans.

DEPOSIT INSURANCE. This special type of insurance, under which depositors are guaranteed against loss in the event of a bank failure, developed in the United States during the depression of the 1930s to meet the serious problems created by frequent bank suspensions. Between 1863 and 1933. more than 17,000 U.S banks closed their doors and depositors suffered heavy losses. Even in the prosperous years from 1921 to 1929, 5,411 banks closed and during the next four years the depression caused the failure of 8,812 more, with losses to depositors of more than $5,000,000,000.

Some states had set up plans to insure depositors against loss as early as 1829 but none proved fully successful. Congress rejected many proposals to place deposit insurance on a national basis until the disastrous collapse of the banking system in 1932 made action to protect depositors imperative.

The federal insurance program came into being in 1933 with the creation of the Federal Deposit Insurance corporation (FDIC) with authority to insure bank deposits in eligible banks up to a maximum of $2,500 for each depositor (later raised to $5,000 in 1934 and to $10,000 in 1950), and to regulate certain banking practices. Costs of the FDIC were to be met out of regular premium payments by insured banks. All members of the federal reserve system were required to insure their deposits. while nonmember banks—about half the United States total—were permitted to do so if they met FDIC standards. The plan proved so attractive that within a few years over 90% of the deposits in commercial banks and a majority of those in mutual savings banks were insured. The deposit insurance principle was also adopted by federally chartered savings and loan associations.

FDIC was able to eliminate losses to depositors in suspended banks almost completely, and—perhaps more important—to prevent failure of many banks which have encountered difficulties. Deposit insurance and other banking reforms in the Banking acts of 1933 and 1935 made insured deposits virtually as safe as any direct obligation of the federal government. (JA. A. C.)

DEPOT, a place where goods may be stored or deposited. In the U.S. the word is also used to denote a railway or bus station, whether for passengers or goods. In Great Britain, when the word is used in this sense, it applies only to goods (freight) stations. In military language the term applies to any storage point for supplies. Large depots not only store supplies but also classify, repair, maintain and salvage matériel and issue it to troops. A particular type of depot is one where recruits are received and undergo preliminary training before joining active troops. Such depots are maintained in peacetime by armies which supply distant or overseas garrisons; in an army raised by compulsory service and quartered in its own country, the regiments are usually stationed in their onn districts and on taking the field for mar leave behind a small nucleus for the formation and training of drafts to be sent out later. These nucleus troops are generally called depot troops.

DEPRECIATION, an accounting charge for the decline in value of an asset spread over its economic life. Depreciation covers wear and tear from use and physical deterioration from age and exposure to the elements. It also includes obsolescence, *i.e.,* loss of usefulness arising from availability of newer and more efficient types of goods serving the same purpose. It does not cover losses from sudden and unexpected destruction of the usefulness of property as a result of fire, accident, theft, war damage or adverse court decisions, or from declining price levels. Depreciation applies both to tangible property such as machinery and buildings and to intangibles of limited life such as leaseholds and copyrights.

Similar costs are involved in two other accounting terms: depletion and maintenance. Depletion is depreciation on property which cannot be reproduced, such as a body of ore being mined or a stand of timber being cut and not reforested. Maintenance is cost incurred in keeping property in good condition, as by painting a house or replacing defective parts in a truck. Tangible property subject to depreciation also involves maintenance. Where "full maintenance" aims to keep the property intact without deterioration. however (as with a railway roadbed), there may be no depreciation charge. A main object of keeping these costs is to measure income correctly so that if the whole supposed income of a business is withdrawn for the private use of the owners it will not later be discovered that the assets of the business have dwindled away. This leads to the rule that depreciation during the working life of a piece of property must equal the original cost of the property, less ultimate scrap value. For convenience, depreciation accounts are usually kept for groups of assets with similar characteristics and working life; and the estimated average working life of the group is used in figuring depreciation. Since this average can take into account minor losses from fire, etc., depreciation covers such losses insofar as they are self-insurable within the business in question.

The general rule of charging off a depreciable asset during its life does not determine what the charge will be each year. Allocation among years is recognized as arbitrary and in practice is strongly influenced by income tax regulations. Straight-line, fixed-percentage and, more rarely, annuity methods of depreciation—giving respectively constant. gradually decreasing and gradually increasing charges—are standard. Sometimes charges vary with use (for instance, with the number of miles per year a truck is driven). Special rules allow depletion for tax purposes to exceed original cost.

Basing depreciation on historical cost rather than on probable replacement cost: and on arbitrary rules rather than on actual use, is presumably necessary for definite tax liability and audits of accounts. But very imperfect measurement of the actual using up of property results in times when price levels change. Thus after a fall of prices, depreciation overrates the using up of capital; and consequently current income and the proportion of new buildings, machinery and other property which exceeds replacement requirements ("net capital formation") are overstated; after a rise of prices the opposite is true, as for example during the inflation following World War II. (A. *G*. HT.; X.)

DEPRESSION, a term used in economics to denote a major downswing in the business cycle. A depression is characterized by sharply reduced industrial production, widespread unemploy-

ment and a general contraction of business activity. Periods of prosperity and depression have succeeded one another at irregular intervals in the United States, Great Britain and other industrialized nations since the latter part of the 18th century. The depression that began in 1929 was the most severe and uidespread economic decline of the first half of the 20th century. Shorter and less severe contractions of business activity are commonly referred to as recessions. See BUSINESS CYCLE; PANIC; UNITED STATES (OF AMERICA): *History*.

DEPRESSION (IN PSYCHIATRY) is not an illness. It follows no regular course and has no particular or specific outcome. It may be fleeting or permanent, mild or severe, acute or chronic. There is no clear line of distinction between normal and abnormal in depression; degree of intensity determines whether a depression is pathological. It is a type of emotional reaction with distinctive characteristics; the roots of these characteristics exist in everyone.

Depression nevertheless has specific characteristics which distinguish it from all other emotional states. It represents a whole class of disorders whose chief features are a reaction to a sense of loss. The reaction is typified by an emotional or psychic state which is expressed by a loss of interest in the world outside the self, loss of activity, loss of capacity to love and loss of feeling of self-regard to a point that finds expression in self-reproach and self-reviling and may culminate in extreme instances as a delusional expectation of punishment and as suicidal impulses. Profound mourning differs from this picture only in that the fall in self-esteem is absent in grief. The findings reported by Sigmund Freud in 1917 in his paper on "Mourning and Melancholia" remain as the basis of all subsequent serious dynamic studies of the psychology of the subject.

The responses to a sense of loss are part of a series of integrated sequential psychic phenomena which are best understood collectively as a loss-complex. This manifests itself in various ways at different phases of psychosexual development and may produce profound changes in the emotional life of the person, wherein some effects are consciously perceived. others are unconscious. The characteristic pathological forms of depression, however, only begin to appear in puberty. It is commoner in adult life than in the younger years. Young adult men react with depression more commonly than young women, whereas toward middle age women are more frequently affected.

The occurrence of psychic depression is as nidespread as anxiety, and hence it may be found to a greater or lesser degree as an accompaniment to all other emotional and bodily disorders. It would be a rare affliction that was not accompanied by some elements of depression. Although the prevalence of depression is wide and the incidence high, most cases go unrecognized. One of the most remarkable aspects of depression is that it may pass off uithout leaving a trace and nith no manifest remains. A further peculiarity is that the symptomatology may turn into its complete opposite, elation; although this is not true of most cases. elation does occur frequently and often unpredictably. Once a cyclic pattern with alternating depression and elation is established, there is a tendency to repeated and intermittent recurrence. After recovery no gross signs may remain.

Even as late as puberty and in young adults elation and mania are rare. Because of the extreme variability, the difficulty in recognizing the disorder and the fact that recovery often leaves no manifest signs, statistics as to prevalence, incidence and recovery have only limited value.

Depression has been well known and described unmistakably from at least the time of Hippocrates, who called it melancholia. The classification of depression into reactive, neurotic, hypochondriacal, manic-depressive. involutional and senile is essentially based upon pre-20th-century descriptive and prognostic concepts; it does not rest on a psychodynamic understanding.

Much psychoanalytic work after 1917 concerned itself with dynamic understanding of the psychological content and meaning of depression. The differences between cases of depression are often more a matter of degree than of kind. The secondary symptoms—such as restlessness or its opposite, insomnia or drowsiness, voracious appetite or no desire for food—are variable, while the basic conflicts are the same.

A significant focus of investigation is the emotional development in childhood, with emphasis upon early forms of reaction to loss in that period. Young children responding actively to a sense of loss. which occurs in reality or in fantasy, may in fact produce pathological reactions. These are exemplified by severe apathy and unresponsiveness to the environment, failure in various aspects of ego development. retardation in intellectual growth, restlessness characterized by overactivity, and periods of sadness and grief. However, the failure of investigators to find the adult form of reaction in childhood supports the contention that responses to the sense of loss in the early years of life are not characterized by depression.

The criteria for depression are not found in this period. Central in the disorder, and by far the outstanding feature, is self-criticism by the conscience. The child, in contrast to the adult, not having a fully developed conscience, responds only to a limited degree in this way, and hence the central feature of depression is essentially absent.

It is this severe self-criticism which compellingly drives the person to represent himself as worthless. His criticisms are extended beyond the present and into the past. In this frame of mind he is frequently sleepless, worried and shows little desire for food or even for life. In many instances the self-accusations, however well they may apply to the person, actually seem more "characteristic of someone who is loved or should have been loved and the reproaches against such a person are not directed to the person but shifted to the self" (Sigmund Freud. "Mourning and Melancholia." in *Collected Papers* of *Sigmund Freud,* vol. iv, p. 158; The Hogarth Press, London, 1948) and are expressed as self-accusations.

This is the key to the disorder. Upon close study, the attacks on the self are revealed to be unconscious expressions of disappointment and anger or hatred toward another person, or even a circumstance or a thing. deflected from their real direction onto the self. The aggression, therefore, directed toward the outside world is turned against the self; in this process the objects of the aggressive impulses come to be viewed consciously with a sense of loss, with feelings of deprivation, and a mood and expression of despair pervades. The torment to the self in its fuller meaning becomes apparent. Hence. it is asked of the person who harbours active suicidal nishes, nhom does he really wish to kill or what does he really want to destroy? What is further revealed is that the feeling of love is complicated by an admixture of hatred. The latter, operating often at an altogether unconscious level, leaves no conscious awareness, and directed toward the self is expressed in suicidal wishes or fantasies.

Thus there are three cardinal psychodynamic considerations in depression: (1) a deep sense of loss of what is loved or valued, which map be a person, a thing or even liberty; (2) a conflict of mixed feelings of love and hatred toward what is loved or highly valued; (3) a heightened overcritical concern with the self. The relative intensity of one factor over another may prevail in individual instances, but in any case the person is divided against himself. The conscious aspects are only a portion of the depression; the unconscious is responsible for most.

There are two chief methods of treatment of depression. One is psychotherapy, addressed to the secondary symptoms; it is aimed at being supportive, watchful and careful, waiting for the condition to pass over. The other is psychoanalytic treatment, which aims at a resolution of the basic conflicts of the reaction. In psychotherapy the use of sedation and anxiety- and tension-reducing drugs is often helpful. In patients who are unresponsive, or for the more severely depressed and often for older persons, shock therapy also may be used adjunctively. Most patients can be treated outside the hospital and often can continue their work, although at a reduced efficiency. Many require hospitalization, since they are unable to care for and may even be dangerous to themselves. The older the patient, the less likely is complete recovery.

See Sigmund Freud, "Mourning and Melancholia," in Collected

Papers, vol. iv (1948); Gregory Rochlin, "The Loss-Complex," *J. Amer. Psychoan. Ass.,* vol. vii, no. 2 (April 1959). (GP. RN.)

DEPRETIS, AGOSTINO (1813–1887), Italian statesman, important chiefly as a leading exponent of the parliamentary tactics known as *trasformismo,* was born at Mezzana Corti in Lombardy on Jan. 31, 1813, of a wealthy family of farmers. As a law student at Pavia university in 1834 he was involved in a Mazzinian escapade directed against the Austrian government. He spent many years managing the family estates, developing the administrative and financial abilities for which he later became famous. In politics he followed Mazzini as a fervid nationalist and a radical well over to the left.

In the revolutionary year of 1848, Depretis. though a Lombard, entered the Piedmontese parliament at Turin, siding nith the democratic opposition against Cavour, remaining in touch with Mazzini and active in journalism. But in 1853 he opposed Mazzinni's attempt at insurrection in Lombardy and showed that he was ready to abjure republicanism and accept the house of Savoy. Nearly always he continued to vote against Cavour, and he opposed joining the Crimean War. After Cavour's resignation in 1859 he became governor of Brescia in the newly annexed province of Lombardy. In 1860 Garibaldi chose him as his pro-dictator in Sicily, but there Depretis worked for Cavour in trying to secure the annexation of Sicily to Piedmont and had to resign when Garibaldi opposed it.

Depretis joined Urbano Rattazzi's cabinet in 1862 as minister of public works. This cabinet encouraged Garibaldi to try to march on Rome, but the matter was mishandled, and in the general outcry the army had to put down Garibaldi's rebellion at Aspromonte. His second ministerial post was also unlucky, for in 1866 he was minister of marine under Bettino Ricasoli when the Austrians defeated a superior Italian naval force at Lissa. Like all Italian ministers of the period, he was in office for too short a time to be responsible for the fleet's poor commanders and equipment; but he had been ill-advised to order Adm. Carlo Persano out of harbour on this occasion. Then in 1867 he was minister of finance for two months when the government connived at Garibaldi's further rebellion, which led to defeat at Mentana.

When Rattazzi died (1873), Depretis succeeded him as head of the left in parliament and developed the "program of Stradella" which called for wider suffrage, social reform and lower taxes. In 1876 Marco Minghetti was defeated in parliament and the left came to power nith Depretis as prime minister. For the next 11 years he was the dominant force in Italian politics. Using every legitimate and some illegitimate means, he built up a huge majority in the 1876 elections. He resigned for a few months in 1878, but was premier again in 1879, and there was little noticeable difference betneen his policy and that of Benedetto Cairoli, who had intervened. Indeed, even the actual ministers themselves did not then normally change when one government technically followed another. Cairoli succeeded again, but Depretis was back in 1881 and formed a succession of different ministries until his death at Stradella on July 29, 1887.

By 1883 Depretis had perfected the art of the *trasformismo* ("transformism") by which, in order to build up his own personal following in parliament, he ignored party labels and took ministers from both right and left. Cavour and others had done much the same, but now it became the established technique of Italian parliamentarism. For a time, Crispi and the left reviled it as a means of confusing all political principle and establishing a personal "parliamentary dictatorship," but by 1887 Crispi himself had been cleverly brought inside this shifting governmental coalition. It was a clever scheme by which a prime minister could stay in office by confusing issues and developing a group system of politics which made persons more important than issues and principles.

During his term of office Depretis carried out many more reforms than his predecessors from the right: educational reforms, abolition of the harsh grist tax and the increasing of the electorate from 500,000 to nearly 3,000,000. The triple alliance with Germany and Austria was signed in May 1882 and renewed in Feb. 1887, thus ending Italy's isolation and diminishing the Italian irredentist claims against Austria. The occupation of Massawa in Eritrea (1885) launched Italy on a colonialist career, and the defeat of the Italians by the Ethiopians at Dogali (1887) showed the dangers of exaggerated nationalism. Depretis gravely impaired the stability of the budget after Minghetti and balanced it in 1876. By his *trasformismo* he helped to corrupt parliamentary liberalism.

See L. Breganze, *Agostino Depretis e i suoi tempi* (1894). (D. M. SH.)

DEPTFORD, a southeastern metropolitan and parliamentary borough in the county of London. Eng., bounded north by Bermondsey. northeast by the Thames river, east by Greenwich, south by Lewisham and west by Camberwell. Pop. (1961) 68.267. The name (Depeford, "deep iord") is connected with a ford over the Ravensbourne, a stream entering the Thames through Deptford creek. In 1885 the parish of St. Nicholas, which included the old village of Lower Deptford, a large stretch of water frontage west of the creek, the old cattle market and Sayes court gardens (a part of the former gardens of Sayes court), was transferred to Greenwich in order to bring the latter up to borough status. Since then the borough of Deptford has comprised only the parish of St. Paul (Upper Deptford), the church of which dates from 1712–30.

Southward from the river the land rises, on a low gravel terrace, to 154 ft. on Telegraph hill. The southern part of the borough is largely residential, factories increasing in number toward the river. There is a variety of industries, one of the chief of which is the timber import-export business that Deptford shares with Rotherhithe, the adjoining district up the river; many timber wharves front the Surrey canal that leads down to the Surrey docks in Rotherhithe.

Henry VIII established a royal naval dockyard at Deptford in 1513 and the shipbuilding industry flourished until wooden ships gave place to iron. Later it became the Royal Victoria Victualling yard and is now an army supply depot. Trinity House (*q.v.*) was founded in 1514 by Henry VIII but moved to Stepney in the 17th century and to Tower hill in 1795. Sayes court was demolished in 1729, after having been the residence of the duke of Sussex in the reign of Elizabeth I, of John Evelyn in the 17th century and of Peter the Great during his short stay in Deptford in 1698. Part of the gardens is now Deptford park (17 ac.). The Goldsmith's college, New Cross, was built in 1843 and the town hall in 1900–03.

DEPTH SOUNDER: *see* ECHO SOUNDER.

DE QUINCEY, THOMAS (1785–1859), the author of *Confessions of* an *English Opium-Eater,* was born on Aug. 15, 1785, at Manchester, and was the fifth of the eight children of Thomas Quincey. He hardly knew his father, a prosperous gentleman-merchant who died when his son was seven, and was brought up by his mother, who added the prefix "De" to the family name. Throughout his life he was profoundly influenced by his early experiences, as he reminds us again and again in his writings; but here only the main outward events can be recorded. He was deeply moved by the death of one of his sisters when he was six (another sister had died when he was two). At Bath grammar school he was already remarkable for his precocious knowledge of Latin. After a period of tuition and a brief spell at a small private school he was sent to Manchester grammar school, where he was (on the whole) kindly treated, but continued to be unhappy. After 18 months there he ran away, and there followed eight months in Wales and London which were of central importance in his development. His money was soon exhausted and he experienced a series of adventures which culminated in his close but innocent friendship with Ann, a young prostitute for nhom he afterward searched London in vain. At the end of 1803 he went to Worcester college, Oxford, then a hard-drinking society where (as at school) he felt himself to be an outcast or "pariah." About this time he abandoned his early poetical ambitions, wishing instead to become "the intellectual benefactor" of mankind by being "the first founder of a true Philosophy." It was in March 1804 that he first took opium, to relieve the pain of acute facial neu-

ralgia. This was the initiation that was to have so much to do with shaping his whole future life.

De Quincey was one of the first to appreciate the importance of the *Lyrical Ballads* and during the second period of his life he was for a while closely associated with the Lake community He first met Wordsworth and Coleridge in 1807: two years later he rented Dove cottage. Grasmere, which was to remain his headquarters on and off until 1833. In 1813 he became "a regular and confirmed opium-eater." keeping a decanter of laudanum by his elbow and steadily increasing the dose. Meanwhile he became estranged from the Wordsworths and married Margaret Simpson, a beautiful local girl who had already borne him a son. His financial affairs went from bad to worse and after many invitations to contribute to periodicals he wrote two articles called *Confessions of an English Opium-Eater* which appeared in Taylor and Hessey's *London Magazine* in 1821 and were reprinted as a small book the following year The first version of the *Confessions* is very different from the text usually reprinted. One notices particularly the unusual combination of introspective penetration and an unexpected journalistic astuteness. R e are going to hear of forbidden things, but only for our own good: it is time that the thinking part of the community should know of the growing menace of opium-eating. De Quincey refuses to accept any blame for his own opium-eating, however, and in the same way he insists on the innocence of his association with the outcasts and prostitutes who had been his friends in London. There is something reassuringly domestic about the whole thing: "These troubles are past," he writes, addressing his wife (whom he calls his Electra). "and thou wilt read those records of a period so dolorous to us both as the legend of some hideous dream that can return no more."

In fact, as he confessed in an appendix, De Quincey had not made his escape from opium. He was to remain an opium-eater for the rest of his life and it is not surprising that near the end of it he should have seized the opportunity provided by the appearance of a collected edition of his works to revise the book that had made him famous. He wished its "crowning grace" to be an account of the "dreams and noonday visions" that had come as a result of opium; but when he found that he had lost most of the accounts which he had been keeping of his visions he had to expand the book in some other way. He therefore lengthened the account of his early years, added numerous digressions and rewrote the whole book in a more elaborate (and frequently verbose) style. The result is less unified than the *Confessions* of 1822 and closer to ordinary autobiography: two-thirds of the book are over before opium makes its appearance. The differences of emphasis and opinion between the two texts are of great interest. De Quincey's attitude to opium (for example) has changed. In 1822, though there are inconsistencies. his main aim is to warn his readers of the dangers of opium: in 1856 he is mainly concerned with the medical value of opium and (more particularly) its mysterious poners "over the grander and more shadowy world of dreams."

The more highly wrought and involved style of the *Confessions* of 1856 throws light on De Quincey's own development and on changes in English taste in the Victorian period. Words and turns of phrase that might be regarded as colloquial or vulgar are softened or replaced by circumlocutions, notably in the passages dealing with the London prostitutes. Although some passages are revised for the better, the 1822 text is in general more impressive than that of 1856 and it is with the earlier form of the *Confessions* that a reader new to De Quincey should begin

During the period of nearly 40 years left to him after the original publication of his *Confessions*, De Quincey led a wandering life, moving from one friend's house to another, one set of lodgings to another, in London. Edinburgh and Glasgow. He fought a losing battle against insolvency, contributing voluminously to *Blackwood's* and other periodicals of the day. Editors treated him nith remarkable forbearance and although he shunned society those nho met him were charmed by his old-fashioned politeness and the astonishing flow of his conversation when he felt himself to be among friends. He had frequently to take refuge from his creditors at Holyrood and it was there that his wife died in 1837. His last task was to revise his work for a collected edition. He died in Edinburgh on Dec. 8, 1859.

As his writings remind us, De Quincey was—as he himself said of Coleridge—a *"Polyhistor,* or catholic student." He wrote on history, biography. economics (stimulated by Ricardo) and many other subjects. Of his works, the more significant are his autobiographical writings, his literary criticism and the unfinished *Suspiria de Profundis.* In the *Autobiographic Sketches* his aim is to trace the development of his own mind. In spite of the handicap that he had already described the most dramatic episode in his life, several of the chapters throw a good deal of fresh light on their creator, while others illuminate the changes that had taken place in England during his lifetime, what he calls "the shifting scenery and moving forces of the age." The *London Reminiscences* (as David Masson, his editor, called them) describe De Quincey's association with the brilliant group of writers who contributed to the *London Magazine* in its heyday. The *Lake Reminiscences,* which gave deep offense to Wordsworth and his friends, remain of great interest: although they are (of necessity) highly subjective and unreliable in matters of detail. As De Quincey himself remarks, through the ruin of his own mind he "looked into and read the latter states of Coleridge."

As a literary critic De Quincey has been underestimated. Unlike Charles Lamb (for example) he was not a literary antiquarian. The writers who interested him were the classical authors of antiquity and the major writers of modern times. Of the 17th-century poets, Milton is the only one on whom he wrote at length, of the 18th, Pope; and on both men he has some valuable observations to make. His only essay on Shakespeare deals with the effect made by the knocking on the gate in *Macbeth* and stands out as a brilliant piece of psychological criticism. The nearest approach to a formal critique in his work deals with the *Lyrical Ballads,* the discovery of which he described as "the greatest event in the unfolding of his own mind." He points out that Wordsworth's theory of diction is historically untenable and goes on to write most penetratingly on the nature of his poetic imagination. His own criticism owes a good deal to Wordsworth and Coleridge, yet he has been given too little credit for the results of his own life-long meditation on the nature of poetry and the use of criticism. It is worth remembering his remark that "in the sense of absolute and philosophic criticism, we have little or none; for, before that can exist, we must have a good psychology, whereas, at present, we have none at all."

The aim of *Suspiria de Profundis* was to expound the philosophy of life which had formulated itself in his mind as a result of his sufferings. A key to the whole scheme may be found in *The Posthumous Works.* "The Daughter of Lebanon," printed at the end of the *Confessions* in 1856, is a splendid fragment of the work which brilliantly exemplifies his ideal of "impassioned prose." The theme of the *Suspiria* as a whole was to be that pain and grief are essential to the development of the soul, but that this truth becomes apparent only to exceptional people and to them only when the original experience has sloughed off its "accidents" and assumed a universal and perhaps symbolical form in the mind. in a'dream or reverie years later. This was to be the final fruit of a lifetime's meditation and there are few unfinished works in the history of literature which one would give more to possess in completed form.

BIBLIOGRAPHY.—De Quincey himself was responsible for *Selections Grave and Gay, From Writings . . . of Thomas De Quincey,* 14 vol. (1853–60). The text is revised and contains the first ed. of the longer version of the *Confessions.* The standard collected edition (which is not wholly satisfactory) is *The Collected Writings,* ed. by David Masson, 14 vol. (1889–90). *See* also The *Posthumous Works,* ed. by *A.* H. Japp, 2 vol. (1891, 1893); *The Uncollected Writings,* ed. by James Hogg, 2 vol. (1890); *A Diary of T. De Quincey, 1803,* ed. by H. A. Eaton (1927); *De Quincey's Literary Criticism,* ed. by *H.* Darbishire (1909). The 1822 text of the *Confessions* has been reprinted several times. Malcolm Elwin's ed. (1936) gives both texts, with a long biographical introduction. The best biographies are A. H. Japp, *Thonzas De Quincey: His Life and Writings,* rev. ed. (1890); H. A. Eaton, *Thonzas De Quincey* (1936); *E.* Sackville West, *A Flame in Sunlight* (1936). *See* also *De Quincey Memorials,* ed. by *A.* H. Japp, 2 vol. (1891); De *Quincey and His Friends,* ed. by James Hogg (1895); Sir Leslie Stephen, "De Quincey," in *Hours in a Library,* 1st series, pp. 349–

392 (1874); M. H. Abrams, *The Milk of Paradise* (1934)—on the influence of opium on De Quincey, Coleridge and others; J. E. Jordan, *De Quincey: Literary Critic* (1952); Ian Jack, "De Quincey Revises His *Confessions*," *Publications of the Modern Language Association of America*, vol. lxxii, no. i, pp. 122–146 (March 1957). Baudelaire was keenly interested in De Quincey—"Un Mangeur d'Opium" (the second half of *Les Paradis Artificiels*, 1860) is a very free paraphrase of the *Confessions*. Fuller bibliographies may be found in the *Cambridge Bibliography of English Literature*, vol. iii (1930) and vol. v (1957) and in *The English Romantic Poets and Essayists*, ed. by Northrop Frye and others (1957). DERA GHAZI KHAN, a municipality and district in the Multan division of West Pakistan. The town, headquarters of the district, was founded at the close of the 15th century and named after the son of a Baloch chieftain, a feudatory of the Langah sultans of Multan, who made himself independent about 1480. The greater part of the city was washed away by the Indus in 1908–09. The new town, built nearby, lies about 50 mi. IV. of Multan where the road from Multan to Quetta crosses that from Jacobabad to Dera Ismail Khan. Pop. (1961) 47,105. It is connected by road over the Taunsa barrage (45 mi. y.) with Kot Adu on the Campbellpur-Multan line, and by a bridge of boats with Ghazi Ghat, on the opposite bank of the Indus and thence with Muzaffargarh (38 mi.). There is a government college affiliated with the University of the Punjab. The town's chief products are wooden toys.

DERA GHAZI KHAN DISTRICT, in the southern part of the tract known as Derajat, is a narrow strip of country, 198 mi. long (north to south), sloping gradually from its western boundary, the Sulaiman hills. to the Indus. Pop. (1961) 776.620. Area 9.359 sq.mi. The hill torrents deposit silt and are dammed at various points to provide water for irrigating a strip 30 to 40 mi. wide. The low-lying tract along the river is irrigated by inundation canals. The latter is known as Sind and the rest Pachhad. In 1958 the Taunsa barrage was completed and construction of new canals was begun. An area, including the Biloch tract and the Barkhan subdivision of Loralai, was added to the district in 1955; this is now known as the "excluded area." The Biloch tract, occupied by Baloch tribes, most of whom are Muslims, lies in the hills to the west. The principal products of the district are wheat and millets. (K. S. AD.)

DERAIN, ANDRÉ (1880–1954), French painter, whose works embody several of the most influential art movements of the early 20th century, was born at Chatou, Seine-et-Oise, June 10, 1880. He studied at the AcadCmie Julian (1898) and Académie Carrière. Between 1899–1902 he worked with Vlaminck at Chatou. He then painted in the south of France with Matisse (1905) and became identified with the Fauve movement. In 1910 he worked with Picasso in Spain, and painted a few cubist pictures. Cézanne's style absorbed Derain next. and he traveled in France painting landscapes. About 1912 his interest in the primitives developed, and he began to paint more still lifes. After his release from military service (1919) he traveled in Italy (1921). In his maturity Derain became more concerned with the French tradition of Courbet, Corot, Delacroix and Renoir, and he painted many classical landscapes, still lifes, portraits and nudes. Derain illustrated numerous books and created designs for S. Diaghilev's ballets. He died at Garches. Seine-et-Oise, Sept. 10. 1954.

DERA ISMAIL KHAN, a district headquarters, district and division of West Pakistan. The town is situated near the right bank of the Indus, which during half the year is crossed by a bridge of boats to Darya Khan (12 mi.), a railway station (Peshawar-Multan line) on the left bank of the river. Pop. (1961) 46.140. The name is taken from Ismail Khan, a son of Malik Sohrab Khan Hot, a Baloch chief whose tribe, toward the end of the 15th century. occupied the northern part of the land between the Sulaiman hills and the Indus as a fiefdom of the Langah Sultan Husain of Multan. The old town was situated about 4 mi. E. of the present town and was washed away by the Indus in 1823. The new town was laid out at the present site by Durrani chiefs. The town has a 24-mi. circular road around it. There are four main gates which are connected with metaled roads crossing each other at right angles, along which lie the four main bazaars. The town hall, government college, civil hospital, Circuit house and government offices are outside the circular road. There is an airstrip to the northeast. The town has no modern amenities. Most of the property left by the non-Muslims who emigrated on the partition of the subcontinent lies in ruins, adding to the untidy appearance of the place. There are two public parks. The town is famous for its lacquered woodwork, glasswork, mat and ivory work and lungis (sarongs).

DERA ISMAIL KHAN DISTRICT (area 4,723 sq.mi.; pop. [1961] 382.746) forms an irregular triangle with its base in the north marked by the Bhittanni and Marwat ranges, its eastern border by the Indus and its western by the Shirani and Sulaiman hills. Its southern extremity, barely 20 mi. broad, adjoins the district of Dera Ghazi Khan. It is mostly alluvial plain divided into the kachi or Indus riverain and the *daman* or area lying between the kachi and the hills. The kachi is a narrow strip of alluvial land beneath the old bank of the Indus, partly overgrown with jungle and tall grasses. It is cultivated by means of wells or with the aid of floodnater. The Paharpur canal, which takes off from the Indus near Bilot, passes through the town of Dera Ismail Khan and falls back into the river below it after irrigating the adjoining area of the *daman.* The *daman* ("skirt of the hills") is strictly only the tract immediately beneath the hills but the term is used for the whole area from the hills to the kachi. It is intersected by numerous torrents which form deep valleys in its level expanse. The soil is hard clay and the embanked fields are cultivated with the help of water from streams, hill torrents and surface drainage. Outside the irrigated and cultivated area the plain is without trees and grass. except for a few scattered bushes. Wheat and bajra (*Pennisetum typhoideum*) are the staple crops. with gram and jowar (*Sorghum vulgare*) occupying smaller areas. Camels are extensively bred in the *daman* and many sheep are grazed. The climate is dry and fairly healthy. Temperatures rise to over 100° F. in summer, but the winters are cold with severe frosts. The district is the junction of Pathan and Balochi tribes, the Pathan element predominating. The chief frontier tribes are the Sheranis, Ustaranas and Bhittannis. Administratively the district is divided into Dera Ismail Khan, Kulachi and Tank tehsils and the special area under the deputy commissioner.

DERA ISMAIL KHAN DIVISION, formed in 1955 when West Pakistan became a single province, now consists of Dera Ismail Khan and Bannu districts, including the special areas attached to them. Wheat, millets, gram, rape and mustard are the chief crops. About 21 6% of the cropped area is irrigated. The area is 11,130 sq.mi. and the population was 1,205,719 in 1961. (K. S. AD)

DERBENT (DERBEND), a town in the Dagestan Autonomous Soviet Socialist Republic of the U.S S.R.. is situated on the southwestern shore of the Caspian sea at the foot of the eastern hills of the Greater Caucasus, on the Baku-Makhachkala railway. Pop. (1959) 42,300. It is a wool and silk spinning centre, and there are fruit and fish canning factories and a wire factory. There are agricultural, medical and teachers' training institutes. a Lezgian national theatre and a museum. It was founded in the 6th century A.D. by the Persians as a defense post against northern invaders guarding a pass known as the Caspian or Iron Gates. Derbent was captured by the Arabs in 728 and by the Mongols in 1220. and was incorporated in the Russian empire in 1813. There are many ancient monuments, including remains of the ancient Caucasian or Alexander wall and gates dating back to the 6th century, a congregational mosque (8th century) and some ancient caravansaries, cisterns and baths. (G. E. WR.)

DERBY, EARLS OF. The 1st earl of Derby was probably Robert de Ferrers (d. 1139), son of one of the Domesday commissioners, who onned lands in Normandy, Derbyshire and Staffordshire. Robert is said to have been made an earl by King Stephen after the battle of the Standard in 1138. He and his descendants retained the earldom until 1266, when Robert (c. 1239–79), the 6th earl, having taken a prominent part in the baronial rising against Henry III, was deprived of his lands and practically of his title. These earlier earls of Derby were also knonn as Earls Ferrers or de Ferrers from their surname; as earls of Tutbury from their residence; and as earls of Nottingham because this county was a lordship under their rule.

The large estates which were taken from Earl Robert in 1266 were given by Henry III to his son Edmund, earl of Lancaster, and Edmund's son Thomas, earl of Lancaster, called himself Earl Ferrers. Thomas was beheaded in 1322, however. and all his honours were forfeited. In 1337 Edmund's grandson Henry (*c.* 1299–1361), afterward duke of Lancaster, was created earl of Derby and this title was taken by Edward III's son, John of Gaunt. who had married Henry's daughter Blanche. John of Gaunt's son and successor was Henry. earl of Derby, who became king as Henry IV in 1399. all his honours being merged in the crown.

In Oct. 1485 Thomas, Lord Stanley, was created earl of Derby, and the title was thenceforth retained by the Stanleys. Thomas also inherited the sovereign lordship of the Isle of Man, granted by the crown in 1406 to his great-grandfather Sir John Stanley, and this sovereignty remained in possession of the earls of Derby till 1736. when it passed to the duke of Atholl.

The earl of Derby is one of the four "catskin earls," the others being the earls of Shrewsbury, Huntingdon and Pembroke. The term "catskin" is possihly a corruption of *quatre-skin*, derived from the fact thak in ancient times the robes of an earl (as depicted in some early representations) were decorated with four rows of ermine, as in the robes of a modern duke, instead of the three rows to which they were restricted in later centuries. The "catskin" earldoms are the only earldoms in existence which date from creations prior to the 17th century, except those which are merged in higher titles.

THOMAS STANLEY, 1st earl of Derby (c. 1435–1504), was the son of Thomas Stanley, who mas created Baron Stanley in 1456 and died in 1459. His grandfather Sir John Stanley (d. 1414) had founded the fortunes of his family by marrying Isabel Lathom, the heiress of a great estate in the hundred of West Derby in Lancashire, from whom was also derived the well-known Stanley crest of the eagle and child. The future earl of Derby was a squire to Henry VI in 1454, and not long afterward married Eleanor, daughter of the Yorkist leader Richard Neville, earl of Salisbury, and sister of "Warwick the kingmaker." At the battle of Blore Heath in Aug. 1459 Stanley, though close at hand with a large force, did not join the royal army, while his brother William fought openly for York. In 1461 Stanley was made chief justice of Cheshire by Edward IV, but ten years later he sided with his brother-in-law Warwick in the Lancastrian restoration. Nevertheless, after Warwick's fall, Edward made Stanley steward of his household. Stanley served with the king in the French expedition of 1475 and with Richard of Gloucester in Scotland in 1482. About the latter date he married, as his second wife, Margaret Beaufort, mother of the exiled Henry Tudor.

Stanley was one of the executors of Edward IV and was at first loyal to the young king Edward V. However, he acquiesced in Richard's accession and retained his office as steward, avoiding entanglement in the duke of Buckingham's rebellion on behalf of Henry Tudor (1483) in which his wife was deeply involved. He was made constable of England in succession to Buckingham and was granted possession of his wife's estates with a charge to keep her safe in some secret place at home. Richard could not well afford to quarrel with so powerful a noble, but he became suspicious when, early in 1485, Stanley asked leave to retire to his estates in Lancashire, and in the summer Richard asked Stanley to send his son Lord Strange to court as a hostage. After Henry Tudor had landed, Stanley made excuses for not joining the king; for his son's sake he was obliged to temporize. Both Thomas and William Stanley took the field: but while William was in treaty with Henry, Thomas professed to support Richard. On the morning of Bosworth (Aug. 22), however, when Richard summoned Thomas to join him he received an evasive reply and thereupon ordered Lord Strange to be executed, although his order was neglected and Strange escaped. In the battle it was William who turned the scale in Henry's favour, but Thomas, who had taken no part in the fighting; placed the crown on Henry's head. Henry VII confirmed him in all his offices and created him earl of Derby. As husband of the king's mother Derby held a great position. which was not affected by the treason and execution of his brother William in Feb. 1495. He died at Lathom on July 29, 1504. Lord Strange had died in 1503, and his son Thomas succeeded as 2nd earl.

EDWARD STANLEY, 3rd earl of Derby (1509–72), second son of the 2nd earl, succeeded to the earldom on his father's death in May 1521. During his minority Cardinal Wolsey was his guardian, and as soon as he came of age he began to take part in public life. He helped to quell the rising known as the Pilgrimage of Grace in 1536 but. remaining true to the Roman Catholic faith, he disliked and opposed the religious changes made under Edward VI. Under Elizabeth his younger sons, Sir Thomas (d. 1576) and Sir Edward Stanley (d. 1609), were concerned in a plot to free Mary, queen of Scots, and he himself was suspected of disloyalty. He died at Lathom house, near Ormskirk, on Oct. 24, 1572.

Derby's first wife was a daughter of Thomas Howard, duke of Norfolk, by whom he had a son HENRY, the 4th earl (c. 1531–93), who was a member of the Council of the North and, like his father, was lord lieutenant of Lancashire and Cheshire. Henry was one of the commissioners who tried Mary, queen of Scots, and was employed by Elizabeth on other high undertakings both at home and abroad. He died on Sept. 25. 1593, at Lathom. His wife Margaret (d. 1596). daughter of Henry Clifford, 2nd earl of Cumberland, was descended through the Brandons from King Henry VII. Two of his sons, FERDINANDO (*c.* 1559–94) and WILLIAM (c. 1561–1642), became in turn 5th and 6th earls of Derby. Ferdinando wrote verses and is eulogized by Edmund Spenser under the name of Amyntas.

JAMES STANLEY, 7th earl of Derby (1607–51), sometimes styled the Great Earl of Derby, eldest son of William, 6th earl, and Elizabeth de Vere, daughter of Edward, 17th earl of Oxford, was born at Knowsley, Lancashire! on Jan. 31, 1607. During his father's life he was known as Lord Strange. He was returned to parliament for Liverpool in 1625, received high offices in the north of England and on March 7. 1628, entered the house of lords as Baron Strange. When the Civil War broke out in 1642, Lord Strange devoted himself to the king's cause. His plan of securing Lancashire at the beginning and raising troops there, which promised success, was, however, discouraged by Charles, who was said to be jealous of his power and royal lineage and who commanded his presence at Nottingham. His subsequent attempts to recover the county were unsuccessful. After several defeats he left for the Isle of Man in June 1643 to deal with the disturbances which had broken out there, and in the summer of 1644 he took part in Prince Rupert's successful campaign in the north, when Lathom house, where Lady Derby had heroically resisted the attacks of the besiegers, was relieved and Bolton castle taken. He followed Rupert to Marston moor and after the complete defeat of Charles's cause in the north withdrew to the Isle of Man, where he held out for the king and offered an asylum to royalist fugitives. His administration of the island was strong rather than just. In July 1649 he refused scornfully terms offered to him by Henry Ireton. By the death of his father on Sept. 29, 1642, he had succeeded to the earldom, and on Jan. 12, 1650, he was nominated knight of the Garter and was chosen by Charles II to command the forces of Cheshire and Lancashire in the proposed royalist rising. On Aug. 15. 1651, he landed at Wyre Water in Lancashire and met Charles on the 17th. Proceeding to Warrington, he failed to obtain the support of the Presbyterians through his refusal to take the Covenant, and on the 25th was totally defeated at Wigan, being severely wounded and escaping with difficulty. He joined Charles at Worcester; after the battle he accompanied him to Boscobel and, while on his way north alone. was captured near Nantwich and given quarter. He was tried by court-martial at Chester on Sept. 29. his quarter was disallowed and he was condemned to death. When his appeal for pardon to parliament was rejected, though supported by Cromwell, he endeavoured to escape, but was recaptured and executed at Bolton on Oct. 15, 1651. He was buried in Ormskirk church. According to Clarendon, Derby was "a man of great honour and clear courage." and his defects the result of too little knowledge of the world. His political usefulness was handicapped by his dislike of the Scots. He was the author of several volumes of historical collections, observations and devotions and a commonplace book, as well as of a discourse on the government of the Isle of Man.

Some of these were later published in the Stanley Papers. He married in 1626 Charlotte de la Trémoille (1599–1664), daughter of Claude, duc de Thouars, and granddaughter of William the Silent, prince of Orange, by whom he had five sons and four daughters. The eldest son, CHARLES (1628–72), succeeded him as 8th earl.

Charles's two sons, WILLIAM, the 9th earl (*c.* 1655–1702), and JAMES, the 10th earl (1664–1736), both died without sons, and consequently, when James died in Feb. 1736, his titles and estates passed to SIR EDWARD STANLEY (1689–1776), a descendant of a brother of the 3rd earl. From him the later earls were descended. The 12th earl (1752–1834), who in 1780 founded the race called, after him, the Derby stakes, was his grandson. His son. EDWARD SMITH (1775–1851), the 13th earl, sat in parliament as a Whig from 1796 until 1832, when he was called into the house of lords as Baron Stanley of Bickerstaffe to support Lord Grey. He took little part in politics but was keenly interested in zoology and set up a private menagerie at Knowsley. He was president of the Linnean and Zoological societies. He died at Knowsley on June 30, 1851, and was succeeded by his eldest son, the 14th earl (see DERBY, EDWARD GEORGE GEOFFREY SMITH STANLEY).

EDWARD HENRY STANLEY, 15th earl of Derby (1826–93), eldest son of the 14th earl, was educated at Rugby and Trinity college, Cambridge, where he took a first in classics and became a member of the society known as the Apostles. In March 1848 he unsuccessfully contested the borough of Lancaster and then made a long tour in the West Indies, Canada and the United States. During his absence he was elected member for King's Lynn, which he represented till Oct. 1869, when he succeeded to the peerage. In 1852, while traveling in India, he was appointed undersecretary for foreign affairs in his father's first administration. From the outset of his career he was known to be a most liberal Conservative, and in 1855 Lord Palmerston offered him the post of colonial secretary. He was tempted by the proposal and hurried down to Knowsley to consult his father, who called out when he entered the room, "Hallo, Stanley! what brings you here? Has Dizzy cut his throat, or are you going to be married?" The offer was declined. In his father's second administration Lord Stanley first held the office of secretary for the colonies and then became president of the board of control on the resignation of Lord Ellenborough. He had charge of the India bill of 1858 in the house of commons, became the first secretary of state for India and left behind him in the India office an excellent reputation. When the Greeks were looking for a king after the death of King Otho and the crown was refused by Queen Victoria for her son Alfred. there was some idea of inviting Stanley to take the vacant throne but the offer was never formally made. After the fall of the Russell government in 1866 he became foreign secretary in his father's third administration. He compared his conduct in that great post to that of a man floating down a river and fending off from his vessel, as well as he could, the various obstacles it encountered. He thought that that should be the normal attitude of an English foreign minister.

Under Prussian pressure, he arranged the collective guarantee of the neutrality of Luxembourg in 1867; he also negotiated a convention about the "Alabama," which, however, was not ratified by the U.S. senate. In 1874 he again became foreign secretary in Disraeli's government. He acquiesced in the purchase of the Suez canal shares; he accepted the Andrassy note urging reforms upon the Turkish sultan, but declined to accede to the Berlin memorandum which called upon him to expedite them. His part in the later phases of the Russo-Turkish struggle has never been fully explained, but it is clear that both the queen and Lord Beaconsfield (as Disraeli had now become) had lost confidence in him by Aug. 1877; indeed Beaconsfield pursued that autumn a foreign policy of his own, without Derby's knowledge. Derby resigned at the end of March 1878. By Oct. 1879 it was clear that he had thrown in his lot with the Liberal party, but it was not till March 1880 that he publicly announced this change of allegiance. He did not at first take office in the second Gladstone government, but became secretary for the colonies in Dec. 1882, holding this position till the fall of that government in the summer of 1885. In 1884 he was created knight of the Garter. In 1886 Derby joined the Liberal Unionists and took an active part in the general management of that party, leading it in the house of lords till 1891. He died at Knowsley on April 21, 1893.

During a great part of Derby's life he was deflected from his natural course by the accident of his position as the son of the leading Conservative statesman of the day. From first to last he was at heart a moderate Liberal. His chief defect as a statesman was that in his anxiety to arrive at the right conclusions he too often turned a subject over till the time for action had passed. He also disliked foreigners, and this dislike combined with his characteristic indecision made him an unfortunate choice as foreign secretary.

Although he cared but little for what is commonly known as society—the society of crowded rooms and fragments of sentences—he very much liked conversation. His talk was generally grave, but every now and then was lit up by dry humour. **A** friend once said to him. after he had been buying some property in southern England: "So you still believe in land, Lord Derby." "Hang it," he replied. "a fellow must believe in something!" He did much work outside politics. He was lord rector of the University of Glasgow from 1868 to 1871 and of Edinburgh from 1874 to 1877. He succeeded Lord Granville as chancellor of the University of London in 1891. From 1876 to 1893 he was president of the Royal Literary fund and attended closely to his duties there. He lived much in Lancashire, managed his enormous esrates with considerable skill and did a great amount of work as a local magnate. He married in 1870 Maria Catharine, daughter of the 5th earl de la Warr and widow of the 2nd marquess of Salisbury.

The earl left no children and he was succeeded as 16th earl by his brother FREDERICK ARTHUR STANLEY (1841–1908), who had been made a peer as Baron Stanley of Preston in 1886. He sat in the commons for various seats in Lancashire (1865–86), and after useful work as undersecretary became secretary for war (1878–80) and for the colonies (1885–86). He was governor general of Canada from 1888 to 1893, and was made knight of the Garter in 1897. By his wife, Lady Constance Villiers, eldest daughter of the 4th earl of Clarendon, he had seven sons and a daughter. He died on June 14, 1908, worth nearly £4,000,000.

His eldest son, EDWARD GEORGE VILLIERS STANLEY, 17th earl of Derby (1865–1948), born in London on April 4, 1865, was M.P. for the West Houghton division of Lancashire from 1892 to 1906. He was a junior lord of the treasury (1895–1900) and financial secretary to the war office (1900–03), though absent for a year at the South African War in 1899–1900, first as chief press censor and then as private secretary to Lord Roberts. In 1903 he became postmaster general, resigning in Dec. 1905 with the rest of the Conservatives. In 1914 he was made knight of the Garter, the 15th member of his line to join that order.

In Oct. 1915 he became director of recruiting and introduced the "Derby scheme," the last attempt to create a large volunteer army. In July 1916 he was made undersecretary and in December secretary of state for war. He was trusted by his friend King George V and strongly supported Lord Haig and Sir W. R. Robertson; this support made him unpopular with some of his colleagues, especially with Lord Milner and with the prime minister, Lloyd George. In April 1918 he was transferred to be ambassador in Paris, a post he held till Nov. 1920. From Oct. 1922 to Jan. 1924 he was once more war secretary, under Andrew Bonar Law and Stanley Baldwin. Though he never held office again—perhaps because he was thought too indecisive by close colleagues—he retained extraordinary influence in Lancashire. This influence rested partly on the tradition of his family and partly on his great wealth, but mainly on his personal character as an upright, shrewd and kindly man. He died at Knowsley on Feb. 4, 1948.

His grandson EDWARD JOHN STANLEY, M.C. (b. 1918) succeeded him as 18th earl. (M. R. D. F.; X.)

DERBY, EDWARD GEORGE GEOFFREY SMITH STANLEY, 14TH EARL OF (1799–1869), English statesman, leader of the Conservative party from 1846 to 1868. three times prime minister and one of England's greatest parliamentary orators, was born at Knowsley, Lancashire, on March 29, 1799, grand-

son of the 12th earl and eldest son of Lord Stanley (afterward 13th earl). After 1834, when his father succeeded to the earldom, he himself was styled by courtesy Lord Stanley; he was called up to the house of lords with that title in 1844, and succeeded to the earldom in 1851. Educated at Eton and at Christ Church, Oxford, he was elected to parliament as a Whig in 1820. His first office was the undersecretaryship of state for war and the colonies. which he held under Lord Goderich in 1827–28. He became chief secretary for Ireland in Lord Grey's government in 1830, and entered the cabinet the following year.

Stanley was a vigorous defender of the Protestant ascendancy in church and state. His family had large estates in Ireland. and he was responsible for much important Irish legislation. In 1832 he promoted an act for the compulsory composition of tithes, a parliamentary reform act and a remarkably ambitious act establishing a national system of state-aided education There followed in 1833 a stringent coercion act and the Irish Church Temporalities act. In carrying through these measures, all highly controversial. Stanley showed himself "a masterful and drastic administrator" and a brilliant speaker. It was generally felt that Daniel O'Connell, powerful as he was, had fairly met his match in Stanley, who, with invective scarcely inferior to his own, evaded no challenge, ignored no argument, and left no taunt unanswered. This was in some ways the peak of his political career, and the moment when Sir Edward Bulwer (after Lord) Lytton's famous lines about him in *The New Timon* were most applicable:

> The brilliant chief, irregularly great,
> Frank, haughty, rash—the Rupert of debate.

In 1833 he became secretary of state for war and the colonies, and introduced and carried the act abolishing slavery in the British empire.

At the height of his parliamentary success, in May 1834, Stanley resigned from the cabinet, in company with the duke of Richmond, the earl of Ripon (formerly Lord Goderich) and Sir James Graham. They disagreed with their colleagues over the Irish Church question, being entirely opposed to the appropriation of ecclesiastical revenues to secular purposes. They attracted to themselves a following of between 50 and 100 members of parliament. O'Connell, misquoting from George Canning's *The Loves of the Triangles*, gave the party a nickname which stuck:

> Down thy hill, romantic Ashbourne, glides
> The Derby dilly, with his six insides.

(The "six insides" seem to have been Stanley and Graham together with their four most important supporters in the commons: Lord George Bentinck. Sir Stratford Canning, Henry Gally Knight and Sir Matthew Ridley.) For a year the "Dilly" held the balance in the house. Stanley and Graham declined to join Sir Robert Peel's Tory government, formed after the fall of the Whigs in Nov. 1834. They probably hoped for an opportunity to form a ministry themselves. But, with the conclusion in May 1835 of the "Lichfield House compact" between Whigs, Radicals and the Irish, the Whigs under Lord Melbourne returned to power, and the third party's chances were gone. Stanley and his friends soon became indistinguishable from Tories.

When Peel came to power in 1841, Stanley again went to the colonial office. There his work was unremarkable, but he made an unsuccessful attempt to carry a measure of Irish land reform in 1845. At the end of 1845, when Peel finally declared in favour of repealing the corn laws, Stanley was the only member of the cabinet who refused to support him. He at once became the recognized leader of the protectionists, with Lord George Bentinck and Benjamin Disraeli as his lieutenants in the commons. The party was small, inexperienced, discontented and unpopular, but the state of parties in the house of commons was so confused that in Feb. 1851 Stanley found himself commissioned to form a government. He gave up the task when he discovered that none of Peel's old colleagues would join the cabinet. The opportunity recurred in Feb. 1852, and Derby, as he now was, decided to try the experiment of governing with a purely protectionist ministry. Disraeli became chancellor of the exchequer, and the earl of Malmesbury foreign secretary. The government at once appealed to the country, but the election did not materially alter the state of parties. and in December the cabinet resigned after a defeat on Disraeli's budget. Three years later, when Lord Aberdeen's coalition was brought down because of its mismanagement of the Crimean War, Derby did not persist in trying to construct a cabinet after Lord Palmerston and W. E. Gladstone had declined to join him.

Derby became prime minister for the second time in 1858. By then his party's policy was more generally Conservative and less distinctively protectionist This government carried two important measures, one to remove Jewish disabilities, the other to transfer the administration of India from the East India company to the crown. The question of parliamentary reform was taken up in 1859, but the bill was rejected by the commons. and a general election left the Conservatives in a minority against reunited opponents. Derby resigned in June, and for the next six years scarcely attempted to displace Palmerston's ministry. The industrial crisis in Lancashire, caused by the stoppage of the cotton supply in consequence of the American Civil War, now absorbed much of Derby's time and thought. He worked unceasingly for its relief, and subscribed several thousand pounds himself. His relations with Lancashire had always been cordial; after the cotton famine the cordiality passed into a warmer and deeper feeling

On the rejection of Earl Russell's reform bill in 1866. Derby formed his third cabinet. Disraeli returned to the exchequer, and Derby's son, Lord Stanley, went to the foreign office. This government lasted for more than two years. and managed to settle the parliamentary reform question. Disraeli's brilliant tactics in the commons during the session of 1867 enabled the ministry to retain control of its Reform bill's progress despite the passage of numerous important amendments. Derby's description of the measure as a "leap in the dark" was eagerly caught up, since it exactly expressed an attitude very common at the time: most experienced statesmen admitted that the grant of household suffrage was a political necessity. though they dared not predict its effect on the constitution and government of the country Declining health compelled Derby to resign office in Feb. 1868, to be succeeded by Disraeli. His subsequent appearances in public were few and unimportant, though his last speech in the house of lords, denouncing Gladstone's Irish Church bill, was marked by much of his early fire and vehemence. He died at Knowsley on Oct. 23, 1869.

Derby has no great reputation as a statesman. His abilities are indisputable but it is questionable whether he had vision and seriousness of purpose. Especially in his youth, he often acted on rash impulses. He could be an overbearing colleague and an unnecessarily bitter foe. He had no sooner left Grey's government in 1834 than he was comparing his late colleagues to "thimbleriggers at a country fair." He disliked the drudgery of office, and never again displayed the power of application he showed under Grey. As leader of the Conservatives he seemed to Disraeli weak and indolent. In fact he is remembered less for his achievements than as the type of the aristocratic amateur in politics. Whatever he did, he did extremely well: he was a large and successful racehorse-owner, a benevolent if autocratic landlord, and a considerable classical scholar. At Oxford he had won the chancellor's Latin verse prize; it was his reputation for scholarship as well as his social and political position that led to his own election as chancellor in 1852; and in 1864 he published his blank verse translation of the *Iliad*. Still, his political career was remarkable enough. As Disraeli said: "He abolished slavery, he educated Ireland, he reformed parliament." Moreover, the Conservative party owes him a great debt for his long period of leadership. He lacked. it is true, the narrow patriotism of party: though he was loyal to the unpopular Disraeli, he realized the inadequacies of the rest of his followers and was reluctant to take office unless it was absolutely essential in order to keep them together. But he deserves much of the credit for the survival of the Protectionists through difficult years, and for educating them to accept Disraeli as his successor and to fit themselves for ultimate electoral victory.

See G. Saintsbury, *The Earl of Derby (1892)*; W. D. Jones: *Lord Derby and Victorian Conservatism (1.956).* (D. E. D. B.)

DERBY, a municipal, county and parliamentary borough and the county town of Derbyshire, Eng., 15½ mi. W.S.W. of Nottingham by road. Pop. (1961) 132,325. Occupying a position almost in the centre of England, the town is situated on the Derwent, at the southern end of the Pennines. It has been the centre of an important network of rcutes since early times and more especially since the Industrial Revolution. A little to the northeast is Little Chester. which was the site of Derventio, a Roman fort or village. Under the Heptarchy (*q.v.*) Derby mas known as Northworthige, receiving its present name from Deoraby as it mas known to the Danes after the peace of Wedmore (878). The first charter was granted by Henry II about 1154–56; this charter confirmed the rights of a market and other privileges granted by Henry I and William I. 4 charter of John (1204) gave the burgesses the right to elect their own reeve. In 1745 Prince Charles marched as far south as Derby. In 1927 Derby became a separate bishopric, after being a bishopric suffragan of Southwell. The borough returns two members to parliament.

St. Peter's church is a fine building of Perpendicular date. All Saints'. with a beautiful choir screen and good stained glass, was made a cathedral in 192'7. Its tower (210 ft.), built in 1509–27, is one of the finest in the midland counties. Derby Grammar school, placed in 1160 under the administration of the chapter of Darley abbey, now occupies St. Helen's house. Derby possesses a county hall (1660). assembly rooms (1763–74), a municipal technical college, a museum and art gallery (1878), a training college (1850), large cattle markets and two theatres. A town planning scheme was adopted in 1929, and further improvements to the river were also carried out. Of the many parks, the Arboretum (1840) designed by John Claudius Loudon, is one of the earliest. At Allenton, a suburb south of the town, there is a war memorial village for the disabled. The municipal airport (1938) is at Burnaston. 4 mi. S.W. of the town. Derby is the birthplace of the philosopher Herbert Spencer and of the painter Joseph Wright (1734–97).

Derby is celebrated for its porcelain; its manufacture mas begun there in 1750 by William Duesbury and Andrew Planche. George III in 1773 visited the factory and gave Duesbury a patent to mark his china with a crown; thereafter it was called Crown Derby until 1890 when Victoria appointed the company manufacturers to the crown and changed its name to Royal Crown Derby. Duesbury in 1784 amalgamated at Derby the Chelsea and Bow factories of London. The china industry declined for a time but was revived from 1877 onward. Silk "throwing," or spinning by machine. was introduced in 1719 from Piedmont, Italy. by Sir Thomas and John Lombe. The fine wrought-iron gates of Lombe's mill are now next to the public library. The manufacture of silk, hosiery (helped by the inventions of Jedediah Strutt in 1758), lace and cotton formerly employed large numbers. and there are still many mills and factories making rayon, yarns and various fabrics. shirts and underwear. Canals helped the early industrial growth of the town, and in the 19th century a principal centre of the Midland railway mas established in Derby: there are still large works making rolling stock. Other industries include the manufacture of aircraft engines (Rolls-Royce); heavy and general engineering; and plastics, printing, paints and chemicals.

DERBY, a city of New Haven county, Conn., U.S.: see ANSONIA.

DERBYSHIRE, a north midland county of England, is bounded on the northeast by Yorkshire, on the east by Nottinghamshire and Leicestershire and on the west by Staffordshire and Cheshire. The area of the geographical county is 1,005.9 sq.mi.

Physical Features. — The county may be divided into two sections: the northern upland region culminating in the High Peak district, of which about 325 sq.mi. lie within the Peak District National park; and the smaller southern lowland area around Derby. It is thus a county of strong contrasts.

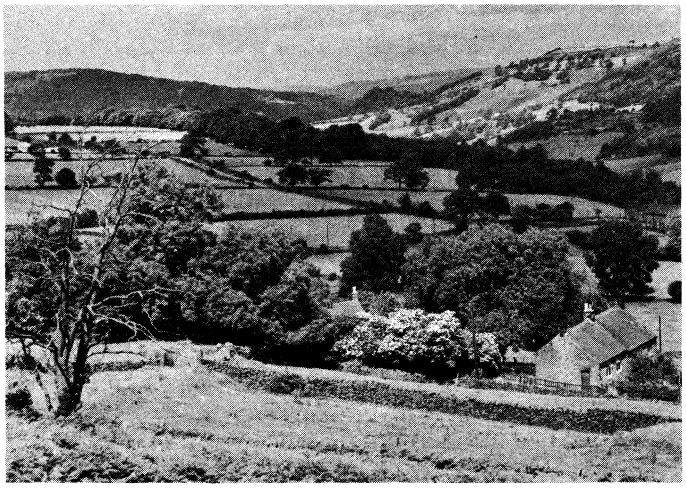
The great anticlinal system of the Pennines reaches its southern termination in the Derbyshire dome, which has been unroofed by erosion and now displays at its centre a large expanse of Carboniferous Limestone. It is in essence plateau country, falling slightly from the Castleton area in the north to Matlock and Wirksworth in the southeast, where it lies at about 1,000 ft. The limestone is deeply gashed by the valleys of the Wye and Dove, and in places the uniformity of its surface is broken by outcrops of volcanic rock. Parts of its margin are scarped and elsewhere it plunges steeply below the Edale Shales, the lowest member of the overlying Millstone Grit which consists of a thick series of alternating sandstones and shales. The shales, though accounting for more than half the total thickness, are easily eroded, leaving the gritstone as bold escarpments, sweeping in a great horseshoe from Axe edge near Buxton, northward by Black edge, then eastward by Rushup edge to Lose hill and Win hill. There the outcrop saings south. its lower members describing a series of zigzags nhere they are brought forward in subsidiary synclines, as at Bradwell and Eyam, at Bakewell and at Stanton. The higher members of the series outcrop east of the river Derrvent. In the north they build fine escarpments, such as Derwent edge. Farther south they underlie Eastmoor. beveled at about 1,000 ft. South again they are sharply folded and the little anticlines of Ashover and Crich have both had their crests eroded away, the former giving rise to a charming little scarp-rimmed vale.

Beyond the horseshoe of scarps the grit builds in the north the moorlands of Kinder Scout and Bleaklow hill, more than 2.000 ft. high and clothed in heather and peat. To the west it passes below the Coal Measure rocks of the Goyt basin and to the east dips under a more extensive outcrop of the same series. Between the coal seams. which, for all their economic importance, account for only a small part of the total thickness. the Coal Measures consist of an alternating series of sandstones and shales. In the Chesterfield area they appear to have been beveled at about 650–700 ft. and then eroded into a succession of sandstone scarps and shale valleys. As the sandstones are much less thick than those of the Millstone Grit, the scarps are smalier-scale features and, on account of the complicated folding of the coal field, they follow sinuous courses. East of the valleys of the Rother and its tributary the Doe Lea is the straight north-south scarp capped by Magnesian Limestone, which overlies the Coal Measures unconformably. Though nowhere more than 613 ft. high, it is a well-marked feature. Creswell caves are situated in one of several gorges cut into its dip slope.

None of these formations above the Carboniferous Limestone makes any appearance on the southern side of the Derbyshire dome. but the succeeding Triassic marls and pebble beds, which on the east lie beyond the county boundary, wrap round the south and underlie the Trent valley, where they are to a great extent masked by boulder clay. The higher northern region of the county bears few of the marks of glaciation and much of it mas probably untouched, at least by the later ice sheets. However, this section of the Trent valley formed a contact zone between ice from the north and west and ice from the east, and heavy deposits mere laid down. first of boulder clay and then of fluvioglacial gravels which form marked terrace features.

The Trent lowland occupies a relatively small part of the county's total area. By far the largest portion is drained by the Derwent, virtually the whole of whose basin falls in Derbyshire. The course of this strikingly direct stream begins in the extreme north. In the area west of Sheffield it receives a sheaf of tributaries from Bleaklow hill. Kinder Scout and the northern fringe of the limestone dome. Continuing southward in a fine and always deeply cut valley, it receives the Wye at Great Rowsley, traverses the very much narrower stretch from Matlock to Ambergate and joins the Trent to the southeast of Derby. The Dove. which for most of its course coincides with the Staffordshire boundary, rises south of Buxton and joins the Trent several miles above the Dern-ent confluence. The Erewash drains a small area in the southeast and joins the Trent between Derby and Nottingham. A considerable area around Chesterfield falls in the basin of the Rother which flows north to join the Don, and the Goyt gathers the streams from the western side of Black edge and Kinder Scout, carrying their waters westrrard to the Mersey.

The winters in the uplands are generally severe and the rainfall



J ALLAN CASH

DERWENT VALLEY NEAR AMBERGATE. DERBYSHIRE. ENG.

heavy. Mean annual rainfall ranges from 52 03 in. at Woodhead in the north to 25.59 in. at Derby in the south. At Buxton the mean January temperature is 36.1" F. compared with 39.4° at Derby and the respective July figures are 57.6° and 60°.

(A. M. F.)

History. — Important traces of the cultures of the Late Paleolithic Age were discovered at the Pinhole in the ravine of Creswell crags. The early settlement of Derbyshire was confined almost entirely to the well-drained Carboniferous Limestone lands of the Peak. The marked Derbyshire group of Beaker pots indicates an important settlement at the dawn of the age of metals around the Peak district. It is thought that the Beaker folk came from the European continent via the east coast, and groups apparently from the East Riding of Yorkshire reached the Derbyshire Peak district; others penetrated from the East Anglian coasts inland over the English plain. There are numerous megalithic remains in the same area, the largest stone circles being those of Arbor Low near Hartington, which retains most of its stones, and the "Bull Ring" at Dove Holes near Chapel-en-le-Frith. Finds of Bronze Age weapons and implements are not so numerous as in the neighbouring counties. Many defensible sites, especially in the north of the county, are capped by ancient camps which were probably in use over a great length of time. Mam tor near Castleton and Carl's Wark near Hathersage are good examples. Structures of this type were important in Romano-British and post-Roman times. The Romans were the first to utilize the lonlands to any great extent. At this period Littlechester, a camp to the northeast of Derby, became a focus of ways, receiving Ryknield street in particular. Aquae Arnemetiae (Buxton), Anavio (near Castleton) and Melandra (west of Glossop) were sites in the north.

The post-Roman centuries revived interest in the north until the conquests of the West Angles in the 6th century brought them up the valleys of the Derwent and the Dove. Later the district formed the northern division of Mercia. and in 848 the Mercian witan assembled at Repton. In the 9th century the district suffered frequently from the ravages of the Danes. who in 874 wintered at Repton and destroyed its famous monastery. Derby under Guthrum mas one of the five Danish burghs. but in 918 was recovered by Aethelflaed. In 924 Edward the Elder fortified Bakewell and during 941–942 Edmund regained Derby from the Danes once more. Saxon barrows are numerous in Wirksworth hundred and the Bakewell district, among them being White-Low near Winster and Boar-Low near Tissington. There are Saxon cemeteries at Stapenhill and Foremark hall.

Derbyshire probably originated as a shire in the time of Aethelstan, but for long it maintained a close connection with Nottinghamshire and Domesday Book gives a list of customs affecting the two counties alike. The two shire courts sat together for the Domesday inquest. and the counties were under one sheriff until the time of Elizabeth I. Early divisions of the county were known as wapentakes, five being mentioned in Domesday Book, while 13th-century documents mention seven, corresponding with the six present hundreds except that Repton and Gresley were then reckoned as separate divisions. In the 14th century the divisions were described as hundreds; Wirksworth alone retained the designation tvapentake until modern times. The miners of Derbyshire formed an independent community under the jurisdiction of a steward and barmasters, who held two barmote courts (*q.v.*) every year. The forests of Peak and Duffield had their separate courts and officers.

At the time of Domesday Henry de Ferrers owned almost the whole of the modern hundred of Appletree. The Ferrers estates were forfeited by Robert, earl of Derby, in the reign of Henry III. Another Domesday landholder was William Peveril, the founder of Peak castle, whose possessions were known as the honour of Peveril. In 1155 the estates were forfeited to the crown. During the reigns of John and Henry III discontent was rife in Derbyshire, and attacks were made on the central power. Riots occurred in 1443. In the 17th century the county first supported the king, but by 1643 Sir John Gell of Hopton had secured almost the whole county for the parliament. Derby. however. was always royalist and Roman Catholic in sympathy, and in 1745 entertained the young pretender, Prince Charles Edward.

Population and Administration. — Thearea of the administrative county (excluding Derby county borough), which contains six hundreds, is 993.2 sq.mi., with a population of 745.223 in 1961. Derby (*q.v.;* pop. 132,325) is the county town. The municipal boroughs are Buxton (19,236), Chesterfield (67 833). Glossop (17.490) and Ilkeston (34.672) (*qq.v.*). There are 16 urban districts, of which the largest are Belper (15,563), Long Eaton (30,-464), Matlock (18.486) (*qq.v.*), Alfreton (22.998), Heanor (23,867), Ripley (17,601), Staveley (18,071) and Swadlincote (19,222), and there are 9 rural districts. The total number of civil parishes is 256. Ecclesiastically the county originally constituted an archdeaconry in the diocese of Lichfield. In 1884 it was transferred to the newly formed diocese of Southwell. but in 1927 was created a separate diocese of Derby, which includes the whole county except three parishes in the diocese of Peterborough.

The assizes for Nottinghamshire and Derbyshire were held at Nottingham until the reign of Henry III. Then they were held alternately at Nottingham and Derby until 1566; thereafter the Derbyshire assizes were held at Derby. The county is in the midland circuit It has one court of quarter sessions and is divided into 17 petty sessional divisions. The boroughs of Derby and Chesterfield have separate commissions of the peace, and that of Derby has also a separate court of quarter sessions. The county returned two members to parliament from 1295 until 1832. after which it returned four members in two divisions until 1868. when six members were returned for three divisions. After 1955 the county returned ten members, one each for the following constituencies: Belper, Bolsover, Chesterfield, High Peak. Ilkeston, North-East Derbyshire, South-East Derbyshire and West Derbyshire: and two members for the county borough of Derby.

Industries and Communications. — Nearly 500,000 ac. are devoted to agriculture. but of this area not much more than one-quarter is arable land. Among the higher parts of northern Derbyshire, where the soil is poor and the climate harsh, grain will not flourish. while even in the more sheltered parts of this region the harvest is usually late. Such districts have heath pasture on which sheep are grazed. there being about 180,000 sheep in the county. Wheat and oats are the most important crops. A large part of the Trent valley is under permanent pasture, being devoted to cattle feeding and dairy farming. Cattle number about 180.000, of which roughly half are cows and heifers in milk and in calf.

Derbyshire has always been a mining and manufacturing county. The lead mines were norked by the Romans and Domesday Book mentions lead mines at Wirksworth, Matlock, Bakewell, Ashford and Crich. Iron has also been produced in Derbyshire from an early date. and coal mines were worked at Alfreton in the beginning of the 14th century. The woolen industry flourished in the county before the reign of John. when an exclusive privilege of

dyeing cloth was conceded to the burgesses of Derby. Thomas Fuller in 1662 mentions lead, malt and ale as the chief products of the county, and the Buxton waters were already famous in his day. The 18th century saw the rise of numerous manufactures. In 1719 Sir Thomas and John Lombe set up an improved silk-throwing machine at Derby, and in 1758 Jedediah Strutt introduced a machine for making stockings. In 1771 Sir Richard Arkwright set up one of his first cotton mills in Cromford and by 1787 there were 22 cotton mills in the county. The Derby porcelain or china manufactory was started about 1750. The industrial districts. based on the coal field, are in the east and extreme south-west. Silk, cotton, iron, papermaking, woolens, lace, malting and brewing are important. Derby and Belper are the silk and rayon centres, while Derby has also its china, lace, braids, chemical and engineering (Rolls-Royce) manufactures. Belper, Glossop, Ilkeston and Cromford specialize in cotton spinning and hosiery. The iron and heavy industries focus on Alfreton, Chesterfield. Clay Cross, Derby, Dronfield, Eckington, Staveley and Stanton. Lead, gypsum. zinc, iron ore, manganese and barites are mined to some extent. The county is famous for its limestone and marble quarries, while the fluorspar of the limestone caverns is made into ornaments. The warm mineral springs at Buxton, Matlock and Bakewell (also famous for bakery products) are well known. Derby is one of the great railway centres of the country. and one of the chief railway works is located there.

The main London-Derby-Manchester railway line runs from south to north .through Derbyshire, and the two Leicester-Sheffield lines pass through the east of the county. Derby is joined to Manchester and Sheffield by trunk roads, and these and other classified roads in the county total more than 1,500 mi. Derbyshire is also served by the Trent and Mersey canal, and Derby has its own airport at Burnaston, 4 mi. S.W.

DERELICT, in law, property thrown away or abandoned by the owner in such a manner as to indicate that he intends to make no further claim to it. The word is used more particularly with respect to property abandoned at sea. Land gained gradually and slowly from the sea belongs to the owner of the adjoining land by dereliction, but in England, in the case of sudden or considerable recession, the land belongs to the crown. *See* SALVAGE.

DERG (DEARGH), **LOUGH,** the name of two lakes in the Republic of Ireland, one of which is on the river Shannon along the boundary of County Tipperary with Galway and Clare, and the other on the river Derg in County Donegal.

Lough Derg on the Shannon (109 ft. above sea level) is 24 mi. long and ½ to 8 mi. wide with a maximum depth of 119 ft.; it is studded with islands and has the small towns of Portumna at its northern end and Killaloe (*q.v.*) with Ballina at its southern end, where it enters a gorge several miles long. The drop of over 100 ft. at the gorge was used for the first modern power scheme in Ireland (1925–29), which tapped the lake waters into a headrace (watercourse) more than 7 mi. long above the power station at Ardnacrusha. Because of the porous nature of the limestones in the Lough Derg area, the general shallowness of the lake and the variable climate, supplies of water for the power station have fluctuated beyond original expectations (*see* SHANNON).

Lough Derg in Donegal on the river Derg, a tributary of the Foyle, is renowned as a centre for a Roman Catholic pilgrimage of great austerity. This three-day retreat at the scene of St. Patrick's vision of Purgatory, takes' place annually (June–August) on Station Island, in the south part of the lake. The island has two churches, hostels and priests' quarters. W. M. Thackeray wrote of the pilgrimage in his *Irish Sketch Book* (1842).

(T. W. FR.)

DERING, RICHARD (*c.* 1580–1630), English organist and composer remembered chiefly for his vocal music. He supplicated for the Oxford B.Mus. in 1610, stating that he had studied music for ten years. In 1612 he may have journeyed to Italy. By 1617 he was organist to the convent of English nuns in Brussels. having become a Roman Catholic. In 1625 he was appointed organist to Henrietta Maria, and in the same year he was "musician for the lute and voice" to Charles I. He died in London and was buried there on March 22, 1630.

Collections of his music, all vocal and with *basso continuo,* were published at Antwerp between 1617 and 1620. His works remained popular after his death: Cromwell admired them and John Playford published some. Dering's compositions include motets, instrumental music, madrigals. English church music and two pieces based on London and country cries. (A. D. F.)

DERMAPTERA, an order of insects (*q.v.*), which includes the earwigs (*q.v.*).

DERMATOLOGY: *see* SKIN DISEASES.

DERMOPTERA, the name for the order of mammals comprising only the flying lemurs (*Cynocephalus* species), which were formerly included in the order Insectivora. *See* CYNOCEPHALUS.

DERMOT MAC MURROUGH (d. 1171), the Irish king of Leinster whose appeal for help first brought the Anglo-Normans to Ireland, was born *c.* 1110. His father Donnchad died as lord of Uí Cinsellaig and king of Leinster (1115). Dermot succeeded his brother Enna (1126), but had to face many rivals in his fight for recognition as king of Leinster. He attained his aim (1141) when he slew or blinded 17 of his chief rivals. To secure control of the abbey of Kildare (1132) he caused the abbess to be violated by one of his soldiers. Dermot abducted (?) Dervorgilla, wife of Tiernan O'Rourke, king of Breifne (Leitrim and Cavan); she returned to Tiernan soon afterward. Later Tiernan allied with Roderic (Rory) O'Conor, king of Connaught (Connacht) and high king (ardrí) of Ireland and drove (1166) Dermot from Ireland. With the permission of Henry II Dermot enlisted the aid of some Welsh marcher lords, notably Richard de Clare, earl of Pembroke (Strongbow) who married Dermot's daughter Eva and succeeded him as ruler of Leinster when Dermot died at Ferns on May 1, 1171. Though guilty of grave misdeeds Dermot was a patron of the monasteries in his kingdom. The abbot of Terryglass who compiled the *Book of Leinster* during his reign laments his expulsion (1166) as a great loss to Ireland.

DERNA (anc. DARNIS), a town on the coast of Cyrenaica, Libya, Africa, 224 mi. E. of Benghazi by road and one of the six administrative centres of Cyrenaica province. Pop. (1954) 15,891. Lying under the barren eastern ridges of the Jebel Akhdar on the small but rich delta of the Wadi Derna, a deep dry ravine which becomes a torrent after winter rain, the town presents a pleasant appearance with its white houses, vine-trellised streets and luxuriant palm gardens, which are watered by fine perennial springs and produce bananas, grapes and other fruit and vegetables. It has secondary schools for boys and girls and a government hospital. The bay is unprotected from northwest to southeast and is inaccessible in rough weather. The harbour is small, taking vessels up to 200 ft. length and 11 ft. draught, but there is good offport anchorage. The port is not busy except as a seasonal sponge-fishing base. Mutilated rock-tombs above the town are almost the only remains of the Darnis of the ancient Greek settlers. The ruins overlooking the town are of a fort built by the Americans who landed there under William Eaton (*q.v.*) in 1805. as a result of piracies on American shipping. (D. G. W.)

DÉROULÈDE, PAUL (1846–1914). French author, patriot and politician who promoted the Franco-Russian alliance. He was

born in Paris on Sept. 2, 1846. On the outbreak of the Franco-German War he enlisted as a private but, after attaining the rank of lieutenant, he was forced by an accident to retire from the army. His patriotic poems, *Chants du soldat* (1872), enjoyed great popularity and were followed by the *Nouveaux Chants du soldat* (1875). In 1882 he founded the *Ligue des patriotes,* inspired by the ideas of the French *"revanche"* (revenge), and was one of the first advocates of a Franco-Russian alliance. A supporter of General Boulanger, he was exiled in 1900 for having plotted against the republic. He received an amnesty in Nov. 1905 and died near Nice on Jan. 30. 1914. Apart from his patriotic poems. he published several plays including *Messire Du Guesclin* (1895).

See J. and J. Tharaud, La *Vie* et *la mort de Paul Déroulède* (1925). (A. PE.)

DERRICK, a type of crane; the name is derived from that of a famous early 17th-century Tyburn hangman, and was originally applied as a synonym *(see* CRANE). The derrick of the petroleum industry is a skeleton framework or tower of wood or steel for hoisting or lowering from a fixed point; the term also is applied to similar smaller structures mounted on motor trucks. Oil-field derricks are used to raise and lower the drilling tools in the well and also to insert and remove the well casing or pipe. *See* also PETROLEUM.

DERVISH in the middle east is a member of a Muslim religious fraternity. whether mendicant or not, resembling in some respects a Christian monastic order. The fraternities arose within Sufism (*q.v.*), which is in origin religion at an individual level, the single soul seeking its own salvation; occasionally such an individual would gather round himself a band of devotees under instruction, who shared his life and religious practices. Such groups were at first ephemeral, becoming in the 12th century continuous organized corporations, with established leadership, prescribed discipline and a "chain" *(silsila)* of reputed spiritual descent from God through Gabriel and Mohammed. Each initiant dervish (*murid*) must know the *silsila* of his fraternity. to which he is bound through his initiating teacher, with whom he is often in rapport through hypnotic control. The main devotional exercise of the dervish is the *Dhikr* (*zikr*), "remembering" (*i.e.,* of God), to emphasize to the worshiper his dependence on the unseen world; the ritual always stresses the emotional aspect of religion, and tends toward hypnotic phenomena and ecstatic trance, engendering physical states which have earned for the dervishes the names "howling," "whirling," "dancing," etc. Besides the few dervishes resident in community there are many lay members (including women), both classes now being largely drawn from the lower levels of society. The greatest expansion of dervish communities was in the central lands of Islam, where they played a vital role in the religious, social and political life of the Muslim community in the middle ages. Their monasteries are now often under governmental control, and their theological standing is discounted by orthodox theologians.

DERWENT, the name of several English rivers. The word is derived from the Celtic *Dwrgent,* meaning "clear water."

1. The Yorkshire Derwent rises 875 ft. above the sea on the heather-covered Fylingdales moor only 6 mi. inland to the north of Scarborough, yet it runs 57 mi. to its junction with the Ouse at Barmby on the Marsh. It drains an area of 787 sq.mi., flows through alternating gorges and vales and presents difficult drainage problems. These peculiarities result from the past blockage of its former easterly course, north of Scarborough, by a glacier in the North sea. Gorges were cut through the Tabular hills around Hackness at Langdale and Forge Valley, and also through the Howardian hills at Kirkham Abbey. The course through the vales of Pickering and York (south of Stamford Bridge) is strikingly flat and is underlain by thick glacial outwash, lacustrine deposits and, nearer the sea, by marine warp. Land drainage in the Vale of Pickering dates notably from the period of enclosures, but the artificial Hertford river in the east of the vale (which cuts the Mesolithic settlement site at Starr Carr) was the result of the Muston and Wedingham Drainage act of 1801. Water was also led along the wide preglacial course of the Derwent from a point north of the Forge valley out to sea at Scalby ness, a fall of 145 ft. in five miles over eight weirs. Mills at Malton, which interfered with drainage, were the subject of an act in 1846, and improvements are continuous. Hardly any part of the course is natural and there are weirs between Kirkham and Sutton, the tidal limit.

2. The Derbyshire Derwent rises on Bleaklow hill, 2,060 ft. above the sea, in bleak gritstone Pennine moorlands. Its upper valley has three reservoirs, Howden and Derwent (filled 1911) and Ladybomer (filled 1943). This last holds 6,300,000,000 gal. and when built was the largest British reservoir contained by an earth embankment. Together they supply the county boroughs of Derby. Leicester, Nottingham and Sheffield and the county council of Derbyshire. The river flows south through Chatsworth park, overlooked by impressive west-facing gritstone scarps, until at Matlock it runs on limestone for a short time. At Belper the beauty of the valley fades as a corner of the Derby coal field is crossed, and a little farther south the river enters the midland plain, runs through Derby and joins the Trent 100 ft. above sea level. Its tributaries are mostly right-bank ones, notably the Noe. a muddy river from Kinder Scout, and the clear Wye draining a limestone area.

3. The Cumberland Derwent rises 2,400 ft. above the sea on Great End in the Lake district in a rugged glaciated upland of Ordovician volcanic rocks. It drains Styhead and Sprinkling tarns. descends rapidly to Seathwaite, traverses the silted-up lake bed around Rosthwaite, where the Stonethwaite beck enters, through the Jaws of Borrowdale (truncated spurs) and into Derwentwater (*q.v.*). The remaining course is over the coal field past Cockermouth to the sea at Workington after a total unnavigable flow of 34 mi.

4. A river Derwent 30 mi. long flows northeast to the Tyne near Newcastle. (JN. P.)

DERWENT, the principal river of Tasmania, rises in Lake St. Clair, in the main highland massif, and flows 107 mi. southeastward to enter Storm bay near Hobart by a magnificent estuary 3½ mi. wide. Near its mouth is a remarkable floating bridge (1938–43) with a total length of 3,807 ft., of which 3,156 ft. are formed by 12 floating sections arranged in an arc convex lo the flood tide and prevailing winds. The principal tributaries of the Derwent are the Jordan. Clyde. Ouse and Dee. (O. H. K. S.)

DERWENTWATER, EARLS OF, an English title borne by the family of Radclyffe or Radcliffe from 1688 to 1716, when the 3rd earl was attainted and beheaded, and claimed by his descendants, adherents of the exiled house of Stuart, from that date until the death of the last male heir in 1814.

SIR FRANCIS RADCLYFFE (1625–96), 3rd baronet, and 1st earl of Derwentwater, was the lineal descendant of Sir Nicholas Radclyffe, who acquired the extensive Denventwater estates in 1417 through his marriage with the heiress of John de Derwentwater. Sir Francis mas created Viscount Radclyffe and earl of Derwentwater by James II in 1688. He died in April 1696 and was succeeded by his eldest son EDWARD (1655–1705), 2nd earl, who had married Lady Mary Tudor, a natural daughter of Charles II. The 2nd earl died on April 29, 1705, and was succeeded by his eldest son JAMES (1689–1716), 3rd earl, who was born in London on June 28, 1689, and was brought up at the court of the Stuarts in France as companion to Prince James Edward, the Old Pretender. He returned to England in 1710 and joined the Jacobite rising of 1715. He surrendered after the defeat at Preston and was then conveyed to London and impeached. Pleading guilty at his trial. he was attainted, and was beheaded on Tower hill on Feb. 24, 1716. declaring on the scaffold his devotion to the Roman Catholic religion and to "King James III."

The 3rd earl's estates were inherited by his only son, JOHN (d. 1731) who, despite the attainder. styled himself earl of Derwentwater. After his death on Dec. 31, 1731, his uncle CHARLES (1693–1746), son of the 2nd earl, inherited his estates and continued to use the title. Charles Radclyffe had fought at Preston in 1715 and was condemned to death for high treason, but, more fortunate than his brother, he escaped from prison and went to live in Rome. He was captured by an English ship in 1745 while proceeding probably to join Charles Edward, the Young Pretender,

in Scotland. and was beheaded for his former treason on Dec. 8, 1746. His grandson ANTHONY JAMES (1757–1814) died without issue in 1814, when the title became extinct *de facto* as well as *de jure*. .

DERWENTWATER, a lake of Cumberland. Eng., in the Lake District (*q.v.*). It is approximately oval in shape, about 3 mi. long and from ½ mi. to 1¼ mi. wide. The greatest depth is 72 ft. The lake, if seen from above, rests in an amphitheatre of mountains of varied outline, overlooked by others of greater height. Several elevations near the lake are famous viewpoints; *e.g.*, Castle Head. Walla Crag, Ladder Brow and Cat Bells. The shores are well wooded, and the lake is studded with several islands, of which Lord's Island, Derwent Isle and St. Herbert's are the principal. Lord's Island was the residence of the earls of Derwentwater. St. Herbert's Isle is so called because there lived St. Herbert. mentioned by Mede, in the 7th century. Derwent Isle (six acres) contains a handsome residence surrounded by lawns, gardens and timber of large growth. The Falls of. Lodore. at the upper end of the lake, consist of a series of cascades in the small Watendlath Beck. which falls over crags from a height of nearly *zoo* ft. The "Floating Island" appears at intervals on the southern end of the lake near the mouth of the beck. and is formed hy the accumulation of decayed vegetable matter floating on the water. The river Derwent (*q.v.*) enters the lake from the south and leaves it on the north, draining it through Bassenthwaite lake, which is separated from Derwentwater by a lacustrine delta, to the Irish sea. To the northeast of the lake lies the town of Keswick (*q.v.*).

DERZHAVIN, GAVRILA ROMANOVICH (1743–1816), notable Russian poet of the 18th century, was born at Kazan on July 14 (new style; old style, 3), 1743. He joined the army in 1762 and was made an officer in 1772. In 1777 he entered the civil service in St. Petersburg and during the next 26 years his posts included those of provincial governor at Olonets and Tambov, senator and minister of justice. His ode *Felitsa* (1783), addressed to Catherine the Great, gained her favour and he was for a time her private secretary. In 1803 he retired to his estate at Zvanka, where he died on July 20. 1816. He published an interesting book of memoirs (*Zapiski,* 1812). His main achievement lies in his lyrics and odes, among which are *Na smert knyazya Meshcherskogo* (1783, "On the Death of Prince Meshchersky"), *Bog* (1781; Eng. trans. *Ode to the Deity,* 1861) and *Vodopad* (1791–94, "The Waterfall"). His style was varied, often alternating between the sonorous and the humorous, and though it is uneven he remains Russia's greatest and most original 18th-century poet.

DESAIX DE VEYGQUX, LOUIS CHARLES ANTOINE (1768–1800), French military officer, was born in Auvergne on Aug. 17, 1768, the son of Gilbert Antoine Desaix, seigneur de Veygoux. Known at first as the chevalier de Veygoux, a regular officer: compromised and imprisoned after Louis XVI's deposition, he had the remarkable fortune in 1793–94 of being retained and promoted general by the deputies with the army of the Rhine, in spite of orders from revolutionary Paris. He showed his worth in the retreat to Strasbourg (1793), in the slow advance to Mainz (1794), in C. Pichegru's battle at Mannheim (1795), in his command of J. V. Moreau's centre corps in Bavaria (1796) and in the retreat through the Black forest. After being wounded at the passage of the Rhine in 1797 he went to Italy to see Napoleon and in his *Journal* de *voyage* (ed. by *A.* Chuquet, 1907) admirably described the army and its chiefs. Desaix took a division to Egypt in 1798 and after the battle of the Pyramids occupied upper Egypt against tough opposition from the mameluke Murad Bey. Napoleon did not take him back to France but called for him when he mas conducting J. B. Kléber's negotiation for evacuating Egypt. He was captured at sea and could not reach Napoleon until June 11. 1800. in Piedmont. Sent at once with two divisions toward Genoa. he had not gone far (because of floods) when he was called to the battlefield of Marengo (June 14). He was beginning the counterattack which turned the battle to victory when he was shot through the heart. Napoleon paid him the highest honours. (I. D. E.)

DE SANCTIS, FRANCESCO (1817–1883), the foremost Italian 19th-century literary critic, was born at Morra Irpina. Campania, March 28, 1817. A liberal patriot, he took part in the Neapolitan revolution of 1848 and was for some years a prisoner of the Bourbons. He then lived in exile in Turin and Zürich, where he became known as a teacher and lecturer. He returned to Italy in *1860*, and took up the work of educational reform, becoming minister of education (1861–62) and, in 1871, professor of comparative literature in the University of Naples. He died in Naples. Dec. 29, *1883*.

A scholar of literature and history, De Sanctis brought to his criticism also a knowledge of philosophy, particularly Hegelian aesthetics. His essays on the Italian poets *(Saggi critici,* 1866; *Nuovi saggi critici,* 1873), especially on Dante, Petrarch, Leopardi and Manzoni, relate these poets to the society of their times and show acute sensibility and unfailing critical judgment. His masterpiece, *Storia della letteratura italiana* (1870; Eng. trans. by J. Redfern. 1931) is not only a history of Italian literature but an illuminating account of the development of Italian society. Although his ideas on poetry and his belief that art is form have become dated. his work remains invaluable for the understanding of Italian literature and civilization. Much of Benedetto Croce's thought mas inspired by De Sanctis.

De Sanctis' *Opere complete* were ed. *by* A. Morano (1947). *See* also L. A. Breglio, *Life* and *Criticism of F. De Sanctis* (1941). (F. Dr.)

DESARGUES, GÉRARD (1591–1661), French mathematician, best known for his work in geometry, was born at Lyons on March 2, 1591. By profession he was an engineer and probably technical advisor to Richelieu and the government. Little is known about his earlier years; in 1636 he belonged to the scientific group in Paris centred around Marin Mersenne. He was fond of music and wrote a little manual on musical composition published by Mersenne. At the same time his *Traité de la section perspective* (1636) appeared. His main work. *Brouillon project* (1639), deals principally with conics and embodies most of his mathematical results of importance: it influenced the studies of Pascal, one of Desargues' disciples. In 1640 he published the manual, *La coupe des pierres en l'architecture* in *Leçons sur tenèbres,* which brought him into violent controversy with contemporary architects.

Desargues died at Lyons in 1661.

See R. Taton: *L'Oeuvre mathe'matique* de *G. Desargues* (1951). (O. OE.)

DESBORDES-VALMORE, MARCELINE (1786–1859), among the greatest of French women poets, standing in the foremost ranks of the minor writers of the Romantic period, was born at Douai on June 20, 1786. and as a girl earned a living on the stage. After desertion by a lover whose identity has not been established. she married the actor Prosper Lanchantin (Valmore), with whom her life was happy. despite poverty and bereavements. Passionate love, her children. Douai, religion and death were the main themes of her poetry, which is elegiac and characterized by spontaneity, sincerity and exceptional musicality. One of her prose works. *L'Atelier d'un peintre* (1833) is autobiographical. Her correspondence reveals her noble character. She was admired by contemporary poets and encouraged by Dumas the elder and by Sainte-Beuve; Verlaine and Baudelaire esteemed her highly. Her success was considerable from 1819 (*Élégies et romances*) until 1843 (*Bouquets et prières*), but she died in Paris. July 23. 1859. in comparative obscurity. Some of her best work was published posthumously (*Poésies inédites,* 1860).

BIBLIOGRAPHY.—*Oeuvres poétiques,* vol. 1–3 (1886), vol. 4 (1922); *Poe'sies complètes,* ed. B. Guégan, 2 vol. (1931); *Lettres* de *Marceline Desbordes-Valmore à Prosper Valmore,* 2 vol. (1924). *See* also C. *A.* Sainte-Beuve, *Madame Desbordes-Valmore. Sa vie et sa correspondance* (1870); J. Boulenger, *Marceline Desbordes-Valmore. Sa vir et son srcrrt* (1926); J. Moulin, *Marceline Desbordes-Valmore* (1955). (D. W. D.)

DESBOROUGH, JOHN (1608–1680), English soldier, was Oliver Cromwell's brother-in-law and played a prominent part in Commonwealth politics. He was born at Eltisley, Cambridgeshire. and baptized on Nov. 13, 1608. He married Jane, Crom-

well's sister, in June 1636. He was a member of Cromwell's cavalry regiment at the beginning'of the Civil War and distinguished. himself in succeeding campaigns, but he carefully avoided all participation in the trial of the king in Jan. 1649. He fought at the battle of Worcester (Sept. 1651) as major general and almost captured Charles II near Salisbury. During the Commonwealth he held many high offices and was a member of the parliaments of 1653. 1654 and 1656. In spite of his near relationship to the lord protector, he violently opposed the suggestion that Cromwell should assume the crown. After Cromwell's death he was. with Charles Fleetwood, the chief instigator and organizer of the hostility of the army toward Richard Cromwell's administration, and forced him to dissolve his parliament in April 1659. Desborough u-as chosen a member of the council of state by the restored Rump parliament. but presenting with other officers a seditious petition from the army council, on Oct. 5. was dismissed. He was ordered to quit London in Jan. 1660. After the Restoration he escaped to the Netherlands where he engaged in republican intrigues. He was ordered home, in April 1666, on pain of incurring the charge of treason, and was imprisoned in the Tower of London from July 1666 to Feb. 1667. Desborough died in London in 1680. His rough person and manners are the constant theme of ridicule in the royalist ballads. and he is caricatured in Samuel Butler's *Hudibras* and in the *Parable of the Lion and Fox.*

DESCANT, in 20th-century music. is generally a type of counterpoint composed above a hymn melody. The word is also applied to 16th- and 17th-century wind and string instruments, particularly the recorder and viol, in the treble range. In 16th-century vocal music, descant might refer to one of the high parts. although treble was probably commoner in this sense.

The word is derived from the Latin *discantus*, which in the middle ages described a musical improvisation on a plainsong. As usual at this period, definitions are not precise. but *discantus* always seems to refer to polyphonic music. In sources of the 12th and 13th centuries *discantus* is defined as note-against-note movement. This is in contrast with organum (*q.v.*), which combines a free voice made up of many notes with a tenor based on the plainsong, so that many notes of the free organal voice are set to each note of the plainsong. Another feature of *discantus,* according to Franco of Cologne (*c.* 1260), was that it was strictly measured in contrast with the organum, which was relatively free rhythmically as well as melodically. Improvised descant is really nothing more in the middle ages than the singing in parallel motion of a second part a fifth above the original plainsong, a third part a fourth above that and a fourth part a fifth above the third part if necessary. This procedure was described in the 9th-century treatise *Musica Enchiriadis,* and the only development in it seems to be a certain ornamentation of the highest voice. This type of improvisation was practised in England, particularly from the 13th to the 15th century, but instead of proceeding in fifths and fourths the singers employed thirds and sixths. The texture was generally three-part and a system of so-called "sights" was used to read the correct intervals above the plainsong. Since the plainsong was on a small four-line stave, the singer would read a small interval below the chant to gain the larger interval above: *e.g.*, a third below sung an octave higher gives a sixth above. Fifths and fourths were retained at the beginning and end of phrases. (G. RE.)

DESCARTES, RENE, otherwise RENÉ DES CARTES or. in Latin. RENATUS CARTESIUS (1596–1650), the greatest of French philosophers, whose astonishing analytical genius was displayed in the invention of co-ordinate geometry and in his contributions to theoretical physics. to methodology and to metaphysics. was born at La Haye in Touraine on March 31, 1596, the third child of Joachim Descartes. councilor of the *parlement* of Rennes in Brittany, and of his wife Jeanne Brochard, who died in the following year. At the age of eight he was sent to the Jesuit college at La Fleche, then "one of the most celebrated in Europe." where he devoted five years to grammatical and literary studies and three to the sciences, elementary philosophy and theology. The college's mathematical teaching was strong. and mathematics soon became his favourite study "because of the certainty of its proofs and the evidence of its reasonings"; but he then supposed it "only to serve the mechanical arts," so that its "true use" did not at first occur to him, though he was surprised, its foundations being "so firm and strong." that nothing "loftier" had been erected on them. He acquired also some notions of the new discoveries in optics, astronomy and the use of the optical instruments recently invented. His delicate health secured for him permission to pursue his studies abed until midday—a practice that he retained throughout life. Leaving La Flèche in 1612. he passed to the University of Poitiers, where he graduated in law in 1616 (he appears, however, never to have practised).

Weary of study and desiring to see the world, he then joined the army of Prince Maurice of Nassau. to whom his mathematical ability was useful in military engineering. At Breda (1618–19) he became acquainted with Isaac Beeckman, a mathematician and rector of the college at Dortmund, who brought his mind back "to science and worthier occupations." With mutual enthusiasm they discussed a new way of treating physical problems. designed to render them amenable to mathematics. Resuming his travels in April 1619. Descartes eventually reached a German town, probably Neuberg, where he shut himself up "*dans un poêle*" (*i.e.,* "in a well-heated room") for the winter. There "a wonderful discovery" and "a marvellous science" were revealed to him in a dream (St. Martin's eve. Nov. 10, 1619), which clarified his purpose and determined his future endeavours, showing him that physics should be reduced to geometry and all the sciences be interconnected "as by a chain." He was to pass the next nine years in applying this method to algebra. Returning to France in 1622, he sold his estate in Poitou "to be free from the obligation of making a living by science." Resuming his travels, now through Switzerland and Italy, he carried out meteorological observations, studied glaciers and computed the heights of mountains. Returning again to France in 1625, he spent the greater part of the next three years in Paris in the company of men of science—Claude Mydorge, Etienne de Villebressieu, Jean de Silhon. J. B. Morin and his former school-fellow, the obliging Marin Mersenne. "in whom was more than in all the universities together." Completely possessed of his method by 1629, he expounded it in the invaluable, though unfinished, *Rules for the Direction of the Mind* (*Regulae ad directionem ingenii,* posthumously published in 1701).

Leaving Paris. Descartes went to Holland; and for more than 20 years from the beginning of 1629 he was to remain almost permanently in that country, profiting from its tranquillity and greater intellectual freedom: he made only three visits to France in all this time. In 1633 he finished *Le Monde* (its two parts dealing with "Light" and "Man"), wherein he reaffirmed the Copernican hypothesis of the earth's movement around the sun. But before publishing this he learned through Mersenne of Galileo's severe censure by the Inquisition for having advanced the same hypothesis; and to avoid conflict with Rome, he immediately stopped publication. Within four years of his scare at Galileo's condemnation. after "suitably" modifying his cosmology, he published his epoch-making work, the *Discourse on the Method of properly Guiding the Reason in the Searclz for Truth in the* **Sci**-*ences; Also the Dioptric, the Meteors and tlze Geometry, which are Essays in this Method* (*Discours de la méthode de bien conduire sa raison et chercher la vérité dans les sciences; plus la Dioptrique, les Météores et la Géométrie, qui sont des essais de cette méthode,* Leyden. 1637), so presenting fully worked-out examples of his method's application. The six-part *Discourse,* which claimed "not to unfold the method but only to talk it over," at the time a highly revolutionary manifesto. mas really an extended preface: it has remained a philosophical classic. It fomented controversies with Pierre de Fermat and several other mathematicians which were a long cause of irritation to Descartes. Five years later his principal metaphysical work appeared: the *Meditations on First Philosophy, in which the Existence of God and the Distinction between Mind and Body are Demonstrated* (*Meditationes de prima philosophia, in quibus Dei Existentia et animae humanae a corpore distinctio demonstrantur,* 2nd ed., Amsterdam, 1642, including "objections" contributed by Thomas Hobbes, by Pierre Gassendi and by Antoine Arnauld and the author's replies to them; the 1st ed., Paris, 1641, had a slightly different title). Meanwhile in

this land of toleration he was to meet nith enmity, the bitterest coming from Gisbert Voet (Gysbertus Voetius). president of the University of Utrecht, who, insinuating atheism. was instrumental in securing Descartes' condemnation by the local magistrates. But he had many friends and admirers in Holland too. and among them the refugee Princess Elizabeth of the Palatinate, daughter of the titular king of Bohemia. whose "most thorough and comprehensive understanding" of the *Discourse* and of the *Meditations* he thought "incomparable." To her he dedicated the *Principles of Philosophy* (*Principia philosophiae,* Amsterdam, 1644), in which the entire system was resumed under separate articles.

Descartes had hardly completed the *Passions of the Soul* (*Traité des passions de l'âme,* Paris. 1649) when Queen Christina requested him to come to Sneden and instruct her. He contemplated wryly this invitation "to live in the land of bears among rocks and ice" and feared too for his habits and independence, but was eventually persuaded by Pierre Chanut, the French ambassador. He left Amsterdam on Sept. 1. 1649, and reached Stockholm about a month later. Five o'clock in the morning was the bleak hour that the queen fixed for her lessons. Descartes. returning one bitter morning. caught a severe chill; and uithin a fortnight he died, on Feb. 11, 1650, having passed about four months in Sweden. His remains were brought back to France and buried in the church of Ste. Geneviève du Mont in Paris.

THE PHILOSOPHY OF DESCARTES

Methodology.—Descartes' earliest activities were confined to the sciences: only later did he turn to metaphysics, and his reason for doing so is of the first importance for understanding the orientation and distinctive character of his whole philosophy. To compass his purpose of enabling men to become "masters and possessors of nature," by improving "medicine, mechanics and morals." he saw that it was insufficient merely to augment the sum of what then passed for scientific knowledge and to continue using the methods that produced it. Confirming Francis Bacon's opinion that "the entire work of the understanding must be begun afresh, and the mind itself be, from the start, not left to take its own course, but be guided step by step," he devised and applied a method of discovery and demonstration whose results should replace the unclear. tentative and ununified conclusions of current scholastic science, the defects of which he traced to two sources: the obscurity of the concepts that it used in formulating and resolving its problems; and the lack of a universally applicable method adequate to the diversity of scientific data. Rejecting both the faltering, hand-to-mouth procedures of medieval science, which produced only "a collection of curiosities" attesting their users' sagacity, and the "occult qualities" and "substantial forms" (*e.g.,* weight, hardness, lightness, heaviness) the obscurity of which contrasted so unfavourably with the lucidity of geometrical ultimates (*e.g.,* point. plane, straight. circle), he would substitute a truly scientific method by which, from applying its few highly general principles, conclusions would he seen to follow necessarily and be verifiable by all. Only when the results in every science were as clear, controllable and certain as those in mathematics would the claim to have attained knowledge be justified. Mathematics thus became the exemplar of science in every field, empirical no less than formal; and its excellence. Descartes saw, mas due to the exactness of its data and lay in its power to explain very much by means of very little, Aristotle too had explained its certainty by its fornal character and. thinking this peculiar to it, denied that like certainty was attainable in other sciences having nonformal, empirical facts for their subject matter. Medieval scientists confirmed Aristotle, maintaining that each science's method must vary with. and answer to, differences peculiar to the materials that it investigated. It is here that the originality of Descartes' reform in methodology is most easily seen. He denied that differences in the diverse data of the various sciences should dictate a difference of method appropriate to them severally, for, disparate though their data be, they all alike advance by reasoning which is of the same fundamental character whatever be the terms. Since it is one and the same reason that is operative in all men, it follows, he thought, that there can be but one universal method, applicable indifferently to every kind of datum and problem'; which eventually would yield a unitary, comprehensive. internally interconnected body of results. It would iurnish not a "collection of curiosities" nor a plurality of detached sciences but a single and universal science. This is Descartes' momentous and historically most influential conception of a revised method, whose purpose and directive character he excogitated in outline at the age of 23. By its means he would first unify the branches of mathematics, then reconstruct and interrelate the nonmathematical sciences as well—a project which he admitted to be "incredibly ambitious." For it is one thing to think out the requirements that such a method must fulfill, quite another to devise one that satisfies them. To the last task he next turned. The several sciences should be so transformed in their constitution as to be unified into one whole, much as are the branches of the trunk of a single tree. And this he thought should be possible because they all employ the same kinds of operation, so that the new method in its application would be but a projection, into the continuous process of conceiving and inferring, of the intrinsic, universal nature of reason itself. That being so, it was incumbent on Descartes to analyze exhaustively the nature of our reason and elicit from it the constitution of that single method which he was seeking. This analysis would perforce be restricted to results established with certainty and finality, ignoring those that were merely possible, probable or tentative—which meant for Descartes that he would limit himself to analyzing reason when employed in mathematics. Its forms there displayed should reveal its precise nature and therewith the conditions of its success in other fields. His analysis, comprising two interdependent doctrines, concerns (1) the intellectual operations together constituting what is meant by "reason"; (2) the character of the subject matter in relation to which alone those operations are possible and successful. These doctrines together define the new. single method to he substituted for the variety of *ad hoc* procedures of medieval science.

1. No more than three kinds of operations are employed in mathematical reasoning: *intuitus, deductio, enumeratio.* The most fundamental is *intuitus,* a noninferential act of direct prehension—single, momentary and infallible—by which we no more than conceive a certain term, complex or simple (*e.g.,* a sphere or straightness). *Deductio* is not syllogistic deduction but an operation consequential upon *intuitus;* it elicits which terms among a series successively intuited depend upon which. or else what are the relations obtaining of necessity between which terms. It proceeds analytically and synthetically; *i.e.,* it passes from more complex to less complex or even simple terms and conversely from simples or relatively less complex to more complex terms. Subsequently recourse is had to *enumeratio* to avoid error due to faulty memory in cases where the steps in a passage of *deductio* are too numerous for all to be comprehended at the same moment. It consists in going over these steps again and again, each time shortening the whole passage by colligating the contents of its several stages under ever fewer but more complex concepts until the whole be so marshaled within a single span of attention as to eliminate all dependence upon memory.

2. No term fitted to be the object of these operations may be a sensible quality of any kind, for these, being all confused, cannot be clearly conceived separately or in combination. Only terms clearly conceivable in themselves and whose differences and connections among themselves are distinctly discernible can be objects for *intuitus,* and these are natures either complex or simple. To understand a complex nature we must decompose it into its constituent simples, discern the special character of each, also the order or manner in which they combine to make up the original complex. such decomposition and recomposition exhibiting the method's analytic and synthetic functions. All the .ultimate indefinable~(other than those of sense) to which we refer and which we use in thinking are called by Descartes "simple natures"; *e.g.,* what is immediately conceived and named by the words unity, independency, universality, cause, existence, substance, motion, point. straight. equality, duration. shape, magnitude, know. doubt, will, like, diverse, etc. The number of these natures he believed

to be very small. Just as the letters of the alphabet, recurrent in ever new combinations. make up the profusion of words in a language, so the variety of natural objects should be reducible to differences of combination and differences of the natures combined; and as we decipher a book by knowing the words and the syntax of its language, so from a knowledge of simple natures and mathematics we may hope to decipher the natural world. Physics and chemistry mould accordingly become "sciences of number, weight and measure." In this way, Descartes expected to reach a unitary and exhaustive system of laws applicable universally throughout nature which should replace the tentative explanations of isolated facts characteristic of medieval science. Now in order to be genuine science and not merely presumed such by convention, our conclusions, besides being clear and compatible, must also be, and be knoan to be, true of what exists independently of us and our thinking. This further requirement, however, the method cannot satisfy, for it relates only to the passage in thought from idea to idea. alone it can furnish no more than an ordered system of ideas, but one—for all that we may know—that lacks any save a supposed and unauthenticated reference to things existing independently of it. Consequently, if ever the hypothetical physics furnished by his method was to be transformed into a certain and final knowledge of nature, Descartes had to make good the inalienable claim of knoaledpe to be "of" what actually exists and not merely of what is conceivable. The step from representation in idea to affirmation of existence must be authenticated. Should these ideas really be true of what exists independently, the very fact that they are so must itself be established But this fact neither mathematics nor methodology is empowered to guarantee. Yet science can be shown to be synonymous with strict knonledge only if Descartes establishes aith certainty that certainty about what exists is attainable and, in particular, is obtainable about those very things nhich we suppose to exist and be the subject matter of physics. There are thus. for authentication, two conditions to be satisfied: first, that uhich authenticates must itself be something existent and discoverable to be so nith certainty; secondly, that uhich authenticates must be such that from its existence we can deduce with certainty the necessary existence of the objects of physics. Consequently. Descartes' first step is one not of demonstration but of search He must discover that of which it is impossible to doubt or to deny the existence, and to this end he adopts systematically the practice of "methodical doubt"

Metaphysics.— He begins by doubting the existence of things that are, and things that are not, commonly found dubious in order to discover whether there be one that withstands his determination to doubt of it. This decision, however. does not imply the assertion that what is doubted must be either false or improbable; the injunction de *omnibus dubitandum* ("that all things must be doubted") is a predetermination by the will to suppose false whatever we can suppose so. in order to test thereby the possibility of its being false. If, among our convictions so tested. one be found that resists indubitably our most thoroughgoing attempt to suppose it false. we shall be assured thereby that it cannot be overturned in the future; for what destroys the strongest possible doubt must by that fact be absolutely certain—be so and not merely be assumed such. Now whatever cause of deception me choose to suppose, however regular we suppose its operation, there is one affirmation that we all can make about ahich it is impossible that we should be deceived: the affirmation of our own existence, at least at that time when we attempt to doubt it. It is impossible for any cause of deception to bring it about that on the occasion when I am being deceived I do not then exist. I. the doubter, must exist while doubting; "the proposition 'I exist' is necessarily true each time I assert or conceive it." Whether or no deception involves an existent deceiver. it necessarily involves someone existing and capable of being deceived, for it is only a person (not "an idea") that could be deceived. In this way Dcscartes reached his first certitude—cogito *ergo sum* ("I think therefore I am"; better reformulated by Spinoza: ego *sum cogitans*, "I, in being conscious, am existent")—shoning thereby that certain knowledge is attainable by having attained it and reaching therenith the first (and only) instance in which the thinker is directly related to something actually existent and not to an idea. For my self's existence is disclosed to me by no intermediary, instrumental idea that represents me to myself. my self is known to me exactly as and for what it is at the moment of my apprehending it. The *cogito* thus expresses the fundamental situation from and within which Descartes claims to demonstrate with a like certainty the existence of other things. But these are not to be known in the same manner, by the thinker's direct apprehension of their existence, but by his inferring that they exist from certain ideas present to *intuitus*. Henceforward, the immediate objects of the thinker's awareness are always ideas.

By having made one's awareness of one's own existence the first certainty. that is, the primary fact and initial datum of metaphysics. Descartes introduced a new orientation of very far-reaching influence into his own and into subsequent European philosophy—one that differentiates it most characteristically from ancient and medieval metaphysics. For he raised from inferior rank and gave primary place to epistemology, by directing attention to the nature of ideas (their status and their relation to existence) and to the significance and implications of the peculiar fact of one's self-awareness. Passing to the second of the conditions to be satisfied for authentication (see above), Descartes has now to deduce the existence of things other than himself. A review of the ideas occurrent in the continuum of our thinking discloses (1) some that are of diversely characterized bodies that move, change and interact in various ways; and also (2) the idea that those bodies are all dependent upon a further existent that is independent of them—that commonly named God. The existence of bodies, since not entailed by our ideas of them, must be demonstrated indirectly; their existence must be shown to follow necessarily from something whose existence does follow directly from our idea of it. Now, the only other idea we have (besides our innumerable ideas of different bodies) is the idea of God. Hence, if an indirect demonstration of the actual existence of bodies be possible at all, it must be consequential to a prior demonstration of God's existence. It is thus the "existential reference" of our ideas—that in them which constrains us to assert actual existence of something, in independence of the idea's suggestion of it—which has to be justified from case to case. For merely to contemplate an idea does not expose us either to truth or to error, but we are committed to one or to the other if we go on to assert or to deny the existence of something to correspond to it. Now, among our ideas, the majority, being supplied by sensation, are confused; but a few, due to our powers of conceiving and inferring, are clear and distinct. hence suitable as sources of knowledge. Further, there are cases in which an idea of one kind claims to represent the same thing as that which one of the other kind claims to represent, and yet these two ideas are incompatible and almost wholly unlike each other; *e.g.*, on the one hand. a sensory idea of "the sun" as being a "flat red disk as large as a florin located over yonder hill" and. on the other, the astronomical concept of that "sun" as being "an uncoloured sphere larger than our earth and located some 90,000,000 miles from yonder hill." Both these ideas, despite their patent incompatibilities, "represent the sun." But the former gravely misrepresents its real nature. and neither alone warrants our assertion that the sun exists. The astronomical concept is a result of employing the method; but any existential affirmation is beyond its competence. Failure to authenticate the existential reference of ideas, however. would commit us irrevocably to the conclusion that never could we have knowledge, astronomical or other, of the universe and that solipsism must be the last word; for our egocentric starting point would be also our closing point, since, by hypothesis, all we could know to exist would be ourselves and our successive ideas. But failure to authenticate the independent existence of material objects certainly will ensue unless there be one idea such that of itself the existence of that of which it is the idea follows necessarily. Such an idea is that of God, and it is the only idea satisfying the condition. It is unique, peculiarly different from all other ideas in that it connotes certain perfections—omniscience, omnipotence, perfect veracity. This idea is incontestably thought by us at times; even

an atheist must think it, or his denial of God's existence would be nonsignifying. But, Descartes asks, how shall such an idea be thinkable, how should ideas of perfections be indeed thinkable? Not, certainly, from finding them in ourselves; we are notoriously imperfect. Nothing, he decides, could explain the very possibility of our thinking such a thought as that of the divine nature save an existent of a nature adequate to cause it. An existent actually possessed of those perfections, however, answers completely to our defining idea: therefore must be its cause, and hence exist. To this demonstration from the empirical fact of the idea's being found in men's minds, Descartes adds a second, adapted from St. Anselm. which, passing from the perfections composing the divine nature, infers the necessary existence of that which possesses them. Since "God" is defined as the most perfect being conceivable, for such a being not to exist would be for it to lack a perfection. But "the most perfect being conceivable" could not lack a perfection and certainly not that of existence. So. from this definition alone, Descartes thought it followed that denial of God's existence involves self-contradiction. From his double assurance of God's existence and essential nature. Descartes thinks, he sees a way by which to pass to demonstrating the necessary existence of an independent physical world. peopled with moving and interacting bodies, of which he formerly had only ideas. From his indubitable assurance of *ego sum cogztans* and *Deus est* ("God exists"). he may demonstrate his third and last assertion of existence: *corpora sunt* ("bodies exist").

The existence of an independent world of bodies is demonstrated from two divine attributes: omnipotence and perfect veracity. Error and deception, being due to what is imperfect. cannot derive from God, for they are incompatible with omnipotence and complete veracity, as with omnipotence and perfect goodness. Our numerous representations of natural bodies inanimate and animate, being mostly sensory ideas, are highly confused, so Descartes has first to replace them by a clear concept that defines the minimum and essential connotation of their common materiality. That which constitutes the materiality of any material thing must be that on account of which it remains the same thing after, as it was before, undergoing its alterations in time. A character that the body displays at one moment but lacks at another cannot be, or be part of, its essential nature. for we declare it to be the same thing when not possessing as when possessing it. Hence, no sensible quality nor single definite shape or determinate rate of motion that it temporarily displays belongs to it essentially. but only contingently. Throughout its course of alterations there are but two properties constantly conserved. its extensity and its mobility. each variously determinable under different causal conditions. These attributes are alone clearly conceived to characterize permanently all physical things and so define their "matter." while definite shapes and varying rates and directions of motion are but ephemeral specifications or limitations of these constant attributes and objects of special study by geometry and kinematics. Thus we have a clear conception of what bodies would essentially be. were they existent; it remains to demonstrate that they do exist. independently of our conception. But with this idea of matter, as with the idea of God, there must be a sufficient reason that accounts for its being thinkable. Having shown that this cannot lie in the thinker's powers of sensing, imagining and willing. Descartes affirms the remaining alternative: it must be an independently existing matter possessed of those defining attributes. And this third affirmation of existence is vouchsafed by the divine veracity previously established; for a God wholly veracious and omnipotent could not deceive us if we affirm no more than is clearly and distinctly deducible. It follows then that normal sense perception is trustworthy in inclining us to assert the existence of bodies, untrustworthy only in reporting their natures. For the characters that bodies appear to possess (colours, odours, temperatures, etc.). being not clearly conceivable but only vividly sensible, are at most "by-products," epiphenomena collaterally occurrent when our sense organs are acted upon by bodies external to our own.

Thus both demonstrations (of God and of matter) are of the same form. Proceeding under the injunction *de omnibus dubitandum,* Descartes nowhere asserts but everywhere supposes the thing thought in idea not to exist, precisely in order to demonstrate that it does exist; beginning in both cases from a clear idea that defines the nature of the thing whose existence is in question. The principle of divine veracity which guaranteed the affirmation that bodies exist independently of our conceiving them is next applied retrospectively to the *cogito.* At that juncture, one was assured of one's onn existence only on occasions of self-awareness. But such momentary disclosures. being intermittent, do not suffice to attest either the continuity or the identity of our self through periods between their occurrences nhen we are unaware of our existence, as in dreamless sleep or unconsciousness. But that principle of divine veracity which was adequate to validate a belief in the continued existence of bodies unperceived serves with like legitimacy to assure us of our own persistence when unperceived—besides authenticating the further affirmation that minds other than one's own exist. Thus the solipsism. which earlier may have seemed insurmountable. is transcended at the close of the *Meditations,* where Descartes concludes that we are indubitably assured of the existence of God. of a plurality of selves that think. of innumerable extended bodies that move and of the complete disparity in nature of selves and bodies. The existence of an independent world whose status was originally only problematical—it being but a working hypothesis of physics—is now, he believes, finally established as veridical or factual. God alone is eternallv existent: whatever exists in time. depending upon God for its continuance, is either a body or a self, having for its ultimate inalienable nature either *extensio* (three-dimensional extensity and potential mobility) or *cogitatio* (awareness, feeling and volition). The continuant body or self displays its attribute throughout its changing existence in a series of actions and states ("modes" of that attribute) all determinate and qualitatively very diverse. Descartes now turns from "questions of existence" to "questions of essence." He makes each disparate attribute in turn the subject of a protracted deduction that shall explicate the principles of connection between its determinate modes and the laws of their causation. These two deductions form his philosophy of nature and his philosophy of mind; they should not however be identified with what are now called physics and psychology, for these he would allow to be only groups of more or less coherent hypotheses whose knowledge-value was highly problematical.

Philosophy of Nature.—To exhibit his "concrete geometry" as a veridical philosophy of nature and not a mere physics of a possible world. Descartes was required to show that it follows necessarily, without break, from his metaphysics. This should be possible, he thought. for his metaphysical conclusions and the initial principles of his natural philosophy are both of universal import, therefore of a character to be deducible, the latter from the former. The transition once effected, the rest of the deduction consists in showing step by step that principles less universal follow from others more universal, all together being adequate to explain the constitution of the natural world and the main types of change occurrent in it. Its laws of the highest generality once ascertained, he thought that he could then apply them to explain facts more special, though still general. of physics, optics. astronomy and other sciences, respecting the varieties, differentiating properties and behaviour of bodies, inanimate and animate. using throughout laws of two kinds only: those of motion and of space. Now the identification of matter with space entails that matter is wholly passive. No property of space necessitates motion, so motion, though presupposing space, is not deducible from it. Further, an explication must be found for the actual division of this intrinsically passive matter, this infinitely divisible but undivided space. into innumerable figured parts—volumes or bodies—and then for their individual changes of condition and of place. Descartes thought to explain both the plurality and individuality of bodies and their changes by means of one "simple nature": motion. But since space cannot impart motion to itself, nor selves impart it. the only source from which motion could be imported into space is the sole existent remaining. namely God. Xnd God is an adequatc cause. for, being omnipotent, this source must be sufficiently empowered; and being immutable, it follows that the quantity of motion imparted to, and conserved throughout, space must be con-

stant, susceptible of being variously distributed from time to time, but not of increasing or diminishing its sum. All multiplicity snd diversity are thus derivative and in origin extraneous to the natural world. The identity of each particular body is founded in the constancy of its magnitude, this alone being conserved throughout its altering shapes and movements. Its locomotions. however. are not from and into independent. fixed places that are "ahsolute." neutral as between their occupants and successively occupied by different bodies, as Aristotle had supposed. The place of a thing at a moment is not "absolute" but wholly relative to the place of another at the same time, which other thing we agree to regard as immovable. That a body has moved means that it is now related to some other body by a distance different from that which related them previously—it is simply a question of convenience which be declared to move and which to be at rest, for "nothing has a permanent place except so far as it is fixed by our thought." Thus. it is convenient to say of a man seated aboard ship that he is "at rest,"—as he is, relatively to the ship's deck; but he is nonetheless "in motion." relatively to the harbour. Though motion is real, place or position is "a distinction of reason." "Motion is the transporting of one body from the vicinity of those bodies then in immediate contact with it to the vicinity of other bodies not then. in contact with it." Neither does movement take place through a space unoccupied by bodies, nor does any body expand or contract. for both suppositions assume the existence of space that is empty. "To move" means simply to be in different places at different times. And since the identity of a body consists wholly in a certain magnitude (a certain constant quantum of extension), to speak of its volume's being increased or diminished can mean only that parts of its divisible extension have become separated by greater or lesser distances than those which previously separated them; there being no alteration of the body's original extension but merely displacement of its constituent parts. So unless "empty space" means space not displaying its usual or expected content, it is a contradiction in terms. From space's being indefinitely divisible it further follows that there can be no atoms; for even bodies so small as to be imperceptible will still be extended and therefore composite bodies further divisible. "Atoms," "empty spaces," "rarefaction" and "condensation" are at best convenient fictions. Having explained. by assigning its "first cause," how there should be motion at all in the world. Descartes next deduces the "secondary causes" sufficient to explain particular motions occurrent in this or that body. The total quantity of imparted motion being constant. the law of inertia immediately follows: no body changes spontaneously; for the initiation. as for the cessation of its motion, a cause is required. since a body always continues in its present state; at rest. unless another move it. or in motion, when moved. until another retard or stop it. And all movement is in a straight line, curvilinear motion requiring the intervention of a cause additional to that which initiated the movement. (These two laws are approximately the same as Sir Isaac Newton's famous "first law," formulated 40 years later.) Descartes now turns to velocity—an intensive: not an extensive or geometrical property of motion—and, to explain it, falls back on mass: their product defining "quantity of movement." Since he identified matter with space, he is able to define mass as volume. But this device does not really serve him, for (as Leibnitz afterward showed) retardation of movement cannot be explained by volume or space alone. What Descartes in fact required was not a geometrical but a dynamical property, and he probably saw this but refused to introduce what he considered "occult" for fear of compromising the wholly geometrical character of his natural philosophy. A third law, that of impact, with these two laws of inertia, exhausts the conditions necessary and sufficient for the occurrence of particular movements: "If a moving body impinging on another has less force to continue moving in a straight line than the other has to resist it, it loses nothing of its movement though it changes its direction; but if the former body has greater force it moves the other with it, losing so much of its movement as it imparts to that other." From these most general laws. applicable to all motions of all bodies indifierently, he then deduced seven special laws, applicable to typically different cases of impact.

The same principles explanatory of the constitution and changes of inanimate bodies are extended to explain those of animate ones—Descartes' anatomy and physiology require no principle additional to those of his celestial and terrestrial mechanics. A mechanistic biology is but a corollary to his mechanistic physics, animate bodies being but natural machines. Though their actions are more complicated and various than those of machines artificially constructed. nevertheless, like these they presuppose no more than a certain disposition of the body's parts or organs. Thus the spider is a natural weaving machine; the mole, a digging and boring automaton.

But there is a subclass of animal bodies—it was forced on Descartes' attention—which are peculiar compounds, such that the body machine exists in a continuous and intimate union with a "thinking thing"—a union that cannot be deduced from the principles of the "concrete physics" but which can be known only from observation and inference: the union of an extended human body with an unextended conscious self. Though experience testifies continually to their association and to its pragmatical efficacy in preserving the body from hurt and destruction, it provides no distinct and adequate explication of how they are united. In Descartes' treatment of this still unsolved problem, the insufficiency of his first principles both in number and in kind becomes only too apparent. He denies causal interaction between body and self to be possible not only because of their utter diversity of nature but also because. if by their volitions selves initiated movements in their bodies. they would create and communicate an ever-increasing quantity of motion additional to the amount originally imparted and declared constant. The interaction commonly supposed is fallaciously inferred from our sensory and emotional experience; in its stead he substitutes a parallelism in which changes of definite kinds occurrent in the nerves and brain synchronize with certain mental states correlated with them. This proposal opens the way to occasionalism (*q.v.*). Descartes, however, does not advance so far, but stops short at the negative conclusion that the two series of changes. physical and mental, remain ever distinct; no change in either causing a change in the other. But this explanation is seriously compromised when he turns to such special "mixed" problems in psychophysics as those of sense perception and volition. Sensation is a wholly physico-physiological transaction terminating in a movement of the pineal gland. Here, however, the continuity is broken, for the perception—the ensuing awareness of what is sensed—cannot be an effect of that movement, for it is an action of the self, of the perceiver himself, not an action of a gland in his body. So a hiatus remains between the set of physiological movements and the act of perception. the former being not the cause but only the occasion upon which the latter occurs. Again the continuity is broken, in converse order. when a volition is said to "initiate" movements in one's body: the same hiatus is indeed apparent throughout Descartes' whole treatment of the mind-body relationship. Selecting the pineal gland as the central reservoir from which the "animal spirits" radiate, he speaks of the self's being "constantly present to" that gland and "inclining" it when it propagates changes along the nerve channels and bloodstream. But he fails completely to show how the nonphysical self can move a pineal gland that is physical when it cannot move an arm or a leg. And to speak of this gland as "the seat of the soul" and of the soul "being present to it" is to use misleading metaphor, for both phrases rest on a spatial analogy that is inapplicable to what is unextended. "Animal spirits" too, however volatile, rarefied or gaseous, are still extensive and mobile. hence certainly material. Interpolating such intermediaries to make physical functions seem more mental and mental functions more physical is mere procrastination. Descartes elsenhere declares, however, that the self's union with the body, though discoverable, is not understandable.

Philosophy of Mind.—Having deduced in his natural philosophy the determinate forms into which motion diversifies space, so explicating the universal nature of bodies, their states and connecting laws, it remained for Descartes to attempt a complementary account of the other essential attribute, cogitatio or *pensée* (consciousness), its forms and their relationships, so explicating the nature proper to selves. Mind he conceives to be analogously

diversified into a continuum of determinate actions and states occurrent from moment to moment and so forming the self's history. They are of three main kinds: acts of awareness (of concepts, sensible appearances, images), states of feeling and emotion ("passions") and acts of volition and affirmation. Knowing. the self's primary function, is independent of the knower's bodily organs and activities ("the soul can work independently of the brain"); and in thinking the pure ideas that constitute its knowledge the self is exhibiting in temporal succession the nontemporal, invariable and universal constitution of human reason. Sensory awareness, though sometimes instrumental, is often obstructive to the acquirement of knowledge. Serer, indeed, is it even partly constitutive of that which is known; its value is utilitarian, enabling animate bodies to conserve themselves and to adapt theniselves to changing physical situations. No clear concepts that alone constitute pure science can be abstracted from the confused qualitative deliverances of our senses. Such pure ideas as those of "simple natures." the divine perfections and axiomatic truths, also the operations by which we apprehend them, a11 are alike "innate" or unlearned. Despite their individual differences all minds are by nature predisposed to think and rethink such thoughts in ever varied contexts, without; in order to do so. receiving any aid from senses. brain or body; experience and training providing only the occasions on which they shall be thought. This power to produce and to pass to and from such concepts complex and simple as the method envisaged—this innate, unacquired cognitive disposition—gives us the radical sense in which our ultimate defining nature is *cogitatio* or *pensée.* Yet this capacity differs from certain others, such as memory, that also are innate. Memory reinstates only what has already been experienced, whereas by this disposition we originate concepts never before conceived and which cannot be extracted from what is given in experience, as well as subsequently reinstating them in the course of our thinking. By *intuitus* we apprehend pure ideas, by *deductio* we educe their connections but no more; neither operation affirms the existence, in the physical world, of independent correspondents to those ideas and connections. Such affirmation or "judgment" is an additional function, distinct irom merely prehensive and contemplative acts, and not simple as they, but complex. For, in being affirmative, it is an act of will; but since it is existence that it affirms, it necessarily has reference to an idea—one respecting the character of that whose existence it affirms—and in this respect it is so far "contemplative." Judgment is thus a complex function of the self. a joint operation of its volition and cognition: it affirms the validity, of that which is contemplated and supposed, to be independent of that very contemplation and supposal and therehy asserts its existence. It is in this way that selves transcend themselves in their knowing: thus a relationship with an independent order of existences is established in true judgment, and the difference between existential affirmation and simple contemplation elucidated. But what is so affirmed valid and independently existent may in fact be so in one case and not in another, judgment being exposed to a risk of error that does not beset simple contemplation. Yet, though no man ever wills to err. it is by his will that he does so. In its forms of choice. decision and affirmation, our will is perfect; the range of assertions possible to it is unlimited. But our cognition is not analogously perfect, for much that we perceive is unclear and cannot be brought to lucidity by mere effort of will. Error must therefore be due not to volition alone, for it is perfect; nor to awareness alone, for it is not affirmative; but precisely to their combination in the same self: the compresence in it of imperfect enlightenment with an unrestricted power of affirmation. Consequently self-deception and error consist in an imperfect use of our perfect freedom, asserting and denying where we do not clearly understand; for we are not compelled or "determined" in our use of will, we can suspend judgment no less than affirm. This self, active in judging and willing, is passive in sensing and feeling. Its emotions and affective states of pleasure. displeasure and pain evince maximum confusedness in their intrinsic qualities and in the subtlety of their varieties: they defy definition and can be treated only in terms of those collateral bodily disturbances of which they are the epiphenomena. Their confusedness is a function. directly of the intensity, indirectly of the location, quantity and direction, of the bodily disturbance; the two former varying in direct concomitance with the last. Contrasted with these epiphenomena of its body's changes—these "passions" to which the self is subjected—are its volitions. It recognizes these to issue from and to be caused by itself. and itself to be competent to counteract the inclinations of its passions, thereupon being again incontrovertibly assured of its own identity and continuant existence. Descartes' philosophy of mind is thus compounded of a science of cognition and a psychophysics of affection and conation.

Our will "is so *entirely* free that never can it be constrained." Its acts are not physically determined as are the changes in our bodies nor interconnected necessarily as are the properties of geometrical figures, but are contingent. Their contingency, manifesting our freedom, is not however unconditional, for a "liberty of indifference" would entail a radical irrationality of the will. The clear perception that a contemplated action to which emotion inclines us is good is of itself sufficient to secure our assent to it and initiation of it: we no longer withhold assent from it. But action so following upon a clear perception of its goodness is not determined, for this clear cognition of its goodness is not vouchsafed to casual inspection but is a result of our purposive effort to discover an idea that is clear and of our freely refusing to decide prematurely; such efforts and refusals in the prefinal stages of a deliberative process being themselves acts of will on the part of a self that is equally free at the time to decide precipitantly as to refrain from doing so. In so refusing to decide prematurely the self is acting freely, for, by hypothesis, it has not yet attained a clear perception of that alternative which it will eventually adopt. And the fact that we are free to refrain from asserting what is unclear is known to us immediately, not by inference but by self-inspection—"without proof, and simply by the experience that we have of it." When the idea contemplated be one concerning a course of social conduct and we conform our action with a precipitous judgment. the ensuing action will probably be vicious or morally wrong. Right or wrong conduct is the expression and the consequence of affirmations of what has been, or has not been, clearly perceived to be good. Thus Descartes in company with Socrates regards rightness of action to depend upon certainty of knowledge, and wrong-doing upon ignorance.

The self's intrinsic nature is successively displayed diversely and determinately in its actions and passions. Accordingly, when asked whether the self's nature consists in its states collectively or in its capacity to have them; Descartes does not hesitate to answer that *"l'âme pense toujours"* ("the soul thinks always") means primarily that it is its inalienable nature to be *pensée* ("conscious"), but, this being intrinsically a capacity diversifiable in time. it means secondarily and derivatively that it will continue self-consciously active and undergo passions so long as it remain united with its body. Thus the self's mortality or immortality properly relates not to whether there will occur an action or passion that is "its last," but to whether it be possible for "the thing that thinks" to become inexistent. The self plainly cannot itself cause this, neither can it be caused by the death of its body, no interaction between them being possible because of their utterly disparate natures. Further. the self cannot die through partition as the body does, for the self has no parts. Bodies cease to be animate and decay because they are not independent substances but only dependent parts ("modes") of a substance; but selves are by nature incapable of annihilation precisely because they are substances, each independent of all others. No self is a part of any other self, but every body is a part of the single extensive whole called matter: there are innumerable thinking substances but only one material substance. So, should a self be mortal, the cause of its mortality, since it can be neither itself nor another self nor matter (of which it is independent), could only be God, upon which it depends in common with all created things. Being the cause of the soul's existence, God could also be the cause of its annihilation. Whether a given self eternally survive its body's death could be answered categorically only from a knowledge of God's future decisions, which we have not: so to the question *quid fncti* ("what is in fact the case") we must reply *ignoramus* et *ignorabi-*

mus ("we are ignorant and shall remain ignorant"). But on the question of possibility it may be added that, if God does not decree its annihilation, since nothing else could cause it the self will continue in existence despite and after its body's death.

SPECIAL PROBLEMS OF THE SCIENCES

In Le *Monde* (first published posthumously, Paris, 1664), a celestial and terrestrial physics, Descartes treats of classes of particular bodies whose existence can be known only by experience but for a knowledge of whose specific characters deduction also is required. In this characteristically Cartesian research Descartes' progressive analysis of one "absolute nature," namely light, is shown to depend upon solutions to certain subordinate problems that compelled him to investigate the sun and fixed stars (its source), the heavens (its transmitter), the comets and our earth with its bodies opaque and transparent (its reflectors and transmitters) and "animal-machines" (its perceivers). Those investigations involved the use of normal observation and of experiment. In many concrete problems that he investigated, relating to the weight of air (1631), to the laws of light and sound (1633) and to magnetism, magnification, the properties of glass, the phenomena of tides, lightning, thunder and the rainbow, the differentia of oils, spirits, common waters and salts! Descartes made a large use of experiment; and, again, his use of observation is apparent in his dissections of the heads of various animals to discover the mechanism of memory and imagination. And this dependence on experiment was not inconsistent with his claim that his method was wholly deductive. For to discover laws is one thing; to apply laws discovered in explaining phenomena quite another. The office of experiment was to facilitate selecting from this deductive system of laws those that are relevant to the particular phenomenon requiring to be explained, for we ought "to explain effects by their causes, not causes by their effects." But, he adds, "since the power of nature is so ample and these principles so general, there was scarcely any effect which I did not straightway recognize to be deducible from them in several ways, and my greatest difficulty was usually to find out in which of these ways it is that the effect depends upon them. In such circumstance, I know of no other plan than to devise experiments of such a nature that their result is not the same if it has to be explained in one of these ways as it would be if explained in another." It seems from this that the function of experiment in Descartes' view is to enable us to decide between a *priori* equipossible explanations of an effect when all that we know is that one of them must truly explain it but we do not know which is that one. Descartes claimed certainty and finality for the universal principles of his natural philosophy, not, however, for his particular conclusions resulting from their applications in his various departmental researches. These conclusions he recognized to be provisional and modifiable with the advance of science, for "to demand geometrical demonstrations in matters depending on physics is to ask me to perform the impossible, and if you restrict the word 'demonstration' to the proofs of the geometers you will be compelled to say that Archimedes demonstrated nothing in mechanics, nor Vitellion in optics nor Ptolemy in astronomy." Explanation of the specific and particular is thus relative to the insight and evidence available at the time, therefore provisional in principle; but this does not entail that the laws that are utilized in explanation are themselves no more than problematical. For laws demonstrated a *priori,* though primarily objects of knowledge, are also instruments by which to explain phenomena, these being of themselves impotent to contribute to natural philosophy any law of even the meanest generality. All phenomena are thus investigated under the dual principle that they are simply constant quanta of three-dimensional, divisible space and that their changes, however various, are but motions referable to a few kinetic laws. By their means alone he explained the phenomena of magnetism and therefrom the constitution of our earth as a whole, comparing it with a vast magnet. Weight, discarded as an unclear notion. he replaced not by gravitation but by motion; viz., that of certain globular particles ("second matter") surrounding the earth which propel bodies toward it in calculable motions. Likewise the action of water pumps is to be explained not by nature's abhorrence of a vacuum but "by the weight of the water which counterbalances that of the air." His denial of a vacuum also led him to discard the supposition that the transmission of light was an emission of corpuscles and to conceive it as a propagation of pressures through a fluid ether, from which conception Huygens developed his undulatory theory. Rays of light were lines along which the pressures were transmitted; if they passed through a transparent medium they were straight; were the medium otherwise. they were deflected. If those rays impinged obliquely on certain surfaces they were reflected, the angle of reflection being equal to the angle of incidence. Were the ,medium such as to diminish the velocity of the rays passing through it, they were refracted. From discovering the law of their refraction—expressed in the trigonometrical function still named after him—he deduced the principles of the chief optical instruments; and by the reflection and refraction of light rays in drops of water he explained the formation of primary and secondary rainbows. It is to Descartes too that the inception of the mechanical theory of heat is due. Heat is no quality of bodies but a violent motion of corpuscles and, establishing its connection with light, he showed that rays of the one could be transformed into rays of the other. So, by investigating the different transformations of which motion is susceptible and by persisting in his resolve to geometrize all nature, Descartes contributed substantially to forming that substructure of modern mathematical physics which Galileo had initiated and Sir Isaac Newton and J. L. Lagrange later improved.

His influence on later physiology was less extensive and profound than that on physics. Using only the same ultimates—the properties of space and motion—he extended the application of his "concrete geometry" from the inanimate to the animate, but in doing so probably assumed too uncritically that all activities of organisms are mechanistic and that their development, in contrast with their mere alterations and locomotions, is but mechanical too. He conceives a fully developed animal, for instance, as simply a body that now has a greater number of other bodies lodged in the interstices between its parts than it had formerly. Both the number and the nature of the ultimates adequate to resolving biological problems seem to have been too severely restricted. He persists in regarding both the structure and the behaviour of all bodies, human and animal, as completely mechanistic—declaring "if all the constituents of the seed of a given animal species were completely known, from that alone and by wholly mathematical reasoning, the shape and the structure of each of its members could be deduced; and conversely, from knowing certain peculiarities of that structure we could deduce what is its seed." Heat, which he calls "the mainspring" of all movements occurring in the body machine and its members, is continually renewed by respiration, "the air, mixing with the blood before it enters the left concavity of the heart, causes its heat to increase." The blood in turn by its continuous circulation (for he corroborated and stoutly defended William Harvey) conveys its acquired heat to all the body's parts. A similar mechanical account is offered of the body's alimentation. Discarding the "faculties" with which parts of the body were then thought to be endowed and which enabled them to discriminate, select and attract each its appropriate aliment, Descartes accounts for alimentation by means of the location of the organ in relation to the path which the particles of nutriment follow and by the sizes and shapes of the pores into which they enter. Other internal activities of the animal body require little besides the system of nerves (imagined as tubes) and the animal spirits flowing within them. Impulsion from without causes pressure of those spirits, this pressure (envisaged as undulation) in turn causing actions and reactions, and motions of flexor and extensor muscles. The overt behaviour of the body as a whole likewise illustrates none but mechanical principles (*cf.* leverage in walking), and its inanimate condition after death is comparable with the difference between a watch wound and unwound.

Descartes' greatest service to the future of science lay in his attempted geometrization of all nature, and his contributions to pure mathematics far surpass in permanent value those which he

made to other sciences. The *Geometry* (1637) was his great and original work in this field; much then revolutionary in it has now been absorbed into standard textbooks of co-ordinate geometry. The originality of the reform by which he laid the foundations of analytic geometry consisted in his introducing into traditional geometry a procedure employing the notions of constant and variable and making it possible to express properties of curves by algebraic equations. Having established a correlation between a set of points and a set of numbers he demonstrated that certain relations between those points correspond with certain relations between the numbers. One may then proceed to treat the numbers algebraically without referring to their correlative points, or conversely deal with the points without reference to their correlative numbers. Each procedure has its advantage: the algebraic treatment greatly facilitates the resolution of complicated problems of geometry, the geometric representation of algebraic results exhibits their import more vividly (*cf.* the value of graphs). Descartes' great merit here was to have applied geometry to algebra; he was not the first to have applied algebra to geometry. In algebra, he systematically employed exponents, interpreted the notion of negative quantities and elaborated his "rule of signs" for determining the number of negative and positive roots in an equation (*see* EQUATIONS, THEORY OF). And to Descartes we owe the first systematic classification of curves. After dividing "geometric curves" which can be precisely expressed in equations from "mechanical curves" which cannot, he classified the former into three classes of increasing complexity according as their equation contains (1) no term of higher degree than the multiple of two unknown quantities, or the square of one (*i.e.,* the circle, the parabola, the hyperbola, the ellipse); or (2) one or more terms of the third or fourth degree in either or both of its unknowns; or (3) a term of the fifth or sixth degree in either or both of its unknowns. The straight line he regarded as the limit of a curve of the second degree; *i.e.,* of class 1. This new geometry (which illustrates some of the rules only announced in the unfinished part of the *Regulae*) is more than a general theory of quantity: it led to the concept of continuity, from which was developed the theory of function and, in turn, the theory of limits. Further, his resolution of the problems of doubling the cube and of trisecting an angle enabled him to contribute to the theory of equations. His general rule for resolving an equation was to express it in zero form and try to factorize the left hand side so as to reduce it to two or more equations of lower degree. If the equation were one of the third or fourth degree, the solution depended upon the intersection of a circle with a conic. For solving equations of still higher degree he proposed to use intersections of circles with the several classes of geometric curves—conics being used to generate curves of class 2, and these again to generate curves of class 3. But he was mistaken in believing that equations of any order could be so resolved.

Scott, *The Scientific Work of René Descartes (1596–1650)* (1952); P. Natorp, *Descartes' Erkenntnistheorie* (1882); E. Cassirer, *Descartes' Kritik der mathematischen und naturwissenschaftlichen Erkenntnis* (1899). (S. V. K.)

DESCENT, SYSTEMS OF. The societies covered in this discussion are chiefly confined to the civilizations of Europe and Asia. Additional material, including similar themes in primitive societies, is contained in the articles KINSHIP; KINSHIP TERMINOLOGY; and SOCIAL ANTHROPOLOGY.

Introduction.—In its broader meaning, the word descent is used for the set of principles according to which individuals are placed in terms of their kinship connections. For example, when a man X is said to be descended from a man Y, the ascription of descent implies that X enjoys a certain status and has certain rights and duties by virtue of his relationship to Y. In the narrower meaning of the term, descent is the principle by which individuals are allocated to clearly defined kinship groups. In the simplest case, unilineal descent (which may be either patrilineal or matrilineal, *i.e.,* through a line of males or through a line of females), divides society up into a number of mutually exclusive clans or lineages.

The distinction between these two senses of descent may be seen by a comparison between the nonunilineal kinship system of most modern western countries and the unilineal (patrilineal) system of traditional China. In the former system an individual may say that he is descended from ancestors whom he traces through a variety of links, and on both sides the chains of descent pass indifferently through males and females. The practical significance of such descent may be either that a man establishes (or tries to establish) some kind of claim on other people descended from the same ancestor or that he enjoys some status or privilege by virtue of his descent. Both structurally and in terms of the rights and duties involved, this system is vague.

In the Chinese system the descendants of a man traced exclusively through males formed a distinct group vis-à-vis other groups similarly constituted. In some parts of China, especially in the central and southeastern regions, patrilineages tracing their origin to an ancestor 20 to 30 generations back and numbering several hundred people constituted local communities or definite segments of such communities. As a local group the patrilineage included the wives married to its men and excluded its own women, who by rule were married to men of other groups. These patrilineages were corporate bodies which had legal, political and economic rights and which formed distinct ritual communities through the worship of common ancestors. Any one lineage might be segmented into patrilineal groups which were in turn further segmented, so that the lineage as a whole consisted of lesser groups nesting within greater ones. Patrilineal descent did not rule out descent in its broader sense since, for certain purposes, a Chinese also traced descent through both mother and father to some nonpatrilineal forebear.

Naming Systems.—The English and Chinese systems resemble one another in that in both systems individuals bear surnames which they acquire from their fathers, but it is important to avoid reading too much into this resemblance. In England, a man's relationships with cousins who bear his surname and with cousins of a different surname are not normally different in principle. In China the surname is an index of patrilineal connection, and even if two men of the same surname are not members of one local patrilineage, the fact that they bear the same name gives rise to certain assumptions about ultimate patrilineal descent and furnishes the basis of a potentially active relationship. A Mr. Ch'en in China regards other Ch'ens as significantly different from people bearing other surnames; for a Mr. Brown in England most other Browns are, as it were, accidents of nomenclature.

It follows that naming systems by themselves must not be taken as simple indices of descent. In common Muslim practice the naming model "A ibn B" (A son of B) indicates each man's father (or each woman's father, on a similar model) but reveals no continuous thread through the generations. In the Spanish surnaming system, a man bears both the paternal element of his father's surname and the paternal element of his mother's; his children carry

forward the paternal element of his surname joined with that of their mother's Such a system stresses the continuity between a man and both his grandfathers and passes on one name in the male line. but it is not the basis for clearly delineated descent groups Neither is the Russian system of naming, in which a surname is transmitted through males and in which each individual is also linked by a patronymic. which precedes the surname, to his, or her. father; e g., Georgi Ivanovitch (son of Ivan) Koslov. In the Chinese patrilineal descent-group system, on the other hand. not only is the surname a basis for marking out groups but within each patrilineage all the males of one generation may bear a common element in their name, so that a Chinese name in the form 4 B–c indicates descent in the first element, generation status in the second and individual identity in the third.

In surnaming systems, it is common to find that a woman either adopts her husband's surname (as in English-speaking countries) or joins her husband's surname to her onn (as in Spain). The significance of the change lies in the transformation of the married woman's legal status—some rights being transferred to her husband. In various European legal systems a married couple form a single personality in some respects, the husband standing as its representative. Therefore, the adoption of her husband's surname by a wife is best regarded as an aspect of the immediate marriage relationship and not necessarily as evidence of the incorporation of a married woman into some group symbolized by the husband's surname. Indeed, where incorporation of this kind does take place (as in China), the woman may well retain her own surname. for her new status is unambiguously indicated by her new residence and a myriad aspects of her everyday behaviour, while her own surname may serve to show the link between the group into nhich she was born and the group to which her children will belong.

Descent Systems in Europe.—The theme of descent has not been well explored in Europe, more exotic parts of the world having largely commanded the attention of anthropologists. The great majority of Europeans live within the framework of nonunilineal (often called bilateral or cognatic) kinship systems. In these systems kinship is reckoned symmetrically on the paternal and maternal sides, according to degrees of proximity. All four kinds of cousin (father's brother's child, father's sister's child, mother's brother's child, and mother's sister's child) are structurally equivalent. The systems of kinship terminology (relationship terms) bring out the symmetry; in English, for example, the terms grandfather and grandmother, uncle and aunt, cousin. nephew and niece. grandson and granddaughter fail to show whether they are on the maternal or paternal side. Terms for more remote relatives leave the particular linkage unspecified among a great number of possible connections. Thus (where F represents father; M, mother; B, brother; Z. sister; S, son; D, daughter). my male second cousin is any one of the following: FFBSS. FFBDS. FFZSS, FFZDS, FMBSS, FMBDS. FMZSS, FMZDS, MFBSS. MFBDS, MFZSS, MFZDS, MMBSS, RIRIBDS. MMZSS, MMZDS. In principle, there are no limits to the range of relatives recognized in such a system. No two individuals. unless they are full brothers or sisters, have exactly the same circle of relatives, and every individual stands at the centre of a circle of relatives who do not as a whole share common ancestors. A cousin on my father's side has no connection by descent with a cousin on my mother's side (unless some cross-marriage has taken place). In technical language the relatives in each circle are knonn collectively as a kindred.

The limits of the kindred are likely to be defined in formal terms only when quite specific obligations are laid upon kinsmen. In modern circumstances one would not expect to find clear definitions of the limits, but if one looks at the historical material on European kinship, examples are found of bounded units of this kind, the demarcation being made in order to take account of important reciprocal obligations among relatives. There are recorded rules of the degrees of cousinship defining the extent of the kindred among several Germanic peoples in northwestern Europe in the middle ages and later, especially in relation to wergild (the payment and receipt of compensation for slaying), although it is important to realize that the evidence is often fragmentary and that there was much variation according to place and time.

The modern systems which have gronn out of the earlier kindred systems of Europe are extremely flexible. Kinship may well play an important part in governing the behaviour betneen members of a long-established farming community. laying down patterns of association and co-operation, but a kindred is not a corporate body uhich is perpetuated through the generations and it cannot in itself be a property-onning unit. On the other hand, members of a kindred may enjoy certain tights in relation to the property held by one of them. In Norway, for example. when a farmer sells land to a stranger, the law of odelsrett entitles his kin, in a fixed order among themselves and within a fixed period, to buy hack the land at the market price Studies of countrymen in Britain and Ireland have shown how kinship may be important without being the framework of community life.

It is often assumed that the wide ties of kinship found in rural communities contract. perhaps to insignificance. in the conditions of urban life Studies in England, however, suggest that these ties may be widely recognized and utilized if there is a fair degree of stability in an urban population. The obligations assumed or expected may be few and seemingly unimportant in relation to the whole field of social life; yet they give rise to a number of utilitarian and symbolic "services" among relatives which make it rewarding to keep alive relationships which the general nature of legal, political and economic institutions does little to support and sanction.

Modern Europe is characteristically a continent of nonunilineal kinship systems The precise nature of the patrilineal institutions of classical Greece and Rome is still a matter of debate as is the unilineal character of other regional forms. By an ironical twist of etymology the nord clan, as used in kinship studies, has very limited application to modern Europe. It is derived from the Gaelic *clann* ("offspring"). but the clans of the Scottish Highland system. which appears to have taken shape during the 11th century and which survived into the 18th, seem to have had more in common with nonunilineal descent groupings than with unilineal ones They mere nonexogamous political groups, subdivided into local segments the members of which traced their descent to common ancestors but not exclusively through male links

The only unambiguous evidence of patrilineal organization in 20th-century Europe seems to be in the Balkans Until the 1930s. a patrilineal kinship system in which the largest units were exogamous clans, each bearing a surname formed from the name of the founding ancestor, persisted among the southern Slavs. A clan was composed of *zadruga,* which consisted of two or more nuclear families (*i.e.,* of two or more families of parents and unmarried children). A *zadruga* did not necessarily occupy the same homestead, but it formed a single unit nith regard to the ownership and control of property Nonpatrilineal kinsmen could be incorporated by adoption. The *zadruga* appears to have taken different forms in different areas of the Balkans: one form in the tribal society of Montenegro and northern Albania; another in central Albania, north and central Macedonia, and parts of Croatia and Bosnia and Hercegovina; and still another in southern Albania. southern Macedonia, western and central Bulgaria and parts of Croatia and Serbia. This type of organization has for the most part disappeared or been radically altered as a result of modern economic and political changes, but it is interesting to find, in a field study of a Serbian village by J. M. Halpern, that while *zadruga* and individual households had come to coincide in the majority of cases, the clan structure nas still in evidence; the households of a clan were usually in the same neighbourhood and individuals were able to recite their genealogies. (See also CLAN.)

Descent Systems in Asia.—Something has already been said about the form taken by patrilineal descent in China. Despite the degree of political centralization. it was possible for localized lineages (*tsung-tsu*) to maintain control over a great many of the political, legal and economic aspects of the lives of their members. The threat to internal solidarity posed by the differences in the political and economic poner of the members was counterbalanced by opposition between lineages (amounting to feuds in

some parts of the country) and between lineages on the one hand and the state on the other. Among all civilized peoples in modern times, perhaps the Chinese came closest to textbook examples of patriliny in the thoroughgoing nature of their patrilineal organization.

There are great similarities between the Chinese system of descent and systems found in Vietnam and Korea. In the latter country, however, the *jongjung* (lineage, corresponding to the tsung-tsu of China) is differentiated internally by the maintenance of a senior line of descent, special rights in property and ancestor worship passing through eldest sons. Japan, in contrast, presents an entirely different system; the dozoku is not a lineage, in the sense of a group made up of all the unilineal descendants of a focal ancestor, but a line running through a succession of main families (honke) to which branch families are attached. The head of the family is succeeded in his status and rights by one of his sons, his son-in-law or an adopted son. Sons who do not succeed in this way form branch families, but the main family may also attach to itself branch families which were not previously related. This flexible system of descent produces a genealogical form and a kind of ancestor worship different from those of the other far eastern systems discussed above. The differentiation in status between main and branch families in the dozoku appears to be more marked in the northwestern part of Japan, but the system as a whole is necessarily changing because of increasing industrialization and modifications in land tenure.

The kinship systems of the various countries of southeast Asia are diverse. While, generally, there is no unilineal principle of organization among the civilized communities. there are a few examples of matriliny and patriliny. In the Malay peninsula, the Malays are an interesting case of a culturally uniform people with different descent systems. Most Malays live in communities based on a territorial principle, the only effect of kinship being to construct a kindred around individuals; and no continuing group of kinsmen emerges. except possibly in the context of patrilineal royal houses. Apart from certain Islamic obligations in the field of marriage, rights and duties inherited through father and mother are symmetrical. In the area of Negri Sembilan, however, there is found a system of matrilineal kinship which is connected historically with immigration from Minangkabau in central Sumatra. In this system every individual is a member of a matrilineage which, grouped in relation to other matrilineages of both like and unlike political status, forms the basis of the traditional political organization of the area. Rights to the ancestral ricefields are transmitted within the matrilineal group, so that when a man goes to live in his wife's house after marriage he becomes concerned in day-to-day economic affairs with property over which he has no traditional right. In modern times, changes in political organization and agriculture (especially the advent of smallholder's rubber plantations) have modified the working, of matriliny and have brought the contradictions between matrilineal and Islamic principles to the fore. The Islamic rules of inheritance (which favour sons) provide people with an argument against the matrilineal rules entailing property in the female line.

Contrasting examples of patriliny and matriliny are to be found in Sumatra among the Batak and the Minangkabau, respectively. Among the former the patrilineal principle governs the construction of hamlets (whose members ideally form a small lineage), the larger lineages nithin one village and nonlocalized clans consisting of many lineages. Within the Minangkabau village there are several matrilineages, each divided into a number of house groups; those bearing the same nanie may be said to form a clan. In the traditional system a man continued to live in his own house after marriage. visiting his wife in her house at night. Succession to the headship of matrilineages and house groups passed from a man to his "sister's son."

The most complex civilization in Indonesia has developed in Java. The kinship system of the largest cultural group, the Javanese. is a nonunilineal system in which the tracing of links is partly determined by the quest for special status and land rights. In neither of the two broad classes of prerepublican Javanese society, nobility and peasantry, did descent form the basis for clearly defined groups, but clusters of kinsmen were produced among the nobility by passing down titles and establishing recognized connections between officeholders, primarily through the father. Among the peasants a man's status in the village, nhich regulated his right to land, was again primarily but not exclusively transmitted paternally.

The analysis of kinship in the nonprimitive areas of Burma, Thailand and the Philippines has not progressed far enough to make detailed comment worthwhile, but in these areas we find nonunilineal systems. The flexibility of such systems allows individuals to align themselves with kinsmen traced in many different ways according to various needs and rights, though there is generally a narrow range of cousinship defining a circle of intimate relations. The Melanau of Sarawak illustrate this flexibility. Though they do not think of their villages as kinship units, most marriages take place between fellow villagers. preferably with a second cousin, so that the inhabitants of one village are linked together in a coinplicated network of kinship ties. Kinship linkages (laian) help to establish a man's status. There are five status groups (*bangsa*) which are endogamous in theory, but in practice approximately half of all marriages are outside their boundaries. so that in any mail's field of kinship there are likely to be people of different bangsa. A man normally assumes the rank of his father, but if his mother's rank is higher he may take hers instead. If he is recognized as being of low rank but becomes rich and influential in village affairs (a cash-crop economy making for social mobility) and wishes to raise his status, he can do so by citing laian which attach him or his wife to higher *bangsa.* He validates his claim by demanding a bride payment appropriate to his nen rank when his daughter marries.

The data on descent in India and Pakistan cannot be summarized satisfactorily, but if one starts with a model of a patrilineal extended family it is possible to gain same insight into the most general pattern. A residential property-owning unit on the framework of patrilineal kinship and spanning three or more generations may be taken as a model. Women marry out of one extended family into another. Units resulting from the partition of such a family may then belong to no formally constituted unit other than the localized subcaste group. They may, however, form localized lineages with rights and duties which give them a separate existence within the subcaste. Furthermore, larger, nonlocal units may be found which are constituted on the basis of like descent from a common patrilineal ancestor and which may be called clans. Generally, in northern India, marriage must take place with women from other villages, but in the south more than one exogamous group of the same subcaste may live in the same village and intermarry. However, it must be stressed that the interpretation of difference~in kinship system between different parts of the subcontinent is beset by difficulties which are matters of professional debate. (See CASTE [INDIAN].)

While Indian kinship may usually be thought of as patrilineal, it is not universally so. Indeed, India has furnished us with an outstanding example of matriliny. the Nayars of the Malabar coast. The Nayars are a caste which was organized traditionally into localized matrilineages, each composed of residential property-onning units. These units consisted of several generations of brothers and sisters, the members of one generation being the children of women of the preceding one. The problem posed by the Nayars, or at least by those in central Kerala, is whether they practised marriage in any real sense. Before puberty, girls were ritually "mdrried" to men from certain specified lineages and thereafter received other men as lovers. After the ritual of "marriage," the "bridegroom" did not necessarily have any relation with his "bride." Once a woman was pregnant it was necessary. for ceremonial reasons, for one or more men of the appropriate subcaste to acknouledge probable paternity. While it is possible to argue that the Nayars practised marriage (in which case they might perhaps be said to be both polyandrous and polygynous), the role of social fatherhood was pared down to a minimum and a child had no kinship relations except through his mother. Of all descent systems, that of the Nayars comes closest to a system where descent in one line is not accompanied by de-

scent in the wider sense, *i.e.*, through the parent from whom descent-group membership is not obtained. It is this unusual aspect of the Nayar case which makes it of great interest. (*See* also NAYAR.)

It is only possible to refer very briefly to certain forms of patrilineal organization in the rest of Asia. Broadly, in the central and southwest regions, tribal organization was arranged on a patrilineal framework, so that smaller units within greater ones were referable to points of segmentation on genealogies. This type of organization has left its mark on many settled and highly developed communities, whose local organization is still affected to a greater or lesser degree by patrilineal alignments.

Conclusion.—The study of descent groups in civilized societies leads naturally to the question of their ability to survive. Will all kinship systems come to resemble the vaguely delineated "bilateral" systems of the industrialized west? In thinking about this problem we must distinguish between the effects of calculated political attacks on traditional institutions, on the one hand, and the unplanned changes brought about by shifts in the economic, political and legal aspects of life on the other. In China the eradication of the "feudal" family system has enjoyed a place of honour in the schedule for social revolution, so that the systems that flourished in many parts of China up to 1949 must now be called traditional lineage organization. In such areas as Malaya, India and Japan, descent-group systems are being worn down more gradually. New legal concepts of individual rights in family property may remove the economic basis of a descent-group corporation, and new concepts of citizenship and allegiance to the state may conflict with membership of lineages. It is interesting to note that matrilineal descent systems suffer from a special disadvantage in modern conditions because the assumption of new rights and duties between father and son is a direct threat to a man's being involved in the affairs and interests of his matrilineal group. New economic opportunities may encourage individuals to withhold the fruits of their enterprise from a common pool, and industrial society may break the ties between kinsmen who were at once neighbours, fellow workers, co-owners and members of the same ritual community. Besides being of practical interest, the study of descent groups in decline may throw light on the conditions in which they are able to emerge and persist.

(MA. FR.)

DESCHAMPS (DE SAINT-AMAND), ÉMILE (1791–1871), French poet, prominent in the development of the romantic movement. Born at Bourges, Feb. 20, 1791, his literary *début* came in 1818 when, with Henri de Latouche, he produced two plays, *Selmours de Florian* and *Le Tour de faveur*. Five years later, with Victor Hugo, he founded the *Muse française*, the journal of the romanticists, and the preface to his *Études françaises et étrangères* (1828) formed a manifesto of the movement. His translations of *Romeo and Juliet* (1839) and *Macbeth* (1844), though never performed, were also important. He wrote several libretti, notably that for Berlioz' *Roméo et Juliette*, and his prose works include *Contes physiologiques* (1854) and *Réalités fantastiques* (1854). He died at Versailles, April 23, 1871.

His brother, ANTOINE (Antony) DESCHAMPS (1800–69), wrote romantic lyrics, revealing brilliance, but also the insanity which ended his career, and translated Dante's *Divina Commedia* (1829).

See Émile Deschamps, *Oeuvres complètes* (1872–74); H. Girard, *Un Bourgeois dilettante à l'époque romantique* (1921).

DESCHAMPS, EUSTACHE (1346?–1406?), prolific French poet famous for his *ballades*. Born about 1346 at Vertus in Champagne, he was educated at Reims by the poet and musician Guillaume de Machaut (whose nephew he may have been) and at Orléans, where he read law and the liberal arts. When about 20 he entered the service of King Charles V. As a squire and king's messenger, he had to ride all over Europe, sometimes under terrible conditions. In 1372 he was made gentleman usher (*huissier d'armes*) to the king, and in 1373 successively bailiff of Valois and master of waterways and forests for the region of Champagne and Brie. In the year of Charles V's death (1380) his house at Vertus was burned down by the English, but he received the castle of Fismes as compensation. In later years he accompanied Charles VI on his campaigns in Flanders, was sent on diplomatic missions, appointed bailiff of Senlis in 1389 and in 1390 entered the service of Valentine Visconti who, through her marriage to the duke of Touraine, had become countess of Vertus. But in 1388 his appointment as gentleman usher ceased; in 1404 he was forced to give up the post of bailiff of Senlis. The king appointed him to other offices, but these were of little use to him. He was unhappy: tired out by the life he had led and racked by arthritis, he thought himself old at 50. Besides, he had a surly disposition, which only grew worse with age. The events he had witnessed and the hardships he had undergone helped to embitter him: as a very young man he had seen French towns laid waste and pillaged by the English invaders; he had seen the signing of the disastrous treaty of Brétigny; and he had endured heat and cold, weariness, discomfort, colds and fevers in the course of his travels. He had married in 1373, had lost his wife three years later and been left with three young children to bring up; the English raiders had ransacked and burned his house. He suffered from baldness and had a pugnose, a squint and a swarthy complexion (hence his nickname "*Morel*," *i.e.*, "the Moor"); he complained of his poverty, railed against women, hated the English and felt the woes of France deeply. He spent the last ten years of his life in this state of hypochondria, and died about 1406.

Since early childhood, Deschamps had had a passion for rhyming; he had learned the poet's craft from Guillaume de Machaut and until the day he died he devoted his leisure to poetry. He has

left a considerable body of work, the most interesting part of which is represented by the 1,500 pieces in M S.840 (1.032 *ballades,* 142 *chants royaux,* 170 *rondeaux,* 84 *virelais* and 84 *lais*) in the Bibliothèque Nationale at Paris. His more considerable works include the *Fiction du Lion* (1382), which in an allegorical fashion explained the duties of a king to the young Charles VI; the *Miroir du Mariage,* a satire of over 12,000 lines against women; two comic plays, the *Farce de Maître Trubert et Antrongnard* and the *Dit des quatre offices de l'Ostel du Roy;* and a prose treatise. the *Art de dictier* (1392), the oldest work on poetics in French.

As a poet. Deschamps lacks breadth of conception; but he has wit and gusto and his originality lies not so much in his love poetry. pleasant though it is, as in the endless variety of his poetry and above all in the realistic way in which he describes the evils of his time and his personal misfortunes.

See his *Oeuvres complètes,* ed. *by* Queux de Saint-Hilaire and G. Raynaud, 11 vol. (1878–1903) including a life (vol. xi); E. Hoepffner, E. *Deschamps, Leben und Werke* (1904). (L.-F. F.)

DESCHANEL, PAUL EUGÈNE LOUIS (1856–1922), French statesman, the tenth president of the third republic, was born on Feb. 13, 1856, in Brussels, where his father, Émile Deschanel, a professor from the Collège de France, was living in exile for opposition to Napoleon III. After having studied law, Paul Deschanel began his political career as private secretary to the prime minister Jules Simon. In Oct. 1885 he was sent to the chamber of deputies by the *département* of Eure-et-Loir and joined the Progressive Republican group. He was constantly re-elected. Having been vice-president (1896) and then president of the chamber (1898–1902), he subsequently presided over the standing committee on foreign affairs, acted as *rapporteur* of the foreign office estimates and in 1912 again became president of the chamber, an office which he kept during World War I. Though never having been a minister, his knowledge of foreign affairs and his oratorical powers made him a prominent figure in French politics, while his affability won him friends in all parties. In Jan. 1920 he was elected president of the republic by 734 votes against 130, thus fulfilling the ambition of his life (the majority of senators and deputies preferred him to Georges Clemenceau as being "safer" and also because he was in favour of resuming diplomatic relations with the Vatican). However, on Sept. 21 of the same year neurotic trouble obliged him to resign. He was soon elected senator but died in Paris on April 28, 1922. He was a member of the Académie Française from 1899.

DESCRIPTIVE GEOMETRY, the study of the spatial relationships of points, lines and planes and other surfaces. It forms the theoretical basis for all architectural and engineering drawing, because it provides the means for solving graphically the problems involved in the representation of three-dimensional objects by two-dimensional drawings. The method employed is called orthographic projection, and its working concepts are based on the theorems and axioms of plane and solid geometry. (*See* also DRAWING, ENGINEERING.)

Orthographic Projection. — An orthographic projection is one made upon the assumption that the projecting lines from the object to the plane of projection are at right angles to that plane. One or more planes may be used. To obtain a clear understanding of orthographic projection, the relationship between four items must be comprehended; these are: (1) the object to be represented; (2) the planes upon which it is projected; (3) the point of sight from which the object is viewed; and (4) the lines of sight or projecting lines from the object to the planes of projection.

The object may be a point, line, plane or any real object, such as those encountered in engineering projects. In descriptive geometry the emphasis is upon the spatial relationships between the points, lines, planes and curved surfaces that comprise real objects rather than upon real objects themselves.

The plane of projection is that upon which the drawing is made. Three planes, mutually at right angles to each other, are normally used and, when spoken of collectively, they are called the principal planes of projection. One plane is assumed to be horizontal and the second vertical; the third. called the profile plane, is at right angles to the other two, as shown in fig. 1.

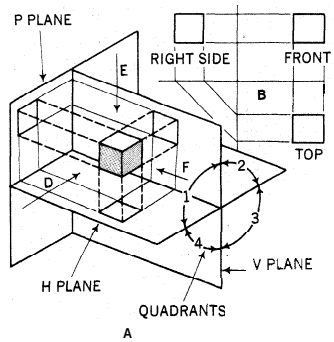

FIG. 1.— FIRST-QUADRANT PROJECTION OF CUBE: (A) POSITION OF PRINCIPAL PLANES, NUMBERING OF QUADRANTS AND THEORETICAL VIEWING DIRECTIONS D, E, F; (B) COMPLETED DRAWING, WITH P AND H PLANES ROTATED INTO COINCIDENCE WITH V PLANE

The projecting line from the object to the three planes (fig. 1) are perpendicular to the respective planes. All lines perpendicular to any one plane are parallel to each other. By definition, parallel lines are said to meet at an infinite distance. Theoretically, therefore, the point of sight for any one view must be assumed to be at infinity.

The point of sight must be different for each view of the object. Thus in fig. 1(A) the arrow lettered D indicates the direction in which the observer theoretically looks to obtain the front view. arrow E indicates the direction for obtaining the top view and arrow F the direction for obtaining the right side view.

When the object is viewed from the front, the horizontal and profile planes are seen edgeways and can be represented by the two reference lines in fig. 1(B). When looking at the top view, of course. the vertical and profile planes appear edgeways, and in the profile view the horizontal and vertical planes appear edgeways.

Quadrants. — The horizontal and vertical planes divide space into four quadrants, customarily numbered as shown in fig. 1(A). The location of the profile plane does not affect the location or numbering of the quadrants in any way.

In first-quadrant projection the object is between the observer and the plane of projection, while in third-quadrant projection the plane of projection is between the object and the observer (fig. 1[A] and 2). In both quadrants the planes of projection are rotated away from the object to give the arrangement of views shown in fig. 1(B) and 3. All problems in this article are illustrated in third-quadrant orthographic projection.

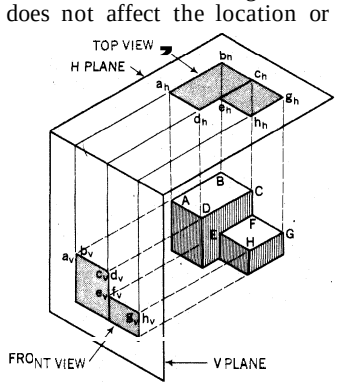

FIG. 2.—TWO-VIEW, THIRD-QUADRANT PROJECTION

Notation. — In the following discussion, standard notation will be used to designate points, lines and other elements.

The principal planes of projection — horizontal, vertical and profile—are called the H plane. V plane and P plane, respectively.

Upper-case letters (except for H, V and P) refer to points in space.

Lower-case letters with subscripts refer to projections of points on planes; thus. a_h, a_v are projections of the point A on the H and V planes, respectively.

H–V is the reference line that represents the edge view of either the H plane (when the observer is looking at the front view) or the V plane (when looking at the top view).

V–1 is the reference line that may represent the edge view of either the V plane or the first auxiliary plane.

The reference line that may represent the edge view of either

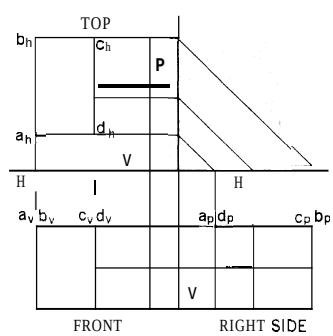

FIG 3.— THREE-VIEW DRAWING OF OBJECT IN FIG 2

the first or second auxiliary planes is designated 1–2.

Basic Considerations. — Line *Parallel* to Principal Planes. — Any line will appear in its true length in a projection on any plane to which the line is parallel. Thus, fig. 4(A) shows pictorially the line AB together with its projections on the H and V planes. The vertical projection or front view $a_v b_v$ in fig. 4(B) shows the line parallel to the H plane. Therefore, the top view $a_h b_h$ shows the true length (T.L.) of the line in the orthographic views. Fig. 4(C) shows a line parallel to the V plane. In both figs. 4(B) and 4(D), one view is parallel to the reference line H–V and the other view shows the true length of the line.

Plane *Parallel* to *Principal Planes*.—The true shape of a plane shows in its projection on any plane to which it is parallel. In fig. 2 and 3. since faces ABCD and EFGH are edgeways to the front view and parallel to the H plane, the top view, taken on the H plane, shows the true shape of these faces.' Obviously the relationships between all lines in these planes will also appear accurately.

Auxiliary Projections. — In actual engineering drawings. lines and planes do not always occur parallel to one of the principal planes; in fact, a line may be inclined to all of the co-ordinate

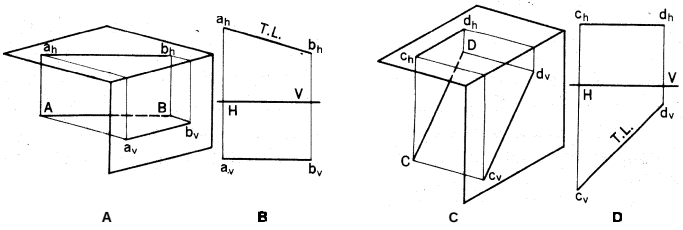

FIG. 4.— VISUALIZATIONS OF LINES PARALLEL (A) TO HORIZONTAL PLANE AND (C) TO VERTICAL PLANE; (B AND D) DRAFTSMAN'S CONSTRUCTION OF THE' PROJECTIONS

planes, as shown pictorially in fig. 5(A). This line is shown in fig. 5(B) as it would appear in a three-view orthographic projection. It is obvious that none of the projections of the line is parallel to the reference lines, and hence the line does not appear in its true length in any view. In such a case an auxiliary plane may be set up to obtain the true length. Auxiliary planes may also be used to perform the four fundamental operations of descriptive geometry used in everyday drawing practice; these are: (1) finding the true length of any line: (2) finding the point projection or end view of any line; (3) finding the edge view of any plane; and (4) finding the true shape of any plane.

The use of auxiliary planes is governed by two simple rules: the first auxiliary plane used in any problem must always be perpendicular to one of the principal planes (*e.g.*, the auxiliary plane in fig. 6 is perpendicular to the H plane); and. to serve a useful purpose, the auxiliary plane must have a specific relationship to the object (*i.e.*, it must be parallel or perpendicular to it).

True Length of *an Oblique* Line. — The true length of the line AB in fig. 6(A) may be obtained by placing an auxiliary plane parallel to the line and projecting upon it. The orthographic solution is shown in fig. 6(B). Having the top and front views given. the true length is found as follows: (1) draw the H–1 ref-

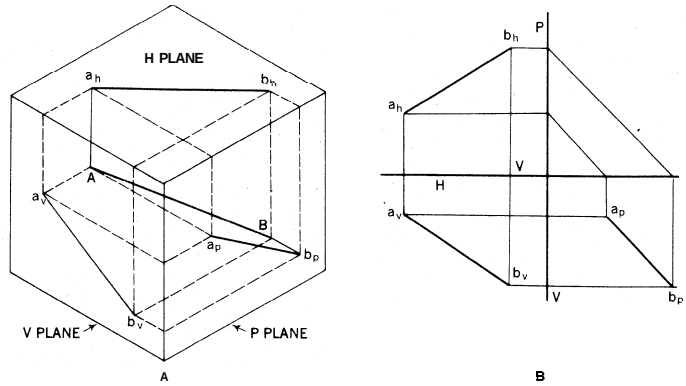

FIG. 5.— (A AND B) PROJECTIONS OF LINE OBLIQUE TO ALL THREE PLANES; NONE OF PROJECTIONS SHOWS TRUE LENGTH OF LINE

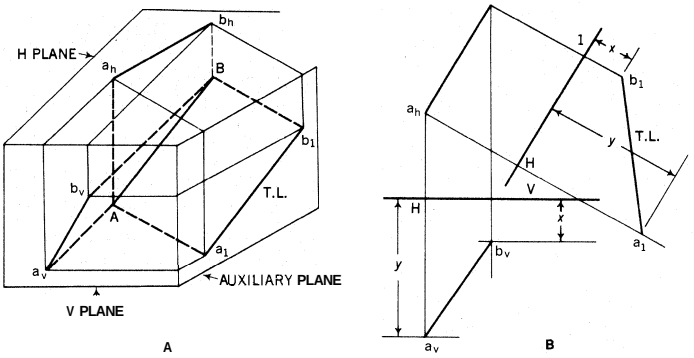

FIG. 6.— (A AND B) TRUE LENGTH (T.L.) OF OBLIQUE LINE OBTAINED BY USE OF AUXILIARY PLANE

erence line parallel to the top view $a_h b_h$; (2) erect projecting lines perpendicular to the reference line from $a_h b_h$; (3) measure the distances *x* and y obtained from the front view on the projecting lines in the auxiliary view, as shown in fig. 6(B). The auxiliary projection $a_1 b_1$ gives the true length of the line.

Point *Projection of a* Line. — The point projection of a line may be obtained on a plane that is perpendicular to the line. Thus. in fig. 7(A) the line CD is perpendicular to the V plane, and therefore its projection on that plane is a point. $c_v d_v$. The line AB in the same figure, however. is parallel to the H plane arid inclined to the V plane. Hence, its point projection can be obtained only on an auxiliary plane, which must he set up so that it is perpendicular both to the H plane and to the line XB. The orthographic construction (fig. 7[B]) can be made in three steps:

1. Draw the reference line H–1 perpendicular to $a_h b_h$ at any convenient place.

2. Draw the projecting lines from a_h and b_h perpendicular to the reference line (these projecting lines will be coincident).

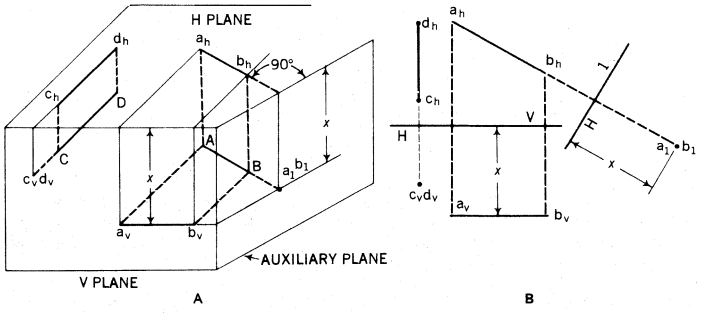

FIG. 7.— (A AND B) METHOD OF OBTAINING POINT PROJECTION OF LINE. LINE CD. PERPENDICULAR TO V PLANE. PROJECTS ON THAT PLANE AS POINT $C_v D_v$. LINE AB, NOT PERPENDICULAR. REQUIRES USE OF AUXILIARY PLANE TO OBTAIN POINT PROJECTION $A_1 B_1$

3. On the resulting line measure off the distance x obtained from the front view. thus locating $a_1 b_1$.

If the line AB had not been parallel to the H plane this construction would not have been possible, since a true-length view must first be available.

For an oblique line such as EF in fig. 8, the first step in obtaining an end view is to set up an auxiliary plane parallel to the line and obtain the true-length view on that plane as at $e_1 f_1$. The next step is to set up a second auxiliary plane (2–1) perpendicular to the first auxiliary plane and to the line. The construction is now the same as before:

1. Draw the 2–1 reference line perpendicular to $e_1 f_1$.

2. Draw the projecting line perpendicular to the reference line.

3. Measure on this line the distance *r* obtained from the first auxiliary view, thus locating the point $e_2 f_2$.

Edge *View and True-Shape View of* a Plane. — The techniques are now at hand to complete the third and fourth operations, namely, to obtain the edge view and the true-shape view of any oblique plane. Oblique planes do not show edgeways in any of the three principal views. Given the top and front views of an

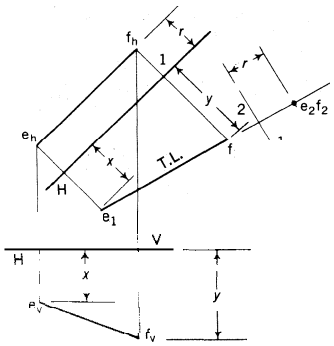

FIG 8 — METHOD OF OBTAINING POINT PROJECTION OF LINE OBLIQUE TO PRINCIPAL PLANES. FIRST AUXILIARY PLANE (H-1) PRODUCES TRUE-LENGTH (T L) PROJECTION: SECOND AUXILIARY PLANE (1–2) GIVES POINT PROJECTION E_2F_2

oblique plane as in fig. 9(A), the first step in obtaining the edge view is to construct a horizontal line in this plane; this is done by drawing the front view of the line horizontally from one side of the triangle to the other fig.

For accuracy. this line should be as long as possible and hence in this example a line is chosen that gives the projection m_va_v. The second step is to set up an auxiliary plane perpendicular to this line; this will give a point projection of the line and therefore an edge view of the plane in which it lies. Distances such as **y** are obtained from the front view.

Having an edge view of the plane, the last step is to set up a second auxiliary plane parallel to the plane by making the reference line 2–1 parallel to $m_1n_1o_1$, as in fig. 9(C). Projecting lines are erected perpendicular to the reference line 2–1. Distances such as *f* and *r*, obtained from the top view, are then measured off on the projecting lines, thus locating m_2, n_2 and o_2, which when connected give the true shape of the plane.

Other Problems.—Many other types of problems can be solved

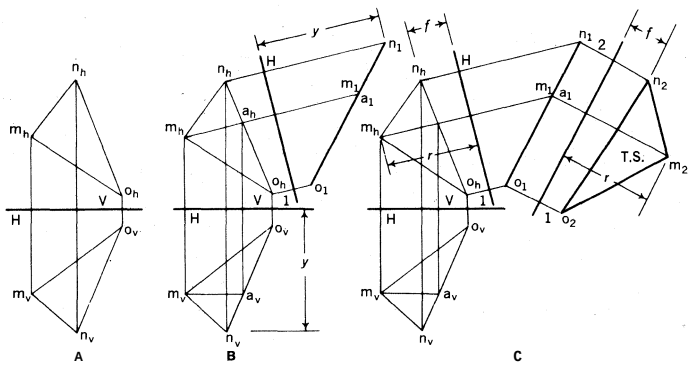

FIG 9.— METHODOF OBTAINING TRUE SHAPE OF AN OBLIQUE PLANE: (A) TOP AND FRONT VIEWS OF GIVEN PLANE MNO: (B) EDGE VIEW OBTAINED BY USE OF AUXILIARY PLANE H-1; (C) TRUE-SHAPE (T.S.) VIEW OBTAINED BY USE OF SECOND AUXILIARY PLANE 1–2

by using auxiliary planes. A fen of these are listed below.

1 Find the angle betneen tno lines. Solution: Obtain the true-shape \iea of the plane of the two lines.

2. Find the distance from a point to a line. *Solution:* Obtain an end vien of the line or the true-shape view of the plane of the point and the line.

3. Find the distance from a point to a plane. *Solution:* Obtain an edge view of the plane, carrying the point along in the construction

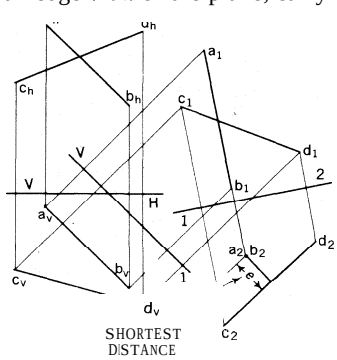

FIG. ID.— SHORTEST DISTANCE (*e*) BETWEEN TWO SKEW LINES (SHOWN IN FRONT VIEW AS A_vB_v AND C_vD_v) OBTAINED BY PROJECTING THROUGH AUXILIARY PLANES V-I AND 1–2

4 Find the angle between two planes Solution: Obtain an end view of the line of intersection of the planes Both planes are then seen edgeways. and the angle between them is shown at its true value

5 Find the shortest distance between two nonparallel, nonintersecting lines. *Solution:* Obtain an end view of one of the lines. carrying the other line along in the constriction. as shown in fig. 10 (the construction is similar to that in the preceding figures).

Intersections.—The problem of finding the intersections of surfaces falls within the province of descriptive geometry. Only a few simple illustrations can be given but the principles used can be applied in many situations. When one of the surfaces is a plane, the principle of finding the piercing point of a line and plane by the edge-view method is most convenient.

Plane and *Cone.*—In fig. 11 a cone and plane are shown, and the edge view of the plane, $a_1b_1c_1d_1$, has been found

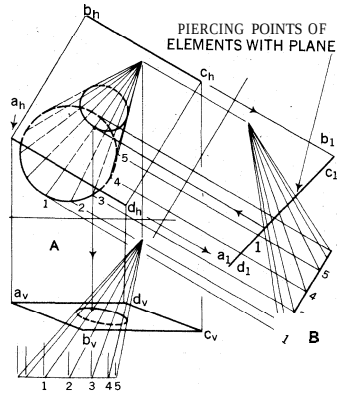

FIG 11 — METHOD OF CONSTRUCTING INTERSECTION OF PLANE AND CONE BY OBTAINING EDGE VIEW OF PLANE, $A_1B_1C_1D_1$, THROUGH AUXILIARY PROJECTION

or more equally spaced elements of the cone may be drawn and the points where these elements pierce the plane can be seen by inspection in the auxiliary view These points can be projected back to the corresponding elements in the top view and then to the front view The location of points in the front view can always be checked by measurement to the same point in the auxiliary view

Two Cones — The intersection of two cones will illustrate a more general method that can be applied in almost all cases of two intersecting surfaces. (1) Imagine a cutting plane drawn through both surfaces in such a manner that it will cut lines from both surfaces that will project as straight lines or circles. The intersection of these lines gives points on the curve of intersection; (2) repeat this process a sufficient number of times to determine the curve. Thus, in fig 12 it is necessary to pass the cutting plane through the vertices of both cones in order to cut a straight line from them. Therefore, a straight line is drawn through the vertices and extended until it pierces the plane of the base of both cones at the point **P**, shown in projections at p_v and p_h From p_h a line can be drawn across the two bases locating the foot of the elements that lie in this cutting plane, numbered 2 in the top view. The crossing of these four lines gives four points on the curve of intersection. Enough additional cutting planes must be drawn to determine a smooth curve In this case, because the first and last cutting planes are tangent to both cones, the intersection will be two separate curves, a circle and an ellipse.

The cutting plane method can be used to find the lines of intersection of such surfaces as two prisms, tno pyramids, a pyramid and a prism two cylinders, a cone and a cylinder, and a sphere

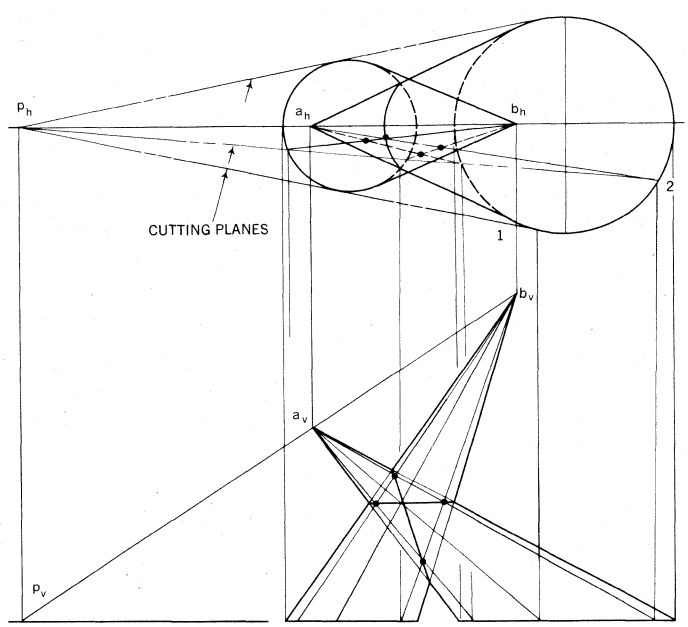

FIG. 12.— CONSTRUCTION OF INTERSECTION OF TWO CONES BY USE OF CUTTING PLANES THROUGH BOTH SURFACES

or spheroid and a cone or cylinder.

Developments.—Many engineering projects involve intersecting cones, cylinders and the like Such objects often are made of sheet metal and their construction requires the development of flat patterns from which the metal can be prepared

The fundamental principle that must be observed in the layout of flat patterns is that every line used in the layout must be shown at its true length

Development oi a Cone.—For the development of the cone in fig 13 it is necessary to have the true length of each element as well as the true length of the chords of the base between elements Only elements 1 and 7 appear in their true length in the front view. All the others 12 through 6) must be revolved to the left until they are parallel to the V plane. thus showing the true length in the front view *(e g.,* element a, 2,) Since the base is parallel to the H plane the chords 1–2 2–3, etc . show their true lengths in the top view The symmetrical half-pattern results from the construction

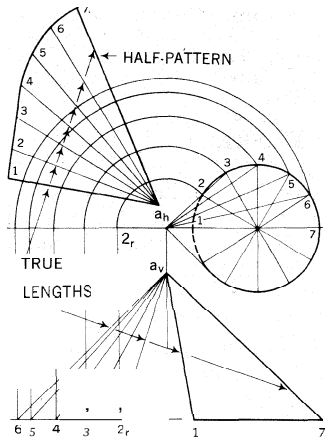

FIG 13 —DEVELOPMENT OF OBLIQUE CONE PRODUCING HALF-PATTERN THAT CAN BE USED FOR CONSTRUCTION

Development of a Cylinder — The development of an oblique cylinder requires the true length of a right section since this line will roll out as a straight line in the pattern and will be perpendicular to the elements In fig 13 half of a right section is shown as a revolved section in the front view. The distances 1–2. 2–3. etc can be laid out on the straight line that is the development of the right section This gives the width of the pattern. All of the elements of the cylinder show in their true length in the front view, and they may therefore be projected direct to the pattern All elements. of course must be kept in their proper order relative to each other This is true for all lines in any kind of development. See also PROJECTIVE GEOMETRY.

See R. P. Hoelscher and C. H. Springer, *Engineering Drawing and Geometry*, 2nd ed. *(1961)*; B. L. Wellman, *Technical Descriptive Geometry, 2nd* ed. *(1937).* (R. P. Ho.)

DESERT, a term popularly applied to any environmentally extreme, deserted. desolate, uninhabitable, waste area. Technically a desert is any of the several biomes (communities of distinctive plant and animal life) occurring on all continents at the dry end of climatic gradients of decreasing water availability. Successively distributed along these gradients are such other biomes as forest, prairie grassland and steppes, beyond which lie the arid deserts. Aridity, a conspicuous and consistent feature of deserts, is but one aspect of a total environment which, although extreme in many ways, is as favourable to the biological assemblages associated with it as those of any other biome.

Deserts are concentrated in high-latitude, circumpolar areas and in tno discontinuous. earth-girdling bands at middle and low latitudes. High-latitude cold deserts include the perennial ice deserts represented by Antarctica. Greenland and the polar ice packs, and tundra deserts of parts of the seasonally snow- and ice-free tundra *(q v.)*. Precipitation is meagre in polar regions. large areas receiving five inches or less per year, but deficiency of biologically usable nater results primarily from physiological drought imposed by low temperature. Desertlike, rocky, barren lands within the tundra result from complex causes partially related to aridity but most tundra areas are adequately supplied with water during the short. cool growing season.

Hot, arid regions furnish examples of the most familiar desert features. which exhibit considerable ecological similarity from one area to another but have little physical or biological relationship to cold polar deserts. Tropical deserts. occurring between approximately 15° and 30" north and south of the equator. include the Sonoran of northwestern Mexico and adjacent parts of California and Arizona, the Sahara *(q.v.)* of north Africa, the Arabian of the middle east. the Thar of northwestern India (see INDIAN DESERT), the Victoria of Australia and the Kalahari *(q.v.)* of southwestern Africa. These owe their origin and location largely to aridity resulting from the high moisture-holding capacity of air warmed by compression in descending from the high-pressure belt of the horse latitudes to the belt of tropical trade winds. Decreased precipitation and high evaporation rates combine to desiccate the land, especiallv on the west sides of continents.

Seasonally hot deserts at mid-latitudes, cool or topographic deserts result from complex and often obscure relationships between climate, geographic position and topography. The desert of Turkistan, east of the Caspian sea, and the Gobi and Takla Makan *(qq.v.)* of central Asia are deep within continental interiors distant from moisture-laden winds, while the Great Basin *(q.v.)* of the western United States and the deserts east of the Andes in southern Argentina exemplify the rain-shadow effect created by high mountains lying across the path of moist winds.

Deserts are highly varied in area. altitude, land forms. geology and other physical characteristics. Among hot deserts, the Sahara. with an area of about 3.500.000 sq.mi., is the largest and extends from 436 ft. below sea level to 11.204 ft. above. North American deserts are in part mountainous, but large areas vary from only a few feet above to well below sea level, the lowest point being reached at 282 ft. below sea level in Death valley *(q.v.)*, California. Terrain may be of rugged mountains. high plateaus or plains, and many deserts occupy broad mountain-rimmed basins termed bolsons. Surface materials include bare bedrock. plains of gravel and boulders and vast tracts of shifting sand. respectively the hammada, reg and *erg* of the Sahara. Wind-blown sands. commonly thought to be typical of deserts, make up only about 2% of North American deserts, 11% of the Sahara and 30% of the Arabian desert.

Climates are characteristically extreme in all deserts, and variations are great from one to another. Differences in seasonal temperature regimes sharply differentiate tropical from mid-latitude deserts. Usually the environment is characterized by cloudless skies, intense sunshine. high percentage of possible hours of sunshine. extreme daily and seasonal temperature ranges, intense heating of surfaces, strong winds, rainfall quantitatively low and erratic in distribution and evaporation rates greatly exceeding precipitation. Rapid heat loss by radiation and convection to the clear sky results in chilly nights, frequently heavy dew and occasional frost even in tropical deserts.

Diurnal and seasonal temperature ranges are greatest in mid-latitude deserts. In the Gobi winter winds are violent and severe blizzards common, and in parts of this area as many as six months each year have mean temperatures below freezing. During the hottest seasons air temperature may average 85°–90° F.. and averages of 105°–110° are not unusual. The highest air temperature recorded in the shade is 136.4°, measured in the Sahara. and a value of 134.1° has been recorded in Death valley. Precipitation is usually less than ten inches annually, and five inches or less is common. Several years may elapse without measurable rainfall, only to be followed by a deluge. At Iquique, Chile, in the Atacama desert *(q.v.)*, 0.6 in. of rain fell in a single shower after four consecutive rainless years.

Desert landscapes are shaped by weathering processes and winds, but (paradoxically) mainly by erosion and deposition by running water. Chemical weathering and mechanical weathering by freezing are retarded in dry regions; and rock fragmentation results principally from expansion and contraction induced by wide temperature fluctuations. Winds transport great clouds of dust and impel large quantities of sand along the ground. all particles behaving as abrasive tools which blast vegetation and carve.

facet and polish rocks, mainly within two to three feet of the ground. Continued removal of fine materials produces deflation basins with surfaces of residual lag gravels and boulders, the desert pavement.

Infrequent rains of high intensity and short duration produce flash floods which rush from highlands as sheet floods or as torrents raging through the usually dry arroyos or wadies. Flowing with high velocity. and often without warning, streams transport large quantities of mud, sand and boulders short distances into the desert basins before the water is dissipated by penetration into the ground and evaporation. Centripetal drainage of bolsons produces gentle piedmont slopes or pediments consisting of upper eroded bedrock surfaces and lower, undulating slopes or bajadas of coalescing alluvial fans. Mineral salts leached from the highlands are carried to the centre of the basins, where they accumulate in usually ephemeral lakes which, lacking outlets to the sea, become increasingly saline. Exposed bottom sediments of dried-out lakes are termed playas and, when containing high concentrations of precipitated, dry, glistening salts, are called alkali flats.

Plant and animal populations differ qualitatively and quantitatively in various deserts, but all possess traits of structure, physiology and behaviour which favour obtaining and conserving a meagre water supply. Plants are mainly low-growing, thorny. small-leaved or leafless. grayish to light green in colour. with extensive and often deep roots, and are usually widely spaced. Reduced surfaces, daytime closure of stomata, water-impervious cuticle and waxy coatings. succulent organs which accumulate large quantities of water and physiological resistance to desiccation are genetic characteristics of significance to perennial species. Drought-evading. ephemeral annuals, dormant during dry periods, appear in profusion following rains. Vegetation is usually simple in composition, as in the Great Basin, n-here it is dominated by only a few species of low deciduous shrubs. A greater number of species and increased complexity of vegetation are often attained, as in the Sonoran desert. where there occurs a large variety of evergreen and deciduous shrubs, small trees. many succulents. including large columnar and other types of cacti. and annuals which constitute about 50% of the total flora. The dominant xerophytic (adapted to arid habitats) desert plants include agaves, cacti, composites. legumes and yuccas (*qq.v.*). Typical plants of American deserts include *Acacia* species, creosote bush, greasewood, mesquite, sagebrush and saguaro (*qq.v.*).

Desert animals include a few large mammals: many rodents, reptiles. birds and insects. Rapid. often leaping locomotion, burrowing and nocturnal habits are well-developed characteristics. although most birds and reptiles of the desert are diurnal. Most animals drink water when it is available, but in its absence depend upon water obtained by eating succulent plants or blood and other tissues of their prey. Many insects and some rodents (kangaroo rat, pocket mouse) utilize metabolic water. and even the camel. better known for its ability to store water in special stomach compartments, derives a significant water supply from oxidation of fats accumulated in its hump. Conservation of water is accomplished in diverse ways. Reptiles and some insects have water-impervious integuments, mammals concentrate urine by reabsorption of water before excretion and reptiles excrete nitrogenous waste as uric acid crystals without water loss. Socturnal habits permit avoidance of water stress, and some animals (as the ground squirrel) estivate during periods of extreme heat and drought.

Large human populations are possible in deserts only where rivers (such as the Nile, Colorado, Tigris and Indus) make irrigation possible. Desert soils are often of high fertility when water is available, and many oases (*q.v.*) are agriculturally productive. The economy of scattered nomadic peoples is based upon subsistence agriculture in small part but depends principally upon grazing herds of sheep, goats, cattle and, less frequently, horses.

Deserts are a source of valuable mineral resources only in part related specifically to desert environment. Aridity and internal drainage are directly responsible for the wealth of evaporites, including borax, nitrates, potash and other inorganic salts, commercially exploited in many deserts, especially those of North America.

DESERTION, in marriage law, the act of leaving one's spouse against the latter's will and without legally justified cause. It is to be distinguished from separation, the situation in which spouses cease to live together by mutual agreement or in which one spouse leaves the other against the latter's will, but with legally just cause. especially when he or she has been authorized to do so by a decree of judicial separation.

Desertion is also committed by the spouse who expels the other from the marital home. and courts also tend to treat as a deserter a spouse who successfully engages in conduct toward the other calculated to induce the latter to leave the marital home. This last-named case is sometimes referred to as constructive desertion.

While ordinarily a husband is supposed to support his wife and children by providing them with a home, nourishment, clothing and recreation, a deserting husband will be compelled to provide maintenance for his wife and support for the dependent children living with her by making money payments to her. In England, maintenance orders for such payments can be made in speedy and inexpensive proceedings by the magistrates up to a maximum amount of £7 10s. a week for a wife and 50*s.* a week for a child. A decree of judicial separation providing for higher payments may be issued by the high court.

The amount of the alimony, as it will be called in such a case. depends on the circumstances of the situation, especially the parties' status in life, the extent of their respective property, income, earning power and needs.

In Scotland the reciprocal duties of the spouses may be enforced through a suit for aliment.

In the United States. too. speedy and inexpensive procedures are generally available to obtain money support at or near the subsistence level, and more formal proceedings exist to obtain separate maintenance at higher amounts.

In 1959 desertion constituted a ground for divorce in England. Scotland and all jurisdictions of the United States except New York, provided it had lasted for the minimum period prescribed by the statute in question. which is three years in England and Scotland. and in the United States from five years in Rhode Island to six months in Hawaii and no time limit in New Mexico.

DESERT WARFARE. In terms of military operations, both topography and climate pose special problems that cause military men to look upon desert warfare as a special form of combat. The surface of a desert may vary from areas of flat, almost featureless terrain to steep ravines and dry river beds with precipitous banks or high rocky escarpments. Some areas have an almost rock-hard surface that presents no obstacle to movement; others are covered with fine drift sand and are, for all practical purposes, impassable. Until the advent of the motor vehicle there were no desert roads and very few tracks; most desert areas had not been surveyed or mapped. Limited supplies of water are to be found. but they are few and far between. Moreover, desert areas suffer from extremes of temperature.

Operationally, battles are won by the power to maneuver, but in desert areas maneuver is difficult. Administratively, the problem of supplying a desert force of any size with all its requirements, including water for men and animals, is tremendous. When armies consisted of marching men, accompanied by horses or other animals, this problem was considered almost insuperable. In the past, therefore, desert warfare was mainly confined to raids or punitive expeditions with a strictly limited scope, generally carried out by inhabitants of the desert who were used to its conditions. Their means of locomotion and transport was the camel, that "ship of the desert" which can be trained to exist without water for several days. (*See* CAMEL CORPS.) Forces organized on European standards were debarred from undertaking large-scale desert operations, though there were a few notable exceptions.

The great advances made in mechanization after World War I revolutionized the concept of desert warfare. Motor vehicles have attained standards of reliability and robustness which enable them to operate continuously under the severest conditions of strain and climate. There is practically no terrain, except precipices or the softest drift sand, which they cannot negotiate when suitably equipped. Thus large modern forces, which are all mechanically transported, can be moved about in the desert and supplied with all their requirements for protracted periods. The lack of roads capable of carrying a heavy volume of traffic has been overcome by modern methods of rapid road construction, so that a system of communication to the supply areas in the rear can be quickly built up in the wake of an advancing army. Water can be supplied in adequate quantities, even for large forces and for a considerable period, by means of special water-carrying transport units. Modern pipe-laying equipment can be used to build up a system of water-refilling points close behind an advancing force and water can then be pumped to these points from the rear areas.

Aircraft have also exerted a great influence on desert warfare. As deserts are devoid of vegetation, they offer virtually no natural concealment from air attack. To minimize the effect of such attacks, forces in the desert must always be widely dispersed; movement must be confined to the hours of darkness, using no lights. Even in easy desert terrain, however, movement in dispersed formation imposes a great strain upon vehicle drivers, and in difficult areas the strain is tremendous. Control of such movement is difficult, especially when an obstacle such as a river bed or an area of drift sand is encountered. Radiotelephony has done much to simplify this problem, but has not eliminated it.

Aircraft have still further simplified the supply in desert operations. It is now possible to maintain large forces at great distances from their base, either by dropping supplies from the air by parachute. or by landing aircraft at forward improvised airstrips. Air-borne operations may also have a decisive effect upon desert warfare if directed against the enemy's supply lines. In any large-scale campaign, supply will probably be restricted to one or two main routes, which will be vulnerable to attack. Their severance by air-borne attack at a focal point, even for a few days, may well give a decisive result for the whole campaign.

To summarize, it can be said that mechanical science has overcome most of the difficulties that previously beset desert warfare, and has made the conduct of large-scale operations in such areas possible. The operations of the Allied armies in north Africa in 1942 and 1943 during World War II are proof of this, and for a fuller study of the subject reference should be made to these campaigns. See WORLD WAR II. (A. W. LE.)

DESERT WILLOW (Chilopsis linearis), a small North American tree of the bignonia family (Bignoniaceae), native to stream banks and the vicinity of springs in deserts from western Texas to southern California and southward to northern Mexico. It grows usually from 8 ft. to 25 ft. high, with stems from 2 in. to 10 in. in diameter, slender, ascending branches and narrow, willow-like leaves. During summer it bears a succession of showy, funnel-shaped, pink flowers. about 1½ in. long and 1¼ in. across, in profuse terminal clusters, followed in autumn by narrow seedpods about 8 in. long.

It is a characteristic plant of southwestern deserts; because of its appearance, suggestive of a slender willow with catalpalike flowers. it is cultivated there as an ornament.

DESGARCINS, MAGDELEINE MARIE (originally LOUISE) (1169–1797). French actress, who during her short career was one of the greatest of French tragediennes. was born at Mont Dauphin (Hautes Alpes). She was the associate of François Talma. nith whom she nearly always appeared.

Mlle Desgarcins made her debut at the Comédie Frangaise on May 24, 1788. in Jean Racine's *Bajazet,* and was at once made a full member of the company. She left the Comédie Frangaise in 1791 for the house in the Rue Richelieu. soon to become the Théâtre de la République, and there her triumphs were no less—in King *Lear, Othello,* La Harpe's *Mélanie* et *Virginie,* etc. She died insane, at Paris. on Oct. 27, 1797.

DESHOULIERES, ANTOINETTE (née DU LIGIER DE LA GARDE) (1638–1694), French poet and, from 1672 until her death, a celebrated literary figure, was born at Paris on Jan. 1, 1638. She received an excellent education..which her marriage in 1651 does not appear to have interrupted, for her husband left soon afterward to support the prince of Condé in Flanders and she, living with her parents, applied herself to poetry and the philosophy of Pierre Gassendi. In 1655 she went to rejoin her husband in Flanders where her pertinacity in demanding from the Spanish authorities the pension which they had promised him led them to imprison her in the château de Vilvorde. Released after several months when her husband and a small band of French officers attacked the chbteau, she returned with him to France, but their marriage was not successful and after 1659 they separated.

Antoinette Deshoulières became a prominent literary figure after the publication of some poems in 1672 in the *Mercure galante.* Voltaire called her the best of French poetesses and by other admirers she was styled the tenth muse. Her *salon* was a meeting place for all the prominent literary figures of her day. Despite a royal pension, obtained through Madame de Maintenon in 1688, her last years were clouded by poverty and painful ill-health. She died at Paris on Feb. 17, 1694. Complete editions of her works were published at Paris in 1695, 1747 and 1882.

DESICCATION: see DEHYDRATION.

DESIDERIO DA SETTIGNANO (d. 1464). Italian sculptor, who created works unrivaled in the 15th century for subtlety and technical accomplishment, was born at Settignano near Florence between 1428 and 1431. He seems to have been trained in the studio of Bernardo Rossellino, and was deeply influenced by Donatello after the latter's return from Padua (1453). At this time he may have executed the so-called "Martelli Baptist" (Museo Nazionale. Florence). which since the time of Vasari has been ascribed to Donatello After 1453 Desiderio designed and carved the monument of the Aretine humanist Carlo Marsuppini in Santa Croce in Florence. With its rich architectural detail and its admirable effigy, this tomb occupies a position of exceptional importance in the history of the Florentine wall monument. Between 1455 and 1460 Desiderio carved the frieze of *putto* heads for Filippo Brunelleschi's Pazzi chapel, and in 1461 completed the Altar of the Sacrament in S. Lorenzo. Stucco versions of the figure of the Child Christ which surmounts this altar seem to have been made in some quantity in the 15th century. Two celebrated busts of children, now in the National Gallery of Art, Washington, D.C., are infused with the same tender sentiment. As a sculptor in relief. Desiderio masterfully employed the technique of *rilievo stiacciato* (low or flattened relief) evolved by Donatello in Madonnas at Turin and Philadelphia and a "Child Christ and the Young St. John Baptist" in the Louvre. Like his contemporaries Antonio Rossellino and Mino da Fiesole, Desiderio executed portrait busts The most notable of these are in the Museo Nazionale, Florence, the Louvre and the Kaiser Friedrich museum, Berlin.

Despite the strongly personal character of his work, Desiderio seems to have been the head of an extensive studio. and Filarete alludes to commissions for decorative carving carried out by the artist and his assistants An example of this survives in a chimney-piece in gray sandstone (*pietra* serena) in the Victoria and Albert museum, London. He died in Florence on Jan. 16. 1464.

See Leo Planiscig, *Desiderio da Settignano* (1942).

(J. W. P.-H.)

DESIDERIUS (8th century A.D.) was the last Lombard king (see LOMBARDS). Duke of Tuscany at King Aistulf's death in 756, he contended for the throne against Aistulf's brother Ratchis, after nhose abdication in 757 he nas generally recognized as king. Despite promises made to Pope Stephen III (II), he sought to recover territories ceded to the papacy by his predecessor. Probably in order to gain freedom of action against the pope, he pursued a policy of friendship toward the Franks, nhich culminated. in 770, in the marriage of a daughter of his to Charlemagne. After the death in 771 of Charlemagne's brother Carloman, however, Franco-Lombard relations deteriorated rapidly; Charlemagne hav-

ing seized Carloman's dominions, his widow sought refuge with her sons at the Lombard court, and about the same time Charlemagne repudiated his Lombard wife. In the same year 772. Desiderius resumed his offensive against the papacy, in order both to compel Adrian I to recognize Carloman's sons and to press his own territorial claims Lombard troops advanced into the Roman duchy; threatened uith a siege of Rome, the pope appealed for help to Charlemagne, who crossed the Alps in the summer of 773 and besieged Pavia, nhere Desiderius capitulated in June 774. Charlemagne assumed the title of king of the Lombards and probably took Desiderius back with him to France to die in captivity.

DESIGN, from the Latin *designare,* "to mark out," is the process of developing plans or schemes of action; more particularly a design may be the developed plan or scheme, nhether kept in mind or set forth as a drawing or model. Thus one can speak of Napoleon's designs on Europe and of the designs for next year's automobiles. The execution of a plan is not, properly, designing, except insofar as the plan may continue to develop in order to meet originally unanticipated requirements. Similarly the end result, either product or activity, is not a design, but it is reasonable to speak of its design, that is. of the antecedent plan or scheme discoverable in it, as in the design of Dante's *Divine Comedy.*

A plan or scheme set forth in a draning or model is an aspect of design close to its etymology and to its most usual specific meaning—design as the pattern for making a product. Design thus meant indicates primarily an interrelation of parts intended to produce a coherent and effective whole. The disposition and detailing of components is ordinarily planned with four limiting factors in mind: the capacities of the materials employed, the influence of methods adapting these materials to their work, the impingement of parts within the whole and the effect of the whole on those who may see it, use it or become involved in it. Design in the sense of a pattern for making a product has become a synonym for work in the applied arts, and a designer is one who practises them. Design in the fine arts is often considered to be the creative process per se, while in engineering, on the contrary, it may mean a concise record of the embodiment of appropriate concepts and experiences. In architecture and product design the artistic and engineering aspects of design tend to merge; that is, an architect, craftsman, graphic or industrial designer cannot design according to formulas alone as an engineer can, nor as freely as can a painter, poet or musician.

Design is a word used loosely in all the arts, and particularly in their instruction, to mean composition, style or decoration. Composition is the framework of relationships in a thing, considered analytically in isolation from the parts and from the whole; this is the meaning of phrases like "the design of Raphael's *Sistine Madonna."* Neoclassic design means the neoclassic style of design. An all-over design is a regularly repeated decoration covering an expanse. Such loose: localized uses of the word are usually comprehensible in context but may confuse readers or listeners who correctly suspect that design in aeronautics, for example, is another thing. *See* DESIGK. 19TH-CENTURY; DESIGN, 20TH-CENTURY; DISPLAY DESIGN; INDUSTRIAL DESIGN. *See* also references under "Design" in the Index volume. (ER. K.)

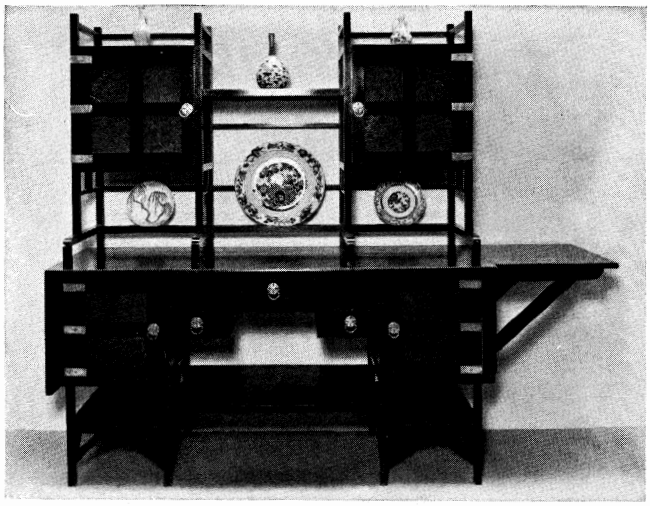
DESIGN, 19TH-CENTURY. In the west. 19th-century design was conditioned by three ideas that had grown strong at the end of the preceding century: human equality. popular cducation and scientific progress. Nineteenth-century products were thus conceived. made and used in a spirit and with means diiferent from those of medieval or Renaissance crafts or academically controlled 18th-century design. Yet. imitation of those very eras characterized 19th-century design in the eyes of later generations. This view obscures the positive accomplishments of the period. Careful investigations have shown 19th-century design to be the matrix of new concepts suited to the modern world, preliminary in fact to 20th-century design.

Historicism **and** Science.—A return to past forms is regular in civilizations; unique, however, were the range, enthusiasm and thoroughness of the 19th-century designers' exploitation of history. The scientific method was being widely applied to the evidence of explorers, archivists and archaeologists; knonledge of every kind poured in almost faster than understanding could deal with it. Much that was derogatorily called eclecticism was an earnest attempt to make use of this spate of information. Designers were convinced that in the mass of documentation lay a key to the principles of their art. Like scientists they compared, experimented, deduced. Systematic analysis of natural forms and colours, it was believed, might provide another approach to fundamentals. This recurrent search for design principles in nature or history demonstrates that 19th-century designers were keenly aware of the need for a firm basis from which to deal with the vast problems presented by the Industrial Revolution

For designers the Industrial Revolution meant unprecedented floods of goods, unprecedented popular markets and division of the once close-knit activities of designers, workers, manufacturers and distributors. The traditional significance of handwork and the individual craftsman vanished. Steam power, in Europe alone, increased a hundredfold between 1800 and 1900; after 1870 gasoline engines and electricity began to augment energy at a rate previously inconceivable. Transportation improved so that, in effect, distances were reduced by seven-eighths. The relationship of raw materials, fuels and labour supply was upset; production centres moved; transmittal of stylistic and technological information nas greatly speeded. Lithography and, later, colour lithography profoundly influenced visual information; softer, fuller, more sensuous images became the rule. Mass production made its first strides in textiles, which were revolutionized again when synthetic dyes mere perfected after 1850. Later, wallpapers became common, further changing the character of interiors. Synthetic materials made their appearance about 1840 with the vulcanization of rubber; gutta-percha, Celluloid, papier-mâché and artificial stone were quickly and widely accepted. Plywood (used by the ancient Egyptians) was mass-produced around midcentury; bent, solid wood furniture, invented around 1840 by Michael Thonet (1796–1871), became commonplace. In metals, mechanized stamping and spinning, improvements in casting and, above all, electroplating made great changes; improved alloys appeared, as well as new metals like chromium and aluminum. No previous period had such a record of continuous change and invention.

Neoclassicism.—As the century opened the style dominant in the arts was neoclassicism, in which elaborate Roman grandeur was revived, chastened by Greek precedent and authority. Neoclassicism had arisen 50 years earlier as a reform directed against the caprice of the rococo. The rediscovery and publication of Greek (as contrasted to well-known Roman and Renaissance) architecture and art relics had stimulated a pristine, earnest style theoretically favouring structural logic, expression of the natural qualities of a few chosen materials and chaste, symbolic ornamentation. Ancient and modern conquests of Egypt occasioned some use of Pharaonic motifs. From 1750 to 1850 one or more variations of neoclassicism flourished. Around 1800 neoclassicism lost its first impetus, though as the official style for Napoleon's empire it enjoyed great prestige. Empire style (*q.v.*) was generally dry, monotonous and cramped, though elegant and correct. In areas relatively free of Parisian influence neoclassicism was often agreeably unforced, as in some provincial Empire products and some norks of the English regency, the Austrian and Russian empires and the United States before 1850.

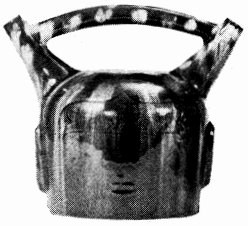
Keoclassicism inherited many intellectual appetites of the Enlightenment but not that movement's fearless logic. Thus Empire ornament tended to reduce symbolism to association, prefiguring the sentimental, anecdotal language of later design. Such symbols as laurels for glory, wheat for plenty and sphinxes to guard the mysteries of royalty and of eternal life communicated to a humanistically educated happy few, but under the pressures of industry and democracy symbols often became mere malapropisms.



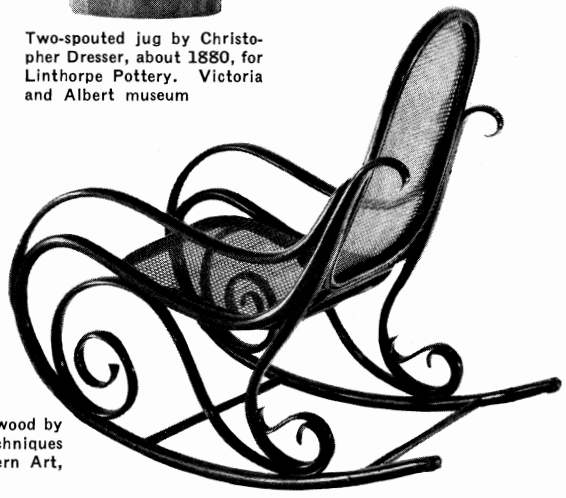
Sideboard of ebonized wood designed by E. W. Godwin about 1877; produced by W. Watt. Collection of Mrs. E. M. Hartree, Victoria and Albert museum

Breakfast room in John Soane's own house, 1812; later the Soane museum, London

"Morris chair" produced by Morris, Marshall, Faulkner and Co. about 1867. Collection of Mrs. A. J. Tozer, Victoria and Albert museum



Two-spouted jug by Christopher Dresser, about 1880, for Linthorpe Pottery. Victoria and Albert museum



Adjustable rocking chair of bent beechwood by Michael Thonet about 1876, using techniques developed in 1840. Museum of Modern Art, New York

Silver teapot designed about 1848 by A.W.N. Pugin. Produced 1861–62 by John Hardman and Company, Birmingham, Eng. Victoria and Albert museum

Dining room of the Waller house, River Forest, Ill., 1899, by Frank Lloyd Wright

Wardrobe by Philip Webb with paintings by Edward Burne-Jones, 1858, a wedding gift to William Morris. Victoria and Albert museum

Sir John Soane (1753–1837) was the most original master of structure, lighting and space in neoclassical architecture. Two other prominent architects, the amateur Thomas Jefferson (1743–1826) in the United States and the highly professional K. F. Schinkel (1781–1841) in Prussia, applied mechanical ingenuity and rational forms to the solution of problems of everyday comfort and convenience. From these men to creative engineers of the period such as Sir Samuel Bentham (1757–1831) and, in the U S., Oliver Evans (1755–1819) was a short step. yet it led outside design.

Early in the century architects of the French Revolutionary era sought the sublime, so called, in forms severely plain, gigantic, visibly indeterminate though logically defined, and strongly contrasted one with another. Cylinders, spheres and circles, pyramids and triangles were preferred. Fluent transitions between parts, gradations mounting to a climax, were abandoned for abrupt juxtapositions.

A curious echo of these efforts reverberated in the Biedermeier, a name given to certain furnishings produced in German-speaking lands from 1810 to 1840. Yet Biedermeier design opposed sublimity; the very name was derived from a literary character of the period, a typically solid, humdrum 19th-century bourgeois.

Romanticism. — Like neoclassicism, medieval design was an inherited interest of the 19th century; many playful evocations of Gothic detail had slipped easily into irregular rococo design. A related 18th-century heritage was the concept of the picturesque, influenced by the wild landscapes with Gothic and other ruins depicted by Claude Lorrain and Salvator Rosa and their schools. In gardens, and then in decorating an infinitude of products, picturesque taste nostalgically evoked the decay of classicism with artificial ruins and contrived wildernesses. As nature seemingly resumed its sway over the works of man, the picturesque could approach the sublime, which was most effective in untouched and savage nature. Nature, raw material for scientific research, was also considered the very stuff of poetic insight. Samuel Taylor Coleridge, lecturing about Shakespeare in 1808, said, "Such as the life is, such is the form," recognizing organic form and process as prototypes for the creations of men. Before the century's end the U S. architect Louis Sullivan (1856–1924) phrased the idea more familiarly: "Form follows function."

Napoleon's ventures in Syria and Spain turned the world's attention toward Islam. Early in the 19th century, Gothic, Romanesque and Islamic design were confused with each other, since none fitted the classicist codification that Europe accepted as its great tradition. The heritage of Greece and Rome was said to have been polluted by travel-stained crusaders, or by Moors and Goths probing deep into the continent during the dark ages. All this barbarism seemed alike.

Another romantic feature can be credited to Napoleon—his omnivorous ambitions aroused modern nationalism that naturally turned to history for its atmosphere and insignia. In Protestant lands the period of transition from Late Gothic to Renaissance most often provided the requisite glamour; in Catholic countries it was the period of the baroque. Thus romantic design revived that of the Elizabethans, the Bourbons, Frederick the Great and Barbarossa—the entire historic pageant, filtered to reinforce each separate national identity and pride.

Mid-Century Design. — The waning of neoclassical design was associated with decreasing confidence in the Enlightenment and its results. Until around 1825 the dislocation and brutalization of traditional ways of life seemed catastrophic; the French Revolution had produced misery and repression. But from 1825 to 1850 the working classes mustered strength; unions began to be legally recognized; Marx and Engels rewrote history from the viewpoint of productivity, discarding humanist values. A great gush of mechanical inventions appeared from 1800 to 1830; by 1850 processes were developed to utilize them. Confidence revived despite repeated economic crises and uprisings across Europe, culminating in the revolutions of 1848. In this situation romanticism flourished, nurtured by escapism that accompanied social chaos and, more significantly for the future, by the revival of ethical and religious standards in which design played an important role. Feeding romanticism, historicism was in its turn reinforced by abundant, increasingly informative, printed words and pictures, largely addressed to the masses.

In 1851 attention was focused on design by the first Great Exhibition of the Industry of All Nations, for which the Crystal palace was built in London. The sensational palace, designed by Joseph Paxton (1801–65), a self-educated gardener, was essentially a huge conservatory; demountable iron and glass members, interchangeable and mass produced, were organized in a building that ever since has been regarded as progressive, practical and inspiring. The fully illustrated catalogues of the 1851 exhibition became the principal records of Victorian design. Their value was challenged on the claim that mostly atypical showpieces were reproduced. Like the great international exhibitions that followed, however, the Crystal palace indicated the dominant design trends of its time. The historic masquerade, with all styles mixed together, was in full swing; heavy, bulging forms prevailed. covered with flat patterns and molded ornaments, often anecdotal and naturalistic. Craftsmanship had flown from the arts to engineering. World trade encouraged generally low standards of material quality, but a growing public demanded many amenities and mechanical ingenuity prospered.

Reform and Realism. — The Crystal palace revealed confusion, but the struggle for order had begun. Early in the century academic art instruction throughout the west formalized the applications of neoclassical art to industry, successfully initiated by Sir Josiah Wedgwood (1730–95). In a dynamic period these efforts were insufficient. An English parliamentary committee of 1835 began to hear expert witnesses on design as it affected the national economy. The dependence on importing and copying, especially of excellent handmade French wares, was to be countered by improving English design and design education. The experts favoured neither Greece nor any other historic precedent, but held that knowledge of nature was the best basis for design. As this idea nas tested, a clear divergence developed: some wanted to copy natural forms as the most perfect ones, a new academic ideal; others wanted to analyze natural forms to extract their principles of structure and relationship, an approach modeled on scientific inquiry. As early as 1835 the influence of engineering on aesthetics was acknowledged; it was said that there was probably no example of a perfect machine which was not at the same time beautiful Design, moreover, should be characteristic of its age and of its nation. Design piracy was decried. These ideas were introduced in instruction and practice with "complete and utter failure" reported in another parliamentary review of 1849.

While these attempts were being tested another approach was made by an eccentric, successful young English architect, A. W. N. Pugin (1812–52), whose greatest task was the creation of all the ornamental details of the new Houses of Parliament. Trained by his *émigré* father, an ardent gothicist. Pugin late in the 1830s established workshops for authentically designed furnishings to complete his churches and houses. Thrice married, he designed his homes, their furniture and even his wives' jewelry. Pugin became a Roman Catholic in 1835, and most of his private work was for wealthy patrons stimulated by the Catholic Emancipation act of 1829.

Pugin was the first in the 19th century to formulate a consistent design code, and it was influential for over a century. He believed design mas primarily a moral act; the attitudes of designers were transmitted to others through their works. Therefore the higher the ideals, the greater the art. Pugin opposed the picturesque which valued effects regardless of means, saying "designs should be adapted to the material in which they are executed." He thought the designer's "skill consisted in embodying and expressing the structure," that is, the purpose of the structure even more than its constructive system. Deriving decorative arts from architecture, he saw the architect as the chief implementer of a good and noble life. Bygone ages offered examples of how good work could be done but not of how it should appear; even in Gothic Pugin sought "not a ***style,*** but a ***principle.***" Thus every age and nation should evolve spontaneously a style that expresses its life—a thought close to Coleridge's. To achieve fitness, repose

and unity, the tests of successful design, Pugin recommended "seeking *the most convenient form* and then *decorating* it" so that "the smallest detail should *have a meaning and serve a purpose.*" He wrote that naturalistic ornament should be conventionalized and disposed geometrically to enhance the underlying form. He hated all sham materials, fought against three-dimensional effects on plane surfaces and criticized the overabundance of draperies. These reformatory ideas, launched throughout the 1840s in books which Pugin wrote and illustrated, were widely accepted. The year before his death, when his products were featured at the Great exhibition, Pugin correctly claimed "my writings, much more than what I have been able to do, have revolutionized taste in England." Pugin anticipated later 19th-century design reformers; he differed, however, from many of them in important ideas and practices. "Any modern invention which conduces to comfort, cleanliness or durability should be adopted," he wrote. "We do not want to arrest the course of inventions, but to confine them to their legitimate uses." Thus he found steam engines, modern plumbing and gas lights "most valuable"; railroads he thought offered great architectural opportunities. Tiles, metalwares, furniture, stained glass, vestments and jewelry by Pugin were manufactured and sold in regular trade. Not fanatic about handwork, he believed it should be supplemented by labour-saving devices and itself used chiefly for significant embellishments.

England at mid-century developed an internationally influential school of Gothicizing church architects, associated with the Oxford movement, founded in 1833. The English Protestant religious revival naturally was more accepted than the similar Catholic activity Pugin served. The Oxford movement's most original architect, William Butterfield (1814- goo), introduced the concept of realism, meaning a clear expression of materials through colourful contrast of textures and patterns, and large. abrupt forms indicating structure and workmanship. Such masculine expression has remained important in design.

Another personality in mid-century England was Owen Jones (1809–74), a colour expert, author and designer of prefabricated metal buildings. In 1856 Jones published *The Grammar* of *Ornament* with large colour plates whose subjects ranged from "Ornament of Savage Tribes" through all history to "Leaves and Flowers From Nature," preceded by "General Principles in the Arrangement of Form and Colour, in Architecture and the Decorative Arts." Jones's *Grammar* was frequently reprinted.

An occasional associate of Jones and Pugin was Sir Henry Cole (1808–82), civil servant, author, editor, entrepreneur in design and other arts and an important figure in the Great exhibition, working closely with its patron, Prince Albert. Subsequently he headed the National School of Design and its collections that grew into the first great national museum of applied arts, the Victoria and Albert.

The school and museum were modeled on a plan suggested by Gottfried Semper (1803–79). who went to England. a revolutionist exiled from Dresden, just as the Great exhibition was taking form. With the gifted English sculptor Alfred Stevens (1817–75) and a French refugee. Léon Arnoux (1816–1902), technical and artistic leader of Minton's ceramic works, Semper helped introduce a neo-Renaissance mode into English design. In the mid-century confusion of styles this seemed livable and reasonable. The Renaissance, moreover, had played an important role in English architecture from the 1830s, and a subordinate one in neoclassicism from the beginning.

Neo-Renaissance design opposed neo-Gothic on the continent also. from the 1860s on. Leading the trends were Semper, active in Germany, Switzerland and Austria, and Eugène Emmanuel Viollet-le-Duc (1814–79) in France. Both gifted, rebellious architects wrote extensive analytic design histories, announcing principles from which a new design could arise, befitting modern man. Viollet-le-Duc the Gothicist and Semper the humanist each exerted great influence on behalf of his favourite style. However divergent their tastes, both believed that the best examples of past eras revealed utilitarian structure, logical expression of materials and distribution of colour and decoration to emphasize structure and materials. Thus Viollet-le-Duc and Semper upheld a rational design evaluation, linking the neoclassical reform of the 18th century to the functionalism of the 20th.

In the 1850s and 1860s the English art critic John Ruskin (1819–1900) won a phenomenally wide audience, American as well as British. His central themes were two: the study of nature, particularly botany and geology (an enthusiasm of Viollet-le-Duc's), to discover therein principles of form and organization; and the importance of the "human touch" that involuntarily but effectively gives character to the surface of an artifact. Ruskin felt that only happy, moral men could make truly beautiful products; skill was not a prime requisite, still less the mathematical perfection of the machine. The touch of the artist or workman was the true source of artistic value, not rationality of structure or rational use of materials. The preference for expressive character over inherent logic brought Ruskin close to the concept of architectural realism. In the importance he attached to the human being behind the product his ideas paralleled Pugin's, but he had shifted emphasis from the intent of the designer to the involuntary character of the handmade surface. Mid-19th century sensitivity to surface quality has been attributed to improvements in printing illustrations; tactile values were readily rendered and became widely appreciated. Ruskin in fact was much concerned with the illustrations in his books. As regards architecture Ruskin and his followers favoured Venetian Gothic.

William Morris (1834–96) adapted a Ruskinian version of Pugin's principles to the applied arts. A constant experimenter, he revived many vanished or dying crafts, and he was an unusually gifted designer of flat patterns. Morris, like Pugin, built and furnished several houses for himself. In Morris' early furnishings, heavy neo-Gothic forms were supplemented with Pre-Raphaelite paintings by himself and his friends. After Morris' example, the idea of design reform through handicraft, with Gothic forms and moral ideas dominant, spread throughout the west. There already was a lively interest in oriental handicrafts. In 1862, at a second international exhibition held in London, Japan exhibited fascinating crafts; Turkey, Arabia and India were challenged Acceptance of these newly revealed crafts was helped by the vogue for Japanese woodcuts and, in the next decades, by the discovery of Japanese architecture.

Idealism and Innovation. — Following the Great exhibition, Pugin's successors in England divided into two camps: eloquent, reforming handicraft workers, nho are remembered by posterity; and pioneering designers for industry who welcomed the machine and believed medieval methods could not satisfy the wants or express the chdracter of their civilization. Three of these stand out. E W Godwin (1833–86) was trained as an architect. He became interested in the Japanese in 1862 and soon after became a friend and collaborator of the painter J A. M. Whistler. Goduin's long association with the actress Ellen Terry led him to costume and scenery design, at which he excelled. His first table was produced in 1868 by William Watt. for whom he designed, over many years, strikingly simple, sensible and original furniture, light in construction, often dark in colour and occasionally ornamented by flat. bright hardware and inset panels. Godwin and Whistler together evolved a style of interior in pale tints, sparsely, asymmetrically furnished. This style and Godwin's "art furniture" launched the Aesthetic movement in design that became the butt of caricaturists (Gilbert and Sullivan, *Patience,* 1881). Christopher Dresser (1834–1904) was a design student who switched to botany: he drew an important page analyzing plant forms for Jones's *Grammar of Ornament.* In 1862 Dresser's first text on design nas published; it was widely used, as were its sequels In the next five years he built an extensive practice as a free-lance commercial designer, like Godwin, of furniture, textiles and wallpapers Dresser also did much in metalwares, pottery and glass; surviving examples are notably above the general level of his times In 1868 he founded a design office and in the 1870s traveled as official representative to international exhibitions at Vienna. Tokyo, Philadelphia and Paris. Dresser's designs in the Aesthetic style were forerunners of 20th-century work—functionally conceived, favouring geometric shapes, often severely plain. He was an ornamentalist especially in textiles and nallpapers, where he

used a surprisingly abstract symbolic expressionism. Bruce J. Talbert (1838–81), after schooling as an architect, began to design furniture for manufacture in 1862. In three years he became the leading gothicist in his field, then within a decade he turned toward the Jacobean style, freely interpreted in furniture. carpets. wallpapers. textiles and metalwork, paralleling the Queen Anne revival in English architecture.

Charles Locke Eastlake (1836–1906) wrote *Hints on Household Taste,* published in 1868 from earlier magazine articles. It resumed Pugin's theories in homely form, showing neo-Gothic furniture rationally constructed and ornamented. These illustrations uere copied and varied commercially, but Eastlake himself did little designing.

In 1866 William Morris' firm received its first commissions: rooms in St. James's palace and the Victoria and Albert museum. The 1870s and 1880s were busy years for this group which included the Pre-Raphaelite painter Edward Burne-Jones (1833–98), uho designed tapestries, stained glass, tiles and embroideries; the "realist" residential architect Philip Webb (1831–1915), who designed metalwork and glass of particular excellence, furniture, embroideries and jewelry; and the American George Jack (1855–1932), who was chief furniture designer. Many textiles, wallpapers and rugs were designed by Morris himself, but the famous Morris chair uith adjustable back, beloved in many variations in the U.S., was produced by the firm without specific authorship. The Morris chair was an elementary example of the "patent" furniture that grew popular in the 1870s and 1880s. Twentieth-century historians also appreciated the inventive engineering and common-sense functionalism of these designs, generally overlooking their ancient sources.

The arts and crafts movement (q *v.)* flourished from 1882 to about 1910, spreading Ruskin's ideals and Morris' practices. Craftsmen's guilds—associations to spread information, maintain standards, exhibit and teach—were formed in England and, later, elsewhere Less medievalizing than that of Morris, their work emphasized materials and workmanship, ornament was reduced and floral elements were more naturalistic than conventionalized. English guilds organized a'n Arts and Crafts Exhibition society in 1888 to demonstrate the unity of all the arts, fine and applied. as Ruskin and Morris taught. This idea, almost an axiom of design in later years, directly opposed the academic approach to the arts Walter Crane (1845–1915), an admired illustrator, was leader of the movement. as was C. R. Ashbee (1863–1942), a distinguished teacher. Arthur H. Mackmurdo (1851–1942) was an early contributor; later, like Ruskin and Morris, he became concerned with social rather than artistic reform. C. F. A. Voysey (1857–1941) was the leading architect of the movement; his original, delightful, cottage-style houses were widely copied. Voysey rose to prominence in the 1890s; even earlier he was known as the best flat-pattern designer after Morris. Perhaps influenced by Whistler and Godwin, Voysey's designs were light-toned; here too his example was very aidely folloned. The arts and crafts movement began a successful reform of lettering, printing, binding, illustrating and related arts; William Morris' epochal Kelmscott Press was founded in 1890; tno distinguished book designers, T. J. Cobden-Sanderson (1840–1922) and Sir Emery Walker (1851–1933), norked there. The arts and crafts movement recruited leading young architects and designers in the Netherlands. Belgium and Germany and in the United States, where the Mission style of furnishings and *The Craftsman* magazine lasted through 1916; Frank Lloyd Wright's (1869–1959) prairie house furnishings (1895–1910) were related.

The arts and crafts movement focused attention on humble, handmade things, leading to a revival of cottage crafts, the diversified crafts originally developed to keep a peasant household self-sufficient. This activity and Voysey's cottage architecture folloaed a century-old interest in peasant huts and hamlets, inaugurated by Queen Caroline of England and Queen Marie Antoinette of France in their garden retreats. The passage of time ensured a change from the picturesque approach to realism, but the attitude of escape from actuality remained.

Glasgow in the latter 1890s produced a vigorous design group centred on the architect C. R. Mackintosh (1868–1928). For a few years this highly romantic, symbolizing version of the arts and crafts movement led insurgent design. Liège, Vienna, Turin, Budapest. Dresden, Munich, Berlin, Venice and Moscow admiringly exhibited works of the group. To the process-bound forms of the movement, Glasgow designers added a feminizing, lyrical complexity and curvilinearity that was the very opposite of realism and led straight to *art nouveau* (*q.v.*), the last flower of 19th-century design.

Art nouveau had three reciprocal but distinct characteristics, all evident before 1900. Reformatory like British work, but centred in Brussels, Nancy and Paris, it fed directly on the rational, progressive ideas of Viollet-le-Duc. It looked to train sheds and viaducts rather than to cottages for inspiration, becoming a style of metal and glass. Second, continental designers were close to the *Symboliste* writers, musicians and painters of the 1880s and 1890s and brought to design the symbolists' love of linearity, undulating rhythms, glowing colours and richly encrusted accentuation, as well as their penchant for mysticism, allusion and psychological tension. Third, the need was strong for a new style, not assembled in bits from historic revivals (by then as stifling as academic classicism had been) but totally modern.

Many *art nouveau* designers, however, took their points of departure from previous nonimitative styles such as rococo, baroque or even Biedermeier, hoping to re-establish the broken chain of western creativity. Despite this tribute to history a fresh spirit was supported by insurgent art periodicals. In London *The Studio* began in 1893; similar magazines followed in New York, Chicago, Vienna, Brussels, Paris, Berlin, Munich, Dresden, Darmstadt, Stuttgart, Amsterdam, Rome and Milan. *Art nouveau* typography and ornament spread far into commercial graphic arts. When not abstractly expressive, *art nouveau* ornament in all fields was often floral. The first and best master of this vein was Émile Gallé (1846–1904) of Nancy, who designed widely influential glass and furniture. An American, Louis C. Tiffany (1848–1933), was the one glass designer and decorator of the 1890s comparably original. Parisian modern designers were the most elegant; three exhibition centres served them, the earliest, founded in 1895, was S. Bing's shop, l'Art Nouveau, which gave the style its name. Bing's first designer was Henry van de Velde (1863–1957), a Belgian who soon thereafter pioneered modern design in Germany. Van de Velde's impetus was derived from the Brussels architect who initiated *art nouveau,* developing it with sudden, peerless genius, Baron Victor Horta (1861–1947). In 1892 Horta designed a residence for Émile Tassel, first of a series of town houses large and small that in fittings, furnishings and structure were rational and unprecedented; they were unified by sinuous linear networks and warm, rich colours. Nothing in France or Germany, where the style took root almost at once, or in Spain before 1900, surpassed the Brussels originals.

The speed and vitality with which *art nouveau* spread demonstrated that the 20th century would be ushered in with what had not been seen for a century—modern design intrinsically free of retrospection. Its principles were those formulated in the 1840s by Pugin; now they found shapes unmistakably independent and apposite.

DESIGN, 20TH-CENTURY. Design in the west during the 20th century has been subject to the social trends that dominated the 19th century: democratization, industrialization and governmental responsibility for education and social security. The year 1900 was the apogee of *art nouveau* (*q.v.*), an original style of design that lately had succeeded, for the first time since the rococo, in uniting progressive efforts in all the applied visual arts. The Exposition Universelle, Paris, 1900, revealed a new growth of modernism arising amid the mass of decadent historic-revival styles. In Barcelona Antonio Gaudí (1852–1926) created buildings and furnishings of unparalleled inventive freedom. Yet, before World War I, *art nouveau* flowered and wilted, weakened by its attachment to the fine arts, then deep in emotional *symbolisme*. The arts and crafts movement (*q.v.*), an older design trend, survived better, purified of medievalisms, invigorated by an augmented interest in folk arts of all eras and areas.

Unlike *art nouveau*, the arts and crafts movement repudiated industrialization; yet the first systematic program of design in industry was initiated in 1907 in Germany by men whose ideals and plans were directly derived from those of the English arts and crafts guilds. Peter Behrens (1868–1940), self-taught artist-designer-architect, was a principal figure in two enterprises begun that year: the entire design program of the German electrical trust—products, advertising, buildings—was placed under his guidance; simultaneously he helped found the Deutscher Werkbund, an association of designers, manufacturers, educators and government officials dedicated to raising design standards especially in low-cost consumer goods. The Werkbund also upheld professional ethics and education. Both these enterprises flourished, becoming models for similar efforts all over the world in succeeding decades. Before World War I the failure of *art nouveau* invited a resurgence of classically correct revival styles. The conditions of modern design, furthermore, were profoundly altered by scientific management, mass production and the revolution in psychiatry.

World War I and After.—The decade of World War I saw two tendencies rise in design: functionalism, that borrowed forms and materials from machine shop and scientific laboratory, and expressionism, that attempted to exteriorize the new insights into subconscious and emotive depths. In the postwar chaos and economic stringencies of Europe, functionalism offered hope of broad improvements in everyday life. Expressionism gradually receded from industrial design and architecture to handicrafts, fine arts and theatre. In design, expressionism and functionalism started as equals, repeating the earlier polarity of *art nouveau* and the arts and crafts movement; as before, rival modern trends had to fight shoulder to shoulder against established historic-revival styles.

The Bauhaus (*q.v.*), a German school for all the arts founded in 1919 by Walter Gropius (1883–), became the symbol of functionalist design, despite the presence of important expressionist talents on its faculty. Its curriculums—notably a preliminary course evolved from kindergarten practices and the use of handicrafts as training grounds for industrial designing—exerted wide, lasting influence on design education, particularly in the United States where several Bauhaus members, migrating under Nazi pressure, established schools or found posts at Harvard, Yale, the Massachusetts Institute of Technology and the Illinois Institute of Technology. Bauhaus graduates spread its ideas widely and designers trained at its American daughter-schools influenced design education and industry.

International decorative arts were exhibited in 1925 at Paris; there was a spate of expressionism, overornamented, trivially neo-Cubist, but well received commercially, particularly in the United States, where a classical-colonial revival had dominated since the 1890s. Progressive observers everywhere were alarmed; at the exposition itself a pavilion of protest was built and furnished by the architect Le Corbusier (Charles Édouard Jeanneret, 1887–) and his colleagues. The furnishings were either architectural miniatures (cabinets and tables) or plain, artless chairs and small articles, modern industrial "folk" art. The lack of forceful modern product design was clear. Two years later a very different international exposition opened in Stuttgart. Under the direction of Ludwig Mies van der Rohe (1886–), a new residential section was laid out on a hill crest, with modern houses and flats fully furnished, designed by leading European modern architects. Furniture had advanced well beyond the Paris showing: expressionism and ornament hardly appeared; an image of modern living began to emerge. Interiors by Mies, Le Corbusier, Gropius, Marcel Breuer (1902–) and their associates in 1929–30 mark the fulfillment of functionalist design. The Netherlands, Scandinavia, England, Italy, Spain and the United States soon followed the lead. Expressionism was subdued, and some earlier modern mannerisms were eliminated. As Adolf Loos (1870–1933), Viennese critic-architect, had predicted for 30 years, ornament became taboo. Handmade surfaces, admired since Ruskin's day, looked artificial. The artiness of *art nouveau* was put aside. Art historians wrote about the influence of 20th-century painters and sculptors over designers, but more significantly there were common enthusiasms—structural engineering, primitive and folk arts —that influenced artists and designers simultaneously.

In the United States, industry, in search of new ways to reach consumers during the Great Depression of the 1930s, turned to modern designers at hand; they were unexpectedly successful. In a few years a new, often crudely handled, but sometimes effective style was born, "streamlining."

Based on engineering studies to reduce friction on bodies moving in liquids or in air, the admired forms were bulbous, sleek, tapered, with easy transitions between parts. Such forms were used frequently for quite static objects, particularly protective shells over machinery. Ornament appeared as bright striping, often grouped in threes. Streamlining existed without benefit of the ethical ideals inherited by functionalist design from the arts and crafts movement, and many thoughtful people deplored it. Yet the popular image of an age of speed had found its embodiment, and with inevitable adaptations streamlining survived and grew, bringing big-business practices and sleek, impersonal design, initiated by Behrens, into wide use. Kitchens, bathrooms and motor vehicles were most affected. Streamlining pioneers included Walter Dorwin Teague (1883–), Norman Bel Geddes (1893–1958), Raymond Loewy (1893–) and Henry Dreyfuss (1904–), men whose later works have often been acclaimed.

In Europe of the 1930s other challenges to functionalist design arose. In richly forested Scandinavia, wood was emphasized. Simple country-house furnishings of the early 19th century were restyled without ornament, scaled for modern rooms and modified to suit modern ideas of comfort; light furniture was made of birch, beech, ash and oak rather than conventional mahogany, walnut or maple. As "Swedish modern" this mild effort was widely accepted in the United States. The Finnish Alvar Aalto (1898–) produced rational furniture in bent plywood, and Bruno Mathsson (1907–) in Sweden, a manufacturer-designer, used Michael Thonet's century-old techniques for bent-frame, strap-seated chairs, forthrightly modern. The chief Bauhaus furniture designer, Breuer, and Le Corbusier's furniture assistant, Charlotte Perriand (1903–), both designed for wood in pliable and solid forms. Functionalist metal furniture continued, a special rather than a leading style; most dinette and porch furniture, commercially important in the United States, was made of metal.

Influenced by the Bauhaus and the Werkbund, Germany in the 1930s produced clear, logical examples of modern design in metalwares, china, lighting fixtures and wallpapers. Later, Scandinavian sources enriched the repertory with excellent decorative and table glassware, textiles of all kinds and peasant basketry. Particularly for homes, the emphasis on machine-finished and technologically sophisticated materials—chromed tubes, Bakelite, etc.

—was relaxed; many craft effects reappeared before the end of the 1930s.

World War II and After.—World War II effectively terminated the design of the 1930s. The creative designers of earlier decades were conspicuously inactive, though some continued with brilliant success as architects. The tone of design changed. Functionalism seemed inadequate; feelings as well as reason demanded expression. Curvilinear, richly detailed, interestingly textured design gradually returned; even *art nouveau,* once spurned, could again be enjoyed and studied.

Just before the war Eero Saarinen (1910–1961) and Charles Eames (1907–), young American architects, had jointly experimented with molded plywood shells for seating. In 1946 the Museum of Modern Art in New York city exhibited Eames's much refined furniture. His plywood chair became a classic. followed soon after (1948) by Saarinen's spacious armchair, upholstered over sheet plastic, which long remained the best modern comfortable chair. Eames produced other brilliant and influential chairs and toys; Saarinen too continued as a furniture designer. In both, a strnng technological interest indicated the heritage of functionalism. but the forms and taste were fresh. These two men changed the basic elements of chair design; with a few others they placed the United States. for the first time, in the forefront of progressive design. American industrial designers shared in this international recognition. American automobile design, challenged from all sides. continued the streamlined trend; alone in modern design at mid-century it featured heavy ornamentation, though by the 1960s it, too. was beginning to reflect the contemporary taste for purity. Industrial design merged into architecture as more building elements were factory finished, like curtain-wall panels and illuminated ceilings. Technological progress affected design directly, as in foam cushioning. 1936; plastic films, filaments and forms, *e.g.,* polyethylene containers, 1945; melamine dinnerware, 1947, and chair shells, perfected by Eames, 1919; and, in 1959, Pyroceram and fluorescent lamp improvements.

Three European countries led design after World War II. Italy was prodigal with effective specialties and displays, particularly at the Milan triennial exhibitions. which consistently presented advanced European designs. Finland began to export glass, earthenware and other products of remarkable subtlety and perfection by a host of designers. chief among them Kaj Franck (1911–) and Tapio Wirkkala (1915–). Denmark, noted early in the century for handmade silver and underglaze-painted porcelain. in the later 1940s spurted into exceptional design activity that won world recognition. In furniture, Finn Juhl (1912–), Hans Wegner (1914–) and Arne Jacobsen (1902–) mere'but three of a long, distinguished roster of designers; Juhl in particular led an antifunctionalist reaction. Typical Danish innovations in modern furniture were teakwood and matte finishes (shiny varnishes had been standard). The Danes were as profuse and skilled in silver, steel, ceramics, textiles and plastics as in wood; outstanding metal designers were Kay Bojesen (1886–1958j and Magnus Stephensen (1903–).

DESLANDRES, HENRI ALEXANDRE (1853–1948), French physicist and astrophysicist, noted for his contributions to spectroscopy and solar physics, was born in Paris on July 24, 1853. Deslandres' research on band spectra (1886–91) proved the structural identity of the various bands emitted by a molecule under given conditions and showed that the wave numbers of individual band heads are—like those of individual lines in a band—nearly in arithmetical progression; he derived a general formula for the wave numbers and inferred the presence of harmonic oscillations.

In 1891 Deslandres and G. E. Hale independently discovered the reversal of the calcium H and K lines on the solar disk and Deslandres invented the *spectro-enregistreur des vitesses* or velocity recorder, an instrument related to the spectroheliograph (*q.v.*). In 1908 he became director of Meudon observatory. where he obtained a long series of excellent spectroheliograms and velocity records. These were used to study the *plages faculaires* and dark filaments, which Deslandres identified as prominences projected on the solar disk, and led to a general picture of the circulation of material at various levels through the sunspot cycle.

Deslandres was elected to the French Académie des Sciences in 1902 and received the gold medal of the Royal Astronomical society in 1913 He was appointed director of the Paris observatory in 1927 He died in Paris on Jan. 15. 1948. (B E J P)

DESMAN, a common name for two species of aquatic insectivores related to the moles *Desmana moschata* (16 in. overall) from southeastern Russia and western Siberia; and *Galemys pyrenaicus* (11 in. over-all) from the Iberian peninsula and the Pyrenees. They have a long snout. no external ears, webbed hind feet and a scaly tail that is flattened at the sides in the larger species The dense fur is dark brown above. light below *See* also INSECTIVORE (L H. M)

DESMAREST, NICOLAS (1725–1815). French geologist who presented the first clear proofs that valleys have been eroded by the streams that flon through them. nas born at Soulaines in the *département* of Xube. on Sept 16. 1725. He nas educated at Oratorian colleges in Troyes and Paris. In 1788 he was appointed inspector general and director of manufactures for France; in 1792 he nas imprisoned but later was recalled to government service. In 1775 he had presented a memoir on the effects of neathering and stream erosion on volcanoes and lava flons, but delayed publication until 1806. Desmarest also prepared a work on physical geography, including much geology, as part of the *Encyclopédie Méthodique* Although it filled four large volumes, this work had progressed only to the letter *N* at the time of his death in Paris, on Sept 28. 1815. (M A F.: C L. FE)

DESMARETS, NICOLAS, SIEUR DE MAILLEBOIS (1648–1721). French minister of finance at the end of Louis XIV's reign. was born in Paris on Sept 10. 1648. A nephew of J B Colbert (q v), he rose rapidly in the financial administration but fell into disgrace on Colbert's death in connection with a scandal over the illicit fabrication of four-sol pieces. Allowed to return to Paris, in 1686, he provided the controllers-general of finance over the next ten years with a remarkable series of memoranda exposing the desperate economic situation of France. Having worked under Michel Chamillart (*q.v.*) from 1699, he succeeded him as controller-general in Feb 1708. during a critical phase of the War of the Spanish Succession. The financial situation was grave; expenses to be met in that year were far in excess of the normal revenue, most of which in any case, together with a large part of that for following years, had already been assigned in advance to secure loans. Desmarets began canceling the assignments on the revenue for 1708 and postponing redemption of the loans till a later date This bold step, which might have been taken for defaulting, paradoxically inspired confidence, and he nas able to raise new loans (at heavy interest). In 1709, when famine still further reduced the ordinary revenue from taxation. he suspended all payments from the Caisse des Emprunts (which had originally attracted investors by offering very high rates of interest on deposits that could be withdrawn at will); and subsequently he converted the deposits into bonds redeemable at various dates and nith a loner rate of interest, which in turn he finally changed into perpetual annuities at 1% He was careful to treat the obligstions sponsored by himself more punctiliously than he did those undertaken by his predecessors. Other expedients were a royal lottery; devaluation and then recall of the metal currency (this was too extreme, and foreign powers profited by offering better prices than the French treasury for coin); state borrowing of precious metals to restore the circulation of coin (as opposed to the note currency of assignments on public funds); and in Oct. 1710 an income tax of one-tenth (based on Vauban's proposals in his *Dîme royale* of 1707). which however the privileged classes contrived to avoid His efforts saw France through the war, though in 1715 he had to recommend that the state should declare itself bankrupt. After

Louis XIV's death. Desmarets was dismissed by the regent duc d'Orléans, though he had proved himself France's greatest finance minister since Colbert. He died in Paris on May 4, 1721.

DESMARETS DE SAINT-SORLIN, JEAN (1595–1676), French writer and first chancellor of the Académie Française, who opened the long literary battle against the ancients on behalf of the moderns with *La Comparaison de la langue et de la poésie française avec la grecque et la latine* (1670). He was born in Paris in 1595. A romance, *Ariane* (1632), gained him admission to fashionable literary circles. and under the patronage of Richelieu he wrote numerous plays, the best being *Les Visionaires* (1637), and received political preferment. After 1645 his growing religious intolerance was directed particularly against the Jansenists. The long heroic poem *Clovis* (1657) and *Les Délices de l'esprit* (1658) both emphasize the Christian basis of his opposition to the ancients. He died in Paris, Oct. 28, 1676.

DES MOINES, the capital of Iowa, U.S., and seat of Polk county, is located in the south-central part. of the state along both banks of the Des Moines river in the heart of the corn belt and surrounded by coal fields.

The first settlement in the area was the establishment of a military garrison (Ft. Des Moines) in 1843 at the strategic juncture of the Raccoon and Des Moines rivers to protect the rights of the Sauk and Fox Indians. In the same year, however, the area was opened to white settlers, and by 1851, with nearly 500 inhabitants, Des Moines was incorporated as a town.

There is much controversy over the origin of the name of the Des Moines river for which the city is named. One explanation is that the original French name! *la rivière dcs moines,* meant the river of the monks, who lived along its banks. Another theory is that it is a derivation of the French *de moyen* ("middle"). inasmuch as the river is midway between the Mississippi and Missouri rivers. Probably the best explanation, however, is that it is a French corruption of the name of an Indian tribe, the *Moingona* or *Moingwena* (a name of uncertain origin), whose village, located on the river. was shown on Jacques Marquette's map of the region.

When the state capital was moved there from Iowa City in 1857, Des Lfoines was chartered as a city and its growth was assured. In 1854, the state capitol building was completed in a park of 80 ac. in east Des Moines. With its gold-gilded central dome, the capitol is an imposing example of the revived classical Roman style of 19th century architecture. Nearby are located the State Historical, Memorial and Art building, and state library. Des Moines was one of the first cities in the U.S. to plan a city development program that took advantage of its natural setting. Along the river front. a civic centre was created in 1924 with the city hall, municipal courthouse, federal building. post office and city library. Along Grand avenue, a wide tree-lined street, great mansions were built in the late 19th century. Of particular interest is Terrace Hill! the Hubbell family home, one of the finest examples of the French mansard roof style of architecture still extant in the U.S.

In the first 50 years after its founding, Des Moines grew to be first in size of Iowa cities. Its most rapid period of growth was in the ten-year period from 1910 to 1920. due in part to the development of the rich coal areas nearby. Pop. (1960) 208.982; standard metropolitan statistical area (Polk county), 266.315. (For comparative population figures *see* table in IOWA: *Population.*) Des Moines, an important communication centre, also has major commercial, wholesale and manufacturing importance. Products include meats, clothing. brick and tile, aircraft parts and farm machinery. Many insurance companies established' their horne offices in the city. Des Moines is also an important publication centre for periodicals, especially farm journals.

In 1907 Des Moines pioneered in the reform of municipal government with the adoption of the commission form of government. This was superseded in 1950 by the council-manager plan.

In the field of higher education, there are Grand View Junior college (Lutheran, founded 1896) and Drake university. a privately endowed institution founded in 1881 and related to the Disciples of Christ. The university, which has eight colleges and a graduate division, co-operates nith the city in the operation of an observatory and a symphony orchestra. The Drake Relays. founded in 1910. is one of the major U.S. track and field meets The Des Moines Art centre. designed by Gottlieb Eliel Saarinen. located in Greennood park. was opened in 1948; in addition to providing a gallery. it conducts a school for training in art and crafts.

Other recreation and educational centres are the Veterans auditorium, KRNT theatre, the largest legitimate theatre in the U.S., and the Iowa State Fair grounds. The Des Moines park system. comprising over 1,400 ac., was one of the first to provide a municipally owned golf course (begun in 1894, the course was opened to the public in 1901). Ft. Des Moines, adjoining the city on the south, was re-established as a cavalry post in 1900. In World War II it became the first training centre for the women's army corps, and Iater was converted into a veterans' housing centre. Walnut Woods State park is nearby. (J. F. WA.)

DES MOINES RIVER, the longest stream in Iowa. U.S., and an important western tributary of the Mississippi, rises in the southwestern part of Minnesota, near the town of Pipestone. From its source the river flows 535 mi. in a sgutheasterly direction until it eventually joins the Mississippi two miles south of Keokuk, Ia. Above Humboldt. in central 1011a. the river is known as the West Fork. The East Fork and the Raccoon river are the two principal tributaries. For a distance of 25 mi. above its mouth the river serves as the boundary between Iowa and Missouri.

From its source to its mouth the river falls a total of 1.375 ft., or about 2.6 ft. per mi.; this rate is nearly constant throughout its entire course. The Des Moines drains an area of 15.807 sq.mi. of rich, glaciated farm land. Floods are common and the damage inflicted upon the cities and countryside of the loner valley is often widespread. At Keosauqua, Ia., 45 mi. above the mouth of the Des Moines, the average discharge is 5.359 cu.ft. per second. During June a maximum of 42.900 cu.ft. per second is reached; in the latter part of September the river ceases to flow for a short time. For the origin of its name, *see* DES MOINES.

The first attempt to use the Des Moines river for navigation came in 1837, and from that time until the close of the American Civil War the river was the main artery of commerce for central Iowa. The city of Des Moines was the main upper terminus for river steamers, although some boats regularly navigated as far north as Fort Dodge. A complete decline in river traffic came with the widespread development of railroads. The river was early utilized for power. Although none survive, a total of 80 mills for grinding grain were built along its banks between 1840 and 1890.

The major cities along the banks of the Des Moines river include Des Moines, Fort Dodge. Ottumwa and Estherville. The river is an important source of water for these cities (R R D)

DESMOND. GERALD FITZGERALD. 14TH EARL OF (c. 1538–1583). Irish leader, known sometimes as the "rebel earl" because of his opposition to the government of Elizabeth I. was the son of James FitzJohn, 13th earl, by his second wife Mor O'Carroll. In 1550 Gerald married Joan, heiress of James (d. 1529). 10th earl. She had previously married James Butler (d. 1546). 9th earl of Ormonde, and Sir Francis Bryan (d. 1550), lord justice. and was mother of Thomas. 10th earl of Ormonde, who in consequence was a claimant to the Desmond inheritance. Gerald succeeded his father as earl of Desmond in Oct. 1558. His neutral attitude toward the reformation legislation in the Dublin parliament of 1560 led to suspicion of hostility toward the government and he was believed to have been involved in an offer of the kingdom of Ireland to Philip II of Spain. Ormonde's return to Ireland in 1554 revived the rivalry between Butlers and FitzGeralds, particularly over the border areas of east Waterford and southwest

Tipperary. Both earls were summoned to London, where Desmond's manner provoked the queen, and he was briefly imprisoned. He was alloned to return to Ireland in 1562 and undertook to enforce the reformation legislation in Munster. The death of his wife (Jan 1565) who had failed to give him an heir, was followed by an open conflict with Ormonde in which Desmond was wounded and captured at Affane early in 1565. Ormonde's representation of this as an action on behalf of the government was not admitted by the queen, but her partiality for Ormonde and prejudice against Desmond caused anxiety to Sir Henry Sidney, the lord deputy.

After a further imprisonment in London. Desmond, fearing charges of treason, surrendered his estates to the queen and was conditionally restored after substantial damages had been awarded to Ormonde. Early in 1566, Desmond married Eleanor Butler. daughter of Lord Dunboyne. After attempting to exercise jurisdiction over lands possessed by Ormonde in southwest Tipperary. he was arrested (1567) and remained in custody for six years. North Kerry. County Limerick and east Cork were experimentally entrusted to a commission including Desmond's more capable brother Sir John FitzGerald, but later Sir John too was arrested and sent with Desmond to the Tomer of London. During Desmond's imprisonment, his cousin James (Fitzmaurice) FitzGerald (q v.) launched a rebellion against the English, but came to terms (Feb 1573) shortly before the earl's release.

After his return to Ireland Desmond resented the imposition by the Irish government of stringent regulations which substantially added to the conditions he had agreed to with the queen. He entered in July 1574 into a "combination" nith other southern Geraldines to resist Lord Deputy FitzWilliam but again submitted and was pardoned in October. In the meantime he made a trust deed for his family which was subsequently regarded as a precaution taken in case he should be driven into rebellion Fitzmaurice left Ireland in 1575 but the situation deteriorated under Sir William Drury whose iron rule and wholesale executions exasperated Desmond. The return of Fitzmaurice. in July 1579. with a small force of Italians and Spaniards, and a papal commissary, Nicholas Sanders, was not at first supported by Desmond. But after Fitzmaurice's death (1579), Sanders induced him to take up the position of general of the papal army. For some time he had attempted to keep in with both sides but he was proclaimed a traitor in Nov. 1579. although the evidence of his complicity did not emerge until later.

Desmond had no military ability and depended upon his prestige in Munster and upon the hope of substantial reinforcement from the continent. He appealed to many Irish lords to join in the defense of "our Catholic faith against Englishmen a-hich had overun our country." The papal army was defeated by Lord Grey de Wilton, but his savagery in suppressing the rebellion led to his recall and the conduct of the war was entrusted to Ormonde who ultimately defeated Desmond's forces piecemeal. The earl was killed on Nov. 11, 1583, in a minor affray in Kerry. (R. D. Es)

DESMOND (*Des-muma,* "south Munster"), an ancient territorial division of Ireland approximating to the counties of Kerry and Cork. In the 11th century the expansion of the O'Briens in Thomond (Tuadmuma, "north Munster") led to the occupation of Desmond by the Mac Carthaigh (Mac Carthies) of Cashel. After the Anglo-Norman invasion, and until the 17th century, it is necessary to distinguish two areas described as Desmond. Gaelic Desmond was divided among families like the Mac Carthies, O'Sullivans, O'Donoghues, O'Driscolls, O'Mahonies, O'Keeffes and O'Callaghans. It extended over the modern County Kerry south of the river Maine, and over the modern County Cork west and north of that city but excluding a western coastal strip between that city and Bandon. This is the area usually described as Desmond in 16th-century Anglo-Irish records. Anglo-Norman Desmond, including the liberty of Kerry and the lordship of the Decies. extended over north Kerry from the river Maine, over most of the modern county of Limerick, southwest Tipperary, east and south County Cork and east Waterford.

Maurice FitzGerald was created 1st earl of Desmond by Ednard III in 1329. His descendants had acquired enormous powers and a large measure of independence by mid-15th century. After Thomas, 7th earl, had been executed by order of Edward IV's viceroy in 1468 his successors practically withdrew all allegiance to the kings of England. The Desmond earls maintained a semi-regal state and. early in the reign of Henry VIII, negotiated directly with the emperor Charles V and the French king Francis I. However, after the destruction of the Kildare FitzGeralds (1537), later Desmonds handicapped by domestic succession disputes, gave nominal recognition to English royal authority. James, 13th earl, accepted the Tudor rule from 1540 but feared the expansion of the Butlers of Ormonde who, through marriage, claimed the Desmond territory. His successor, Gerald *(see* DESMOND GERALD FITZGERALD), lost his life and lordship in 1583 after he had become involved in the rebellion of his cousin James (FitzMaurice) FitzGerald (*q.v.*) against Elizabeth I. An act of the Irish parliament in 1586 declared the FitzGerald lordship of Desmond forfeited, but grants of the title of earl nere made to the 14th earl's son James (d. 1601) in 1600 and to Richard Preston, Lord Dingwall (d. 1628), in 1619. After 1675 the title was held in conjunction with the earldom of Denbigh. (R. D. Es.)

DESMOULINS, CAMILLE (1760–1794), one of the greatest and most influential pamphleteers and journalists of the French Revolution, was born on March 2, 1760, at Guise, in Picardy, where his father was lieutenant-general of the *bailliage.* On completing his studies aith distinction at the Collège Louis-le-Grand in Paris (a here Robespierre was his contemporary), Desmoulins planned to become a lawyer and was called to the bar in March 1785, but his stammer made this choice unfortunate. The opening of the estates-general in 1789, however, roused him to enthusiasm and he went to match its sessions at Versailles.

On July 12, 1789 when Louis XVI's dismissal of Jacques Necker became known in Paris, Desmoulins, with a green leaf in his hat to symbolize hope, delivered an impromptu speech to the crowd in the Palais-Royal and was the only orator there to make an impression After the storming of the Bastille, he issued a pamphlet. *La France libre,* summing up the main charges against the *ancien régime.* During the September crisis, when the king refused to sanction the Declaration of the Rights of Man and the Citizen and the decrees of Aug. 4, Desmoulins issued another pamphlet, *Discours de la lanterne aux Parisiens*, supposedly giving the views of the streetlamp in the Place de Grève. on which several people had been summarily hanged in July. These tno pamphlets established his reputation. He then launched a paper, *Révolutions de France et de Brabant* (86 nos, Nov. 1789–July 1791), in nhich his lively style and his ready attacks on everyone who seemed to him to be deviating from the common cause did much to advance the Revolution. He lost heart. honever, after Louis XVI's flight to Varennes (June 21, 1791) and the massacre on the Champ-de-Mars (July 17, 1791) and said farewell to his readers in his paper's 66th issue. On July 22. 1791, the arrest of Desmoulins was ordered together nith that of other patriots, and he had to go into hiding until the Assembly granted an amnesty on the voting of the new constitution (September). It mas during this period, as a member of the Cordeliers club, that he had formed his close association nith Georges Danton (*q.v.*).

In the early days of the Legislative Assembly, Desmoulins attended the Jacobin club, where on Oct 21, 1791, he delivered his *Discours sur la situation politique de la nation,* violently attacking the new constitution as based on a property qualification for electoral rights. On the great question of war or peace, he supported Robespierre for a time against Brissot's war policy. This period of his career, however. is chiefly important for his break with the future Girondins. At the beginning of 1792 he posted up in Paris a counsel's opinion signed by himself, contesting the right of the correctional tribunal to imprison two people condemned for keeping a gaming house. Thereupon he was violently attacked in Brissot's paper *Le Patriote français.* Holding Brissot himself responsible for this attack. he answered him with an angry pamphlet, *Jean-Pierre Brissot démasqué.*

On July 24, 1792. Desmoulins delivered his *Discours sur la situation de la capitale,* before the general council of the Paris Commune. In this he denounced the distinction made by the constitution between "active" and "passive" citizens in qualification

for the vote; foretold the overthrow of the monarchy; and demanded precautionary measures against court intrigue and foreign invasion His actual role in the overthrow of the monarchy (Aug. 10) is hard to assess. but on Aug. 12 he became secretary-general to the ministry of justice, under Danton. In September he was elected to the Convention as a deputy for Paris. During the trial of Louis XVI he published his condemnatory *Opinion. . . sur le jugement de Louis XVI* and voted for the death sentence without reprieve.

In 1793 at the height of the struggle between the Girondins and the Mountain. Desmoulins wrote his *Histoire des Brissotins* as a pamphlet against the former; and on the overthrow of the Girondins (May 31) it was he who composed the Jacobin club's explanation to the *départements* about what had happened. In October, however, nhen the Revolutionary tribunal sentenced the Girondins, he sadly blamed himself and his *Brissot démasqué* for their deaths.

When the Mountain began to split into factions, Desmoulins sided nith Danton and the "Indulgents" or moderates against Hébert and the "Exagérés." In the first two numbers of his new paper. *Le Vieux Cordelier* (6 nos.. Dec. 5–30. 1793) he attacked those responsible for the policy of dechristianization (specifically P G. Chaumette and Xnacharsis Cloots). Robespierre tacitly approved of this attack. but in the third number (Dec 15) Desmoulins criticized the law of the suspects and the policy of the Terror and in the fifth he attacked Hébert and his friends openly. Robespierre. seeing how the factional dispute might upset the Revolutionary government, now called on Desmoulins to explain himself to the Jacobins. proposed the burning of the paper and frankly condemned his conduct (Jan. 7–8. 1794), but still saved him from expulsion from the club. Desmoulins was expelled. however, from the Cordeliers. This was the end of his political career. Then, in March. a few days after striking the Hébertists down, the government struck finally at the "Indulgents." In the night of March 29–30. Danton, Desmoulins and their friends were arrested. Sentenced by the Revolutionary tribunal. they were guillotined on April 5, 1794. Eight days later. on April 13, Desmoulin's widow, née Lucile Duplessis. whom he had married in Dec. 1790 and dearly loved, nas likewise executed — nith Hébert's widow and Chaumette.

There is a critical edition of *Le Vieux Cordelier* by A. Mathiez and H Calvet (1936).

See G. Claretie, *Camille Desnzoulins, Lucile Desmoulins (1875).*

(A So)

DESNOYERS, AUGUSTE GASPARD LOUIS BOUCHER, BARON (1779–1857), French engraver. was born in Paris on Dec. 19, 1779. He studied engraving under Louis Dareis and drawing in the atelier of Lethière. After visiting Italy he entered the studio of Alexandre Tardieu in 1800 and became one of the most eminent line engravers of his time. His fame was established in 1805 by an engraving after Raphael. whereupon Napoleon I commissioned him to reproduce his full-length portrait in coronation robes by Gerard. He became a member of the Institute (1816) and engraver to the king (1825). He is accredited with 75 plates. He died in Paris on Feb. 16. 1857.

DE SOTO, HERNANDO (FERNANDO) (1496?–1542), Spanish explorer of southeastern United States and discoverer of the Mississippi river, mas born at Jeréz de los Caballeros. Estremadura, Spain. He became the protégé of Pedrarias Dávila and accompanied him to Central America in 1519 In 1532 he joined Francisco Pizarro in Peru, aided in capturing the Inca king, Atahualpa, and led the way to the Inca capital, Cuzco *(See* PERU: *History*) He then retired to Spain but in 1536. inspired by the reports of Cabeza de Vaca, he secured permission from Charles V to conquer Florida, then a vast undefined region in North America. As *adelantado* of Florida and governor of Cuba, De Soto left San Lucar in April. 1538. His greatest achievement was his exploration of the southeastern part of the present United States.

Sailing from Havana, May 18, 1539. with nine vessels and a force. besides sailors. of over 500 men and more than 200 horses, he reached Tampa Bay, on May 25. Exploring the interior northwest he wintered in the Tallahassee area and left in March traveling northeast to the Indian town, Cofitachequi, near Silver Bluff, or possibly, Columbia, S.C. Carrying a treasure in pearls, De Soto moved northwest. east of the Savannah river, into the area that later became North Carolina. Turning west, the Spaniards reached the Coosa Indians in what is now Talladega county, Ala. Below, in Chief Tuscaloosa's territory. they turned west and crossed the Alabama river near modern Camden. In the northern part of what is now Clark county, De Soto fought his memorable battle at Mabila, the location of which remains unidentified. Forgoing contact nith Cuba, De Soto marched northwest between the Tombigbee and Alabama rivers and entered the area that later became the state of Mississippi near Columbus. In Pontotoc county. or near Tupelo, the expedition established winter quarters. Modern authorities believe the Spaniards discovered the Mississippi river, June 18, 1541. in the southern part of what is now Tunica county. Miss. Crossing the great river into modern Arkansas, the explorers circled north and east above the mouth of the St. Francis river. whence they marched southwest to the White river and along it to the White-Arkansas delta. Moving up the Arkansas to the vicinity of modern Little Rock, the Spaniards crossed over the Ouachita river, and far down that stream wintered near Camden, Ark. Early in March, the expedition followed the Ouachita to a point near modern Ferriday. La.. where De Soto died, May 21, 1542, and was buried in the Mississippi.

Luis de Moscoso now led the expedition overland to reach Mexico. Honever, after crossing the Red river near modern Shreveport. La., he possibly reached only the Trinity river before he returned to the Mississippi near Ferriday. There the Spaniards made boats, floated into the Gulf of Mexico, and coasted westward until they reached Tampico, Sept. 10. 1513. The expedition is significant for giving the first view of Indian cultures from Georgia to Texas and opening southeastern North America to European colonization.

BIBLIOGRAPHY.—The most scholarly tracing of De Soto's route is *Final Report of the United States De Soto Expedition Commission,* 76th Congress, House Document no. 71 (10328) (1939). Directed by John R. Smanton, Smithsonian institution, it includes an extensive bibliography, and rests upon an examination of the terrain and on the De Soto narratives: Elvas, Garcilaso, Bicdma and Rangcl. For Elvas, *see* James Alexander Robertson, *True Relation of the Hardships Suffered by Governor Fernando de Soto . . . by a Gentleman of Elvas,* 2 vol. (1933). For Garcilaso, *see* John G. Varner and Jeanette J. Varner, *The Florida of the Inca (1951).* For Rangel and Biedma, *see* Edward Gaylord Bourne, *Narratives of the Career of Hernando de Soto,* 2 vol. (1904). The best biography of De Soto is Theodore Maynard, *De Soto and the Conquistadores* (1930). (A. B. T.)

DESPARD, EDWARD MARCUS (1751–1803), Irish soldier, who organized a large-scale conspiracy against the British government in 1803, was born in Queen's county. Ire., in 1751. He entered the British army in 1766 and was stationed at Jamaica. He was promoted captain after the San Juan expedition of 1779; at his trial Nelson testified to his bravery on that occasion. Despard was made governor of Roatan in 1781, and soon afterward of the Mosquito shore and Bay of Honduras. He led a successful expedition against the Spanish possessions on the Black river in 1782. Despard took over the administration of Yucatan in 1784. In his six years' rule he supported the claims of new immigrants against the old settlers, and on the complaints of the latter group he was recalled in 1790. The charges against him were dismissed in 1792, but he was given no further employment. He was imprisoned from 1798 to 1800 on no specific charge. probably as a result of his persistent demands for employment or compensation. It has however been suggested that he was involved in the Irish rebellion. On his release he began to organize a conspiracy. in which he hoped to combine a mutiny in the army with a rising by the London mob, and to assassinate George III and capture the Tower of London and the Bank of England. This overambitious plot was soon revealed to the government, and Despard, with six of his fellow conspirators, was convicted of high treason in 1803. He was executed at Newington jail on Feb. 21, 1803.

See Sir Charles Oman, *The Unfortunate Colonel Despard (1922).*

DESPENSER, the name. probably derived from the office of *dispensator* (steward) to the earls or constables of Chester. of an English family, two of whose members achieved notoriety during the reign of Edward II.

HUGH LE DESPENSER (*c* 1223–65) was a prominent member of the baronial opposition to Henry III from 1258 to 1265 He was one of the 12 baronial nominees on the council of 24 chosen by the 1258 Oxiord parliament to inaugurate reforms The barons nominated him justiciar in 1260 he was removed by the king a year later. but his reinstatement as justiciar and constable of the Tower in 1263 had the assent of both parties He fought at the battle of Lewes in May 1264, and subsequently arbitrated between the king and the barons and in the dispute betueen Simon de Montfort and Gilbert de Clare, earl of Gloucester. Despenser was killed at the battle of Evesham on Aug 4. 1265

HUGH LE DESPENSER (1261–1326) "the elder." son of the justiciar. was summoned to parliament as a baron in 1295 He fought in France and Scotland for Edward I and was sent by him on several embassies including two to the pope. He nas one of the few supporters. in 1308, of Piers Gaveston. Ednard II's favourite; after Gaveston's death in 1312 he became the king's chief adviser until Thomas. earl of Lancaster. leader of the baronial opposition. procured his dismissal from court and council in Feb. 1315. He then norked to further the interests of his son. HUGH LE DESPENSER (d. 1326), "the younger." who had been in the king's household when he was prince of Wales. The younger Hugh was appointed chamberlain in 1318, but both father and son were attacked in parliament by the magnates in 1321 and the king was forced to agree to their disinheritance and exile. The elder Hugh went abroad but the younger remained in the Cinque Ports and engaged in piracy. After the collapse of the opposition at the battle of Boroughbridge (March 1322), the Despensers returned to poner and the elder Hugh was created earl of Winchester. Hugh the younger worked to enhance the importance of the chamber. diverting to it from the exchequer the revenue from certain lands and developing it as a department equipped with its own seal and providing private income for the king. But he was rapacious and grasping. and his administration aroused discontent. He had married (1306) Eleanor, coheiress of Gilbert de Clare, earl of Gloucester (d. 1314). Hugh's attempt to acquire the sole inheritance had been foiled by a division of Clare's estates in 1317; but even so he received lands then worth £1,276 in Glamorgan and Wales At the rebellion of Queen Isabella and Roger Mortimer, both Despensers fled westward with the king. The elder, sent to defend Bristol, surrendered it to Isabella on Oct. 26, and after summary trial was hanged on Oct. 27, 1326. The younger Despenser was captured with the king, tried and hanged at Hereford on Nov. 24. 1326. He left two sons. HUGH (*c*. 1308–49) and EDWARD (d 1342). A younger son of Edward. HENRY LE DESPENSER (C 1341–1406) became bishop of Norwich in 1370. A soldier in early life, Henry was always addicted to warfare. and in the Peasants' Revolt (1381) he effectively suppressed the Norfolk rising, capturing and hanging the rebel leader at North Walsham. Pope Urban VI commissioned him in 1382 to lead a crusade in Flanders against the supporters of Clement VII, the antipope elected by the French cardinals. Although such an abuse of the crusading ideal was denounced by John Wycliffe and the Lollards, the project was favoured in England as victory would have assisted the wool trade; but after capturing several towns, Henry was checked at Ypres and defeated by the French. He was impeached and deprived of his temporalities; but he regained his revenues after two years. Almost alone among his peers, Henry remained faithful to Richard II in 1399, attempting to raise an army in his support. He was subsequently imprisoned for a short while. He died on Aug. 23. 1406.

Henry's elder brother, EDWARD LE DESPENSER (1336–75), fought in the French wars. Edward's son THOMAS LE DESPENSER (1373–1400) achieved prominence through his marriage with Constance, daughter of Edmund Langley. duke of York, and granddaughter of Edward III. He was among the eight who, acting for Richard II, accused Thomas of Woodstock. duke of Gloucester. and the other lords appellant of treason in 1397, and caused their fall. In the pa-rliament of Sept. 1397 Despenser was created earl of Gloucester. and shortly afterward obtained the reversal of the 1321 attainder which had been confirmed in 1326. He deserted Richard II in 1399 but was deprived of his earldom on a charge of complicity in Gloucester's death. He joined in a plot 'against Henry IV but nas seized and executed by a mob at Bristol on Jan. 13. 1400.

The barony of Despenser, called out of abeyance in 1604, was held by the Fanes. earls of Westmorland, from 1626 to 1762: by the notorious Sir Francis Dashwood, friend of John Wilkes and member of the Hell Fire club, from 1763 to 1781; and by the Stapletoni from 1788 to 1891. It was inherited in 1891, through his mother by the 7th Viscount Falmouth, and is now held by his son the 8th viscount.

DES PÉRIERS, BONAVENTURE (*c*. 1500–c. 1544), French writer and humanist, who attained notoriety as a freethinker. He was born at the end of the 15th century, probably at Arnay-le-duc in Burgundy, although both the date and place of his birth are in dispute. In 1533 or 1534 Des Périers visited Lyons, then the most enlightened town of France and a refuge for many liberal scholars. He gave some assistance to Robert Olivetan and Lefèvre d'Étaples in the preparation of the vernacular version of the Old Testament, and to Étienne Dolet in the *Commentarii linguae Latinae.* In 1536 he put himself under the protection of hfarguerite d'Angoulême, queen of Navarre, who made him her *valet-de-chambre.* He acted as the queen's secretary and transcribed the *Heptaméron* for her. It is probable that his duties extended beyond those of a mere copyist and some writers have gone so far as to say that the *Heptaméron* was his work. The free discussions permitted at Marguerite's court encouraged a licence of thought as displeasing to the Calvinists as to the Catholics. This free inquiry became skepticism in Bonaventure's *Cymbalum Mundi* (1537), at which the queen disavowed the author, though she continued to help him privately until 1541. The book consisted of four dialogues in imitation of Lucian. Its allegorical form did not conceal its real meaning and the Sorbonne secured its suppression (*c*. 1538) before it was offered for sale, but the book was reprinted in Paris in the same year. It made many bitter enemies for Des Périers, who prudently left Paris and settled at Lyons. Tradition has it that he killed himself in 1544 by falling on his sword, but this is questionable.

In 1544 his collected works were printed at Lyons. The volume, *Recueil des oeuvres de feu Bonaventure des Périers,* included his poems, the *Traité des quatre vertus cardinales après Sénèque* and a translation of the *Lysis* of Plato. In 1558 appeared at Lyons the 'collection of stories and fables entitled the *Nouvelles récréations et joyeux devis* on which his fame rests. Some of the tales are attributed to the editors, Nicholas Denisot and Jacques Pelletier, but their share is certainly limited to the later ones. The stories are models of simple, direct narration in the vigorous and picturesque French of the 16th century.

BIBLIOGRAPHY.—Des Périer's *Oeuvres françaises* were ed. *by* L. Lacour (1856); *see* also A. Chenevière, *Bonaventure Despériers, sa vie, ses poésies* (1885); P. A. Becker, *Bonaventure des Pe'riers als Dichter und Erzähler* (1924); L. Febvre, *Origène et Des Pe'riers* in *Bibliothèque d'Humanisme et Renaissance,* vol. II (1942).

DESPIAU, CHARLES (1874–1946), French sculptor, mas born at Mont-de-Massan (Landes), Nov. 4, 1874. His heroic "Appollon" stands in front of the Musée d'Art Moderne in Paris. Although associated with Auguste Rodin at the beginning of the 20th century, his style showed a more pronounced influence of classical sculpture. Modeling principally in plaster but sometimes working in stone, Despiau was interested in portrait heads. busts, life-size figures: often nude and usually of classical inspiration. Among his works in bronze are: "Faunesse" (1924), "Eve" (1925), "Dominique" (1926), "Petite Fille de Landes," "Mme. André Derain." "Mme. Othon Friesz," "Assis" (1938). He is noted also for his drawings of nudes. He died on Oct. 30. 1946, at Paris.

DES PLAINES, a city of Cook county. Ill., U.S., on the Des Plaines river, is best known for its greenhouses and for the Methodist summer encampment held there annually since 1860. Originally called Rand, for Socrates Rand. from Massachusetts, who settled there in 1835 and established the first school in his home, it was renamed after the river in 1869 and incorporated as a city in 1925. Explanations of the origin of the designation Des Plaines vary: some attribute it to the French word ior a maple found locally. others to the flat terrain. Early settlers were mainly from the northeast United States. Canada and Great Britain. but the German element soon came to predominate. A rapidly growing suburb of Chicago, Des Plaines is primarily a residential commuting centre and a market garden area (mushrooms are a leading product). Its industries are greenhouses, hothouse plants and equipment and small manufactures, including electrical appliances and radio parts. For comparative population figures *see* table in ILLINOIS: *Population.* (M. Ws.)

DESPOINA, "mistress." the Greek word used from the earliest times as an honorific address to a woman. and also, particularly, to a goddess. In Arcadia, the queen of the underworld was called Despoina. She had had originally no personal name. probably from superstitious fear; and in later times was usually identified with Persephone. (H. W. PA.)

DESPORTES, PHILIPPE (1546–1606). French courtier poet second to Pierre de Ronsard, was born at Chartres in 1546. He modeled his poetry on that of the Italians Petrarch, Ariosto and Bembo, and also on minor poets. About 1567 he became the favourite poet of Henry, duke of Anjou. whom he accompanied to Kracow when Henry was elected king of Poland (1573), returning with him on the death of Charles IX (1574). Desportes' *Premières Oeuvres* (1573) made him Ronsard's rival. In fluid. graceful alexandrines he wrote sonnets and elegies for Henry III and others to present to their mistresses. In 1582 he received the abbeys of Tiron and Josaphat. He enjoyed the revenues of other benefices also and entertained an intellectual circle in a princely manner. His *Dernières Oeuvres* (1583) mark his farewell to secular verse. His translations of the Psalms (1591, 1598, 1603) provoked the brutal *mot* of Malherbe: *Votre potage vaut mieux que vos psaumes* ("Tour soup is better than your psalms"). Desportes died on Oct. j, 1606, at the abbey of Bonport.

Desportes is not a personal poet like Ronsard. His elegant poems, often imitated in England, sound much the same whether addressed to his own mistresses or to those of the great. His poetry never reaches Ronsard's loftiness or variety of inspiration but it avoids obscurity and pedantry. Clear, harmonious and seductively smooth, it prepared the way for the new taste of the 17th century.

BIBLIOGRAPHY.—There were many 16th-century editions of Desportes' works. Later editions include *Oeuvres,* ed. A. Michiels (1858); *Cartels et masquarades; Épitaphes,* ed. V. *E.* Graham (1958). *See* also J. Lavaud, *Un poète* de *cour aux temps des derniers Valois: Philippe Desportes* (1936); *R.* M. Burgess, *Platonism in Desportes* (1954). (M. *G.* M.)

DESPRÉS, JOSQUIN (usually known as JOSQUIN) (c. 1440–1521), Flemish composer whose works mark the transition from the late middle ages to the Renaissance. was the most renowned musical figure of his time. Born at Condé-sur-L'Escaut or elsewhere in the province of Hainaut, he was probably a chorister at the collegiate church of St. Quentin. He was a singer in Milan cathedral from 1459 to 1472, in the service of Duke Galeazzo Maria Sforza in Milan from 1473 to about 1479 and later in the papal chapel (1486–c. 1494). Between his service in the papal chapel and 1503, when he became choirmaster of the chapel of Ercole I. duke of Ferrara, he seems to have had connections with the chapel oi Louis XII of France and probably also with the cathedral of Cambrai. In Ferraro he wrote in honour of his employer the Mass *Hercules Dux Ferrariae* (based on the theme *re ut re ut re fa mi re,* the Guidonian syllables corresponding to the vowels of the title), and his motet *Miserere* was composed at the duke's request. On the death of the duke (1505) Josquin seems to have left Ferrara. On the conclusion of an alliance between the Netherlands and England he composed the chanson *Plus nulz regretz.* From about this time onward he was provost of the collegiate church of Notre Dame in Condé, where he died on Aug. 27. 1521.

Of the 20 Masses that survive complete and are certainly written by him, 17 were printed in his lifetime in three sets (1502, 1505 and 1514) by Ottaviano del Petrucci. His motets and chansons were included in other Petrucci publications from the *Odhecaton* of 1501 onward. Three musical laments on his death by Nicolas Gombert, Benedictus Appenzeller and Hieronymus Vinders are extant. Luther expressed great admiration for Josquin's music. calling him "master of the notes, which must do as he wishes; other composers must do as the notes wish." Adrian Petit Coclico, self-styled pupil of Josquin, described and praised his methods of teaching. Until late in the 16th century his works were widely copied, examples of his technique were cited by theorists and his pieces were used as models by many composers.

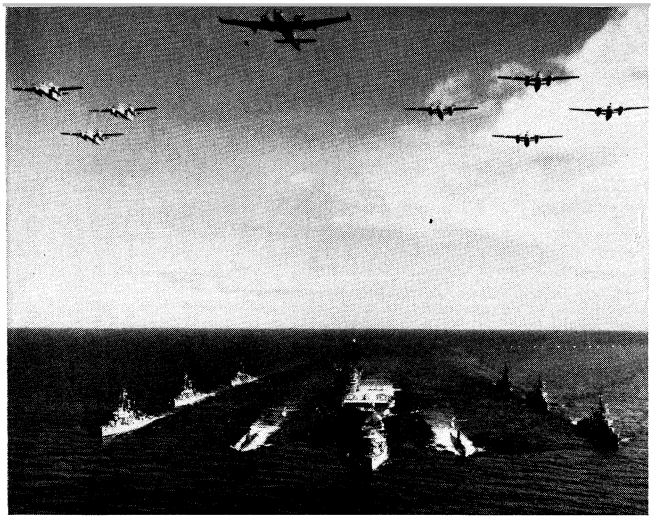
In his Masses Josquin developed notably the methods he inherited from Guillaume Dufay, Jean d'Okeghem and Jacob Obrecht (*qq.v.*), progressing from the *cantus-firmus* type. in which a pre-existing theme was used in a single part in the medieval manner. to the paraphrase and parody types, in which pre-existing melodic and contrapuntal material was woven into the texture of the writing in the Renaissance manner. His motets and antiphons show a parallel growth in integration by the use of imitative and antiphonal techniques. Many of his secular chansons also employ canonic and closely imitative writing. A modern edition of his complete works was begun under the editorship of A. Smijers in 1921. (F. L. HA.)

DESSALINES, JEAN JACQUES (*c.* 1748–1806), regarded in Haiti as the chief hero of the Haitian war for independence. was the illiterate slave of a free Negro. He reached high rank and acquired a reputation for bravery and cruelty in the war after the slave revolt of 1791. He surrendered to the French with other Negro leaders in 1802, but became the principal leader of the revolt that ended French rule in 1803. After his election as governor general of Haiti for life in Jan. 1804. he ordered the massacre of the French remaining in the country. In Sept. 1804 he was proclaimed emperor. He revived agricultural production by reinstituting forced lsbour under military control on the plantations. His cruel and corrupt rule caused discontent. especially among the mulattoes in the south, and while attempting to suppress a revolt there he was killed in an ambush at Port-au-Prince in 1806. (D. G. M.)

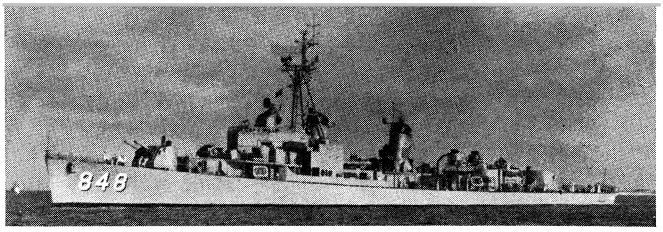
DESSAU, a town of Germany which after partition of the nation following World War II became a regional capital in the *Bezirk* of Halle in the German Democratic Republic. It extends along both sides of the Mulde up to its confluence with the Elbe and is 108 km. (69 mi.) S.W. of Berlin. Pop. (1959 est.) 93.273. Until World War II Dessau, which was extensively bombed. had many historic buildings such as the Schlosskirche with paintings by Lucas Cranach, the old Landestheater and the Amalienstift with its valuable collection of paintings. After the war the town, including the Landestheater, was rebuilt. In the Rlosigkau castle there is also a large collection of paintings with works by Peter Paul Rubens, Titian and Sir Anthony Van Dyke. Dessau, a railway junction, with repair shops, on the Berlin-Belzig-Leipzig line, has an inland harbour. and at the confluence of the Mulde and Elbe there is a big shipyard where dredging machines are produced. The large armaments enterprises are nationally owned. Industry is mainly machinery, vehicle and apparatus manufacturing. The town developed from a Sorbish settlement. Lower Saxon and Flemish colonists expanded it in the 12th century and it was granted municipal rights in the 13th century. From 1340 until 1918 it was the residence of the counts, princes and dukes of Anhalt. In the 18th century they had a castle built in the Mosigkau district of the town in the southwest; it contains a museum of the rococo period.

DESSOIR, LUDWIG (1810–1874), German actor, whose fame rested on his portrayals of Shakespearean parts, notably those of Othello and Richard III, was born in Posen on Dec. 15,

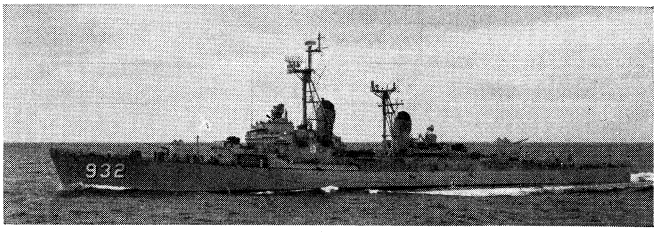
DESTROYER



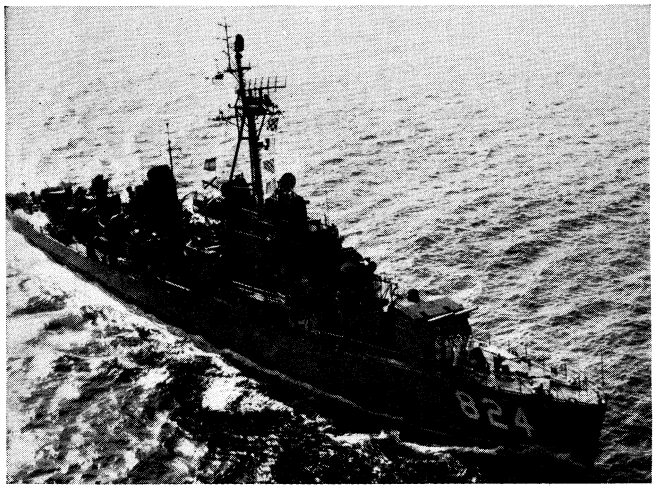
U.S. navy antisubmarine task group Alfa, a hunter-killer unit developed in 1959. Composed of both sea and air craft, it includes the aircraft carrier "Valley Forge" (the flagship), seven escort destroyers (DDE), two submarines, and supporting planes of both conventional and helicopter types for search and patrol



"Witek," experimental destroyer (EDD) of the U.S. navy, world's first jet-propelled warship. Launched (as conventional destroyer) in 1946; equipped with pump-jet propulsion system in 1959

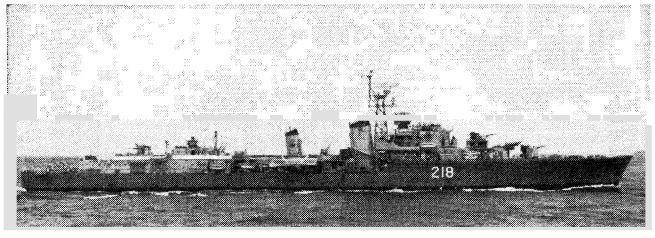


"John Paul Jones," U.S. navy destroyer (DD) of the "Forrest Sherman" class, heaviest (displacement 3,900-4 000 tons full load) conventional destroyer class in the fleet. Launched 1955

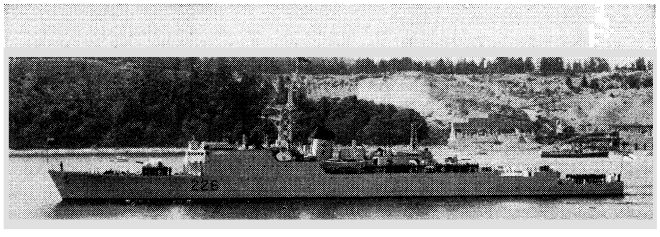


"Basilone," U.S. navy escort destroyer (DDE) of the "Gearing" class. Launched as a destroyer (DD) in 1945, later converted for antisubmarine warfare and completed as an escort vessel in 1949

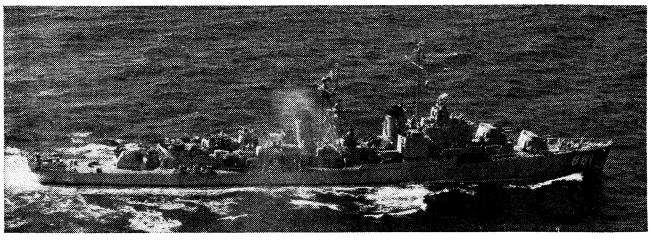
"Mitscher," U.S. navy destroyer leader (DL), officially rated as a frigate. The vessels of the "Mitscher" class are larger than some rated as light cruisers in other countries. The "Mitscher" was launched in 1952



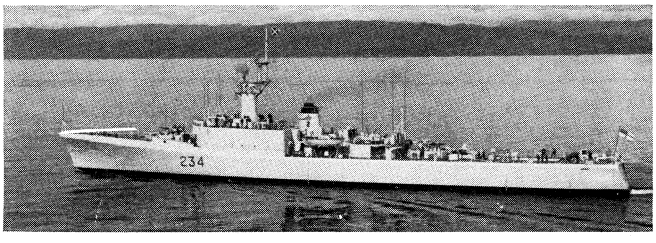
"Cayuga," destroyer escort (DDE) of the Royal Canadian navy, improved "Tribal" class: displacement 2,200 tons standard, 2,800 tons full load. Launched 1945, refitted and modernized 1953–54



"Crescent," antisubmarine destroyer (DDE), Royal Canadian navy, "Algonquin" class. "Crescent" originally a British "C" class destroyer, converted in 1958 for antisubmarine duty



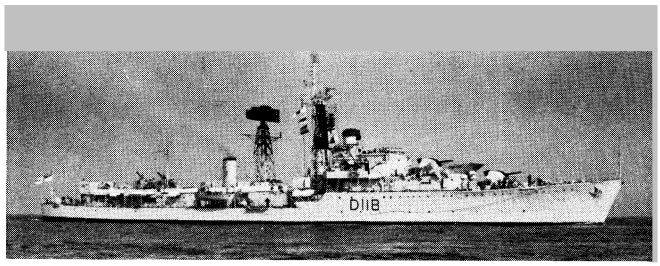
"Bordelon," radar picket destroyer (DDR), U.S. navy, converted "Gearing" class destroyer equipped with early-warning radar. Originally launched 1945



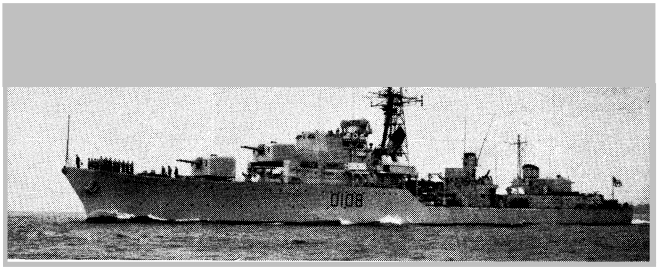
"Assiniboine," antisubmarine destroyer (DDE), Royal Canadian navy, of the "St. Laurent" class designed especially for ice conditions in the North Atlantic. The "Assiniboine" was launched in 1954

DESTROYERS AND DESTROYER ESCORTS OF THE U.S. AND CANADA

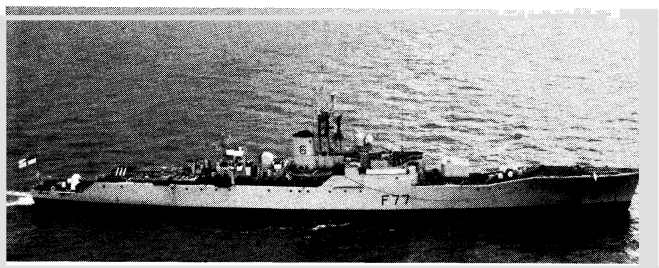
DESTROYER



"Battleaxe," British Royal navy. A radar picket destroyer of the "Weapon" class. Originally equipped as an antisubmarine escort, it was launched in 1945; converted 1958–59



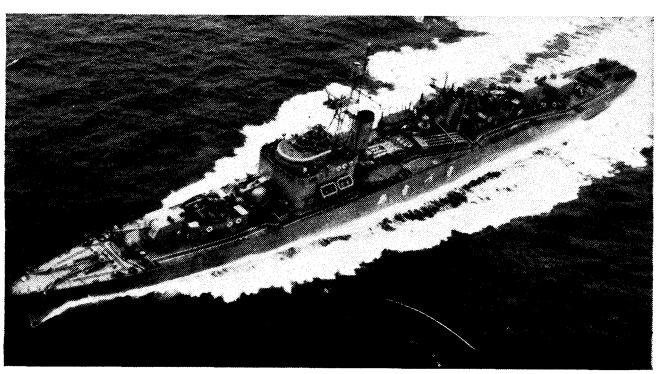
"Dainty," British destroyer of the "Daring" class, launched in 1950. The "Dainty" and other vessels of the class are the largest regular armament destroyers in the fleet



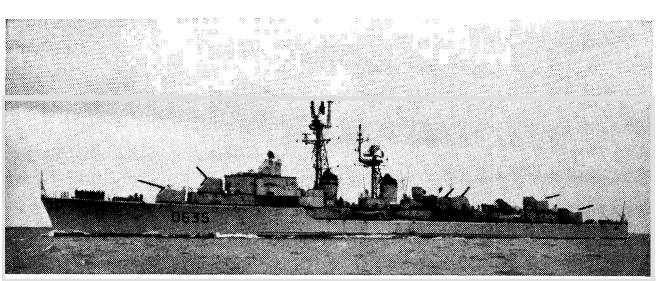
"Blackpool," antisubmarine frigate, British Royal navy. Launched in 1957, it is of the "Whitby" type, a class of fast ships equipped with detection and destruction devices to combat modern submarines

"Alamein," British destroyer of the "Battle" class, somewhat larger than vessels of the "Weapon" class. Outfitted as a destroyer leader when it was launched in 1945, it was scheduled for eventual conversion to radar picket service

"Svobodni," a modern Soviet destroyer of the "Skoryi" class in service in the Baltic sea. Equipped with radar tire control and depth charge throwers; displacement 2,600 tons standard (3,500 tons full load)

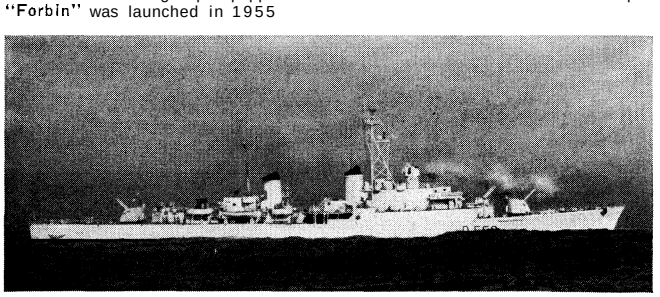


"Akizuki," Japanese destroyer built under the auspices of the U.S. military aid program and launched in 1959. Designed as flotilla leader, it was equipped with radar and sonar systems, two homing torpedo launchers and 5-in. guns

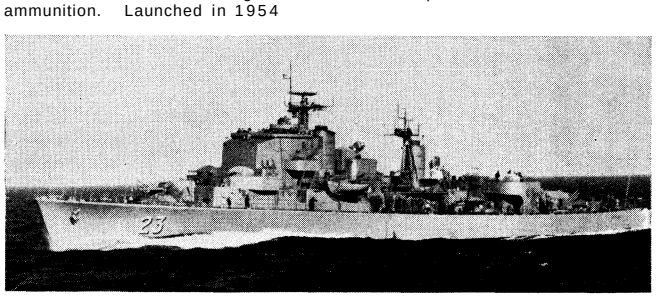


"Forbin," French radar picket destroyer (rated as Escorteurs *d'Escadre*) of the "Surcouf" group equipped as aircraft direction and command ships. "Forbin" was launched in 1955

"Vauquelin," also of the French "Surcouf" group but designed for anti-aircraft service. The 5-in. guns were built to operate with standard U.S. ammunition. Launched in 1954



"Indomito," Italian destroyer officially rated as Cacciatorpediniere. Launched in 1955, the "Indomito" and its sister ship "Impetuoso" (1956) the name ship of its class, were the first Italian destroyers built after World War II



"Hälsingland," destroyer of the Roya! Swedish navy, "ostergotland" class equipped with improved antiaircraft and antisubmarine devices. "Hälsingland" was launched in 1957

DESTROYER8 OF GREAT BRITAIN, EUROPE, THE U.S.S.R. AND JAPAN

BY COURTESY OF (ALL EXCEPT THIRD ROW RIGHT) JANE'S FIGHTING SHIPS, PHOTOGRAPHS (TOP LEFT TOP RIGHT FOURTH ROW LEFT) WRIGHT & LOGAN, (SECOND ROW LEFT) OFFICIAL BRITISH ADMIRALTY PHOTOGRAPH (SECOND ROW RIGHT ANTHONY & JOSEPH PAVIA (THIRD ROW LEFT) SKYFOTOS, (THIRD ROW RIGHT) UNITED PRESS INTERNATIONAL, (FOURTH ROW RIGHT) FRENCH NAVY OFFICIAL PHOTOGRAPH, (BOTTOM LEFT) ITALIAN NAVY OFFICIAL PHOTOGRAPH, (BOTTOM RIGHT) ROYAL SWEDISH NAVY OFFICIAL PHOTOGRAPH

1810. After years of apprenticeship on many stages he joined, in 1839. the court theatre at Karlsruhe, where he stayed for ten years. From 1849 to 1872 he was associated with the Berlin court theatre, traveling extensively all over Germany to give guest performances. In 1855 he played Othello in London, and G. H. Lewes placed him in certain scenes above Edmund Kean, while the *Athenaeum* critic preferred him in this part to Lr. Macready. There was a quiet intensity about his Othello that was in marked contrast to the melodramatic violence with which it had become customary to play the Moor. Dessoir died in Berlin on Dec. 30, 1874. (A. M. N.)

DESTINN, EMMY (EMA DESTINNOVA) (1878–1930), Czech soprano whose reputation was based not only on the power and vibrant richness of her voice but also on her great intelligence and dramatic gifts. She was born Ema Kittl in Prague. Feh. 26. 1878. but adopted the name of her singing teacher. Maria Loewe-Destinn. She made her debut in 1898 at the Berlin Kroll opera as Santuzza in blascagni's *Cavalleria Rusticana,* and Richard Strauss chose her to sing the title part in the first performances at Berlin and Paris of his *Salome* (1906). Destinn made her Covent Garden debut in 1904 as Donna Anna in Mozart's *Don Giovanni* and a triumphant first appearance at the Metropolitan opera. New York, in 1908. In 1910 she sang Minnie there in the premiere of Puccini's *La Fanciulla del West,* and she continued to appear in New York until 1916 in roles as varied as Pamina in Mozart's *Die Zauberflöte,* Valentine in bleyerbeer's *Les Huguenots* and Eva in Wagner's *Die Meistersinger.* She sang again in London and New York after World War I but retired in 1921. She died at České Budějovice (Budweis) on Jan. 28, 1930. (WI. S. M.)

DESTOUCHES, ANDRÉ CARDINAL (1672–1749). French opera composer. Born in Paris, April 1672, he was a pupil of the College des Jésuites there, and was one of the few Europeans to visit Siam in the 17th century. Later he became a "mousquetaire du Roy" before finally leaving military service to study with André Campra, to whose opera-ballet. *L'Europe Galante,* he contributed three airs. Destouches' first opera. *Issé,* was produced in 1697. He wrote nine further operas (one in collaboration with M. de Lalande) and in 1713 was appointed inspector-general of the Paris Opéra. Fifteen years later he became director and in the same year "surintendant de la musique du roy" and remained in that post until his death in Paris on Feb. 7, 1749. His works also include drinking songs, cantatas, motets and a Te *Deum.* (B. P.)

DESTOUCHES, PHILIPPE (real surname probably NÉRICAULT) (1680–1754), French dramatist, author of more than 20 successful comedies, was born at Tours. April 9, 1680. He was attached successively to the French embassies in Switzerland and in London. His election to the Academy on his return to France (1723) probably rewarded public service rather than literary merit. although his early comedies such as *Le Curieux impertinent* (1; 10), *L'Ingrat* (1712), *L'Irrésolu* (1713) and *Le Médisant* (171j) were well received. His masterpiece, *Le Glorieux* (1732), depicting the conflict between the old nobility and the *nouveaux riches,* was acclaimed on its debut and received 30 performances. Destouches purchased the governorship of Melun in 173j but continued to write plays, and also produced more than 800 epigrams and an indifferent verse translation of *The Tempest.* He died at Fortoiseau. July 4, 1754. As a comic dramatist in the tradition of Moliere he differed from Molière in giving greater emphasis to character and in making virtue attractive, as well as satirizing vice. His additional moral seriousness was an element of the so-called *comédie larmoyante.*

BIBLIOGRAPHY.—G. Leroy, *Néricault Destouches* (1862); J. Hankiss, *Philippe Néricault Destouches, l'homme et l'oeuvre* (1918); *see* also his collected works in editions of 1745, 1757, 1811 and 1820.

DESTROYER, a speedy, heavily armed naval vessel. smaller than a cruiser (*q.v.*), capable of performing many naval tasks. Although destroyers have grown from 320 to nearly 4.000 tons. most modern destroyers displace between 1.500 to 2,600 tons and are from 320 to 450 ft. long. Destroyers have a complement of from 140 to 350 officers and men. are armed with torpedoes. guns and depth charges. and have underwater sonar (asdic) devices; speeds vary between 30 and 37 knots. They have no armour although their gun shields protect against machine gun fire. The U.S. navy designates a destroyer as a DD, while a larger type fitted to serve as a flagship is a DL. destroyer leader or frigate. A smaller. slower, less powerful type designed for escorting convoys is a DE. destroyer escort, and vessels especially fitted for radar picket duties are designated DDR and DER. Guided missile destroyers are designated DDG.

Role of the Destroyer.—Because the destroyer is generally considered the most versatile of modern naval vessels: It follows that differentnavies and commanders have held divergent views as to its proper role. No fleet commander has ever considered that he had enough destroyers; and yet, as is shown in the paragraphs which follow, destroyers have been in great demand for specialized activities such as antisubmarine warfare in all phases. The destroyer started as a supertorpedo boat, and the torpedo has remained one of its primary weapons, but the passing of the battle line has not decreased the demand for destroyers. Destroyers may be compared with the cavalry of a former day and the tanks of a modern army.

Origin and Development of Destroyers.— The torpedo boat, the destroyer and the submarine were developed in their modern form to use the torpedo invented by Robert Whitehead (*q.v.*). The first torpedo boat (TB), completed for the Royal Navy in 1878, was the "Lightning," designed to carry a spar torpedo. She was 84 ft. long and had a speed of 19 knots. Two tubes for Whitehead torpedoes were installed in her in 1879. The first torpedo boat for the U.S. navy, the "Cushing," was named for Lieut. W. B. Cushing who sank the Confederate ironclad "Albemarle" with a spar torpedo, Oct. 27, 1864. Authorized in 1886, she displaced 130 tons, was 139 ft. long, had a speed of 22 knots and a complement of 22. (*See* TORPEDOES.) Adm. John A. Fisher of the Royal Navy ordered "Havoc" and "Hornet" from the Yarrow shipbuilding firm; when they were completed in 1893 he called them torpedo-boat destroyers, later shortened to destroyer. As the Royal Navy expected to retain superiority in capital ships, Fisher intended to use the new vessels in two roles: defensively against enemy torpedo boats and offensively as TB's against enemy big ships. Fitted with three 18-in. torpedo tubes instead of the earlier 14-in. tubes, these ships made a record speed of 28 knots. They mounted one 12-pounder and three 6-pounder guns, were 180 ft. long with $5\frac{1}{2}$ ft. draft and displaced 320 tons fully loaded.

The earliest destroyers for the U.S. navy were authorized in 1898; they displaced 510 tons and carried 3 officers and 60 men. Five destroyers authorized in 1907 were the first turbine ships in the U.S. navy; they displaced 800 tons and carried 4 officers and 90 men. The Royal Navy and other navies still had a number of torpedo boats in service in World War I.

Destroyers in World War I.—Great Britain had nearly 300 and Germany 144 destroyers in Aug. 1914. Although the Royal Navy built many new destroyers it never had enough during the war. The admiralty was unable to adopt the convoy system when unrestricted submarine warfare began, Feb. 1, 1917, because of a shortage of destroyers. But, after 196 ships of about 600,000 tons were sunk in the month of April 1917, destroyers were employed in convoys in the North Atlantic beginning in May. When the United States entered the war, 67 destroyers of the U.S. navy were in commission and 27 others under construction. Convoys were established in the Mediterranean in Aug. 1917 and Japan sent some destroyers for use with these convoys. British, French and U.S. destroyers were used for the escort of merchant convoys in the North Atlantic and in the Mediterranean, and proved effective.

Losses of shipping declined steadily under the destroyer escort system. The destroyers employed guns, torpedoes and depth charges against the submarines. The depth charges were rolled from racks on the stern or shot out by Y guns to form a pattern around the calculated position of the submerged submarine which had been determined sometimes by echo-ranging equipment. Later depth charges carried 300 lb. of TNT, during the war, and they could be set to explode at various depths. Destroyers ranged

in size from 500 to 1,200 tons: carried from 100 to 150 officers and men, mounted 3- or 4-in. guns and had a speed of 28 to 32 knots.

Adm. Sir John R. Jellicoe did not use his grand fleet destroyers to attack the German high seas fleet during daylight in the battle of Jutland (*q.v.*), May 31, 1916. His destroyers attacked that night and their torpedoes sank the pre-"Dreadnought" "Pommern" and the small cruiser "Rostock." Jellicoe was severely criticized afterward by Comdr. C. Bellairs, M.P., and others for his alleged failure to use his destroyers aggressively. By contrast, Adm. Reinhard Scheer twice used his destroyers for daylight attacks at Jutland and on both occasions the British battle line turned away. "Destroyers Dismiss Battleships!' was the heading of one chapter of the book by Bellairs on the battle. The Royal Navy had 80 destroyers in the battle and lost 8; the Germans had 63 and lost . Effective use of the German destroyers saved their fleet from destruction.

Perhaps the most dramatic of many fights between British and German destroyers took place on the night of April 20, 1917, in the English channel, when the British destroyers "Swift" and "Broke" sank two German destroyers after a hand-to-hand struggle. After entering the war, the United States began a huge building program which included 247 destroyers, but very few of these were completed prior to the Armistice of Nov. 11, 1918. Wartime losses of destroyers were: Great Britain 67, Germany 66, Russia 20, France 12, Italy 8, Austria 6, Turkey 3, United States 2 and Japan 1. Germany also surrendered 92 destroyers.

For many years after 1919 tactical doctrine for destroyers was based on studies of the battle of Jutland and the escort-of-convoy experience of 1917–18. Day and night torpedo attacks by groups of destroyers were rehearsed. In war maneuvers at sea a fleet commander would attempt to deploy about two-thirds of his destroyers ahead of his battle line and one-third astern, while dividing his cruisers in the same way. His objective was to enable his destroyers. accompanied by cruisers to protect them, to reach a position ahead of the enemy battle line from which they could launch a torpedo attack on the enemy battleships, thus lessening the enemy's gunnery efficiency at the most critical moment of battle and possibly inflicting severe damage on the enemy ships. Destroyers also accompanied aircraft carriers for plane guard duty and for antisubmarine and antiaircraft protection. Limitations of the Washington treaty of 1922 and London treaty of 1930 did not apply to destroyers.

Destroyers in World War 11.—Destroyers enhanced their earlier reputation and won new prestige during World War II. Improved devices for underwater sound detection and the introduction of radar made them more effective than before. The demand for destroyers to escort convoys was so great that a new subordinate class of vessel, the destroyer escort (DE), was introduced, as mentioned above. These vessels had less speed, less armament, and were less costly to build than destroyers, but, with depth charges and underwater echo-sounding devices, as well as radar, they proved highly effective as escorts for merchant-ship convoys.

The U.S. navy evolved the carrier task group which included two to five carriers, fast battleships, cruisers and eight to ten destroyers. Hunter-killer groups consisting of one carrier and five or six DD's operated against submarines in the Atlantic with great success. By rescuing many friendly aviators in the Pacific, the destroyers not only saved trained men but kept up morale among naval pilots and crewmen. With special equipment, destroyers undertook a new assignment in the battle of Okinawa when they served as radar picket ships. On the coast of Sicily, at Salerno and in the Pacific, destroyers close inshore used their guns to support troops who had just landed. This fire support was effective even against tanks. In the struggle for Guadalcanal, Aug. 1942 to Feb. 1943, Japanese destroyers under Rear Adm. N. Tanaka made a brilliant record. There and elsewhere Japanese destroyers gave the U.S. navy some unpleasant surprises with efficient night fighting tactics and torpedo firing. Around Guadalcanal the Japanese lost 11 destroyers to 14 lost by the U.S., while inflicting very severe damage to U.S. cruisers.

In Sept. 1939 the Royal Navy had 188 destroyers; Germany had 30; Japan had 138; and the U.S., 97 modern vessels besides 153 that were begun in 1917. Fifty of the latter were transferred to Britain in the "destroyers-bases deal" of Sept. 1940. Between Dec. 7, 1941, and Oct. 1, 1945, the U.S. completed 349 new DD's and 412 DE's besides 92 of the DE's transferred to Allies. Various navies built motor torpedo boats which accomplished little. U.S. losses were 71 DD's and 11 DE's during the war.

Postwar Developments.— Both the Royal Navy and the U.S. navy continued to build larger DD's while the type replaced cruisers in the great majority of the navies of the world. A number of DD's were converted to DE's or antisubmarine frigates in the 1950s. The British "Daring" class displaced 3,700 tons, fully loaded; it carried 308 officers and men and had 5 torpedo tubes and 6 guns of 4.5 in.; its length was 390 ft., beam 43 ft. and draft 13 ft. The U.S. "Forrest Sherman" class displaced 3,850 tons. In the late 1950s the major navies introduced large destroyers equipped with antiaircraft guided missiles such as the U.S. "Tartar" and "Terrier" and British "Seaslug" and "Seacat" weapons.

Naming of Destroyers.— The Royal Navy names destroyers by classes. The names of the eight ships of the "Daring" class begin with the letter *d,* such as "Decoy," "Defender" and "Delight." The weapons class includes "Battleaxe" and "Crossbow." The battle class includes "Trafalgar," "Camperdown" and "Solebay." The U.S. navy names destroyers for heroic officers and men of the navy, marine corps and coast guard, for other deceased officers with distinguished records, for deceased former secretaries of the navy and for members of congress who have had special association with naval affairs.

DESTRUCTOR: *see* INCINERATOR.

DESTUTT DE TRACY, ANTOINE LOUIS CLAUDE, COMTE (1754–1836), French philosopher and one of the chief "Idéologues," was born in Bourbonnais on July 20, 1754. He belonged to a noble family of soldiers originating from Scotland and settled in France in the 15th century. He made a brilliant career in the army and was colonel of the Penthièvre regiment. Elected deputy of the nobility to the estates-general (1789) he voted the reunion of the nobility and clergy with the *tiers-c'tnt.* He mas raised to the rank of *maréchal de camp* in the spring of 1792. but. when the Marquis de La Fayette crossed into the Austrian lines, refused to follow him and later resigned his commission. He settled with his family in the village of Auteuil and joined the group of younger "philosophes" who gathered in Madame Helvétius' salon. Under the Terror he was imprisoned for nearly a year; liberated after the fall of Robespierre (July 1794) he returned to Auteuil. where he met with D. J. Garat, the Comte de Volney and P. J. G. Cabanis. He was an associate member of the Institut and a member of the Académie Française (1808), a senator under Napoleon and a peer under the Restoration. He never actively engaged in politics, but accepted the different regimes. while holding on to his liberal creed. He corresponded with Thomas Jefferson. He died in Paris on March 9. 1836.

Of his philosophy, which he called "ideology," he gave a first outline in 1801. It was an offspring of Condillac's sensationalism; but under the influence of Cabanis, with whom he closely associated. Destutt refined the analysis of sensations and emphasized their physiological character. "Ideology is a part of zoology;" but it was far more inclusive and corresponded to the "anthropology" of the German philosophers. The four activities of conscious

life, perception, memory, judgment and will are all varieties and combinations of sensations. Thought is nothing but an elaboration of sensations and an activity of the nervous system. Destutt developed the consequences and applications of his theories in memoirs and treatises published between 1801 and 1815 under the general title of Ele'ments *d'Idéologie* and dealing with grammar, logic and political economy; he left unfinished his Traitk de la *volonté,* to which Stendhal was much indebted. His *Commentaire sur l'Esprit* des Lois de Montesquieu written in 1808 was published in a translation revised by Jefferson in 1811 and in French only in 1819.

DETAILLE, (JEAN BAPTISTE) EDOUARD (1848–1912), French painter of battles and military life, was born in Paris on Oct. 5, 1848. In his youth he studied with J. L. E. Messionier and employed a technique of literal exactitude based on that of his master. Detaille developed a wide knowledge of military detail. He first exhibited at the Salon of 1867, but it was his paintings of the war of 1870–71 which made him famous. His most characteristic works, infused with legend and sentiment, are his pictures of Napoleon I and his armies. Detaille visited Algeria. England and Russia, and worked for the prince of Wales and Tsar Alexander III. In 1883 he produced, together with A. de Neuville, a profusely illustrated two-volume work: *L'Armée française.* Detaille also painted some portraits and nonmilitary subjects. He was a gifted actor. He died in Paris on Dec. 23, 1912.

(D. C. T. T.; X.)

DETECTION (ELECTRONIC), the process whereby the information or audio signal is recovered from the modulated radio-frequency carrier wave. This process is also commonly referred to as demodulation and is accomplished by a circuit arrangement ahich is termed a detector or demodulator.

One or more detectors may be used in radio receiving apparatus depending upon whether the radio-frequency power, received at the antenna in the form of electric oscillations, is converted directly into audio power or into some intermediate-frequency power and then into audio power. After the audio-frequency wave is detected it is amplified sufficiently to operate an indicator, of which the loud-speaker is the most common type. The speaker actually converts the audio signals into mechanical vibrations which the ear interprets as sound. This sound has essentially the same wave form as that picked up by the microphone in the broadcast station from which the modulated carrier wave originated.

There are as many detection or demodulation schemes as there are types of modulation, namely, amplitude demodulation, frequency demodulation, phase demodulation and pulse demodulation. The last three types are of later development and the circuit arrangements for detecting these are not so numerous as those for detecting amplitude-modulated waves. The most common type of detector is the diode vacuum tube operated on the nonlinear portion of its characteristic curve, thereby converting a modulated radio-frequency current into a modulated direct current. DETECTIVE STORIES: see MYSTERY AND DETECTIVE STORIES

DETERDING, SIR HENRI WILHELM AUGUST (1866–1939), the first managing director of the Royal Dutch-Shell group of companies, was born in Amsterdam on April 19, 1866. He rose rapidly in the Indonesian branches of the Nederlandsche Handel Maatschappij, showing that grasp of essential figures and data which throughout his life allowed him to take quick, well-balanced decisions in complicated situations. In 1896 he joined the Royal Dutch Petroleum company to reorganize the sales in north Sumatra, and on the death of J. B. A. Kessler, Sr. (1900), succeeded him as managing director.

He convinced the other East Indian producers that only combined sales would maintain them against Russian and U.S. competition. Contacts with the Shell Transport and Trading company led to the formation of the Royal Dutch-Shell group in 1907, of which Deterding remained director-general until 1936. He was the first to see the importance of the European gasoline market for Indonesian producers, and this provided a return cargo for his tankers transporting Russian kerosene to the far east. Deterding unified the Royal Dutch-Shell group and gave it world-wide interests. In 1920 he was made a knight of the British empire. He died on Feb. 4, 1939, at St. Moritz, Switz. (R. J. F.)

DETERGENTS AND WETTING AGENTS are substances that, when dissolved in a liquid, give it cleansing and penetrating properties; soap (*q.v.*) is the best-known agent of this type. Soap has disadvantages, however, in many applications: when used with hard water it reacts with calcium and magnesium in the water and leaves a sticky residue of lime soaps; soap also hydrolyzes in slightly acid solutions, decomposing into insoluble fatty acids or acid soaps. The detergent and wetting properties of soap are physical rather than chemical: they depend not on specific chemical reactions with dirt or with surfaces but on physical effects such as adsorption and surface tension. A large number of different substances that vary widely in chemical composition possess the physical characteristics that enable them to act as substitutes for soap. The prime property required of such agents is that they be surface-active; *i.e.,* that they concentrate at surfaces and interfaces (adsorption). To possess this property the molecule of the agent must contain a polar or hydrophilic (soluble in water) portion combined with an oily or lipophilic (soluble in lipids) portion; the hydrophilic part confers affinity for water or polar surfaces and the lipophilic part confers affinity for hydrocarbons or nonpolar surfaces. The balance or ratio between these parts of the molecule can be controlled by the organic chemist, who is thus able to produce compounds particularly suited for specific detergent or wetting applications. In the early 1960s several hundred such preparations were on the market.

The first requirement in designing a synthetic detergent is to adjust the hydrophilic-lipophilic balance of the molecule so that the agent will be soluble in the medium in which it is to be carried: if this medium is water, hydrophilic groups that can be used are: $-COO^-$, $-SO_3^-$, $-NH_3^+$, $-CONH_2$, $-SH$, or $-(CH_2CH_2O)_nH$; if the medium is nonaqueous, then alkyl, aryl (aromatic) or combinations of the alkyl and aryl organic units are to be emphasized and the contribution of the hydrophilic group is either directly diminished by using one of minor power or overbalanced by the lipophile. At the same time, care must be taken not to carry the balance too far in favour of solubility in the medium, since detergent and wetting action depend on adsorption, and in adsorption the solvent competes for the agent with the surface to be cleaned or wetted; if the agent is too closely linked to the solvent, therefore, it will have less tendency to be adsorbed by the surface. Apart from this general rule, the fine adjustment of the hydrophilic-lipophilic balance of the agent to make it optimum for its application is a matter of trial and error, although experience and a number of empirical aids can reduce the number of necessary trials.

Types **of** Detergents.—The major classification of detergents is based on the nature of the ionic dissociation of the molecule in aqueous solution. Four types are recognized: (a) anionic-active, in which the surface-active part of the molecule is a negative ion; (b) cationic-active, in which the surface-active part of the molecule is a positive ion; (c) nonionic, in which the whole molecule is surface-active; (d) ampholytic, in which the surface-active part of the molecule may be either positively or negatively charged, depending on the pH of the solution.

Anionic-active.—Soaps are the commonest examples of anionic-active agents. The usual soaps of daily use are the sodium or potassium salts of fatty acids, which are derived from vegetable oils or animal fats. These soaps are mixtures of homologs (members of a family of compounds having the same general formula) ranging from 12 to 18 carbon atoms in the alkyl chain. although longer chains can be tolerated if the fatty acids are unsaturated. Soaps are gradually being replaced in industrially advanced countries by synthetic detergents, which are also, save for special applications, anionic-active agents. The most common of these, for

use as a heavy-duty household detergent, is sodium dodecylbenzene sulfonate, which is prepared from petroleum products and sulfuric acid. The general formula of a sulfonate detergent is RSO_3Na, where R refers to a lipophilic or organic group containing about 18 carbon atoms. Next in importance are the alkyl sulfates, made by the reaction of a fatty alcohol with sulfuric acid; the general formula of an alkyl sulfate is $ROSO_3Na$; these too are based on petroleum products. Synthetic detergents are superior to soap in many respects; for example, they are more stable to chemical change and have superior detergent action.

Cationic-active agents are strong electrolytes; the surface-active part is the positive ion, or cation. The salts of long-chain amines are examples, though they are ionized only in acid solution. Another type is the quaternary ammonium salt, which is a substituted ammonium chloride; *e.g.,* cetyltrimethylammonium bromide (CTAB) or cetylpyridinium chloride; these substances dissociate in aqueous solution into large positive ions and small inorganic anions. (*Cetyl* is used in industrial chemistry to denote an alkyl chain 16 carbon atoms long.) The cationic-active agents are incompatible with anionic-active agents, since the two large ions of opposite charge tend to combine to form a water-insoluble substance. The cationic-active agents are also more costly and may be poisonous; for these reasons they are not used as household detergents. But because of their properties they are used in surgery as bactericidal agents and, in dilute nonpoisonous concentrations, as detergents in bars and restaurants, where care must be taken to avoid mixing them with ordinary (anionic) detergents. Cationic-active agents also are used as emulsifying agents for asphalt in the surfacing of roads; these emulsions are expected to "break" soon after being applied and to deposit an adhering coat of asphalt on the surface of the stone aggregate; cationic-active agents adsorb strongly on minerals, particularly silicates, and so make a strong adhesive bond between the asphalt and the aggregate.

Nonionic agents do not dissociate in water and therefore depend on structural features other than ions for their ability to confer sufficient hydrophilicity to make the substance soluble in water. The presence of hydroxyl groups and amide, ether or ester linkages helps to offset the lipophilic radicals; and double or multiple use can be made of the hydrophilic nature of amide, ether or ester linkages by placing them as connections between two or more carbon atom segments that are themselves too small to add much lipophilic character. For this purpose a useful reagent is diethanolamine, $HN(CH_2CH_2OH)_2$, which can react with a fatty acid or its methyl ester to form a surface-active alkanolamide. Adding a polyoxethylene chain offers another way of introducing a number of oxygen atoms, and this can be done by reacting ethylene oxide with a fatty alcohol, such as an alkylphenol: the ethylene oxide polymerizes and confers more hydrophilicity upon the original lipophile; but its effectiveness in this respect does not continue beyond about 20 ethoxy groups. Polyhydric alcohols (those containing two or more hydroxyl, or —OH, groups) such as the sugars, provide oxygen atoms, which are hydrophilic, and so can be used to make surface-active agents by esterification with a fatty acid.

All these nonionic agents are unaffected by hard water, salts, acids and mild alkalies; they are also compatible with either anionic- or cationic-active agents. They are in fact often used in combination with anionic-active detergents, e g., in shampoos, since they stabilize the foam and enhance the detergent action. Another application is in the food industries: nonionic surface-active agents are used as wetting agents—*e.g.,* the deep frying of fish or doughnuts, where even action of the hot fat over the entire surface is desired. Ionic agents cannot be used in foods because they have an unpleasant taste and may have more serious adverse physiological effects.

Ampholytic detergents contain both anionic and cationic groups, such as are found in amino acids; some actions of ampholytic detergents are similar to those of amino acids. For example, in acid solution the carboxyl group of an amino acid is not dissociated, but the amino group is a cation; in alkaline solution the amino group is not dissociated, but the carboxyl group is an anion. Ampholytic agents can be designed to combine useful features of both anionic- and cationic-active detergents, but their applications are for special and limited purposes.

Miscellaneous.—Other surface-active substances that can be used for special purposes are water-soluble polymers, such as sodium carboxymethylcellulose, polyvinylpyridine and polyvinyl alcohol; these are anionic, cationic and nonionic respectively. The surface activity of these polymers is conferred by the hydrophilic-lipophilic balance of the final molecule; the monomer is not surface-active since it does not possess enough of each characteristic, though they are present in the same ratio.

Other types of polymeric surface-active agents can be made by co-polymerizing lipophilic and hydrophilic monomers, or by synthesizing block co-polymers, in which one block is hydrophilic (*e.g.,* polyethylene oxide) and the other lipophilic (*e.g.,* polypropylene oxide). The low free energy of surfaces that are formed of silicones or of fluorocarbons make these materials extremely effective as hydrophobic or lipophobic constituents of a surface-active molecule: a fluorocarbon chain of only 5 carbon atoms has the same effect as 16 carbon atoms in an alkyl chain. Silicone or fluorocarbon surface-active agents can lower the surface tension of water from 72 dynes/cm. to less than 20 dynes/cm., whereas agents based on hydrocarbon chains generally cannot reduce it below 28 dynes/cm.; for this reason silicone or fluorocarbon agents are surface-active not only in water but also in hydrocarbons and other organic liquids. Polyurethane foam makes use of a block co-polymer containing silicone and designed to be surface active in a nonaqueous medium.

FIG. 1.—STAGES IN THE "ROLLING-UP" OF OLEIC ACID, BY MEANS OF A DETERGENT SOLUTION, FROM THE SURFACE OF OILED WOOL FIBRE

Physical Process of Surface Action.—A detergent replaces dirt on a surface by (1) being preferentially adsorbed and (2) then facilitating the carrying away of the dirt as a stabilized emulsion or suspension. The process is illustrated in the series of photomicrographs shown in fig. 1: a wool fibre that had been "dirtied" by an oily deposit of oleic acid was placed in an aqueous solution of a detergent; in a short time irregular swellings were observed on the surface; they were accumulations of oleic acid, which had been replaced by detergent and so "washed off" the surface of the wool; when the oleic acid had been removed completely, it appeared as drops clinging to the fibre; but these drops were only loosely attached, so that gentle agitation was enough to detach them; after the drops were detached they became emulsified particles in the body of the solution.

The surface and interfacial tensions that determine this behaviour are shown diagrammatically in fig. 2; they are related by the expression (Thomas Young's equation):

$$F_{so} = F_{sw} + \gamma_{ow} \cos \theta$$

where F_{so} is surface-free energy of the solid-oil interface, F_{sw} is the surface-free energy of the solid-water interface, γ_{ow} is the surface tension of the oil-water interface, and θ is measured in water as shown in fig. 2. For a greasy surface θ may be about 150°, but when a surface-active agent is dissolved in the water both F_{sw} and γ_{ow} are greatly decreased. To regain the equilibrium expressed by Young's equation cos θ must change sign; *i.e.,* θ becomes less than 90°. To "roll up" the oil from

the surface of the solid, θ should be nearly zero, at which point the adsorbed layer of detergent may be regarded as preferred energetically to the grease on the surface; finally, if F_{sw} and γ_{ow} are reduced sufficiently, no value of θ, no matter how low, can restore the equilibrium condition, with the result that the oil is completely displaced from the surface. The decrease of F_{sw} results from the adsorption of surface-active solute molecules onto the solid, and the decrease of γ_{ow} results from the adsorption of the same molecules at the oil-water interface. The latter action also produces the second effect of the detergent: it causes the globules of oil or grease to be more readily dispersed as a stable emulsion in the water. This effect is important in preventing the redeposition of the dirt back onto the surface.

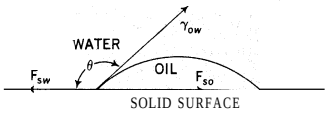

FIG. 2. — SURFACE AND INTERFACIAL TENSIONS THAT DETERMINE THE CONTACT ANGLE OF A LIQUID DROP ON A SOLID SURFACE

N. K. Adam has summarized the process as follows: "In their action on the solid surface, the detergent molecules undermine the grease, performing much the same function as road-sweepers — who collect the dirt, at first spread more or less uniformly over the roads, into heaps that may easily be transferred to a cart."

It is possible to imagine another set of conditions under which the surface-active solute adsorbs well at the oil-water interface but is not much adsorbed at the solid surface: the aqueous solution would then be able to spread evenly over the surface of the oily layer, but it would not displace the oil from the solid surface. Agents of this type are wetting agents but not good detergents. A good detergent, however, is necessarily also a wetting agent. To some extent the specific nature of the solid and of the oily contaminant enter into these relations; for solids of extremely low surface energies, such as certain tetrafluoroethylene resins, it is difficult to find a wetting agent; and for certain oily contaminants, such as silicone oils, it is difficult to find a detergent. But apart from these extreme situations, agents that are surface-active in water will affect γ_{ow} or both γ_{ow} and F_{sw} for most common oily and solid surfaces, and so will display a general ability to act as netting agents or as detergents.

A detergent solution as a rule does not spontaneously remove solid dirt particles from the surface of a fibre, even when such a removal is favoured by a decrease in total free energy. Additional mechanical force is needed to release large particles from between fibres or to break the adsorptive bonds between small particles (less than 1 micron) and the fibre surface; hence the need for the mechanical action of fabric rubbing against fabric, as in the washtub or washing machine. The smaller the size of the particle, the more adsorptive bonds per unit of mass it forms with the surface. and the greater the mechanical difficulty in removing it. An extreme case is that of an adsorbed dye, where the particles are molecules and contact points are so numerous that often the stain cannot be removed by washing; in such cases, bleaching (i *e.,* chemical modification) is necessary.

Other Uses for Surfactants. — Surface-active agents (surfactants) have practical uses other than as detergents or wetting agents. These uses are varied; frequently the function that is performed by one surface-active agent can be reversed by another, which displaces it from the surface or forms a mixed film of different properties. Thus one is used as an emulsifier, another as a demulsifier; one is a foam promoter and another is an antifoaming agent; one disperses a powder into a suspension and another flocculates the suspension. These pronounced differences in effect are due entirely to differences in the hydrophilic-lipophilic balance of the molecular structure. For example, the substance may be too lipophilic to be soluble in water, which would be a requirement of a foaming agent or an emulsifying agent, but sufficiently hydrophilic to be spread at an aqueous surface or to adsorb at oil-water interfaces; such substances act as antifoams or demulsifiers respectively. The molecular structure of surface-active agents can also be adjusted to obtain optimum effects as germicides, fungicides or insecticides. Surface-active agents are also used in corrosion inhibition: in ore flotation; as aids in the dyeing of textiles, where they promote even penetration of the fabric; as carriers for insoluble dyes or perfumes; to promote flow of oil in porous rocks; to produce aerosols; and to retard the process of evaporation.

Historical. — (For a history of soap *see* the article SOAP.) The first synthetic detergent was turkey red oil, an anion-active sulfated castor oil introduced in the middle of the 19th century as a carrier in the application of the dye alizarin in the dyeing of fabrics to produce the colour turkey red. The synthetic detergents that gained favour about a century later as replacements for soap were introduced in Germany in 1930 as sulfates of long-chain alcohols prepared by the hydrogenation of fats. These agents gradually were improved and became widely adopted. For example, by 1953 the production of synthetic detergents in the United States exceeded that of soap.

Widespread household use of synthetic detergents introduced a new and vexatious problem in sewage treatment and disposal: the foam stability of synthetic detergents, which is superior to that of soap and was welcomed at first as an advantage, often results in the accumulation of large volumes of unmanageable foam not only in the treatment plants but occasionally in canals, rivers and other waterways. The problem is particularly severe in Britain. Remedies consist of using detergents with low foaming action, such as those used in automatic clothes washing machines, or designing the detergent to be more susceptible to bacterial attack, which destroys it as a foaming agent during the usual course of sewage treatment. Straight-chain alkyl groups are readily destroyed by bacteria; branched chain or aromatic substituents are resistant to bacterial action.

(S. R.)

DETERMINANT, an algebraic expression associated with a square array of numbers or other numberlike mathematical quantities. Determinants form a branch of matrix theory *(see* MATRIX) and simplify the solution of simultaneous linear equations.

A determinant of n rows and n columns is called an n-rowed determinant. or a determinant of order n. Let the element in its ith row and jth column be designated by the symbol a_{ij}. Then the accepted notation for the array or matrix of elements is

$$A = (a_{ij}) \qquad (i, j = 1, \ldots, n)$$

and the notation for the determinant of this square matrix A is

$$|A| = |a_{ij}|$$

Determinants of orders one and two, respectively, are defined as follows:

$$|a| = a \qquad \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

Thus a number a defines a one-by-one matrix (a) whose determinant is the number a.

Determinants of order n are defined as follows: let $A = (a_{ij})$ be an n-rowed square matrix. The diagonal term of $|A|$ is the product $d = a_{11}a_{22} \ldots a_{nn}$. If P is the permutation which carries the integers $1, 2, \ldots, n$ into the rearrangement $i_1 i_2 \ldots i_n$ there is a corresponding product $d_p = a_{i1} \ldots a_{in}$. There are $n! = n(n-1) \ldots 3.2$ permutations P on the first n integers and so there are $n!$ products d_P. These are all the possible products obtainable by selecting one and only one element from each row and column of A. Apply P to the so-called alternating function $f = f(x_1, \ldots, x_n) = (x_n - x_{n-1})(x_n - x_{n-2}) \ldots (x_2 - x_1)$ and obtain the function $f_P = f(x_{i1} \ldots, x_{in})$. It can be shown that $f_P = t_P f$ where $t_P = 1$ or -1. Add the $n!$ terms $t_P d_P$ and define the n-rowed determinant $|A|$ to be the sum of these n! signed products.

This definition appears to have been formulated first by Leibniz in a letter which he wrote to Guillaume F. l'Hôpital in 1693. The

discovery does not seem to have had any influence, and determinants did not come into general use until they were rediscovered by G. Cramer, who published this same definition in 1750. The vertical bar notation was first intreduced by Arthur Cayley in 1841.

Determinants arise in the study of the solution of a simultaneous system of n linear equations in n unknowns. For example, consider the system

$$ax + by = e$$
$$cx + dy = f$$

in which the letters a, b, c, d stand for known quantities and x and y are to be determined. We may eliminate y by subtracting b times the second equation from d times the first equation and obtain $(ad - bc)x = ed - bf$. Hence if $D = ad - bc$ is not zero, we can express x as the quotient of two determinants. Indeed,

$$x = \frac{\begin{vmatrix} e & b \\ f & d \end{vmatrix}}{D} \qquad y = \frac{\begin{vmatrix} a & e \\ c & f \end{vmatrix}}{D}$$

Similarly, consider a system of n linear equations of the form

$$a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = k_1$$
$$a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = k_2$$
$$\cdots \quad \cdots \quad \cdots \quad \cdots$$
$$a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n = k_n$$

with $D = |a_{ij}|$ as the determinant of its coefficients. Define K_j to be the determinant obtained by replacing the jth column of D by the column of constants $k_1, \ldots, k_n$. Then $Dx_j = K_j$. This is called Cramer's rule for the solution of linear equations. It implies that if $D \neq 0$ the system has the unique solution $x_j = K_j/D$.

Determinants are useful as an instrument by means of which systems of linear equations may be classified. Thus, in dealing with linear equations with $D = 0$. one possibility is that in which one K_j is not zero. Then there will be no values whatever satisfying all the equations. Criteria for deciding when systems of linear equations have solutions and how many of these solutions are independent can be obtained from the theory of determinants.

Expansions of Determinants. — The array formed by the elements in r rows and r columns of a matrix A is an r-rowed square matrix whose determinant is called a minor of A. The minors of a determinant $|A|$ are merely the minors of the square matrix A. If r rows and r columns of an n-rowed square matrix A are selected the remaining $n - r$ rows and columns are thereby also selected. Thus every r-rowed minor of an n-rowed determinant $|A|$ determines an $(n - r)$-roned minor of $|A|$, and these two minors are said to be complementary minors of $|A|$.

Every element of a determinant $|A|$ may be regarded as a one-rowed minor of $|A|$ and the elements of $|A|$ then have complementary minors which are $(n - 1)$-rowed. If d_{ji} is the complementary minor of the element a_{ij} we shall call the signed determinant, $k_{ij} = (-1)^{i+j}d_{ji}$, the cofactor of a_{ij}. If we multiply the elements of any row (or column) of $|A|$ by their cofactors, and add, the resulting sum is the determinant of A. For example.

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{11}\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{12}\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + a_{13}\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix}$$

The sum of the products of the elements of the ith row (column) by their cofactors is called the expansion of $|A|$ according to its ith row (column). The expansion of a determinant according to the elements of its first row may be used as an inductive definition of a determinant and provides an alternative basis of the theory of determinants. Note, finally, that the sums obtained by multiplying the elements of any ron (column) by the cofactors of the elements of any other row (column) are all zero.

A generalization of the expansions given above is due to P. S Laplace and may be described as follows. select any r rons of $|A|$. Compute all r-roved minors aith elements in these r rows. There are $C_{n,r} = n(n-1)\ldots(n-r+1)(r!)^{-1}$ such minors, where $C_{n,r}$ is then the number of ways of selecting r columns from n columns. Multiply each of these r-roaed minors M_r by its complementary minor M_{n-r} and prefix the sign $+1$ or -1 according as the sum of all of the r row subscripts and all of the r column subscripts of M_r is even or odd. The sum of these $C_{,,}$ signed products will be the determinant of A. The sum of the signed minors in r rows by the complementary minors of a different selection of r rows is zero. There are corresponding results on column expansions.

The Laplace expansions imply the following important consequence. Suppose that the matrix of a determinant has the form

$$A = \begin{pmatrix} B & O \\ C & D \end{pmatrix}$$

nhere B is an r-rowed square matrix, C has $n - r$ rows and n columns. D is an $(m - r)$-rowed square matrix and the symbol O represents an array with r rows and $n - r$ columns of elements all zero. Then $A = |B|\,|D|$. Matrices of this kind occur frequently in algebraic research. The main use of the result is that we can state that if $|A| \neq 0$ then $|B| \neq 0$ and $|D| \neq 0$ and conversely if $|D| \neq 0$ and $|B| \neq 0$ then $|A| \neq 0$.

Elementary Properties of Determinants. — The computation of a determinant whose elements are numbers may be simplified to a considerable extent by the use of certain properties of determinants Suppose first that the rows of the matrix of a determinant are interchanged with the columns. Then the value of the determinant is unchanged. This law permits the restatement of any property given in terms of the roms of a determinant as a corresponding property in terms of columns. The row properties are the following:

If two rons of a determinant are interchanged, the determinant is changed in sign only

If a row of a determinant is multiplied by a number k the determinant is multiplied by k.

A determinant is not changed in value if a multiple of any one of its rows is added to another row.

If two rows of a determinant are proportional or one row consists of elements all zero, the value of the determinant is zero.

Let $(A, |B|$ and $|C|$ differ only in the ith row and suppose that every element of the ith row of C is the sum of the corresponding elements in the ith row of A and B. Then $|A| + |B| = |C|$.

The properties above — which, as explained. are applicable to both rows and columns — are not only useful for the computation of determinants but are also of iundamental importance in the theory of matrices.

Special Properties. — Determinants may be used to determine whether or not two polynomial equations in one variable have a solution in common. Let the equations be

$$f(x) = a_1x^n + a_2x^{n-1} + \cdots + a_{n+1} = 0$$
$$g(x) = b_1x^m + b_2x^{m-1} + \cdots + b_{m+1} = 0$$

Form the determinant of order $m + n + 2$ given by

$$D = \begin{vmatrix} A \\ B \end{vmatrix}$$

where A has $m + 1$ rows, B has $n + 1$ rows and we have the formulas

$$A = \begin{pmatrix} a_1a_2\cdots a_{n+1} & 0 & \cdots 0 \\ 0\ a_1\cdots a_n & a_{n+1}\cdots 0 \\ \cdots\cdots & \cdots & \cdots \\ 0\ 0\ \cdots & \cdots & \cdots a_{n+1} \end{pmatrix} \qquad B = \begin{pmatrix} b_1b_2\cdots b_{m+1} & 0 & \cdots 0 \\ 0\ b_1\cdots b_m & b_{m+1}\cdots 0 \\ \cdots\cdots & \cdots & \cdots \\ 0\ 0\ \cdots & \cdots & \cdots b_{m+1} \end{pmatrix}$$

The two equations will have a solution in common if and only if $D = 0$. For example let $f(x) = x^2 + x - 2$ and $g(x) = x - 1$. Then the expansions we have given may be used to show that

$$D = \begin{vmatrix} 1 & 1 & -2 & 0 & 0 \\ 0 & 1 & 1 & -2 & 0 \\ 0 & 0 & 1 & 1 & -2 \\ 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 \end{vmatrix} = -4\begin{vmatrix} 2 & 0 & -2 \\ 1 & -1 & 0 \\ 1 & 0 & -1 \end{vmatrix} = 0$$

and the equations have a solution in common. The result was due to James J. Sylvester and is called Sylvester's dialytic method of elimination.

Another topic connected with the theory of equations is the subject of alternants. An alternant is an n-rowed determinant

which is a function $d = d(x_1, \ldots, x_n)$ such that the interchange of any two of the variables changes the sign of d. The alternating function $f(x_1, \ldots, x_n) = (x_n - x_{n-1})(x_n - x_{n-2}) \ldots (x_2 - x_1)$ which was used in the definition of determinants is expressible as an alternant; namely,

$$f(x_1, \cdots, x_n) = \begin{vmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \cdots & x_2^{n-1} \\ \cdot & \cdot & \cdot & \cdots & \\ 1 & x_n & x_n^2 & \cdots & x_n^{n-1} \end{vmatrix}$$

and this determinant is called the Vandermonde determinant of order n. Every alternant with polynomial elements has the alternating function as a factor. The discriminant 6 of the equation $F(x) = (x - x_1)(x - x_2) \ldots (x - x_n) = 0$, whose roots are $x_1, \ldots, x_n$, is the square of the alternating function. The coefficients of δ are polynomials in the coefficients of $F(x)$ with integer coefficients. The importance of 6 lies in the fact that formulas for computing it in terms of the coefficients of $F(x)$ are known and $F(x) = 0$ has a multiple root if and only if $6 = 0$.

Symmetry and Skewness.—Symmetric and skew determinants are especially interesting. Since there may be symmetry with respect to a line or a point there are two kinds of determinants which possess symmetry. Those which are symmetric with respect to the centre are called centrosymmetric. The term "symmetric" is usually reserved for those determinants which are symmetric with respect to the main diagonal.

In a centrosymmetric determinant the $(n - r)$th row coincides with the rth row read in reverse order. Every centrosymmetric determinant of even order $2m$ is expressible as a product of two determinants each of order m. A determinant is said to be skew-centrosymmetric when every element is the negative of the element symmetrically placed with respect to the centre. Every skew-centrosymmetric determinant of even order is expressible as the difference of two squares.

A symmetric determinant $|A| = |a_{ij}|$ is defined by the property that $a_{ij} = a_{ji}$ for $i, j = 1, \ldots, n$. Determinants may be multiplied by the law for the product of matrices (*see* MATRIX) and so $A|^2 = |A|\,|A'| = |AA'|$, where A' is the result of interchanging rows and columns' in A. The product Ad' is symmetric and it follows that the square of every determinant is expressible as a symmetric determinant. The product $|A|\,|B|^2 = BAB'$ of any symmetric n-rowed determinant $|A|$ by the square of any n-rowed determinant B is expressible as the n-rowed symmetric determinant of the matrix product BAB'. It is also true that any power of a symmetric n-rowed determinant is expressible as a symmetric n-rowed determinant.

A determinant $|a_{ij}|$ is called a skew determinant if $a_{ij} = -a_{ji}$. The diagonal elements are then all zero. Every skew determinant of odd order is zero. A skew determinant of even order is the square of a polynomial in its elements.

The adjoint of a determinant $A = |a_{ij}|$ is the determinant $|d_{ij}|$ where d_{ji} is the cofactor of a_{ij}. Then $|d_{ij}| = |a_{ij}|^{n-1}$. The adjoint of a skew determinant of even order is again skew.

BIBLIOGRAPHY.—T. Muir, *The Theory of Determinants in the Historical Order of Development*, vol. i–iv (1906–20); A. A. Albert, *College Algebra* (1946); E. T. Browne, *Introduction to the Theory of Determinants* and *Matrices* (1958). (A. A. AT.)

DETERMINISM, the name given to the theory that all events, even moral choices, are completely determined by previously existing causes (Latin *determinare*, "to fix or settle"). opposed to indeterminism or free will. On this theory an agent cannot be held responsible in the indeterminist sense, according to which a man is responsible if and only if he could have still acted differently, everything before, including his character, being nhat it was. The indeterminist view is supported by the experience of remorse. It need not involve saying that our actions are not affected by causes. only that they are not completely determined by them. Determinists. however. have commonly claimed that their view is quite compatible with moral responsibility in any sense in which this is really needed for practical purposes. Even if determinism is true, it remains a fact that some actions have bad consequences and that most agents are in some degree influenced against an act by having its badness pointed out to them, so that ethical argument and blame will still be useful as decreasing the number of undesirable acts. Even punishment will have a point insofar as it prevents wrongdoing, though the indeterminist will rejoin that it is unjust unless the action punished is free. It has also been argued by determinists that a rational action must be determined by motives and that. if a man's wrong action is not due to something bad in his nature, he is not to blame for it, so that it is indeterminism. not determinism, that is incompatible with responsibility. The indeterminist would usually reply that a man's nature is not something there already. prior to and apart from his free actions. and that propositions about a man's character are simply generalizations about the kinds of free actions that he performs. He cannot avoid admitting that a man causes his free actions in the sense of doing them, but he would deny that they could even conceivably be predicted n-ith certainty from events which had occurred in the past together with properties of the agent and of his environment existing prior to the action.

There is a lack of arguments outside ethics to settle the issue, and in the absence of a generally accepted philosophical proof of universal causation it would seem best to accept indeterminism if this is really entailed by ethics. For we know some ethical propositions as well as we know anything. It may be doubted however whether determinism need involve more than a minor modification of ethics, and a world in which everything is causally explicable would seem more rational.

By the second half of the 20th century indeterminism had come to be the more popular doctrine among philosophers and even among physical scientists, but the issue remained open and was clearly not to be settled in the sphere of science. It has been argued also that determinism is incompatible with freedom only if we introduce illegitimately into causation the notion of compulsion over and above regular sequence.

The question raises great theological difficulties: theologians have often argued that, if determinism be true, the problem of evil is insoluble because God would then be responsible for sin; but others (less numerous) have deduced determinism from the omnipotence and omniscience of God.

See ETHICS. HISTORY OF; FREE WILL; PREDESTINATION. *See* also references under "Determinism" in the Index volume.

(A. C. E.)

DETMOLD, a town of Germany which after partition of the nation following World War II was included in the Land of North Rhine-Westphalia, Federal Republic of Germany. It is situated on the east slope of the Teutoburger Wald and on the Werre river, *30* km. *(18.6* mi.) E.S.E. of Bielefeld by road. Pop. *(1959* est.) *31.080.*

Detmold was the capital of the former Land of Lippe. The Renaissance château of the princes of Lippe-Detmold *(1550)* is an imposing building in the town centre, while at the entrance to the large park on the south is the New palace (1708–18; enlarged 1850). Detmold possesses a natural history museum, an opera house. the North West German Music academy, trade schools for painters and cabinetmakers, a *Land* library and the Federal Institute for Grain Research. The furniture industry is predominant, and the town is also a well-known tourist centre.

On the Grotenburg. 5 km. (3 mi.) S.W., stands Ernst von Bandel's colossal statue of Xrminius (*q.v.*), or Hermann, the leader of the Cherusci who defeated the Roman legions in A.D. 9. Detmold (Thiatmellii was in *783* the scene of a conflict between the Saxons and the troops of Charlemagne. In World War II Detmold was captured by the Allies in April *1945.*

DETONATOR, a device employing certain sensitive explosives, called initiating or primary, to cause explosion of other less sensitive materials, called high explosives. Mercuric fulminate (*q.v.*), lead azide and some organic diazo derivatives are used in the initiating charge of the detonators.

This charge is usually followed by a larger charge of a sensitive high explosive, such as tetryl or PETN (*q.v.;* pentaerythritol tetranitratej to enhance the initiating action of a detonator without employing a large quantity of a hazardous primary explosive. The

charge of a detonator is usually contained in a thin-walled copper or aluminum capsule sealed against moisture.

Detonators are manufactured in various sizes, numbered 1 to 8, to indicate the strength of the charge they contain. They may be exploded by heating electrically a thin bridge wire (of electric detonators) or by igniting the initiating charge (of blasting caps) by a fuze.

In some military fuzes the detonator is exploded by the action of a primer. Each high explosive requires a certain minimum size of detonator for a reliable initiation. In general, the less sensitive to percussion an explosive is (*i.e.*, the safer it is to handle), the stronger is the detonator required to explode it. See EXPLOSIVES; *see* also references under "Detonator" in the Index volume.

(G. B. K.)

DETROIT, a city of southeastern Michigan, U.S., seat of Wayne county, is 267 mi. E. and slightly north of Chicago. It is on the Detroit river, connecting Lake St. Clair and Lake Erie and a link in the St. Lawrence seaway (*q.v.*). The course of the river puts Canada to the south; directly across from the city of Detroit, in Ontario, is Windsor (*q.v.*), a chief gateway to Canada. Traffic to Canada is facilitated by the Ambassador bridge, a vehicular tunnel, a railroad tunnel and two railroad-car ferries. The mean average temperature is 49.3" F. and the average rainfall is approximately 31.03 in.

History.— Detroit was founded by Xntoine de la Mothe Cadillac, who was seeking a strategic location for a new post to protect and encourage the French fur trade and to advance his own economic interests. On July 24. 1701, he landed near the present site of the Veterans' Memorial building with 50 soldiers, an equal number of voyageurs and settlers and about 100 friendly Indians. A palisaded enclosure, about 200 ft. square. was erected and named Fort Pontchartrain in honour of Cadillac's patron. Count Pontchartrain, one of Louis XIV's ministers. The civilian community within the walls was called the Ville d'Etroit ("town of the strait"), but in time the name was shortened and anglicized to Detroit. Despite his success. Cadillac was plagued by enemies in Quebec and Paris. To placate them the king removed Cadillac from Detroit in 1710 and appointed him governor of Louisiana.

In the next half century Detroit grew in size and importance. and was eyed enviously by the British. On Nov. 29. 1760. during the French and Indian War, it was surrendered without resistance to a British force under the command of the famous ranger Major Robert Rogers. Some of France's Indian allies, notably the Ottawas under Chief Pontiac. disliked and distrusted the English. In May 1763 Pontiac devised a plan to seize the fort through a ruse, but Major Henry Gladwin, commandant, learned of the plan and foiled the conspiracy. In the treaty of peace, France ceded her claims to the territory east of the Mississippi, and England came into undisputed possession of the area.

At the close of the American Revolution, Great Britain ceded the lands west of the Alleghenies to the U.S., but, in violation of the treaty, refused to withdraw troops from Detroit and various other posts. Since England then had the friendship of the Indians. it kept stirring them up against the Americans migrating to the west. After a series of campaigns against the Indians culminating in the battle of Fallen Timbers and the Treaty of Greenville, the Jay treaty provided for the evacuation of the British posts. On July 11, 1796, Capt. Moses Porter arrived at Detroit with 65 soldiers to receive the surrender.

In Jan. 1802 Detroit was incorporated as a town with a board of trustees as the governing body. Immigration into the surrounding region was so great that the federal government opened a land office in the city which did a brisk business. In 1805, Michigan Territory (later to be Michigan. Wisconsin and a part of Minnesota) was created by congress and placed under a governor and judges, with Detroit as the capital. Gen. William Hull was appointed governor; Augustus B. Woodward and Frederick Bates, judges; and Stanley Grismold, secretary.

On June 11. 1805, the whole town was swept by a devastating fire. Every building except one was burned to the ground, but miraculously no lives were lost and only two persons were injured. When the new territorial officials arrived later in June, they saw only blackened ruins. Under Woodward's inspiration and leadership, a new, larger city was soon rebuilt, his plan being. based on a design of Pierre Charles l'Enfant who had laid out Washington. D.C. There were squares, circles and radial streets, but as the city spread beyond its original boundaries the plan was not extended In the second half of the 20th century, therefore, Woodward's plan existed only in the downtown area. Each citizen whose home was burned was awarded a larger piece of land than he had previously held. and the city became less compact. The Michigan Territory government revoked the charter of 1802; a new charter in 1806 provided a mayor appointed by the governor and an elected council of two houses with three members each.

Soon after the outbreak of the War of 1812. General Hull surrendered the town to the British without a defense. The British held Detroit until Sept. 28, 1813. when Lieut (later Commodore) Oliver Perry's victory in the battle of Lake Erie (Sept. 10) made further occupation untenable. Back in U.S. hands, Detroit became the base for Gen. William Henry Harrison's invasion of Canada to the Thames (Moraviantown).

Michigan became a state in 1837 and the capital remained at Detroit until 1847 when it was moved to the new town of Lansing. The change in the capital in no way hindered Detroit's progress. The city emerged from the status of a frontier post soon after the War of 1812. In 1815 it was reincorporated as a city, with a board of trustees. who chose their own president, as the governing body In 1824 a new charter provided for a mayor and a council of aldermen elected by wards. With variations this form of government prevailed until a new charter in 1918 provided for a nonpartisan mayor and a council of nine, the latter being elected at large The same act also provided for similar changes in the school system of the city. The old board of education. composed of inspectors elected by wards on party tickets, was supplanted by a new board of seven members elected at large for staggered terms and without a party designation.

In 1817 the first newspaper, the *Detroit Gazette,* was published, and in 1818 the "Walk-in-the-Water," the first steamboat on the Great Lakes. began regular runs between Buffalo and Detroit. Soon thereafter other lines appeared, and shipbuilding and chandlering became profitable enterprises. Forwarding and commission houses also flourished. By mid-century, although not the queen of the Great Lakes, Detroit was a prominent member of the queen's court. The peak of water transportation was reached in the 1880s. Then gradual decline set in until the St. Lawrence seaway project of the mid-20th century revived interest in the port of Detroit. not only for domestic but for foreign commerce as well.

In the 1830s several railroads were incorporated and construction started from Detroit. A decade later a number of miles of track stretched into the hinterland. In 1852 through-rail connection was made with Chicago when the Michigan Central completed its line. By railroad and water. grain and other produce poured into Detroit for reprocessing and forwarding to other parts of the nation or to Europe. By mid-century, Detroit was one of the recognized flour-milling centres of the United States with lively transactions on the Board of Trade.

Before the Civil War the city was an important station on the Underground Railroad, and through it hundreds of runaway slaves passed to freedom in Canada. During the war Detroit furnished about 6,000 men. money, provisions and supplies of all kinds. It was not immune from the draft and anti-Negro riots that spread throughout the north in 1863. but the disturbances were not so virulent as in other cities. Detroit was also a centre of a plot by the Confederacy to free prisoners of war. In Sept. 1864 southern agents and sympathizers seized the "Philo H. Parsons" and sailed for Johnson's Island to free the prisoners there. Before reaching the island, however, the scheme fell apart, and the conspirators took refuge in Canada.

In the 35 years following the Civil War, Detroit changed from its earlier role as a country merchant to that of industrial magnate. Iron and steel, foundry, railroad car, boot and shoe. stove. wheel and axle. chemical and pharmaceutical industries all flourished by the end of the century. In 1896, Charles B. King drove a horseless carriage through the streets of Detroit, and the city's automotive

industry was born. A new era dawned for Detroit which was to make it the automobile capital of the world. Soon thereafter Henry Ford and other men who were to become giants in the industry were producing automobiles, and by the second decade of the 20th century the name Detroit was synonymous with the word "automobile." The booming industry acted as a magnet which drew increasing numbers of people to the city, especially after Ford's announcement in 1914 of a $5-a-day minimum wage.

Detroit furnished its share of men during the Spanish-American War and World War I (about 65,000 in the latter). During World War I it was also noted for its contributions of the materials of war, and during World War II the city was popularly nicknamed the "Arsenal of Democracy."

Although Detroit did not become a one-industry city, the manufacture of automobiles dominated its economy, and after World Wars I and II the city suffered from normal recessions. The depression of the 1930s struck Detroit particularly hard. There was a gradual recovery, but in 1936 the average wage of the auto workers was only 76 cents per hour. In Feb. 1937 sit-down strikes against General Motors were settled by recognition of the United Auto Workers as the bargaining agent. Ford did not recognize the U.A.W. until 1941.

Detroit is more than a mere industrial complex; its citizens have long been interested in sponsoring education and the arts. In 1817, through the efforts of Woodward, Gov. Lewis Cass, Father Gabriel Richard and Rev. John Montieth the territorial legislature created the University of Michigania in Detroit. In reality the university was a sort of public school system culminating in an academy. It was not a successful venture, however, and in 1821 the legislature repealed the act (see MICHIGAN: Education).

Until 1842, Detroit was a school district under territorial and state control. In 1842 the legislature made the city an autonomous school district with its own board of education and the right to establish and control its own school system. Graded elementary schools were immediately organized. but not until 1858 was a high school added. A normal school for teacher training, the Detroit Teachers college, was started in 1881. In 1917 the board of education established a junior college which in 1923 became a four-year school, the College of the City of Detroit. Meanwhile, the board acquired a medical school (the privately owned Detroit College of Medicine begun in 1868), a law school and a college of pharmacy, the last two created by the board. In 1933 a reorganization of the administration of all the colleges of the city resulted in Wayne university, which remained under the board of education until July 1956. when the state assumed control and the name was changed to Wayne State university. In addition to public schools, private and parochial schools helped meet the demand for education from the elementary to the college level.

Numerous cultural and social societies, such as the Lyceum, Mechanics' society, Young Men's society, Athenaeum, fraternal groups, musical, charitable and religious societies, reading clubs, and scientific organizations contributed to the intellectual life of the citizens. Some of these established libraries for members' use, and when the organization disbanded the books were given to the Detroit Public library. which was started in 1865. With the great influx of immigrants in the 70 years after 1850, numerous cultural and social societies of the various nationality groups were started. some of which existed into the second half of the 20th century. The city also officially sponsored such projects as the Detroit Institute of Arts. Detroit Historical museum and Detroit Zoological park. In 1920 the city created a department of recreation, which became a recognized leader in public recreation.

Population. — In 1810 the population of Detroit was 1.650. By 1820 it had declined slightly to 1.442. partly due to the War of 1812. The opening of the Erie canal. growing commerce on the Great Lakes and development of the railroads helped increase the population to 21.019 by 1850. The importance of the city continued to draw increasing numbers of people, so that in 1860 the population had jumped to 45,516. In 1870. with a population of 79.577. it was the 18th largest U.S. city, and by 1900 the population had reached 285.704.

The development of the automobile and other industries after 1900 was the greatest stimulant in Detroit's rapid increase in population. By 1910, the population was 465,766, and in 1920, with 993.678, it passed St, Louis to become the nation's fourth largest city, a rank it held until 1950 when it was passed by Los Angeles. The population of the city in 1960 was 1,670,144; of the standard metropolitan statistical area (Macomb, Oakland and Wayne counties) 3,762,360. Other cities in the metropolitan area include Dearborn, East Detroit. Ferndale. Hamtramck, Highland Park, Lincoln Park, Pontiac, Royal Oak and Wyandotte (*qq.v.*).

From the early part of the 19th century Detroit was a cosmopolitan community. French, Canadians and Americans were prominent. In 1850, 47% of the population was of foreign birth. The Irish and the Germans predominated, respectively, making up more than 50% of the foreign born. Although an increasing number of foreigners moved to Detroit before the immigration laws of 1921 and 1924, the percentage of total foreign-born population gradually declined, and the composition of the foreign born also changed. In 1880 those of German birth alone constituted 20.4% of the total population in the city, while the Irish made up only 5.8%. By 1900 the foreign born constituted about 34% of the population. Russians, Austrians and Hungarians began arriving in considerable numbers between 1900 and 1910, and in 1910 made up 8% of the total population, ranking behind the Germans (9.6%) and the Canadians (9%). The greatest Polish immigration came in the next decade; by 1920 they constituted 6% of the population. In 1920 the foreign born were 29% of the whole population. The percentage dropped to about 26% in 1930, about 20% in 1940 and about 17% in 1950. By 1950 most of the foreign born were older people. with less than 20% under 35 years of age. After the immigration laws of the 1920s, the great migration from the south set in, and continued in the second half of the 20th century.

Administration and Finance. — Detroit has a mayor-council, nonpartisan type of government. The charter adopted in 1918. which abolished the ward system, provided for the nomination and election of the mayor. city clerk, city treasurer. council and board of education, without party designations. The mayor has broad powers to appoint most of the administrative officials and commissions: board of assessors, board of health, city planning, public lighting, water, street railway, fire, public welfare, police and other commissions. The common council is composed of nine members elected at large. In the primary elections the 18 highest candidates receive the nomination, and in the regular election the nine receiving the highest number of votes are declared elected. The councilman-elect with the most votes automatically becomes president of the council and acting mayor in the absence of the mayor. The new nonpartisan government took office in Jan. 1919. Originally the officials were chosen for two-year terms, but in 1953 an amendment to the charter lengthened the terms to four years. The charter also ,provides for recall, and in 1930, at a special election, Mayor Charles Bowles was recalled, the first mayor of a major U.S. city to be recalled.

The chief source of revenue for Detroit is the real estate tax. It was one of the hardest hit U.S. cities in the depression of the 1930s; by early 1932 thousands of unemployed were on public welfare. In Feb. 1933 Governor Comstock proclaimed the Michigan bank holiday and many Detroit banks never reopened. In April of that year the city issued script to meet obligations. Although the script was receivable at face value in payment of city taxes and other debts, the public market value fluctuated. Eventually all script was retired under a refunding program.

Housing and Planning. — In 1934 when the federal housing program began. Detroit sponsored slum clearance and low-cost housing projects, which continued into the second half of the 20th century, notable examples being the Edward J. Jeffries, Brewster, Parkside and Conant Gardens projects.

After World War II municipal planning included a new civic centre on a 58.3 ac. river-front site. Many old and unsightly buildings were demolished, and in 1950 the first of the new civic buildings was completed, the Veterans' Memorial. Other buildings include a combined city-county building, replacing the former city hall and the old court house; the Henry and Edsel Ford

auditorium where the Detroit symphony orchestra plays; and the Cobo Convention and Exhibit building. At the time of condemnation of the old area, a famous seafarers' mission, Mariners' Church, was moved several blocks and kept not only for religious services but as a historical shrine.

Expressways and Transit. — After World War II two limited access expressways were built to accommodate traffic pouring into the city from the outlying industrial and residential communities. The north-south John Lodge expressway, on the west side, connects with the James Couzens highway near the northwestern city limits and runs south to the Detroit river. The east-west expressway, the Edsel Ford. extends from the eastern side of the city westward to the Industrial expressway at the western limits. A complex interchange where the Lodge and Ford expressways meet allows transfer from one to the other. Davison, an important east-west artery on the northside, is also depressed through the more congested traffic areas. Other streets, such as Woodward, Gratiot and Grand River. were widened, with over- or underpasses at important cross streets.

Dissatisfied with privately owned streetcar lines as early as the 1890s, Detroit in 1913 voted for a change in the city charter to allow for municipal ownership, but it nas not until 1921 that the first such line was operated. The bitter feud betaeen the city and the private lines ended when the city purchased the lines in Jan. 1929. In the late 1920s, the city began operation of a fev motorbuses. but again met with private competition. the Detroit Motor Bus company, the lines of which nere taken over by the city in Jan 1932 and brought under complete municipal ownership. After 1950 streetcars were discontinued and replaced by buses, although one or two trackless trolleys still operated The Detroit Street railway, under control of a commission, is organized along the lines of a private company, designed to be self-supporting with no appropriations from the city budget, and paying taxes as though it were a private corporation. This system was not very successful and the D.S.R., despite rising fares; operated mostly in the red. Various proposals submitted to the voters to relieve it of payment of taxes were defeated.

Buildings. — Most of the city's largest office buildings, hotels, department stores and banks are in the downtown area. The tallest is the 47-story Penobscot building, and the largest office building outside downtown is the General Motors building in the New Center area at Grand boulevard and Second avenue. Another large office building in the same neighbourhood is the Fisher building. The General Motors. Fisher and New Center buildings (a third but smaller office building) are connected by underground pedestrian tunnels.

To accommodate the growing metropolitan area, two large out-city shopping centres, Northland and Eastland, were built by private capital. They are laid out with co-ordinated architecture, flower beds, fountains and adequate parking space. Many of the downtown stores have branches at these centres. To meet the parking needs downtown. where curb parking is prohibited, the city built two large underground parking garages — one under Grand Circus park and another under the Ford auditorium, which together accommodate about 2,000 cars.

Industry, Commerce, Transportation, Communications and Welfare. — In the early days, fur was the only trading commodity. This trade continued to be of prime importance until after the War of 1812 when a gradual decline set in. A few gristmills, soap factories and distilleries, making products chiefly for local use; were in existence by 1810, with a total annual volume of approximately $2 5,000. The growth and development of water transportation after the first quarter of the 19th century made Detroit one of the large shipbuilding cities on the Great Lakes. By mid-19th century it was also a recognized flour and grain centre, and manufactured steam engines and other machinery. At the outbreak of the Civil War, the total annual volume of business was over $600,000. By 1900, Detroit had a diversity of industries — foundry and machine shops. druggist preparations! stoves and furnaces, carriages, woodcrafts, meat packing and cigar making.

The invention of the automobile was, perhaps, the greatest industrial stimulant that Detroit experienced. Charles King's first automobile in 1896 provoked considerable excitement, and other men immediately became interested. Pioneers in the field were W. C. Durant, Walter P. Chrysler, Henry Ford (*qq.v.*), Ransom Olds, Henry Leland and the Dodge brothers. Although many automobiles were made elsewhere, the industry centred in Detroit. As early as 1904, with only 0.4% of the U.S. population, Detroit made 20% of the country's automotive products. By the second half of the 20th century the big three (Ford, General Motors and Chrysler) had greatly decentralized production.

Detroit is more than an automobile city, however, even though at mid-20th century it still made one-half of the products of the country's largest industry. About 1920 Detroit became a steel centre. The chemical business also prospered after the discovery of a layer of rock salt 34 ft. thick. 1,000 ft. below the surface. The Detroit Rock Salt mine has approximately 60 mi. of tunnels with fully mechanized equipment and transportation. In the second half of the 20th century Detroit ranked at or near the top in U.S. production of pharmaceuticals, adding machines and calculators, foundry products, machine-tool accessories, paints and heavy chemicals. Other important industries include light machinery, metal stampings, hardware. wirework, machine-shop products, rubber products and electrical household appliances. The Chrysler corporation is the city's largest single employer.

During World War II more prime contracts for war materials were awarded to Detroit area plants than to any other region in the U.S. Reconversion to peacetime production was accomplished without great disruption. Government contracts: especially for missile work, continued after World War II.

Because of Detroit's location on the Great Lakes, the Michigan customs district ranked third of U.S. ports in foreign trade at mid-20th century. Exports totaled about $700,000,000 a year. Imports included about 300 various items used in automobile production. Detroit is a port of call for cargo boats and ocean-going freighters operating on the Great Lakes.

Nine major railroad systems serve the city. Three airports, City, Metropolitan and Willow Run, serve more than a dozen private passenger and freight-carrying air lines. Motor-truck lines also facilitate intra- and interstate transportation.

There were in the late 1950s 3 daily papers in Detroit.. the *Free Press, News* and *Times;* 7 Detroit and 6 area AM radio stations; and 16 Detroit and area FM stations. There were five TV stations (one a UHF).

Industrial and civic groups have long co-operated on various community projects. In the 1880s the Associated charities was organized to centralize aid to the unfortunate. In the 20th century the United foundation permitted all agencies that solicit for charity and similar purposes to concentrate their efforts into one sustained drive for funds, the Torch drive.

Education and Culture. — The public school system, begun in 1842, had over 250,000 students in the second half of the 20th century. Its physical facilities include trade schools as well as the usual elementary, junior high and high schools. The great influx of rural people, particularly from the south, placed a great strain on the accommodations as well as on the curriculum. A citizen's committee completed in 1958 a survey of school needs and suggestions for reform.

Parochial and private schools had over 80.000 students. Higher education is provided for by Wayne State university and by the University of Detroit (Roman Catholic, established 1877); Marygrove college (chartered 1910) and Mercy college (established 1941), both Roman Catholic colleges for women; Highland Park Junior college in Highland Park (established 1918) and Henry Ford Community college in Dearborn (founded 1938). both public junior colleges. The University of Michigan has a branch campus at Fairlane, the old Ford estate in Dearborn. Wayne State university and the University of Michigan co-operate in an adult non-credit educational program and jointly operate the Institute of Labor and Industrial Relations, located on Wayne's campus.

Several wealthy individuals have done much to contribute to the cultural development of Detroit. In 1927 George and Ellen Booth created the Cranbrook foundation, and in 1928 the Cranbrook Academy of Arts was opened on their estate, Cranbrook, in sub-

urban Bloomfield Hills. In 1930 the Cranbrook Institute of Science was founded. Such renowned men as Eliel Saarinen, the architect, and Carl Milles, the sculptor, have been associated with Cranbrook. Also at Cranbrook are the Cranbrook School for Boys, the Kingswood School for Girls, and the Brookside School for Young Children. In 1926 Sebastian S. Kresge established a $25,000,000 foundation for education, religion and charity. A Detroit beneficiary is the Kresge Science library of Wayne State university. In 1929 Henry Ford opened Greenfield village and the Edison institute as a tribute to his old friend Thomas A. Edison and because of his own interest in preserving the history of the past. In 1936 the Ford foundation was established and has done much to aid and encourage cultural, social and economic advancement. The will of Lizzie Merrill Palmer provided for a school in 1920, which accepts advanced students from co-operating colleges all over the U.S. for special work in human growth and child development. It has pioneered also in home economics.

Bordering Wayne State university is the Cultural centre. Here are located the main public library, the Detroit Institute of Arts, the Detroit Historical museum, the Horace H. Rackham Educational memorial and the Children's museum. The municipally owned Institute of Arts houses paintings, sculptures and decorative arts from prehistoric to modern times. The Detroit Historical museum preserves the city's history in physical survivals. In cooperation with the Detroit Historical society it also sponsors a large number of historical projects. The Children's museum contains mobile and permanent exhibits to supplement the curriculum of the public schools. The Rackham Educational memorial is the Detroit headquarters for the University of Michigan's extension services, and the home of the Engineering Society of Detroit.

Since 1913 Detroiters have maintained a symphohy orchestra, by private subscription and benefits. which gives 20 regular concerts a season in addition to a series of "Family Concerts" and "Children's Concerts." In 1928, the Detroit Civic theatre. with Jessie Bonstelle as director, was begun as a community venture. Its playhouse, named after its director. was later taken over by Wayne State university for its drama projects. Because of the large number of foreign born or persons of foreign extraction an International institute has been organized, and in addition to other activities it maintains a program of folk music and dancing.

Detroit is also a city of churches, there being more than 1,000 of all denominations. St. Anne's Catholic church is the oldest, dating from the settlement in 1701. The first Protestant society, interdenominational, was organized in 1820, and in 1825 became the First Presbyterian church. All other main Protestant faiths are represented in Detroit. Temple Beth-El, the first Jewish society. was organized in 1850.

Parks **and** Recreation.— Detroit and the metropolitan area is well supplied with parks and recreational facilities. In the second half of the 20th century there were 46 parks in the city covering an area of approximately 3,400 ac. Among the larger ones that offer a variety of entertainment are Belle Isle and Palmer parks. Belle Isle, a wooded, 1,000-ac. island in the Detroit river, was acquired by the city in 1879. Noted for its beautiful drives, formal rose gardens, carillon tower and fountains, it has riding stables and bridle paths, a bathing beach, a small zoo and a children's zoo, a botanical conservatory, boating and picnic areas. Palmer park, on the north side of the city, has no waterfront, but offers ice skating in season, golf, riding, tennis; archery and picnic grounds. Other parks in the metropolitan region (under county or state jurisdiction) which offer similar diversions, including swimming and skiing, are the Rouge, Kensington, Lola valley, Metropolitan beach and Plymouth.

Spectator sports are popular. and Detroit is the home of several professional teams: the Tigers (baseball), Lions (football), Red Wings (ice hockey) and Pistons (basketball). Briggs and Olympia stadiums are the scenes of most professional sporting events. Throughout the city and metropolitan area there are a large number of public and private golf courses. Bois Blanc (Bob Lo) Island on the Canadian side of the Detroit river offers typical amusement-park entertainment. Great Lakes cruises and various excursion trips are available during the summer months.

DETROIT RIVER, long an artery for Great Lakes shipping and, with the opening of the St. Lawrence seaway in 1959, an important link in the seaway system, connects Lake Erie with Lake St. Clair and, through the St. Clair river, with Lake Huron. About 32 mi. long, it forms a part of the U.S.-Canadian boundary between southeastern Michigan and southwestern Ontario. The major cities on the river are Detroit, Mich., on the north bank and, across the river, Windsor, Ont., on the south. The river channel, which formerly provided a minimum depth of 21 ft. for vessels sailing up to Lake Huron and 25 ft. for those sailing down to Lake Erie, was deepened to 27 ft. to accommodate seaway shipping. *See* GREAT LAKES. THE; SAINT LAWRENCE SEAWAY.

DETTINGEN, BATTLE OF, an engagement in the War of the Austrian Succession (*q.v.*), fought on June 27, 1743. near Dettingen on the Main in Bavaria (10 mi. N.W. of Aschaffenburg) and resulting in a victory for the allied Anglo-Hanoverian and Austrian forces under George II of England, the 2nd earl of Stair (John Dalrymple) and the duke of Arenberg (Leopold Philip) over French forces under the marshal duc de Noailles (Adrien Maurice) and the duc de Gramont (Antoine Adrien Charles). The superior strategy of Noailles had caught 40,000 allied troops between the Spessart hills and the Main river: Gramont with some 30.000 men was blocking the route to Hanau at Dettingen, while Noailles advanced on the allied rear from Aschaffenburg. The allies were thus forced to fight to continue their retreat. Gramont, however, unwisely took the initiative, and his attacking cavalry and infantry were roughly handled by the allies. The confined terrain gave no scope for the exercise of tactical skill: and the allies' success was mainly due to the steady bearing of the British and Austrian infantry. Suffering some 6,000 casualties and having inflicted about 2,500, the French withdrew across the Main; the allies marched on to Hanau. The day is famous as the last time that a British monarch personally led his troops in battle.

(D. M. *Sc.)*

DEUCALION, in Greek legend, son of Prometheus, king of Phthia in Thessaly, husband of Pyrrha and father of Hellen, the mythical ancestor of the Hellenic race. When Zeus had resolved to destroy all mankind by a flood. Deucalion constructed a boat in which he landed on Mt. Parnassus with his wife.

Having offered sacrifice and inquired how to renew the human race, they were ordered to cast behind them the "bones of their mother"; that is, the stones from the hillside. Those thrown by Deucalion became men; those thrown by Pyrrha, women. Other versions of the legend made Deucalion land in other mountainous parts of northern Greece. Alternatively the myth of a flood was linked by the Greeks with Ogyges or Ogygos. a primeval king of Boeotia. He, however, remains an entirely shadowy figure. See also FLOOD (IN RELIGION AND MYTH). (H. W. PA.)

DEURNE, an eastern suburb of Antwerp, Belg.. 3 km. (2 mi.) from the city, is situated on the arterial road to Likge. Pop. (1955 est.) 61,715. Deurne, formerly agricultural, is now mainly residential, though there are industries. The chief of these is the manufacture of bottle tops. the factory being one of the largest in Europe. At Deurne is the airport for Antwerp. Burned down during the Norman conquest (836), Deurne was later owned by the bishops of Likge and dukes of Brabant. During the 16th century rich merchants from Antwerp settled there in their newly built ***hofs*** or castles and the little town was temporarily prosperous. It was almost wiped out by Spanish troops in 1586 during the wars of religion. Merchants and bankers from Antwerp brought prosperity again in the 18th century, and five castles built then survive. Cnder French rule from 1795 to 1814, Deurne became part of the United Netherlands in 1815 and of Belgium in 1830.

(R. M. AN.)

DEUS, JOÃO DE (1830–1896), eminent Portuguese Roman-

tic poet, was born at Messines, in Algarve, on March 8, 1830. He graduated in the faculty of law at the University of Coimbra in 1859, having taken ten years to complete an ordinary course of five. While an undergraduate he spent most of his time in writing verses, which circulated in manuscript. He had a versatile talent and a gift for improvisation. Many of his short poems were declaimed to a small group of friends. accompanied by a guitar. This explains in part the musical quality and the sprightly rhythm of his poems. which range from satires to lyrics. in simple or elaborate forms. He never cared much about the publication of his own poems and the first to be printed were *Pomba* (1851) and A *Lata* (1860) in an edition organized by his friends.

After a brief career at the bar, João de Deus left Coimbra for Beja to become the editor of *O Bejense* (1862–64) and the *Folha* do *Sul* (1866). Constantly in financial difficulties, he moved to Lisbon, where he was forced to take menial jobs. His friends tried to assist him and in 1869 succeeded in having him elected as liberal deputy for the constituency of Silves. But João de Deus was a man of dour Catonian rectitude and promptly renounced his mandate. This attitude won him as much popularity as his verse. which had appeared in book form the previous year in a collection *(Flores* do *Campo)* compiled by José António Garcia Blanco, who ruched a new series to the press in 1869. At about this time, João de Deus noticed the old-fashioned primers in use at the Portuguese schools and devoted his attention to educational problems. writing the *Cartilha Maternal* (1876). which was officially approved in 1888. Despite his modesty he was by now a famous man and the first comprehensive edition of his poems, including the *Folhas soltas* (1876), was published by Teofilo Braga in 1893 (*Campo de* Mores) and reprinted in an enlarged version in 1896. soon after his death in Lisbon on Jan. 11.

Publicly acclaimed in 1895 as the greatest Portuguese poet of his generation. João de Deus was widely read and greatly admired in the first quarter of the 20th century. He is mainly appreciated for the directness of his imagery. which is visual rather than aural, and for his tender sincerity and simplicity in the expression of love. By combining the lyrical tradition of the old medieval songs with the more refined manner of the Renaissance he succeeds in being natural and unrhetorical. In some of his best works ("Marina," "Adeus," "Descalça," "Vida") he conceals eroticism under a delicately expressed religious ideal in which woman is regarded as the supreme power of creation. Lacking deep intellectual interests. he was confined to a limited number of themes and could not avoid a certain monotony in form and content. Among his contemporaries he had the merit of pruning the excesses of romanticism and of coining a new and more expressive poetic language.

See "O lirismo de João de Deus" in Vitorino Nemésio, *Sob os signos de agora* (1932). (L. DE S. **K.**)

DEUSDEDIT, SAINT (d. 618), pope from 615 to 618, sometimes styled ADEODATUS I, was a Roman, the son of a subdeacon. Very little is known of his pontificate, which began in Oct. 615 and witnessed an unsuccessful resumption of the Byzantine war against the Lombards in Italy. Reversing the policy of Gregory I and Boniface IV, Deusdedit favoured the secular clergy rather than monks. Rome experienced an earthquake and pestilence in 618, and in November the pope died. His feast day is Nov. 8. (A. G. BI.)

DEUTERIUM AND TRITIUM, sometimes described as forms of "heavy hydrogen," are the isotopes of hydrogen of approximate atomic weights 2 and 3; their nuclei have double and triple, respectively. the mass of the nucleus of ordinary hydrogen. The hydrogen bomb. with its uncontrolled thermonuclear reaction, exploits the nuclear properties of deuterium and tritium; the explosion represents the collision and fusion of the nuclei. Should a method be found of controlling this process of fusion, as was done with the fission process of the earlier atomic bomb. the raw material for a practically unlimited supply of energy would be available in the hydrogen content of water.

Deuterium is a stable atomic species found in natural hydrogen compounds (water being the most abundant) to the extent of 0.014% to 0.015%. Tritium is a radioactive species emitting negative beta particles of 19,000 electron volts energy and having a half life of 12.5 years; it occurs in natural water with an abundance of 10^{-18} of that of natural hydrogen. The names, symbols and some atomic constants of the three hydrogens and the neutron are given in Table I.

TABLE I.— Atomic Constants of Neutron and Hydrogens

Name	Symbol	Atomic weight (physical scale)	Nuclear spin	Nuclear magnetic moment*
Neutron	n^1	1.008938	½	−1.9135
Protium	H or H^1	1.008128	½	2.7926
Deuterium	D or H^2	2.014719	1	0.8576
Tritium	T or H^3	3.01703	½	2.9795

*In units of nuclear Bohr magnetons $\left(=\frac{eh}{4\pi M_{HC}}\right)$.

Deuterium was discovered (1931) by H. C. Urey with the help of F. G. Brickwedde and G. M. Murphy. Urey. using the third law of thermodynamics and the Debye theory of the solid state, predicted a difference in vapour pressures of H_2 and HD and thus the possibility of separating these substances by distillation of liquid hydrogen. The deuterium was detected in the residue of a distillation of liquid hydrogen by its atomic spectrum. E. Rutherford. with M. L. Oliphant and P. Hartack (1934), discovered tritium by bombarding deuterium with high-energy deuterons,

$$D^2+D^2=H^1+T^3 \qquad (1)$$

W. F. Libby and A. V. Grosse showed that it is present in natural water. Neutrons produced by the action of cosmic rays probably produce this tritium by reacting with nitrogen in the high atmosphere,

$$N^{14}+n^1=C^{12}+T^3 \qquad (2)$$

Deuterium was first prepared in pure form by G. N. Lewis using the electrolytic method of concentration discovered by E. W. Washburn. When a water solution of an electrolyte (NaOH usually) is electrolyzed, the hydrogen produced contains a smaller fraction of deuterium than the water and hence deuterium is concentrated in the residue. Very nearly pure deuterium oxide (heavy water! is secured when the residue is reduced to $\frac{1}{100.000}$ of the original water. This method of preparation was used before World War II for the commercial preparation of D_2O and later in Norway for the large-scale preparation.

During the war other methods for the preparation of D_2O were devised and subsequently used to produce large quantities of this substance. These methods depend upon the substantial differences in chemical and physical properties of the compounds of protium and deuterium. F. G. Brickwedde used the distillation of liquid hydrogen to produce hydrogen deuteride (HD) and studied its properties *(see* below).

Tritium is produced most effectively by the nuclear reaction between Li^6 and neutrons from nuclear fission reactors; *i.e.*,

$$Li^6+n^1=He^4+T^3 \qquad (3)$$

The compounds of the three hydrogen isotopes differ quantitatively in their physical properties though they are very similar to each other qualitatively. This is shown by the physical propertier of the naters (see Table II) and of the elementary substances (see Table III). The same is true of their chemical properties as is illustrated by the exchange reactions,

$$HD+H_2O=H_2+HDO \qquad K \text{ (at } 2j^\circ \text{ C.)}=3.6$$
$$HT+H_2O=H_2+HTO \qquad K \text{ (at } 25^\circ \text{ C.)}=6.0$$

If the protium and deuterium or tritium compounds had exactly the same chemical properties, the equilibrium constant for each reaction would be unity. Since both constants are greater than unity the ratios of the isotopes D/H and T/H are less in the hydrogen gases than in the corresponding waters nhen equilibrium is established. Similar differences are characteristic of other exchange reactions of this type. Such differences in properties are potentially useful for devising separation processes for protium and deuterium.

The velocities of reactions of the compounds containing deuterium or tritium are usually less than those in which protium is present and these differences are often large. Protium reacts 13.4

times as rapidly with chlorine at 0° C. than does deuterium.

The nucleus of the deuterium atom, the deuteron, proved to be especially useful in understanding the structure of atomic nuclei. It consists of one proton and one neutron and hence is the nuclear two-body problem just as the hydrogen atom consisting of one nucleus and one electron is the two-body problem of atomic structure and theory. Because of the comparative simplicity of the theoretical problem it has been possible to compare theoretical calculations effectively with observational data. The theory shows that the attractive forces between the neutron and proton are very short range in character and cannot follow any inverse square law. They appear to be the meson forces introduced by H. Yukawa. The normal state of the deuteron is $^3S_1$, with a binding energy of 2,186,000 electron volts. The symbol signifies that the spins of the proton and neutron composing the deuteron are parallel and add vectorially to one unit of spin. This is the only stable

TABLE 11.—Physical Properties of the Waters

	D_2O	H_2O
Specific gravity $d_{25}^{25°}$	1.10775	1.00000
Melting point (° C.)	3.81	0
Boiling point (° C.)	101.41	100
Temperature of maximum density (° C.)	11.2	3.98
Critical temperature (° C.)	371.5	374.2
Critical pressure (atm.)	218.6	218.5
Critical density (g./ml.)	0.363	0.325

TABLE 111.—Physical Properties of the Elementary Substances

	H_2	DH	D_2	T_2
Gram molecular volume of the solid (c.c.) at the triple point (° K.)	23.25	21.84	20.48	—
Triple point, ° K.	13.96	16.60	18.73	20.62
Vapour pressure at triple point (mm.)	54.0	92.8	128.6	162.0
Boiling point (° K.)	20.39	22.13	23.67	25.04
Heat of fusion at triple point	28.0	38.1	47.0	—
Heat of vaporization (cal./mol. at temperature shown)	216. (20.39° K.)	257. (22.54° K.)	293. (23.67° K.)	333. (25.04° K.)

state. The triton consists of two neutrons and one proton and already presents a three body problem of much greater complexity, but still of great usefulness in these problems.

The biological effects of deuterium oxide are of considerable interest. It has been established that neither plants nor animals continue to live and thrive in water containing deuterium oxide of high concentrations. In the early 1960s, no case of acclimatization to the deuterium oxide was known.

Both deuterium and tritium are very useful as isotopic tracers in the investigation of chemical and biochemical reactions, although the rather marked differences in chemical properties are sometimes troublesome (more so in the case of tritium than in that of deuterium). Deuterium particularly has been used in this way since it is readily available and easy to analyze. These tracers made possible a much greater understanding of biochemical processes. In general the heavier isotopes of hydrogen have proved to be of interest in so many aspects of the chemistry of hydrogen that no general review .is possible since an adequate review would cover the entire chemistry of the element.

Deuterium oxide is useful in atomic energy engineering problems as a moderator in reactors. It has the advantage of being a liquid which absorbs neutrons only slightly, with an absorption cross section of only 0.00092×10^{-24} cm.^{2} for D_2O as compared with 0.6×10^{-24} cm.^{2} for H_2O.

Because of their low atomic numbers. *i.e.*, charges on their nuclei. deuterium and tritium are of interest in connection with thermonuclear reactions. The mass change in reaction (1) is 0.004285 g., and using the relativity relation between mass and energy, namely, $E=mc^2$. this gives 4.5×10^{13} calories per gram atom of deuterium. Thus about 0.1% of the mass is converted to heat energy. Tritium is likewise capable of liberating large quantities of energy but must be produced by costly processes! while deuterium is relatively inexpensive.

DEUTERONOMY (in the Hebrew Bible, DEVARIM), the fifth and last book of the Law, or Pentateuch, in the Old Testament. The name is derived from a mistranslation in the Greek Septuagint of the Hebrew term *Mishneh hat-Torah*, "copy of the Law," found in Deut. xvii, 18 (*cf.* Josh. viii, 32). The Greek name apparently meant "the second Law." The book purports to consist largely of speeches of Moses delivered in the plains of Moab just before his death; the theory of the book is apparently that the first Law given 38 years earlier at Horeb was confined to the "Ten Words" (*see* DECALOGUE), and that the present precepts and exhortations are offered for life in the land of Canaan which Israel will soon enter.

Outline.— The book falls into the following well-marked divisions:

i, 1–iv, 43:	introductory discourse by Moses, mainly a historical retrospect of the journey of Israel from Horeb to the place where he was speaking
iv, 44–xi, 32:	a second introduction, consisting of a repetition of the Decalogue and an exhortation to observe the Law
xii–xxviii:	a code containing both religious and civil laws, and including in ch. xxvii instructions for the solemn ratification of the Law after the conquest of Canaan
xxix–xxxi:	concluding exhortation, with Moses' farewell to Israel
xxxii–xxxiii:	two poems ascribed to Moses, the latter being a "blessing," or collection of tribal songs, similar in form to Gen. xlix
xxxiv:	death and burial of Moses

The tone and style of Deuteronomy are very clearly marked, and are fairly homogeneous throughout the book. It is not a legal code in the usual sense, since it includes repeated exhortations to Israel and explanations as to why the people should keep the Law. Because of its strongly homiletical tone, it has been aptly described by Gerhard von Rad as "preached law." The whole has a strong humanitarian outlook, manifested both in modifications of existing laws and in the promulgation of new regulations.

Themes.— Deuteronomy has a very lofty set of religious teachings, usually set forth with clarity and force and found in various parts of the book. Yahweh is the only God for Israel, and he is a divine being of both power and grace. The only passage in which monotheism is clearly expressed is in iv, 35–39—probably a later addition to the original work—where it is said: "The Lord is God; there is no other besides him." On the whole the book is concerned to teach not that Yahweh is the God of the entire world but that he is the God of Israel. He has chosen Israel to be a people holy to him. He led them out of Egyptian slavery and has led them through the wilderness; now he is about to give them the land of Canaan as their inheritance. The reason for the Lord's choice of Israel was not her merit or her size but rather his gracious love for the nation. Deuteronomy says this clearly in several passages; for example, "The Lord [Yahweh] your God has chosen you to be a people for his own possession, out of all the peoples that are on the face of the earth. It was not because you were more in number than any other people that the Lord set his love upon you and chose you, for you were the fewest of all peoples; but it is because the Lord loves you, and is keeping the oath which he swore to your fathers" (vii, 6–8; *cf.* also iv. 37; x, 15).

Deuteronomy emphasizes the promise that Yahweh will destroy the original inhabitants of the land he is about to give his chosen people. Thus the book places much stress upon the ancient institution of the "holy war," which had existed during the period of the judges and through the time of David. In their concept of the holy war, the Israelites believed that Yahweh himself would fight for them and destroy their enemies. The warriors had to

consecrate themselves to him, but the number of warriors was not in itself important, since the Lord was thought of as the principal agent in battle. Thus Deuteronomy has a number of regulations regarding war in xx–xxv, and the principle of the holy war is set forth in vii. 16–26; ix, 1–5; xxxi. 3–8. It is possible that the authors thought of this institution as being directed against the Assyrians and other enemies of their own age.

Israel is expected to worship Yahweh both by a purified ritual and by a high social morality. Though Deuteronomy often enjoins Israel to fear Yahweh, this does not mean so much dread and terror before his power as reverence arising from love and gratitude for what he has done for Israel in the past. The basic attitude is expressed in vi, 5: "you shall love the Lord your God with all your heart, and with all your soul, and with all your might."

The statutes or legal prescriptions of Deuteronomy cover a great variety of subjects, including both religious duties and moral or social obligations. Israel is to worship God by bringing tithes and offerings, observing the three festivals described in ch. xvi, and withal by a pure and properly motivated cult. Israel must also worship Yahweh by practising justice in the law courts, honesty in commercial dealings, good family life and so on. Generosity and charity toward the unfortunate members of society are repeatedly enjoined. In this book the teachings of Amos, Hosea and other prophets become crystallized in law.

Yet Deuteronomy insists that the laws it contains are not visionary but quite practicable. Israel can obey the Lord: "For this commandment which I command you this day is not too hard for you, neither is it far off. . . . But the word is very near you; it is in your mouth and in your heart, so that you can do it" (xxx, 11, 14).

The principle of divine retribution is important. The righteous God rewards with temporal blessings those who obey him and punishes those who disobey. This is set forth most fully in ch. xxviii; it is a basic principle of the Deuteronomic history.

There is an element of exclusiveness or particularism in this book that is not attractive, but it can be understood in the light of the book's origin and purpose. The law is for the Israelite, and Yahweh is the God of Israel. The relationship of Yahweh to other nations is rarely mentioned, but there are passages that express antagonism toward foreigners (xv, 3; xxiii, 3–6, 20). As a program for the reforms of Josiah, Deuteronomy could not be expected to show the universalism found in some parts of the Old Testament.

Literary History. — Though it appears to consist of speeches by Moses, Deuteronomy does not claim to have been written by him. and the last chapter recounts his death and burial. The theological outlook and the type of society presupposed by the regulations it contains make it most unlikely that the book is from the Mosaic age. Most modern Old Testament scholars believe that it is the third in the four strands that comprise the Pentateuch, the two preceding it being "J" and "E" and the one that follows being "P" (see PENTATEUCH).

Specifically, Deuteronomy in its original form is believed to have been the "book of the Law" or "book of the covenant" that was found in the Jerusalem Temple in the 18th year of King Josiah. 621 B.C., and made the basis of far-reaching religious and civil reforms. This view, first propounded by W. M. L. de Wette in 1805, has come to be accepted by the majority of Old Testament scholars. It rests upon the fact that the reforms of Josiah, as described in II Kings xxii–xxiii. correspond in large measure to the prescriptions of Deuteronomy. They involved the centralization of sacrificial worship in the Temple at Jerusalem, the purification of the cultus from foreign influences and the renewal of the convenant between Israel and Yahweh.

It is not certain how much of the present Book of Deuteronomy constituted the original nucleus found in 621 B.C. It may have been iv, 44–xxvi, xxviii. Ch. xxvii, xxix–xxxi, xxxii–xxxiii and xxxiv are apparently later additions, the dates of which cannot be accurately determined. The present introduction to the whole book. i, 1–iv, 43, may have been written to serve as an introduction to the Deuteronomic history, which mas compiled in the 6th century B.C.

The question as to the origin and authorship of Deuteronomy, however, is not settled simply by stating that the book in its original form constituted the basis for Josiah's reforms. According to II Kings xxii, 8, Hilkiah the high priest reported to a royal official that he had "found" the book of the Law in the Temple. Why was it there? Who had put it in that place? When was the book written? Widely differing answers have been given to these questions.

Deuteronomy undoubtedly contains old laws, some of which are similar to those in the covenant code, Ex. xxi–xxiii. Some of the practices it enjoins may be ancient, though they are not known from other sources. A law such as that in xvi, 21, which forbids the planting of any tree as an Asherah beside the altar of Yahweh, must have originated in a time before centralization of worship in a single sanctuary was envisaged. On the other hand, the sections in Deuteronomy concerning matters such as prophets (xiii, 1–5; xviii, 9–22), kings (xvii, 14–20) and divorce (xxiv, 1–4) must be relatively late.

The theory that is perhaps most widely held is that the original Deuteronomy mas written by someone (or a group) living in the reign of Manasseh (*c.* 692–c. 638 B.C.), a period when prophets were persecuted and the religion of Israel was suffering a serious decline. Deuteronomy was composed as a compromise of priestly and prophetic ideals of religion, and then set aside to be brought forth at the first opportune moment. This moment appeared with the 18th year of Josiah. Whether the book was deposited in the Temple and actually found there at a later time, or whether it was planted there and intentionally "found" by a priest, no one can say. In any event, there was no element of pious fraud involved.

Since King Hezekiah (*c.* 715–*c.* 686 B.C.) made certain religious reforms similar to those of Josiah (II Kings xviii, 3–6; cf. II Chron. xxix–xxxi), it has been conjectured that Deuteronomy may have originated in his reign, or that the book may have been the result of the experience with the short-lived reform under Hezekiah.

A few interpreters of Deuteronomy have placed the origin of the book, or of its original nucleus, much earlier than the 7th century, and some have placed it later than Josiah. Deuteronomy does not name Jerusalem as the place where sacrifice is to be offered, and passages such as xi, 26–32 and xxvii seem to imply centralization in the northern kingdom, at Shechem, rather than at Jerusalem. Some Old Testament scholars believe that the original work was composed in the period of the early monarchy in north Israel, and was concerned with cultic purity rather than with cultic unity; Deut. xii, 1–7 is an addition to the original code, and the phrase usually translated "the place which the Lord pour God will choose" should be rendered "every place which the Lord your God will choose." According to other scholars, the ultimate source of the Deuteronomic tradition was the sanctuary at Shechem.

The view has been advanced that Deuteronomy originated with the rural Levites, who were teachers of the laity and had access to priestly traditions. They acted on behalf of the "people of the land," the property-owning, free citizens of the land, who were interested in reviving the old institution of the holy war. In this case, centralization of worship and prophetic elements were not important constituents of the original work.

On the other hand, a few scholars date Deuteronomy later than Josiah, and view it as the product of that king's reforms rather than their basis. They emphasize the impracticality of some of the regulations of the book, believing that they originated with visionary priests in the small land of Judah in the postexilic period, rather than in the pre-exilic period when the nation was larger and had its own king. These objections to a ith-century date for Deuteronomy can be met by pointing out that the book embodies a program rather than a law code, and that every reformation necessarily includes both old and new elements — and some of the latter may in time prove to be impractical.

If it is recognized that the Book of Deuteronomy includes some old laws and traditions, stemming very likely from the northern kingdom, and that it was by no means a completely new work, there is no objection to the view that the form of the book used by

Josiah comes from the latter part of the 8th century, or the early part of the 7th century (perhaps from the reign of Manasseh); that it represents a compromise or harmonization of both priestly and prophetic viewpoints; and that it was "found" at an opportune time uhen Josiah was favourable to a revival of what was believed to be the old Yahwistic faith. The reformation concerned itself with both cultic unity and cultic purity, and included civil as well as religious reforms. The opportunity for such reforms was made in part by the decline of Assyrian power in Palestine. Josiah promoted independence from Assyria, and in fact extended Judaean political control over territory that had been in the Assyrian province of Samaria. Centralization of political power in Jerusalem went along with centralization of worship in the Jerusalem Temple.

Influence.— Deuteronomy had great influence in Hebrew-Jewish history. It forms a middle point in the history of Old Testament literature: before it were the Yahwist and Elohist documents (see PENTATEUCH) and most of the great prophets of Israel; after it was to come a new era in the religion of Israel. when the written book and the priesthood were to have commanding roles. It is the one document of the Pentateuch whose date of publication or promulgation can be fixed with approximate precision.

It is probable, too, that Deuteronomy was the first part of the Old Testament to be considered as "Scripture." It had the sanction of both priestly and prophetic circles, and was apparently enforced by royal authority as a kind of constitution of the nation. "For the first time in the history of mankind," said Robert H. Pfeiffer, "a book was canonized as sacred scripture" (Introduction to the Old Testament, p. 52, Harper & Brothers. New York, 1941).

Deuteronoiny provided some of the inspiration for the writing of an extensive history of Israel. An editor (or editors) imbued with the spirit and ideas of Deuteronomy, and in the same style as that book, wrote and compiled the long history that is now contained in the books of Joshua, Judges. I–II Samuel and I–II Kings. Deut. i, 1–iv, 43 may have been nritten to serve as the introduction to the complete corpus Deuteronomy–II Kings. The two important Deuteronomic doctrines of cultic centralization and divine retribution are basic in this history. The same editor or editors compiled an edition of the book of Jeremiah.

Deuteronomy is one of the four books of the Old Testament that are cited most frequently in the New Testament (the others being Genesis, Isaiah and Psalms). Jesus is reported to have quoted it three times in his temptation (Matt. iv, 1–11, quoting Deut. viii, 3; vi, 16; and vi, 13). The first commandment is cited from Deut. vi, 5 (Matt. xxii, 37; Mark xii. 29–30). Deuteronomy is quoted 83 times in the New Testament, and only six New Testament books fail to quote it.

DEUX-SEVRES, an inland *département* of western France, formed in 1790 mainly from Poitou, together aith small portions of Saintonge and Aunis (*qq.v.*). It is bounded north by Maine-et-Loire. east by Vienne, south by Charente and Charente-Maritime and west by Vendée. Pop (1954) 312.842. Area 6,055 sq.km. (2,338 sq.mi.). The Sèvre Niortaise crosses the south of the de'partement toward its mouth in the Bay of Biscay and the north is drained to the Loire river by the Sèvre Nantaise and the Thouet. the low-lying watershed area forming the western part of the gate of Poitou which connects the fertile, populous lowlands of north and south France between the Massif Central and the Armorican massif. The eastern part of the extension of the Armorican massif south of the Loire, in the district known as the Gbtine, is included in Deux-Skvres. It is hilly country with poor soils and, as its name indicates, is occupied by extensive stretches of heath and degraded forest. Farther east is the Plaine, highly cultivated farmland on smooth, dry limestone country. It is traditionally cornland, with old-established village clusters. In the southwest the de'partement includes the inland portion of the Marais Poitevin, reclaimed marshland along the alluvial flats of the Sèvre Niortaise below Niort. Market gardens and lush meadows occupy the checkerboard of plots lined by drainage ditches.

The climate has mild minters and warm summers and is within the northern limit of cultivation of the vine. Wheat, potatoes and fodder crops are important features of the mixed farming practised in this part of France, and a variety of livestock is maintained. More specialized farming is especially concerned with co-operative dairying in some districts and with market gardening near Niort. The de'partement is predominantly rural, with little mineral wealth or manufacturing, and its largest town and capital, Niort (*q.v.*), has only 30,199 inhabitants (1954). There is still a considerable Protestant element in the population in some districts. Bressuire, Niort and Parthenay, the centres of its three arrondissements, are market towns that have grown up round castles occupying naturally defensible sites. Melle has three fine Romanesque churches. Deux-Sèvres forms the western part of the bishopric of Poitiers and also comes under its acaddmie (educational division) and court of appeal. (AR. E. S.)

DEVA (DEWA), the Sanskrit word for god. Whereas in Vedic India the devas were the gods of polytheism (*e.g.,* Indra, Agni, Soma), in the later monotheistic or atheistic systems (Brahmanism, Hinduism, Buddhism, Jainism) they became subordinate to the one supreme being (who was never called deva, but *Ishvara* [lord], etc.) and/or subject to *samsara* (rebirth). In Iran, under the Iranian form of the name, daeva, their cult was opposed by Zoroaster and in Zoroastrianism, which spread all over Iran prior to Islam, they were regarded as demons. They still survive as such in the divs of Persian folklore, especially through Firdousi's famous epic, *Shahnama.* (J. D.-G.)

DEVADATTA, a cousin of the Buddha. Both he and Ananda (*q.v.*), who may have been his brother, joined the brotherhood in the 20th year of the Buddha's ministry. Devadatta, 15 years afterward, having won over the crown prince of Magadha, Ajatasattu, to his side, made a formal proposition, at the meeting of the order, that the Buddha should retire and hand over the leadership to Devadatta. This proposal was rejected, and Devadatta is said in the tradition to have successfully instigated the prince to the execution of his aged father and to have made three abortive attempts to bring about the death of the Buddha. Shortly afterward, relying upon the feeling of the people in favour of asceticism, he brought forward four propositions for ascetic rules to be imposed on the order. These being refused, he appealed to the people, started an order of his own, and persuaded over 500 of the Buddha's community to join in the secession. Nothing further is heard about the success or otherwise of the new order, but it may possibly be referred to under the name of the Gotamakas, in the *Anguttara* (see Dialogues of *the Buddha,* i, *222*), for Devadatta's family name was Gotama (Gautama). His community was certainly still in existence in the 4th century A.D., for it is especially mentioned by Fa-hsien (*q.v.*), the Chinese pilgrim. It possibly lasted till the 7th century, for Hsuan Tsang (*q.v.*) mentions that in a monastery in Bengal the monks then followed a certain regulation of Devadatta's. There is no mention in the canon as to how or when Devadatta died; but the commentary on the *Jātaka,* written in the 5th century A.D., has preserved a tradition that he was swallowed up by the earth near Savatthi, when on his way to ask pardon of the Buddha. The spot where this occurred was shown to both Fa-hsien and Hsuan Tsang.

DE VALERA, EAMON (1882–), Irish statesman, was head of his country's government with little interruption between 1932 and 1959, when he became president of the Republic of Ireland. He was born in New York city on Oct. 14, 1852. His father, a Spanish artist, having died, De Valera was sent as an infant to his mother's family in a labourer's cottage in County Limerick. Educated at the local national school and at Blackrock college,

Dublin, he graduated in the Royal university and became a teacher of mathematics and an ardent supporter of the Irish language revival. In 1913 he joined the Irish Volunteers organized to resist the Ulster Unionist campaign. and in the Dublin uprising of Easter 1916 he commanded one of the occupied buildings and was the last commander to surrender. Because of his U.S. birth he escaped execution. but was sentenced to penal servitude.

Released in 1917 but arrested again and deported to England in May 1918. De Valera was acclaimed as the chief survivor of the uprising and elected president of the Sinn Fein party, which won three-quarters of all the Irish constituencies in Dec. 1918. After a dramatic escape from Lincoln jail in Feb. 1919, he went in disguise to the United States, where he collected funds, He returned to Ireland before military repression ended with the truce of 1921 and appointed plenipotentiaries to negotiate in London, but he repudiated the treaty which they signed, because it accepted the exclusion of '(Northern Ireland" and imposed an oath of allegiance to the British crown.

Dail eireann (the assembly of Ireland) ratified the treaty by a small majority, but De Valera supported the republican resistance in the ensuing civil war. W. T. Cosgrave's Irish Free State ministry imprisoned him, but he was released in 1923 and then organized a Republican opposition party that would not sit in the duil. In 1927 he persuaded his followers to sign the oath of allegiance as "an empty political formula," and his new Fianna Fail party then entered the dail. They demanded abolition of the oath of allegiance, of the governor general and the senate as then constituted. and retention of the land purchase annuities payable to Great Britain. The Cosgrave ministry was defeated by Fianna Fail in 1932. and De Valera, as head of the new ministry, embarked quickly on severing connections with Great Britain. He withheld payment of the land annuities. and the economic war resulted. Increasing retaliation by both sides enabled him to develop his program of austere national self-sufficiency in an Irish-speaking Ireland. while building up industries behind protective tariffs. In 1937 the Free State declared itself a sovereign state; as Ireland or Eire, conceding voluntary allegiance to the British crown.

De Valera's prestige was enhanced by his success as president of the League of Nations council in 1932 and its assembly in 1938. The menace of war in Europe induced Neville Chamberlain in 1935 to conclude the "economic war" with mutual concessions. Great Britain relinquished the naval bases of Cobh. Berehaven and Lough Swilly, but De Valera gave no promise that Britain could use them in case of war. In Sept. 1939 he proclaimed at once that Ireland would remain neutral and resist attack from any quarter. His policy, backed by the enrolment of a formidable force for home defense. won general support in Ireland. Besides avoiding the burdens and destruction of war, he had brought temporary prosperity, and he retained office after repeated elections.

In 1948 a reaction against the long monopoly of power and patronage by De Valera's party enabled the opposition, with the help of smaller parties, to form an interparty government under John A. Costello. But this precarious coalition collapsed within three years, and De Valera resumed office until 1954, when he appealed unsuccessfully for a fresh mandate. and Costello formed his second interparty ministry. No clearly defined difference now existed between the opposing parties, in face of rising prices, continued emigration and a backward agriculture. But De Valera claimed that a strong single party government was indispensable and that all coalitions must be weak and insecure. On this plea, he obtained in March 1957 the over-all majority which he demanded, and he formed another ministry. consisting chiefly of his contemporaries in the early struggle for national independence. In 1959 De Valera agreed to stand as a candidate for the presidency. He resigned his position as *Taoiseach* (head of government) and leader of the Fianna Fail party. In June he was elected by 538,003 votes as against 417,536 for his opponent. Gen. S. MacEoin. Ke was installed as president on June 25. 1959.

De Valera's command of public confidence owed little to popular appeal. but rested upon his long record of austere integrity and patriotism and his sagacity as a political leader. His academic attainments and status also inspired wide respect; he became chancellor of the National University of Ireland in 1921 and was founder of the Dublin Institute of Advanced Studies. His greatest handicap was encroaching blindness, which for years made him almost unable to read or to see those whom he met. He was inevitably thrown back upon himself and his memories, relying largely upon the colleagues of early years.

See Mary C. Bromage, *De Valera and the March of a Nation (1956)*; Dorothy MacArdle, *The Irish Republic,* 4th *ed. (1951).* (D. G.)

DE VALOIS, DAME NINETTE (EDRIS STANNUS; 1898–), Irish dancer and choreographer, was founder and has since directed the ballet school and the company at Sadler's Wells that in Oct. 1956 became the Royal Ballet. She was born at Blessington. County Wicklow, Ire., on June 6. 1898. After a varied experience as a dancer, in pantomime. revue and opera, she joined the Diaghilev company as a soloist (1923–26) and after that as a guest artist. She then founded her own school in London and produced for Lennox Robinson at the Abbey theatre in Dublin and for Terence Gray at the Festival theatre in Cambridge. It was the success of her ballet Job for the Camargo society in 1930, followed by her association with Lilian Baylis at Sadler's Wells the year after, that led to the founding there of the ballet school and the company whose story she has traced in *Invitation to the* Ballet (1937) and *Come Dance With Me* (1957). Besides actively directing the company that she created. Ninette de Valois composed a remarkable series of ballets, typically English in inspiration, The Rake's Progress (1935), inspired by William Hogarth, and The Prospect Before *Us* (1940), after Thomas Rowlandson. She was created dame commander of the order of the British empire in 1951. (A. L. HL.)

DEVELOPMENT, ANIMAL. During its lifetime each animal undergoes progressive changes that constitute its development. These changes probably occur continuously. but they proceed at very different rates at different times of life. They are conspicuously rapid in the earliest phase. in the embryo. so much so that the term "development" is often tacitly confined to this period. The concentration of so much change at the beginning of an animal's life is the outcome of the way that most new individuals arise.

Reproduction.—*Sexual.*—Sexual reproduction is paramount among animals. It is a mechanism by which a selection of the hereditary factors, the genes. of two individuals are mixed. The ad-vantages to a species of having the offspring differ from their parents by mixing of the genes are enormous. Sexual reproduction achieves the maintenance of plentiful variability in the population and also provides opportunity for combining together the successful characteristics of different lineages. Natural selection (see EVOLUTION, ORGANIC; SELECTION) gains, thereby, a rich substrate to work on. Probably only in rather special circumstances can an animal species afford to dispense with sexual reproduction for long, in spite of its developmental complications. Sexual reproduction necessarily involves the fusion of one cell from each parent at fertilization; the outcome is a single cell, which is the new individual.

The multicellular animals therefore first appear in the world in a form extraordinarily different from their parents; they start as single-celled, motionless, spherical eggs. A period of rapid change has to ensue to produce an organism that can begin to obtain its living from the world around it without dependence on its own necessarily limited stores or on the succour of its parents.

Asexual.—Asexual reproduction! though uncommon as compared with sexual, is found as a supplementary reproductive method in a wide variety of animals. It usually entails a much less extensive development of its products; but it varies widely, from fission of a sea anemone into two organisms. which requires relatively little reconstruction. to the budding of ascidians, which requires almost as much as does embryonic development. (See REPRODUCTION.)

Embryonic Development.— Cell *Division and Differentiation.* —The embryonic period of multicellular animals. during which very rapid transformation is made, essentially involves the building up of a large population of cells by repeated cell division and the syntheses of the special materials that distinguish the different tissues and organs of the functioning animal. In the vertebrate,

for instance, hemoglobin must be formed in the red blood cells, but keratin in the epidermis.

In all animals the construction of a large cellular population starts quickly after fertilization and during an initial period of cleavage it is the most conspicuous change. The development by the different regions of the embryo of their specific compositions, the process of differentiation, follows. Curiously enough it is unusual for cells to begin their differentiation in the precise relative position that they will ultimately occupy in the functional animal. During the process there is much movement of cells, in definite patterns, by means of their own powers of locomotion. Multicellular animals in all their developmental processes use cell locomotion to achieve the proper arrangement of cells; in this they are sharply distinct from higher plants. (See EMBRYOLOGY.)

Larval Phases. — When an animal has developed an organization sufficient to enable it to live off its surroundings, its rate of development is likely to slow down greatly, but it may not remain slow. For many animals the outcome of embryonic development is not a small edition of the adult, but a larva, an animal sexually immature and able to fend for itself, though in quite a different way from the adult. Often such larvae are the outcome of the development of an egg with limited food resources, and they occupy an ecological niche suitable for the very small, where they can feed and grow. Often larvae serve to disperse a species whose adults are sedentary.

The transitions from larval to adult form may involve a reorganization, a metamorphosis, as swift and radical as that of an embryo. An additional complication is that much larval tissue may have to be destroyed (destruction of temporary embryonic tissues is also quite common). An alternative way of achieving the same progression from niche to niche is to interpolate an episode of reproduction at each transition and in this way develop a suitably adapted phase of the species. Such an "alternation of generations" is highly characteristic of parasites.

Larval phases are particularly interesting to the student of evolution because, as W. Garstang and Sir Gavin de Beer have emphasized, if sexual maturity is shifted forward to the larva, it can become the starting point for a new line of evolution of organisms already adapted to a niche and now freed from the selection pressure on the old adult form. (See METAMORPHOSIS.)

Postembryonic Development. — Sexual maturation, with formation of associated secondary sexual characters, is rarely a part of embryonic development. It is deferred till later, and usually involves then a development spurt analogous to that of metamorphosis. Developmental spurts, since they involve synchronous change throughout the body, are often co-ordinated by hormones circulating in the blood (as with metamorphosis in Amphibia and insects, and sexual maturation in vertebrates).

Yet another kind of development spurt in postembryonic life must be noted. The majority of animals have powers of regeneration by which they can restore damaged or destroyed parts. The regeneration of the limb of a newt is not the same as its embryonic development, but it involves many of the same basic processes: division, locomotion and differentiation of cells. (See REGENERATION.)

These spurts of development apart, it seems improbable that any animal settles down to a state of complete immunity from progressive change. In many species it is known that growth, inevitably involving reorganization, is continuous, and in many, perhaps most, slow aging obviously occurs.

Aging. — The progress of aging and senescence is closely bound up with the cumulative effect of environmental damage, although there is also an intrinsic change in many cases. How far other developmental changes are referable to concomitant change in an individual's surroundings may now be considered. It is clear that the common course of embryonic development in members of a species is rarely referable to systematic environmental change, though instances could be found in viviparous animals, where the environment is provided by the parent and therefore subject to controlled change. Later in development environmental change is more important, in stimulating the onset of sexual maturity, for example; and learning is probably to be thought of as development. But examples are not easy to find, and on the whole, development seems to be very largely self-generating. (See also DEATH [BIOLOGICAL].)

Mechanisms of Development. — What the mechanisms of development are is best known for the embryo. It seems that the single cell from which the individual starts life is always different in its various parts and the cells that arise from it embody these differences, which may be of quite a simple kind. Interactions between the various parts of the embryo (*e.g.*, inductions) then elaborate the differences and after some time the special composition found in each of the parts of the functioning adult is laid down. The developmental interaction of cells and regions of the embryo decreases as development proceeds, and in some species their autonomy may be already high at the beginning. In fact, interaction in its different forms is so prominent in the embryo that it has been the main object of study of experimental embryologists.

The similarity of the development of all the individuals of a species is, as is known from genetics (*q.v.*), largely referable to the fact that they have similar sets of genes in the nuclei of their cells. Modern genetics strongly suggests that the primary function of each gene is to determine the exact structure of one particular protein, and the proteins hold a key position in the make-up of organisms since enzymes are proteins. On the other hand, within a single individual there are many kinds of cells, each kind characterized by specific proteins (though having many proteins in common). It appears, therefore, that differentiation must involve the activation or inactivation of certain genes in the cells of particular regions of the embryo and that the interactions within the early embryo are largely directed to bringing this about. The discovery of how gene activity is so controlled is likely to be the next major advance in genetics.

This account of development has concerned itself only with multicellular animals. It remains to be added that unicellular animals, whether reproducing sexually or asexually, show development too, which in certain forms with elaborate structure, such as ciliates, may be quite complicated.

(MI. A.)

DEVELOPMENT AREAS. This term denotes areas created in Great Britain by the Distribution of Industry act, 1945. This act was passed to rehabilitate the industrial life of certain parts of Great Britain which, because of the decline of their staple industries and the virtual lack of new industries during the years between World Wars I and II, suffered abnormal unemployment. Legislation designed to stimulate the building of factories and to promote the industrial development of these areas was passed in 1934, 1936 and 1937. The powers made available by it, however, were so limited and their use by the government was so meagre that few factories were erected. Not more than 12,000 persons were employed in them in 1939.

The Distribution of Industry act, 1945, stemmed from the report (Cmd. 6157) of the Royal commission on the Distribution of the Industrial Population published in 1940 and the White paper on employment policy (Cmd. 6527) published in 1944. The former favoured control of the location of industry by the government as a means of injecting new industry into the special areas. The latter announced that the government would attack the problem of unemployment in "particular industries and areas" in three ways: "By so influencing the location of new enterprises as to diversify the industrial composition of areas which are particularly vulnerable to unemployment. By removing obstacles to the transfer of workers from one area to another, and from one occupation to another. By providing training facilities to fit workers from declining industries for jobs in expanding industries."

The 1945 act was concerned with the first of these. The act named four development areas embodying the former special

areas, but adding certain towns and districts not previously contained within those areas. The four areas were northeastern (Northumberland and Durham and the town of Middlesbrough together with surrounding districts in north Yorkshire); west Cumberland; south Wales (Glamorganshire, parts of Pembrokeshire, Brecknockshire and Monmouthshire); and Scottish (Dunbartonshire, Lanarkshire, Renfrewshire and parts of Ayrshire, Dumfriesshire, Stirlingshire, West Lothian, Midlothian and town of Dundee). In 1946, two more development areas were added: M'rexham (town of Wrexham and surrounding districts) and south Lancashire (towns of Wigan and St. Helens, together with surrounding districts). Another two followed in 1949: Merseyside (towns of Liverpool, Bootle, Birkenhead and Wallasey and adjacent parts of Lancashire and Cheshire) and north Scotland (towns of Inverness, Cromarty, Dingwall, Fortrose. Invergordon and Tain and nearby parishes). In 1953 the development area of north Lancashire was created (towns of Nelson, Colne and Burnley and nearby parts of Lancashire, the district of Barnoldswick and adjacent districts in the West Riding of Yorkshire).

The powers provided by the 1945 act included the building in the development areas (by industrial estate companies to be set up by the government) of factories to let; the improvement of public utility services; the reclamation of derelict land and its conversion into industrial sites; treasury grants and loans to firms which proposed to undertake industrial projects in the development areas and could satisfy the treasury that alternative sources of finance were not available; and the requirement that all firms should notify the government of proposed new industrial buildings of 10,000 sq.ft. or more. These powers were vested in the board of trade.

As events turned out, up to 1948 the board of trade found that its most important power derived from the necessity of firms to obtain a licence to build factories, due to the shortage of building materials immediately after World War II. The board of trade favoured the granting of licences to firms willing to build in the development areas and firms readily availed themselves of this valuable preference. The board of trade was also able to induce firms to undertake projects in the development areas by according them priority in access to scarce raw materials. Other useful inducements were provided by the building of "advance" factories for rent on new industrial estates; the offer of vacated munitions factories to buy or lease; and the imposition of restraints by the board of trade upon industrial building in congested areas. These inducements, coupled with the industrial activity generated by the postwar boom and reinforced by the abundant labour available in the development areas, were very effective. By June 1948 the development areas had acquired 443 new factories and 530 factories nere being erected. This represented more than one-half of the industrial building undertaken in Great Britain.

By 1948, however, shortages of building materials and industrial ram materials had eased and preferences to firms to obtain these had therefore become less effective as inducements. But the Town and Country Planning acts. 1947, provided the board of trade with a new means of influencing the location of new factories which it used effectively after mid-1948. This required that firms which applied to planning authorities to build in excess of 5,000 sq.ft. must obtain an industrial development certificate from the board of trade stating that ". . . the development in question can be carried out consistently with the proper distribution of industry." The board of trade could refuse to grant this certificate. In practice, it refused only a small proportion of applications, preferring to grant industrial development certificates freely to firms willing to build in the development areas. More important, it successfully persuaded many firms which could operate effectively in a development area to locate their new projects there instead of elsewhere. Lastly, the board of trade greatly helped firms going to the development areas to establish themselves.

Other factors that favoured the growth of industry in development areas after 1948 were their plentiful labour; government-financed factories to let at attractive rents (although this inducement became less significant after the middle 1950s, when the building of "advance' factories was given up); the reluctance of the board of trade to acquiesce in new industrial development in congested areas which could be carried out elsewhere; and, lastly, the fact that many firms which sited their projects in the development areas (by 1954 over 500 firms from other parts of Great Britain had done so) found that they could operate successfully and so encouraged other firms to copy their example.

After 1952 the development areas received a smaller proportion of industrial building than before. One reason was that until then they had had much more than their share (nearly one-half) as judged by their share of Great Britain's insured population (under one-fifth). This favourable treatment could not be expected to be continued; other parts of Great Britain also needed new industrial development, such as the new towns and other areas having abnormal unemployment. Much more important, the need to foster national economic growth caused the board of trade to assent readily to industrial projects in other parts of Great Britain which could offer advantageous locations. Nevertheless, the 443 factories completed in the development areas by mid-1948 had grown to 3.488 by the end of 1958.

How far was the industrial rehabilitation of the development areas achieved? Between 1945 and 1958 they had nearly 28% of the total industrial building completed in Great Britain. Since their share of Great Britain's labour force was only about 18%, they had more than their share of industrial building and this helped the development areas to benefit from the prosperity enjoyed by Great Britain during the postwar period. Uneinployment during 1945–48 was about two-and-a-half times the average percentage figure for Great Britain, but by 1958 it had fallen to about one-and-a-half times that figure. The new industries — representing most of the 112 industries in the standard industrial classification — diversified the industrial structure: there was less dependence upon a few industries. Moreover, a number of the new industries expanded their output and employment. Their workers mere trained in modern industrial techniques. This training, together with schemes introduced by the ministry of labour to transfer unemployed workers — giving effect to the second and third measures announced in the White paper on employment policy mentioned earlier — enabled such workers to find employment elsewhere. The four administrative regions containing the development areas recorded higher rates of outward migration of workers than the other seven administrative regions of Great Britain.

But the number of persons employed increased less and the number unemployed decreased less in Scotland, northeast Lancashire and Merseyside than in the development areas as a whole. Moreover, some districts did not share the prosperity of the development areas as a whole; *e.g.*, west Wales and Lanarkshire. The development areas generally were much dependent upon contracting industries such as cotton textiles, shipbuilding and agriculture and upon investment goods industries peculiarly liable to suffer when industrial depression occurs. Many new firms from other parts of the country established branches only in the development areas and these were liable to be closed in bad times. Some of the new plants in the development areas had higher costs than similar plants in other parts of Great Britain, but this drawback was probably not marked, because over one-half of the new plants were in industries successfully located in the development areas before 1945 and some others were in industries that could operate successfully in widely different parts of Great Britain.

What verdict can be passed? The development areas were substantially rehabilitated, partly because the efficiency of old industries was improved and partly because they acquired new, expanding industries. The policy initiated by the Distribution of Industry act, 1945, of controlling the location of industry to revive the development areas, met with much success.

DEVELOPMENT COMMISSION. The development commission was founded by act of parliament (1909) "to promote the economic development of the United Kingdom." It was to recommend advances for aiding and developing agriculture and rural industries, forestry (which passed to the forestry commission on its creation in 1919), the reclamation and drainage of land (which later became mainly the responsibility of other departments), the development and improvement of fisheries and the construction and improvement of harbours (which passed to the ministry of agriculture, fisheries and food and the Scottish home department under the Fisheries act, 1955). After 1921 Ireland ceased to benefit under the act. There are eight commissioners appointed by royal narrant; one retires in each year, but may be reappointed The grants or loans recommended are made by the treasury from the development fund. into which the total amount paid by the exchequer was by the middle of the 20th century of the order of £1,500,000 annually. The commissioners' recommendations require treasury approval. Before deciding upon an application. the commissioners must receive a report from any government departments concerned. The commissioners may frame schemes themselves. They may also appoint advisory committees. Advances may be made to government departments, public authorities or educational or other institutions but not to individuals or to associations or companies trading for profit.

In 1921, the Rural Industries bureau was set up to provide an intelligence and a technical advisory service for the development of rural industries in England and Wales. It is financed from the development fund, whence grants are also made to rural community councils for work carried out under a general policy framed by the bureau. A Scottish Country Industries Development trust was created in 1935. (B. E. L.)

DEVENTER, a town in the province of Overijssel, Neth., is situated on the IJssel river, 15 km. (9 mi.) E.S.E. of Apeldoorn by road. Pop. (1957 est.) 52,678 (mun.). Deventer has many buildings of historical interest, including the 11th–16th century Grote Kerk (St. Lebuinus) nith an 11th-century crypt; the Bergkerk (St. Nicolaas), partly 13th century with Romanesque towers; the Broederenkerk and the ruins of the Mariakerk (both 14th–15th century); the small provost's palace (12th–17th century) with parts of a Carolingian building; the town hall (13th century–1693); parts of the city walls (14th–15th century); the Gothic weigh house (1528), now a museum; and many 16th- and 17th-century façades of houses. The town has valuable archives and in the Athenaeum library (the municipal library) are many manuscripts dating from the 10th century onward. There is a school of tropical agriculture. Famous for its tapestry weavers and pastry bakers (*Deventer* koek), Deventer also produces books, metal, meat and flour.

Deventer was founded in the 8th century, had its heyday at the end of the 10th and the beginning of the 11th centuries and in the late middle ages. About 1500 it was famous for its five annual fairs, for its trade office at Bergen in Norway and for being the most important Dutch printing centre. The famous Latin school was attended by Erasmus as a youth. In the 14th century Deventer was the birthplace of Gerhard Groote (*q.v.*) and his religious movement known as the Brethren of the Common Life (*q.v.*). (A. C. F. K.)

DEVERS, JACOB LOUCKS (1887–), one of the highest ranking U.S. army commanders in World War II, was born in York, Pa.. Sept. 8, 1887. On graduation from the U.S. Military acddemy at West Point in 1909, he was commissioned second lieutenant of field artillery. He mas commanding general of Ft. Bragg. N.C., and the 9th infantry division in 1940, becoming in 1941 chief of the armoured force. In 1943 he was appointed commanding general, European theatre of operations. and at the pear's close became commander of the North African theatre of operations arid deputy supreme Allied commander. Mediterranean theatre. In Sept. 1944 he took command of the 6th army group, made up of United States and French forces. These units cleared Alsace, crossed the Rhine and pushed through southern Germany to the Austrian and Italian borders. Devers headed the army ground forces before his retirement as a full general in 1949. In 1951 he was chief military adviser of the United Nations mission to India and Pakistan. (F. C. PE.)

DEVIL (derived from Gr. diabolos, "slanderer," "accuser") is the generic name for a spirit of evil, especially the supreme spirit of evil, the foe of God and man, but also for minor evil spirits or demons. This article is concerned only with the devil as the chief of the fallen angels, the supreme spirit of evil, as the source of evil in dualist systems and as the chief evil power according to the Christian faith.

In the Bible. — There is little mention of the devil in the Old Testament, though his connection with the fall of man (in Gen. iii) is clear enough, and the scattered references to him all represent him as the tempter and tormentor, the deceiver. Later, pseudepigraphical Jewish literature offers a more developed demonology with some evidence of the influence of pagan literature. General Christian belief about the devil can be summarized as follows. Men and angels were created for the beatific vision, but neither were to possess it without previous testing. The angels were created as pure spirits, endowed with supernatural life, but some of them failed in their testing through some form of self-assertion. Christ speaks of the "prince of the devils" (Matt. ix, 34) and of the "devil and his angels" (Matt. xxv, 41) and it is usually held that one devil (Lucifer, Beelzebul or Satan; *qq.v.*) seduced the rest. (Lucifer, which occurs in Scripture only in Isa. xiv, 12, where the meaning is uncertain, is said to have been his name before the fall.) In the New Testament the power of the devil is frequently mentioned, and whatever may be meant by some of the references to this power over the world and mankind (*e.g.,* Luke iv, 6) it appears clearly that the devil is the adversary, the tempter of man. The primary effect of the redemption was the undoing of Adam's sin and the destruction of the power of the devil, but God permits the devil to tempt man not directly but through his nature, through his body.

There are at least two clear references in the New Testament to the fall of the devil: in II Peter ii, 4 ("God did not spare the angels when they sinned, but cast them into hell") and in Rev, xii, 7–9 ("War arose in heaven: Michael and his angels fighting against the dragon; and the dragon and his angels fought, but they were defeated . . . and the great dragon was thrown down, that ancient serpent who is called the Devil and Satan, the deceiver of the whole world"). From this passage it appears that the "great dragon," the devil, was the leader of the fallen angels as Michael was of those who did not fall.

In Early Christian Theology. — In the early church and during the mhole patristic period, although teaching on the subject appears to have been fluid, considerable influence was exerted by the apocryphal scriptures, especially the book of Enoch, which, with the help of a faulty reading in the Greek version of the Hebrew Old Testament ("the angels of God took wives with the sons of men," Gen. vi, 2), gave rise to demonologies of the oddest kind. The view that the demons are the sons of the fallen angels and human mothers is to be found in Justin Martyr, Tertullian, Cyprian, etc., but the story is given in its clearest form in the pseudo-Clementine homilies. In the east. Basil and Athanasius, following Origen, asserted that the devil is a spiritual being fallen from heaven on account of his pride and reject the stories from Enoch; Augustine in the west also held that the devil fell through pride.

In Hagiology.—In addition to this early theological speculation account must also be taken of another class of Christian literature, the lives of the first hermits who went to the Egyptian desert in the 3rd/4th centuries. The life of Anthony, written shortly after his death in 355 or 366 by Athanasius. is a document of capital importance, Here is found, so to say, the embodiment of the theological speculation about the devil that was prevalent at the time; Anthony's life is one long struggle against the devil: "the decision he had taken to serve henceforth God alone was intolerable for the devil who is the enemy of all good." Anthony is tempted in every way imaginable; he was infested (the word is

Athanasius') with attacks in such a way that those who witnessed them in broad daylight were convinced that they were real hand-to-hand encounters. At night the devil conjured up obscene visions which Anthony repelled by prayer and acts of physical penance. "And it was thus," says Athanasius, "that he who believed himself equal with God was outplayed by the adolescent." The subject of the temptations of Anthony has frequently been used in literature and art and is well known, but such manifestations, though generally in a less excessive form, are a recurrent theme in hagiographical literature in all centuries and may be patterned to some degree in, for example, the lives of St. Benedict of Nursia, many medieval saints and even as late as the 19th century in the life of St. John Vianney (the Curé d'Ars). Many of these manifestations can of course be equated with poltergeist phenomena or psychological illness; while such matters are outside the scope of this article, what is relevant here is that these recorded cases, and a host of others, are clear evidence of the beliefs held at the times at which they occurred.

Middle Ages and After.—Medieval theology contains much speculation on the subject. The Dominican school (Albertus Magnus, Thomas Aquinas, 13th century) held that the devil's first sin, fixing him in evil, was one of pride; he had been created in a state of grace and not of beatitude and his sin was not in desiring equality with God but in seeking a natural beatitude obtained by his own powers. The Franciscan school (Duns Scotus, d. 1308), on the other hand, taught that the devil's sin was in the desire for equality with God. Francisco de Suarez in the 16th century endeavoured to reconcile these views by holding that the sin of the devil consisted in the desire of his own hypostatic union with the Word. In the Protestant tradition both Luther and Calvin with the doctrine of the "slave will" (de servo arbitrio) necessarily gave a large part to the devil in their theology, and in Luther particularly countless statements are to be found concerning the devil, his power, brutality and manifestations.

The whole question of the devil and of his place in the Christian scheme is fraught with difficulty. Modern liberal Protestantism tends to deny the necessity of belief in a personal devil, preferring to understand the biblical and other references to him as to a personification of the principle of evil, or to recognize that the mutual action of individual sinners on one another constitutes a kingdom of sin opposed to the kingdom of God. Catholics and other Protestants, on the other hand, hold that man is tempted not only by the world and the flesh but also by the devil and justify their belief from the Bible, the teaching of the Fathers of the Church and the constant tradition of the church.

This raises two important questions: Why does God allow, and therefore give power to, the devil to tempt men, and in what manner does the devil tempt? These questions have exercised theologians at all periods. According to James, temptation is inherent in free will, but God is not to be regarded as its author (James i, 13); Paul teaches that God does not allow it beyond what the soul can endure (I Cor. x, 13). Both John Chrysostom and Thomas Aquinas have answered the question on the assumption that if God were obliged to destroy all that occasions evil he would have to destroy nearly everything. Since, effectively, the devil is an occasion of sin, and we can overcome the traps that he lays for us, temptation can be for us an opportunity for glory as it provides the occasion to overcome an opponent superior in intelligence and power. Aquinas adds that to inhibit or abolish the influence of evil spiritual forces in human life would be a violent and capricious interference with the normal effects of the causes created by God, on a par with interference with the laws of nature.

The influence of good and evil spirits upon us is as natural as is the influence of good and bad men; the existence of evil, indeed, raises questions which ultimately we cannot answer, but granted that problem, the permission of God to the devil to tempt us raises no particular difficulty, though it may perhaps sharpen or intensify to certain minds the general problem (B. Leeming, in Satan, p. 37; Sheed & Ward, Ltd. 1951).

It is usually held that the devil does not know the secret thoughts and intentions of men, save to the extent that they are revealed by some outward sign—since knowledge of the hearts of men is, according to Scripture and the Fathers, an attribute of God—and that temptation is effected by the devil's power to exert influence on the imagination, nerves and physical organism. The modern psychological approach regards sin as principally a psychological disorder, and holds that forms of temptation arising from the appetites are primarily natural instincts requiring some sort of satisfaction, while mental temptations are of a more serious order; the Christian moralist may obtain help from these analyses, since they can furnish him with a better estimation of the roots of moral action and a clearer determination of moral responsibility, but they do not affect the basic Christian concept of sin.

In Early Dualist Beliefs.—Although in orthodox Christianity down the centuries any form of dualism has been consistently and strongly opposed it was manifested very early in some of the sects which are to be found at the beginning of Christianity. It is possible that the "synagogue of satan" in Rev. ii, 9 is a reference to the first of these. The identification of the serpent with the devil led among some of these sects to his worship. The Ophites (from Gr. *ophis,* "serpent"), also called Naassians (from Hebrew nahash "serpent"), were a branch of the Gnostics of the 2nd century. They attached special importance to Satan as the tempter in view of their great respect for *gnosis,* the knowledge of good and evil which the serpent had enabled men to obtain. They held that the Creator had withheld this knowledge from the first man and that the serpent was a real liberator of mankind since he taught men to rebel against God. Some evidence of this teaching can be found in the Gnostic Marcion, but there is an obvious affinity between the Ophites and the Cainites who venerated as heroes all the Old Testament rebels against God such as Cain, Esau and the Sodomites. They worshiped Korah (one of Esau's sons) and also, and especially, Judas Iscariot for his freeing mankind from Jesus. (It is to the Cainites that the quotation above from Rev. ii, 9 possibly refers.)

In Manichaeism.—Persian dualism was brought into contact with Christian thought in the doctrine of Mani, and it is perhaps permissible to believe that the pessimistic views of Augustine regarding man's condition are due in some measure to this influence. In all the dualist sects there is a glorification of the devil because the essence of dualism consists in setting up the devil as God's rival, eternal and independent of him. Manichaeism was one of the principal forms of this dualism. In the "chapters of Mani" (Kephalaia) discovered in a Coptic translation in 1931, there are clear assertions on this point. Here the devil is "the king or prince of darkness" not in the biblical sense, but as a precosmic, uncreated, omnipotent power, the maker of the world and the equal with God. Inconsistently, however, Mani did not call him God and forbade his worship. Nevertheless, the prohibition was not always observed and sects influenced by Manichaeism—the Paulicians, Bogomils and Cathari (Albigensians)—seem to have contained secret groups known as Luciferians who worshiped the devil under the name of Satanael (the God-Satan) or of Sammaël. This cult is mentioned by the 11th-century Byzantine writer Euthymius Zigabenus as prevalent among the Bulgarian Bogomils, who held that Satanael seduced Eve and that he, not Adam, was Cain's begetter. (See also BOGOMILS; CATHARI; DUALISM; MANICHAEISM.)

Diabolism Within the Church.—Throughout the middle ages beliefs of this sort make a sporadic appearance side by side with orthodox Christianity only to be recurrently suppressed by the latter. In 1022, for example, some canons belonging to a chapter at Orléans were burned at the stake because, it was asserted, they worshiped the devil. Joachim of Flora (d. 1202) attributes similar practices to the Cathari and in 1236 the chronicler Matthew Paris cites Milan as a city in which the Luciferians found refuge. Konrad von Marburg, the first German inquisitor, was particularly active against the Luciferians and arousing hatred by his violent methods was killed, it was said, by those he had persecuted. Rome took a hand in the struggle against the Luciferians. A bull of Gregory IX in 1233 (*Vox* in Rama) contains a description of the initiatory rites of the Luciferians, though it requires to be borne in mind that the information was probably gathered from the German inquisitors who obtained much of their evidence by torture. The dissolution of the Knights Templar at the beginning of the

14th century on charges including diabolism is an example to the point here; some of the evidence, so far as it can be tested, seems to bear the stamp of authenticity and there appears to be a connection with the practices of the Luciferians, but on a final analysis these are matters that must be classed among the enigmas of history. After 1233. in any case. Gregory IX showed less severity in his treatment of the Luciferians.

Witchcraft and sorcery, of course, were closely connected with these matters and all through the middle ages and beyond were much in the forefront of men's minds as is shown by the many prosecutions. But the importance of witchcraft and sorcery within the context of this article lies in their claim to harness the devil, to make him act, to force him to further the projects of the sorcerer. There is no need to accept the validity of the sorcerers' claims, or of the charges brought against them by their ecclesiastical and other opponents, in order to appreciate the preoccupation with the idea of the devil during these centuries. Superstitions and theological divagations assumed extraordinary proportions and it is not difficult to detect a species of animism in some of the writings of the period. While the great theologians such as Albertus Magnus, Thomas Aquinas and Duns Scotus confined their speculations within the narrower limits of orthodox Christianity, popular preachers and witch hunters were not so guarded. Johann Nider (d. 1438) in his book *Formicarius* goes to great lengths in his exposition of the various superstitions of his time and his account of the witches' sabbath has been drawn upon by later writers. *Malleus maleficarum* (the "witches' hammer") by Jacob Sprenger (*c.* 1486; revised and expanded by Heinrich Institoris, 1489) contains similar lurid descriptions; it formed the handbook of antisatanism in Europe and ran through some 28 editions between 1486 and 1600; it was used by the Inquisition in its many trials of alleged witches and satanists.

With the advent of the 17th century and through the influence of Balthasar Bekker and the Jesuits Adam Tanner and his disciple Friedrich Spee, a more liberal attitude began to prevail in some countries, but elsewhere through the influence of Luther and Calvin popular belief in the pervasive and manifest power of the devil was developed to excess. (See also WITCHCRAFT.)

Exorcism. — Such divagations, despite their extravagant nature, should not distract attention from the constant Christian belief in the devil as the enemy of mankind and the source of evil. In the earlier centuries, and still among Roman Catholics, the rite of baptism contained exorcism (*q.v.*) and a renunciation of the devil and his works, and the renunciation is still contained in the Protestant formularies. And there is also a long Christian tradition in favour of the possibility of the possession (*q.v.*) of men and women by the devil from whom he is "cast out" by exorcism. In the Gospels Jesus casts out devils and gives his disciples powers to do so; and he distinguishes between healing the sick and casting out devils: "Heal the sick, raise the dead, cleanse lepers, cast out demons" (Matt. x, 8). Exorcism has been practised in all centuries, though the trend among Roman Catholics is to confine its use to certain rare and well-defined cases. Here again it must be recognized that many of the cases of possession in the past nere in reality of psychopathological origin. Unbiased review of the complex problem of witchcraft, sorcery, possession and cognate phenomena, and appraisal of the extant evidence, would seem to show that almost all the cases indubitably were due to morbid and hysterical mental conditions provoked among the superstitious and ill-educated by a prevailing atmosphere of terror, mystery and suspicion. Outstanding figures such as Gilles de Rais (1404–40) and a few others no doubt believed in the reality of their communications with the spirit of evil and stopped short at no crime.

In Art and Literature. — It is natural that the devil is to be found down the centuries in art and literature. The fall of the damned depicted in the mosaics of the baptistery of Florence cathedral is a good example of medieval treatment of the theme. Hieronymus Bosch, with his fantastic creations of the ape of God, portrays the devil as the lord of disorder, of anticreation; Albrecht Diirer represents him as a pig, skulking behind death, following a man on horseback, ready to snatch his soul; Goya shows him as a goat, Delacroix reduces him to the absurdity of Mephistopheles. In medieval church carvings he often appears in the familiar form with horns and tail, a grotesque shape reflecting the ideas of the mystery plays. But it is to the east rather than to the west that the most telling examples of an early date are to be found. In popular Chinese art, in Iranian carvings, in Assyro-Babylonian remains the devil figures frequently, and it was from the latter that Judeo-Christian representations of him seem to be copied. There is a similarity between the bronze statuette in the Louvre (7th century B.C.) of the devil Pazuzu symbolized as the southwest wind, the bearer of fever and delirium, and the devil as he is represented in illuminated manuscripts and in the carvings of the churches of Europe.

Literature, reflecting the ideas prevailing at its epoch. portrays the devil in various guises. In the medieval mystery plays he is reduced to a comic figure, a buffoon; in Dante's *Divina commedia* he appears as an outcast from heaven. At the same time popular imagery has its part; the devils in hell are frightening though sometimes figures of fun in the medieval tradition. Principally however Dante's conception is based on Revelation and on orthodox theology, though sometimes in rudimentary form. The devil to whom Faust sells his soul is a familiar spirit called Mephistopheles (*q.v.*), whose character is strongly differentiated in the plays of Christopher Marlowe and Goethe, but in the 7th-century Greek legend of Theophilus of Adana, which is the earliest version of the story of an infernal pact, it is the devil himself whom the hero agrees to serve (see FAUST). Satan is a prominent character in *Paradise Lost*, where Milton seems at pains to reconcile his Christian belief with his humanist, Renaissance mentality and though he believes in the Bible narrative he alters it on occasion. *See* DEMON; SATAN; *see* also references under "Devil" in the Index volume.

DE VILLIERS, JOHN HENRY DE VILLIERS, 1ST BARON (1842–1914), first chief justice of the Union of South Africa. who in this capacity modernized the Roman-Dutch law of Cape Colony, was born at Paarl, Cape Colony (Cape Province), on June 15, 1842. He was educated at the South African college, Cape Town and at Utrecht and Berlin universities.

In 1865 he was called to the bar by the Inner Temple and began practice in Cape Colony. Entering Cape politics in 1866, he was elected a member of the house of assembly, became attorney general of the colony in 1872 and two years later was appointed chief justice of the Cape. He was appointed president of the national convention in 1908 and in 1910 was raised to the peerage on becoming chief justice of the Union of South Africa. He died at Pretoria on Sept. 2, 1914.

DEVILS TOWER NATIONAL MONUMENT, first U.S. national monument, was established in 1906 pursuant to the Antiquities act of that year. Located near the Belle Fourche river in the northeast corner of Wyoming, the area of 1,346.91 ac. was set aside to preserve a remarkable natural rock tower of volcanic origin. The tower, with its flat top and fluted sides making it look not unlike a great petrified stump, is 865 ft. from base to summit, and stands on a rounded ridge which rises 415 ft. above the river. The top of the light gray and buff tower is inhabited by chipmunks and other rodents and there is a protected colony of prairie dogs near the river. It was first climbed in 1893.

Among several Indian legends explaining the origin of the tower one relates that seven little girls who were chased by bears sought refuge on a low rock. To save them the gods raised the rock beyond the reach of the bears, pushing the girls into the sky where they are still visible as stars, the Pleiades in the constellation Taurus. The bears left permanent claw marks, the fluting, on the tower. (T. A. LN.)

DE VINNE, THEODORE LOW (1828–1914), the most eminent U.S. printer during the later 19th century and the first decade of the 20th, was known as an authority on the history of typography and was the author of many scholarly books on the subject. Born at Stamford, Conn., on Dec. 25, 1828, he took the first steps toward learning his trade in 1843 in a printing office at

Fishkill, N.Y., but entered on his regular apprenticeship soon after in the office of the *Gazette* at Newburgh, N.Y. In 1847 he went to New York city and, after working in several offices, in 1849 entered the employ of Francis Hart, one of the leading printers in that city. From work as a job compositor, he graduated in 1850 into the position of foreman; nine years later, Hart made him a member of the firm. At that period the business of Francis Hart and Co. was tending more and more to book printing, a field to which De Vinne devoted most of his efforts from that time onward. About 1864 De Vinne began to write on printing. his earliest contributions dealing with the economic aspects of the business: but he soon turned to the aspects of typographic style and the history of the craft.

In 1873 the firm began to print *St. Nicholas* and soon after took on the *Century Magazine*, in printing the illustrations for which some new standards were established. The *Century Dictionary* was another job of importance produced under De Vinne's direction. Francis Hart died in 1877, and in 1883 the name of the firm was changed to Theodore L. De Vinne and Company. The De Vinne press earned a reputation as the outstanding printing plant of the country. De Vinne was one of the founders of the Grolier club and one of its most active members. printing most of the early books issued by that organization and writing or editing a number of them. He died on Feb. 16. 1914. As a printer De Vinne was a craftsman of high standards, but he could not be regarded as a great creative artist. His simplest books were his best.

De Vinne's most important contributions to typographic literature were *The Practice of Typography* (1900–04), a series of four manuals; *The Invention of Printing* (1876); *Christopher Plantin and the Plantin-Moretus Museum at Antwerp* (1888); and *Notable Printers of Italy during the Fifteenth Century* (1910).

(D. C. McM.)

DEVISE, in the strict terminology of Anglo-American law, is a disposition of real property by will, as distinguished from a legacy or bequest, the disposition of personal property by testament. Since the late 19th century the terms devise and legacy, as well as will and testament, have come to be used interchangeably. *See* LEGACY; WILL. (M. RN.)

DEVIZES, a market town and municipal borough in the Devizes parliamentary division of Wiltshire. Eng., 25 mi. N.W. of Salisbury by road. Pop. (1901) 8.497. Its castle was built on a tongue of land flanked by two deep ravines, behind which the town grew up on a stretch of exposed tableland. Its main streets, in which a few ancient timbered houses survive, radiate from the large market place, where stands a market cross with an inscription commemorating God's judgment on referring to a woman who was struck dead in 1753 after praying she might drop dead if she was guilty of withholding money in a transaction; the money was found clutched in her hand. The Kennet and Avon canal, now practically disused, has a chain of 29 locks; the canal and its banks have a rich fauna and flora. St. John's church (12th century), one of the most interesting in Wiltshire, is cruciform with a massive central tower and fine Norman chancel and contains several ancient monuments besides some beautiful carved stonework and oak ceilings. St. Mary's; a smaller church, is partly Norman but was rebuilt in the 15th century and restored in the 19th century. Roundway down, on the edge of which the town stands, stretches eastward and is the site of an ancient earthwork. The museum of the Wiltshire Archaeological society has a good representative collection of prehistoric finds and is also the depot of the Wiltshire regiment. There is a big corn, cattle and pig market. Devizes has bacon, cheese and tobacco factories, tileworks, engineering works and is the oldest manufacturer of snuff in the country. Assize courts are held at Devizes, which has its own commission of the peace and court of quarter sessions.

The construction at Devizes in the reign of Henry I of a castle of exceptional magnificence by Roger, bishop of Salisbury, at once made the town a political centre, and the name itself is possibly a corruption of the medieval Latin referring to the "castle at the boundaries" (*ad divisas*). After the disgrace of Roger in 1139 the castle was seized by King Stephen. It was dismantled after Cromwell took it in 1643. The town's first charter was granted in the reign of Matilda and was followed by charters of other monarchs. Devizes returned two members to parliament from 1295 until deprived of one member in 1867; its representation was merged in that of the county in 1885.

DEVOLUTION, WAR OF, the war of 1667–68 between France and Spain. Following the Anglo-Dutch War of 1664–67 and preceding the Franco-Dutch War of 1672–78, it is best considered in the context of the Dutch Wars (*q.v.*). Devolution was a local custom governing the inheritance of land in certain provinces of the Spanish Netherlands, by which daughters of a first marriage were preferred to sons of subsequent marriages; and Louis XIV of France began the war on the pretext that this custom should apply to sovereign territories also, so that his wife Marie Thérèse should succeed her father Philip IV of Spain (d. 1665) in the majority of the Spanish possessions in the Netherlands in preference to her younger half-brother, Charles II of Spain. The war was ended by the treaty of Aix-la-Chapelle; for its provisions *see* AIX-LA-CHAPELLE, CONGRESSES OF. (I. F B.)

DEVON, EARLS OF. From the family of DE REDVERS (de Ripuariis, Reviers), earls of Devon from 1141, this title passed to that of Courtenay (*q.v.*), which held it until the death (1556) without issue. of Edward. the 11th Courtenay earl. The title then became dormant in the Courtenay family until a claim by a collateral branch was allowed by the house of lords (1831) and the earldom of Devon was restored to the peerage. The earlier earls of Devon were sometimes referred to as earls of Devonshire; but this variant is now solely used for the earldom and dukedom held by the Cavendish family

DEVON, a county of England, part of the southwestern peninsula, with a northern and southern seacoast and including Lundy (*q.v.*) island, is bounded on the west by Cornwall and on the east by Somerset and Dorset Its area. 2 612 7 sq mi, is exceeded only by that of Yorkshire and Lincolnshire among the English counties.

Physical Features. — Devon has the boldest relief of the counties of southern England. Its coastline, with the contrast between rugged cliffs and deep winding estuaries, offers a great variety of colour and scene. but gives way almost everynhere to hilly country. The main physiographic feature is an extensive dissected platform — the mid-Devon plain — lying at about 430 ft above sea level In the south this plain is dominated by the rolling granite upland of Dartmoor. whose tors rise above 2,000 ft.; in the northeast it gives way to the hills of Exmoor.

The geology of the county is complex in detail but simple in outline The oldest rocks are early or pre-Palaeozoic schists occurring in the extreme south between Start point and Bolt Tail. To the north lie folded sediments of Devonian Age which extend in a great syncline or trough outcropping south of Dartmoor and northeast of the Taw-Torridge estuary These sandstones and shales are broken by massive limestones in the south, but in the Exmoor area only a few limestone bands are found The centre of the Devonian syncline and about one-third of the county's area is occupied by intensely folded and faulted sandstones and shales of the Carboniferous Age, known as the Culm measures. These old rocks were influenced by the Armorican folding and, particularly in the south, by igneous activity. The great granite mass of Dartmoor there protrudes through the Devonian and Carboniferous sediments, with widespread evidence of metamorphism. East of these outcrops, and approximately along the line of the river Exe, New Red rocks of Permian and Triassic age cover the old sediments. These weather down to the rich red soils of the Tor bay and Exeter areas, so often quoted as typical of Devon, though they cover but a small proportion of the county. The little-disturbed Trias strata, whose boundary with the Permian is usually considered to be the Budleigh Salterton pebble bed, dips under Lias limestone and marls which are themselves covered by Cretaceous rocks in the southeast of the county. Outliers of Cretaceous material (*e.g.*, the Haldon hills) lie farther west. Between Seaton in Devon and Lyme Regis in Dorset the widely known landslip of 1839, caused by the erosion of the Greensand and the slipping of the Middle Chalk upon it, was made a national nature reserve in 1955. Oligocene clays, with interbedded lignites, occur between Newton

J. ALLAN CASH—RAPHO GUILLUMETTE

ANSTEY'S COVE. NEAR TORQUAY, DEVON. ENG.

Abbot and Bovey Tracey and in the Peters Marland area. These "ball clays," notably whiteware and stoneware, are extensively worked from both open pit and mine. The county was not directly affected by the Quaternary ice sheets, but much of the valley gravels and "head" date from that period and, with the drowned river valleys and raised beaches, demonstrate the different conditions then prevailing.

The wet uplands, Dartmoor and Exmoor, both designated as National parks, are the source of most of the Devon rivers. From Dartmoor the streams flow in a radial pattern to the south coast (the Teign, Dart, Avon, Yealm and Plym) and to the north coast (Taw, Okement), or to the Tamar (Lyd, Tavy) which flows south to Plymouth sound and forms over most of its length Devon's boundary with Cornwall. Most of Exmoor drains to the Exe (*q.v.*), which flows south through rich farming country, its wide basin forming another major physiographic unit. The remainder is drained by a series of short rivers, the principal one of which is the Lyn, falling steeply to the north. East of the Exe the land rises to the east Devon plateau, which, again, is deeply dissected by rivers (the Otter, Sid, Axe) flowing southward to the coast.

Climate.—The climate is generally mild but there are marked variations according to height above sea level and distance from the sea. The annual average rainfall varies from about 30 in. at the mouth of the Exe to over 80 in. at the centre of Dartmoor and exceeds 60 in. at the centre of Exmoor.

Along the coastal areas the temperature is equable due to the influence of the sea and the estuaries which penetrate up to 8 mi. inland. Away from the sea, and especially on higher ground, the daily range of temperature increases and winter weather grows more severe. On the coast the number of days with snow varies between 5 and 79 a year, while on the high land of Dartmoor above 1,000 ft., it increases to about 25.

Soils.—The great variety of rocks give a number of different types of soils, many of which, because of the nature of the rocks and the heavy rainfall, are deficient in lime. This is especially true of the western part of the mid-Devon plain, where the Culm measures, themselves deficient in lime and subject to heavy rainfall, give rise to cold, heavy clays on the shaley horizons and shallow stony soils on the sandy layers. The highly folded and resistant rocks of north Devon result in upland tracts with soils of moderate fertility. These are deficient in lime except, as in the Combe Martin valley, where they are associated with local beds of limestone. Drainage is better than on the Culm measures. The varied character of rocks in south Devon, including limestone, volcanic and schistose rocks. afford a variety of soils correspondingly varied and on the whole superior to those of north Devon. In east Devon and along the strip from Hatherleigh to Crediton is the red soil derived from the red rocks laid down under the desert conditions of Permian times. It is a warm, fine, easily worked loamy soil, arid the most valuable agricultural land in the county.

Vegetation and Animal Life.—About a quarter of the county is heathland, moorland and rough grazing, principally Dartmoor and Exmoor with secondary areas on the Culm measure moors and the plateau heath of east Devon. The remainder is now largely pasture land. though considerable deciduous woodland survives.

The county has an abundant wild life. The Dartmoor and Exmoor ponies are well known. Foxes are common, and rabbits are numerous in the Dartmoor area as well as badger and otter. Characteristic birds are the buzzard, raven, carrion crow, kestrel, stonechat, whinchat, dipper and gray wagtail. Common lizard and adder are frequent in heather and moorland areas. Roach, dace and bream, as well as salmon and trout are fished in the rivers, and bass and flatfish abound in the estuaries.

National Parks.—Part of the Exmoor National park and the whole of the Dartmoor National park lie within the boundary of the administrative county. Dartmoor covers 365 sq.mi. and its special features are rounded hills capped with "tors" (large blocks of bare granite) and "clitters" (heaps of granite boulders and stones). Exmoor covers 265 sq.mi., approximately 77 of which are within the Devon boundary. The heather, bracken and grass moorland is seamed with combes, or valleys providing shelter for a vigorous scrub and tree growth. The northern coastline is an outstanding feature with cliffs, woods, steep gorges such as Heddons Mouth, the Lyn valley and the bold promontory of Foreland point. (See DARTMOOR; EXMOOR.)

Antiquities **and** History.—Traces of Paleolithic man have been found in the limestone caves of south Devon around Tor bay and Plymouth sound, and in the gravel pits near Axminster. Kent's cavern, Torquay, is one of the two oldest known human dwellings in Britain. A few Neolithic remains include a house at Haldon. Bronze Age man turned to yet higher ground, particularly to Dartmoor. Here there are several thousand prehistoric monuments: hut circles of which the best known is Grimspound, barrows and stone rows, circles and cairns. There are several series of Bronze Age barrows in north and east Devon, particularly Farway. The Iron Age newcomers girdled Dartmoor and guarded the river routes inland with a series of earthworks or hill forts. Hembury fort, the largest, may have been the headquarters of the Dumnonii until Exeter was founded as the Roman frontier station (Isca Dumnoniorum) lying at the end of the Fosse way. From Exeter, Roman roads ran to Topsham (formerly the Roman and medieval port of Exeter), to Teignbr'idge and north of Dartmoor to the river Taw. Villas have been found in Seaton and Uffculme, and a Roman fort at Martinhoe.

The British Dumnonii, who gave their name to Devon, largely survived the Saxon conquest. which began in the late 7th century and was partly military in character and partly peaceful colonization of the lowland districts. Saxon and Briton together were subjects of Wessex and in the late 8th century Devon was recognized as a shire. It was included in the see of Sherborne (set up in 705) until 909 when it was made into a separate diocese of Crediton. In 1050 the see was moved to Exeter, a walled city, where it is still. There are a few Saxon remains: a crypt at Sidbury and a few decorated stone crosses. The many undated stone crosses on Dartmoor possibly mark trackways and medieval manor boundaries.

From 851 to 1003 the area suffered from Danish raids. In 1068 Exeter was taken by William I after its citizens refused him fealty. A castle mas built there which in 1348 was granted for life to Edward. prince of Wales. There was skirmishing during the' wars between Stephen and Matilda, in the Wars of the Roses and again during the Civil War. Local as opposec! to national risings had little success, and Exeter withstood sieges by Perkin Warbeck in 1497 and by the western rebels of 1549. Raids on the coast occurred during most wars, but in the 15th and 16th centuries Devon pirates and privateers were probably doing even more damage to shipping.

Tin mining on Dartmoor was an important industry from the mid-12th to the early 17th century. and the miners formed a separate community with its own courts governed by the lord warden of the stannaries. Silver and lead mines were worked until the

16th century, iron ore from the 16th to the 19th and copper and manganese in the 18th and 19th centuries. The cloth industry came to the fore in the middle ages and remained a staple industry until the 19th century. The export of cloth and tin led to the rise of the ports, chief among them being Exeter, Plymouth. Barnstaple and Dartmouth. Devon sea fisheries (with those of Newfoundland from Tudor times) provided training and opportunity for the seaman of Elizabeth I's reign and later. Sir Francis Drake, Sir Walter Raleigh, Sir John Hawkins. Sir Richard Grenville and, in the 20th century, Capt. R. F. Scott of the Antarctic were among the n any famous seamen and explorers born in Devon. The decay of the woolen and mining and other local industries, such as paper and lacemaking, resulted in a drift from the county from the 19th century onward This drift was partly halted by the growth of the seaside towns and the tourist industry, which began in the late 18th century.

Devon was represented at the council of 1258 and in parliament in 1290 From 1295 Devon and four boroughs were continuously represented, and other regular and casual boroughs were added until there were 26 Devonshire members. In 1832 this was reduced to 22. by 1918 to 11, and in 1954 to 10.

During World War II the South Hams district was used as a battle-training ground by U.S. forces which necessitated the evacuation of many villages and farms. Plymouth was a major embarkation port for the Normandy invasion.

Architecture. — Rougemont castle. Exeter, the remains of which are preserved, dominated Norman Devon both structurally and administratively. The keeps of Gidleigh, Lydford and Okehampton date from the 12th and 13th centuries. Exeter cathedral is the outstanding example of medieval architecture, built in the late 13th-century plan; and Ottery St. Mary (*q.v.*) is an almost untouched early 14th-century church. Most of the medieval, Tudor and Jacobean buildings are in local stone, with limestone quarried at Beer much used for finer carving in the south. This variety of stone adds interest to the churches which date mostly from the 14th century in Perpendicular style. Tudor and later structural additions are usually aisles and are generally of the same height as the nave with timber wagon roofs. Richly decorated rood screens, the earliest in stone and later in wood. are an outstanding feature of the churches. Monastic remains are scanty: in Exeter chiefly the Benedictine priory of St. Nicholas, in the Mint and the 13th-century priory of St. Katherine's, at Polsloe; Tavistock (*q.v.*) abbey (founded 961); and the 13th-century Cistercian abbey of Buckland. Buckfast abbey, near Buckfastleigh (*q.v.*), founded as a Cistercian house in 1137, was acquired by French Benedictines in 1882 and on the ruined site they rebuilt the abbey and its church. which was consecrated in 1932.

Among many fine houses are Weare Giffard and Bradley manors, both of the 15th century; Dartington hall, since 1925 used as a centre for rural economics and education, Powderham castle, Compton castle and Wortham manor, all medieval houses with important later additions, the last two being fortified. Traditional country buildings are in colour-washed cob with thick walls and thatched roofs. The late 18th and early 19th centuries are characterized by planned street architecture in Plymouth and Exeter and the terraces and crescents of the new seaside towns such as Torquay, Teignmouth and Ilfracombe. Princetown gaol, on the bleakest part of Dartmoor, became a convict prison in 1850.

Properties administered by the National trust include Buckland abbey, Bradley manor, Compton castle, Holne woods, Watersmeet, Kipling Tors near Westward Ho!, Arlington court, Hayes Barton, and many other fine properties.

Population and Administration. — In 1961 the resident civil population was 204,279 for Plymouth, 80,215 for Exeter and 538,412 for the administrative county. The main concentrations of population in the county are in the Plymouth fringe area, in the Tor Bay area. in the lower Exe valley and in the Taw-Torridge estuary area. Both the northern and southern coastal strips tend to be more densely populated than inland where generally there is a pattern of rural settlement, market town. village. hamlet and farm, which has persisted over many hundreds of years.

The 1961 resident civil population figures show that the five largest towns in the county are Torquay (53.915); Paignton (30,289); Exmouth (19,740); Newton Abbot (18.066); and Barnstaple (15.907) (*qq.v.*). Bideford, Brixham, Sidmouth, Teignmouth and Tiverton (*qq.v.*) are in excess of 10.000, while Dartmouth, Dawlish, Ilfracombe, Tavistock, Totnes (*qq.v.*) and Northam all have populations of between 5,000 and 10,000. The high average age of residents is an indication of the popularity of Devon with retired people.

The county is divided into the administrative county of Devon and two county boroughs, Plymouth. well known as a naval base, and Exeter (*qq.v.*), the cathedral city and administrative and business centre. The administrative county, the largest local authority in area in England and Wales, is subdivided into 10 municipal boroughs, 20 urban districts and 17 rural districts.

The **Economy.**—Devon's rural economy is based on livestock. Out of about 1,150,000 ac. of crops and grass. about 900,000 are in grass and less than 20.000 are used for the main cash crops of wheat, potatoes and sugar beet. Furthermore, much of the 360,000 ac. of moorland provides rough grazing and is linked to the economy of the peripheral farms.

There are two indigenous breeds of cattle. The North Devon, or Red Ruby, is the smaller of the two and is an excellent beef animal. The large South Devon or South Ham is used as a dual purpose animal for high quality milk as well as for beef. Dairy farming is found in most parts of the county, particularly in east Devon and near the south coast towns, but beef cattle are important. especially in the north and west and in areas associated with the Dartmoor and Exmoor grazings. Exmoor and its fringing lands are pre-eminently stock raising localities. many of the large sheep flocks there being the native Exmoor Horn or the Devon Closewool. There are other native breeds of sheep—the Devon Longwool in west Devon, the South Devon in the south and two Dartmoor breeds. now less numerous on the main moorland than the hardy Scottish Blackface Highland.

The countryside has a pattern of small fields and hedgerow banks much more suited to a pastoral economy than to mechanized tillage. The tillage acreage is limited chiefly by the climate. The heavy rainfall and high winds often militate against an easy grain harvest. Cereals become of significance only where the rainfall is less than 40 in. per annum. particularly in the lower Exe basin and the South Hams. A high proportion of the cereals is grown for animal feeds. Pigs and poultry are numerous, but are generally regarded as ancillary to the main farm enterprise. The growing of early vegetables and fruit (*e.g.*, strawberries in the Tamar valley and at Combe Martin, and flowers in the Dawlish-Teignmouth area) is important. The acreage of orchards is steadily declining and although Devonshire "Clotted" cream is still made on many farms, the other famed produce, cider, is mainly made in factories.

The total area of woodlands suitable for economic management accounts for only 5.4% of the land. In the early 1960s, the Forestry commission held about 24,000 ac. and a further 24,000 ac. in private ownership was being worked under a plan of operation approved by the Forestry commission.

Apart from the importance of the naval dockyard to Plymouth, the chief employment in the coastal towns is provided by the tourist trade. Estimates suggest a peak holiday population of about 250,000 persons, and probably 2,000,000 are accommodated during the year. The variety of the enterprise is considerable, but except for some minor centres round Dartmoor, and scattered fishing interests, the industry has little direct effect on rural Devon. Torquay, Paignton and Brixham, Exmouth, Sidmouth. Dawlish, Teignmouth and Dartmouth are the main south coast resorts, and Ilfracombe the only sizable one of the north coast. The small picturesque towns of Salcombe, Seaton, Lynton and Lynmouth (*q.v.*), Woolacombe and such villages as Beer, Newton Ferrers and Clovelly (*q.v.*), do much to make the county a favourite tourist area. Exeter, Barnstaple and Bideford are inland holiday centres and Plymouth is a seaside resort as well as a naval base., At Dartmouth is the Britannia Royal Naval college and also the headquarters of the Royal Dart Yacht club.

Sea fishing is less important than in the past and practically

all the county's fishing industry is centred on Brixham and Plymouth. The Marine Biological laboratory at Plymouth was established in 1855. Salmon fishing is both commercial and recreational.

Almost every town has some factory or works where skills have been handed down over many generations. Shipbuilding at Brixham, on the Dart, Teign and Torridge, and the complex industry associated with the Devonport dockyard are typical; also gloving in Torrington and the wool industries of Axminster, Buckfastleigh and Ashburton, the textile enterprises of Tiverton and the paper-making works of the Culm and lower Exe valleys., Plymouth and Exeter are the main industrial centres. At Tiverton, Barnstaple, Newton Abbot and Axminster the proportion of the population employed in factories is above the county average. However, none of these towns can be described as industrial as nearly all the individual enterprises are small. The dairy industry is important, and vehicle and machine maintenance and repair enterprises, from village smith to the large Newton Abbot railway works, illustrate the emphasis on the manufacturing processes and distribution of dairy products in the county's economy. Of all employees in the county, 66% work in the "services" group of trades and professions, as compared with a national proportion of 52%. This reflects the size of the tourist industry and Devon's function as a residential area for retired people. These factors support such industries as printing, enterprises associated with the building industry (*e.g.*, woodworking and the making of bricks and concrete products) and gas and electricity undertakings.

Ball clays and china clays (kaolin) from southwest Dartmoor are now the chief mineral export. Ball clays, dispatched by rail or ship from Teignmouth and Fremington, are the basis of some local industry and are used mainly in ceramics. China clay is used particularly as a filler in paper, rubber and paints. Devon's production of china clay, exceeded 110,000 tons annually in the early 1960s.

Ground limestone for agriculture is sent to Cornwall and the Channel Isles, small quantities of polished "Devon marble" are exported, and there is a coastal trade in industrial limestone. Igneous stone is transported for railway ballast and monumental purposes.

The county road and railway network focuses on Exeter. From the east the Leeds-Exeter trunk road and the British railways Western Region main line enter from Taunton, and the London-Plymouth trunk road and Southern Region main line enter from Honiton. From Exeter the Western Region line follows the coast to Newton Abbot, thence to Plymouth and Cornwall, with a branch to Tor bay. The Southern Region line strikes north from Exeter, one branch going round Dartmoor to Plymouth and the other serving Barnstaple, Ilfracombe and Bideford. The road pattern is similar. There are civil airports at Exeter and Plymouth, and air traffic is also handled at the Chivenor field in north Devon. Inland waterways are of little significance, and the only canal working is the Exeter ship canal. Bideford, Fremington, Exmouth, Teignmouth and Plymouth are worthy of note as ports, but the fine harbour of Dartmouth has lost trade through the decrease of the business of ships' coaling, and the main traffic on the Dart to Totnes is now pleasure boats.

DEVONIAN SYSTEM. The Devonian system of rocks includes those that originated during the Devonian period of time, or roughly the interval from 285,000,000 to 320,000,000 years ago. In practice both time and rocks are defined with reference to distinctive fossils, which differ from those of the previously deposited Silurian rocks below, and the more recent Lower Carboniferous, or Mississippian, above. The Devonian is a middle division of the Paleozoic era (*q.v.*), as indicated in the accompanying geologic time chart.

In addition to the cross references to related articles given throughout this article, for related information see GEOLOGY, PALAEOBOTANY, PALAEONTOLOGY, SEDIMENTARY ROCKS and FOSSIL. For further information on both ancient and modern forms of life mentioned in this article the reader is referred to the separate articles on the various phyla, as BRACHIOPODA; MOLLUSCA, etc.

The main divisions of this article are:

I. THE DEVONIAN SYSTEM AND PERIOD

Devonian sediments contain the earliest really abundant remains of land plants and of fishes, although both originated long before and have changed drastically since. These fossils, those of the continuously evolving marine invertebrates, and the sediments tell us that the Devonian climates were mild and apparently not markedly zoned latitudinally, that there was land with bodies of fresh water and primitive vegetation in the far North Atlantic, and that the sea spread widely over present continents.

During the Devonian period the first four-footed vertebrates arose from the fishes, and the conquest of the lands began. Mountain building, accompanied by granitic intrusion and volcanism, played an important part in modeling the Devonian scene and in providing sediments to fill the subsiding areas.

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
	CENOZOIC ERA		
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000
	MESOZOIC ERA		
Cretaceous		Extinction of dinosaurs	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
	PALEOZOIC ERA		
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes	400,000
Cambrian		Marine invertebrates	500,000
	PRE-CAMBRIAN TIME		
		Few fossils	3,500,000–4,000,000

Devonian rocks are important petroleum reservoirs and host rocks for various metallic mineral deposits of later origin. The tin that brought the Romans to Cornwall and Devon was in lodes in Devonian rocks. Many of the Upper Devonian black shales

contain as much as 0.01% primary uranium, and hence are possible ore reserves.

Cement rock, glass sand, refractory brick, building stone and abrasives are common Devonian industrial resources.

Some of the world's most storied landscapes result from the erosion and weathering of Devonian rocks. This has produced the best north Rhineland scenery, including the Lorelei and Wagner's Grosser Feldberg. Other examples are found in the Ardennes, Brest harbour and the higher parts of Brittany, Cape Town's Table mountain, the Catskills, the scenic tip of the Gaspé Peninsula in Quebec, the Ramparts of the Mackenzie river, Moray firth and the hillier parts of the Scottish central lowlands, and the historic and lovely south coast of Devonshire, in southwest England, where the name comes from.

Identification of rocks from any other part of the world as Devonian (or a specific part of it) is based on comparison of the fossils they contain against those of the type marine section in Devonshire, or on relationship to or correlation with other rocks so dated. The absolute age in years is only crudely estimated by extrapolation from rare radiogenically dated control points, whose determined ages are believed to be within about 10% of true values, but whose stratigraphic position is only approximately known. Geologists, therefore, do not ordinarily think or talk of Devonian or other rocks in terms of years, but in terms of named subdivisions based on the physical characteristics of the rocks and the fossils found in them. The correlation table shows the principal Devonian subdivisions for selected regions. The map indicates the distribution of land and sea in the Devonian world, somewhat distorted by emphasis on fossiliferous marine deposits and very ditierent from similar maps for brief intervals of Devonian time.

Historically, recognition of the Devonian deposits as a system was delayed by absence of Devonian rocks with marine fossils from areas where the stratigraphically adjacent systems were most intensively studied. As early as the 18th century, deposits called the Old Red Sandstone were known in England north of Bristol and in Scotland; but lacking marine fossils these deposits could be interpreted as equivalent to some part of the previously described Lower Carboniferous (Mississippian) system above or the Silurian system below. The first inkling of an intermediate system came from William Lonsdale's studies of south Devon fossils (corals intermediate between those of Silurian and Carboniferous rocks) in the late 1830's. Shortly thereafter (April 24, 1838; published 1840), Roderick Impey Murchison and Adam Sedgwick, on the verge of the same conclusion from geologic mapping, went before the Geological Society of London to baptize the new system—with full credit to the help of Lonsdale. Later, by general consent, the richly fossiliferous Devonian sequence of the Ardennes and west Rhine was accepted as the standard for comparison, in place of the more strongly metamorphosed and structurally complicated Devonshire succession.

1. Physical Events and Features.—Great events altered the earth during Devonian time. Mountain building convulsions (the Caledonian orogeny), probably beginning before the end of the Silurian period, squeezed the thick older Paleozoic deposits of northwestern Europe into a northeast-southwest curving folded belt, eradicated the troughs in which they had accumulated, and erected the highlands from which the sediments for the Old Red Sandstone were eroded. New subsiding belts (geosynclines) and rising borderlands were created. The sea, which had been restricted during Late Silurian and Early Devonian, spread widely with advancing time. At one time or another, and to varying depths, it seems to have covered large parts of all continents as shown on the distribution map.

Only between Greenland and Scandinavia does there appear to have been extensive land where there now is sea—the Old Red continent. sometimes called the North Atlantic continent or Eria. Physical characteristics of the continental sediments of east Greenland imply derivation from high or rapidly rising land to the east, and those of both Greenland and Europe contain similar nonmarine or fresh aater fishes and land plants. Evidence such as this, and the close affinities between bottom-living marine faunas on opposite sides of the Atlantic, has also been interpreted as indicating the drifting apart of a once united supercontinent into the pieces now given separate names—but this is a highly controversial hypothesis.

There are also records of important warping of the earth's crust and changing of seaways outside of Europe during Devonian time. The so-called Acadian disturbance, for instance, created highlands along the eastern border of central North America and folded the Devonian and older rocks of the northern Appalachian and Acadian region. Eastern Australia underwent several strong paroxysms of mountain building that produced discordances within and beneath Devonian rocks and erected the Kanimbla Mountains. In north Africa, the Urals and the Andes, thick detrital Devonian sections indicate adjacent elevated or rising tracts. Deep seated axial intrusion of granitic and other plutonic rocks accompanied the rising mountain belts that bordered the subsiding sedimentary troughs or geosynclines. Concurrent volcanism shed its wastes alike on terrestrial slopes and basins and into the seas, where they were mixed and interbedded with more normal detritai and organic sediments.

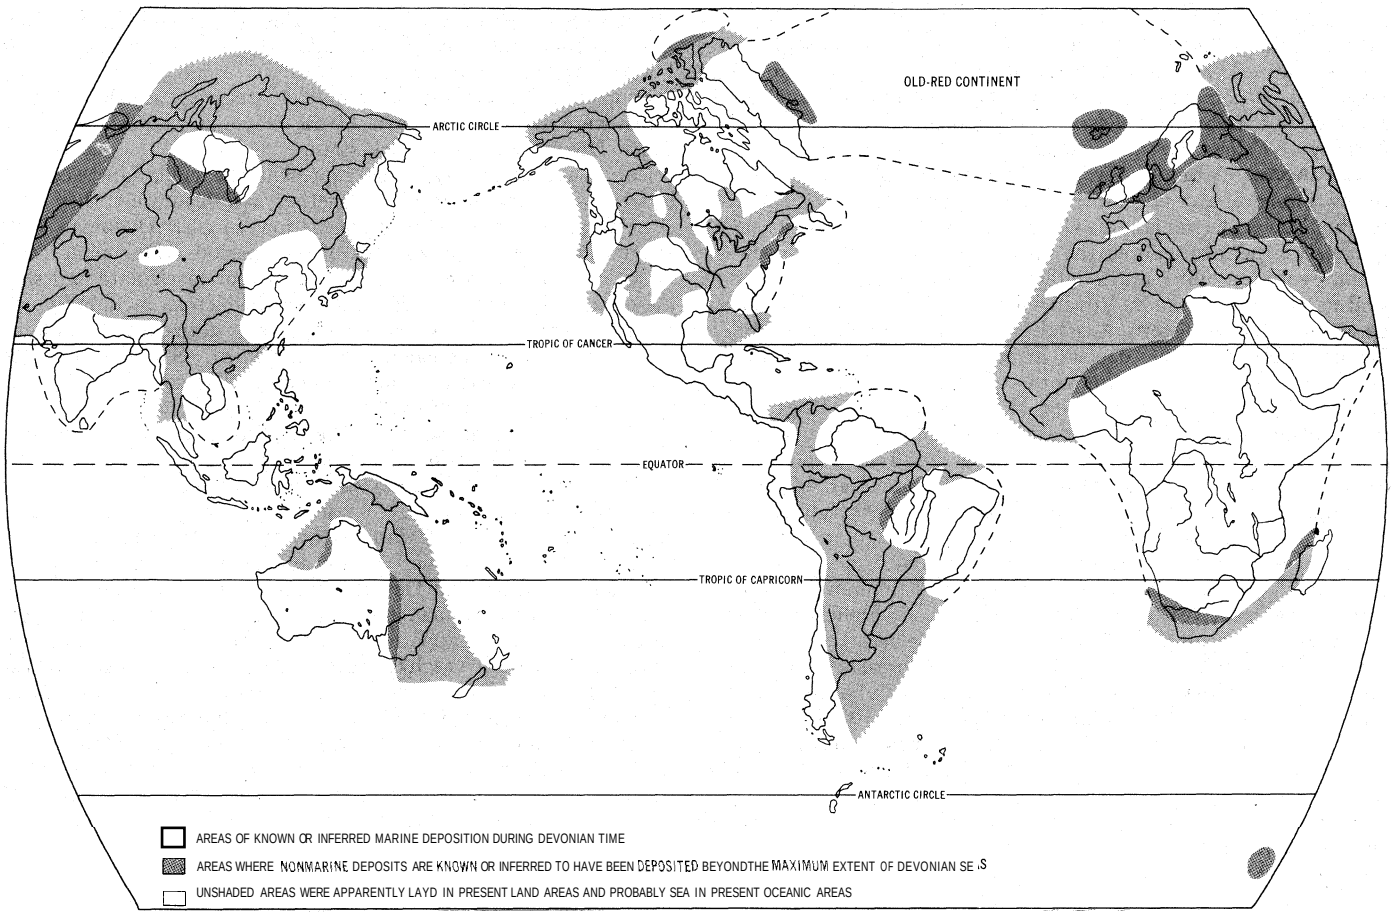
Late Devonian time saw the first crustal movements of the Hercynian, or Variscan, and Appalachian orogenies, pulses of which recurred through the rest of the Paleozoic era and eventually created mountains from the sediments of subsiding belts throughout the world.

2. Climate and Ecology.—The rising mountains of Devonian time doubtless interfered with wind circulation and created some climatic diversification, especially of rainfall. Extensive seaways, however, provided a heat transfer system that had strongly equalizing thermal effects. A generally warm climate throughout the world is suggested by the wide development of thick Devonian limestones and dolomites with an abundance of reefs formed by corals and stromatoporoids or stony Hydrozoa, as well as by hordes of shelly bottom-living organisms that show strong similarities over wide ranges of latitude.

Principal ecologic variations were presumably interrelated with physical and chemical changes due to increasing depth at sea or altitude on land, or special geographic configuration. Reef-building organisms flourished in clear circulating waters at shelf edges, or in shoals not exposed to floods of sediment. In the shelf seas were deposited calcium carbonate sands of biologic origin and terrestrial detritus, together with remains of associated molluscan and brachiopod faunas; terrestrial detritus predominating where circulation was restricted, as behind some reef belts. In the deeper sedimentary basins or troughs were soft oxygen-poor muds (commonly with sandy or calcareous interlayered beds), in which free-swimming cephalopods (ammonoids) and floating pteropods are the principal forms of life preserved. Some ammonoids are also found associated with the reef deposits and on the back-reef shelves. Local mass transport of sediments down the slopes of basins led to the mixing of sediments and remains of organisms from different depths, and the creation of a distinctive complex of sedimentary features. On land, the poor sorting, red colour, fossil content and textural characteristics of the Old Red Sandstones and similar deposits imply formation principally in intermontane basins, deltas or estuaries in a warm climate of marked seasonal rainfall. If the inference is correct, such conditions existed in many parts of the northern hemisphere, and from Greenland to Antarctica.

3. Devonian Rocks.—Particular kinds of rock and biologic associations, called facies, result from the interplay of variation of source, history of deposition or emplacement, and environmental factors. In the Devonian, as in other systems, different rock or biologic facies may be equivalent in time, and the same or similar rock or biologic facies may recur at different times. The concept of facies as associations of particular kinds of rocks is equally applicable to sedimentary, metamorphic or igneous rocks. Among Devonian sediments the reef limestones and the Old Red Sandstone are common facies types, but there are many others.

An especially distinctive facies of Upper Devonian and Devonian-Carboniferous transition deposits consists of fissile black shales bearing fossil records of spores and conodonts or small



MAP SHOWING DISTRIBUTION OF DEVONIAN SEAS AND LANDS

toothlike objects, at places accompanied by chert or novaculite. This is prevalent in the central U.S., where representatives are the Chattanooga, Ohio and Woodford shales. It may also be represented in the lower Amazon basin of Brazil, and elsewhere. Beside distinctive conodonts, as Palmatolepis, and megaspores of plants, such shales frequently contain silicified logs of primitive conifer-like wood, remains of tiny conical floating pteropods, inarticulate Brachiopoda (*q.v.*) and the bones of fishes. It is clear that there were no high or rising lands near the sites of deposition of such sediments, yet they commonly overlap older deposits at their margins as though approaching land. The fossils point toward free connections with the open sea, but the specific depth and other environmental conditions of the black shale deposition are debatable.

II. DEVONIAN LIFE

The Devonian is sometimes called the age of fishes because of the relative abundance and variety of fossil fishes found in the Old Red Sandstone and in some marine deposits. It was once supposed also that the higher plants first arose in Devonian time, because no ancestral forms had been found in older rocks. Both of these circumstances are fortuitous; actually the invertebrates are the numerically dominant Devonian fossils, and their evolutionary sequence is the reference standard for Devonian correlation.

1. Vertebrates. — Hundreds of species and all classes of fishes, from a few inches to several feet long, are known from the Devonian, commonly from finds in fresh water or estuarine deposits or associated with black shales of marine origin. In North America alone over 100 genera are recognized, with two or three times as many in Upper Devonian deposits as in Middle or Lower.

Late in the period the first four-footed vertebrates arose from the lobe-finned crossopterygian fishes. which have persisted to modern times in waters of moderate depth off Madagascar where the living coelacanth (*q.v.*) has been found. The first vertebrates to emerge from the seas were labyrinthodont amphibians! of which nine Devonian species were recorded up to the second half of the 20th century. It is a delicate and not too important point whether some of these fishlike amphibians are not really amphibianlike fish; the dispute merely fortifies the indicated evolutionary connection. (See AMPHIBIA: *Evolution.*)

Despite their conspicuousness in some deposits, the Devonian vertebrates were far from the earliest of their line. The oldest vertebrate fossils known are fragments of bony arrnour from relatives of the jawless hagfishes and lampreys, found in Middle Ordovician deposits in the American Rockies. Four of the five orders of these jawless fish (Agnatha) are recorded from both Silurian and Devonian deposits, but none are known to have survived the Devonian. (See CYCLOSTOME.)

A second class of fishlike vertebrates related to the sharks, the placoderms. with armoured heads and soft bodies, is almost limited to the Devonian. Only one of the six orders of these bizarre creatures, the acanthodians, has significant records in either older or younger rocks. Numerous and distinctively Devonian mollusk-crushing varieties do appear at the top of the Silurian, however, and one is recorded from the Lower Carboniferous. Real jaws were present, although only the lower one was movable. These were probably the first vertebrate predators. With the arrival of the sharklike fishes or Chondrichthyes (selachians) who left their first known records in the Middle Devonian, the last major step in fish evolution was achieved. Jaw articulation was now entirely free. (See CHONDRICHTHYES.)

Meanwhile fishes with bony internal skeletons, the class Osteichthyes, had become abundant in Middle Devonian freshwater deposits. Among this group, the lobe-finned crossopterygians and the lungfishes (Dipnoi) held the upper hand through the rest of Devonian time, while the subsequently dominant ray-finned fishes were greatly subordinate. The development of internal nostrils in both Dipnoi and crossopterygians, and of lungs in the former, indicate adaptations to air breathing, probably as

a result of seasonal droughts. Despite the later lack of success of these sharp-toothed but sluggish predators, both have living representatives, and descendants of their backward minnowlike Devonian contemporaries, the ray-finned paleoniscids evolved in a direct line to paddlefishes and sturgeons. (See FISHES. The History of Fishes: Archaic Fishes)

2. Plants.—Although Sir William Dawson had found and correctly interpreted the simple vascular plant called *Psilophyton* in the Lower Devonian of Gaspé (Canada) as early as 1859, botanists generally ignored the implications of this discovery for plant evolution until much later. The discovery of similar as well as structurally more advanced plants in undoubted Silurian deposits in southeastern Australia in 1908, and of the Middle Devonian Rhynie chert deposit in Scotland in 1917 caused a reevaluation of paleobotanical data. A broad morphologic unity has been recognized by grouping all vascular plants together as the Tracheophyta, with four major subdivisions (Psilopsida. Lycopsida, Sphenopsida and Pteropsida), the first three present throughout the Devonian and the last (Pteropsida) arising toward the end of this period (see PALAEOBOTANY: Classification of Possil Plants). The competitive advantages of a vascular water-conducting system are so great, the basic vascular structure is essentially so simple, and the other morphological differences between early representatives of the different groups of higher plants are so marked that paleobotanists increasingly suspect their repeated independent origin. In any event the long pre-Devonian existence of noody plant diversification seems corroborated by the repeated reports of Cambrian spore discoveries in Estonia and north India and the announcement of leaf bearing, though asporangiate, woody shoots from marine Middle Cambrian deposits in eastern Siberia.

A relatively rich record of the land plants, and many noteworthy evolutionary advances, are. nevertheless, first recorded in the Devonian. The known Lower Devonian floras were low, herbaceous, semiaquatic plants without clear differentiation into true root, stem and crown—similar to those of the Silurian, and resembling living club mosses. A much higher degree of differentiation is observed among Middle Devonian plants, which include several of the principal races of the woody plants and even a few treelike gymnosperms. A fossil forest of a fernlike plant, *Aneurophyton,* in eastern New York has yielded trunks several feet in diameter and leaves six feet long. Forests were well established by Late Devonian time, made up of the predecessors of the Carboniferous coal-swamp forests. Indeed, thin Devonian coal seams are found at a few places. Trunks up to five feet in diameter of the great cordaite gymnosperm, Callixylon, were floated out to sea, and silicified logs are common in marine and near shore Upper Devonian deposits all over the eastern U.S. and in the Donetz basin of southwest Russia

The lower plants are known from the occasional remains of red and brown algae, siphonaceous green algae, dextrally spiraled stoneworts (Charophyta), and various composite algal structures, all marine. Identifiable smaller algae obtained from chert in the uppermost Lower Devonian Onondaga beds of New York state include greens (desmids and Ulotrichaceae) and blue-greens (Chroococcaceae). (See ALGAE) A variety of well preserved fresh-water fungi and algae have been obtained from the Rhynie chert of Aberdeenshire.

3. Invertebrates and Associated Fossils.—Devonian marine invertebrate faunas are dominated by brachiopods and corals, with large numbers also of bivalve mollusks (pelecypods) and of stony Hydrozoa (stromatoporoids) locally. Shell-bearing cephalopods with complicated internal partitions, the nautiluslike ammonites, became common in the Upper Devonian—the beginning of a long line of distinctive, short-lived, widely-distributed species of superior value as time indicators. Conodonts are frequently common where other fossil evidence is rare or missing, and hence are also of special interest in rock correlation. Unicellular (or noncellular) organisms (Protozoa) are represented by a few Foraminifera and many Radiolaria. Tracks and trails, burrows, markings made by drifting objects, unclassified fossils, and unidentified objects resembling fossils, are common in Devonian rocks as in others—they are the crossword puzzles of paleontologists, commonly spelling messages of great interest when worked out. (*See* FOSSIL; ANNELIDA. *Fossil Annelids.*)

Simplest of the many-celled animals (Metazoa) are the sponges, which were numerous in parts of the Devonian, especially in the Upper Devonian of New York state.

Corals and stony Hydrozoa represent the cnidarians (coelenterates with stinging cells). Together and separately they constructed reefs and thicketlike associations in clear Devonian shelf waters from beginning to end of the pericd. Devonian coral faunas are characterized by predominance of fasciculate and simple tetracorals whose tubular calcareous skeletons included vertical septa arranged in fours and numerous horizontal to oblique internal partitions (tabulae and dissepiments). Simple cones with a cystose internal structure are abundant. The colonial tabulates, which were abundant in the Silurian, are subordinate and all but a few forms die out at the end of the Devonian; reported Devonian occurrences of the chain coral Halysites have not been authenticated. Tetracorals with axial structures such as characterize the Carboniferous first became common at the very top of the Devonian (Strunian stage), with the dwindling of colonial and solitary, dissepimented forms. Stony hydrozoans are about equally common in Silurian and Devonian reef assemblages, but are represented in post-Devonian (post-Strunian) strata by only a few aberrant types which apparently carried through until Cretaceous time. One aberrant twiglike variety with a radial canal and distinctive network tissue (*Amphipora*) is distinctive of upper Middle and lower Upper Devonian (Givetian and Frasnian stages) limestones and dolomites throughout the world. It commonly is abundant in black carbonate rocks that lack other fossils, or with nothing else but large thick-hinged pelecypods—the so-called spaghetti or vermicelli beds of some stratigraphers. The stony Hydrozoa (stromatoporoids) are related to but do not closely resemble the millepores that contribute so importantly to modern reefs (see HYDROZOA). The tetracorals and tabulates are quite unlike modern corals of either shallow or deep water.

Polyzoa (*q.v.*) or Bryozoa (moss animals) are abundant throughout the Devonian. Stony types (trepostomes) were common, but apparently diminishing, while the lacy varieties (fenestellids) forged ahead.

Devonian brachiopods show bursts of evolution among the loop and spire bearers (terebratuloids and spiriferoids), continued abundance and expansion of rhynchonellids, and the beginning of expansion of the spiny productoids. Dalmanelloids and strophomenoids were somewhat more abundant than in later times, but the true orthoids dwindled out early in the period. The many short-ranged loop-bearing terebratuloid genera are especially helpful in Lower Devonian correlation; the wide-hinged spiriferoids throughout the system.

Marine clams (Lamellibranchiata) and snails (Gastropoda) increased greatly during the Devonian, the former locally outnumbering the brachiopods in near-shore facies. The oldest records of fresh-water clams (*Archanodon*) are also Devonian. The great Ordovician-Silurian surge of nautiloid cephalopod evolution continued the decline in the Devonian that had begun in the Silurian. Their cousins, the ammonoids, evolved to fill the predatory niches vacated by the nautiloids, and to take their place as index fossils. Devonian ammonoid septa and sutures were simpler than later forms, a feature sometimes recognized by calling them goniatites.

Trilobites, strongly reminiscent of their Silurian ancestors, are common in the Lower Devonian, a spiny variety reaching a length of two feet. They dnindle in number and diversity during the rest of Devonian time, foreshadowing their extinction in the Permian. Minute bivalved Crcstacea, the ostracods. are abundant, and apparently planktonic species have been found particularly useful in correlation in Europe. Branchiopod Crustacea are fairly common and occasionally nonmarine (Estheria). Giant arachnidlike arthropods, the Eurypterida (*q.v.*), lived mainly in freshwater bodies and estuaries; where they perhaps preyed on the early fishes and their smaller fellow invertebrates. Ancestral spiders which are found in the Rhynie chert presumably evolved

from unknown arachnid ancestors during the Silurian.

Echinoderms, except cystoids, were advancing. Blastoids, echinoids and starfishes increased in numbers and variety, and crinoids became locally abundant. Single bladed types of graptolites died out with the Silurian, and only occasional net-formed (dendroid) graptolites are found in the Devonian.

4. Biogeography and Migration Routes.—Although the faunas and floras of the Old Red facies seem much alike the world over, some of the Devonian marine faunas show marked division into mainly southern hemisphere (austral) and mainly northern hemisphere (boreal) types. These two major provinces seem to have been most clearly defined in later Early Devonian time, when the boreal fauna was also most clearly divisible into European and North American subprovinces.

The austral Lower Devonian is particularly characterized by sandy and silty sequences containing the brachiopod Australocoelia in South America, South Africa and Tasmania. An unusual and apparently rare brachiopod, *Scaphiocoelia,* of South American and African Lower or Middle Devonian beds appears to be another distinctive element. The boreal Lower Devonian commonly displays a sedimentary facies similar to that of the austral province, but only in North America does it contain possible faunal ties, especially the brachiopod genus Leptocoelia, a close relative of Australocoelia.

In addition to general circum-antarctic connections, therefore, there was evidently some later Early Devonian communication between North America and the austral provinces. There are strong ties between North American later Early Devonian faunas and those of the Reefton beds in New Zealand, for instance; while the somewhat older Baton river beds of the same area are more closely allied to the European faunal subprovince. Related boreal Middle and Upper Devonian faunas can be traced clear across Europe, Siberia and the orient to Australia; and some of the same elements (*Amphipora,* Pachyphyllum, *Stringocephalus*) got into North America. Possible connections can be seen even on the highly generalized distribution map. North America seems to have been a sort of mixing pot, with at least temporary connections to Europe, to Siberia and to the southern hemisphere. In Middle and Late Devonian time its internal seaways probably connected with both Europe and Siberia through far northern channels. During parts of Lower Devonian time there was probably communication between Europe and New England, and from Tennessee to South America.

III. REGIONAL SUMMARY

The composite and highly generalized distribution map shows where Devonian deposits of different ages and broadly different types might have been laid down on the present land areas. Beside those here indicated, nonmarine sediments also will be found to interfinger with the marine deposits along the margins of the ancient seaways mapped; and the sediments of subsiding basins may be widely overlapped by shelf-sea deposits.

The map and the correlation table together, however, provide a framework of data on the distribution of Devonian rocks and seas that gives a general idea of the local complexities and supplements the discussion that follows.

1. Great Britain.—The type sequence of the Devonian system in south Devon consists of 1,000 ft. or so of Middle and Upper Devonian limestones and some interbedded shales, resting on an unknown thickness of impure sandstones and clayey beds of Early Devonian Age. In north Devon the sequence is about 13,000 ft. thick and consists of sombre graywackes, slates, shales, sandstones, volcanic sediments and occasional discontinuous limestones. The lower part (Foreland grits), of which the base is unknown, consists of red sandstones and conglomerates with land plants. The top beds are in depositional sequence with overlying Lower Carboniferous strata. The Devonian sections of both north and south Devon contain distinctive marine fossils in common with the west Rhineland and Ardennes sections, which have been accepted as correlation standards.

The north Devon sequence is replaced northward across the Bristol channel by the Old Red facies, with the base of which the Foreland grits are probably continuous. The detrital north Devon and lower south Devon sediments contain land plants, fish and shallow water types of brachiopods, corals and mollusks; whereas the post-Lower Devonian limestones of south Devon include coral-stromatoporoid reefs. Faunal and sedimentary facies hold the same natural geographic relationships as in the Ardennes region, only slightly foreshortened by structural compression. Thus similar reef limestones and shales occur from Ireland to the Rhine between near shore shelf or shallow basin sediments to the north and a deep basin shale-sandstone facies with open sea elements to the south, as in Brittany.

Wales, the Scottish Lowlands, and the area around Moray firth were the sites of major Devonian continental basins into which as much as 40,000 ft. of mainly red detritus poured from the erosion of surrounding mountains and volcanoes. It was buried so rapidly that much of the ferruginous colouring matter remained in an oxidized state. Robert Jameson mistakenly called this detritus the Old Red Sandstone in 1808, thinking it to be the British equivalent of Abraham Gottlob Werner's "Aelter rother Sandstein" in the Permian system. The mistake stuck, and Werner's Permian deposits eventually got a new name, the Rotliegende, while Old Red was extended to Devonian continental deposits all over the world. Fishes are the local basis for relative time subdivision and correlation of the Old Red.

Between the Old Red, of continental origin, and the underlying Silurian, of marine origin, in England are the so-called Downtonian beds, which were long referred to the Silurian because they contained marine fossils. Studies of the fishes and plants in these and correlative beds eventually suggested strong Devonian affinities, and mapping showed generally disconformable relationships with the underlying beds in south Wales. Finally it was established from the marine fossils that the Downtonian is the equivalent of certain strata (the Mondrepuits clayey rocks or argillites) near the base of the Devonian in the standard Ardennes section.

2. Ardennes and North Rhineland.—Thanks to the efforts of five generations of Belgian and French paleontologists and stratigraphers the world's best known Devonian sequence is the wonderfully complete and fossiliferous marine section of the Dinant basin and adjacent parts of Belgium and France. The 18,000 ft. or so of shale, siltstone, sandstone and limestone comprising this sequence is easily accessible for study in artificial and natural cuts, including sawed quarry surfaces that transect entire coral and stromatoporoid reefs of Middle Devonian Givetian and Upper Devonian Frasnian age several yards thick. Moderate folding has repeated parts of the section so that lateral changes of facies may be studied.

This Ardennes sequence is strikingly similar to that of south Devon when distance and deformation are taken into account. The Ardennes reefs and detrital limestones have been studied particularly by M. Lecompte who finds that they change laterally to and are interbedded with shales, and attain maximum dimensions of over 800 ft. thickness and more than one-half mi. in length. They began to grow in early Middle Devonian time at the shoaling edge of an open basin to the south. Thereafter, the reefs formed intermittent local barriers to circulation in the shelf seas that stretched northward behind them to the border of the Old Red continent. Their shelf equivalents are red and green silty shales and patches of dolomite, relatively thin, with basal beds increasingly younger northward. The pile of siltstones, sandstones and silty shales below the oldest reefs suggest that the latter appeared late because they were unable to gain a foothold until the supply of debris was reduced by erosional lowering of the source area. They were eventually killed off by a flood of mud in the Dinant basin in late Frasnian and Famennian time. This mud became a shale, which grades northward to the nearshore Condroz sandstones in the Namur basin.

Continuing eastward into the Rhenish Slate mountains (Rheinisches Schiefergebirge) of north Rhineland, is a roughly similar but changing suite of rocks. The Eifel section, farthest west, has almost the same thickness as the Ardennes section and is also richly fossiliferous. Its lowest beds are continental in origin,

STRATIGRAPHIC RANGES (SOLID LINES) OF CHARACTERISTIC GENERA OF THE DEVONIAN SYSTEM

rather than marine, however, and it also differs in the greater amount of calcareous shale and the reduction of reef limestones in beds of Givetian and Frasnian age It is, nevertheless, richer in well-preserved brachiopods and other shelly fossils than the Ardennes section. Natural exposures are poor. but in the early days trenches and quarries were dug especially to collect the fossils, and they became well known through the descriptions of German paleontologists.

The Sauerland sequence, in the northeastern Slate mountains attains thicknesses of 25,000 to 30,000 ft., and is much sandier than equivalent beds of the Eifel or Harz. It includes relatively deepwater deposits with floating types of minute bivalved crustacians and conical gastropods (ostracods and pteropods) in the upper part; but reefs of colonial tetracorals and stromatoporoids are found in Givetian to Frasnian equivalents locally. These reef limestones are the Massenkalks of German geologists, good sites for quarries and hilltop cathedrals. The lower beds are mainly sandstones. slates and metamorphosed silty shales with occasional zones that are rich in brachiopods and other shelly fauna indicative of relatively shallow water These retain a generally similar nature from Sauerland westward to the gorge of the Rhine, where a bluff and river shallows of Emsian sandstone produced the legend of the Lorelei.

Probably parts of the area of the Slate mountains tended to be high in Devonian time as some do today. This would account for complications in the depth facies of the sediments in this area. Evidences of contemporaneous volcanism suggest that parts of the area were volcanic islands.

3. Central and Southern Europe.— Eastward across Europe from the north Rhineland Slate mountains the lowest and highest Devonian formations drop out, and the remaining Lower and lower Middle Devonian becomes increasingly calcareous. In the Harz region the beds are calcareous shales and shaly limestones. and at Prague they are pure limestones that have yielded myriads of well preserved brachiopods and trilobites for the museums of the world. The Upper Devonian is missing here, presumably because of non-

deposition due to emergence of the Bohemian positive area. as foreshadowed by the shallow water deposits of Givetian Age that comprise the Srbsko beds. Preponderantly calcareous Devonian sequences in Europe are sometimes referred to as the Bohemian facies, in contrast to the Rhine or Rhenish facies—calcareous sedimentation in contrast to sandy sedimentation. The intermediate facies of the Harz Mountains is then called Hercynian.

Actually the calcareous Devonian in Europe is mainly an Alpine (or Tethyan) type deposit. In the Carnic Alps, for instance, a possibly complete Devonian sequence is represented by fossiliferous limestone. Lower and Middle Devonian beds are commonly reef rock, locally dolomitic. while the Upper Devonian begins with a brachiopod facies and ends in a sandy basinal facies, with ammonoids. These deposits were formed in the Tethyan seaway, which occupied the present site of the Alps and south Asian mountain ranges. Broadly similar deposits occur generally in the Mediterranean region.

Elsewhere in Europe, Devonian rocks occur in the Vosges, Montagne Noire, and Massif Central of France; the Pyrenees, Catalonia and other parts of Spain; in several of the larger Mediterranean islands; and in Rumania. A good and fossiliferous section, with representatives of all series is found in the Holy Cross mountains (Gory Swietokryzskie) near Kielce, in Poland, and outcrops of Old Red and Downtonian deposits are known in the gorges of the Dniester river drainage in western Podolia, now a part of Russia.

4. **U.S.S.R.**—A shallow but subsiding gulf of the European epicontinental sea spread northeast beyond Moscow, where a maximum of about 4,000 feet of limestone, marl, clay and some dolomite at the centre and south grades laterally into thinner sandstones with fossil fish, fossil plants, and generally strong Old Red affinities. In the vicinity of Moscow this sequence is known from borehole records only, but it rises southward to expose a thin edge of marine Upper Devonian limestones between Kursk and Varanezsch.

A Devonian subsiding trough ran the length of the Urals (Uralian geosyncline), to merge with the Tethyan channel to western Europe, and to spill eastward as the Siberian epicontinental sea, eventually crossing China to Australia and connecting with Alaska. Geological knowledge of the Urals and Siberia was increased by investigations after the middle 1920's, and especially after 1945. Thus, the Altai foothill section (Kuznetsk coal basin, south central Siberia) given on the correlation table incorporates extensive revisions of older work introduced by G. N. Kartseva and V. B. Tsyrlina in 1956.

The Ural sections are shales, marls and limestones, of great thickness, representing all major divisions of the period above the Lower Devonian Siegenian. The same sedimentary trough stretched the length of the Novaya Zemlya arctic islands and northwestward, probably to connect with the Cordilleran geosyncline in North America. Central Siberian sections, reaching to the Lena delta area, show Middle and Upper Devonian limestones and shales, commonly rich in shelly faunas and corals. These deposits are apparently not very thick. From Tomsk almost to Kamchatka they grade shoreward into a variety of volcanic deposits, and to red and green clays, marls and sandstones of Old Red facies with fossil fishes. The distinctive Uralian and Siberian brachiopod, the spiriferoid genus *Theodossia,* characteristic of Givetian and Upper Devonian deposits, gets into central North American deposits, presumably via the arctic.

5. **Asia.**—Yünnan province (southwest China) has a thick and nearly complete marine sequence of Middle and Upper Devonian rocks somewhat reminiscent of that in Siberia. The Lower Devonian is represented only by a thin nonmarine sandstone. Devonian sections, generally poorly represented in the loner part. are also known from Kwangsi, Szechwan, Kweichow, and Hunan in China and from Indochina and at places throughout the high mountain ranges leading west to Iran and the Bosporus. In the Kitakami mountains of northern Japan all series of the Devonian are represented by fossiliferous marine volcanic sediments, some with land plants.

6. Australia, New Zealand and Approaches. — The only known Devonian between Malay and Australia is found in central Netherlands New Guinea. These strata contain a Frasnian marine fauna.

In the Kimberly embayment of western Australia, however, the Devonian section reaches a thickness of 10,000 ft. or more. It consists of clastic debris from the erosion of rising adjacent lands and limestones of post-Couvinian (Middle Devonian) Age, with a marine fauna allied to that of Europe. Interbedded with the marine sediments are extensive volcanic deposits.

The eastern mountain ranges of Australia display thick Devonian sequences in Tasmania, Victoria, New South Wales and Queensland, all including both marine and continental deposits with a strong to predominating volcanic element. A composite section ranges from about 10,000 to 16,000 ft. thick, but no complete section is known at any one place. The Upper Devonian is widespread, but outcrops of the Lower and Middle parts are scattered and restricted. The locally rich marine faunas resemble those of Europe. In Tasmania the brachiopod *Australocoelia* provides a southern hemisphere flavour. Radiolarian cherts are abundant, perhaps because of local enrichment of the water in silica as a result of volcanism. Although radiolarian cherts are sometimes considered to indicate deep water deposition, these are associated locally with shallow water limestones containing reef building tetracorals, the stony hydrozoan *Amphipora,* and the large stringocephalid brachiopod *Bornhardtina.*

The Devonian record in New Zealand is limited to the two sequences previously mentioned under *Biogeography and Migration Routes,* the Reefton beds of Siegenian to Emsian Age, and the apparently somewhat older Baton river beds, containing the brachiopod *Eospirifer.*

7. South America. — A Devonian sedimentary trough extended the length oi western South America from Venezuela to the Falkland Islands. Apparently separate subsiding basins also existed in Brazil, Paraguay and Uruguay. The best known section is in Bolivia, where shales and sandstones below the Middle Devonian Sicasica beds represent the Lower and perhaps lower Middle Devonian. The Andean Sicasica series of shales and sandstones contains Middle Devonian fossils, especially the trilobite *Dipleura dekayi.* It is overlain by shales and sandstones of possible Late Devonian Age. Partial equivalents of the Sicasica beds, with faunal affinities to the North American Middle Devonian occur in Colombia (Floresta beds), Venezuela (Kio Cachiri beds), and Brazil. Curua black shale beds (Pará, Brazil), containing the brachiopod *Schizobolus concentricus,* probably transgress the boundary from Middle to Upper Devonian.

8. Antarctica and South Africa. — The terrestrial Beacon sandstone and shale of Victoria Land, eastern Antarctica contains Upper Devonian fish in the lower shales at Granite Harbor, and post-Devonian plants above. These deposits attain a thickness of 5,500 ft. but it is not known how much of this is Devonian.

South Africa exposes a thick clastic section with a few marine fossils between Cape Town and the Cape of Good Hope. Brachiopods in it, including *Australocoelia,* indicate affinities with South American and Tasmanian Lower Devonian.

9. North Africa. — Devonian seas covered the western third of north Africa, from the Gold Coast (Ghana) to the central Sahara. Nearly complete sequences 6,500 ft. or so thick accumulated in a northwestern trough that subsided markedly, from shallow beginnings, in Middle and Late Devonian time. This trough ran northeastward through central Morocco to the northwestern Sahara. South and east of an intermittently high axis in western Algeria, the sea was shallow and deposition irregular. Land northwestward beyond the subsiding trough toward Gibraltar is heralded by nearshore sands with plant remains in that direction. Limestone deposition and reef formation prevailed in clear shoal waters at the southern margin. Above the Lower Devonian, ammonoids and other open sea species are found both in the trough sediments and, episodically, in the shelf areas, indicating local deepening or good communication channels from shallow to deep water. In central Morocco is an apparently complete fossiliferous marine sequence mainly of limestone and shale, with quartzite at the base.

10. North America.—A broad and mainly shallow seaway brought an arctic fauna down through the Cordilleran region of western Canada and the western U.S. This seaway at times had east-west connections across the northern and southern U.S. (and into Mexico) that permitted mixing of eastern and western faunal elements. For the most part, however, the eastern epicontinental seas seem to have had separate connections with the ocean. Faunal affinities of the eastern deposits are closer with the German Eifel succession than with the coral rich Ardennes. The fossil record shows that even if the larvae of reef corals were brought to the area they could not ordinarily survive in the turbid waters of the eastern seas except during parts of the Early Devonian and much shorter intervals of the Middle. On the other hand, corals and stromatoporoids, with reef associated brachiopods, were able to spread through the relatively shallow seas of Canada and the western U.S., because adjacent lands were generally low and waters clear. Strikingly diiferent faunas are found in Alaska and northern California, with affinities to Siberia and the Urals.

The Devonian system in the central Appalachians and New York state is particularly important as one of the world's classic reference sequences. The Lower Devonian is mainly shallow-water (platform) limestones and shales with sandstone in the middle part. In New England and the northern Appalachians, however, the largest part of the section is siliceous detritus: some in the upper part (Gaspé sandstone) with plants. The Middle Devonian of New York state forms a great wedgelike succession of beds, thinning westward. On the east, in the Catskill mountains, it is represented by thick red and green sandstones and conglomerates containing fishes, the remains of an *Aneurophyton* forest, freshwater pelecypods, and large Eurypterida (*q.v.*). Westward toward the centre of the state the beds interfinger with marine sands and shales, and at the western New York border black shales occupy most of the section. Further westward these grade into marls, limestones, and dolomites containing the great coral plantations of a former platform sea in southwestern Ontario, Michigan, Wisconsin and Indiana. A similar facies development occurs east to west throughout the Appalachians far southwestward from New Uork. The Upper Devonian of eastern New York and the Appalachian region is almost wholly of Old Red facies in the eastern part and finer sandstones and silty shales to the west. In Ohio the sandstones pass into black shales. In the midwest and the south the black shales are collectively known as Chattanooga shale, locally including parts of Early Carboniferous Age.

In Iowa and Missouri the Middle Devonian is mainly limestone and dolomite; the Upper Devonian consists of limestones and marls, commonly containing corals and, in the lower half, the ammonoid goniatite *Manticoceras.* A red-bed facies with fishes and plants occurs locally. In Wyoming and Utah, channel fillings in pre-Devonian beds have yielded fishes resembling those of the lower Old Red, but possibly pre-Devonian. In the far west and central Canada carbonate rocks (limestones and dolomites) predominate, with some sandstone and shale, as much as 3,000 to 6.500 ft. thick. Faunas show affinities with both eastern U.S. and Europe.

DEVONPORT, a seaport town on the north coast of Tasmania. Austr., lies on both sides of the Mersey estuary 82 mi. N.W. of Launceston by rail. Pop. (1954) 10,597. The town developed from the villages of Torquay on the east and Formby on the west bank. The district is mainly agricultural with secondary industries (food processing, textiles, milk products); the chief exports are potatoes, cement and timber. The excellent harbour has sheltered wharfage on the west bank. Devonport is linked by ferry services with Melbourne (210 mi. N.N.W.) on the Australian mainland and by air services with Melbourne and Launceston.

DEVONSHIRE, EARLS AND DUKES OF. From 1618 the Devonshire title has been held by the Cavendish family, one of the most powerful of the great Whig families. Previously it was held by CHARLES BLOUNT (1563–1606), 8th Lord Mountjoy, who as lord deputy of Ireland (1600–03) combated the earl of Tyrone's rebellion. He was created earl of Devonshire in 1603, but the title died with him. In the Cavendish line the 1st earl of Devonshire was WILLIAM (1552–1626), second son of Sir William Cavendish (d. 1557) and of Bess of Hardwicke (afterward countess of Shrewsbury). He was given the title by James I in 1618 and was succeeded by his son WILLIAM (1590–1628), 2nd earl, and grandson WILLIAM (1617–84), 3rd earl.

The 3rd earl's eldest son and successor, WILLIAM (1641–1707), 4th earl and 1st duke of Devonshire, was born on Jan. 25, 1641. He entered parliament in 1661 and soon showed himself a determined and daring opponent of the general policy of the court. He was one of the committee appointed to draw up articles of impeachment against the earl of Danby in 1678. In 1679 he was re-elected member of parliament for Derby and made a privy councilor by Charles II. He withdrew from the board with his friend Lord William Russell when the duke of York (afterward James II) was recalled to the court (1680). He carried up to the house of lords the articles of impeachment against Lord Chief Justice William Scroggs. and when the king declared his resolution not to sign the bill for excluding the duke of York from the succession. he moved in the house of commons that a bill might be brought in for the association of all his majesty's Protestant subjects. He appeared in defense of Lord Russell at his trial, and after Russell's condemnation offered to exchange clothes with him in the prison, remain in his place and so allow him to effect his escape. Cavendish succeeded to the earldom in Nov. 1684. He opposed the government under James II with the same consistency and high spirit that he had displayed during the previous reign. An imprudent quarrel at court was punished by a fine of £30,000 which he could not pay and he was in prison for some time. After his discharge the earl occupied himself with the building of his great house at Chatsworth (*q.v.*). The revolution of 1688 again brought him into prominence. He was one of the seven who signed the original paper inviting William of Orange to England and was the first nobleman who appeared in arms to receive him on landing. He received the order of the Garter and was made lord high steward of the new court. In 1690 he accom-

panied King William on his visit to the Netherlands. He was created marquess of Hartington and duke of Devonshire in 1694.

The 1st duke had married in 1662 a daughter of James, duke of Ormonde. and was succeeded by his eldest son, WILLIAM *(c.* 1673–1729). 2nd duke, whose son WILLIAM (1698–1755). 3rd duke, mas viceroy of Ireland from 1737 to 1744 The 3rd duke's son WILLIAM (1720–64), 4th duke. married the daughter and heiress of Richard Boyle earl of Burlington and Cork, who brought Lismore castle and the Irish estates into the family. From Nov. 1756 to July 1737 he was prime minister, mainly in order that William Pitt. nho would not then serve under the duke of Newcastle, should be in power. His son WILLIAM (1748–1811), 5th duke, was the husband of the beautiful Georgiana Spencer (1757–1806) and of the intellectual Elizabeth Foster (1757–18243, both of whom Gainsborough painted. The 5th duke's son WILLIAM (1790–1858). 6th duke. died unmarried He was the patron and friend of Sir Joseph Paxton The title passed in 1858 to his cousin WILLIAM (1808–91), 2nd earl of Burlington, as 7th duke.

The 8th duke is noticed separately *(see* DEVONSHIRE, SPENCER COMPTON CAVENDISH, 8th Duke of). He died aithout issue and his successor as 9th duke was his nephen VICTOR CHRISTIAN WILLIAM CAVENDISH (1868–1938), who was financia! secretary to the treasury (1903–05). civil lord of the admiralty (1915–16), governor general of Canada (1916–21) and colonial secretary (1922–24) In 1892 he married a daughter of the marquess of Lansdonne One of his daughters married Harold Macmillan who became prime minister in 1957. The 9th duke was succeeded by his son EDWARD WILLIAM SPENCER CAVENDISH (1895–19503, 10th duke, who held his father's seat in parliament for West Derbyshire (1923–38) and served as a parliamentary undersecretary from 1936 to 1945 His second son. ANDREW ROBERT BURTON CAVENDISH (1920–). 11th duke, became parliamentary undersecretary to the commonnealth relations office in 1960

DEVONSHIRE, SPENCER COMPTON CAVENDISH, 8TH DUKE OF (1833–1908), British statesman who became leader of the Liberal Unionist party in 1886, was born at Holker hall. Lancashire. on July 23. 1833 He was the son of the 7th duke (then earl of Burlington) and his wife. Lady Blanche Howard (sister of the earl of Carlisle) Educated at home and at Trinity college. Cambridge, he was returned to parliament as Palmerstonian member for North Lancashire in 1857. At the opening of the new parliament of 1859 the marquess of Hartington, as he had then become. was chosen by Lord Palmerston to move the amendment to the address uhich overthrew the government of Lord Derby. In 1862 he visited the United States, meeting both Lincoln and Jefferson Davis, and in 1863 he became first a lord of the admiralty and then undersecretary for war in Lord Palmerston's government. In Feb. 1866 he entered Lord John Russell's cabinet as war secretary. He retired with his colleagues in July and used his comparative leisure to visit Germany and to meet Bismarck. He lost his seat in 1868, but became M.P. for Radnor early the next year. He entered Gladstone's first cabinet as postmaster general, an office which he exchanged against his own inclination, in Jan. 1871, for that of secretary for Ireland. When Gladstone temporarily withdrew from the leadership of the Liberal party in Jan. 1875, Lord Hartington reluctantly accepted the position of Liberal leader in the house of commons. He was a moderate critic of Disraeli's foreign policy in the near east, but emphatically condemned the conduct of Indian aifairs which led up to the Afghan War of 1878. After the Conservative defeat in the general election of 1880, the queen sent for him as leader of the opposition, but Hartington had to decline her request to form a government, in view of Gladstone's position in the party. Hartington joined the new Gladstone government as secretary of state for India. from which office. in Dec. 1882. he passed to the mar office. All through the life of this cabinet he led its conservative wing, especially on Irish matters. Gladstone's attempt to conciliate him through his younger brother Lord Frederick Cavendish (1836–82), aho was made Irish secretary on May 4, 1882. resulted in the tragedy of Cavendish's murder two days later in Phoenix park. Dublin.

Hartington shared the responsibility for sending Gen. C. G. Gordon (q *v.)* to evacuate the Sudan, but he repeatedly warned the cabinet of the urgency of the Wolseley relief expedition and threatened resignation when a decision was delayed. In June 1885 he resigned along with his colleagues, and in December was elected for the Rossendale division of Lancashire, created by the new Reform bill. Immediately afterward Gladstone's proposal of Home Rule for Ireland forced on Hartington the great political decision of his life. His refusal to follow his leader in this course inevitably made him the chief of the new Liberal Unionist party. In the house of commons he successfully moved the rejection of Gladstone's bill on the second reading. This led to the dissolution of parliament, and in the general election Gladstone was decisively defeated.

In the new parliament Hartington held a position much resembling that which Sir Robert Peel had occupied after 1846— the leader of a small, compact party, the standing and ability of whose members were out of all proportion to their numbers, a man much esteemed and trusted in the country, yet in his own opinion forbidden to think of office. Lord Salisbury's offers to serve under him as prime minister. after the general election of 1886 and again in Jan. 1887, after Lord Randolph Churchill's resignation, were declined and Hartington continued to discharge the delicate duties of the leader of a middle party. It was not until 1895, when the differences between Conservatives and Liberal Unionists had become attenuated by changed circumstances and by the habit of acting together, that the duke of Devonshire, as he had become in 1891, entered Lord Salisbury's third ministry as lord president of the council, an office which carried the responsibility for education. He also presided over the cabinet committee on defense. In 1892 he succeeded his father as chancellor of the University of Cambridge. In that year he married the widow of the 7th duke of Manchester.

He continued to hold his office till Oct. 3, 1903, when he resigned on account of differences with A. J. Balfour over the latter's attitude toward free trade *(see* BALFOUR, ARTHUR JAMES BALFOUR, 1ST EARL). He necessarily became the leader of the Free Trade Gnionists who were neither Balfourites nor Chamberlainites, and his weight was thrown into the scale against any association of Unionism with the constructive policy of tariff reform, which he identified with sheer protection. A struggle at once began within the Liberal Unionist organization between those who followed the duke and those who followed Chamberlain; the latter were in the majority, and the duke resigned his chairmanship of the Liberal Unionist association (May 1904), and became president of the new organizations, the Unionist Free Food league and the Unionist Free Trade club.

In the autumn of 1907 his health gave way and he wintered in Egypt. He died on his way home, at Cannes, on March 24, 1908.

The duke's reputation as the last of the great Whigs rested as much on personal character as on political ability. His strong sense of duty was shown no less in his administration of his estates and care for the library and art treasures at Chatsworth than in his public life. A typical country gentleman, his own keenest personal pleasure was in racing and he owned several famous horses. As an orator he was remarkable more for clarity and cogency than brilliance. He owed much of his success to "the transparent honesty and simplicity . . . quiet and inflexible courage . . and absolute disinterestedness" which, as Balfour said after his death. won "the respect and confidence of men of every shade of opinion."

See B. Holland, *Life of the 8th* ***Duke of Devonshire,*** 2 vol **(1911).**

(M. **R.** D. F.)

DE VOTO, BERNARD AUGUSTINE (1897–1955), U.S. novelist, journalist, historian and critic, best known for his works on American literature and the history of the western frontier, was born in Ogden, Utah, on Jan. 11, 1897. He attended the University of Utah and Harvard university (B.A., 1920), and taught at Northwestern university (1922–27) and Harvard (1929–36) before becoming editor of the Saturday *Review* of *Literature.* After two years he resigned and returned to Cambridge. Mass., where he lived during the remainder of his life. Although he wrote a number of novels, his essays in the "Easy Chair" depart-

ment for *Harper's Magazine* perhaps brought him his largest popular audience. His ability to combine sound scholarship and a vigorous. outspoken style made him one of the most widely read critics and historians of his day. He died in New York city on Nov. 13, 1955.

Among the works De Voto wrote or edited are: *Mark Twain's America* (1932); (ed.) *Mark Twain in Eruption* (1940); *Mark Twain at Work* (1942); *The Year of Decision* (Pulitzer prize, 1946); *The World of Fiction* (1950); *The Hour* (1951); *The Course of Empire* (1952); and (ed.) *The Journals of Lewis and Clark* (1953).

See G. Mattingly, *Bernard De* Voto: *A Preliminary Appraisal* **(1938);** and the obituary in *New England Quarterly* (Dec. **1955).**

DEVRIENT, the name of a family of German actors.

1. LUDWIG DEVRIENT (1784–1832) was born in Berlin on Dec. 15, 1784. He served his apprenticeship with a provincial company in Thuringia and then joined the court theatre in Dessau, where he developed his talent for character parts. After the death of A. W. Iffland he was called to Berlin, where he was a member of the royal court theatre from 1814 to his death on Dec. 30, 1832. He counted among his most famous roles Franz Moor in Schiller's *Die Riiuber,* Richard III, Shylock and Falstaff.

Three of Ludwig Devrient's nephews, Carl August. Eduard Philipp and Emil Devrient, made important contributions to the history of the German stage:

2. CARL AUGUST DEVRIENT (1797–1872) began his career in Brunswick (1819). From 1821 to 1835 he acted in Dresden, marrying there the singer Wilhelmine Schroder-Devrient. Karlsruhe (1835–39) was the steppingstone for Hanover, whose playgoers acclaimed him for his portrayals of King Lear, Shylock and King Philip (in Schiller's *Don Carlos).* He died in Hanover on Aug. 3, 1872.

3. His brother EDUARD PHILIPP DEVRIENT (1801–1877) started as an opera singer in Berlin. From 1844 until 1852 he was an actor and a stage director in Dresden, from where he was called to Karlsruhe. There he reorganized the grand duke's theatre and finished his *Geschichte der deutschen Schauspielkunst* (1848–74), a work that still has to be consulted for its information on acting.

4. EMIL DEVRIENT (1803–1872) faced his first audience in Brunswick (1821). Via Bremen, Leipzig and Hamburg he reached Dresden (1831), where he remained associated with the court theatre until his retirement in 1868. His Hamlet was favourably received in London (1852 and 1853).

5. OTTO DEVRIENT (1838–1894) was coached as an actor by his father, Eduard Devrient. His early engagements included Karlsruhe (1856–58), Stuttgart (1858–60), Berlin (1860–61) and Leipzig (1862). In 1863 he returned to Karlsruhe to assume the duties of a stage director, and ten years later was called to Weimar. There he played Mephistopheles in his own production of Goethe's *Faust,* parts i and ii. Subsequently he served as stage director in Mannheim, Frankfurt, Oldenburg and Berlin. After his retirement to Jena he emerged occasionally for guest appearances as an actor. He died in Stettin on June 23, 1894. (A. M. N.)

DE VRIES, HUGO (1848–1935), Dutch botanist and geneticist best known for his studies on mutation, introduced the experimental method in the study of plant evolution. De Vries was one of the three investigators (the others being E. Tschermak von Seysenegg and K. E. Correns) who, in 1900, independently rediscovered and confirmed G. J. Mendel's laws of heredity. He was born at Haarlem. Neth., on Feb. 16, 1848. Educated at Leiden. Heidelberg and Wiirzburg, he became a professor at the University of Amsterdam in 1878. His attention was drawn to plant evolution by the discovery of new forms among a display of *Oenothera lamarckiana* (an evening primrose) growing as a garden escape in a aaste meadow. This suggested to De Vries that evolution might be studied by a new, experimental method rather than by the old method of observation and inference. This new method may be regarded as his greatest contribution to science and resulted in a new epoch in the history of evolution. He discovered in his cultures of *O. lamarckiana* new forms appearing among the hosts of ordinary forms, and the name "mutation" was given to this method of producing new species and varieties, which he showed to arise suddenly, as distinct from Charles Darwin's variation of species through natural selection. He visited the United States to investigate the behaviour of *O. lamarckiana* in its natural environment. After his retirement in 1918 from the University of Amsterdam De Vries lived in Lunteren, where he continued his experimental work in producing new forms through many generations of culture. He died on May 21, 1935. His best-known works are *Intracellular Pangenesis* (1889); *The Mutation Theory* (Ger. ed., 1900–03; Eng. trans., 1910–11); and *Plant Breeding* (1907; Ger. trans., 1908).

DEW, a deposit of waterdrops formed at night by the condensation of water vapour from the air onto the surface of objects freely exposed to the sky. It forms on clear nights when the air is calm or. preferably, when the mind is light. If the temperature of the surface is below the freezing point of water, the deposit takes the shape of hoarfrost. Dew forms on clear nights because on such nights freely exposed surfaces lose heat to the sky by radiation. Unless this loss is offset by an efficient conduction of heat from the interior of the object. the surface will cool. Most objects, including grass blades, leaves and petals, are much better radiators than air and, as a result, are usually colder at night than the air. The cold surface cools the air in its vicinity and if the air is sufficiently humid, it may cool below its dew point (*q.v.*). Water vapour will then condense out of the air onto the surface.

The formation of dew is sustained by the diffusion of water vapour. Regarding the vertical diffusion of water vapour over soils carrying vegetation, there are two possible situations. First, there is the downward movement of water vapour from the atmosphere, occurring when the water vapour content of the air increases with height. Second, there is the upward movement of water vapour, occurring when the soil surface temperature is higher than that of the leaves. Accordingly, dew may be classified: (1) as formed when water vapour diffuses downward in the air, and (2) as formed from water vapour diffusing from the underlying soil surface. The name "detvfall" is proper to (1). Dew arising from (2) may be called "distillation." (J. L. Monteith, *Quart. J.* R. *Met. Soc.,* no. 83, London, 1957.)

There have been various attempts to measure dew. Among the various instruments are R. Leick's porous gypsum plates and S. Duvdevani's dew gauge consisting of a wooden slab treated with paint. To determine the amount of dew, Leick's plates are weighed while Duvdevani's gauge involves the use of an optical dew scale. Other investigators (*e.g.,* J. M. Craddock, E. G. Jennings and J. L. Monteith) developed recording dew balances whose surface and exposure conform with the surrounding surface as far as possible. It is by means of such dew balances that one can best observe the phenomenon of distillation: on occasions no gain in weight or even some loss in weight may be recorded though dew had formed on the leaves. Clearly, this dew must be attributed to the diffusion of water vapour from part of the weighed system to another; *i.e.,* from soil to leaves.

The amounts of dew formed on plants are not well known. It would appear that during dew nights the amounts vary from very small quantities to about $\frac{1}{50}$ in. G. Hofmann *(Die Thermodynamik der Taubildung,* Bad Kissingen, 1955), estimated that the maximum possible amount is about & in. for a ten-hour night, but such amounts would occur only under exceptional circumstances. Total annual dew precipitation may lie between about one-half inch in cold climates and in nearly arid warm climates, to about three inches in semihumid warm climates. Since dew produced by distillation from the soil cannot be regarded as a gain of moisture, not the whole of the annual dew may be significant from a hydrological point of view. Even so, in semiarid regions the net gain may be a substantial fraction of the rainfall. From the biological viewpoint, the usefulness of dew is sometimes doubtful as dew may stimulate the growth of fungi harmful to plants.

In ancient times it was believed that dewdrops fell from the sky. Aristotle in his *Meteorologica* suggested that dew or hoarfrost was formed by the condensation of water vapour which had evaporated from the surface by day. Louis-Constant Prévost (*Recherches Physico-Mécanique sur la Chaleur,* 1792) was probably the first to connect dew with radiation losses from the surface.

However, the first thorough investigation of dew was made by Charles Wells, physician to St. Thomas's hospital. London. He showed *(An Essay on Dew and Several Appearances Connected With It,* London, 1814) that dew was the result of cooling of the air at night. He also pointed out that although dew tended to form on windless nights, "a slight agitation of the air . . . when the air is pregnant with moisture . . . will render greater the quantity of dew"—the first statement appreciating the effect of slight turbulence on dew. In 1885 John Aitken *(Tmns. Roy. Soc. Edinb.,* no. 33) published the results of his studies which demonstrated, among other things, that trays of turf at times lost weight when dew formed on the blades. He interpreted this as the result of vapour diffusion from the soil. Aitken also made a distinction between dewdrops proper and drops formed by guttation; *i.e.*, the exudation of water from leaves under the action of root pressure. (JA. N.)

DEWAN: *see* DIWAN.

DEWAR, SIR JAMES (1842–1923), British chemist and physicist. remembered for his studies of low-temperature phenomena and for his invention of the vacuum flask (*q.v.*) which bears his name. He was born at Kincardine-on-Forth, Scot., on Sept. 20, 1842. He was educated at Dollar academy, Dollar, Clackmannanshire, and Edinburgh university. In 1875 he was elected Jacksonian professor of natural experimental philosophy at Cambridge, and in 1877 he succeeded J. H. Gladstone as Fullerian professor of chemistry in the Royal institution, London.

Dewar's scientific work covers a wide field. His earlier papers deal with organic chemistry, with measurement of high temperatures, with electrophotometry and the chemistry of the electric arc. With J. A. Fleming, of University college, London, he investigated the specific inductive capacity of substances at very low temperatures. His work on the liquefaction of the so-called permanent gases *(see* LOW-TEMPERATURE PHYSICS), and his researches at temperatures approaching absolute zero are well known. His interest in this branch of inquiry dates back at least as far as 1874. when he discussed the "Latent Heat of Liquid Gases" before the British association. By 1891 Dewar had constructed a machine for producing liquid oxygen in quantity. He made use of this liquid for some low-temperature experiments on meteorites, and in 1891 showed that both liquid oxygen and ozone are magnetic. He introduced the use of liquefied gases as aids in studies at very low temperatures.

About 1892 the idea occurred to him of using vacuum-jacketed vessels for the storage of liquid gases, and so efficient did this device prove in preventing the influx of external heat that it was found possible to preserve the liquids for comparatively long periods; this apparatus, which he designed, is known as the "Dewar flask" and is invaluable for low-temperature work. The principle has been used extensively in the common Thermos bottle or vacuum flask. He next experimented with a high-pressure hydrogen jet by which low temperatures were realized through the Joule-Thomson effect *(see* THERMODYNAMICS), and the successful results thus obtained led him to build at the Royal institution the large refrigerating machine by which hydrogen was first liquefied in 1898 and solidified in 1899. He investigated the gas-absorbing powers of charcoal cooled to low temperatures, and applied them to the production of high vacua and to gas analysis.

He was president of the Chemical society in 1897 and of the British association in 1902, served on the Balfour commission on London water supply (1893–94) and, as a member of the committee on explosives (1888–91), invented cordite jointly with Sir Frederick Abel. He was awarded the Rumford medal of the Royal society in 1894; and the Smithsonian institution, the French Academy of Sciences, the Italian Society of Sciences and the Royal Society of Arts honoured his work. He was knighted in 1904, and died on March 27, 1923.

DEWAS, a town and district in Madhya Pradesh, India. The town (pop. [1951] 27,879), is 22 mi. N.N.E. of Indore on the main Bombay-Agra road. It was formerly the joint capital of Dewas Senior and Junior states. It lies at the foot of the conical (300-ft.-high) Chamunda hill with a shrine, Devivasini, on top. Two miles south stands a steep, highly eroded group of hills, with peaks rising 400–500 ft. above the general level. The town, a municipality, contains cotton-spinning and weaving mills and an agricultural college and a teacher's training college affiliated to Vikram university.

DEWAS DISTRICT (area 2.706 sq.mi.; pop [1961] 447,090) comprises the main part of the former Dewas Senior state with much additional territory. Dewas was founded by two Ponwar Maratha brothers uho came into Malwa with Baji Rao in 1728. From 1841 the senior and junior branches of their family ruled their own portions independently. The lands of both were intimately entangled. Dewas Senior's main tract lay north and south of Dewas town; that of Dewas Junior centred on Sarangpur, 50 mi. N E. Both states mere merged in Madhya Bharat on June 15, 1948. Madhya Bharat became part of Madhya Pradesh state on Nov. 1, 1956. (S. M. A.)

DEWBERRY (TRAILING BLACKBERRY), of the genus *Rubus* (family Rosaceae), is the name given to any blackberry so lacking woody fibre in the stems that it trails along the ground. In the eastern and southern area of the United States several trailing native species of *Rubus,* especially *R. flagellaris, R. baileyanus, R. hispidus, R. enslenii* and *R. trivialis,* produce excellent fruits and some varieties, especially Lucretia, are cultivated. *See* BLACKBERRY. (G. M. D.; X.)

D'EWES, SIR SIMONDS (1602–1650), English antiquarian whose collection of documents, together with his personal diaries, are a mine of historical information, was born in Coxden, Dorsetshire, on Dec. 18, 1602. He was educated at St. John's college, Cambridge, and the Middle Temple, London. Knighted in 1626, he was sheriff of Suffolk in 1639 and 1640. when he was prosecuted in the Star Chamber for his failure to collect ship money. A moderate Puritan, he was elected for Sudbury to the Long parliament, and in its early years took an active part in debate, offering his vast historical knowledge to the house. Created a baronet in 1641, he later turned royalist and was expelled in Pride's purge of 1648. He died on April 8, 1650, at Stow Langtoft hall, Suffolk.

Though an avid collector of historical materials, D'Ewes published nothing but a tract called the *Primitive Practise for Preserving Truth* (1645). His *Journals of all the Parliaments During the Reign of Queen Elizabeth* is the basic source for the years 1584–1601, as the commons journal for this period has disappeared. It was published by his nephew, Paul Bowes, in 1682. His *Autobiography and Correspondence* was published by J. O. Halliwell-Phillips in 1845. *The Journals of Sir Simonds D'Ewes* covering the Long parliament began to be published in 1923; NOV. 1640—March 1641, ed. by W. Notestein (1923) and Nov. 1641—Jan. 1642, ed. by W. H. Coates (1942). (RD. C. G.)

DE WETTE, WILHELM MARTIN LEBERECHT (1780–1849), German theologian, described by Julius Wellhausen as "the epoch-making opener of the historical criticism of the Pentateuch," was born on Jan. 12, 1780. at Ulla. near Weimar. He was educated at Weimar and at Jena, and held chairs in theology at Heidelberg (1807), Berlin (1810) and Basel (2822). He was dismissed from his post at Berlin in 1819, nominally because of a letter of consolation he wrote to the mother of the murderer of August von Kotzebue, but in fact because of his radical rationalism. De Wette died on June 16, 1849.

His most important works are *Beiträge zur Einleitung in das Alte Testament,* 2 vol. (1806); *Kommentar über die Psalmen* (1811); *Über Religion und Theologie* (1815); *Lehrbuch der christlichen Dogmatik* (1813–16); *Lehrbuch der historisch-kritischen Einleitung in die Bibel (O.T.,* 1817; N.T., 1826); *Christliche Sittenlehre* (1819–21); *Das Wesen des Christlichen Glaubens* (1846). De Wette also edited *Briefe, Sendschreiben und Bedenken Luthers,* 5 vol. (1825–28), and wrote a drama, *Die Entsagung* (1823).

DEWEY, DAVIS RICH (1858–1942), U.S. economist and statistician, was for nearly 30 years (1911–1940) managing editor of the influential *American Economic Review.* He was born in Burlington. Vt., April 7, 1858, and was educated there and at Johns Hopkins university. For many years he was professor of economics and statistics at the Massachusetts Institute of Technology. His principal work is a *Financial History of the United States*

(1902). He died in Cambridge, Mass., Dec. 13, 1942.

(FK. L. K.)

DEWEY, GEORGE (1837–1917), U.S. naval commander who defeated the Spanish fleet at the battle of Manila bay, was born at Montpelier, Vt., on Dec. 26, 1837. He studied at Norwich university, then at Norwich, Vt., and graduated from the United States Naval academy, Annapolis, Md., in 1858. He was commissioned lieutenant in April 1861.

In the Civil War Dewey served on the steam sloop "Mississippi" (1861–63) during Adm. David Farragut's passage of the forts below New Orleans: La., in April 1862 and at Port Hudson, La., in March 1863; he took part in the fighting below Donaldsonville, La., in July 1863. In 1864–65 he served on the steam gunboat "Agawam" with the North Atlantic blockading squadron and took part in the attacks on Fort Fisher in Dec. 1864 and Jan. 1865. He became a commander in 1872, captain in 1884 and commodore in 1896.

In Nov. 1897 he was assigned, at his own request, to sea service, and sent to Asiatic waters. In April 1898, while with his fleet at Hong Kong, he was notified by cable that war had begun between the United States and Spain, and was ordered to "capture or destroy the Spanish fleet" then in Philippine waters.

Arriving off the island of Luzon in the Philippine islands on the night of April 30, Dewey entered Manila bay about midnight. The Spanish fleet, consisting of about 10 ships under Admiral Montojo, was anchored near the village and arsenal of Cavite at the southern end of the bay. Dewey, with six ships in line at intervals of about 400 yd., opened fire shortly before 6:00 A.M. of May 1. After passing the Spanish anchorage twice, the U.S. forces withdrew about 7:35 A.M.

At 11:16 A.M. the action was resumed against the remaining Spanish ships and the shore batteries around Cavite. The victory, won without the loss of a single U.S. seaman, was complete. All the Spanish ships had been sunk or destroyed and Cavite had been captured. *(See* SPANISH-AMERICAN WAR OF 1898.)

Congress, in a joint resolution. tendered its thanks to Commodore Dewey, and to the officers and men under his command, and authorized "the secretary of the navy to present a sword of honor to Commodore George Dewey, and cause to be struck bronze medals commemorating the battle of Manila bay, and to distribute such medals to the officers and men of the ships of the Asiatic squadron of the United States." He was promoted rear admiral on May 10, 1898, and on March 3, 1899, was named admiral of the navy. a title created for him by congress on March 2, 1899, and the highest rank ever held by a U.S. naval officer.

On Aug. 18, 1898, Dewey's squadron assisted in the capture of Manila and after remaining in the Philippines under orders from his government to maintain control he returned home, arriving in New York city, where, on Sept. 30, 1899, he received a great ovation. He was a member (1899) of the Schurman Philippine commission, and in 1901 acted as president of the Schley court of inquiry.

By special provision Admiral Dewey was not retired, but continued in the service up to his death, being president of the general board of the navy for the last seven years of his life. To the end of his life he continued to urge the building of large battleships, citing their superiority in the battle of Jutland. In 1913 he published his *Autobiography*. He died in Washington, D.C., on Jan. 16, 1917, and was buried in the Arlington National cemetery. His body was transferred March 28, 1925, to the crypt of the Bethlehem chapel of the National Episcopal cathedral in Washington.

BIBLIOGRAPHY.—John Barrett, *Admiral George Dewey* (1899); C. M. Dewey (ed.), *The Life and Letters of Admiral Dewey* (1899); *T. W.* Handford, *Admiral Dezoey, the Hero of Manila (1899); J, L,* Stickney, *Admiral Dewey at Manila* (1899).

DEWEY, JOHN (1859–1952), U.S. philosopher, psychologist and educator, was born in Burlington, Vt., on Oct. 20. 1859. He graduated from the University of Vermont in 1879 and taught school for two years in Pennsylvania and in rural Vermont. In 1884 he received the Ph.D. degree from Johns Hopkins university. He taught philosophy at the University of Minnesota in 1888–89 and at the University of Michigan from 1889 to 1894. In 1894 he went to The University of Chicago, where he became head of the combined departments of philosophy. psychology and pedagogy. There he established in 1896 The University of Chicago's Laboratory school. which he directed until 1904. At that time he went to Columbia university as professor of philosophy and remained there until his retirement in 1930.

Dewey was president of the American Psychological association, of the American Philosophical association and of the American Association of University Professors, which he had helped to organize. He was lecturer in philosophy and education at the University of Peking in 1919 and again in 1931 He visited Turkey at the request of the Turkish government and prepared a report on the reorganization of the national schools of that country in 1924. Later he visited Japan, Mexico and the U.S.S.R. to study the practices, problems and possibilities of education in those countries.

Dewey's work in psychology and philosophy was largely centred in his major interest, educational reform. In 1944 he wrote that "There is probably no better way to realize what philosophy is about when it is living, not antiquarian, than to ask ourselves what criteria and what aims and ideals should control our educational policies and undertakings." ("Challenge of Liberal Thought," *Fortune,* Aug. 1944.) These criteria, aims and ideals he drew in large part from psychology, specifically the psychology of learning. The task of the Laboratory school he directed at The University of Chicago was, he said, "the problem of viewing the education of the child in the light of the principles of mental activity and processes of growth made known by modern psychology." (John Dewey, *School and Society,* University of Chicago Press. 1899; p. 88, 2nd ed.. 1915.)

The terms "activity." "process" and "growth" were central and controlling in his analysis of the psychology of learning. As he saw it. thought and learning is a process of inquiry starting from doubt or uncertainty and spurred by the desire to resolve practical frictions or to relieve strain and tension. Education must therefore begin with experience, indeed at its best it is ever-enlarging experience. which has as its aim growth and the achievement of maturity.

A second basis of educational reform, as Dewey saw it. required an analysis of contemporary society, its aims and needs. He found two aspects of modern society of basic importance to education: first. that society is in the process of momentous change of which the Industrial Revolution is one of the chief marks: second. that the great advances of modern society are results of modern science. "Ultimately and philosophically," he said. "science is the organ of general social progress." (John Dewey, *Democracy and Education,* p. 270, The Macmillan Company, New Tork 1916.)

As educational reformer. Dewey therefore sought to relate education to the students' interests. to free it from "recapitulation" of human experience or "retrospection" of human thought. "The idea of education advanced in these chapters is formally summed up in the idea of continuous reconstruction of experience." (John Dewey, *Democracy and Education,* p. 93, The Macmillan Cornpany. New Tork. 1916.) Given the advancing society of our time, he declared. we must "make each one of our schools an embryonic community life, active with types of occupations that reflect the life of the larger society and permeated with the spirit of art, history, and science." (John Dewey, *The School and Society,* Chicago: The University of Chicago Press, 16th Impression, 1949, p. 27.)

Dewey's ideas and proposals strongly affected United States education and thought about education. Aspects of his views were seized upon by the "progressive movement" in education, which stressed the student-centred rather than the subject-centred school. education through activity rather than formal learning, and vocational or occupational education rather than the mastery of traditional subjects. The movement did not. however, draw upon the full range of Dewey's thought. As early as 1897 Dewey wrote regarding the "child study movement" that "the features of child study against which criticism has been justly directed are the results partly of the exaggeration incident to all large

movements in their inception, partly of the misdirected gyrations of those camp followers . . . hanging about education as about all progressive forces . . . and partly of the unwise zeal of those who lacking in stability are blown about by every new wind of doctrine and lose the just perspective." By 1938. when Dewey was asked to discuss conflicting theories and practices of "traditional" and "progressive" education, he was moved to sharp criticism of educators who sought merely to interest or amuse students, disregarded organized subject matter in favour of mere activity on the part of students, and were content with mere vocational training.

The philosophy on which Dewey's views of education rest has been labeled pragmatism. Dewey himself seems to favour the term instrumentalism or experimentalism. William James's *Principles of Psychology* early stimulated Dewey's rethinking of logic and ethics by directing his attention to the practical function of ideas and concepts, but Dewey and the "Chicago school" of instrumentalists went further than James had gone in that they conceived of ideas as instruments for transforming the uneasiness which is connected with the experience of having a problem into the satisfaction of some resolution or clarification of it.

His model of inquiry was scientific investigation. It has been pointed out that the basis of Dewey's reconstruction of philosophy is the analysis of experiment. As he saw it, the experimental methods of science provided the most promising approach to all problems, social and ethical as well as scientific in the narrow sense of "scientific." He consequently rejected the idea of a "fixed and immutable" moral law derivable from the consideration of the essential nature of man, insisting that such a view forces us to go "to the past for instruction," thus becoming authoritarian, and obliges us, moreover, to hold "that one method obtains in natural science and another, radically different, in moral questions," thus creating disunity in the intellectual life of our time and denying the promise which he believed empirical and scientific methods can hold even in the field of ethics. (John Dewey, *Problems* of *Men,* pp. 150–155, Philosophical Library, Inc., New York, 1946.)

Dewey developed from these views a philosopliical ground for democracy and liberalism. He conceived of democracy not merely or primarily as a form of government, but rather as a mode or method of association, one which provides the members of a democratic society opportunity, maximum experimentation and growth. The good society was one which provided the conditions for ever enlarging the experience of all its members. Society faces three possibilities in times of change. It may drift and thus "perpetuate the present confusion and possibly increase it." It may be intelligently conservative, attempting to maintain "the old order intact against the impact of new forces." Or it may "select newer scientific: technological, and cultural forces that are producing change in the old order; it may estimate the direction in which they are moving and their outcome if given freer play, and see what can be done to make the schools their allies." *(Social Frontier,* Urbana, Ill., May 1937.)

Attacks on Dewey's philosophy and his educational program have centred on his preoccupation with process and growth, his insistence on the experimental or scientific approach to social. ethical and philosophical problems, and his consequent denial of ethical absolutes. Opponents of his views have charged him with valuing activity and experience for their own sakes and with failing to provide, and in effect undermining, any qualitative criteria with respect to experience.

Full analysis of the meaning Dewey gives to such terms as "science" and "experimental" and of the extent to which such ideas as "growth" and "freedom" are more than relative terms in his system of thought might uncover substantial areas of agreement between Dewey and his critics. In the absence of such developments, however, Dewey's followers and their opponents have served to bring into focus some of the most troublesome and some of the most urgent problems of our time.

Dewey's publications include *Psychology* (1887); "The Reflex Arc Concept in Psychology," *Psychological Review* (1896); *The School and Society* (1899); *The Child and the Curriculum* (1902); *Ethics,* with James Tufts (1908); *How We Think* (1910); *Democracy and Education* (1916); *Reconstruction in Philosophy* (1920); *Human Nature and Conduct* (1922); *Experience and Nature* (1925); *The Public and its Problems* (1927); *The Quest for Certainty* (1929); *Art as Experience* (1934); *Logic, The Theory of Inquiry* (1938); *Freedom and Culture* (1939); *Problems of Men* (1946).

Baker, *Foundations of John Dewey's Educational Theory* (1955). (C. H. F.)

DEWEY, **MELVIL** (1851–1931), U.S. librarian who devised the Dewey Decimal system of classification for library cataloguing and probably more than any other single person was responsible for the sound development of library science in the U.S., was born at Adams Center, N.Y., on Dec. 10, 1851. He graduated in 1874 from Amherst college, Mass., and became acting librarian there. In 1877 he moved to Boston, there founding, with R. R. Bowker and Frederick Leypoldt, and editing the *Library Journal.* He was also one of the founders of the American Library association. In 1883 he became librarian of Columbia college, New York city, and there founded the school of library economy, the first institution established for the instruction of librarians.

This school, which was very successful, was re-established in Albany, N.Y., as the State Library school under his direction; from 1889 to 1906 he was director of the Sew Pork State library, from 1889 to 1900 secretary of the University of the State of New York and from 1904 to 1906 state director of libraries. He completely reorganized the state library, making it one of the most efficient in the U.S., and established the system of traveling libraries and picture collections. Dewey's decimal system of classification, first proposed in 1876, is extensively used *(see* CATALOGUING, LIBRARY). He died Dec. 26, 1931.

DEWEY, THOMAS EDMUND (1902–), U.S. lawyer who was twice nominated for the presidency by the Republican party, was born in Owosso, Mich., March 24, 1902. He graduated from the University of Michigan, received his law degree from Columbia university in 1925 and was admitted to the New York bar the following year. He became chief assistant to the U.S. attorney for the southern district of New York in 1931, and, except for brief intervals, remained in public life thereafter until 1955. He gained national attention as special prosecutor in an investigation of organized crime in New York, 1935–37, by obtaining 72 convictions in 73 prosecutions. Elected district attorney of New York county in 1937, he was unsuccessful as Republican party candidate for governor of New York in 1938 but won this office in three successive elections—1942, 1946 and 1950. He gained as governor a reputation for political moderation and administrative efficiency. He was an unsuccessful candidate for the Republican presidential nomination in 1940 (when Wendell Willkie was nominated) but became the party nominee in 1944 and again in 1948. In losing to Pres. Franklin D. Roosevelt in 1944, Dewey received slightly over 22,000,000 popular votes and 99 electoral votes. Although his victory was widely predicted in 1948, Dewey lost to Pres. Harry S. Truman; his popular vote fell slightly below 22,000.000 but his electoral vote increased to 189. In 1952, after traveling in the far east, he published an account of his experiences, *Journey to the Far Pacific.* Dewey, as a leader of the eastern Republicans, played an important role in the 1952 Republican national convention in bringing about the nomination of Dwight D. Eisenhower for president. At the conclusion of his third term as governor of New York in 1955; Dewey re-entered private law practice. (C. F. McI.)

DEWING, THOMAS **WILMER** (1851–1938), U.S. painter, one of the leaders of a group called the Ten American Painters. was born in Boston, Mass., on May 4, 1851. He studied in Paris at the Académie Julian under Boulanger and Lefebvre and also received training in Munich. Despite this academic beginning he turned to a more atmospheric style and, together with men like Childe Hassam and J. Alden Weir, became devoted to the cause of Impressionism. In 1887 he was elected as an associate

of the National Academy and the following year became a full academician. He died in New York city on Nov. 6, 1938.

Dewing was especially fond of depicting young women in a sort of evening dress which became more of a classical garment than a modish gown. These enigmatic figures devoid of emotion were painted with subtle colour and the utmost taste and refinement. What was important to him was not the subject itself but his inner vision of the subject. He often placed his figures on fragile chairs in a sparsely furnished room where the very emptiness added to the restrained poetic mood. (F. A. Sw.)

DE WINT, PETER (1784–1849), English landscape and architectural painter of Dutch extraction who was one of the chief English water colourists of the early 19th century. Born at Stone. Staffordshire, on Jan. 21, 1784, he studied (1802–06) under the engraver John Raphael Smith and in 1809 entered the Royal Academy. In 1811 he became a member of the Society of Painters in Water-Colours, where he exhibited for many years, as well as at the academy. He died in London on Jan. 30, 1849.

DEW POINT, the temperature at which the atmosphere is saturated with water vapour, when it is cooled without changing its pressure or vapour content. A given volume of air containing much water vapour has a higher dew point than the same volume of drier air; thus the dew point gives an indication of the humidity. In meteorology the dew point is applied, for example, in predicting the height of the base of certain types of clouds, including summer cumulus. *See* also HUMIDITY, ATMOSPHERIC.

DEWSBURY, a market tonn, county and parliamentary borough of the West Riding of Yorkshire, Eng., on the Calder river. 9 mi. S S.W. of Leeds by road. Pop. (1961) 52,942. The parish church of All Saints, mostly rebuilt in the 18th century, retains Anglo-Saxon carvings. Dewsbury, which was mentioned in Domesday Book, had a woolen industry in the 13th century, but there was no great expansion until the Industrial Revolution when the town became the natural centre of a heavy woolen district. The chief industries are mungo and shoddy manufacture (for which large-scale rag selling by public auction is carried on), blanket weaving, coal mining and engineering. Dewsbury was incorporated in 1862 and became a county borough in 1913.

There is a tradition that Paulinus, the first archbishop of York, preached in **AD.** 627 at Dewsbury, which had in Saxon times a parish over 400 sq mi. in area. Another tradition holds that Robin Hood died and was buried in the extensive park at Kirklees where are the remains of a 12th-century Cistercian convent.

DEXIPPUS, PUBLIUS HERENNIUS (c. **A.D.** 210–d. after 270), Roman historian and Athenian statesman, is one of the principal authorities for the history of the mid-3rd century A.D. The 9th-century encyclopaedia called the *Bibliotheca* by Photius, patriarch of Constantinople, credits him with three major works, a history of events after the death of Alexander the Great, a *Scythian War,* and an annalistic chronicle from legendary times to 270 A.D. Though none of these survives, numerous fragments have been recognized in the compilations of later historians.

Several Athenian inscriptions attest the high birth and public offices *(archon, basileus,* etc.) of Dexippus, his father and children. He himself relates (fragment 28) how, when the frontiers of the Roman empire suddenly and catastrophically collapsed, he rallied about 2,000 of his fellow citizens to repel a barbarian attack on Athens. probably about 267 A.D.

BIBLIOGRAPHY.—The fragments are collected by F. Jacoby, *Fragmente der griechischen Historiker,* ii *A,* pp. 452 *et seq.* (1926); *see* also *E Schwartz* in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertunzswissenschaft,* v, 288–293 (1905).

DEXTRIN or DEXTRINE, a class of substances prepared by the incomplete hydrolysis of starch or by the heating of dry starch. Dextrins are used chiefly as adhesives and as sizing agents for textiles and paper. *See* STARCH.

DEY (a corruption of the Turkish word meaning "maternal uncle"), an honorary title used in the North African possessions of the Ottoman empire, applied in a heroic sense to Turkish corsair leaders and janizary officers. There were deys in Tunis (until replaced by the hereditary beys in 1705), in Algeria (until 1830) and in Tripoli. In practice the dey was absolute, though he flouted the wishes of his troops at his peril. He was cut off from his family to prevent succession claims. (A. D. A.)

DEYSSEL, LODEWIJK VAN (real name KAREL JOAN LODEWIJK ALBERDINGK THIJM) (1864–1952), leading Dutch writer and critic of the late 19th and early 20th centuries. was born in Amsterdam, Sept. 22, 1864, son of J. A. Alberdingk Thijm (who promoted a Catholic cultural revival in the Netherlands). He joined the largely agnostic individualistic group associated with the magazine *De Nieuue Gids* ("The New Guide"). His passionate critical writings were published as *Verzamelde Opstellen* ("Collected Essays." 11 vol., 1894–1911). He began writing as an admirer of Émile Zola and published a naturalistic novel himself, *Een Liefde* ("A Love Affair," 1889). Later he abandoned naturalism and wrote highly personal impressionistic prose. A sensitive artist with great powers of observation and a keen eye for detail, he was a powerful influence on Dutch literature, both as an original and as a critical writer, for many years. His "prose-verses" were clever, somewhat overwrought verbal experiments. His collected works appeared in 6 vol. (1922–24). When. with his friend Willem Kloos (1859–1938), he was awarded an honorary doctorate in Amsterdam in 1935, he had already outlived his own importance. He died at Haarlem, Jan. 26, 1952.

See F. Jansonius, *Lodewijk van Deyssel* (1951). (GD. W. Hs.)

DEZFUL (DIZFUL), a city in the province of Khuzistan, Iran, is situated on the high left bank of the Dez (or Diz), a tributary of the Karun river, 10 mi. from the edge of the foothills of the Zagros mountains and 650 ft. above sea level. Pop. (1956) 52,153, mainly Persians and Lurs and some Arabs. The name, meaning "Dez bridge," is derived from the imposing 450-yd.-long bridge which spans the river there, originally erected, according to tradition, by the Sassanid king Shahpur II. The climate is oppressively hot in summer. Underground chambers are therefore largely used. which are easily cut into the dry conglomerate.

Dezful is the most important regional centre of the northern Khuzistan plain and the principal winter market of the nomad population of Luristan. Extensive dry farming areas are situated north and east of the city, while about 75,000 ac. of irrigated land lie to the south on both sides of the river. Dezful is connected by roads through Khoramabad with the highland and southward with Ahvaz by two roads, one through Shushtar, and the other west of the river through Andimeshk and Shush, the ancient Susa *(q.v.).* Andimeshk (pop. [1956] 7,324) is the station on the Transiranian railway on the other side of the river, 6 mi. N. of Dezful. It was once called Salehabad. It is there that most of the modern development of the region is taking place (railway yards, a headquarters of the Khuzistan Development service, a large military camp and an airfield). The great Dez dam (started in 1960) 20 mi, upstream was designed to provide abundant power and to increase the possibilities of irrigation by regulating the water supply. (H. Bo.)

DEZHNEV, SEMEN IVANOV (c. 1605–73), Russian explorer and the first man known to have sailed through the Bering strait, was born in Velikiy Ustyug, north Russia. He served as a cossack in Siberia, where he traveled much in the north between 1638 and 1670. In 1648 he sailed from the Kolyma eastward, rounded the northeast tip of Asia (now called Cape Dezhnev) and reached the Anadyr. He thus proved the separation of Asia and America, but his report lay buried in the archives at Yakutsk until the historian G. F. Müller found it in 1736, so the discovery was not known about until nearly a century had passed, and after Vitus Bering *(q.v.)* and others had explored the area. (T. E. A.)

DHAHRAN (AZ ZAHRAN), the administrative centre of the American oil industry in Al Hasa province of Saudi Arabia, is located in the Dammam oil field, 230 mi. N.E. of Riyadh. It was the scene of the original discovery of oil in Saudi Arabia in the 1930s. Dhahran has well-laid-out modern buildings. gardens and recreation grounds within a barbed-wire fence, as well as a model Arab village for the local employees and their families. Out of a total payroll of about 18,000 in the late 1950s about 13,000 were Arabians, nearly 2,700 were U.S. citizens and there were approximately 2,000 Indians and Pakistanis and some others. Dhahran has a large modern airport with accommodation for the working

personnel and a hotel for visitors. (H. ST. J. B. P.)

DHANBAD, a town and district in Bihar state, India. The town, headquarters of the district. is 168 mi. from Calcutta on the Eastern railway and 5 mi. S. of the Grand Trunk road near the eastern edge of the Jharia coal field. Pop. (1951) 34.077. It is a comparatively new and open town surrounded by artificial lakes and is the home of the Indian School of Mines and Applied Geology affiliated with Bihar university.

DHANBAD DISTRICT, to which a part of Manbhum mas added in 1956, is the smallest among the districts of Bihar. Pop. (1961) 1,158,363. Area 1,114 sq.mi. The district consists of an undulating erosion plain. 500–900 ft. above sea level, and is dotted with irrigation tanks and a few patches of wood. The Damodar (*q.v.*) runs east-west through the centre of the district. The chief crops are rice. maize and oilseeds and some lac. Dhanbad, containing the whole of the Jharia and part of the Raniganj coal fields, leads the districts of India in coal production. The Sindri fertilizer factory is on the Damodar 16 mi. S. of Dhanbad. The Maithon and Panchet dams of the Damodar valley project fall in this district. (E. AH.)

DHAR, a town and district in Madhya Pradesh, India. The town is 35 mi. W.S.W. of Indore, with which it has road connections. Pop. (1951) 23.652. It is picturesquely situated among lakes and trees surrounded by barren hills. on the northern slopes of the Vindhyas, commanding one of the gaps leading to the Narmeda valley. The Lat Musjid, or Pillar mosque, was built by Dilamar Khan Ghori in 1405 out of the remains of Jain temples. Its name derives from an iron pillar (13th century) bearing a later inscription recording the seven days' visit of the Mogul emperor Akbar in 1598. The pillar, which was 43 ft. high. is overthrown and broken. The Kamal Maula is an enclosure containing four tombs, the most notable being that of Sheikh Kamal (Maulvi Kamal ud-Din). a follower of the famous 13th-century saint Nizam-ud-Din Auliya. The mosque known as Raja Bhoja's school was built from Hindu remains in the 14th or 15th century; its name is derived from the slabs, covered with inscriptions giving rules of Sanskrit grammar, with which it is paved. On a small hill north of the town stands the fort, a pile of red sandstone, said to have been built by Mohammed Tughluq of Delhi in the 14th century. It contains the raja's palace.

The town became famous as the capital of the Paramara chiefs of Malwa when Vairisinha II transferred his headquarters from Ujjain at the close of the 9th century. Under the celebrated Raja Bhoja (1018–60) it was a great centre of learning. It was conquered by the Muslims at the beginning of the 14th century. In the time of Akbar, Dhar fell under the dominion of the Moguls, in whose hands it remained until 1730, when it was conquered by the Marathas.

DHAR DISTRICT, with an area of 3,150 sq.mi., includes the ruins of Mandu (*q.v.*) or Mandogarh, the Muslim capital of Malwa (12 mi. S. of Dhar town). The population of the district was 643,601 in 1961.

The princely state of Dhar included a number of Rajput and Bhil feudatories and was divided into two main tracts in the Narmeda valley, separated by 30 mi. of Indore territory. Pop. (1941) 253,210. Area 1,798 sq.mi. The rulers were Ponwar Marathas, whose founder, Anand Rao Ponwar, claimed descent from the Paramara clan of Rajputs who ruled Malwa from the 9th to the 13th century from their capital at Dhar. In 1742 Anand Rao received Dhar as a fief from Baji Rao, the Maratha peshwa. Later the state was subject to a series of spoliations by the neighbouring rulers Sindhia and Holkar; by a treaty of 1819 Dhar passed under British protection. Dhar was controlled through the Malwa subagency of the Central India agency. When India became independent it was merged into Madhya Bharat (June 15, 1948) and, with the accession of additional territory, made into a district. Madhya Bharat was merged into Madhya Pradesh on Nov. 1, 1956. (S. M. A.)

DHARWAR, a town and district in Mysore, India. The town, the headquarters of the district, was incorporated in 1961 with Hubli, 13 mi. S.E., and lies 290 mi. S.S.E. of Bombay on the Southern railway. Pop. (1961), 77,235. It is the seat of Karnatak university and has a broadcasting station of All India Radio. It contains an agricultural college and farm, an engineering institute. an art school, three colleges and training colleges for men and women. There are a Borstal school, a temporary detention home for juveniles and a mental hospital. Dharwar mas fortified in the 16th century by the 'Adil Shahi kings of Bijapur (*q.v.*); its original name, Daravada, means a gateway town.

DHARWAR DISTRICT has an area of 5.303 sq mi. Pop. (1961) 1,950.540. In the north and northeast are plains of black soil, favourable to cotton growing; in the south and west are ranges of low hills with flat fertile valleys between them. The whole district lies on the western edge of the Deccan plateau and is drained by the Gangawali, which flows westward into the Indian ocean, and the Malprabha, a tributary of the Krishna which flows eastward across the plateau into the Bay of Bengal. The principal products are millets, pulses, cotton and timber. The centres of cotton trade are Hubli and Gadag.

In the Malprabha basin interesting collections of Stone Age tools have been made. From the 7th century the district was ruled by the Chalukyas, Rashtrakutas and kings of Vijayanagar, and later by the sultans of Bijapur and the Marathas. A feudatory family of the Kadambas ruled at Hangal from the 11th to the 13th centuries. Buddhist remains have been discovered at Dambal and Kolivad, and Jainism flourished during the middle ages when Gadag, Kolivad, Lakkundi and Lakshmeshwar were centres of literature and art. A college for grammar and exegesis was founded in A.D. 1012 at Kotumachigi from a state endowment. On the final overthrow of the peshwas. in 1817. Dharwar was incorporated within the territory of the East India company.

(V.V. B.; P. B. D.; M. S. H.)

DHENKANAL, a town and headquarters of Dhenkanal district in Orissa state, India, lies about 40 mi. N.W. of Cuttack, with which it is connected by rail. Pop. (1951) 10,352. It is called after a medieval chieftain of the Savara tribe named Dhenka, who is still remembered. The raja's palace is situated on the brow of a hill surrounded by double moats. Dhenkanal college was founded in 1959.

DHENKANAL DISTRICT was formed after the merger of the princely states with Orissa in 1948. Area 4,181 sq.mi. Pop. (1961) 1,030,632. Density 247 per square mile. In most parts the district is covered with thick forest and hills, with many streams. It is intersected by two main rivers, the Mahanadi and the Brahmani. The chief occupation of the people is agriculture, aided by tank irrigation. Textiles, wickerwork, stonecutting and the manufacture of brass utensils are the principal cottage industries. The coal fields at Talcher yield about 350.000 tons per year and are connected with Cuttack by a branch of the South Eastern railway. Angul, 38 mi. W.N.W. of Dhenkanal, has a science college, a basic training college and the state police training institute. The large village of Bhuban, 23 mi. N.E. of Dhenkanal, is famous for brass utensils. At Bhimakanda and Saranga are found reclining images of Vishnu (9th century A.D.) measuring 41 ft. 6 in. and 32 ft. long respectively. Saptasajya (Vishnuism), Kapilas (Saivism) and Joranda (Mahima cult) are religious centres. (MA. M.)

DHOLE, the "red dog" of Asia, Cuon species, distinguished from the true dogs (*Canis*) by one molar less in the lower jaw. A reddish brown in colour, the dhole is larger than a jackal and hunts in large packs. It is reported to kill animals as large as the buffalo and tiger, but deer are most hunted. Cuon is found from India north to Siberia and east to Sumatra and Java.

DHOW: *see* BOAT.

DHULIA is a town and headquarters of Dhulia (formerly West Khandesh) district, formerly of Bombay state and from May 1, 1960, of the state of Maharashtra, India. Pop. (1961) 98,342. It lies on the southern bank of the Panjhra river, 35 mi. N. of Chalisgaon with which it is connected by a branch line of the Central railway. Until the 19th century Dhulia was an insignificant village; thereafter its progress appears to have been steady. With the development of trade in cotton and linseed in the 20th century, the town acquired commercial importance. Coarse cotton and woolen cloth and turbans are manufactured for local

use and there are cotton presses and ginning mills. (M. R. P.)

DHULIP SINGH (1837–1893), Sikh maharaja of Lahore from 1843 to 1819, was born in Feb. 1837, acknowledged by Ranjit Singh and proclaimed maharaja on Sept. 18, 1843. under the regency of his mother the rani Jindan. After the first Sikh War (1845–46) he was recognized by the British as maharaja of the reduced Sikh kingdom, and by the articles of agreement of Dec. 16, 1846, was made the ward of the government of India. whose resident at Lahore, aided by a council of regency, ruled in his name. In 1848 an anti-British outbreak at Multan and another in Hazara, which was provoked by the violence and suspicions of the commissioner, Capt. (later Sir) James Abbott, were allowed to develop into widespread Sikh risings which led to the second Sikh War (1848–49). The war ended in the defeat of the Sikhs at the battle of Gujrat on Feb. 21, 1849, and although Lord Gough, the British commander in chief, was acting in the name of the maharaja and the council of regency, the maharaja was deposed and his kingdom annexed in March of that year. He was given a pension, became a Christian and chose to live in England where he became persona grata in society. In 1882 he appealed for a larger pension, and when this was refused went abroad. abjuring Christianity. He died in Paris on Oct. 22, 1893, leaving one son who died without issue.

See E. Bell, The Annexation of the Punjaub and the Maharajah Duleep Singh (1882); J. G. A. Baird (ed.), *Private Letters of the Marquess of Dalhousie* (1910). (J. B. HA.)

DIABASE or DOLERITE. Diabase is the American term; dolerite is the British term. Diabase is a fine- to medium-grained, dark gray to black intrusive igneous rock of basaltic composition. It is extremely hard and tough and is commonly quarried, under the name of trap, for crushed stone. Although not popular it makes an excellent monumental stone and is one of the dark coloured rocks commercially known as "black granite." About one-third to two-thirds of the rock is calcium-rich plagioclase feldspar (*q.v.*), whereas the remainder is mostly pyroxene (*q.v.*).

Chemically and mineralogically diabase closely resembles the volcanic rock basalt but is somewhat coarser and rarely contains glass. In diabase poorly formed pyroxene crystals wrap around or mold against long, rectangular plagioclase crystals to give it the characteristic texture known as diabasic or ophitic. The larger pyroxene grains may completely enclose plagioclase; but, as the quantity of the latter increases, pyroxene appears more interstitial.

Generally considered an intrusive rock, diabase is wide spread and occurs in dikes, sills, sheets, and other relatively small shallow bodies. It is largely on the basis of its intrusive character that diabase is distinguished from basalt. In fact, many specimens from thick basalt flows have all the characteristics of diabase. With increase in grain size diabase may pass into gabbro (*q.v.*).

Crystallization.— Under the microscope plagioclase crystals (usually labradorite) are commonly seen to consist of concentric shells of differing composition. Outermost shells are usually more sodic (sodium-rich) and cores more calcic (calcium-rich). Augite, frequently titanium-rich, is the common and early formed pyroxene; but orthopyroxene, not usually abundant, may also form early. Pigeonite may form later contemporaneously with much augite, but the crystallization period of augite may outlast that of any other pyroxene. Within each variety of pyroxene early formed crystals are enriched in magnesium; whereas later ones are richer in iron. Olivine is uncommonly a major constituent, but like pyroxene shows magnesium enrichment in the earlier crystals. Small patches of micropegmatite (an intergrowth of quartz and alkali feldspar) in some diabases represent the last portions to crystallize. Other minor constituents of diabase include biotite, hornblende, magnetite. apatite, and feldspathoid.

Certain flat tabular masses (thick sheets or sills) of diabase, like that forming the Palisades of the Hudson near New York city, show concentrations of heavy minerals (olivine, pyroxene) in their lower portions. These concentrations are commonly believed to have developed by settling of early formed crystals in molten diabase (see SILL). For further discussion of processes of crystallization see PETROLOGY.

Alteration.—Diabase may show varying degrees of alteration in which plagioclase is converted to saussurite; pyroxene to hornblende, actinolite, or chlorite; and olivine to serpentine and magnetite. In the British usage such altered rock is known as diabase. Some diabase masses have been subdivided by systematic fractures into rectangular blocks. Subsequent alteration and weathering along these fractures have disintegrated and rounded off block corners and edges (spheroidal weathering) leaving regularly spaced spherelike masses of fresh diabase enveloped by shells of progressively more altered and disintegrated material.

Chemical Analysis.--An average chemical analysis (in weight per cent) of diabase is as follows: silica (SiO_2), 50.48; alumina (Al_2O_3), 15.34; ferric iron oxide (Fe_2O_3), 3.84; ferrous iron oxide (FeO), 7.78; magnesia (MgO), 5.79; lime (CaO), 8.94; soda (Na_2O), 3.07; potash (K_2O), 0.97; water (H_2O), 1.89; and titania (TiO_2), 1.4j. (C. A. CN.)

DIABELLI, ANTON (1781–1858), Austrian publisher and composer known for his waltz or Landler on which Beethoven wrote his 33 Variations for piano (Op. 120), was born on Sept. 6, 1781, at Mattsee, near Salzburg. He was intended for the priesthood and was educated at the monastery of Raitenhaslach where his studies were supervised by Michael Haydn. On the secularization of the Bavarian monasteries in 1803 he went to Vienna where his piano pieces were widely played and where he became known as a teacher of the piano and the guitar. In 1818 he founded a publishing firm with Peter Cappi which six years later he took over entirely. He published works by Schubert. Czerny and Beethoven, and in 1851 issued the first thematic catalogue of the works of Schubert. Known for his sure instinct in publishing matters, he was called by Beethoven "Diabolus Diabelli." His own works include operettas and church music, piano works and numerous light pieces for the flute, guitar and other instruments. He died in Vienna on April 7, 1858.

See H. Rietsch, *Diabellis "Vaterlandischer Künstlerverein"* (1906).

DIABETES INSIPIDUS is a disease characterized by the excretion of large volumes of urine of a low specific gravity accompanied by an abnormally great thirst, probably secondary to the excessive urine excretion. It is caused by destruction of the neural lobe of the pituitary gland or by lesions in the nervous connections between the hypothalamus and that lobe. The condition can be alleviated but not cured by the administration of posterior pituitary extract. See also HYPOTHALAMUS; METABOLIC DISEASES; PITUITARY BODY. (F. L. A.j

DIABETES MELLITUS is a condition in which the body is unable to metabolize sugars and other food materials efficiently. This disease is commonly termed "diabetes" and it appears when there is a relative but not necessarily an absolute deficiency of insulin in the body (see METABOLIC DISEASES: Endocrine *Disturbances).* The first suggestion that the pancreas is necessary for the complete utilization of carbohydrates in the animal body was made by Johann Conrad Brunner in 1682. The relationship of the pancreas to diabetes was first suggested in 1788 by Cawley, an English physician. In 1889 J. von Mering and O. Minkowski showed that the complete removal of the pancreas from dogs resulted in a condition that is practically identical with diabetes mellitus in man. Although scores of investigators attempted to secure an antidiabetic substance from the pancreas. this substance, called insulin, was not proved to be present until 1921 (see INSULIN). In some cases the diabetic condition may be the direct result of a decrease in the formation and secretion of insulin by the pancreas, while in others the defect may be primarily the result of an altered activity of other glands.

Diabetes is a common disease. There are clear references to it in the ancient literature of Egypt, China and India. No age group is exempt. but most patients are over 40 at the onset of the disease and there are more female than male patients at this age. Obese persons are more liable to develop diabetes than are persons of normal weight. About 25% of all diabetics have relatives who are diabetics; hereditary predisposition toward the disease is well established. Estimates of the occurrence vary from 1.5 to 2%

of the population; about half of these cases are believed to occur in persons who are unaware that they have the disease.

Signs and Symptoms. — The untreated diabetic patient suffers from extreme thirst, hunger, weakness and loss of weight. He excretes abnormally large quantities of urine of high specific gravity (1.030 to 1.050, compared with a normal 1.015 to 1.020); his urine contains sugar and other substances not usually present. He is very susceptible to infection, and the infection when established is difficult to eliminate.

The diabetic condition is suspected when a patient complains of one or more of these signs or symptoms. A person may be a mild diabetic for a long time before he is aware of his condition. Diabetes as a rule advances comparatively slowly except in the young, in whom it often progresses so rapidly that the patient develops an acidosis. vomits and lapses into coma within a few days of what is apparently an acute onset of the disease. The routine analysis of the urine as a part of the physical examinations given to persons applying for life insurance or entering the armed forces has resulted in the early diagnosis of many cases of previously unsuspected diabetes. The prognosis of the early case is, of course, much better than that of the advanced, since treatment can be instituted earlier in the course of the disease. The amount of sugar in the blood under certain standard conditions is a valuable indication of the severity of the disease. The presence in the urine of the so-called ketone bodies (acetone, aceto-acetic acid and β-hydroxybutyric acid), which appear in the urine as a result of the excessive breakdown of fats, is a warning that acidosis and coma are imminent. The presence of these substances in the body can sometimes be suspected from the odour that acetone imparts to the breath.

The most characteristic finding is that of sugar in the urine, though it alone is not diagnostic of the diabetic condition. The amount of sugar thus excreted may be small or very great, depending upon the severity of the disease and upon the amount of sugar or starchy food eaten by the patient. Because the diabetic person does not use sugar as readily as a normal person. sugar accumulates in the blood to higher levels than normal and the excess is excreted in the urine. The metabolism of fats is increased to such an extent that the ketone bodies, which are the intermediary products of fat metabolism, are not completely oxidized as in the normal person, and these substances also accumulate in the blood and are excreted in the urine. Two of these ketone bodies are acids and are excreted in combination with alkali, which is thus removed from the body; the removal of alkali produces a condition of acidosis that may lead to coma.

The complications of inadequately treated diabetes are many and serious. Vision may become impaired. Skin affections of all kinds may occur and prove very intractable. Boils, carbuncles and gangrene are all apt to occur as life advances. There is especial danger of gangrene of the toes and feet. Diabetics are especially liable to tuberculosis. Digestive troubles, kidney diseases and diseases of the heart and particularly arteriosclerosis commonly occur. But the most serious complication of all is diabetic coma. The onset of this condition is often insidious but may be indicated by loss of appetite, a rapid fall in the quantity both of urine and of sugar in the urine, and by either constipation or diarrhea. At first the condition is rather that of collapse than of true coma, though later the patient is completely comatose. He suffers from a peculiar kind of dyspnea (difficult breathing) and the breath and skin have a sweet ethereal odour. In the pre-insulin days coma was the major cause of death in diabetics, but today this condition never appears in well-treated patients.

Treatment. — Patients suffering from diabetes mellitus are treated by dietetic measures and, if the condition is of moderate or severe intensity, by the administration of insulin. In certain cases in adults, successful treatment may consist of diet and hypoglycemic sulfonylureas given orally. Before the discovery of insulin the lives of many patients with severe diabetes were prolonged by the drastically restricted diets introduced as treatment by Frederick Madison Allen and by Elliott P. Joslin.

Several important principles underlie the dietetic treatment of the disease. The diet must supply sufficient calories to keep the patient's weight at the proper level. Protein, preferably as lean meat, eggs and milk, must not be reduced below a certain minimum value. If the dietary intake of protein is unduly reduced, the proteins in the tissues of the patient's body are drawn upon. Excess sugar is excreted in the urine, and the amount of sugar so excreted can readily be determined by chemical analysis.

The diabetic diet should resemble a normal diet as closely as possible. It is much more satisfactory for the patient to obtain the essentials of his diet from among common foods than to be largely dependent upon specially prepared diabetic foods. The diabetic diet need not be monotonous.

Insulin. which is distributed as a sterile, slightly acid solution, is injected hypodermically. There is no substitute for insulin. The amount necessary depends upon the severity of the disease, upon the quantity and nature of the diet, and upon the activity of the individual. In general, enough insulin is given to reduce the concentration of sugar in the blood to the level of a normal person. It is given every day, usually before breakfast; supplementary amounts sometimes are given later in the day.

If the diet is unbalanced with respect to the relative amounts of proteins, fats and carbohydrates, or if there is a serious lack of insulin. a diabetic may pass into coma. The treatment of coma before insulin was available was to put the patient to bed, supply fluids, heat and stimulants, and give sugar by mouth or by vein. These general measures are in large part still necessary. Insulin has proved a specific remedy in the treatment of this condition, and when it is given early enough and in large doses, the results have been very successful.

A very serious condition called hypoglycemia may be produced in a diabetic patient by an overdose of insulin or by insufficient or delayed food intake, excessive physical exertion, nervous tension, diarrhea, menstruation or infection. Whatever the cause, the result is a lowered concentration of sugar in the blood. Insulin shock, which results from insulin overdosage, can be avoided if the physician carefully balances diet against dosage of insulin, and if the patient closely follows the diet and learns to recognize the premonitory symptoms of the beginning of a hypoglycemic reaction. These early symptoms include sudden hunger, fatigue, a peculiar restlessness often described by the patient as a feeling of "inward trembling," pallor or flushing of the face and an increased pulse rate, a particularly valuable sign in children. If the overdose of insulin is large and corrective measures are not taken, the patient may show profuse perspiration, tremor. emotional disturbances, collapse and unconsciousness. The treatment of mild or moderate degrees of hypoglycemia consists of the administration of carbohydrate in any convenient form such as ordinary sugar or candy or diluted corn syrup. In severe cases a sterile solution of glucose is given intravenously by a physician.

Insulin Adjuvants. — Hundreds of plant extracts and pure chemicals have been suggested as substitutes for or adjuvants of insulin. A very large proportion of the few agents that have proved effective are liver poisons that decrease the output of sugar from this organ. The orally administered hypoglycemic sulfonamides, however, earned a place in therapeutics on the basis of tests completed in the late 1950s. There is evidence that they liberate some insulin from the patient's pancreas; they probably have other actions that in the early 1960s mere still unknown. These drugs are useful in the treatment of mild cases in adult obese diabetics; they are not effective in children or in patients with ketosis. In some patients, the sulfonamides lose their effectiveness and must be replaced by insulin. In cases that can be treated effectively by dietary restrictions alone, neither insulin nor the oral drugs should be used.

Prognosis. — Before insulin became available, fewer than 20% of patients suffering from severe diabetes lived more than ten years. Children, who usually have the disease in a severe form, seldom lived for more than a year. As knowledge about the disease and its treatment accumulated. the life expectancy of a diabetic patient in the early 1960s was much nearer that of the general population. Diabetic women who follow a carefully prepared dietary regime while receiving insulin and other necessary treatment can bear healthy babies. Most persons who have diabetes

can keep well and lead successful and useful lives, but constant and intelligent attention to the details of treatment by both patient and physician are necessary.

DIADOCHI (Gr. diadochoi) means "successors" and is the name given to the Macedonian generals who fought for the empire of Alexander the Great after his death in 323 B.C. The name includes Antigonus I and his son Demetrius I; Antipater and his son Cassander (*qq.v.*); Seleucus (see SELEUCID DYNASTY); Ptolemy (see PTOLEMIES); Eumenes and Lysimachus (*qq.v.*). The kingdoms into which the Macedonian empire was divided under these rulers are known as Hellenistic. The chief were Asia Minor and Syria under the Seleucid dynasty, Egypt under the Ptolemies, Macedonia under the successors of Antigonus II and Pergamum under the Attalid dynasty (*q.v.*). Gradually these kingdoms were merged in the Roman empire. See also MACEDONIAN EMPIRE.

DIAGENESIS, the geologic process by which, after deposition. a sediment may be materially altered or modified. These modifications may occur before burial at the common boundary, or interface, between sea water and the sediment. after burial but before consolidation or after consolidation either at normal temperatures and pressures or at elevated temperatures and pressures. The term diagenesis is applied to those changes which take place in a newly deposited sediment, prior to its consolidation, either at or below the sediment-water interface. Changes in the sediment produced by higher temperatures and pressures are properly called metamorphic. There is some uncertainty where diagenesis leaves off and metamorphism (*q.v.*) begins. Some writers would restrict diagenesis to reactions taking place on the sea floor and would use the term epigenesis for those changes which occur after consolidation and uplift but prior to the advent of truly metamorphic conditions. The changes or processes operating on a sediment clearly overlap and form a continuum so that it is commonly difficult, from a study of the results alone, to be sure in which stage a particular feature was produced.

Diagenetic changes are brought about mainly by chemical reaction of the solid particles of the sediment with the surrounding fluid, either the superjacent medium from which the sediment was deposited or the fluids trapped in the intergranular voids or pores of the sediment. The processes, solution and reprecipitation and exchange of ions between solid and liquid, alter the physical properties and the chemical or mineralogic composition of the sediment. Included among the changes are compaction, which is largely physical and results in decrease of porosity of the rock; cementation, usually by the precipitation of interstitial cement; recrystallization (such as conversion of aragonite to calcite); replacement (such as the conversion of precipitated calcium carbonate to dolomite, the double carbonate of calcium and magnesium); selective solution of some components; and the regeneration and growth of others.

Among the many products of diagenetic action are the authigenic minerals (those formed on the spot) that grew in the sediment after deposition. These may occur as secondary overgrowths on pre-existing detrital grains or as crystals without detrital cores. The quartz and feldspars of some sandstones commonly show authigenic overgrowth; both may occur also in limestones as small authigenic euhedral crystals; *i.e.,* having well-formed faces. Some concretions, most glauconite, much dolomite, the chlorite and clay mica of shales and some cherts have been attributed in part to diagenesis. See also SEDIMENTARY ROCKS. (F. J. P.)

DIAGHILEV (DIAGHILEFF), **SERGEI PAVLOVICH** (1872–1929), Russian ballet, art and music impresario, whose ballet company introduced modern ballet to the western world in 1909 and from then until his death exerted enormous influence on dancing, painting and music. He was born in Novgorod province on March 19, 1872, and studied law in St. Petersburg. where he founded the magazine *Mir* Iskusstva ("The World of Art"). While serving as assistant to Prince Sergei Volkonsky, director of the imperial theatres, Diaghilev edited the 1899–1900 edition of the theatre annals; he resigned the position in 1901. An exhibition of Russian historical portraits that Diaghilev organized in St. Petersburg in 1905 led the following year to an exposition of Russian art in Paris. In 1907, he presented Chaliapin and other Russian musicians in Paris concerts, and in 1908 he produced *Boris Godounov* there.

After 1908 Diaghilev devoted himself exclusively to ballet. The first performance of the Diaghilev Ballet Russe took place at the Théâtre du Châtelet, Paris, May 18. 1909. It introduced Vaslav Nijinsky. Anna Pavlova, Tamara Karsavina and Adolph Bolm to the western world. The choreographic genius of Michel Fokine was revealed in his *Pavillon d'Armide* and Prince Igor. The vital, exhilarating art of the Russian dancers was a revelation to western eyes and marked the beginning of a great renaissance of the ballet.

Diaghilev had an uncanny ability to recognize incipient talent. His collaborators included the composers Stravinsky, Ravel, Prokofiev, Poulenc and Milhaud, the choreographers Fokine, Nijinsky, Massine and Balanchine and the painters Bakst, Picasso, Benois, Matisse, Derain and Chirico.

In successive seasons, Diaghilev produced such impressive works as Les *Sylphides,* Petrouchka, *Scheherazade, L'Oiseau* de Feu, *L'Après-midi* d'un Faune, La Boutique Fantasque and Le Tricorne. In 1921 he revived the great Tschaikovsky ballet The Sleeping *Beauty* in the original choreography by Marius Petipa. Later he experimented with new trends in music, décor and choreography.

Although the Diaghilev company disbanded after its founder died in Venice on Aug. 19, 1929, its influence on 20th-century ballet can hardly be overestimated.

DIAGNOSIS. Man, because of his physical and mental ills, has from time immemorial turned to the physician for aid. In the past a certain mystery or magic was associated with medical diagnosis. The modern physician, however, proceeds in a logical, rational manner. avoiding the supernatural but calling for aid not only upon medicine but also upon chemistry, physics and bacteriology. While many who are ill recover without treatment, thanks to what the ancients called the vis medicatrix naturae, the healing power of nature, the first step toward successful treatment is a correct diagnosis.

In making a diagnosis the physician consciously or subconsciously follows certain definite procedures in logic. First, he recognizes the problem that the patient presents; second, he collects data that more clearly outline the problem; third, he thinks over the facts and the possible solutions; fourth, he reasons out the implications of the suggested solutions; and, lastly. he compares the actual facts with the suggestions to see if there is an identity between the facts established and the suggested solutions. These facts are obtained from the anamnesis, or history, from the psychical and physical examination and from laboratory tests and the data obtained from the employment of instruments of precision, such as the X-ray, the electrocardiograph, the electroencephalograph and similar instruments.

These are the methods of diagnosis whether the disease is to be treated by medical or by surgical procedure. The methods of medical and surgical diagnosis are one and the same; only the methods of treatment vary.

Patient's History. — The importance of a careful history has been recognized from the earliest times. Rufus of Ephesus, who practised during the reign of Trajan (c. A.D. 100), wrote a work, On *the* Interrogation of Patients, that still ranks as one of the classics of medical literature.

In the history, the influence of heredity is often of great importance since certain physical characteristics of individuals are transmitted from one generation to another. The thin, gracile, sthenic type is more prone to develop certain diseases than is the heavy, muscular. phlegmatic individual who. in turn, is more likely to suffer from certain other diseases. High blood pressure and diabetes mellitus show a marked tendency to appear in suc-

cessive generations of the same family. Cancer and tuberculosis show a marked hereditary tendency. Nervous and mental diseases are particularly prone to appear in certain families. Some diseases of the nervous system are always hereditary, familial or congenital Friedreich's disease and Huntington's chorea are hereditary; Wilson's disease is familial; meningocele, spina bifida and many cases of hydrocephalus are congenital. Psychoneuroses show a marked familial tendency, as do certain psychoses, notably manic-depressive psychosis.

Not only the family history but also the past history of the patient himself should be noted carefully. Certain diseases of childhood may give the clue that indicates the correct diagnosis. For instance, the history of enlarged glands of the neck, or even of scrofula, during childhood suggests that the cough from which the adult patient suffers is caused by pulmonary tuberculosis.

The patient's occupation and habits, moreover, may offer clues to diagnosis. Certain occupations present definite health hazards. Those who work in an atmosphere of dust, as do coal miners, metalworkers, stonemasons and woodworkers, inhale dust particles that lodge in the lungs and may later produce severe pulmonary disease. Workers in chemical plants may suffer from acute or chronic poisoning, and painters are prone to develop lead poisoning unless proper precautions are observed. Nursery workers who spray plants with solutions of arsenic, mercury and other poisonous ingredients are subject to hazards from these poisons. It is also important to know where the patient has lived or still lives. Malaria, for example, is very common in the Mediterranean area but very rare in Labrador.

The excessive use of alcohol and tobacco has long been recognized as a cause of disease. Chronic alcoholism causes certain types of psychoses. Cirrhosis of the liver is closely associated with the overuse of alcohol, as the old designation "gin-drinker's liver" indicates. More than one-half of the cases of cirrhosis of the liver in the United States are seen in alcoholics. The excessive use of tobacco plays its role in the production of disease, particularly of the vascular system. Tobacco causes, in many individuals, a constriction of the capillaries of the skin with a lowering of skin temperature, while other individuals develop cardiac irregularities from excessive smoking. Excessive cigarette smoking may be a major factor in the causation of lung cancer.

The patient's eating habits, his favourite foods and foods that agree or disagree with him suggest possible diagnoses. The patient with hyperacidity of the stomach cannot eat pickles, while the man with too little acidity enjoys them. The patient's psychological background and environment may play a deciding role in the causation of a disease. An environment of fear, or repression, or hostility may produce physiological as well as mental abnormalities.

History of the Illness.— Next, the physician investigates the history of the patient's illness. He asks if the symptoms are general or local; if they are local, he asks where they are localized. Since the local symptom is most commonly pain, the physician wishes to know where it is located, whether it is constant or occasional, uhether it is sharp or dull, and whether it remains localized or travels to another region. In many diseases, such as angina pectoris, duodenal ulcer, intermittent claudication and tabes dorsalis, an accurate description of the pain, including its location, duration, periodicity and the conditions under which it appears or disappears. is often sufficient to indicate the diagnosis. The duration (chronicity) of the disease is always investigated. Some diseases are acute, some are chronic, some tend to regress spontaneously and others never regress nith or nithout assistance. Lobar pneumonia is an acute disease in which either recovery or death occurs in a few days. A patient who has been ill a month or longer is not suffering from uncomplicated lobar pneumonia. Conversely. diabetes mellitus is a chronic disease in nhich complete recovery rarely if ever occurs. A patient who has had sugar in the urine but later finds that it has completely disappeared probably does not have diabetes

History taking is an art of great value. Some physicians estimated that the history itself contributes 50% to the correct diagnosis; others raise the percentage as high as 75. Hippocrates, the father of medicine, compiled case histories so accurately that more than 2,000 years later the correct diagnosis can be made from them.

Physical Examination.— After he obtains the history of the patient and of the disease, the physician next proceeds to examine the patient, making use of his trained senses of sight, touch, hearing and smell. In this physical examination he employs four methods: (1) inspection; (2) palpation; **(3)** percussion; and (4) auscultation.

Inspection.— This is the oldest of these methods. Inspection alone may be sufficient to diagnose diseases that cause alterations in the patient's appearance; such diseases are acromegaly, which produces marked enlargement of the jaws, nose and frontal bone, and leprosy. which often causes thickening of the tissues of the face so that the patient's face resembles that of a lion— the leonine facies. The expression of the face is characteristic of certain diseases. In Parkinson's disease the face is often singularly devoid of expression, or masklike, the so-called Parkinsonian mask. In paralysis of the facial nerve, Bell's palsy, the patient is unable to close his eye. smile or show his teeth on the affected side. The gait of the patient may be characteristic of a certain disease, such as tabes dorsalis, hemiplegia or Parkinson's disease.

The eyes may be protruded or sunken; the pupils may be irregular, not of the same size in each eye or may not constrict when exposed to light. All of these abnormalities have special significance. Inspection of the blood vessels of the neck may reveal irregularities in the beat of the heart so characteristic as to indicate the diagnosis. Inspection of the chest may reveal a marked difference in size and inequality of respiratory movements on the two sides. and the apex beat of the heart reveals by its position whether the heart is enlarged and by its character whether the heart is irregular. An enlarged stomach. liver or spleen or a tumour in the abdomen are often readily seen on careful inspection.

The ancients devoted a great deal of attention to the pulse and wrote many tomes on the subject. Paul of Aegina. who practised during the 7th century A.D., distinguished 62 varieties of pulse. While the modern physician thinks that many of these varieties were figments of the imagination, he has found that certain diseases are almost invariably associated with a certain type of pulse and that certain heart diseases have pulses that are slow or fast, small or bounding, regular or irregular.

Palpation.— By palpation, the physician confirms what is seen on inspection. · Firmness or softness, or irregularity in outline or of the surface, of an enlarged organ may not be apparent on inspection alone. Pain may be elicited on pressure, and edema of the ankles. which may have been suspected on inspection, is confirmed when pressure with the finger produces a pitting that persists.

Palpation may reveal tenderness over the gall bladder in gall bladder disease; tenderness on pressure over the appendix is diagnostic of appendicitis unless the symptoms and the other findings disagree with this diagnosis. Palpation is of great value in the diagnosis of suspected fractures because it can reveal abnormal motility of the bones or crepitation. After palpation the physician proceeds to percussion.

Percussion.—Percussion. or tapping with the fingers. was discovered by Leopold Auenbrugger and described in his *Inventum novum,* one of the classics of medical science, published in 1761. Auenbrugger, the son of an innkeeper in Graz, learned as a boy to tell how much wine was in a cask by tapping on the end. As a physician he discovered he could tell which side of the chest contained fluid by tapping on it and that he could determine the size of the heart, the presence of fluid, pneumonia and other disease conditions by this method.

Percussion of the chest reveals whether the lungs contain air or are consolidated, and whether pneumonia or pulmonary tuberculosis should be suspected as well as whether fluid in the chest or thickening of the pleura or air in the chest may be present. Percussion is important in determining the position and the size

of the heart, liver, spleen and stomach. Its value is greatly enhanced by auscultation.

Auscultation.—Auscultation, or listening, was discovered by René Théophile Hyacinthe Laennec, a pupil of Jean Nicolas Corvisart, who introduced percussion into medical practice in France. Laennec, according to his biographers, was watching a group of 'children playing on a beam in the courtyard of the Louvre. One youngster scratched the beam with a pin, and the others, while pressing their ears against the beam, yelled every time he scratched. Laennec, who made the observation nhile on his way to see a patient, had an inspiration. On reaching the patient's house, he took a sheet of paper, rolled it into a cylinder and applied one end to his ear and the other end to the patient's chest. To his delight he heard the heart sounds perfectly, and at that moment the stethoscope was discovered. He described his instrument and its value in his De l'auscultation *médiate,* published in 1819. The stethoscope remains one of the indispensable aids in the diagnosis of disease of the lungs and heart. With it the physician determines whether the breath sounds are normal or whether there are signs of inflammation, bronchitis, consolidation or cavitation in the lungs. He also can tell whether the heart sounds are normal or whether there is disease of the myocardium or lesions of the four sets of heart valves. (See AUSCULTATION.)

Instruments of Precision.—After the physical examination has been finished, the physician turns to instruments of precision for additional aid.

Sanctorius (1561–1636), professor at Padua, was the first physician to employ instruments of precision in the practice of medicine. The legend goes that Galileo, while watching a lamp swing in the cathedral at Pisa, counted its oscillations by feeling his pulse and established the law of the isochronism of the pendulum. Sanctorius, his colleague and friend, reversed the process and timed the pulse by the swinging of a pendulum that consisted of a weight attached to a cord. The length of the cord, which was adjusted until the rate of the oscillation agreed with that of the pulse. was measured on a scale and this measurement was taken as the pulse rate. Sanctorius also employed a type of thermometer, probably the one invented by Galileo, to determine the patient's temperature and weighed his patients on a steelyard to measure accurately the effect of food, exercise and various activities upon what he called the insensible perspiration.

Although Sanctorius published his method of estimating the pulse and determining the temperature in 1625 and his work on insensible perspiration in 1614, only the latter made much impression upon medical thinking. Accurate timing of the pulse first became a recognized procedure when Sir John Floyer published in 1707 his *Pulse Watch,* in which he stated he at first employed a minute glass such as was used by mariners, "but because that was not portable, I caused a Pulse-Watch to be made which runs 60 Seconds. and I placed it in a Box to be more easily carried, and by this I now feel Pulses."

Registration of the temperature lagged even further behind, the first systematic recording dating from 1852 when Ludwig Traube published the first temperature curve in fever from the Leipzig clinic.

Sir James Mackenzie (1853–1925), while a general practitioner in Burnley, Eng., devised an instrument with which he could simultaneously register the pulse waves in the radial artery at the wrist and in the jugular vein in the neck. By comparing the two sets of curves, the jugular pulse indicating the action of the auricles and the radial pulse the changes in the ventricles, he demonstrated the mechanism by uhich irregularities of the pulse were produced and made some of the most noteworthy contributions in the history of cardiology.

Blood Pressure.—Measuring the blood pressure is an important part of the examination of the patient. While the skilled physician in the past could tell whether the blood pressure was elevated by palpating the pulse, this method was inexact and often misleading. In 1896 Scipione Riva Rocci devised the form of the sphygmomanometer used today for measuring blood pressure; it consists of a rubber bag surrounded by a cuff, which is pumped up until the pulse (the systolic pressure) disappears at the wrist. Later it was found that by listening at the bend of the elbow, systolic pressure as well as diastolic pressure could be estimated. The systolic pressure is the pressure during the systole, or the beat of the heart; the diastolic pressure is the pressure during diastole, or the pause of the heart between beats. Although there is still much discussion regarding the normal systolic and diastolic pressures, it is safe to state that a systolic pressure of more than 140 mm. of mercury and a diastolic of more than 100 mm. is elevated. (See BLOOD PRESSURE)

Electrocardiograph.—No study of the heart or circulation is complete without the records obtained with the electrocardiograph. Augustus D. Waller showed in 1887 that an electrical current produced by the beating of the heart could be demonstrated in man by attaching electrodes to the body and connecting them with a capillary electrometer. Willem Einthoven in 1903 substituted for the capillary electrometer a string galvanometer of hi; own design, and the electrocardiograph became a practical clinical instrument. In the original instrument the feeble current coming from the body through the arms and legs was carried into a quartz string placed in a magnetic field. Each heartbeat caused a vibration of the string, whose movements were photographed on a moving film or sensitized paper—the electrocardiogram. Later improvements consisted of employing electron tubes similar to those used in radio that step up the weak current until it moves a string rnore sturdy than the original delicate quartz fibre, or even marks directly upon prepared paper. The latter method avoids the inconvenience of photography and allows the physician to watch the record as it is being written.

The information that can be obtained from study of the electrocardiogram is amazing It shows whether the heart is enlarged and where the enlargement occurs, whether the heart action is irregular and where the irregularity originates, whether a coronary vessel is occluded and where the occlusion is located, and whether a slow rate is physiological or caused by heart block. It also indicates high blood pressure, thyroid disease and certain types of malnutrition.

Cardiac Catheterization.—This procedure, carried out first by Werner Forssmann in 1929, has been of great value in diagnosing diseases of the heart, particularly congenital malformations. The procedure, which consists of introducing a small catheter into a vein and then passing it into the heart, gives the doctor accurate measurements of the (blood) pressure within the auricles and ventricles and also of the oxygen and carbon-dioxide content of the blood in each auricle and ventricle.

Electroencephalograph.—One of the latest instruments of precision, the electroencephalograph, was first described in 1929 by Hans Berger of Jena. It records the electrical activity of the human brain and has been of special value in diagnosing epilepsy and locating lesions of the brain, such as tumours, abscess or hemorrhage.

X-rays.--No examination tool has been more useful to general diagnosis than X-rays, or Rontgen rays, which were discovered by Wilhelm Conrad Rontgen in 1895. The original X-rays mere photographs made on sensitive plates. With the development of fluoroscopy, X-ray diagnosis became even more helpful. When a patient is placed in front of the X-ray tube and behind the fluorescent screen, the physician sees clearly the outlines of the body, can watch the heart beat and note any irregularities, and can watch the lungs expand in respiration and observe whether this expansion is normal. When the patient swallows a gruel containing barium or any other substance opaque to the X-ray, the course of this material can be followed by the physician as it passes from the mouth, through the esophagus and stomach and into the intestines. The X-ray demonstrates the structure of the bones of the body and lesions of the bone such as defects of structure, fractures. tumours, arthritis and inflammations. It reveals the size of the heart; irregularities and defects of the heart; pulmonary diseases such as bronchitis; pulmonary tuberculosis; collapse and abscess of the lungs; tumours of the lung: thickening of the pleura; fluid in the pleural cavity; enlargement of the liver spleen and kidneys; and stones in the kidneys, gall bladder, bladder and pancreas.

The employment of contrast mediums, which is the name given to the opaque solutions that cast shadows. greatly enlarged the scope of X-ray diagnosis. This method made possible the demonstration of bronchiectasis; diverticula and cancer of the esophagus, stomach and intestines; and lesions of the kidneys, ureters and bladder. Similarly, the employment of the opaque dye iodophthalein, which mas first used by Evarts A. Graham and W H. Cole in 1924, demonstrates enlargement of the gall bladder and lack of function or the presence of gallstones. Lesions of the heart and blood vessels and obstructions to the blood flow through the heart. arteries or veins can be revealed by injecting partially opaque solutions into the circulatory system Ventriculography, introduced by Walter E. Dandy in 1918, consists of introducing air into the ventricles of the brain and then taking an X-ray of the skull. The resultant picture shows the size and location of the ventricles, which may be displaced or distorted by a tumour or abscess of the brain. (See RADIOLOGY: Diagnostic Radiology.)

Basal! Metabolism Test.—Another method of examination, the basal metabolic test, is of great value in certain patients. The method employed consists of estimating the amount of oxygen consumed in a certain amount of time. When more oxygen than normal is consumed, the metabolic rate is increased; when the amount of oxygen consumed is less than normal, the rate is decreased. The test is of especial value in the diagnosis of the thyroid disease. In hyperthyroidism or exophthalmic goitre the metabolic rate is increased; in hypothyroidism the rate is decreased.

Other *Instruments*.—In addition to these instruments of precision, the physician also has at his disposal the ophthalmoscope, which permits inspection of the retina; the bronchoscope, which shows the interior of the bronchi; the gastroscope, which gives a clear view of the interior of the stomach; the laryngoscope, for studying the larynx and vocal cords; the cystoscope, with which the interior of the bladder can be seen; and the proctoscope, which can be used to reveal lesions of the rectum and sigmoid flexure.

Laboratory.—After the physician has completed the physical examination and his examination with instruments of precision. he turns next to the laboratory for study of the blood, urine, body fluids, secretions and any tissue that was removed for microscopic examination. In an examination of the blood. the red cells and white cells are counted; the amount of hemoglobin is determined; the white blood cells are then stained and the relative percentages of the different types are estimated. The number of red cells is decreased in the anemias and is increased in the polycythemia. In most infectious diseases the number of white blood cells is increased, but in some infectious diseases a decrease in the number of white blood cells is characteristic. In the leukemias, the number of white blood cells is often tremendously increased. The clotting time of the blood is increased in hemophilia; the formation of the clot is often abnormal in purpura. The number of blood platelets, a third type of blood cell, is markedly diminished in purpura haemorrhagica, or Werlhof's disease (thrombocytopenic purpura). Blood typing is of the greatest importance in certain conditions and in connection with treatment by transfusion. The sedimentation rate. a valuable aid in the diagnosis of certain diseases, is determined by placing the blood in a test tube containing an anticoagulant and noting the rate of settling or sedimentation of the red blood cells. The direct study of the bone marrow has been of great value in the diagnosis and treatment of blood diseases. A small amount of bone marrow is obtained by puncture, usually of the sternum. The physician can study the processes of blood formation by examining the immature cells that have not yet been released from the marrow into the circulation.

The blood serum yields important information in many diseases. For example the serum contains substances in syphilis that produce a positive Wassermann reaction; in typhoid fever. the serum contains specific agglutinins that agglutinate the typhoid bacillus (Widal's reaction) ; other specific agglutinins are present in brucellosis (undulant or Malta fever), tularemia and other less common infections.

Blood cultures are a routine procedure in establishing diagnosis of many infectious diseases and may demonstrate the presence in the circulating blood of the typhoid bacillus, the pneumococcus, the meningococcus and the streptococcus, to mention a few well-known examples.

Studies of the blood chemistry are of great importance in many diseases. In diabetes, for example, the amount of sugar in the blood is greatly increased; in nephritis (Bright's disease), when the kidney is unable to excrete properly, the blood values for urea, uric acid, protein and creatinine may rise sharply. The blood cholesterol may be diminished in hyperthyroidism and greatly increased in hypothyroidism. In many diseases a study of the patient is incomplete without certain determinations of the blood chemistry.

By means of the stomach tube, the physician is able to study the gastric contents. The most important finding is the degree of acidity present. Gastric acidity is usually greatly increased in gastric or duodenal ulcer and decreased in cancer of the stomach; in pernicious anemia no acid is present.

Lumbar puncture, which was introduced by Heinrich Quincke in 1891, consists of introducing a small needle between the lumbar vertebrae into the subarachnoid space. The pressure of the spinal fluid is measured, and the fluid itself can be studied. This procedure is of great value in the diagnosis of meningitis, poliomyelitis, syphilis, brain tumours and many other diseases of the nervous system.

Tissue examination is a valuable aid in the diagnosis of cancer. (See CANCER: Diagnosis.)

Functional Tests.—These tests are assuming increased importance in diagnosis. The functional capacity of the heart is tested by noting the increase in the heart rate and in the blood pressure following exercise, and also by recording the time necessary for both to return to their normal values. Kidney function is tested by noting the rate at which the dye phenolsulfonphthalein when injected in the cubital vein is excreted in the urine and by the urea clearance test, in which the blood urea and the amount of urea present in 75 ml. of urine is estimated. Functional tests for the liver employ the intravenous injection of dyes, such as sulfobromophthalein sodium, which a normal liver withdraws from the circulation in 30 min. Carbohydrate function tests are performed by giving the patient 100 g. of glucose by mouth on an empty stomach, Normally the level of blood sugar rises sharply from the normal of 100 mg. per 100 ml. of blood to 130 mg. or 150 mg., then falls sharply and returns to its original level in two hours. In diabetes mellitus it may rise to two or three times its normal value and remain quite high for two, three or even four hours.

Skin tests are valuable in diagnosis. When the skin is scratched and a drop of tuberculin is placed on the spot, an area of redness with induration of the skin appears within 24 to 48 hours in persons who are or have been infected by tuberculosis (Von Pirquet test). This test is of special value in children. Similarly, when a drop of diphtheria toxin is employed, individuals who have no immunity to diphtheria show a reaction (Schick test). A similar test is employed in the allergic diseases, notably asthma and hay fever, where the offending material, such as milk, wheat, horse serum or ragweed pollen, causes a reaction.

In many patients an examination of pathological secretions for bacteria may be a deciding point in diagnosis. The exudate from an inflamed tonsil. pharynx or nostril when stained by proper methods may reveal the diphtheria bacillus or the streptococcus as the cause of the disease. Cultures of such secretions or of the urine, feces, pus or sputum demonstrate the organism even more conclusively. The demonstration of a single tubercle bacillus in the sputum makes positive, often, a suspicion of pulmonary tuberculosis.

Final Diagnosis.—The physician has now collected his data. He now thinks over the facts that he has obtained and the suggested solurions—sugar in the urine. for instance. would suggest diabetes mellitus. Then he reasons out the iinplications of the suggestions; thus a diabetic patient in addition to having sugar in the urine should have an abnormal amount of sugar in the blood

and should give a history of excessive thirst, excessive urination and loss of weight.

The physician next arrives at the last stage of the mental process required in making a diagnosis. He compares the actual facts with the suggestions that have occurred to him to see if there is an identity between such facts and the suggested solutions. If further study brought out the existence of all of the above symptoms. the actual facts would agree with the suggested solution. The diagnosis would be diabetes.

This is the method pursued by the physician in making a diagnosis. While the task of collecting data on the patient—history. physical examination, special examinations and laboratory tests—requires accurate observation. the process of correct reasoning is, in the last analysis, more importan . False diagnoses often result not from false data but from faulty interpretation. To assemble the data, to make use of the relevant and to discard the irrelevant information, and to pass final judgment—all of which are important steps in making the diagnosis—often requires a mental ability of the highest order.

DIALA: *see* DIYALA.

DIALECT, a peculiar manner of speech in the language of a person, community. profession. social group, country or district (from Gr. *dialektos).* In its widest sense, languages which are branches of a common or parent language are its dialects, as Attic. Ionic: Greek, and the various Romance languages of Latin. Where there have existed side by side. as in England, various branches of a language, such as the languages of the Angles, the Jutes and the Saxons, and the descendant of one particular language has predominated, the traces of the others remain in the dialects of the districts where once the original language prevailed. Thus a dialect of a language represents a variation. *See* also LANGUAGE: *Historical Development of Languages.*

DIALECT GEOGRAPHY, or linguistic geography (areal linguistics), deals with the geographic dissemination of linguistic features and their interpretation in terms of population history (demography).

The data are secured from the speech (vocabulary, grammar, pronunciation) of representative speakers in selected communities within an area. The findings are mapped separately for each item investigated. Lines are drawn around areas of uniform or majority usage (inner isoglosses, setting off the focuses) and around areas of minority usage (outer isoglosses, setting off the margins of the focuses).

Such word lines (isolexes), form lines (isomorphs) and phonetic lines (isophones) furnish the basis for establishing major and minor dialect boundaries within the area. For, although isoglosses rarely follow precisely the same course, they are apt to run in more or less closely knit bundles. The relative importance of such bundles (dialect boundaries) depends partly upon the number of isoglosses they contain and partly upon their character, structural isoglosses (phonemic or morphological) being obviously more important than nonstructural ones (isolexes, incidental isophones and isomorphs).

The dialectal subdivisions of an area established in this way lend themselves to historical interpretation by determining correlations with areas of settlement and trade. political subdivision and culture areas. Relatively uniform focal areas and their margins are usually directed toward important cultural centres: dialect boundaries often coincide with political, social and economic barriers, where features disseminated from these centres are apt to he arrested. However, usage is always in flux, shifting with a complex of factors in the history of the population.

Though concerned chiefly with regional folk dialects, linguistic geographers also turned their attention to social dialects and their interrelations. especially in the United States, where class usage shades off from the "folk" to the cultured.

Linguistic geography has developed its techniques since 1875, and has achieved highly significant results. It has taken its place

DIALECTIC (DIALECTICS), a term in logic, generally used in common parlance in a contemptuous sense for verbal or purely abstract disputation devoid of practical value (from Greek *dialektos,* "discourse"; *dialektike* [*techne*], "art of debate"). According to Aristotle, Zeno of Elea "invented" dialectic, which was in his hands a method of refuting an opponent's opinion by accepting it hypothetically and then forcing the opponent to admit that it led to contradictory conclusions. This destructive form of dialectic was much used by the Sophists. In the hands of Socrates dialectic became the art of eliciting a satisfactory definition (or of rejecting an unsatisfactory definition) of some ethical or other term by the systematic use of question and answer. In Plato this dialectical quest for definition was transformed into an investigation of the forms or ideas, which were thought of as entities shared in by, or copied by, the things to which a general term may be applied. This dialectic was envisaged (perhaps at different stages in Plato's development) as a study which connects the forms with the culminating "Idea of the Good" *(Republic,* vii), or as a science which arranges forms hierarchically from the most narrowly specific to the most comprehensively generic and which also determines whether they will or will not "blend" (that is, n-hether they can or cannot be predicated of one another or of the same subject). In Aristotle's use the dialectical is opposed to the demonstrative use of reasoning (which alone yields knowledge): in the former one's premisses are the opinions of the many or the experts, whereas in the latter one may only make use of such premisses as are either true and primary, or else deducible

from true and primary premisses. The Stoics divided logic into rhetoric and dialectic. and from their time till the end of the middle ages dialectic was either synonymous with, or a part of, logic.

In modern philosophy the word has received certain special meanings In the critical philosophy of Kant the part known as the "transcendental dialectic" endeavours to expose the illusion involved in attempting to use the categories and principles of the understanding beyond the bounds of phenomena and possible experience. In the system of Hegel dialectic becomes the tendency of a finite object or notion to "suppress itself," to "develop contradictions" and to pass over into its own negation Such dialectic occurs in the realm of thought and science, but it also occurs in the spheres of nature and history: "Wherever there is movement, wherever there is life . . . there dialectic is at work." The Hegelian nord and notion were taken over by Karl Marx (see MARXISM; DIALECTICAL MATERIALISM).

See also references under "Dialectic" in the Index volume.

(J. N. F.)

DIALECTICAL MATERIALISM, the philosophy of the world Communist movement, is derived from the philosophical and social teachings of Karl Marx (1818–83) and Friedrich Engels (1820–95) (*qq.v.;* see also MARXISM). Its essential feature is the combination of philosophical materialism with dialectics.

For Marx and Engels, materialism meant that the material world, perceptible to the senses. had objective reality independent of mind or spirit. They did not deny the reality of mental or spiritual processes. but affirmed their dependence on material processes of which they were the product. Feeling, sensation, thought, etc., were functions of the brain. Ideas could arise, therefore, only as products and reflections of material conditions—though having once arisen, they play an essential part in human activity. Marx and Engels understood materialism as the opposite to "idealism," by which they meant any theory which treats matter as dependent on mind or spirit, or mind or spirit as capable of existing independent of matter. For them, the materialist and idealist views were irreconcilably opposed, throughout the historical development of philosophy. They adopted a thoroughgoing materialist approach. holding that any attempt to combine or reconcile materialism with idealism must lead to confusion and inconsistency. Stressing the priority of matter and the secondary or derivative character of mind and ideas, they denied the possibility of supernatural or transcendental reality.

While acknowledging their debt to the materialism of the philosophers of the 18th-century French "Enlightenment." Marx and Engels criticized earlier materialist philosophy as "mechanistic" or "metaphysical." They saw in it tao major defects. First, it unjustifiably extended the conception of mechanical causes to all processes of nature and society, thus seeking to reduce everything to the mechanical interaction of material particles. Secondly, and consequently, it could not cope mith development, either in nature or society Marx and Engels saw the scientific discoveries of their time—notably in thermodynamics, in geology and in biology (cell theory and theory of evolution)—as confirming their general criticism of mechanistic materialism. Motion, they insisted. was the mode of existence of matter. Within the material world there mas continual change and development, one form of motion arising from another. For example, chemical processes gave rise to living processes and living organisms developed consciousness—life and consciousness being higher forms of the motion of matter, arising from and based on lower forms but having their own qualities and laws of development. Materialism, therefore, must cease to be "mechanistic" and become "dialectical."

Marx's and Engels' conception of dialectics owes much to Hegel. In opposition to the "metaphysical" mode of thought. which viened things in abstraction, each by itself and as though endowed nith fixed properties, dialectics considered things in their movements and changes, inter-relations and interactions. Everything is in continual process of becoming and ceasing to be, in which nothing is permanent but everything changes and is eventually superseded All things contain contradictory sides or aspects. whose tension or conflict is the driving force of change and eventually transforms or dissolves them. Processes of gradual quantitative increase or decrease. at a certain stage when internal tensions reach breaking point, give rise to fundamental changes of quality. But while Hegel saw change and development as the expression of the world spirit, or Idea, realizing itself in nature and in human society, for Marx and Engels it was inherent in the nature of the material world. They therefore held that one could not, as Hegel tried, deduce the actual course of events from any "principles of dialectics"; the principles must be inferred from the events.

The theory of knowledge of Marx and Engels started from the materialist premise that all knowledge is derived from the senses. But against the mechanist view which derives knowledge exclusively from given sense impressions, they stressed the dialectical development of human knowledge, socially acquired in the course of practical activity. Men can gain knowledge of things only through their practical interaction with those things. framing their ideas corresponding to their practice; and social practice alone provides the test of the correspondence of idea with reality; *i.e.,* of truth. This theory of knowledge is opposed equally to the "subjective idealism" according to which we can know only sensible appearances while things-in-themselves elude us, and to the "objective idealism" according to which me can know supersensible reality by pure intuition or thought, independent of sense. For it rules out supersensible reality as illusory and holds that, by applying our ideas of things in social practice and by experimental techniques, we come to know not merely "phenomena" but things-in-themselves, though this knowledge always remains incomplete.

Marx's and Engels' materialist conception of history was consistent with their general philosophical views. They held that man's mental and spiritual life, his ideas and aims, reflect his material conditions of existence, the growth of which conditions human development. Above all men must co-operate to produce the means of life. Independent of any conscious decision, men enter into the social relations required by the level of their productive forces. These relations of production, which include property relations, define the economic structure and determine the class relations in society Social institutions and the prevailing patterns of ideas arise as a superstructure on this economic basis. As the forces of production develop, existing relations of production tend to hinder further advance. Then a period of social revolution begins. when an old social system, with its typical institutions and social ideas, is more or less violently replaced by a new one.

In his detailed analysis of contemporary society (especially in the three volumes of Capital), Marx sought to show that capitalist production was merely a temporary phase of social evolution: itself a result of the breakup of feudalism, it must in turn be replaced by socialism. The contradictions of capitalism, under which private appropriation frustrates the full development of production to satisfy social needs, must lead to socialism. where all means of production become social property, while exploitation of man by man and class antagonisms would cease. Production would now be planned to meet human needs, leading to a communist society organized on the principle "from each according to his abilities, to each according to his needs." This would also mark the dawn of human freedom: men would become the masters of their own conditions of existence, no longer constrained and limited in their ideas and actions by circumstances beyond their control.

The political philosophy of Marx and Engels followed from their materialist conception of history. From the beginnings of private property in means of production. society had split into antagonistic classes—exploiters and exploited; and all politics was the expression of the consequent class struggle The state arose as an instrument of the domination of a ruling class over the rest of society. Religious, philosophical, political and moral systems of ideas ("ideologies") had always expressed the outlook of particular classes. serving to support either the dominance of one class or the struggle of another to resist or overthrow it. The socialist revolution could be achieved only by the contemporary working class. which must wrest state power from the ruling capitalist class, break up its "bureaucratic-military machine" and create a workers' socialist state. With the eventual transition to

classless communist society, the state would in the end wither away and the government of men be replaced by the administration of things.

After Marx and Engels, the main contribution to dialectical materialism was made by V. I. Lenin (1870–1924; [*q.v.*]). To him was chiefly due the conception of a political party "of a new type," highly organized and disciplined and in each country leading the class struggle of the working class to the victory of socialism. The party, Lenin insisted, must adopt as its own the philosophy of dialectical materialism and use it as a guide in all its activities. This was above all necessary to resist the intrusion of alien ideas which would weaken the party's theoretical clarity and unity in action. He wrote against those in the world socialist movement who considered Marx's and Engels' philosophical teachings as superseded by later developments, especially by new advances in the natural sciences, and sought to show that recent scientific discoveries confirmed the dialectical materialist philosophy. In these polemics he contributed especially to dialectics and to the theory of knowledge.

There exists no systematic exposition of dialectical materialism by its founders, who stated their philosophical views mainly in the course of polemics arising from their political activities and sociological and economic researches.

DIALLAGE: *see* PYROXENITE.

DIALOGUE, in its widest sense, is the recorded conversation of two or more persons. As a literary form it is a carefully organized exposition, by means of invented conversation, of contrasting philosophical positions or intellectual attitudes; or it is an element in drama and fiction. The oldest known dialogues are the Sicilian mimes, written in rhythmic prose by Sophron of Syracuse in the early 5th century B.C. Although none of these have survived, their nature may be inferred from the verse mimes of Herodas (Herondas), an Alexandrian of the 3rd century B.C. They depict brief realistic scenes of everyday life involving common character types. Although Plato knew and admired the Sicilian mimes, the form of philosophic dialogue that he had perfected by 400 B.C. was sufficiently original to be an independent literary creation. With due attention to characterization and the dramatic situation from which the discussion arises, it develops dialectically the main tenets of Platonic philosophy. To Lucian in the and century A.D. the dialogue owes a new tone and function. His influential *Dialogues of the Dead* with their coolly satirical tone inspired innumerable imitations in England and France during the 17th and 18th centuries; of these, the best known are works of the same name by Bernard de Fontenelle (1683) and François Fénelon (1712).

The revival of interest in Plato during the Renaissance encouraged numerous imitations and adaptations of the Platonic dialogue. In Spain Juan de Valdes used it to discuss problems of philology (1533) and Vincenzo Carducci, theories of painting (1633). In Italy dialogues on the Platonic model were written by Torquato Tasso (1580), Giordano Bruno (1584) and Galileo (1632). The Renaissance also adapted the dialogue form to uses unsuspected by either Plato or Lucian. It was widely used in the teaching of languages by the direct method.

In the 16th and 17th centuries dialogue lent itself easily and frequently to the presentation of controversial religious, political and economic ideas. Berkeley's *Dialogues Between Hylas and Philonous* (1713) are perhaps the best of the English imitations of Plato. The best-known 19th-century examples of the form are Walter Savage Landor's *Imaginary Conversations* (1824–29), sensitive re-creations of historical personages. G. Lowes Dickinson's A *Modern Symposium* (1905) and André Gide's *Imaginary Interviews* (1944) illustrate the continued appeal of this ancient form in the 20th century.

DIALYSIS, a mechanical-physical separation process first employed by Thomas Graham (1861) to separate colloidal particles from those of ionic or small molecular dimensions (crystalloids). If such a mixture is placed in a sack made of parchment, collodion or cellophane, or in a drum provided with a bottom of such material, and suspended in water, the ions and small molecules pass through the membrane, leaving the colloidal particles in the drum or sack.

The process is a slow one and may, in some cases, be accelerated by heating or by an electric field (electrodialysis). The separation depends upon the difference in size between the colloidal and crystalloidal constituents, and the difference in the speeds at which they diffuse through the pores of the semipermeable membrane. *See* COLLOID; DIFFUSION. (A. E. A.)

DIAMAGNETISM. Some substances, like iron, are attracted strongly by the pole of a magnet and are said to be ferromagnetic; others are attracted weakly and are called paramagnetic; still others are repelled and these are called diamagnetic. In 1778 S. J. Brugmans observed for the first time the repulsive action of bismuth and antimonv in the strong nonuniform field of an electromagnet.

In 1845 and the following years Michael Faraday examined a great many substances and found many of the elements and most of the compounds to be diamagnetic; it was he who first used the words diamagnetic and paramagnetic. The most highly diamagnetic substance known is bismuth; in a nonuniform field its repulsive force is measured by its susceptibility, -0.000013, a value very small compared to the (paramagnetic) susceptibility often found in iron, $+1000$. Diamagnetic materials are composed of atoms that have completed electron shells *(see* ATOM: *Atomic Structure and Periodic System)* and no permanent magnetic moments. The electrons circulating in such atoms are either speeded up or slowed down by the application of a field, and the resulting change in magnetization, the "induced" moment, opposes the field. This opposition of the magnetic field and the induced magnetism is characteristic of diamagnetism. *See* MAGNETISM: *Diamagnetism.* (R. M. B.)

DIAMETER, in geometry, a straight line passing through the centre of a conic section and terminated by the curve (from the Greek *dia,* "through," *metroh,* "measure"). The most familiar type of diameter is that bisecting a circle. The principal diameters of the ellipse and hyperbola coincide with the axes and are at right angles; conjugate diameters are such that each bisects chords parallel to the other.

The diameter of a quadric surface is a line at the extremities of nhich the tangent planes are parallel. Newton defined the diameter of a curve of any order as the locus of the centres of the mean distances of the points of intersection of a system of parallel chords with the curve.

See CIRCLE; CONIC SECTION; ELLIPSE; HYPERBOLA; PARABOLA.

In architecture, the term is used with reference to the lower part of the shaft of a column *(see* ORDER).

DIAMOND, a mineral composed of pure carbon, is the hardest naturally occurring substance known to man. Its great hardness, brilliance and fire make it chief among precious stones. Because of its unsurpassed hardness, diamond also has many important industrial uses.

Origin of Name.—The name *adamas,* "the invincible," was probably applied by the Greeks to hard metals and thence to corundum and other hard stones. The first known undoubted application of the name to diamond is found in Manilius (A.D. 16). Pliny (A.D. 100) speaks of the rarity of the stone, "the most valuable of gems, known only to kings." Later Roman authors men-

tion various rivers in India as yielding the *adamas* among their sands. The name *adamas* became corrupted into the forms adamant, *diamaunt,* diamant and diamond.

Varieties.—There are four varieties of diamond: (1) diamond proper; (2) bort; (3) ballas; and (4) carbonado. The term "diamond proper" includes the well-crystallized, transparent stones valued as gems. Bort (*q.v.*), also called boart or bortz, is poorly crystallized gray to brown, translucent to opaque diamond widely used in industry. The term is also applied to diamond crystals and fragments useless as gem stones. Ballas is a name given to spherical masses of minute diamond crystals arranged more or less concentrically. It is extremely hard and very tough and has important industrial applications. Carbonado (*q.v.*) is an opaque, black or gray, tough compact variety of diamond, also used in industry.

Unit of Weight (Carat).—Diamonds are invariably weighed in carats: 1 metric carat (now nearly universally used) = 0.200 g. or 200 mg. Some confusion exists in the recorded weights of famous diamonds because the value of the carat has been changed from time to time. (See CARAT.)

This article deals with diamond as a gem and the cutting of gem stones, the expanding industrial uses of diamonds and the development of industrial-grade synthetic diamonds, the physical properties of diamonds, their origin, their occurrence and the history of famous diamonds.

USES OF DIAMONDS

GEM

As noted previously, diamond uses may be divided into two main categories, gem and industrial. The use of diamonds as gems is well known, for their great hardness, brilliance and fire make them unsurpassed for this purpose.

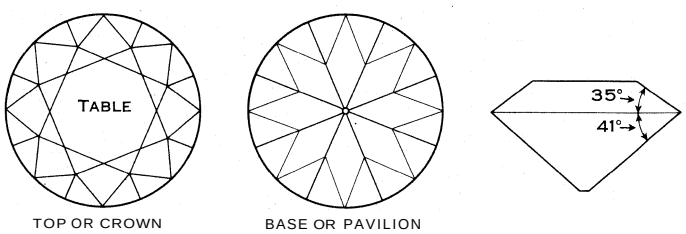
The most popular style of cut for diamonds is the 58-facet brilliant. a round stone having 33 facets above the girdle and 25 below (fig 1). When cut to the proportions shown in fig. 1, a diamond will possess its maximum brilliance and fire Other cuts frequently used are the emerald and marquise. Important fancy cuts include kite, triangle and baguette.

The term melee is applied to stones cut from small fragments of diamonds resulting from sawing or cleaving. Usually from 8 to 16 melees are required to make a carat, and many are cut with the usual 58 facets. Smaller melees commonly have only 18 facets and may be so small as to require several hundred to make a carat. (G. S. SR)

Diamond Cutting.—On account of its extreme hardness, the treatment of the diamond in preparation for use in jewelry constitutes a separate and special branch of lapidary art. Any valuable gem must first be trimmed, cleaved or sawed into suitable shape and size, then cut into the desired form and finally polished.

The stages in diamond working are, therefore: (1) cleavage or division; (2) cutting; (3) polishing; but in point of fact there are four processes, as the setting of the stone for cutting is a somewhat distinct branch.

Cleaving or Dividing.—Gem diamonds are always found as crystals, usually octahedral in form, though often irregular or distorted. The problem involved in each case is twofold: (1) to obtain the largest perfect stone possible; and (2) to remove any portions containing flaas or defects. These ends are generally met by sauing or by cleaving the crystal; *i.e.,* causing it to split along certain natural planes of structural weakness, which are parallel with the faces of the octahedron.



BY COURTESY OF GEORGE SWITZER

FIG 1.—THREE VIEWS OF THE BRILLIANT-CUT DIAMOND. OF THE 58 FACETS. 33 ARE ABOVE THE GIRDLE AND 25 BELOW

The stone is first examined closely, to determine the directions of the cleavage planes, which are recognizable only by an expert. The cleaver then cuts a narrow notch, at the place selected, with another diamond having a sharp point; a rather dull iron or steel edge is then laid on this line, and a smart blow struck upon it. If all has been skillfully done, the diamond divides at once in the direction desired.

When the stone is large and valuable, the cleaving is a most critical process. In the case of the immense Excelsior diamond of 995 2 carats. which was divided at Amsterdam in 1904 and made into ten splendid stones, the most elaborate study extending over two months was given to the work beforehand, and many models were made of the irregular stone and divided in different ways to determine those most advantageous. This process was applied in 1908 to the most remarkable piece of work of the kind ever undertaken—the cutting of the gigantic Cullinan diamond of 3,106 carats. This stone also was taken to Amsterdam to be treated by the old-fashioned hand method, with innumerable precautions of every kind at every step, and the cutting was successfully accomplished after nine months' work (see History of Famous Diamonds, below).

This process of cleavage is still used but sawing by means of a high-speed saw employing a thin disk charged with diamond particles is generally employed.

After the cleaving or sawing, however, the diamond is rarely in a form for cutting the facets, and requires considerable shaping. This rough "blocking out" of the final form it is to assume, by removing irregularities and making it symmetrical, is called brutage. Well-shaped and flawless crystals, indeed, may not need to be cleaved. and then the brutage is the first process. Here again, the old hand methods have given place to mechanization. In either case tao diamonds are taken. each fixed in cement on the end of a handle or support, and are rubbed one against the other until the irregularities are ground away and the general shape desired is attained. The old method was to do this by hand—an extremely tedious and laborious process. The machine method, invented about 1885, employs the principle of the lathe with a diamond as the cutting tool.

Cutting and Setting.—The next process is that of cutting the facets; but an intervening step is the fixing or setting of the stone for that purpose. One method used is to embed it in a fusible alloy, melting at 440° F., in a little cup-shaped depression on the end of a handle. the whole being called a dop. Only the portion to be ground off is left exposed; and two such mounted diamonds are then rubbed against each other until a face is produced. This is the work of the cutter; it is laborious, and requires great care and skill whether done by hand or by machine using a diamond lathe. The powder produced is carefully saved, as in the former processes, for use in the final polishing When one face has been produced, the alloy is softened by heating, and the stone reset for grinding another surface. As this process is necessary for every face cut, it must be repeated many times for each stone. A metal clutch or adjustable dop has been devised in which the diamond is held by a system of teeth claws so that the heating and resetting can be obviated, and the cutting completed with only two changes.

Polishing.—The faces having been cut, the last stage is the polishing. This is done on horizontal iron wheels called skaifs, made to rotate up to 2,500 r.p m. The diamond powder saved in the preceding operations, and also made by crushing inferior diamonds here comes into use as the only material for polishing. It is applied with oil, and the stones are fixed in a dop in much the same way as in the cutting process. Again, the utmost skill and watchfulness are necessary, as the angles of the faces must be mathematically exact in order to yield the best effects by refraction and reflection of light, and their sizes must be accurately regulated to preserve symmetry.

The rapid development of mechanical and electric devices for the several stages of diamond cutting has greatly influenced the art. (G. F. K.; X.)

Industrial Uses

Industrial uses of diamonds are so important that a deficiency of industrial diamonds would cause a breakdown in the modern metalworking industry and devastate mass production. Bort, which is the cheapest grade of industrial diamond and is used in the largest amounts. is crushed and graded into powders of various sizes for use in a great variety of grinding and polishing operations. The chief use of diamond powder is in the manufacture of grinding wheels for sharpening sintered carbide metal cutting tools. Diamond powder is also used as loose grains suspended in oil or water for many types of lapping and polishing operations. Another important application of industrial diamonds is as diamond drills, used for many purposes, and ranging in size from dental to oil-well drills. Rock-coring drills are made by mounting diamonds around the rim of a hollow metal drill crown. As the drill is turned and bites downward, it cuts a continuous rock core, which can be withdrawn for examination. Such drills are widely used in exploring for new mineral deposits (see Drilling Machinery). Other important applications include saws for cutting rock and other hard materials, tools for truing or dressing grinding wheels, glass cutters, phonograph needles, hardness testers, lathe and other types of cutting tools and wire-drawing dies.

Synthetic Diamonds

Principal efforts in the past to make diamond in the laboratory were by J. B. Hannay and Henri Moissan. In 1880 Hannay reported that he had made diamonds by heating a mixture of hydrocarbons, bone oil and lithium at red heat in sealed wrought-iron tubes. Moissan, in about 1890, dissolved sugar charcoal in molten iron and quenched the solution in cold water in order to crystallize the carbon under the great internal pressure supposedly generated by contraction as the mass cooled. Both workers claimed to have succeeded in making diamonds, but attempts to repeat their work proved unsuccessful. The question of success or failure of Hannay and Moissan was discussed and evaluated by various leading authorities; the conclusions, however, were confusing, and the modern consensus is that up to 1955 the successful synthesis of diamond had not been reported in the literature.

On Feb. **16,** 1955, the General Electric company, Schenectady, N.Y., announced the successful accomplishment of the task of making diamonds in the laboratory. The diamonds were made by subjecting carbonaceous material simultaneously to pressures in excess of 1,500,000 lb. per square inch and to temperatures above 5,000° F. Single runs produced up to one-tenth of a carat of diamond. The diamonds were of industrial quality. The General Electric company by **1960** was producing industrial diamonds on a large scale. Production figures were not made public but were estimated to have reached at least **1,000.000** carats annually. Prices were comparable to natural diamonds of the same category. Details of the company's process for making diamonds were made public in 1959. In that same year synthetic diamonds were also made in several other laboratories including the De Beers Adamant laboratory in Johannesburg, S.Af.

PHYSICAL PROPERTIES

Hardness. — The scratch hardness of diamond is ordinarily given as 10 on the Mohs' scale of hardness, and corundum, the mineral next to diamond in hardness, is rated as 9. Actually diamond is very much harder than corundum; its true value on the Mohs' scale is about 42. Synthetic cubic boron nitride (see Boron: Boron Nitrides) is said to be as hard as diamond but the artificial abrasives silicon carbide and boron carbide have values of 14 and 19.7, respectively, on this same scale. The abrasion hardness of diamond is still greater in comparison with these abrasives. Diamond has been found to be as much as **200** times more effective in its abrasion action than boron carbide and silicon carbide.

The hardness of a diamond varies significantly in different directions. The optimum directions for polishing are those parallel to a crystallographic axis. Facets parallel to faces of the cube (fig. 3[A]) are easiest to polish, for these faces are parallel to two crystallographic axes. Octahedron faces (fig. 3[B]) are equally inclined to three crystallographic axes and are the most difficult to polish. (See also Mohs' Scale.)

FIG. 2.— REFRACTIVE QUALITIES OF PROPERLY CUT DIAMOND

Refraction and **Colour.**—The very high refractive power of diamond (index of refraction = 2.42 for ordinary light) gives the stone its extraordinary brilliance when properly cut and polished. Light incident within a diamond at an angle greater than 24½° to any facet is reflected back into the stone instead of passing through it. The corresponding angle for rock crystal (quartz) is 42½°. Hence, a diamond cut to proper proportions (fig. 2) will return a greater amount of light to the eye of the observer than will gems of lesser refractive index and will appear more brilliant. The very high dispersion (index of refraction for red light = 2.407, for violet light = 2.465) gives diamond its fire, caused by the separation of white light into the spectral colours as it passes through the stone (fig. 2). Because of its very high index of refraction, diamond has a brilliant lustre, best observed on polished stones. The stones as they come from the mine are usually somewhat rounded and have a rather greasy appearance. Anomalous double refraction! caused by internal strains, is often noted. Some diamonds fluoresce or phosphoresce on exposure to ultraviolet, cathode and X-rays. Gem diamonds often fluoresce blue under ultraviolet light.

The colour of diamond varies from colourless to black, and it may be transparent, translucent or opaque. Most diamonds used as gems are transparent and colourless or nearly so. Colourless or pale-blue stones are considered best, but these are rare; most gem diamonds are tinged with yellow. Stones having a high degree of transparency and a distinct body colour (such as green, blue, pink or yellow) are known as fancy stones. Gray. brown: black, milky and opalescent stones are sometimes found. Most industrial diamonds are gray or brown, translucent to opaque, but better quality industrial diamonds grade imperceptibly into poor quality gem stones.

Artificial Coloration. — The colour of a diamond may be changed by bombarding it with atomic projectiles of various types. Exposure of white and yellow diamonds to radium radiation colours a thin surface film of the stone green. White diamonds may also be changed to other colours, including green. amber and yellow, when bombarded by deuterons or alpha particles in a cyclotron. Such treatment likewise only induces colour

PROCESSES IN DIAMOND FINISHING

1. Notching the stones for cleaving by a single blow. Before cleaving, the stones must be notched or grooved so that they will break on the exact line which the operator desires. Cleavage takes place along planes parallel to the octahedron faces of the crystal
2. Splitting or cleaving diamonds. After the diamond has been notched to determine its plane of cleavage, it is held in the instrument illustrated and split by a single sharp blow
3. The metal clutch which holds the diamond in secure position for cutting. The gem is placed beiween the prongs of the apparatus, and the teeth are tightened by screwing down on the ring at the base. This holds the stone firmly clamped
4. Turning on a lathe; the abrasive used in the cutting process must be another diamond. which is the hardest substance known
5. Inspecting the work of a group of diamond cutters
6. Diamond polishers giving the gems their final polish under the eyes of an inspector

JONKER DIAMOND NUMBER ONE

Colour photograph of Jonker Diamond Number One, which is mounted in a platinum necklace set with baguette diamonds. The stone is the largest emerald-cut diamond in existence, with a weight of 125.35 carats, and is shown in actual size. It has a magnificent bluish-white colour, and is expertly cut to bring out the maximum of its brilliancy and fire. Jonker Diamond Number One is the largest of 12 stones cut by Lazare Kaplan & Sons, Inc., from the 726-carat rough Jonker diamond, which was found in 1934 at Elandsfontein, Pretoria, by Jacobus Jonker, an impoverished South African prospector

into a thin surface film. The colour may be induced all the way through the stone by neutron irradiation either in a cyclotron or in an atomic pile. Bombardment of a white diamond with high-energy electrons produces a pale-blue colour. In all cases diamonds which have been bombarded appear to retain their change in colour permanently. even when exposed for long intervals to sun or artificial light at room temperature.

FIG. 4.—TWIN CRYSTAL OF TWO OCTAHEDRA

Crystallography.—Diamond crystallizes in the isometric crystal system (fig. 3). Some features of the crystallography of diamond indicate hextetrahedral symmetry. and others indicate that diamond has hexoctahedral symmetry. The most common crystal form is the octahedron (8 faces), but other forms are also found. such as the cube (6 faces). dodecahedron (12 faces). trisoctahedron (24 faces) and hexoctahedron (48 faces). The crystal faces are commonly curved by growth and solution facets and are often striated. Twin crystals are common, in which two octahedra (fig. 4) are united by contact along a surface parallel to an octahedron face. These twins are often flattened and are called macles. Other types of twins include penetration twins, cyclic groups and grooved octahedra resulting from the interpenetration of twinned tetrahedra.

The atomic structure of diamond has been determined by X-ray studies (fig. 5). Each carbon atom is linked to four equidistant neighbours so that a tetrahedral linkage occurs throughout the entire crystal. The distance between adjacent carbon atoms is 1.54 Å (1 Å = $\frac{1}{10,000,000}$ mm.).

Two types of diamond are known, type I and type II. Type II diamond gives a normal X-ray diffraction pattern, but patterns of type I show extra spots and streaks. The photoconductivity of type I diamond is poor. of type II good; type I diamonds are birefringent (show double refraction). and type II diamonds are not. The two types also differ in their infrared and ultraviolet absorption characteristics. Diamonds intermediate between type I and type II have also been noted, as well as two varieties of type II. Large diamonds of gem quality are always type I.

FIG. 5.—ATOMIC STRUCTURE OF A DIAMOND

Other Properties.— Diamond has a perfect cleavage (referred to as grain by diamond cutters) in four directions. parallel to its octahedral crystal faces (fig. 3[B]). This property is made use of by diamond cutters to split a large stone. The specific gravity of diamond is 3.52. and its melting point is 3,700° C. Since diamond is composed of pure carbon, it will burn in an atmosphere of oxygen. or in air if heated to a very high temperature. The stone is unattacked by acids. *See* also CARBON.

ORIGIN OF DIAMOND

Only in diamond pipes, especially well exemplified by those in the Kimberley district. South Africa. are diamonds known to occur in the original rock matrix in which they formed. These pipes are funnels. more or less oval in section and narrowing with increasing depth. They go downward to unknown depths (some have been mined to depths of more than 4,000 ft.), and are evidently the result of some type of eruptive action. The rock filling the pipes is an altered and brecciated basic rock related to peridotite and known as kimberlite or blue ground. The kimberlite must have been forced up from great depths because it is entirely unrelated to the country rock surrounding the pipes. There is no evidence to indicate that the blue ground was extremely hot when forced into its present position. Therefore, it is concluded that the diamonds were formed in the depths of the earth under conditions of great heat and pressure, and reached the surface by extrusion up pipes of the kind found in South Africa and elsewhere. Diamonds in alluvial deposits originally must have been formed in kimberlite, later released by erosion from their mother rock and redeposited in rivers and streams. The theory that diamonds were formed deep within the earth under great pressure and temperature is substantiated by the known occurrence of diamond in iron meteorites. Synthesis of diamond was accomplished in a machine which simulated pressure-temperature conditions 240 mi. deep within the earth. See also ECLOGITE.

WORLD OCCURRENCE

The most important localities for diamonds have been: (1) India. where diamonds have been mined from earliest times; (2) South America, where they have been mined since the middle of the 18th century; and (3) Africa, to which almost the whole of the diamond-mining industry has been transferred since 1870. Annual world production in the second half of the 20th century amounted to more than 26,000,000 carats, or nearly 4½ tons. Of this total 20,000,000 carats, or about 77% were of industrial grade.

India.—Diamonds are found in the states of Madras, Madhya Pradesh, Orissa and Gujarat. Annual production averages about 2.000 to 1.000 carats. In the second half of the 20th century, 95% of the production came from the Panna district. Madhya Pradesh. Richest deposits are in the area around Mujgawan, Panna district. where diamonds are found in the kimberlite pipe, in Pre-Cambrian conglomerates older than the pipe and in recent stream gravels. Many of the large diamonds of antiquity came from the mines in the Kollur group, near the Kistna river.

South America.— Diamonds are mined in South America in Brazil, British Guiana and Venezuela. Annual production in the second half of the 20th century was: Brazil. about 300.000 carats; British Guiana, 100.000 carats; Venezuela, 90.000 carats.

Brazil.—Diamonds were discovered in Brazil about 1725 at Tejuco (now Diamantina) in Minas Gerais. Mining became important about 1740, and from that time until the discovery of the South African deposits in 1867 Brazil was the world's largest diamond producer. The most important producing areas are in the states of Minas Gerais. Bahia and Mato Grosso, but they are found also in six other states: Goiis. São Paulo. Paraná, Piaui, Maranhão and Amazonas. Principal production is from gravel in river valleys. Most mining is done by natives in a primitive fashion. Carbonado. a valuable type of industrial diamond, occurs in the stream beds in northern Minas Gerais. One mass of carbonado weighing 3,148 carats (more than the weight of the Cullinan diamond; see History of *Famous Diamonds,* below) was found in the Chapada Diamantina district in the state of Bahia. A number of large gem diamonds have been found. including the Star of the South (261.9 carats?. English Dresden (119.5 carats) and President Vargas (726.6 carats). Annual production averages about 50% gem quality.

British Guiana.—A diamondiferous belt from 10 to 30 mi. wide is known to run across nearly the whole of British Guiana. The diamonds occur in the gravels of rivers and streams: the most important areas are along the following five rivers and their tributaries: Mazaruni, Puruni. Potaro. Cuyuni and Berbice.

The diamonds are generally small, averaging six to the carat, but occasionally as large as ten carats. The largest, found in 1926 at the Potaro river, weighed 56 carats. Production is about 40% gem quality.

Venezuela.—The diamondiferous area of Venezuela is in the state of Bolivar, particularly in the area known as the Gran Sabana. Diamond-bearing gravels have been reported also in Amazonas. Both of these areas are along the Brazilian border and are little known and sparsely populated. The richest deposits are around Peraitepu in the upper Caroní on the Gran Sabana. Other diamondiferous gravels are found along the Paragua and Uriman rivers and at Icabaru. The diamonds produced are generally small, and production averages about 73% industrial quality.

Africa.—More than 97% of the world's annual diamond production comes from Africa. The chief producing countries and territories have been: Republic of the Congo. Ghana, Republic of South Africa, Sierra Leone, Guinea, Angola, South-West Africa, Liberia, Tanganyika, Ivory Coast and Central African Republic. The Republic of South Africa has a much higher ratio of gem to industrial quality than the Republic of the Congo.

Republic of South Africa.—The first African diamond was discovered in 1867 on the bank of the Orange river. A second stone weighing 83.j carats was discovered in 1869; this was purchased by the earl of Dudley for £25,000 and became famous as the Star of South Africa. Prospectors rushed to the banks of the Orange and Vaal rivers, and by 1870 about 10,000 persons were engaged in recovering diamonds from river gravels, using primitive hand methods.

Toward the close of 1870 stones were found at Jagersfontein, Dutoitspan and Bultfontein, far from the Vaal river, and in 1871 at what is now known as the Kimberley mine. These diggings were at first thought to be alluvial in origin, but it was soon found that the diamonds were restricted to vertical pipes having a roughly oval cross section and nearly vertical sides. In the Kimberley district five of these pipes were found within an area a little more than three miles in diameter. The pipe at Kimberley (*q.v.*) occupies about 10 ac., that at Dutoitspan 23 ac. The pipes are filled with the heavy dark-blue rock, known as blue ground or kimberlite, in which the diamonds occur.

Many more kimberlite pipes were discovered in South Africa, most of them unworkable because of low diamond content. Principal mines are the Premier, near Pretoria in the Transvaal; the Jagersfontein and Koffiefontein mines in the Orange Free State, near Kimberley; and the Wesselton, Bultfontein. Dutoitspan, De Beers and Kimberley mines in northern Cape Province, also near Kimberley. In the second half of the 20th century the Wesselton, Bultfontein. Jagersfontein and Premier mines were major producers. Largest of the mines is the Premier, discovered in 1902. It is a pipe with a surface area of about 75 ac. and has an annual production of about 1.250.000 carats. The Cullinan diamond, weighing 3,106 metric carats, was found there in 1905.

Mining in the early days was done by individual miners, each allowed to work a 31 by 31 ft. claim. At first each miner worked an individual pit, and roadways were left across the pipe to allow access to the claims. Soon the roadways crumbled, and the diamondiferous blue ground was hauled to the edge of the mine by means of windlasses.

In a few years open-pit mining became impossible because of the fall of barren rock left standing in the mine and landslides from the sides. Some consolidation of claims began to take place, and mining using modern underground methods was begun. Finally, under the leadership of Cecil Rhodes, all of the major pipe mines were consolidated into the De Beers Consolidated Mines, Ltd., apd were worked by this company or its subsidiaries.

The pipe mines are worked underground by a method known as chambering. A main hoisting shaft is located 800 ft. or more from the rim of the pipe, and sunk to a depth well below that of the lowest level being worked. The working levels are 40 ft. apart vertically. Cuts of blue ground are mined out between adjacent levels, supported by pillars of rock. The mining method depends upon natural caving and recovery of the pillars when undermined by the level below.

Block caving (see MINING, METAL) was introduced in the second half of the 20th century. The broken ore is loaded into cars, hauled by an endless cable to the main shaft for hoisting to the surface. As the blue ground comes from the mine, it contains only about 1 part of diamond to 14,000,000 parts of worthless rock.

Blue ground hoisted from the mines is passed through three main stages of treatment before the diamonds are recovered: (1) crushing plant; (2) washing plant; and (3) recovery plant. The ore is crushed into fragments $1\frac{1}{4}$ in. or less in size and hauled to the washing plant, where by various washing and concentrating processes the material is reduced to a small fraction of its original volume. Concentrates from the washing plant go to the recovery plant. There the recovery of diamonds depends almost entirely on their property of being nonwettable when in contact with water. The concentrates are fed onto sloping flat or stepped tables. The tables are covered with a thin layer of grease. Wash water is played on the grease tables and the concentrates are dropped onto the grease through the stream of water. An oscillating motion causes the waste rock to move across the table and drop off, while the diamonds adhere to the grease. Periodically the grease is scraped from the tables, and the diamonds recovered by boiling off the grease.

Recovery methods used in the alluvial mines, as in Namaqualand in Cape Province, differ considerably from those used in the pipe mines. The diamondiferous gravel is taken from open pits using draglines, bulldozers and other types of modern earth-moving machinery. Alluvial diamonds do not adhere to grease as do diamonds from the pipe mines. Therefore, concentrates from the washing plant are either hand-picked or passed through an electrostatic separator.

Republic of the Congo.—The Republic of the Congo has been the world's largest producer of diamonds in quantity. Production is about 95% industrial grade, and it supplies about three-fourths of the world's supply of crushing bort. The diamondiferous area occupies a wide area covering the tributaries of the Kasai-Sankuru river system. The two principal deposits are (1) the Kasai field, an extension of the Angola deposits; and (2) the Bakwanga deposits, located between the Kanshi and Bushimaie rivers. About 95% of the production comes from the Bakwanga deposits. The deposits are all alluvial, and worked on a large scale as open pits using modern earth-moving machinery. Pipes of low diamond content are known in the Katanga district. Production dropped from a peak of 225,000 carats in 1920 to 164,000 carats in 1921 and thereafter increased steadily, reaching more than 14,000,000 carats a year in the second half of the 20th century, although there was some decrease due to political unrest after independence was proclaimed in 1960.

Ghana.—Diamond deposits of Ghana are in the Birim river district. about 65 mi. N.W. of Accra. The diamonds occur in beds of gravel two to five feet thick lying near or in stream beds. Production averages about 3,000,000 carats annually, of which about 70% is industrial grade. The deposits are worked in part by European companies.

Angola.—The diamondiferous area of Angola is a continuation of the diamond-bearing region of Kasai, Republic of the Congo. The deposits lie within the basins of the Chicapa, Luachimo. Chiumbe and Luembe rivers, tributaries of the Kasai. Exclusive diamond mining rights were acquired by a European company. Annual production is about 1,000,000 carats, of which 58% is gem quality.

South-West Africa.—The alluvial deposits of South-West Africa are a northward extension of those in Namaqualand. They extend from the mouth of the Orange river north 300 mi. to Conception bay. Mining is on a large scale. Production approaches 1,000,000 carats a year, of which about 80% is gem quality. Average size of the stones recovered is about 0.9 carats.

Sierra Leone diamondiferous gravels lie within the Bafi-Sewa river drainage system. Most production is from the Kono district. Production is in excess of 1,500.000 carats annually, of which about 55% is industrial quality. In deposits along the Woyie river some very large diamonds have been found, including stones of 294, 532 and 770 carats. To the southwest, Liberia and the Ivory Coast have become diamond producers.

Guinea.—The alluvial diamond deposits in Guinea are midway between Beyla and Kissidougou. Total production reaches over 800,000 carats, of which about 66% is industrial grade.

Central African Republic.—The principal diamond production comes from alluvial deposits in the Carnot-Berbérati-Nola region in the Haute-Sangha. Production amounts to about 80,000 carats, of which about 66% is industrial quality.

Tanganyika.—Most of the diamond production in Tanganyika is from the surface portion of a pipe deposit at Mwadui in the Shinyanga district. Production amounts to more than 500.000 carats, of which about 50% is industrial grade.

Othek Countries.—Diamonds are also found in small quanti-

ties in other countries, including Borneo, Australia, Southern Rhodesia. Surinam and the United States. Total production from these probably does not exceed 3.000 carats yearly.

New discoveries of diamonds were made in the U.S.S.R. in 1954. in northwestern Yakut (Yakutia). Production in 1960 reached approximately 950,000 carats.

Production and Distribution.— Practically the entire world output of diamonds is controlled by De Beers Consolidated Mines, Ltd., and its subsidiary companies. The company operates some mines, and has contracts to purchase the entire output from all other major mining areas except those in South America. Marketing of the diamonds is also handled by De Beers subsidiaries.

After being mined, diamonds are sorted into the two main types —gem and industrial. Each type is then further sorted into many categories of size and quality. The gem diamonds are divided into parcels containing varying proportions of high and lower quality diamonds to give the cutters a wide choice. The distributing company then invites certain cutters to apply for sights, that is, the cutters are asked to apply for parcels, specifying the total amount they wish to pay and the proportions of different kinds of diamonds they wish in the parcels. The cutters are offered the parcels which most closely conform to their wishes. A buyer attending a sight must buy the entire contents of a parcel, for the parcels are never broken up. The sights are held only in London. Industrial diamonds are also graded into many categories depending upon the use to which they are to be put, and are sold in parcels in much the same way as are gem diamonds.

HISTORY OF FAMOUS DIAMONDS

All of the famous diamonds of antiquity must have been Indian stones. Large and extremely valuable diamonds discovered since about 1730 have come from South Africa and Brazil.

The Great Mogul was found in the Golconda mines in India in about 1650, and was said to have weighed 787 carats in the rough. It was seen in the treasury of the Mogul Aurangzeb in 1665 by the French traveler and jewel trader Jean Baptiste Tavernier, who estimated its weight after cutting as 280 carats and described it as a rounded rose-cut stone, high on one side. It has been unreported for many years and some believe that what Tavernier saw was the Koh-i-nor; others hold it may have been the Orloff, which although of smaller size is much like the description of the Great Mogul.

The Orloff, stolen by a French soldier from the eye of an idol in a Brahman temple, was finally bought by Prince Orloff for £90,000 and given to Catherine the Great, empress of Russia. The exact weight of the gem is 199.6 carats. It is $\frac{7}{8}$ in. in height, $1\frac{1}{4}$ in. wide and $1\frac{3}{8}$ in. long. It is mounted in the sceptre of the Romanoffs and was placed in the diamond treasury of the U.S.S.R. in Moscow.

The Koh-i-nor has the longest known history of all famous diamonds. Sultan Ala-ed-din is credited with having taken the jewel in the year 1304 from the raja of Malwa, in whose family it had been for unknown generations. The Koh-i-nor (*q.v.*) changed hands many times and finally was acquired by the British in 1849. The Koh-i-nor weighed, when brought to England, 191 carats. It was recut in London and now weighs 108 carats. It is the central stone of the queen's state crown, made for the coronation of Queen Elizabeth, consort of George VI, in 1937. There has been much discussion concerning the possibility that this stone may have once been part of the Great Mogul.

The Shah weighs 88.7 carats. is of yellowish colour and is bounded by eight slightly rounded facets. Three ancient Persian inscriptions partly cover the gem; the oldest indicating that the stone was discovered before 1591, probably in Golconda. The stone is in the U S S R diamond treasury in Moscow.

The Akbar Shah originally weighed 116 carats and had two Arabic inscriptions. One of these read "Shah Akbar, the Shah of the World, 1028 A.H.," and the other "To the lord of two worlds, 1039 A.H. Shah Jehan." The first date corresponds to A.D 1650 and the second to 1661. The location of the stone was unknown from about 1700 to 1866, when it was brought to London, recut and sold to the gaekwar of Baroda for about $175,000. The stone now weighs 71 7 carats.

The Sancy is about the size and shape of a peach pit and weighs 55 carats. It is a stone of Indian origin and has been owned successively by Nicolas Harlay de Sancy, King James I of England, Henrietta Maria, King James II and Louis XIV. It was stolen during the French Revolution, along with the Regent. It reappeared about 1828 and was sold to Prince Demidoff and later became the property of the maharaja of Patiala.

Coloured Indian—and especially sapphire-blue—diamonds are very rare. Tavernier bought one weighing $112\frac{1}{2}$ carats and brought it to Paris, where it was sold to Louis XIV and cut into a triangular stone weighing about 68 carats. This stone was stolen in 1792, along with the Sancy and the Regent. It was never recovered, but in 1830 there appeared on the market a 443-carat blue diamond, now known as the Hope, that is probably part of the missing stone. The stone was owned successively by Henry Thomas Hope, Habib Bey, Mrs. Evalyn Walsh McLean and Harry Winston, who in 1958 gave it to the Smithsonian institution, Washington, D.C., to start a jewel collection.

Other large and famous Indian diamonds include the Florentine and Regent. The Florentine, a pale-yellow stone weighing 137 carats, at one time one of the Austrian crown jewels, was seized by the Germans after the *Anschluss* (1938); it was restored to Austria after World War II and is in the Schatzkammer, Vienna. The Regent was one of the last of the large diamonds to be found in India. It is said to have been found in the Partial mines on the Kistna river about 1701 and as a rough stone weighed 410 carats. It was purchased by Thomas Pitt, the governor of Madras. for about $100.000. It was cut into a cushion-shaped brilliant $1\frac{1}{16}$ in. long, 1 in. wide and $\frac{3}{4}$ in. deep, weighing 140.5 carats. The gem was subsequently sold to the duke of Orléans, then regent of France. It was stolen in 1792, along with the Sancy and Hope diamonds. but was recovered. It was used as security for a loan which is said to have been a great aid to Napoleon after he assumed the dictatorship as first consul in 1799. The gem is now in the Louvre museum in Paris.

Most famous Brazilian diamonds are the Star of the South and the President Vargas. The Star of the South was found in the mines at Bagagem in 1853. It weighed in the rough 261.9 carats. It was sold to the gaekwar of Baroda for about $400,000 and cut into a gem weighing 128.8 metric carats. The President Vargas was discovered in 1938 by a poor prospector who found the stone in the San Antonio river in Minas Gerais. Its weight was 726.6 carats. The prospector sold the stone for $10,000 to a broker who resold it to an exporter for about $425,000. It was later purchased by a U.S. importer, who cut it into 29 stones having a total weight of approximately 411 carats, the largest of which is 48.26 metric carats.

The first large South African diamond, discovered in 1869, was the Star of South Africa or Dudley, 83.5 metric carats rough, 47.75 carats cut. Since that time many fine large stones have been found in the South African diamond mines, the most famous of which are the following (weights in metric carats): the Jubilee, 650.8 carats rough, 245.35 carats cut; the Victoria, 469 carats rough, 184.3 carats cut; the Excelsior, 995.2 carats rough, cut into 21 stones ranging in weight from less than a carat to 70 carats; the Stewart, 296 carats rough, 128 carats cut; the Tiffany, a yellow stone weighing 128.7 carats cut; and the Jonker, found in 1934, 726 carats rough, cut into 12 stones of from 5.30 to 125.35 carats.

The world's largest gem diamond, the Cullinan, was found in 1905 at the Premier mine in the Transvaal, South Africa. It weighed in the rough 3,106 metric carats, or about $1\frac{1}{3}$ lb. It was purchased by the Transvaal government in 1907 and presented to King Edward VII. It was sent to Amsterdam to be cut and was fashioned into nine principal gems, the four largest of which weigh 530.20, 317, 95 and 63.7 metric carats, respectively. They are part of the crown jewels of England. See GEM.

DIAMOND NECKLACE, AFFAIR OF THE, was a scandal at the court of Louis XVI in 1785 which gravely discredited and weakened the French monarchy on the eve of the Revolution. It began as an intrigue on the part of an adventuress, the comtesse de La Motte (Jeanne de Luz de Saint-Rémy de Valois, 1756–91; descended from a bastard of Henry II) to procure, supposedly for the queen, Marie Antoinette, but in reality for herself and her associates, a diamond necklace worth 1,600,000 livres. This was the property of the Parisian firm of jewelers Boehmer and Bassenge, who had tried unsuccessfully to sell it, first to Louis XV as a present for his mistress Madame du Barry, and later to Louis XVI for the queen. The other leading person involved was cardinal de Rohan, bishop of Strasbourg, provisor of the Sorbonne.. grand almoner of France and a member of one of the greatest noble families. Rohan, who as French ambassador to Vienna from 1772 to 1774 had aroused the dislike of the queen's mother, the empress Maria Theresa, and who had subsequently incurred the hostility of Marie Antoinette herself, was anxious to be restored to favour at the French court.

The comtesse de La Motte saw her opportunity of posing as a mediator between him and the queen. She suggested to Rohan that the queen wished to acquire the necklace surreptitiously and would be prepared for a formal reconciliation at court if he would facilitate its purchase by negotiating with the jewelers. Rohan consented to these arrangements after consulting his friend the fashionable imposter Alessandro di Cagliostro (*q.v.*). He did so, however, mainly on the strength of spurious letters from the queen to himself forged by La Motte and, after a brief nocturnal interview in the gardens of Versailles with a prostitute disguised as the queen, Rohan entered into a contract with the jewelers to pledge his credit to pay for the necklace in installments. The imposture came to light, however, when the cardinal failed to raise the first installment in full and the jewelers applied directly to the queen. Meanwhile the necklace, which Rohan had supposed to be in the queen's possession, had been broken up and sold in London.

Instead of concealing the intrigue, Louis XVI allowed the secretary of state for the royal household, the baron de Breteuil (Louis Auguste le Tonnelier), a personal enemy of Rohan, to arrest the cardinal at Versailles while he was preparing to officiate in the royal chapel on Assumption day, Aug. 15, 1785. When Rohan was imprisoned in the Bastille his friends and sympathizers depicted this act of authority as an exercise in royal despotism and as the result of Breteuil's vendetta against the man who had replaced him as ambassador at Vienna. The cardinal was tried, along with his alleged accomplices, before the *parlement* of Paris. Though he was eventually acquitted of the charge of having fraudulently acquired the necklace (May 31, 1786), he was deprived of all his offices and exiled to the abbey of Chaise-Dieu in Auvergne. Cagliostro was acquitted but banished from the kingdom, while the real criminal, the comtesse de La Motte, was sentenced to be flogged, branded and imprisoned for life in the Salpêtrière prison in Paris. She later escaped to England and there published scandalous *Mémoires* vilifying the queen.

Though Marie Antoinette was guiltless, the scandal confirmed the belief of contemporaries in her moral laxness and frivolity. The arbitrary arrest of the cardinal, the pressure put on his judges by Breteuil and his final disgrace deepened the impression of the king's weakness and the despotic character of his government. The incident also encouraged the aristocratic resistance to the crown and provoked an alliance of the higher magistracy with the upper clergy which facilitated the aristocratic opposition of 1787. In that sense Napoleon was correct in regarding the affair as one of the causes of the French Revolution.

DIANA, an Italian goddess later identified with the Greek Artemis (*q.v.*). Her name has the root di ("to shine") and probably means "bright one." Although indistinguishable from Artemis in Roman literature, she was originally an independent Italian deity. A woodland goddess, perhaps a tree spirit, by extension she became the mistress of forest creatures and the hunt, and like her Greek counterpart also a goddess of domestic animals. With strong associations as a fertility deity she was invoked by women to aid conception and delivery (cf. Juno, with whom she sometimes shares the epithet Lucina [*q.v.*]).

There was probably no original connection between the Italian deity and the moon, but Diana later absorbed Artemis' identification with both Selène (*i.e.,* Luna) and Hecate (or Trivia), a chthonic deity; hence the poetic characterization *triformis* sometimes used in Latin literature.

The most famous place of worship for the Italian spirit was the grove of Diana Nemorensis (*i.e.,* Diana of the Wood) on the shore of the lake of Nemi near Aricia. Nineteenth-century excavations there disclosed a temple, an extensively terraced sacred precinct and votive objects revealing all the aspects of her divinity outlined above. There were held female processions in her honour, reflecting her role as a goddess of women. The Aricia cult was traditionally founded by the Latin dictator Egerius Baebius, although other evidences indicate a shrine of even greater antiquity. It is certain, however, that it became a shrine common to the cities of the Latin league and hence of some political importance. Associated with Diana there were two lesser divinities: Egeria (*q.v.*), spirit of a nearby stream who shared with Diana the functions of causing and easing childbirth, and the hero Virbius, an Italian counterpart of Hippolytus (q v.). Traditionally, after he had been trampled to death by his horses. Hippolytus was restored to life by Asclepius and was removed by Artemis to the grove at Aricia from which horses were excluded; there as Virbius he became the first priest of Diana. *rex nemorensis.*

A unique and peculiar custom, perhaps derived from a primitive human sacrifice, dictated that the *rex nemorensis* be a runaway slave and that he slay his predecessor in combat after a formal challenge consisting of the plucking of a certain branch from the sacred grove. Associations arose with the Tauric Artemis, who required the sacrifice of all strangers, and it was said that Orestes (*q.v.*) had brought the image of the goddess from Taurus to Aricia. The unusual ceremony at the Arician grove is the point of departure for Sir James Frazer's Golden Bough. Regarding the myths of Hippolytus and Orestes at this shrine Frazer concludes that they are later rationalizations of a primitive and barbarous ritual.

At Rome the most important temple of Diana was on the Aventine. Traditionally it was founded as a sanctuary of the Latin league by Servius Tullius, the founding being interpreted as an attempt to transfer not only the cult but also the political leadership to Rome. The worship of Diana at Rome was early associated with the plebeians, who were probably responsible for her introduction. In the cult on the Aventine, itself a plebeian settlement, Diana was the protector of the lower classes, especially slaves (cf. the ritual at Aricia); the ides (13th) of August, her festival at Rome and Aricia, was a holiday for slaves. The Aventine Diana was the sister of Apollo, and they were worshiped together in the secular games (*q.v.*), in which their importance was greatly increased by Augustus. Another famous shrine of Diana was on Mt. Tifata near Capua, where she was worshiped as Tifatina. In Roman art she usually appears as a huntress with bow and quiver, accompanied by a hound or deer (*cf.* the Artemis of Versailles).

DIANE DE FRANCE (1538–1619), the natural daughter of Henry II of France and of a young Piedmontese, Filippa Duc, was born in Paris in 1538. A true Renaissance princess, Diane was not only beautiful but also cultured and intelligent. Legitimized in 1547, she was married in 1553 to Orazio Farnese, duke of Castro, the third son of Pierluigi Farnese, first duke of Parma, but Orazio was killed at Hesdin in the same year. In 1559 she married François, eldest son of Anne, constable duc de Montmorency, after the dissolution of a clandestine marriage of his. During Charles IX's reign she helped to make her husband chief of the Politiques (see FRANCE: History). Widowed a second time in 1579, she enjoyed even greater influence with Henry III and in 1582 received the duchy of Angoulême in appanage. She did much to prepare the king's reconciliation with Henry of Navarre (1589). When the latter became king of France as Henry IV he always showed her great consideration. She moreover acted as mother to her niece Charlotte de Montmorency, later princesse de Condé, with whom the king fell madly in love before he died. After Henry IV's death the duchesse d'Angoulême conducted the bodies of Catherine de Médicis and Henry III to St. Denis. She died in Paris at the Hôtel d'Angoulême on Jan. 11, 1619.

(P. ER.)

DIANE DE POITIERS, DUCHESSE DE VALENTINOIS (1499–1566), mistress of Henry II of France, was born on Sept. 3. 1499. Daughter of Jean de Poitiers, seigneur de Saint-Vallier, she was married in 1515 to Louis de Brézé, comte de Maulevrier, grand seneschal of Normandy. She came to court as a lady in waiting, first to Francis I's mother, Louise of Savoy, then to Queen Claude. Shortly after her husband's death in 1531, the prince Henry, then duc d'Orléans, 20 years her junior, fell violently in love with her and she became his mistress.

Before Henry became king, Diane de Poitiers was the great rival at court of Francis I's mistress, Anne de Pisseleu, duchesse d'Étampes. Throughout Henry's reign she held court as queen of France in all but name, while the real queen, Catherine de Médicis, lived in comparative obscurity. Writers anxious to justify the kings of France at the expense of their favourites' reputations have ascribed a major role in politics to Diane (accusing her. for instance, of having inspired the persecution of the Protestants), but in iact she seems to have concerned herself rather with augmenting her income and with making provision for her iamily and protégés than with public affairs, which Henry kept in his own hands. Henry, however, gave her the duchy of Valentinois in appanage in 1548. On Henry's death (1559), Catherine forced her to restore those of the crown jewels that Henry had given her and to accept the chbteau of Chaumont in exchange for Chenonceaux. Diane then retired to Anet, where she died on April 22, 1566.

Even in their own time legends grew up around the love of Henry and Diane de Poitiers. It has been maintained, without much foundation, that Diane had previously been Francis I's mistress, so as to secure a pardon for her father, who was compromised in the constable duc de Bourbon's treason in 1523. Some serious writers alleged that Diane, who was nearly 60 years old when Henry died, had used magic to retain his love. Diane was certainly beautiful: she also had a lively, cultivated mind and was a friend and patron of poets and artists; *e.g.*, Pierre de Ronsard. Philibert de l'Orme, Jean Goujon and Jean Cousin. Philibert de l'Orme built her chbteau at Anet, which was decorated with Goujon's statues and with Cousin's stained glass. It was for Diane that Goujon executed his masterpiece, the statue of Diana, now in the Louvre. The Lettres *inédites* de Diane de *Poitiers* were published by G. Guiffrey (1866).

(Ro. M.)

DIANTHUS is a genus of herbs, some of which, for their showy flowers, are cultivated in the garden. Most oi the almost 300 species are native to Eurasia. The name *Dianthus* is derived irom the Greek for "flower of god." See PINK; CARYOPHYLLACEAE; CARNATION; SWEET WILLIAM.

DIAPASON, a term in music originally denoting the interval of an octave. It is derived from the Greek dia *pason,* an abbreviation of dia *pason chordon* ("through all the strings"), signifying in medieval theory the interval encompassing all the degrees of the scale. The French term diapason indicates the range of a voice and is also the word for a tuning iork. The latter meaning is connected with the use of the same word in French to mean pitch (see PITCH, MUSICAL). The name is also given to the two foundation stops of the organ, the open and stopped diapason (see ORGAN).

DIAPHONY: see ORGANUM; DESCANT; GREEK MUSIC (ANCIENT).

DIAPHORETICS (SUDORIFICS), those remedies that promote perspiration. Among the best known are vapour or hot-water baths, or that part of the process of the Turkish bath that consists in exposing the body to a dry and hot atmosphere. Such measures, particularly if followed by the drinking of hot liquids and the wrapping of the body in warm clothing, seldom fail to excite copious perspiration. Numerous medicinal substances have the same effect, such as pilocarpine, which stimulates the sweat glands, or camphor and ammonium acetate, which stimulate the sweating centre.

(F. O. K.)

DIAPHRAGM, in human anatomy, a large fibromuscular partition between the chest and abdominal cavities; it is convex toward the chest, concave toward the abdomen, and consists of a central tendon and a muscular margin. The central tendon (see fig.) is trefoil in shape. The fleshy fibres rise in front from the back of the xiphoid cartilage; at the side by six serrations from the inner surfaces of the lower six ribs; at the back from the five arcuate ligaments, two external, two internal and one median.

There are three large openings in the diaphragm. The aortic opening is behind the middle arcuate ligament and transmits the aorta, the azygos vein and the thoracic duct of the lymphatic system. In the right leaflet is an opening for the inferior vena cava and a branch of the right phrenic nerve. In front and a little to the left of the aortic opening is an opening from the esophagus and the two pneumogastric nerves. Through the processes by which the diaphragm is attached to the spinal column pass the splanchnic nerves. The sympathetic nerves usually enter the abdomen behind the internal arcuate ligaments. The phrenic nerves. which are the main supply of the diaphragm, divide before reaching the muscle and pierce it in a number of places to enter its abdominal surface, but some of the lower intercostal nerves assist in the supply.

The diaphragm is at first developed in the neck region of the embryo. With growth of the body and development of the lungs the diaphragm shifts its position downward.

A complete diaphragm is characteristic of all mammals; it usually has the human structure and relations, except that below the Anthropoidea (monkeys, apes and man) it is separated from the pericardium by the azygous lobe of the lung. In some mammals (*e.g.*, echidna and porpoise) it is entirely muscular. In the whales it is remarkable for its obliquity; this allows a larger lung space in the dorsal than in the ventral part of the chest, and may be concerned with the equipoise of the animal. Below the mammals incomplete partitions are found in turtles, crocodiles and birds. and in amphibians (*Xenopus* and *Pipa*).

For the action of the diaphragm see RESPIRATION.

DIARRHEA, a looseness of the bowels. This is understood to mean frequent soft or watery stools, which may contain mucus and blood, usually accompanied by griping pain or colic. It may be due to many causes, differing somewhat in adults and children.

In adults diarrhea may result from a large variety of causes, including food poisoning. sprue, infective conditions such as typhoid iever, toxic causes, avitaminosis, antibiotics. colitis, polyposis, foreign bodies in the rectum and nervous conditions. Diarrhea in children may be caused by all these. In addition, children may suffer from errors in diet, such as excess fruits and vegetables; the bacillary dysenteries; amoebic dysentery (rare); celiac disease (fatty diarrhea); intussusception; and polyps. See also DYSENTERY: GASTROINTESTINAL TRACT. DISEASES OF.

DIARY, a book in nhich are preserved the daily memorandums regarding events and actions which come under the writer's personal observation or are related to him by others.

Diary-keeping of a sort was common among the Romans (see

COMMENTARII), but it was not until the close of the Renaissance that diaries (as distinguished from memoirs) began to have literary value. In the 17th century they began to be largely written in England, although in most cases without any idea of even eventual publication. Sir William Dugdale (1605–86) had certainly no expectation that his slight diary would ever see the light. Bulstrode Whitelocke (1605–75), whose *Memorials of the English Affairs* covers the ground from 1625 to 1660, was a genuine diarist. So was the elder George Fox (1624–91), who kept not merely "a great journal," but "the little journal books," and whose work was published in 1694.

The famous diary of John Evelyn (1620–1706) professes to be the record of 70 years and, although large tracts of it are covered in a perfunctory manner, while in others many of the entries have the air of having been written in long after the event, this is a most interesting and diverting work; it was not published until 1818. It would hold a still higher position in the history of literature than it does if it were not overshadowed by what is unquestionably the most deservedly celebrated of the diaries of the world, that of Samuel Pepys (*q.v.*). This was begun on Jan. 1, 1660, and was carried on until May 29, 1669. The exceptional value of Pepys's diary consists in its fidelity to the portrayal of its author's character. In the age which succeeded that of Pepys, a diary of extraordinary emotional interest was kept by Jonathan Swift from 1710 to 1713, and was sent to Ireland in the form of a *Journal to Stella;* it is a surprising amalgam of ambition, affection, wit and freakishness.

The diary of the celebrated dissenting divine Philip Doddridge (1702–51) was printed, in 1829. Of far greater interest are the admirably composed and vigorously written journals of John Wesley (1703–91). But the most celebrated work of this kind produced in the latter half of the 18th century was the diary of Fanny Burney (Madame d'Arblay), published in 1842–46. These works were all posthumously published. James Boswell's *Journal of a Tour to the Hebrides* (1785), a genuine diary though somewhat expanded, was published during the author's lifetime.

Many of the diaries described above were first published in the opening years of the 19th century, and the interest which they awakened led to their imitation. Diaries ceased to be rare, but as a rule those which appeared did not present much literary interest. Sir Walter Scott's *Journal* (published 1890) and the diaristic portions of B. R. Haydon's *Autobiography and Journal* are eminent exceptions. Exception must also be made in favour of the journals of two minor politicians, Charles Greville (1794–1865) and Thomas Creevey (1768–1838), whose indiscretions added much to the gaiety of nations; the papers of the former appeared in 1874–87, those of the latter in 1903. The diary of Henry Crabb Robinson (1775–1867), printed in 1869, contains excellent biographical material. Tom Moore's journal, published in 1856 by Lord John Russell, disappointed its readers, and Lewis Carroll's diaries, first published in 1954. proved a somewhat dry matter-of-fact record. Charles Darwin's historic *Voyage Round the World* is written in diary form. R. W. Emerson's *Journals* are the notebook of an author rather than a book of intimate confessions. Of the many women who kept interesting diaries in the 19th century, three may be mentioned as of special and contrasting value—Queen Victoria, excerpts from whose diaries appeared in *Leaves From the Journal of Our Life in the Highlands* (1862) and *More Leaves* (1883); Dorothy Wordsworth, whose vivid and sensitive *Journals* (1897) emphasized her influence on her brother William's poetry; and the Quaker Caroline Fox, whose literary diary was first published in 1882. The child-diarist Marjorie Fleming (1803–11) also deserves her place; her diaries may be read in L. Macbean's *The Story of Pet Marjorie* (1914).

In the 20th century many men and women published their diaries during their lifetimes. Col. Charles Repington's diary of World War I was a monument of indiscretion. "W. N. P. Barbellion" was still alive when his tragic *Diary of a Disappointed Man* (1919) was published. Of later diaries none has possessed more literary grace than the *Journal of Katherine Mansfield* (1927).

The diary has lent itself to parody, and has inspired at least one humorous masterpiece, *The Diary of a Nobody* (1892) by George and Weedon Grossmith, most of which originally appeared in *Punch.* The fictional *Mrs. Dale's Diary* engrossed British Broadcasting corporation audiences in the 1950s.

It was natural that the form of the diary should appeal to a people so sensitive to social peculiarities as the French. A medieval document of immense value is the diary kept by an anonymous curk during the reigns of Charles VI and Charles VII. This *Journal d'un bourgeois de Paris* was kept from 1409 to 1431, and was continued by another hand until 1449. The marquis de Dangeau (1638–1720) kept a diary from 1684 till the year of his death; this is an inexhaustible storehouse of facts about the reign of Louis XIV. Saint-Simon's own brilliant memoirs, written from 1691 to 1723, may be considered as a sort of diary.

The song writer Charles Collé (1709–83) kept a *journal historique* from 1748 to 1777; it is full of vivacity, but very scandalous. Petit de Bachaumont (1690–1771) had access to remarkable sources of information, and his *Mémoires secrets* contains a valuable mass of documents. The posthumous publication of the diaries of the Russian artist, Marie Bashkirtseff (1860–84), produced a great sensation in 1887. The brothers Jules and Edmond de Goncourt kept a very minute diary of artistic and literary Paris; after the death of Jules, in 1870, this was continued by Edmond, who published three volumes in 1887–88, the work being extended to nine volumes covering the years up to Edmond's death in 1896; the complete *Journal* was first published in 1956–59. Among later French diaries, the *Journal* (its parts covering the period 1889–1949) of André Gide is perhaps the most notable. The chief historians of the diary have been Arthur Ponsonby, 1st Baron Ponsonby of Shulbrede (1871–1946), and the American William Matthews.

HN.)

DIAS DE NOVAES, BARTOLOMEU (fl. 1478–1500), Portuguese navigator and the discoverer of the Cape of Good Hope, was a knight of the royal household. The date and place of his birth are unknown. In 1478 a certain Bartolomeu Dias, probably identical with the navigator, was exempted from certain customary dues on ivory taken to Portugal from the Guinea coast. In 1481 the navigator commanded one of the vessels under Diogo d'Azambuja dispatched to the Gold Coast by John II. Five years later he was granted an annuity of 6,000 reis for "services to come" by John II.

In Aug. 1487 he sailed from Lisbon with two ships, probably caravels. and a storeship with the triple object of continuing the charting of the African coast (so greatly advanced by Diogo Cam, *q.v.*), of finding Prester John and of discovering a sea route to India. With him were two Negroes whom Cam had taken to Portugal. Passing Cape Cross (21° 50′ S.), the farthest point reached by Cam, Bartolomeu landed the two Negroes at Angra do Salto (Port Alexander). He probably then left his storeship in Walvis bay before continuing to Cabo da Volta, near Angra Pequena, where he erected a stone pillar to mark the overlordship of Portugal. From this point (according to João de Barros) he ran 13 days southward; then failing to find land he turned north and struck the coast at Mossel bay (Bahia dos Vaqueiros) on Feb. 3, 1488. Thence he coasted eastward and set up a second pillar at Cape Padrone. There his officers and men insisted that the expedition return to Portugal, and Dias could persuade them to continue only as far as the mouth of the Great Fish river. There the northeasterly trend of the coast became unmistakable; thus Dias confirmed a sea route round the south coast of Africa, but was prevented from sailing further and from opening the Cape route to India.

On the return voyage to Portugal, he erected a pillar at the Cape of Good Hope (which one tradition says he named the "cape of storms"). Then he returned to Lisbon, calling at Prince's Island (southwest of the Cameroons) where he took aboard Duarte Pacheco Pereira (who had been sent by John II to reconnoitre the rivers on the adjoining mainland) and at Mina where he obtained gold dust. He finally arrived at Lisbon in Dec. 1488. He

had discovered 1,260 mi. of coast, and his voyage, taken with letters received not long afterward from Pedro de Covilhdo (*q.v.*) who, by way of Aden and Cairo, had reached (1487–88) the Malabar coast on one side of the Indian ocean and Sofala (20° 8′ E.) on the other side, was considered to have solved the question of an ocean route round Africa to India.

Dias was greeted with enthusiasm on his return, but there is no record of his having been rewarded for his great achievement. John II and his successor, Manuel I, alike preferred Vasco da Gama to command the great expedition to India in 1497. Dias was employed to supervise the building of the "St. Gabriel" and the "St. Raphael," but he was allowed to sail with the expedition only as far as the Cape Verde Islands. Three years later he sailed with Alvares Cabral and landed on the coast of Brazil on April 22, 1500, en route to India. He perished in a storm off the Cape of Good Hope on May 29, 1500.

DIASIA, a festival of Zeus (*q.v.*), particularly that held outside Athens in honour of Zeus Meilichios ("easily entreated"). It was a ritual of atonement celebrated annually on the 23rd day of Anthesterion (early March). Whole burnt offerings of animals or sacred cakes in animal shapes were offered to the god. represented as a snake. This cult appears to have been a survival of primitive ritual connected later with the name of Zeus.

See L. Deubner, *Attische Feste,* p. 155 ff. **(1956).** (H. W. PA.)

DIASPORA is the term generally applied to Jenish communities living outside Palestine. The word, which has its origin in the Septuagint translation of Deut. xxviii. 3j and is used as the equivalent of the Hebrew terms *Gola, Galut* and *Tefuzot,* describes a historical manifestation but also has religious-eschatological and philosophical-political connotations. Historically. Diaspora Jewry goes back to the period of the Babylonian exile in the 8th century B.C. With the re-establishment of the second commonwealth the coexistence of an independent Jewish centre in Palestine with Jewish community life in various parts of the world became an established and continuing fact in Jewish history.

The largest, most significant and most creative Diaspora centre in the early period of Jewish history was the Jewish community in Alexandria in the 1st century B.C. Over 40% of the population of the city was Jewish, and the flowering of Hellenistic Jewish culture took place there. It is estimated that there were over 4,000,000 Jews within the Roman empire and about 1,000,000 in areas not under Rome who lived outside Palestine but looked to Palestine as the centre of Jewish religious and cultural life. Diaspora Jewry thus by far outnumbered the Jews in Palestine even before the destruction of the second Temple.

The extinction of Jewish statehood in A.D. 70 led to elimination of the central role of Palestinian Jewry. Jewish history from then on is a history of Diaspora Jewry, with shifting centres of hegemony from epoch to epoch—Babylonia and Persia, Arab and Christian Spain, France and Germany, Poland and Russia and most recently the United States. Variations in language, ritual and culture developed within the general frameaork of common tradition, and autonomous institutions governing internal Jewish community life were fashioned nithin the various centres. The Diaspora saw the emergence of the "Jewish problem" and anti-Semitism as well as the continuing struggle between the forces leading to assimilation to the non-Jewish environment and those tending to maintain Jewish national identity.

The very use of the term Diaspora implies a special relationship between the land of Israel and the Jewish settlements outside Palestine and hence involves basic religious and eschatological conceptions in Judaism. These range from the messianic hope of traditional Judaism for the eventual ingathering of the exiles to Zion to the "mission idea" of Reform Judaism which holds that the dispersion of the Jews was providentially designed to further the cause of pure monotheism throughout the world. In medieval Christian teaching the Diaspora gave rise to the image of the "wandering Jew" who had been relegated to the position of a pariah nation as punishment for having rejected Jesus and who was to continue to live on as the eternal symbol of divine visitation. The growth of secularism and nationalism in the 19th and 20th centuries produced diverse attitudes to the Diaspora. Political Zionism (*q.v.*) regards the land of Israel as the sole "home" for the Jews, negating the future of Jewish life in the Diaspora. Cultural Zionism as expounded by Ahad Ha-am regards the world-wide Jewish community as one cultural unit, with its vital centre in Palestine. The Diaspora nationalism of Simon Dubnow (*q.v.*) and of the Jewish Workers' Bund regarded all Jewish settlements as equal partners in one cultural enterprise, with no particular pre-eminence for Palestine. For those Jews who reject every form of Jewish nationalism the concept of Diaspora no longer has meaning or validity. In this view, all Jewish communities are simply disparate cultural-religious associations. The creation of the state of Israel in 1948 has made the problem of the relation of Zion to Diaspora Jewry once more acute.

In 1939 the estimated number of Jews in the world was about 16,000,000, of whom about 475,000 were in Palestine. The destruction of European Jewries by the Nazis and the establishment of the state of Israel radically changed the population picture. According to the best estimates there were in the 1960s a total of about 12,300,000 Jews in the world. Of these, 1,920,000 were in the state of Israel, approximately 2,250,000 in the U.S.S.R. and about 5,500,000 in the United States. Zion and the Diaspora were once again the twin poles of Jewish existence.

DIASPORE, an aluminum oxide mineral, is associated with corundum and at times is a major constituent of bauxite (*q.v.*), an important source of aluminum, and aluminous clays. It occurs as platyorthorhombic crystals and as lamellar or scaly masses, the flattened surfaces being the direction of a perfect cleavage and having a markedly pearly lustre. It may be colourless, grayish, greenish, brownish, yellowish or pink, and sometimes violet with marked pleochroism. It is readily distinguished from other common platyminerals, such as mica, talc, gypsum and brucite, by its greater hardness, 6.5 to 7. The specific gravity is 3.4. When heated in the blowpipe it decrepitates violently, forming white scales, hence the name from the Greek *diaspora,* a scattering. In composition it is a monohydrate of aluminum, $Al_2O_3(H_2O)$. *See* ALUMINUM: *Chemical Compounds.* (L. S. RL.; X.)

DIATESSARON ("out of the four [Gospels]") is an edition of the Gospels by Tatian, written as a single narrative, perhaps about A.D. 170 (according to Eusebius). Tatian occasionally included elements from another tradition, and sometimes the mark of his ascetic convictions also can be seen in the text. Whether it was composed originally in Syriac or in Greek is a matter of dispute; however, a 3rd-century Greek papyrus fragment discovered in the 1920s at Dura Europos (on the Euphrates, between Aleppo and Baghdad) exhibits the flavour of a Syriac original. Apparently the Diatessaron found acceptance immediately in the Syrian orient, and for generations it was the standard Gospel text. When it finally was replaced by the four separate Gospels, beginning in the 4th century, it continued to be used privately. It must early have been translated into Latin and would have been welcomed among the Latin-speaking Christians at a time when only Greek was used in the liturgy. Centuries later, it had a new and enormous success, for during the middle ages it enjoyed wide attention in the occident and recensions circulated in European languages. A considerable part of this material has survived.

The Diatessaron would have been an invaluable source for the history of the 2nd-century Gospel text, but no original manuscript survived. Not a fragment of the Syriac escaped, except for quotations in ancient Syriac literature. It was translated into several languages, however, and late manuscripts of these texts have been salvaged, in Arabic and particularly Persian. See also GOSPELS.

(AR. VÖ.)

DIATOMACEOUS EARTH (DIATOMITE) is a hydrous form of silica or opal composed of the siliceous shells of diatoms. which are unicelled aquatic plants of microscopic size. It is light coloured and occurs in sedimentary beds that somewhat resemble chalk: but it is much lighter and will not effervesce in acid. Under a high-powered microscope the form of the diatoms can be distinguished. These are so small and abundant that several million are contained in one cubic inch of diatomite. Many thousands of different varieties of diatoms are known (see DIATOMS).

Diatomite, formerly used principally as a filter in clarifying sugar and sirups, has been adapted to almost all industrial filtration applications, including processing oils, alcoholic and nonalcoholic beverages. antibiotics. solvents and chemicals. A second major use is as a filler or extender in paper, paints, brick, tile. ceramics, linoleum, plastics, soap, detergents and a large number of other products.

Still another major use of diatomite is in the insulation of boilers. blast furnaces and other places where high temperatures are maintained. At temperatures higher than 1,000° F. diatomaceous earth is a more efficient insulator than asbestos or magnesia because it is more resistant to shrinkage and does not fail at red heat. It is also used for sound insulation and as a vehicle for herbicides and fungicides. In Europe, under the name kieselguhr. it has been used as the inert ingredient of dynamite. The oldest and best-known commercial use of diatomite is that of a very mild abrasive in metal polishes and tooth paste. The amount used in polishes increased greatly with the utilization of diatomaceous dust as the base of polishes for automobiles finished in artificial lacquers.

The largest deposit worked in the United States is in northern Santa Barbara county, Calif. Miocene beds more than 1,000 ft. thick extend over several square miles and vary from soft earth to hard compact rock that can be sawed into blocks. The principal production in the United States has come from these deposits and those of Nevada and Oregon. Denmark. France and the Federal Republic of Germany have well-developed diatomite industries and numerous deposits exist in Algeria. (V. T. A.; X.)

DIATOMS (BACILLARIOPHYCEAE) are microscopic unicellular or colonial algae. distinguished by the complex structure of their cell walls, which are usually strongly impregnated with silica. The majority are minute. and one with a length of $\frac{1}{200}$ in. is well beyond the medium size. The first forms were discovered by O. F. Müller toward the close of the 18th century. With the perfection of modern microscopes and microscopic methods, the study of these minute plants progressed, until over 5,500 species of diatoms have been described.

INTRODUCTION

Occurrence and Distribution. — Moisture and light are needed for the growth of diatoms, and wherever these factors coexist. diatoms will almost invariably be found. They occur abundantly in cultivated soils, and mixed with other forms on the surface of moist rocks; in pools and other small pieces of water they form a brownish stratum on the surface of the mud, or cover the stems and leaves of water plants or floating twigs with a furry investment. Marine forms are usually attached to seaweeds. and many are found in the stomachs of mollusks, holothurians. ascidians and other ocean creatures. Both in fresh waters and in the sea. moreover. there are myriads of free-floating diatoms, which at times indeed make up the main bulk of the plankton (*q.v.*). Diatoms are most abundant in cold latitudes. having a general preference for cold water, and exist in prodigious numbers in the Arctic and Antarctic oceans. The fresh-water species are almost always distinct from those found in salt or brackish water.

Diatomaceous **Earth.**—Large numbers of fossil diatoms are known. Since the siliceous wall is practically imperishable, it persists after the death of the individual. so that where diatoms occur abundantly there is an unceasing rain of their minute valves onto the bottom of sea or lake. In this way extensive deposits of diatomaceous earth may arise, and such are not only being formed at the present but have been produced abundantly in the past. Deposits of diatomaceous earth have been discovered in various parts of the earth, some of fresh-water, others of marine origin. Most deposits are a few feet in thickness but some are much thicker, the thickest deposits thus far discovered being in California, where there is a subterranean deposit about 3.000 ft. thick. Most of the fossil deposits are in Tertiary rocks. although there are records of diatoms in the Triassic period (extending from about 160.000.000 to 200.000.000 years ago). Industrial uses of diatomaceous earth are covered in the article DIATOMACEOUS EARTH.

STRUCTURE AND FUNCTION

Structure. — In spite of the immense number of diverse forms included in it, the class of diatoms as a whole exhibits a remarkable uniformity of structure. The individual cells of diatoms are called frustules, and the cell wall consists of two similar halves, each composed of a slightly convex valve to whose incurved edges is attached at right angles a broad, hooplike, connecting band. The two connecting bands together form the girdle (fig. 2). One half is slightly smaller than the other, the smaller fitting into the larger much as a box fits into its cover (fig. 2). By visualizing a circular, oval or otherwise shaped box, a mental picture of the varied forms assumed by the frustules of diatoms may be obtained; the sides of the box correspond to the connecting bands. As the protoplasmic contents increase in volume, the siliceous valves are pushed apart and the connecting bands become broader.

Diatoms are usually described from two aspects, one in which the surface of the valve is exposed, the valve (top) view; and one in which the girdle is exposed, the girdle (side) view. The valve view exhibits great variety of form; the girdle view is much more uniform and commonly rectangular. The valves may be circular, triangular or oval in outline. Some are linear, others more or less crescentic; others again are wedge shaped. The prevailing forms, however, are boat shaped (naviculoid), as in the genus *Navicula*, which embraces more than 1,000 species.

FIG. 2.— DETAILOF FRUSTULE OF PENNATE DIATOM: (A) SIDE VIEW; (B) TOP VIEW

Many diatoms are free-floating, but some (*Gomphonema*) are attached to foreign bodies by simple or branched gelatinous stalks. The frustules of some are connected to form ribbon-shaped colonies (*Fragilaria*) or zigzag chains (fig. 3[E]). In a few genera numerous individuals are enclosed in a tubelike gelatinous envelope.

The valves are thin and transparent and generally ornamented with a variety of markings. The latter often appear as fine lines on the face of the valve, and the best lenses show them in many cases to consist of a series of separate dots which correspond to small cavities within the siliceous wall. The valves of certain marine genera exhibit a beautiful areolated structure due to the presence of larger chambers within the wall. A good many diatoms, especially those of the naviculoid type, have thickenings at the centre and at each extremity of the valve, known as nodules (fig. 2). These possess a complex structure and are generally connected by a long narrow cleft, the raphe (fig. 2), which appears as a straight or slightly undulating line in the valve view.

The contents of diatom cells are very similar to those of other algae. Beneath the wall there is a lining cytoplasmic layer enclosing the cell sap and connected either by two broad bands or by a number of anastomosing strands with the central cytoplasm in which the nucleus is embedded. The chromatophores are either one or two of large size, or numerous small lobed disks. The former often include a variable number of glistening bodies called pyrenoids. The characteristic brown colour is due to diatomin, a pigment resembling that. of the brown algae and masking the chlorophyll. The cells often contain abundant oil.

Many diatoms, but only those that possess a true raphe in their valves (*Navicula,* etc.), are able to move through the water, sometimes with considerable rapidity. The movements are, in all cases, doubtless related to the presence of the raphe, which in all probability contains streaming cytoplasm connected with that in the interior of the cell by a complex system of canals within the nodules.

Some believe that the movements depend upon an extrusion of mucilage from the region of the raphe. In Cocconeis, whose disc-shaped frustules are found attached in enormous numbers to *Cladophora* and other fresh-water plants, only the valve in contact with the substratum possesses a raphe.

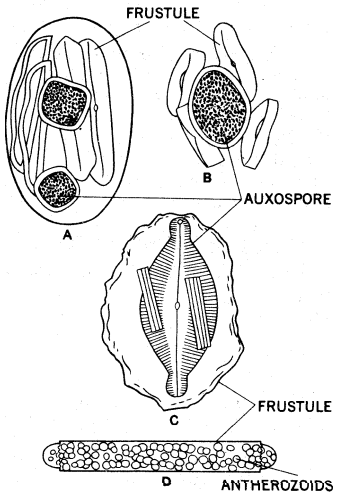
Reproduction. — The ordinary mode of multiplication is by cell division, which usually occurs at night. The cell contents divide into two masses and the halves of the cell wall commence to separate; thereupon, fresh valves, which are at first very delicate, are secreted on the surfaces of the new protoplasmic masses opposite to the valves of the parent. The new valves are situated within the girdle of the original frustule, but as their own connecting bands develop, those of the parent separate. Each of the new individuals thus has one valve derived from the parent, and one that is newly formed and more or less parallel to it. This process of division is repeated at frequent intervals. and it has been calculated that from a single frustule 1,000,000,000 new individuals may arise in the course of a month.



FROM G. S. WEST "ALGAE," BY PERMISSION OF THE CAMBRIDGE UNIVERSITY PRESS

FIG. 4.— REPRODUCTIVE STRUCTURES IN: (A) NAVICULA LIMOSA; (B) ACHNANTHES FLEXELLA; (C) NAVICULA AMPHISBAENA; (D) CORETHRON VALDIVIAE (BEFORE LIBERATION OF FRUSTULE)

The individual diatom, owing to the rigidity of the siliceous wall, is ordinarily incapable of any increase in length and, since the new valves are always formed within the girdle of the old ones, it would follow that one of the two cells in every succeeding cell generation is reduced in length by the thickness of the girdle. This is not, however, strictly true: as daughter cells are sometimes formed that are larger than the parent cell. so that the reduction in size is not always proportional to the number of divisions. The progressive diminution in size does not continue indefinitely because cells of small size may produce special rejuvenescent cells (auxospores) of considerably larger dimensions.

In pennate diatoms the auxospore is a zygote produced by union of two nonflagellate gametes. Two small cells become surrounded by a common gelatinous envelope and the valves of the cell walls spread apart. In most species the protoplast of each cell functions as a gamete and there is a formation of a single auxospore (fig. 4[B]). In some other species each cell produces two gametes and there is a formation of two auxospores. Cells functioning as gametes always have a reduction (meiotic) division of their nuclei.

Cells of centric diatoms always produce a single auxospore. For a long time these were thought to be asexual in nature. However, auxospores of certain centric diatoms are now known to be produced sexually, and there is a strong presumption that this holds for the entire group. In auxospore formation of centric diatoms the valves of certain cells of a species pull apart and the protoplast rounds up to form a single egg. Other cells of the species have the protoplast dividing into 8, 16, 32, 64 or 128 flagellated antherozoids (called microspores before their sexual nature was discovered). Antherozoids liberated from a cell producing them swim to and fuse with the eggs. The zygotes thus formed become auxospores. Cells producing either antherozoids or eggs have a meiotic division of their nuclei.

CLASSIFICATION

The diatoms, or Bacillariophyceae, are one of the three classes of the phylum (or division) Chrysophyta. The class is divided into two orders, Centrales and Pennales.

Valves of Centrales have an ornamentation that is radial or concentric about a central point. The cells usually contain many chromatophores, are immobile, form microspores and produce auxospores asexually. The order includes about 100 genera and 2,400 species, the great majority of which are marine.

Valves of Pennales have an ornamentation that is bilaterally symmetrical or asymmetrical. The cells usually have but one or two chromatophores, never form microspores, and form auxospores by a fusion of two gametes. Species with a raphe move spontaneously. The order includes about 70 genera and 2,900 species.

The number of fresh-water species is somewhat smaller than the number of marine species. *See* ALGAE; *see* also references under "Diatoms" in the Index volume.

DIATONIC SCALE: *see* SCALE.

DIATRYMA, a group of extinct birds known from the Eocene fossil deposits of New Jersey, Wyoming and New Mexico (laid down about 60,000,000 to 40,000,000 years ago). These huge flightless species, as large as the larger of the extinct moas of New Zealand or the fossil *Phororhacos* of South America, were well adapted for an active: aggressive terrestrial life. *Diatrynta steini,* described by *W.* D. Matthew and Walter Granger from a nearly complete skeleton, stood almost seven feet high and towered over the contemporaneous terrier-sized horse.

The neck was short and strong, and the head huge, the skull being 17 in. long with a compressed beak, which, as preserved without the horny sheath (rhamphotheca), measured 9 in. long and $6\frac{1}{2}$ in. high. The postorbital and squamosal bones were joined distally to form a temporal fenestra. The jawbone (mandible) was massive, though having a slender tip, with strong muscular attachments.

The coracoid and scapula bones were fused, and the humerus much reduced; the wing was completely nonfunctional for flight. The pelvis and leg were large and strong; the femur was 15 in. long and the tibia nearly 2 ft. The metatarsus (part of the foot skeleton) mas incompletely preserved, but was a heavy bone with two perforations of the shaft at the upper end. The three anterior toes were strong, whereas the hind toe (hallux) was small and elevated.

Three other species, *Diatryma ajax, D. giganteum* and *Omorhamphus storchii,* have been described and another, *Baronis regens* from the Eocene of New Jersey, is placed with these somewhat uncertainly. *Diatryma sarasini* was named from Monthelon near Épernay, France. These form the family Diatrymidae. which. is placed in the order Diatrymiformes, near the cranes, with which, however, it does not show close affinity. The fossil family of the Gastornithidae, represented by six species from the Eocene of western Europe. is olaced tentativelv in this order.

See W. D Matthew and Walter Granger, "The Skeleton of *Diatrynza,* a Gigantic Bird From the Lower Eocene of Wyoming," *Bull. Amer Mus. Nat. Hist.,* vol. xxxvii, pp 307–326 (1917); Kálmán Lambrecht, *Handbuch der Palaeornithologie,* pp. 566–579 (1933). (A. WT.)

DIAVOLO, FRA (1771–1806), the popular name of a famous Italian guerrilla leader whose real name was MICHELE PEZZA Of low parentage, he was born at Itri, near Foggia, on April 7, 1771. After a serious childhood illness, his mother made him wear a monk's habit, a customary form of thanksgiving; because of his violent nature his schoolmates called him *diavolo* ("devil"). Hence the nickname "Brother Devil," which later lent itself to popular superstition.

Fra Diavolo was apprenticed to a saddler, whom he mortally wounded with an awl after an altercation. To escape justice, he took to the hills in the Terra di Lavoro, where he committed several robberies and murders. He surrendered and was pardoned (Jan. 20, 1798) on condition that he join one of the bands raised by Ferdinand IV of Naples against the French occupation. His band promptly interrupted French communications between Rome and Naples and he received the rank of colonel.

Fra Diavolo took terrible reprisals on the French invaders for their atrocities, and the behaviour of his men at the sack of Alhano eventually led to his arrest and imprisonment in the Castel Sant' Angelo. He escaped, and the king pardoned him (Dec. 2, 1800). After a period of rest until 1806 he again led Bourbon troops against the French and took part in the defense of Gaeta, which earned him the title of duca di Cassano.

Joseph Bonaparte put a price on Fra Diavolo's head. For a time he evaded his pursuers, but at length he was arrested at Baronissi (Avellino) and hanged at Naples on Nov. 11, 1806.

See E. Jallonghi, *Fra Diavolo* (1911).

DIAZ, ARMANDO (1861–1928), Italian chief of general staff in World War I and marshal, was born in Naples on Dec. 6, 1861, the son of a naval captain. He served in the Italo-Turkish War, and in 1914 was promoted to major general. On Italy's entry into World War I he was director of military operations, and in 1916 became lieutenant general in command of the 49th division. In 1917 he was put in command of the 23rd corps and saw much hard fighting on the Carso.

In Nov. 1917, after Caporetto, Diaz succeeded Luigi Cadorna as chief of the general staff. Under him the battle front was successfully reconstituted and the Austrian armies were destroyed at Vittorio Veneto (Oct.–Nov. 1918). After the signature of the armistice he became inspector general of the army. He received many honours. Italian and foreign, and in Dec. 1921 was created duca della Vittoria.

On the advent of the Fascist government he was appointed minister of war, in Oct. 1922. Ill-health obliged him to resign in April 1924. On Nov. 4, 1924, the newly created rank of marshal was conferred on him. He died on Feb. 29, 1928, in Rome.

DIAZ, PORFIRIO (1830–1915), Mexican soldier and president, was born in the city of Oaxaca, state of Oaxaca, Sept. 15, 1830, of a poor family; his mother was part Indian. At the age of 15 he entered training for the priesthood, but during the war with the United States (1846–48) he served in the army, and in 1849 began to study law at the suggestion of the liberal state governor, Benito Juárez (*q.v.*). During the War of Reform (1858–61) he supported the presidency of Juárez against the conservative proclericals, and he was one of the most prominent Juarist military leaders in the struggle against the French intervention (1861–67). His gallantry as a line officer at the battle of Puebla (1862) won him much of the credit for that unexpected victory.

After the restoration of peace Diaz resigned his command and retired to Oaxaca, but he became dissatisfied with Juárez' policies, ran for the presidency in 1871 and, when Juirez was re-elected, led an unsuccessful revolt in protest. After Sebastian Lerdo de Tejada succeeded to the presidency in the following year, Diaz bided his time in his native hills, and in the spring of 1876 launched a second revolt against Lerdo's re-election. Temporarily defeated, he fled to the United States but returned after six months to counterattack and decisively defeat the government forces in the battle of Tecoac (Nov. 16). In May 1877 he was formally elected president of Mexico.

During his first four-year term of office Diaz built up a political machine, suppressed revolts and bandits and made a few modest public improvements. Having opposed Lerdo's re-election, he decided not to run for another term himself, and in 1880 he engineered the election of a loyal subordinate, Gen. Manuel González. Diaz served for a time in the cabinet as minister of *fomento* (development) but soon dissociated himself openly from the González government, nhich had begun to attract unfavourable criticism for extravagance and corruption. In 1884 Diaz was elected to the presidency again. Within two years he had reduced congress to subservience, and in 1890 the constitution was amended to permit him an indefinite number of re-elections.

For over 26 years after 1884 Diaz brought the mixed blessings of peace and stability to hlexico. His government imprisoned opponents, occasionally assassinated political prisoners "trying to escape" and regularly subsidized and censored the press. Diaz cleverly played off his subordinates against each other, and his uell-lubricated machine kept up the forms of democracy in periodic elections, mainly for the benefit of Mexico's reputation abroad Meannhile. banditry diminished until life and property were safer in Mexico than in many parts of the United States at the beginning of the 20th century

The economic policies of the Diaz regime, though sometimes haphazard and imperfectly planned, greatly stimulated Mexican industry, mining and agriculture. Diaz himself was no economist, but his two principal financial advisers, Matías Romero and, after 1893, José Y. Limantour, invited foreign capital and technology to Mexico to build railroads and bridges, dig mines, irrigate fields and establish colonies of immigrants. Investments from the United States, the most important source of capital, rose from a few million dollars to between $800,000,000 and $1,000,000,000 under the Diaz regime. (No exact figures of investments exist, and estimates vary.) Railroad mileage increased from 416 mi. in 1876 to about 15,360 mi. in 1910, and Mexican exports are said to have risen from 27,318,788 pesos in 1874–75 to 293,752,150 pesos in 1910–11, although the simultaneous inflation of the Mexican silver peso robs these statistics of some of their force.

While Diaz ushered his country through the first stages of its industrial revolution, he made little effort to divide the benefits of economic expansion among the common people, and at the end of his regime the gap between rich and poor was as wide as ever. Wealthy Mexican landowners and foreigners received most of the irrigation and survey grants, railroad and mining concessions and government subsidies, but the starvation wages of most of rural Mexico and wretched conditions in the Mexico City slums belied the official propaganda of peace and prosperity and made social revolution inevitable.

In 1910 Diaz allowed Francisco I. Madero to run against him for the presidency. As everyone expected, Madero lost the election by a wide margin, but when he resorted to military revolution, the government forces proved surprisingly weak, and a few victories released the pent-up hatred against the dictator. In May 1911 Diaz, then senile, resigned his office and went into exile in Paris, where he died on July 2, 1915.

DIAZ DE LA PEÑA, NARCISSE VIRGILE (1808–1876), French painter and lithographer of the Barbizon school, was born in Bordeaux of Spanish parents. He became famous for his paintings of the forest of Fontainebleau, and for his landscape fantasies with mythological figures. He had no well-known pupils, but Léon Richet followed markedly his methods of tree painting, and J. F. Millet at one period painted small figures in avowed imitation of Diaz' then popular subjects.

When he was 15 Diaz began working as a porcelain painter at Sèvres. He then studied with Cabanel and Souchon, and became acquainted with Dupré, Raffet and Cabat. As a young artist he was strongly influenced by the romantics, and enthusiastically admired the art of Delacroix, the middle ages and the near east. He entered several exotic subjects in the *salons* of 1831, 1834 and 1835, but his strongly coloured figure subjects met with little public success.

About 1840 Diaz turned more toward subtly toned landscape painting and, together with Corot and others, began to frequent the forest of Fontainebleau near the village of Barbizon. Although Diaz showed regularly in the *salons* of the late 1830s and the 1840s, he seldom exhibited publicly during the last 15 years of his life. After 1871 his work became especially favoured among collectors. and he worked constantly and successfully. He died at Mentone on Nov. 18, 1876. *See* also BARBIZON SCHOOL.

DÍAZ DEL CASTILLO, BERNAL (*c.* 1492–*c.* 1581), Spanish soldier and author, who took part in the conquest of Mexico, was born in Medina del Campo, and died in Mexico. In protest against the academic chronicles of sedentary historians he wrote his *Verdadera historia* de *la conquista de la Nueva España* (1632), insisting that, as actor and eyewitness, he was better situated to record the truth of the expeditions in their topographical and military details. This "true history," written in an unassuming, colloquial style enlivened by popular expressions, has important historical and artistic values and is a source book of idiomatic 16th-century Spanish. (I. L. MCC.)

DIAZO COMPOUNDS. A diazo compound is an organic substance containing two nitrogen atoms that are bonded together; one of the nitrogens is attached to a single carbon atom. Both aromatic and aliphatic diazo compounds are known.

AROMATIC DIAZO COMPOUNDS

The first known compound of this group was prepared by P. Griess at Marburg, Ger., in 1858. As Griess continued his work, first in London at the Royal College of Chemistry and later in the laboratories of Allsopp's brewery at Burton-on-Trent, the technical importance of the compounds became rapidly apparent, and by 1863 azo dyes derived from them were being manufactured and sold. Their multifarious reactions. which lead to aromatic compounds of a large number of types, soon made aniline and the simple aromatic amines in general the most important intermediates known and gave great impetus to technical organic chemistry and especially to the utilization of coal tar as raw material for manufacture.

Aromatic diazo compounds can exist in three distinct isomeric forms; the reasons for the structures given are summarized below. As usually prepared they are diazonium salts which contain the cation of a strong base, $(ArN{\equiv}N)^+ -OH$, where Ar is an aromatic radical. The free bases are hardly known since in alkaline solution they change into the normal diazoates which contain the anion of a weak acid. Ar.N:N.OH; this is usually quite unstable. The normal diazoate ion can be converted by simple means into a more stable isomeric form, the isodiazoate ion. Lastly, the weak acid liberated from an isodiazoate by acetic acid is known to change in certain cases into a neutral form to which the structure of a primary nitrosamine, Ar.NH.NO, must be allotted. All these three last forms are reconverted into a diazonium salt by a mineral acid. In general, all forms of a diazo compound are unstable, the diazoate usually the most, though certain isodiazoates are sufficientlystable to be manufactured and sold as intermediates in dye manufacture. This instability has been a constant handicap in elucidating the structures of the isomeric forms.

The most important method of preparation is by the action of nitrous acid on a primary aromatic amine in presence of a mineral acid: $Ar.NH_2 + ONOH + HCl \rightarrow [Ar.N_2]Cl + 2H_2O$. If the solid diazonium salt is required, the reaction can be carried out by passing nitrous fumes into a paste of the amine hydrochloride and water; addition of alcohol and ether to the resulting solution precipitates the diazonium chloride.

For many years most chemists regarded diazonium formation as the result of interaction of nitrous acid and the arylammonium salt $(ArNH_3{}^+Cl^-)$. It is true that hydrochloric acid does react with aniline to form a salt but an aqueous solution of this salt undergoes considerable hydrolysis into aniline. The purpose of the mineral acid is to convert nitrous acid into the nitrosyl positive ion $(HONO + H^+ \rightarrow H_2O + {}^+NO)$ which then reacts with the free amine. One may interpret the mechanism in this way:

$$ArNH_2 + {}^+NO \xrightarrow{-H^+} ArNH{-}N{=}O \rightleftarrows ArN{=}N{-}OH \xrightarrow{H^+}$$

$$[ArN{=}NOH_2] \rightarrow H_2O + ArN{\equiv}N$$

The solid diazonium salts are explosive and are seldom prepared. Usually an aqueous solution suffices and is obtained by adding sodium nitrite to a solution of the amine in excess (two to three equivalents) of the mineral acid. The temperature must usually be kept below 10° C. during and after the reaction because of the

decomposition of the diazonium salt if warmed. Other methods of preparation are known; *e.g.*, the oxidation of salts of phenylhydrazine by mercuric acetate and the action of bromine on phenylhydrazine in alcohol; they have no practical importance, though they are interesting from the point of view of structure.

The chemical reactivity of the aromatic diazo compounds is the reason for their importance in the laboratory and in industry. Aromatic compounds in general can be nitrated with ease and the product reduced to the primary amine. Diazotization of this amine followed by a diazo reaction chosen to give the desired product is a method used in innumerable cases. The reactions can be divided into two classes, those in which the two nitrogen atoms are lost and are evolved as gaseous nitrogen and those in which they are retained in the molecule of the product. In the first class the diazo group is replaced by some other group. Examples are:

Replacement by hydroxyl, leading to a phenol, usually takes place easily by warming the aqueous solution of the diazonium salt:

$$[Ar.N_2]Cl + H_2O \rightarrow ArOH + N_2 + HCl$$

Side reactions may interfere, especially the coupling of the phenol with an undecomposed diazo compound, and this can be avoided by working in strongly acid solution or by passing steam into the solution to remove the phenol as formed.

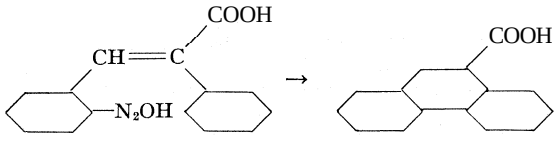
Replacement by hydrogen is brought about by reducing agents such as formic acid, hypophosphorous acid and sodium stannite. Addition of alcohol often gives the same result but sometimes the ethoxy compound, $ArOC_2H_5$, is formed together with, or instead of. ArH. This reaction is of value where an amino group has been introduced to act as a powerful directing group for some desired substitution. The amino group can later be eliminated by diazotization and replacement by hydrogen.

Replacement by a halogen takes place readily with iodide ion since diazonium iodides decompose spontaneously into nitrogen and the iodo compound. With chlorine the usual methods are to treat the diazonium chloride with cuprous chloride (Sandmeyer's reaction) or with finely divided copper (Gattermann's reaction). Similar methods are used for bromine. Fluorine is best introduced by precipitating the sparingly soluble fluoborate. $[Ar.N_2]BF_4$, by adding fluoboric acid to the solution. The dry fluoborate decomposes smoothly on heating into boron fluoride, nitrogen and the fluoro compound.

Replacement by cyanogen can be achieved by Sandmeyer's method. by use of a solution of cuprous cyanide in potassium cyanide. Since the product is a nitrile, it can be hydrolyzed to a carboxylic acid and the reaction is valuable for effecting the change $Ar.NH_2 \rightarrow Ar.COOH$. There is evidence to show that the reactions mentioned so far are those of the positively charged aromatic radical formed by loss of nitrogen from the diazonium cation.

Groups containing sulfur can be linked to the aromatic ring in a variety of ways and the processes are. of technical importance since they give intermediates for the preparation of dyes containing sulfur. An example is to treat the diazo compound with potassium ethyl dithiocarbonate (xanthogenate). The product, $Ar.S.CS.OC_2H_5$, can be hydrolyzed to the thiophenol, ArSH, or heated alone to give the thioether, $ArSC_2H_5$.

Linkage between carbon atoms sometimes occurs in the decomposition of diazonium compounds, especially when a new aromatic structure is formed. An example is R. Pschorr's synthesis of phenanthrene-carboxylic acid by the decomposition of diazotized *o*-amino-α-phenylcinnamic acid.

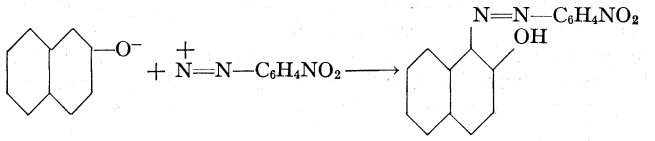


Of the second class of reactions, in which nitrogen is not lost, an example is reduction to a hydrazine. $ArNH.NH_2$; this is carried out with stannous chloride or sulfites and is the general method for preparing phenylhydrazine and related cbmpounds. The most important example of this class is diazo coupling with anilines and phenols to produce azo compounds (*q.v.*). The industrially important azo dyes are prepared in this way. Coupling occurs by adding alkali to a mixture of the diazonium salt and phenol or aniline. Alkali converts the phenol into phenoxide ion and liberates the free aniline from its salt, following which these bodies react with the diazoniurn ion. The diazonium ion is a resonance hybrid oi structures I and II:

$$Ar{-}\overset{+}{N}{\equiv}N: \longleftrightarrow Ar{-}\overset{+}{\underset{\cdot\cdot}{N}}{=}N:$$

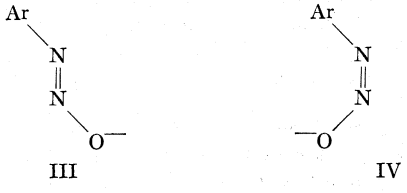
I II

In a strongly acidic medium, the ion usually reacts in accordance with structure I, but in a less acidic or in a basic medium it more frequently reacts in accordance with structure II. The terminal, electron-deficient nitrogen of the cation is attracted to the electron-rich ortho or para positions of the phenoxide ion or of the aniline as the azo bond is created. As an illustration, diazotized para nitroaniline couples in alkaline solution with 2-naphthol to give a red dye (para red) much used for cotton.



Coupling also takes place with aliphatic amines, phenolic ethers, aliphatic β-ketonic esters and β-diketones and with reactive unsaturated hydrocarbons such as isoprene. With most amides (as acetanilide) there is no coupling. but the 2-acetamido derivative of thiophene couples readily, even in acid solution. In some cases the product first formed is not the azo compound; thus primary amines, both aliphatic and aromatic, often give diazoamino compounds. Ar.N:N.NHR; such a product can. however, usually be transformed into the azo compound. Because of the technical importance of the reaction there is an enormous mass of empirical knowledge on the rates of coupling and conditions and factors which affect the reaction.

Constitution of the Aromatic Diazo Compounds. — The reasons for the structures of the various forms of a diazo compound which have been given above can be summarized as follows: a diazonium salt behaves as the salt of a strong bnse and resembles a salt of an alkali metal. The carbonate is soluble in water with an alkaline reaction. The salt must contain a cation similar to that of a quaternary ammonium salt and hence one nitrogen atom must he tetracovalent. Christian Blomstrand's view that this cation is $[Ar.\overset{+}{N}{\equiv}N]$ is clearly correct. As stated above. this structure is considered to be one of those which contribute to the state of the resonance hybrid. A second contributing structure is $ArN{=}N^+$, which is related to that of the normal diazoate, ArN═NONa, iormed when the diazonium salt is treated with alkali in excess. Acidification of sodium benzenediazoate with a weak acid yields benzenediazoic acid. $C_6H_5N{=}NOH$. This is a weak acid like nitrous acid (O═NOH) to which it is structurally related. Heated with excess alkali: the diazoate is converted into the isodiazoate which, though more stable, resembles the normal diazoate in all its properties. The two anions must be geometrical isomers which can be represented by the formulas,



The main reason for this view is that a similar isomerism occurs in the diazo sulfonates, $Ar.N:N.SO_3K$, and the diazo cyanides, Ar.N:N.CN, and all these cases must almost certainly arise from a common cause which can only he geometrical isomerism. In the diazo cyanides careful study of the physical properties shows that any other type of isomerism is excluded. It also shows that the

more stable isomer has the *anti* coniiguration so that on the presumption that all the more stable forms have the same configuration the isodiazoate is the anti-diazoate (III) and the normal diazoate is the syn-diazoate (IV).

Acidification of III with strong acids changes it back to the diazonium form, whereas acidification with weak acids yields the *anti*-diazoic acid. The latter. $C_6H_5N{=}NOH$, is colourless. In chloroform solution it tautomerizes into a yellow, neutral isomer for which the nitrosamide structure is offered, $C_6H_5NH{-}N{=}O$.

Diazo compounds of the aromatic type occur not only in the benzene and naphthalene series, but also in many heterocyclic aromatic systems, as pyrazoles, thiazoles and triazoles. With pyridine and quinoline only the β-amino compounds can be diazotized.

ALIPHATIC DIAZO COMPOUNDS

If aliphatic' amines such as carbethoxymethylamine (glycine ester), $C_2H_5OOC{-}CH_2{-}NH_2$, or cyanomethylamine (aminoacetonitrile), $NC{-}CH_2{-}NH_2$, underwent diazotization in the manner of aniline, the products would be diazonium salts $R{-}CH_2{-}N_2Cl$ ($R = {-}COOC_2H_5, {-}CN$); however. coinpounds with this structure are not formed. Instead, the structure is that of a substituted diazomethane, $R{-}CHN_2$, as if the elements of HCl had been detached from the RCH_2N_2Cl. This method fails in the synthesis of diazomethane itself or its homologs, since nitrogen gas is evolved instead on reaction of nitrous acid with simple aliphatic ainines.

Thus, these aliphatic diazo compounds are sharply difierentiated from the aromatic diazo compounds in that they show neither basic nor acidic properties. With the exception of diazomethane, which is used in the laboratory as a inethylating agent. they have little practical interest, but the problem of the structure of the group was a subject of dispute for many years and was solved only when quantum mechanics gave a clearer picture of chemical valence.

There are three chief methods for obtaining these compounds:

1. Reaction of substituted nitrosamides with alkali:

$$X{-}N(CH_3){-}NO + KOH \rightarrow X{-}OK + CH_2N_2 + H_2O$$

Nitrosamides used in this approach are *p*-tosylmethylnitrosamide (X=tosyl), carbethoxymethylnitrosamide or N-methyl-N-nitrosourethan (X=carbethoxy), carbamylmethylnitrosamide (X=carbamyl) and others. By substituting other groups for methyl, *i.e.*, by starting with $X{-}N(CH_2R){-}NO$, one may obtain other aliphatic diazo compounds. For example. if CH_2R is ethyl there is formed diazoethane CH_3CHN_2. and if it is allyl there is formed vinyldiazomethane $CH_2{=}CHCHN_2$.

2. Reaction of a-amino ester. a-amino nitriles and a-amino ketones with nitrous acid. This was the method used by T. Curtius in 1883 to prepare the first aliphatic diazo compound, namely, diazoacetic ester: $N_2CH{-}COOC_2H_5$, from ethyl aminoacetate. Diazomethane itself was not discovered until 1894.

3. Oxidation of the hydrazones of aldehydes and ketones. Thus, diphenyldiazomethane, $(C_6H_5)_2CN_2$, is obtained by shaking benzophenone hydrazone with yellow mercuric oxide in cold hexane for six hours.

The aliphatic diazo compounds vary in stability over a wide range. Those with hydrocarbon residues attached to the diazo group are coloured and unstable; those with a carbonyl or carbethoxy group on the next carbon atom, such as diazoacetic ester, are paler yellow and more stable while those with two such groups. as $C_6H_5CO.CN_2COCH_3$, are colourless and comparatively unreactive, so much so that at one time they were allotted a different constitution. Diazomethane is a deep yellow gas boiling at -23° C.; higher members are liquids or low-melting solids. Nearly all explode on rapid heating but are reasonably stable in solution. A solution of vinyldiazomethane is wine red in colour, but on standing for several hours it becomes colourless because of isomerization to pyrazole.

Aliphatic diazo compounds react readily with carboxylic acids causing esterification, an example being the quantitative conversion of benzoic acid into methyl benzoate by means of diazomethane. Phenols and imides react similarly, with evolution of nitrogen, but as a rule alcohols fail to react with diazomethane unless catalyzed by aluminum ethoxide.

Diazomethane reacts at the carbonyl group of aldehydes and ketones to give either ethylene oxide derivatives or homologous ketones. Acid chlorides. R—CO—Cl. react similarly with diazomethane at the carbonyl group to yield any one of three types of products. depending on experimental conditions: a chloromethyl ketone $R{-}CO{-}CH_2Cl$, an acyldiazomethane $R{-}CO{-}CHN_2$ or the homologous acid $RCH_2{-}CO{-}OH$.

Unsaturated compounds. as acetylenes or dienes, frequently add to diazomethane with no loss of nitrogen, yielding pyrazoles or pyrazolines. The structure of the characteristic group $>CN_2$ was a matter of controversy for many years. Curtius in 1883 proposed the formula

which was accepted until A. Angeli in 1907 pointed out that the relationship to hydrazones, both in oxidation and reduction, was evidence for a straight chain formula, written as $>C{=}N{\equiv}N$.

Electron diffraction by diazomethane vapour (H. Boersch, 1935) shows beyond doubt that the straight chain is correct. In modern representation the linear structure of diazomethane is represented as $CH_2{=}\overset{+}{N}{=}\overset{-}{N}$; other structures contributing to the state of the resonance hybrid are $\overset{-}{C}H_2{-}\overset{+}{N}{\equiv}N$: and $CH_2{=}\underset{+}{N}{-}\underset{:}{N}:$.

Isodiazomethane, of structure $H{-}C{\equiv}N{-}\bar{N}H$, is produced from diazomethane by reaction with methyl-lithium, followed by treatment of the lithium derivative ($LiCHN_2$) in ether with potassium dihydrogen phosphate. The colourless isodiazomethane in ether solution reacts with acids (RCOOH) to yield N-acyl-N′-formyl-hydrazine, $RCO{-}NH{-}NH{-}CHO$.

(T. W. J.T.; C. D. Hᴅ.)

DIBDIN, CHARLES (1745–1814), British composer, author, actor, theatrical manager and entertainer, was born in Southampton and baptized on March 4, 1745. From 1756 to 1759 he was a chorister at Rinchester cathedral and in 1760 he went to London and worked for a music publisher, but decided to try his luck on the stage and began his career at Richmond in 1762. He secured an engagement at Covent Garden, where his first operetta. The *Shepherd's* Artifice, was performed in 1764. He made a hit the following year as Ralph in Samuel Arnold's The Maid *of* the *Mill* and in 1768 produced his first great success. *The* Padlock, at the Drury Lane theatre. Later came The *Waterman* (1774) and The *Quaker* (1775). Dibdin then spent two years in France (1776–78). He was always restless and often irascible. and as a result many of his theatrical ventures ended in quarrels. In the 1783 season he had a short success as manager of the Royal Circus (later the Surrey theatre). His ballad opera Liberty Hall, which included the popular song "The Bells of Aberdovey," was produced at Drury Lane in 1785. He went on a tour of England (1787–88) to raise money for a projected visit to India. which never came about. Next he devoted his talents to his celebrated one-man "table entertainments," at which many of his famous sea songs were first heard; the best-known of all is the elegaic "Tom Bowling," said to have been written in memory of his brother. In these Dibdin appeared as author, composer. singer and accompanist. In 1803 the government granted him a pension in recognition of his services as a writer of patriotic songs during the Napoleonic Wars. He died in London on July 25, 1814.

Dibdin wrote about 100 dramatic pieces and about 1,400 songs. often to his own words, and a number of instrumental works. He also published The *Musical Tour* of Mr. Dibdin (1788). The *Professional* Life of *Mr.* Dibdin, four volumes (1803). *A Complete History* of the English Stage, five volumes (1800), and various music textbooks and several novels. As a composer he was largely self-taught. and his technique was always rather clumsy. It is as a composer of songs that his reputation must stand or fall. He was a born melodist and knew how to write a song that suited the

voice. Some of his best tunes occur in his operas, and led to 20th-century revivals of some of his stage works, including *The Waterman, The Recruiting Sergeant, The Padlock* and *Lionel and Clarissa.*

See E. R. Dibdin, *A Charles Dibdin Bibliography* (1937).

(Cs. Ch.)

DIBDIN, THOMAS FROGNALL (1776–1847), English bibliographer who helped to stimulate interest in bibliography by his own enthusiastic though often inaccurate books, by his share in founding the first English private publishing society and by his beautifully produced catalogue of Lord Spencer's private library. Born in Calcutta and educated at St. John's college, Oxford, Dibdin began a legal career, but took orders in 1805. His *An Introduction to the knowledge of rare and valuable editions of the Greek and Latin Classics* (1802) attracted the notice of Lord Spencer. through whose patronage he became in 1824 rector of St. Mary's, Bryanston square, London, where he remained until his death, Nov. 18, 1847. Lord Spencer also employed him to catalogue and augment his library at Althorp (which later formed the basis of the Rylands library, Manchester). His *Bibliotheca Spenceriana* (1814–15) became famous as an example of fine printing. Dibdin traveled widely in search of books and manuscripts and his *Bibliographical, Antiquarian and Picturesque Tour in France and Germany* (1821) is typical of his work in containing much lively anecdote, many errors of fact and excellent engravings.

His *Bibliomania* (1809) contributed to the passion for old and rare books which reached a peak in the famous Roxburghe sale (1812), to commemorate which Dibdin proposed a dinner for bibliophiles from which developed the Roxburghe club.

DIBDIN, THOMAS JOHN (1771–1841), English actor, dramatist and song writer, best known for the songs "The Oak Table" and "The Snug Little Island," was born in London, March 21, 1771, the illegitimate son of Charles Dibdin (*q.v.*), by the actress Harriet Pitt. He was apprenticed to a London upholsterer, then to William Rawlins, later sheriff of London, but ran away to join a company of actors. Returning to London in 1795, he became prompter and joint stage manager at Sadler's Wells theatre and was later prompter and pantomime writer at Drury Lane theatre. In 1816 he took the Surrey theatre, but this proved disastrous. After this he managed the Haymarket theatre but without success. He died in London. Sept. 16. 1841.

Dibdin was a prolific writer of operas, comedies, farces and pantomimes, and composed many songs. These works brought him great popularity and the theatres great profits. His pantomime *Mother Goose* (1807), in which Grimaldi appeared as clown. is said to have brought over £20,000 to Covent Garden. and another pantomime, *The High-mettled Racer* (1812), adapted from his father's play, £10.000 to the Royal amphitheatre. He wrote nearly 200 plays and operas, and published several collections of songs.

See *Reminiscences of Thomas Dibdin* (1827).

DIBELIUS, MARTIN (1883–1947), German biblical scholar, one of the originators of "form criticism" in New Testament studies *(see* EXEGESIS AND HERMENEUTICS, BIBLICAL). was born in Dresden on Sept. 14, 1883. He became New Testament *Privatdozent* at Berlin (1910) and then professor of New Testament at Heidelberg (1915), where he remained till his death on Nov. 11, 1947.

Dibelius' first publications on the demons and spirits in Paul's theology (1909) and on John the Baptist (1911) showed the connection of two questions that remained characteristic for his work: the search for the oldest tradition by literary analysis and observation of the form of the individual tradition and the religio-historical derivation. Both interests were united in the exegesis of the Epistle of James (1921), whose connection with Jewish hortatory literature he proved, and in the analysis of the forms of the tradition in the Synoptic Gospels, *Die Formgeschichte des Evangeliums* (1919; 2nd ed. 1933; Eng. trans.. *From Tradition to Gospel,* 1934). In this work, which gave the name to a new method of investigation, Dibelius tried not only to sort out the individual items of the oral tradition from the written gospels but also to draw inferences about the genesis and the original sense of those traditions by studying the motives that governed the forming of the traditions. He applied this method to other parts of the New Testament. especially Acts, and investigated the ethical teaching of the New Testament, working at these questions in connection with the theological research of the ecumenical movement. His books on Jesus (1939; Eng. trans. 1951) and Paul (1951; Eng. trans. 1953) are valuable representations for the general reader.

See list of Dibelius' works in "Bibliographia Dibeliana atque Bultmanniana," *Conjectanea Nestestamentica,* vol. viii, pp. 1–22 (1944). *See* also memorial notice by W G. Kümmel in *Theologische Literaturzeitung,* vol. lxxiv, pp. 129–140 (1949) (W. G. Kü.)

DICAEARCHUS (fl. *c.* 320 B.C.), of Messene in Sicily, Peripatetic philosopher, was a pupil of Aristotle. Neglecting systematic philosophy as did most Peripatetics of his generation, he cultivated special branches of knowledge. including the history of literature and of music, biography, political science and geography. Under the title *Bios Hellados* ("Life of Greece") he wrote a history of Greek civilization from the beginning; in another monograph he seems to have characterized Sparta as a happy mixture of monarchy. aristocracy and democracy, thus foreshadowing Polybius' interpretation of Rome and its stupendous rise. In psychology he shared the anti-Platonic view of Aristoxenus that the human soul is mortal.

See the fragments ed. by F. Wehrli, *Dikaiarchos* (1944), part i of *Die Schule dcs Aristoteles: Texte und Kommentar;* also "Dikaiarchos" in Pauly-Wissowa, *Realencyklopädie der klassischen Alterlumswissenschaft,* v (1903). (F. Wi.)

DICE, small cubes used in gaming. each individual cube being called a die. Usually the six faces of the die are marked with a number of small dots, from one to six. The dots are arranged in conventional patterns and placed in conventional relative locations, thus: the dots on the opposite faces must always total seven, one opposite six, two opposite five, three opposite four. When the visible vertical face is two and the top face is four, then six must be to the left and one to the right. These conventional locations have no significance in games, and mathematical probabilities applying to dice are constant so long as no two faces of a die are similarly marked.

In all games played with dice, the dice are cast (or thrown, or rolled, or shot, or tossed) in such a way that they will turn at random in the air and then come to rest on some flat surface. The combination of the topmost surfaces of the dice decides, according to some predetermined pattern, whether the caster wins or loses.

Dice in various forms are the oldest gaming implements known to man, and innumerable games are and have been played with them. Craps, the most popular gambling game of the U.S., is played with two dice; chuck-a-luck, another popular gambling game. with three dice; in more social play there are poker dice, played with five dice, and various games, notably yacht and Cameroons. played with ten. In backgammon, parcheesi (pachisi) and hundreds of "track games" two or more dice are cast to determine the moves.

The forms of dice are almost as varied as the games played with them. Like many other gaming implements *(see* GAMBLING AND BETTING) dice apparently evolved independently in many primitive societies and ethnic groups. Sophocles' attribution of the invention of dice to Palamedes. a Greek, during the siege of Troy and Herodotus' attribution to the Lydians have been discredited by numerous archaeological finds. Cubical dice with markings practically equivalent to those of modern dice have been found in Egyptian tombs dated earlier than 2000 B.C. and in Chinese excavations dated as early as 600 B.C.; dice are mentioned also in the Rigveda.

American Indians. both north and south, used waferlike dice having only two effective faces. Perhaps the earliest gaming implements equivalent to dice were knucklebones (the anklebones of sheep), marked on four faces and used in games of chance or skill long before the times of written history. Similarly pyramidal dice. and also pentahedral and octahedral dice: have been used.

The first use of dice may have been for religious purposes (divination) and for lottery; the markings on early Korean and

FIG. 1.— (LEFT) EGYPTIAN DIE REPUTED TO BE FROM THE TOMB OF OSIRIS, ABYDOS. EGY.; (CENTRE) CHINESE DIE OR KNUCKLEBONE; (RIGHT) ETRUSCAN DIE FROM CHIUSI, ITALY

Chinese dice have led some scholars to that conclusion. but there is no evidence as to whether the gaming or the divinatory use was earlier. In ancient times and in primitive societies dice were most often cast from receptacles (now called dicecups) and this practice has persisted in many games but has been generally abandoned in craps The ancient Greeks cast dice from conical beakers and the ancient Romans from cylindrical vessels similar to modern dicecups. American Indians wove special baskets, usually about 10 in. in diameter, in which they tossed their dicesticks.

Modern dice are almost all made of a cellulose or other plastic material. They are sawed from extruded rods of the material and the best dice must be within .003 in. of perfect cubes. The dots are stamped into the faces of the dice and often are then coated or filled with a paint. The most popular dice are transparent, which is considered to give protection against "loading" (introduction of a heavy metal into the dots so that one face will be most likely to come to rest downward). The corners of the dice may be rounded, but square corners are usually preferred. The earliest Asiatic and Mediterranean dice were made of bone, but ivory, wood. stone, metals, glass, amber and jade and gem stones. and even plum pits, nutshells, teeth and an almost unlimited variety of other materials have been used.

Specially made dice for cheating have been found in some of the most ancient excavations. They were not much different from "crooked" dice whose manufacture and sale is a flourishing modern business. "Loaded" dice have been mentioned. Dice that are not "square" (not perfect cubes) will tend to land more often on certain faces than on others. Dice with certain faces duplicated and certain numbers omitted will tend to produce some numbers in disproportionate frequency and never to produce certain other numbers; for example. two dice marked respectively with duplicates of 3–4–5 and 1–5–6 can never produce combinations totaling 2. 3, 7 or 12, which are the only combinations with nhich one can lose in the game of craps. Such dice, called "tops," must be introduced into the game by sleight of hand and so are used only by accomplished practitioners of cheating. Since it is impossible to see more than three faces of a die at any one time, mismarked dice are unlikely to be detected except by a suspicious person.

Cheating at dice is possible also by the exercise of manual skill on "square" dice. The cheater may cause one die to slide, so that its top face when it comes to rest will be the same as nhen it left his hand; or he may cause one or both dice to roll straight ahead, so that the two faces at the sides of each die cannot appear at the top. Such manipulations affect the mathematical probabilities and permit the cheater to make favourable bets. In many games a person may win by no other expedient than superior knowledge of the probabilities; his method is to make only bets that give him a mathematical advantage. Though this may objectively be considered an exercise of skill, which is deemed legitimate in other games, in most dice games it is considered unethical to exploit such an advantage.

Probabilities.— Assuming the use of square dice, skill in dice games consists solely in knowing the mathematical likelihood that any total number will appear when two or more dice are cast at random. The ultimate probabilities are subject to the theory of combinations and permutations, but in most dice games they can be ascertained by application of the most simple arithmetic. The basic assumption is that any one face on each die is as likely to appear face up as any other face. Given a standard six-faced die, when one tosses it there is one chance in six that any specified face will appear, which is to say that the odds are 5 to 1 against the appearance of any specified face. When two dice are used, the number of nays in which the faces can appear is $6 \times 6 = 36$. In these 36 combinations there is only one combination (1–1) that will produce the result 2, and 35 that will not, so the chances are 35 to 1 against casting a 2. There are 6 combinations that will produce 7 (4–3, 3–4, 5–2, 2–5, 6–1, 1–6) and 30 that will not. so the odds against casting a 7 on any particular cast are 30 to 6, which is 5 to 1. When three dice are cast, as in chuck-a-luck, the combinations are $6 \times 6 \times 6 = 216$; when four dice are cast the combinations are $6 \times 6 \times 6 \times 6 = 1.296$; and so on. The chances of success are calculated by comparing the number of favourable casts nith the number of unfavourable casts. For example, the only casts that will produce the total 5 with four dice are 1–1–1–2, 1–1–2–1, 1–2–1–1 and 2–1–1–1, making the odds 1,292 to 4, or 323 to 1, against such a cast.

GAMES PLAYED WITH DICE

Craps.— Early in the 20th century craps replaced faro (*q.v.*) as the principal gambling game of the United States. The game of craps is played in all U.S. gambling houses and has been introduced into several European casinos including that at Monte Carlo. Its popularity with U.S. military personnel caused it to spread to many other parts of the world during World Wars I and II.

The name craps derives from a nickname of the cast 1–1, which was called "crabs" at least as early as the 16th century. The modern rules of craps grew out of an old English dice game called hazard (*q.v.*). There are considered to be three ways to play craps (in U.S. idiom invariably called crapshooting or shooting crap); they are respectively called a crap game (all participants amateurs, with no common gambler present), bank craps (the gambling house game, in nhich all bets must be made against the house) and open craps, a game in which the players are permitted to bet among themselves but a common gambler is present to serve as arbiter and to accept (on his own termr) any bet that a player is unable to place with another player. In bank craps and open craps, the proprietor fixes the rules so that he has a mathematical advantage on every bet, but usually this advantage is quite small (for example 1.4%) and is not objectionable to the players.

The bank craps game requires a special table, in size and form not unlike a billiard table, which includes a layout or marked area in which players may place their bets and an open area in which the dice are thrown. In open craps a layout is used. but no other special equipment. In an amateur crap game the players stand or sit in a circle, in the centre of which the bets are placed and the dice are thrown.

The following rules apply to all forms of craps:

Tno matched dice are used. One player, the shooter, "has the dice." He bets whatever amount he wishes. Any other player may "fade" (accept, or cover) all or any part of this bet. When the entire bet has been faded (or when the shooter has "dragged down" any part of the bet that was not faded or that he wishes to withdraw), the shooter rolls the dice.

On the first roll, if the uppermost faces of the dice total 7 or 11 (a "natural"), the shooter wins; if they total 2, 3 or 12 ("craps"), the shooter loses but remains the shooter ("keeps the dice") and may place another bet. If on the first roll the total is 4. 5, 6, 8, 9 or 10, the respective number becomes the shooter's "point." He continues to throw the dice until his point appears again, in which case he wins. or until a seven appears, in which case he is said to "miss," "missout," "seven out" or "crap out"—he loses the bet and the dice, and the man at his left becomes the next shooter.

Every time the shooter wins a bet either by throwing a natural on the first roll or by "making a point," he is said to "pass"' or "make a pass." After each pass, the shooter may drag down, taking part of his winnings and leaving the rest for his next bet; "let it ride," betting his original stake plus all his winnings; or withdraw all his money and "pass the dice" (let the next player in turn become the shooter). A player is said to be "right" when he wins and "wrong" when he loses.

There are no official rules for any dice game, but the following are generally accepted in amateur games:

1. When the dice have come to rest. they must not be touched until the shooter and all who faded him have had an opportunity to see them.

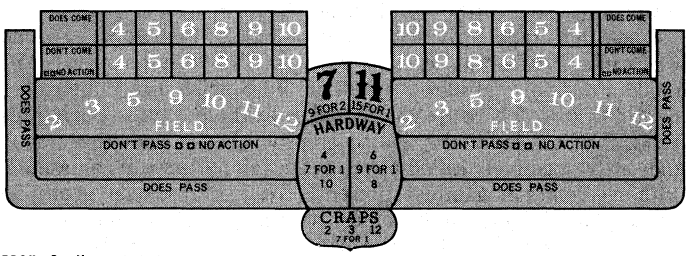
2. If either die rolls outside the playing area (formed by the circle of players) or is "cocked" (leaning against a foreign object) the cast is void.

3. Any player who has faded part of the bet may intercept either die before it comes to rest, in which case the cast is void. It is usual to say "No dice" when stopping a die.

4. The wlayer who last lost the dice has the first privilege of fading as much as he wishes of the next shooter's bef.

In bank craps the equipment makes the first two of these rules unnecessary. but it is invariably required that the dice be thrown over a string or wire stretched across the table a few inches above its surface, or that the dice strike a wall of the table and bounce back. The third rule is not used and the fourth is inapplicable because all bets must be placed against the house. Bets are usually made with chips but sometimes nith cash. and a player signifies his bet by placing (before any roll) the chips or cash on the appropriate part of the layout.

The shooter. or anyone wishing to bet that the shooter will win, places his bet "on the line" (in the area marked DOES PASS in fig. 2, LISE in fig. 3 or WIN on some layouts). Anyone betting against



FROM S. M MACDOUGALL

FIG. 2.— DOUBLE DEALER LAYOUT. EMPLOYEES OF THE HOUSE ARE POSTED AT EACH END OF THE TABLE AND BETTORS MAY PLACE THEIR BETS AT EITHER END. THIS LAYOUT OFFERS THE BETTOR MORE FAVOURABLE ODDS THAN THE PHILADELPHIA LAYOUT

the shooter places his bet in the area marked DON'T PASS. Anyone wishing to bet on a special contingency, such as that craps (2. 3 or 12) will or will not be thrown on the next roll. places his bet in the appropriate space in the layout; such bets are called proposition bets. A bet on the "held" is a bet that one of the numbers shown in that area will come up on the next roll. A "come bet" is a bet that the shooter nill win, treating his next roll as the first. whether or not it actually is his first roll. "Point bets" are bets that the shooter will make his point, after his first roll has proved not to be a natural or craps.

In every bet. the house retains a mathematical advantage. The odds against the shooter's winning are 251 to 244, so that the shooter is always at a disadvantage of 1.41%, which means that of every $100 he bets he will lose an average of $1.41. The player who fades has a reciprocal advantage! but to offset this the gambling house provides that there shall be a standoff, or 'no action," on either the 1–1 or the 6–6 first roll (one or the other, but not both). When such a number appears, instead of winning the player may merely withdraw his bet. With this special rule the house has about 1.4% advantage even when a player "bets wrong" (bets against the shooter).

The exact odds are 6 to j that the shooter will not make his point if it is 6 or 8. but the house offers even money; 3 to 2 that he will not make his point if it is j or g. but the house offers 7 to j; 2 to 1 that he nill not make his point if it is 4 or so. but the house offers 5 to 3. On all the other bets the house reserves an even greater advantage. The "hard way" or "gag" bets are bets by the gambling house that the shooter will not make a point of 6 with 3–3. a point of 8 with 4–4 (in each case the mathematical odds are 10 to 1 but the house bets 9 to 1), a point of 4 with 2–2 or a point of 10 with j–j (in each case the mathematical odds are 8 to 1 but the house bets j to 1).

FIG. 3.— THE PHILADELPHIA ,LAYOUT IS USED IN GAMBLING HOUSES WHERE THE PATRONS ARE NOT WELL-INFORMED ON THE PROPER ODDS IN CRAPS. THE TERM "FOR" IN QUOTED ODDS MEANS THAT THE PAYOFF INCLUDES THE BETTOR'S STAKE AND IS NOT IN ADDITION TO IT

Some gambling houses use the so-called Philadelphia layout (see fig. 3), which reserves a far greater advantage to the house. The cast 1–2 instead of 1–1 or 6–6 is barred (a standoff), increasing the house advantage to 4.13%; and bets are quoted as, for example. 7 *for* 1, which is equivalent to odds of 6 *to* 1 because the payoff of seven includes the original bet of one.

There are many special bets offered by gambling houses and by individuals at amateur and open games. The disadvantage in accepting such bets is considerably greater than the disadvantage when betting only on the shooter to win or to lose. (A. H. MD.)

Chuck-a-Luck.— This gambling game is played chiefly in the western hemisphere. A layout numbered from 1 to 6 inclusive. a table, three dice and a dicecup are the essentials. The dice may be kept in a wire cage shaped like an hourglass. When the cage is reversed the dice fall through the centre opening to the bottom half. In this form the game is often referred to as the bird cage. The dice may also be dropped through a cone-shaped chute, made of leather or metal and called a "horn," to come to rest on the table within the base of the chute. The chute is then lifted to reveal the faces of the dice. The term "tin horn gambler" derives from gamblers who set up games of chuck-a-luck with scant capital and a metal chute, which was cheaper than a leather one.

Players may bet any amount within the minimum and maximum limits on one or more of the six numbers. When all bets are down the dice are thrown or dropped through the chute, or the wire cage is upended. The uppermost faces of the three dice determine the outcome. If the player's selected number shows on one die, he wins the amount he wagered; if on two dice, he wins double; if on three dice, he wins triple. The house breaks even when three different numbers are thrown; averages a profit of one unit when a pair and a single are thrown; averages a profit of two units when three of a kind are thrown. This amounts to 7.87% of the total.

Crown and Anchor.—A game much played in Canada, uses the same equipment as chuck-a-luck except for the markings on the dice. Instead of dots, the six sides bear various symbols: anchor, crown, club: diamond, heart and spade. The layout used displays these same symbols. Method of play, amount of payoff and house, percentage are identical with chuck-a-luck.

Hazard.—This is the game from which chuck-a-luck evolved. In the United States almost all houses with hazard layouts refer to the game as chuck-a-luck. This game of hazard should not be confused with the old English and French game of hazard from which the dice game craps evolved (see HAZARD).

The only material difference between hazard and chuck-a-luck is in the layout. (See fig. 4.) Besides the six chuck-a-luck numbers the hazard layout provides spaces for wagering on odd or even; on high or low; on triples (called raffles); and on any number the dice may total, from 4 to 17. Three, the lowest number possible. and 18, the highest number possible, can only be made with triples so they are not included in the regular line.

The payoff on single numbers is the same as in chuck-a-luck. A player betting on high. low. odd, or even, collects even money if he wins. The banker's advantage lies in the fact that he does not pay off if triples show. There are 216 possible combinations of 3 dice. 6 of which are triples. On this type of bet the house

advantage is 2.78%. If a player bets that any three of a kind will come up, he collects 30 to 1. (Correct odds—35 to 1; house advantage—13.9%.) If he bets that a particular triple will show, and he wins, he collects 180 to 1. (Correct odds—215 to 1; house advantage—16.2%.) The percentage in favour of the house nhen a player bets on any particular number varies considerably, as shown by this table.

Combination	*Actual Odds*	*House Pays*	*House Advantage*
4 or 17	71 to 1	60 to 1	15.3%
5 or **16**	35 to 1	30 to 1	13.9%
6 or 15	23 to 1	**18** to 1	20.8%
7 or 14	67 to 5	12 to 1	9.7%
8 or **13**	**6**5 to 7	**8** to 1	12.5%
9 or 12	8 to 1	**6** to 1	**22.27%**
10 or 11	7 to 1	**6** to 1	12.5%

To explain how the percentages are figured: suppose the chosen number is 6. There are 10 ways to make 6 with three dice—1–1–4, 1–4–1, 1–2–3, 1–3–2, 2–2–2, 2–1–3, 2–3–1, 3–1–2, 3–2–1, 4–1–1. The house does not pay off when 6 is made with three deuces, leaving 9 winning combinations for the player. There are 216 possible combinations. Deduct the 9 winning combinations. The odds are 207 to 9, or 23 to 1. The house pays

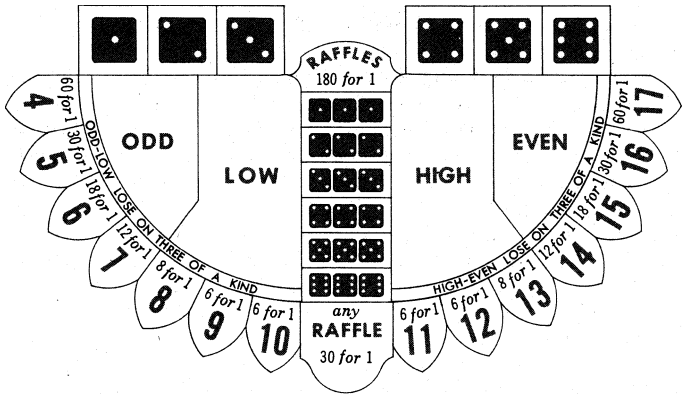

FIG. 4.— LAYOUTSED FOR HAZARD

18 to 1. The difference between these two figures—24 for the house, 19 for the player—constitutes the house "edge" (advantage)—$\frac{5}{24}$ of 100 is 20.8%. (S. M. M.; A. H. MD.)

Barbooth or **Barbudi.**—This is a two-dice game of Balkan and Levantine origin. It is much played in the U.S., chiefly by persons of Greek, Armenian and Syrian ancestry. Alone among popular dice games it provides no mathematical advantage for any player or for the gambling house. It is commonly played in gambling houses that charge fees (usually $2\frac{1}{2}$% of the amount betj for providing the space and equipment for the game.

Two persons play against each other. Each in turn casts two dice from a dicecup. If a player casts 3–3, 5–5, 6–6 or 6–5, he wins; if he casts 1–1, 2–2, 4–4 or 1–2, he loses. All other casts are meaningless. The shooter has the right to cover the stakes, which are named by his opponent; if he leaves any part uncovered other players may take it and the other players may also bet among themselves as to which shooter will win or lose. After each bet is decided, the losing shooter passes the dice to the player at his left, who becomes the shooter against the player who won the preceding bet.

4, 5, *6* or See-Low.—This is one of the most popular games of the U.S. and Canadian Pacific northwest and among members of the U.S. armed services. It is derived from a Chinese game several hundred years old, called Sz' 'ng Luk ("Sing luck").

Three dice are used. Each player in turn may be the banker, or one person may be a permanent banker (the latter arrangement is unusual; because the banker has an advantage). The banker stakes some amount of money and each player in turn to his left may cover any portion of his stake not already covered.

The banker casts the dice first. If he casts any three of a kind (such as 1–1–1), or any pair plus 6 (such as 2–2–6), or 4–5–6, he wins all bets. If he casts 1–2–3 or any pair plus 1 (such as j–j–I): he loses all bets. If he casts any pair plus 2, 3. 4 or j (such as 5–5–2), the unpaired number is his "point." All combinations except the ones stated are meaningless and the banker casts again.

If the banker gets a point, each other player in turn to the banker's left rolls the dice to determine the outcome of his bet against the banker. The winning and losing numbers are the same for each such player as for the banker (three of a kind, 4–5–6 or a pair plus 6 wins; 1–2–3 or a pair plus 1 loses). If the player gets a point and it is higher than the banker's point, he wins; if it is lower than the banker's point, he loses; and if it is the same as the banker's point, the bet is called off.

The banker's advantage lies in the fact that there are more winning than losing combinations and he has the first chance to roll them; in 162 bets he should win 83 and lose only 79, giving him an advantage of about 2.47%.

Poker Dice.—Five standard dice may be used, but there are also special dice whose six faces are marked as playing cards, with ace, king, queen, knave (jack); ten and nine. Each player may cast three times, and after each cast he may leave any number of dice standing and cast the remaining dice. The faces of the dice at the end of his third cast are his "hand." The rank of the hands is the same as in poker (*q.v.*), except that there are no flushes and, in most games, straights do not count; in the version generally known as Horses (played in taverns for drinks) five aces lose.

Liar Dice.—A form of poker dice, popular in the U.S. army, in which a screen divides the two contestants. After casting the dice as in poker dice, a player announces the best poker hand he can make, but his announcement need not be truthful. His opponent may roll for a higher hand, or challenge the announcement, in which case the player must reveal his dice and he wins if his announcement was correct, loses if it was not.

Yacht, Other Ten-Dice Games.—In a number of games in which ten dice are used, the procedure is much the same as in poker dice. Each player has five casts. After each cast he may leave standing such dice as satisfy him and cast the rest. Various dice combinations are assigned scoring values. The ten dice faced at the end, scored by the rules of the game, determine the player's standing.

Twenty-Six, Other Counter Games.—In midwest U.S. and in some other parts of the country, taverns have dice games in which customers may play, for a small fee such as 25 cents, to win checks or tokens that can be cashed for drinks, cigarettes or other merchandise. The most popular such game is "Twenty-six." The player selects any number from one to six before he begins to cast the dice. He then throws ten dice 13 times. If his number appears 26 or more times he wins; if it appears fewer than 26 times he loses. The player's expectancy is to throw his number only $21\frac{2}{3}$ times in 13 casts, so that on each 25 cents bet against it the house should make a profit of 43 cents.

Other popular counter games are "Bingo," a two-dice game; "Klondike," a five-dice game similar to poker dice except that the house wins in case of a tie; and "Qualify," a game similar to poker dice except that the player tries to reach a total of 25 points, counting the spots on the dice thrown. In all such games except Qualify the house has an advantage; the game of Qualify is used chiefly to stimulate sale of merchandise.

BIBLIOGRAPHY.—John Scarne and Clayton Rawson, *Scarne on Dice*, the definitive work (1945); A. Morehead, Richard L. Frey and G. Mott-Smith, *New Complete Hoyle* (1958); Michael MacDougall, *MacDougall on Dice and Cards* (1944). (A. H. MD.)

DICENTA, **JOAQUÍN** (1863–1917), Spanish dramatist and journalist. whose *Juan Jose'* (189j), a simple yet powerful tragedy of jealousy with class-war overtones, was one of the greatest Spanish theatrical successes of the 19th century. Born in Calatayud, and baptized on Feb. 3, 1863, he spent most of his somewhat bohemian life in Madrid and died in Alicante, Feb. 20, 1917. His first play, *El suicidio* de *Werther* (1888), was a conventional verse drama in the romantic manner of José Echegaray. but *Los irresponsables* (1890) and *Luciano* (1894) caused scandal by their treatment of matrimony. After the success of *Juan Jose'*, he found subsequent similar works less remunerative and turned to writing

lighter forms of entertainment, but he never entirely abandoned his mission as social dramatist, as is shown by the naturalistic mass drama, Daniel (1907). (H. B. HL.)

DICENTRA, a genus of perennial herbs of the fumitory family (Fumariaceae) that includes the familiar garden plants bleeding heart (D. *spectabilis*) and dutchman's breeches (*D. cucullaria*). See BLEEDING HEART; DUTCHMAN'S BREECHES.

DICEY, ALBERT VENN (1835–1922), English jurist and author of a standard and seminal work on constitutional law. Born at Claybrook hall, near Lutterworth, Leicestershire. on Feb. 4, 1835, and educated at Balliol college, Oxford, he became a fellow of Trinity college in 1860, and was called to the bar of the Inner Temple in 1863. He became first Vinerian professor of English law at Oxford, and a fellow of All Souls, in 1882, and took silk in 1890. He retired from his academic posts in 1909, but continued to practise until 1916. He died at Oxford. April 7, 1922.

Dicey's Introduction to the Study of the Law of the *Constitution* (1885) took its rise from his professional lectures, and revealed his knowledge of both English and U.S. constitutional law. A series of lectures at Harvard (1898) formed the basis for another authoritative book. Lectures on the Relation between Law *and Public Opinion* in England during the *19th* Century (1905). That detailed knowledge did not prevent him from relating specific problems to wider issues is also revealed in *A* Digest *of* the Law *of* England with *Reference* to the Conflict *of* Laws (1896). Clarity of thought and brilliance of exposition combined to make his works classics in their kind. A determined opponent of Home Rule for Ireland, he also published political works in support of Liberal Unionism.

His elder brother, EDWARD JAMES STEPHEN DICEY (1832–1911), was a noted journalist and writer on foreign affairs. As special correspondent and leader-writer for the Daily Telegraph (1862–69), and editor of the Observer (1870–89), he exercised considerable influence on public opinion, and his descriptive skill, easy manner and shrewd judgments gave his many books, based on his journalistic travels, considerable popularity.

DICHOTOMY, literally a cutting asunder, the technical term for a form of logical division, consisting in the separation of a class into two subclasses, one of which has and the other has not a certain quality or attribute (Gr. dicha, "apart"; tome, "cutting"). Men may be thus divided into white men and men who are not white; each of these may be subdivided similarly. On the principle of contradiction this division is both exhaustive and exclusive; there can be no overlapping. and no members of the original genus or the lower groups are omitted. This method of classification, though formally accurate, has slight value in the exact sciences, partly because at every step one of the two groups is merely negatively characterized and may be unreal; but it sets forth clearly the gradual descent from the most inclusive genus (*summum genus*) through species to the lowest class (*infima* species); which is divisible only into individual persons or things. (See DIVISION.)

In astronomy the term is used for the aspect of the moon or of a planet when apparently half illuminated. so that the illuminated part of its disk has the form of a semicircle.

DICK, GEORGE FREDERICK (1881–), U.S. physician, codiscoverer with his wife, Gladys Henry Dick, of the cause, prevention and cure of scarlet fever (*q.v.*), was born at Ft. Wayne, Ind., on July 21, 1881. Trained in Europe as a pathologist, Dick, a graduate of Rush Medical college, Chicago (M.D. 1905), chose scarlet fever as his research field while serving as a major in the medical corps with the American expeditionary forces in France during World War I. From 1918 to 1933 he was professor of clinical medicine at Rush. In 1933 he became chairman of the department of medicine at The University of Chicago? where he served until his retirement in 1945.

Dick's researches were presented in more than 150 papers on many subjects. In 1923 he and his wife isolated the hemolytic streptococcus that causes scarlet fever and prepared the toxin and antitoxin that act as a preventive and cure. In 1924 they developed the Dick test, a skin test for susceptibility to scarlet fever. (L. ER.)

DICKCISSEL (*Spiza* anzericana), **a** North American finch characteristic of the midwestern grasslands. A brown-backed, sparrowlike bird with yellow breast, and with black bib in the male, it is often called little meadow lark. The common name derives from the bird's metallic, grating song—*dick-dick-cissel-cissel*—often heard along the roadside in summer. The grass-cup nest is placed on the ground or in a shrub. The four or five greenish-blue eggs require 11 days to hatch, and the young receive nest care for another 11 days. In the northern part of the range. populations shift unaccountably from year to year. (W. J. BE.)

DICKENS, CHARLES JOHN HUFFAM (1812–1870), the most popular and perhaps the greatest of English novelists, was born on Feb. 7, 1812, in Landport, a division of Portsea (later in Portsmouth), in what is now 393 Commercial road. The house is a museum; and perhaps the actual address indicates little more than the drifting and often decaying fortunes of the class and family from which Dickens came. It would be an exaggeration to compare it to Lant street, in the Borough, in which Rob Sawyer (of *The Pickwick* Papers) had his lodgings and of which, it will be remembered. "the inhabitants were migratory, disappearing usually towards the verge of quarter-day." But there is the note of something nomadic about the social world to which he belonged. We talk of the solid middle class; he belonged, one might almost say, to the liquid middle class; certainly to the insecure middle class.

Parentage and Early **Life.**—Dickens' father, John Dickens, was a clerk in the navy pay office, and all through life a man of wavering and unstable status, partly by his misfortunes and partly by his fault. It is said that Dickens sketched him in a lighter spirit as Micawber (in David *Copperfield*) and in a sadder and more realistic spirit as Dorrit.. The contrast between the two men should be a warning against the weakness of taking too literally the idea of Dickensian "originals." The habit may have done injustice to a few people, such as Leigh Hunt (Skimpole of Bleak *House*); it involves some unfairness to John Dickens; and perhaps even more to his wife, née Elizabeth Barrow, who is reported to have been the real Mrs. Nickleby. Some may question (not without grief) whether there ever really could be a real Mrs. Nickleby. But in any case we shall misunderstand the whole nature of the Dickensian imagination if we look on these things as mechanical portraits in black and white taken by "the profeel machine," as Mr. Weller (of The *Pickwick* Papers) said. It is almost the whole point of Dickens that he took hints from human beings; and then turned them, one may say, into superhurnan beings. He relied on reality, but transformed it by his imagination. Yet it is true that, like Micawber. John Dickens was of the type that is often shifted from place to place; and this is the chief significance of Charles Dickens' connection with Portsea, or rather of his lack of connection with it. He was only two years old when the household moved to London. The family returned to Chatham in 1817. It was perhaps lucky that the formative period of Dickens' early childhood was also the most fortunate period of his not very fortunate family. The dockyard of Chatham, the towers of Rochester. the gardens and the great roads of Kent, remained with him through life. They were his native soil and the birthplace of his fancy. His house in later years looked down on the great Dover road from Gad's Hill and the cathedral tower of Rochester rose again in his last vision, in the opium dream called "Edwin Drood." There he had leisure to learn a little from books, who was so soon to learn mainly from life; first in the stricter sense of school books, from a Mr. Giles, a Baptist minister in Chatham; and second, and probably with greater profit, from a random heap of old novels that included much of the greatest English literature and even more of the type of literature from which he could learn most: Roderick *Random* and Robinson Crusoe and Tom. Jones and The Vicar of *Wakefield.*

He was no more than ten years old when the household was once more upon the march. John Dickens had fallen into debt. His wife, the mother of eight children of whom Charles was the second, tried to open a dingy sort of school. No one ever came to it; the old novels went to the pawnshop; and Charles lingered at home. Then, "in an evil hour for me," so Dickens wrote, he

was thrown forth to earn his own living by tying and labeling pots of blacking in an old blacking warehouse, which was managed by a relative on his mother's side. The blacking was symbolical enough; Dickens never doubted that this piece of his childhood was the darkest period of his life; and he seems indeed to have been in the mood to blacken himself all over like the Othello of the Crummles company in *Nicholas Nickleby*. His father continued his tendency to change his private address; and his next address was the Debtors' prison of the Marshalsea. Of the heart-rending monotony and ignominy of this pessimistic period Dickens has given no more than a bitter abbreviation in both *David Copperfield* and in the striking fragment of autobiography preserved by his friend and biographer John Forster. But he was storing up much more than bitterness; it is obvious that he had already developed an almost uncanny vigilance and alertness of attention. By the time his servitude came to an end, by his father's falling into a legacy as he had fallen into jail, the boy was no longer a normal boy, let alone a child. He called his wandering parent "the prodigal father" and there mas something of the same fantastic family inversion in the very existence of so watchful and critical a son. Some of the best passages about prison life in *Pickwick* and *Little Dorrit* derive directly from the 12-year-old boy's observation; for everything he saw then, so Dickens wrote later, was perceived "quite as well as I should perceive it now."

On his father's release he shared in the improved fortunes of the family. He went back to school, he served as a solicitor's clerk and he worked hard to educate himself. He learned shorthand and became a reporter. first in the lam courts and then in parliament. He was employed on the *True Sun,* on his uncle's *Mirror of Parliament* (Hansard's rival) and, in 1834, on the *Morning Chronicle.* In all these aspects he appears as alert. sharp witted and detached. Even at this time, or soon after. he had an air of vitality and the countenance of a man of action. "Light and motion," remarked one observer. "flashed from every part of it." "It seemed as if made of steel," Mrs. Carlyle was to write four or five years later. It is worth noticing, perhaps, because certain healthy social emotions which he always championed have rather falsified his personality in the eyes of the prigs whom he loved to rap over the head. He was a genuine champion of geniality; but he was not always genial; certainly not only genial. All his life he defended the pleasures of the poor and the need for generosity; but this has sometimes clouded his character with the fumes of mere conviviality and irresponsibility which were very far from being really characteristic. In his youth, which is the period of irresponsibility, Dickens appears in many ways as highly responsible. He was in sharp reaction against the futility of his family. Even an early and intense attachment to a Miss Maria Beadnell. who was the "original" of Dora Spenlow in *David Copperfield,* did not end in tears or sentiment but in a self-confessed "habit of self-suppression" which, so Dickens explained. "makes me chary of showing my affection even to my children." He was both ambitious and industrious, and there were some who even found him hard. In many moods he had as angry a dislike of the selfishness of the irresponsible, cheerful Skimpoles as of that of the "practical" hard-hearted and hard-headed Gradgrinds (*Hard Times*).

Beginnings of Literary Career. — Dickens soon came in more ways than one to the high turning point of his fortunes. His marriage and his first real literary work can be dated at about the same time. He began by contributing to the old *Monthly Magazine* and went on to write a series of sketches which were, in the broadest sense, caricatures of the life and manners of the time. Many of them appeared in the *Morning Chronicle* and *Evening Chronicle;* they were illustrated by George Cruikshank; and they mere brought out in two series, in 1836, as *Sketches* by *Boz.* Earlier in the same year, the publishers Chapman and Hall had wanted to approach the author with a suggestion for a larger scheme. though at first they did not know who he was. A well-known humorous artist of the time, Robert Seymour, was to produce a series of plates illustrating the adventures. or misadventures, of the Nimrod club, a group of amateur sportsmen, destined to dwindle and yet to grow infinitely greater in the single figure of Mr. Nathaniel Winkle. Dickens agreed to write the letterpress, which was to be little more than a running accompaniment like an ornamental border around the drawings; and in that strange fashion, secondary, subordinate and even trivial. first formed itself in the human fancy the epic and pantomime of *The Pickwick Papers* (1836–37). Dickens persuaded the publishers to let the Pickwick club represent more varied interests or eccentricities, retained Mr. Winkle to represent or misrepresent the original notion of sport; and by that one stroke of independence cut himself free from a stale fashion and started a new artistic adventure and revolution. He gave as one of his reasons the fact that he had no special knowledge of sports or games, and proceeded to drive his argument home triumphantly by his description of the cricket match at Dingley Dell. And yet that cricket match alone might illustrate exactly the game which Dickens so gloriously won; and why that wild and ill-instructed batsman has had so many thousand runs and is not out. What did a few mistakes in the description of cricket. or even in the description of real life, matter in a man who could invent that orator at the cricket dinner, who complimented the defeated eleven by saying, with the gesture of Alexander, "If I were not Dumkins, I would be Luffey: if I were not Podder, I would be Struggles"? Men do not read that sort of thing to learn about cricket! or even about life, but to find something more living than either. There had broken through the entanglements of that trumpery bargain a force of comic genius which swallowed up its own origin and excuses; a wild animal big enough to eat all its direction labels. People forgot about Seymour; forgot about sport; forgot about the Nimrod club; soon forgot about the Pickwick club. They forgot all that he forgot and followed whatever he followed; much bigger and wilder game than any aimed at by the mere gun of Mr. Winkle. The track of the story wandered; the tone of the story changed; a servant whom Pickwick found cleaning boots in an innyard took the centre of the stage and towered even over Pickwick; Pickwick from being a pompous buffoon became a generous and venerable old English gentleman; and the world still follows that incredible transformation scene and wishes there were more of it to this day. This was the emergence of Dickens into literature. It had, of course, many secondary effects in life. One was the first of his literary quarrels. Seymour shot himseif. His family was to claim that Dickens had gained glory from another man's ideas. Nobody, we may well imagine, believes that the oration of Sergeant Buzfuz or the poem of Mrs. Leo Hunter originated with Seymour. Dickens had an inexhaustible torrent of such ideas; and no man on earth could pretend to have provided them. But it is true that in this quarrel, as in others, some found a touch of sharpness and acid self-defense in Dickens; and he was never without his enemies. His ideal was certainly the leisure and geniality of Pickwick; but he was fighting rather too hard for his own hand and had too much at stake and too pressing a knowledge of poverty to be anything but practical.

As Pickwick was the foundation of his public life. his marriage mas naturally the foundation of his private life. His wife was Catherine Hogarth, eldest daughter of George Hogarth, editor of the *Evening Chronicle.* Their marriage has been the object of criticism and curiosity, though little good is done by making guesses about a relationship of which the spiritual balance and proportion were probably never known to more than three or four people. It is significant that those who were nearest to it agreed to be silent rather than impute blame. At the time of the marriage the bride was a bright, pleasant and rather dreamy young woman. She became the mother of a large family, of ten children in all, born over a period of 15 years. Her younger sister, Mary Hogarth, came to live with them, but died suddenly; she was extravagantly mourned by Dickens and enshrined as "Little Nell" *(The Old Curiosity Shop).* After 1842 another sister. Georgina. joined the family to help with the children; and she stayed after Catherine left. For many years the marriage was a happy one, and when the separation came it seems largely to have been due to Dickens' overpowering restlessness, to his demand to put himself and his writing first and to "that wayward and unsettled feeling which," he wrote, "is part (I suppose) of the tenure on which one holds an imaginative life." All this, however, happened long afterward.

For the moment he was a popular writer and a power in the world.

Development as a Novelist. — It is notable that Dickens' next work was *Oliver Twist (1838)*; which might be meant for a contrast to *Pickwick*. If the first trick had succeeded, nobody could accuse the conjurer of trying the same trick twice. He was probably proud of proving his range; but he mas certainly courageous in testing his popularity. It is true that *Oliver Twist* consists of a queer mixture of melodrama and realism; but both the realism and the melodrama are deliberately dark and grim. Nevertheless it is fortunate that with his second book he thus brought into play what may be called his second talent. It is too common to compare his humour with his pathos; for indeed there is no comparison. But there really is a comparison between his humour and his horror; and he really had a talent for a certain sort of horror, which is exactly rendered by the popular phrase of supping on horrors. For there is a sort of lurid conviviality that accompanies the panic; as if the nightmare could accompany and not follow the heavy meal. This suppressed vitality is due to his never for an instant losing the love of life. He enjoyed writing it. The sort of horror which afterward conceived the death of Krook (in *Bleak House*) is already found in *Oliver Twist;* as in that intolerable repetition throbbing in the murderer's ears: "will wash out mud-stains, bloodstains" and so on. For the rest, the plot is preposterous and the flashes of fun excellent but few: yet there is another aspect of the book which makes it important in the story of Dickens. It is not only the first of his nightmare novels but also the first of his social tracts. Something of social protest could be read between the lines of Pickwick in prison; but the prison of Pickwick was very mild compared with the charitable almshouse of Oliver. Dickens is witness, with Thomas Hood and William Cobbett and many others. that the workhouse, created by the Poor law of *1834,* was felt by all generous people as something quite unnaturally new and hard and inhuman. It is sometimes said that he "killed" Bumble (the beadle); it would be truer to say that, by making Bumble live, he created something by which it will always be possible to kill bureaucracies.

Whether we call the transition from *Pickwick* to *Oliver Twist* a change from comedy to tragedy, or merely a change from farce to melodrama. it is notable that the next act of Dickens is to mix the two in about equal proportions. Having shown how much he can vary, he tries to show how well he can combine. It is worth noting because it explains much of the failure as well as the success of his art as a whole. We may even say that. to the last, this sort of exhibition of power remained his principal weakness. When the critics, like those of *The Quarterly,* called him vulgar, it meant nothing except that the critics themselves were snobbish. There is nothing vulgar about drinking beer or describing the drinking of beer, or enjoying the humours of really humorous people who happen to black boots, like Sam Reller. But there is something just a little vulgar about professing to be a Universal Provider; a man who writes not only something that he wants to write but anything that anybody wants to read. Anything in his work that can really be called failure is very largely due to this appetite for universal success. There is nothing wrong about the jester laughing at his own jokes; indeed they must be very poor jokes if even he cannot laugh at them. Dickens. in one of those endless private letters which are almost more entertaining than his published novels, describes himself as "a gentleman with rather long hair and no neckcloth, who writes and grins as if he thought he were very funny indeed"; and so he was. But when he set out to prove that he was not only very funny but very pathetic, very tragic, very powerful, he was not always enjoying the sense of power over his work, he was enjoying the sense of power over his audience. He was an admirable actor in private theatricals; and sometimes, unfortunately. they were public theatricals. At best he was that rather rare thing a real democrat. At worst he could be something of a demagogue: not one of the crowd but one trying to dazzle and drive it. It pleased the actor in him to show his versatility and his ease in turning from one to the other. He did not realize clearly enough that in some of the parts he was a first-rate actor and in some a second-rate and in some a fifth-rate actor. He did not remind himself that though he turned to each topic with equal ease. he did not turn to each with equal effect. But, whatever the disadvantages of the universal ambition, it definitely dates from the period of his next book.

Pickwick has a prevailing tint of gaiety and *Oliver Twist* of gravity, not to say grimness; but with *Nicholas Nickleby (1838–39)* we have the new method, which is like a pattern of bright and dark stripes. The melodrama is if possible even more melodramatic than in *Oliver Twist;* and what there is of it is equally black and scowling. But the comedy or farce has already displayed the rapid ripening of his real genius in letters. There is no better company in all literature than the strolling company of Mr. Vincent Crummles. Mr. Mantalini also is one of the great gifts of Dickens to the enduring happiness of humanity. For the rest. it is very difficult to take the serious part of the story seriously. There is precious little difference between the rant and claptrap of the Crummles plays, which Dickens makes fun of, and the rant and claptrap of Ralph Nickleby and Mulberry Hawke which Dickens gravely narrates to us. All that, however, was of little consequence either immediate or permanent. Dickens was not proving that he could write smooth and probable narratives, which many people could do. He was proving that he could create Mantalini and Crummles, which nobody else could do.

Nevertheless, this pretense of providing for all tastes, which produced the seriocomic novel, is also the explanation of the next stage of his career. There runs or recurs throughout his whole life a certain ambition to preside over a more or less complex or many-sided publication; a large framework for many pictures; a system of tales within tales like the Arabian Nights. It is the ambition that he later gratified by becoming the editor of two successive magazines, *Household Words* and *All the Year Round.* He had been for a time editor of something of the sort in *Bentley's Miscellany;* and, in April *1840,* this mild and genial megalomania (if we may so describe it) took the form of a weekly publication called *Master Humphrey's Clock.* It was a serial scheme, which was meant to consist chiefly of different stories told by a group of friends. With the idea of making them the more friendly he turned some of them into old friends; reintroducing Mr. Pickwick and the two Wellers, though these characters were hardly at their best, the author's mind being already on other things. One of these things was a historical novel, conceived more in the romantic manner of Scott than the prosaic manner of Smollett, which Dickens had generally followed. It was called *Barnaby Rudge (1841)* and the most interesting part of it is the business of the Gordon Riots; and the mob that has a madman for its mascot and a penny-dreadful prentice for its comic relief. *Barnaby Rudge,* however, is not so directly Dickensian as the romance that preceded or the romance that followed it. The second story, somewhat insecurely wedged into the framework of *Master Humphrey's Clock,* was *The Old Curiosity Stop* (1841). Its public reception sharply illustrates what has been said about the double character of his success. On the one side was his true success as a craftsman carving figures of a certain type, generally gargoyles and grotesques. On the other side was his inferior success as a jack-of-all-trades tending only too much to be a cheap-jack As a matrer of fact, *The Old Curiosity Shop* contains some of the most attractive and imaginative humour in all his humorous work; there is nothing better anywhere than Mr. Swiveller's imitation of the brigand or Mr. Brass's funeral oration over the dwarf. But in general gossip and association, everything else in the story is swallowed up in the lachrymose subject of Little Nell. There can be no doubt that this unfortunate female had a most unfortunate effect on Dickens' whole conception of his literary function. Little Nell was better dead. but she was an unconscionable long time dying; and we cannot altogether acquit Dickens of keeping her lingering in agony as an exhibition of his power. It tended to fix him in that unfortunate attitude, of something between a showman and a magician, which explains almost all the real mistakes of his life.

About this time a determining event interrupted his purely literary development, his first visit to America It was destined to have, apart from any other results, a direct effect upon his next book, which was *Martin Chuzzlewit (1843–44).* There were, of course, many purely practical and personal elements in the criticism

which he directed against the western democracy. An unjust copyright law had enabled Americans to pirate his most popular works. It was stifling their own literature, but it was supported by the newspaper proprietors who profited by it most. Their differences with Dickens developed into a feud; while, for his part, his sense and sensibility were alike irritated by some real divisions in the international relation. There were things in the American culture, or lack of culture of that time, which he could not be expected to understand and which he might reasonably be expected to dislike. His English law-abiding liberalism would in any case have been startled by a certain streak of ferocity and persecution that there really is in the Americans; just as he might have recoiled from the same fierceness in the Irish or the Italians. But in the Americans it was also connected then with something crude and incomplete in the society, and was not softened by tradition or romance. He was also both annoyed and amused at the American habit of uttering solemn idealistic soliloquies and of using rhetoric very rhetorically. He was revolted by slavery. But all these impressions are important chiefly as far as they were incorporated in his next novel.

All the early books, from *Pickwick* onward, appeared, it must always be remembered, serially and in separate parts. They were awaited eagerly and were sometimes only just written up to time. One effect of this method was that it at first encouraged the novelist in a sort of opportunism and hand-to-mouth habit of work. As time went on, however, it had a very different effect: the mere fact of serial publication meant that the writer had to think ahead. Standards altered, the form of the novel was developed and public taste changed. By the time of *David Copperfield* (1849–50), a critic could write that "the serial tale . . . is probably the lowest artistic form yet invented." But by then Dickens was writing in earnest explanation to a friend: "the world would not take a *Pickwick* from me now." Though he wrote little or nothing about "the art of the novel" (a phrase which had yet to be coined) all his later books show an increasing constructive skill and a growing interest in technique. By the time he had finished his last complete work. *Our Mutual Friend* (1864–65), he could write in an almost Jamesian fashion of the difficulties for the reader of a serial in perceiving the relations of the finer threads of the story "to the whole pattern which is always before the eyes of the story weaver at his loom." All this is worth remembering, because a great deal has sometimes been made of the remarkable decision which Dickens made, in the course of writing *Martin Chuzzlewit,* when he found that the public was not taking to Pecksniff and Mrs. Gamp with the same delight that they had shown in Pickwick and Miss Squeers *(Nicholas Nickleby).* He conceived the bold idea of breaking the story in the middle and putting in a purple patch woven from his wild memories of America. However extraordinary this may seem, it was completely successful in the comedy sense. It has been remarked that there was something peculiarly Dickensian in suddenly sending Martin Chuzzlewit across the Atlantic, and that one can hardly imagine Thackeray suddenly hurling Pendennis from Mayfair into the middle of Australia. or George Eliot dislodging Felix Holt and flinging him as far as the north pole. But the difference was largely a matter of period rather than personality. From the time of *Martin Chuzzlewit* it happens that Dickens began to make written plans for the novels; and certainly from this time, each was always evolved in relation to a central idea. There may have been little to show for it at first, but it was an important new development.

At this point there is a break in the life of Dickens, in more ways than one. It is represented by his decision to live abroad for a time, chiefly on grounds of economy. He took a villa in the neighbourhood of Genoa in 1844; and he and his family, already a fairly large one, settled down there with a certain air of finality that deserved for a time the name of exile. But it is curious to note that the literary work done there has something of the character of an interlude, and indeed of a rather incongruous interlude. For it was in that Italian landscape that he concentrated on a study so very domestic, insular and even cockney as *The Chimes* (1844); and industriously continued the series of short Christmas stories which had recently begun in the very London fog of *A Christmas Carol* (1843). Whatever be the merits or demerits of the *Christmas Carol,* it really is a carol; in the sense of being short and direct and having the same chorus throughout. The same is true in another way of *The Chimes;* and of most things that occupied him in his Italian home. He had not settled down to another long and important book; and it soon became apparent that he had not settled down at all. He returned to London. the landscape which for him mas really the most romantic and even historic; and did something so ominously typical of the place and time as almost to seem like tempting providence. He became the first editor of the *Daily News,* a paper started to maintain those liberal, if not radical, opinions of which he always shared the confident outlook. The first number appeared in Jan. 1846. Dickens' editorship lasted only three weeks. He at once went to Lausanne and immediately wanted to return to London.

It seems probable that this break in his social life corresponded to a break in his artistic life: which was in a sense just about to begin all over again and begin at the other end. He did indeed write one more full-size novel of the earlier type, *Dombey and Son* (1846–48); but it has very much the character of the winding up of an old business, like the winding up of the Dombey firm at the end of it. It is comic as the earlier books were comic. and no praise can be higher; it is conventional as the earlier plots were conventional, and never really pretended to be anything else; it contains a dying child (Paul Dombey) upon the pattern of Little Nell; it contains a very amusing major much improved from the pattern of Mr. Dowler *(The Pickwick Papers).* But underneath all this easy repetition of the old dexterity and the old clumsiness the mind of the conjurer is already elsewhere. *Dombey and Son* was more successful in a business sense than *Martin Chuzzlewit;* though really less successful in many others. Dickens settled again in England in a more prosperous style; he was persuaded to send his son to Eton and, what was more sensational, took a rest. It was after a long holiday at Broadstairs, in easier circumstances more favourable to imaginative growth and a general change of view, that there began to appear in 1849 an entirely new novel in an entirely new style.

There is all the difference between the life and adventures of David Copperfield and the life and adventures of Nicholas Nickleby, that there is between the life of Charles Dickens and the life of Amadis of Gaul. The latter is a good or bad romance; the former is a romantic biography, only the more realistic for being romantic. For romance is a very real part of life and perhaps the most real part of youth. Dickens had turned the telescope round or was looking through the other end of it; looking perhaps into a mirror, looking in any case out of a new window. It was life as he saw it, which was somewhat fantastically; but it was his own life as he knew it, and even as he had lived it. In other words, it is fanciful but it is not fictitious; because not merely invented in the manner of fiction. In *Pickwick* or *Nickleby* he had in a sense breathed fresh imaginative life into stock characters, but they were still stage characters; in the new style he may be extravagant, but he is not stagey. That vague glow of exaggeration and glamour which lies over all the opening chapters of *David Copperfield,* which dilates some figures and distorts others, is the genuine sentimentalism and suppressed passion of youth; it is no longer a convention or tradition of caricature. There are men like Steerforth and girls like Dora; they are not as boys see them; but boys do see them so. This passionate autobiography, though it stiffens into greater conventionality at the real period of passion, is really, in the dismally battered phrase, a human document. But something of the new spirit, more subtle and sympathetic but perhaps less purely creative, belongs to all the books written after this date.

The next novel was *Bleak House* (1852–53), in which he once again made a new departure. Dickens himself said of it, "I have purposely dwelt on the romantic side of familiar things." It is a satire directed against chancery and the law's delay, which opens out to satirize the whole of society. The description of the feverish idleness of young Richard Carstone has the new note of one for whom a well-meaning young man is no longer merely a "first walking gentleman." It is a note of disillusion, though in spite of the satire of Mrs. Jellyby the novel as a whole is still inspired by

Dickens' vigorous faith in social reform, which for many years had found a practical outlet in mork he undertook in co-operation with a well-known and wealthy philanthropist. Miss Angela Burdett-Coutts (*q.v.*). Hard *Times* (1851) may be considered as historically important as the revolt of a radical against the economic individualism which was originally identified with radicalism. It is not simply an attack on capitalist society, but on the soulless and sordid industrial life it had brought about and on human nature itself. Like all the novels that follow. including its immediate successor, Little Dorrit (1855–57), it demands the regeneration of men as well as social reform.

Hard Times shows a new mastery of form; Little Dorrit a lack of it. This was largely because the latter appeared in the old way as a monthly serial stretching over 20 parts, whereas Hard Times was concentrated into weekly installments for Dickens' new periodical, *Household Words* (1850–59). A Tale of Two Cities (1859), a historical romance about the French Revolution, appeared in the periodical which took its place, All the Year Round; it was rather too dramatic. an overbold simplification designed to appeal to the even wider audience that Dickens hoped to reach through his new medium. Yet the height of his new method was eventually attained in his next mork, Great Expectations (1860–61), and perhaps he never did anything better than its opening chapters. There is no fine writing in it, however; it has all the virtuoso's brilliance with none of his tricks. Even his exuberant fancy was kept in check and subordinate to the main design. It revealed more than a glimpse of the Dickens world from a new window, for it showed that the writer could turn his gaze both on himself and on the nature of the world we all live in. It was a triumph of art. "I work slowly and with great care," Dickens explained to Bulwer Lytton a few years later, "and never give way to my invention recklessly, but constantly restrain it." This was evidently written in reply to Lptton's comments on *Our Mutual* Friend (1864–65). This was Dickens' last complete novel: and it is more complete than most. Indeed, it is one of his best, though not one of the most Dickensian. Its interest lies less in the story, which is of the usual complexity. but in what one supposes was meant by it; and this depends more on scenes linked by the dark river than the symbol of the Dust-heap of which, perhaps, too much has been made. Too great a preoccupation with the themes and symbols indeed, or with any limited aspect of his work, may blind a reader to the best that Dickens has to offer. For there is something about Dickens that prevents the critic from ever being quite content with criticizing his work as literature. Something larger seems involved, which is not literature but life. And he who remembers Pickmick and Pecksniff, creatures like Puck or Pan, may sometimes wonder whether the work had not most life when it was least lifelike.

Last Years.—In his last decade, Dickens both retired into private life and took up a new career which brought him directly before the public. Both appear to have been the result of the breakup of his marriage in 1858. According to his own account he felt that he could no longer live with his wife; yet, even before the separation, there is no doubt that he was deeply attracted by a young actress, Ellen Ternan. It seems clear that sometime during the 1860s she became his mistress. He provided her with somewhere to live; he left her £1,000 when he died; and, meanwhile. he divided his time between her, his public career and what remained of his family at Gad's Hill. More than this, remarkably little is certainly known. In view of Dickens' special relation with the public, and his reputation for frankness and as a champion of the home, there appears every excuse for curiosity. Yet so far there has been little reward for considerable research, except the confirmation that he was a more complex person than has sometimes been supposed. From the time of the separation he was also launched on a career as a public reader. He had a natural wish to make money and he succeeded; he enjoyed the limelight; and, however great he found the strain, it was no more than he put upon himself when he was writing. Yet his own letters, ragged with insomnia and impatience, full of desperate fatigue and more desperate courage, are enough to show that he was playing a dangerous game for someone approaching 60. The truth is that he enjoyed the danger. He was still a man of action and, in the mild mid-1860s, in a world of Twemlows and Podsnaps (Our *Mutual* Friend). he lived with zest. When he went once again to the United States, in Nov. 1867, his campaign of public reading was truly American in its scope and scale. It helped to ruin his health, but he had long ago begun burning the candle at both ends; and there have been few men. in the matter of natural endowments, with so great and glorious a candle to burn. He retired from his readings to take up his last novel. nhich was a detective story rather in the manner of his friend Wilkie Collins; the sort of story that begins with asking a question; in this case the question about the secret and sequel of the hero, Edmin Drood. The question will never be answered; for it was cut short by the only thing that could be more dramatic than the death of the hero: the death of the author. He died very suddenly, at Gad's Hill, on June 9. 1870.

Character and the Nature of His **Genius.**—He was buried in the poet's corner of Westminster abbey: and new and vulgar as many critics had called his work, he was far more of a poet than many who were buried there as poets. He left a will commending his soul to God and to the mercy of Jesus Christ, and leaving his works to the judgment of posterity; and in both respects the action was symbolic and will remain significant in history. Intellectually limited as he was by the rather cheap and optimistic negations of an age of commercial rationalism, he had never been a bitter secularist or anticlerical; he was at heart traditional and mas drawn much more toward Anglican than Puritan Christianity. Contemptuous of the past and its survival in what seemed to him outworn institutions, he centred the meaning of many of his novels on the values that some call essentially Christian and which others would like to preserve under the name of humanism. Just where he stood in matters of religion it would be rash to claim, largely because he never appears to have tried to define it for himself. But even though we may feel that rather too much has been written about Dickens and Christmas (especially since it has been so commercialized) he shared much with its general spirit as a festival. No doubt it is true that in his later novels, which have sometimes been known as "the dark novels." there are new shades of irony, an earnest questioning and even a tone of resignation which is much more disturbing still. The paternal Mr Weller (of *Pickwick*), for example, is succeeded by the paternal Mr. Dolls (of Our *Mutual* Friend); or Christmas at Dingley Dell. by Christmas round the blacksmith's forge (in Great Expectations) repairing the handcuffs for the hunted convicts. Yet if there was a new note of dismay in what he saw in his contemporaries, it was largely because the values he held to were still as affirmative and ordinary as those of Arthur Clennam (Little Dorrit), Joe Gargery (Great Expectations) and Rumpty Wilfer (Our *Mutual* Friend). It is this which has given him such a universal appeal; and, of course, it is this which makes him so unappealing. in spite of all his skill, to those who find it rather too savourless for a major novelist.

Indeed, even the charge of exaggeration in his manner has itself been exaggerated; and, what is more important, it has often been repeated mechanically without thought as to its true meaning. Dickens did exaggerate; but his exaggeration was purely Dickensian. In this sense his very vulgarity had the quality of distinction. Mere overstatement. to say that a tall man is ten feet high, to say that a frosty morning froze Niagara; this is something relatively easy to do. But the distinction of Dickens can be stated even in the common charge against him. He is said to have turned men into monsters of humour or horror, whereas the men were really commonplace and conventional persons in shops and offices. If any critic depreciates the Dickensian method as mere overstatement, the answer is obvious: let him take some of these commonplace people and overstate them. He mill soon discover that he has not the vaguest notion of what to overstate. He will soon realize that it is not a simple matter of mere exaggeration, in the sense of mere extension. It is not a matter of making a man a little taller or a morning a little colder; the challenge to imagination is not whether he can exaggerate but whether he can find anything worth exaggerating. Now the genius of Dickens consisted in seeing in somebody, whom others might call merely prosaic, the germ of a

sort of prose poem. There was in this or that man's attitude, or affectation, or habit of thought, something which only needed a touch of exaggeration to be a charming fantasy or a dramatic contradiction. The books of Dickens are in fact full of bores; of bores who do not bore us, merely because they did not bore him. We have all of us heard a hundred times the tiresome trick of public speakers, of asking themselves rhetorical questions which they do not want answered. Any of us might have heard a fat Dissenting minister doing it at a tea party and thankfully forgotten all about him. But Dickens seized on the fallacy and turned it into a fantasy; into Mr. Chadband's demands to know why he could not fly, or his wild and beautiful apologue about the elephant and the eel *(Bleak* House). We talk of the power of drawing people out; and that is the nearest parallel to the power of Dickens. He drew reels and reels of highly coloured caricature out of an ordinary person, as dazzlingly as a conjurer draws reels and reels of highly coloured paper out of an ordinary hat. But if anybody thinks the conjuring trick is easy to perform, let him try it with the next ordinary person he sees. The exaggeration is always the logical extension of something that really exists; but genius appears in seeing that it exists. That is something totally different from giving a man a long nose; it is the delicate surgical separation or extension of a living nerve.

There were other reasons for the injustice of the accusation of exaggeration in the particular case of Dickens. Though his characters often were caricatures, they were not such wild caricatures as was supposed by those who had never met such characters. And the critics had never met the characters; because the critics did not live in the common life of the English people; and Dickens did. England was a much more amusing and horrible place than it appeared to the sort of man who wrote reviews in The *Quarterly.* The poverty and anarchy of Dickens' early life had stuffed his memory with strange things and people never to be discovered in Tennysonian country houses or even Thackerayan drawing rooms. Poverty makes strange bedfellows, the same sort of bedfellows with whom Mr. Pickwick fought for the recovery of his nightcap. In the vivid phrase, he did indeed live in Queer street and was acquainted with very queer fish. Yet it is true that he caught many of these queer fish because he liked fishing in such troubled waters. A good example of this combination of opportunity and eccentricity is to be found in his affection for traveling showmen and vagabond entertainments of all sorts, especially those that exhibited giants and dwarfs and such monstrosities. Some might see in this truth a sort of travesty of all his travesties. It would be easy to suggest a psychological theory. by which all his art tended to the antics of the abnormal; it would also be largely false. It would be much truer to say that Dickens created so many fantastic caricatures because he was himself commonplace. He never identifies himself with anything abnormal. in the more modern manner. In his traveling show, the Giant always falls far short of being a Superman. And though he was tempted only too easily to an obvious pathos, there was never anything particularly pathetic about his dwarfs. His fun is more robust. It was precisely because he had an ordinary and sensible view of life that he could measure the full madness both of Gradgrind's greed and Micawber's improvidence. It was because he was what we call commonplace that Dombey appeared to him so stiff or Jellyby so slovenly. In a later generation a real person often assumed such an unreal pose and lost the power of merely laughing at it; as, for example, when Oscar Wilde said seriously all that Skimpole had said absurdly. The Victorian common sense was not a complete common sense; and Dickens did suffer from having a narrower culture than Swift or Rabelais. But he did not suffer from being oversensible, for he mas able to give us a radiant fairyland of fools.

Above all he was a great writer. At times, superficially considered, he may seem to have abused his great gifts. No doubt occasionally he did. Some of his defects are glaring; they hardly need emphasizing because, unfortunately, he always emphasized them himself. It may be a fault, but it is certainly a fact that for the first part of his career he enjoyed writing his worst work as much as his best. Yet it is not true of his career as a whole. He had an extraordinarily sensitive ear for tone and emphasis; with all but his most serious characters, he had an incomparable command of dialogue; he could even write with great economy as well as vitality and force; and the unmistakable characteristic of his writing is its sustained and imaginative fancy. Whether this imaginative fancy is expressed in the form of the absurdities of Mrs. Bayham Badger, for example, or in such a set piece as the description of Chesney wold ("the waters are out in Lincolnshire") which carries us straight into the wasted heart of Lady Dedlock; whether it is in the extraordinary aberrations of "Lord Chancellor" Krook and Miss Flite, or in the verbal excursions of Skimpole and Chadband (all of *Bleak House)*; it so sustains these things, as a variable and purposeful style, that one can say that they almost never drop into mannerism but are part of the living pattern of the whole novel.

His literary work produced of course much more than a literary effect. He was the last great poet, in the true sense of maker, who made something for the people and was in the highest sense popular. He still gives his name, not to a literary clique, but to a league or fellowship numbering thousands all over the world. In this connection it is often noted that he achieved many things even considered as a practical political and social reformer. He let light into dark corners, like the dens of dirt and brutality often called schools, especially in Yorkshire; he probably had much to do with making the professional nurse a duller but more reliable person than Mrs. Gamp; it is likely enough that his vivid descriptions, assisted by the whole trend of the time, hastened the extinction of ordinary imprisonment for debt and were responsible for improvements in public health. But precisely because this has often been said, it will be well not to say it too often. It has the effect of making his satire appear much more superficial and utilitarian than it really was; for the great satirist is concerned with things not so easily destroyed. We do more honour to Dickens in noting the evils he did not destroy than those he did. The eager worship of a man merely wealthy, however dull and trivial, which appears in the affair of Merdle *(Little Dorrit),* has by no means disappeared from our own more recent affairs; the pompous old Barnacle and the agreeable young Barnacle (in the same book) are still almost as much alive as in Dickens' day. The sweeping away of a genuine gentry, in the person of Mr. Twemlow, on the tide of a new plutocracy, represented by Mr. Veneering *(Our Mutual Friend),* has gone much farther than in Dickens' day. But this makes Dickens' satire the more rather than the less valuable to posterity. The other mood, which pictures all such abuses as things of the past, tends not to reform but only too much to repose. In that spirit we may hear to this day a Stiltstalking saying that Stiltstalkings have perished–before the march of progress. or a Buzfuz quoting Buzfuz and jeering at himself as an extinct monster.

Reputation. — The future of Dickens' fame is established. For a time, soon after his death, he was written down in comparison with such masters of the novel as Tolstoi and Dostoevski and in reaction against the spirit of his age. Ironically enough, these two writers meanwhile left no doubt that they were aware of his greatness and aims as a novelist. The first remarked that "all his characters are my personal friends"; the second referred to their author as "the Great Christian — Dickens." His irresistible greatness has always been recognized. Dickens is still tremendously popular in the Soviet Union, but though it is sometimes thought that this is because the Russians find it particularly easy to believe in the picture he gives of life in Britain, it would be rash to assume that this is the only reason. Indeed, wherever he finds readers, there is now no question of the importance of Dickens either as a writer or as a human event in history; as a sort of conflagration and transfiguration in the very heart of what is called the Victorian era; a naked flame of natural genius, whose best work was creative, and who has added something to life which it is hard to believe will ever entirely be taken away.

BIBLIOGRAPHY.—*Editions:* For Dickens' novels, any edition of the *Works,* with Collected Papers (for prefaces) and Miscellaneous Papers (journalism); a selection of Letters was ed. by M. Dickens and G. Hogarth (1880–82); the most complete edition is the Nonesuch Letters (1938), to be replaced by the Pilgrim edition; Speeches, ed. by K. J.

Fielding (1960). *Biography and Criticism*: J. Forster, *Life* (1872–74), ed. with notes by J. W. T. Ley (1925); E. Johnson, *Charles Dickens: His Tragedy and Triumph*, 2 vol. (1953), the main modern biography; G. K. Chesterton, *Dickens* (1906), *Appreciations and Criticism of Dickens* (1911); G. Orwell, "Charles Dickens," *Inside the Whale* (1940); E. Wilson, "Dickens: the Two Scrooges," *The Wound and the Bow* (1941); A. H. House, *The Dickens World* (1941); F. R. Leavis, in *The Great Tradition* (1918); S. Monod. *Dickens, romancier* (1953); K. Tillotson. *Novels of the Eighteen-Forties* (1954) and with J. Butt, *Dickens at Work* (1957); G. H. Ford, *Dickens and His Readers* (1955); K. J. Fielding. *Dickens: a Critical Introduction* (1958); J. H. Miller, *Charles Dickens: the World of His Novels* (1958).

(G. K. C.; K. J. F.)

DICKINSON, EMILY ELIZABETH (1830–1886), U.S. author considered almost universally the greatest American woman poet. was born at Amherst, Mass., Dec. 10, 1830. in the sturdy brick homestead built by her grandfather Samuel Fowler Dickinson. a lawyer. sixth in the line of descent from Connecticut valley settlers. His son Edward. Emily's father. settled in Amherst where he practised law. engaged in politics and served as treasurer of Amherst college from 1835 until 1872, two years before his death. In 1828 he married Emily Norcross, and to them were born three children. William (1829–95). Emily and Lavinia (1833–99). Like her younger sister Lavinia. Emily never married and throughout her life lived at home. Together the sisters shared the later burden of caring for their mother. an invalid from 1873 until her death seven years later. One measure of the dependence of each member of this closely knit family upon each other is the fact of their lifelong residence in the same or neighbouring houses.

Slender in form, light and quick in motion. Emily Dickinson was remembered for her plain features. abundant reddish chestnut hair and brown eyes. Her early letters. those which survive from her 12th to her 18th year. show her to be natural. eager. interested in people and books; and bear out reports that in conversation she was witty and vivacious. After intermittent attendance at Xmherst academy she was admitted at 16 to the middle of the three classes at Mount Holyoke Female seminary in nearby South Hadley in the autumn of 1847. Her initial enthusiasm palled during the year. in part because she could not bring herself to become a "professing" Christian as the girls were hopefully expected to do; in part because any break in the tie with her home was distasteful. She completed the year's work but did not return. Thenceforth her home and her gardens became exclusively the world she chose to inhabit. With the exception of a trip to Washington. D.C., early in 1855 with her sister. to visit her father. then serving in congress. and an enforced sojourn in Boston and Cambridge, Mass., during the summer months of 1864 and 1865 to undergo treatment for an eye affliction which seems to have been cured, she never left Xmherst again.

Emily Dickinson apparently began writing poetry soon after her return from Mount Holyoke, encouraged by Benjamin Newton, a young law student in her father's office. In 1850 he moved to Worcester. Mass., soon married and died three years later. She cherished his memory over the years as her earliest guide, but her function as poet did not commence in earnest until about 1858. when she began to collect her verses into manuscript packets. small "volumes" of a few sheets of folded stationery, threaded at the spine. In 1862 her creative talent was at flood. and by 1866 most of her poetry was written. It was in April 1862 that she sensed her destiny as a poet, for in response to an *Atlantic Monthly* article written by the critic and publicist Thomas Wentworth Higginson, she brought herself to his attention by sending him four carefully chosen poems. Their metrical originalities bewildered Higginson, but he requested to see more and by midsummer gave his opinion—a verdict. as it turned out for Miss Dickinson—that her obscurity and fracture of grammar and dictionary stood in the way of public acceptance. Unable to express herself other than as she saw things, she elected obscurity and did not willingly allow any publication during her lifetime.

The correspondence thus initiated with Higginson continued all her life. and the fact that she called Higginson her "safest friend" and often signed herself "Your Scholar" opens a vista into her needs. Intense by nature, she was possessive in her friendships. The death of Newton deprived her of a mentor or muse. Perhaps soon after she felt that she had found another in the person of the noted clergyman. the Rev. Charles Wadsworth of Philadelphia. Pa., whom she evidently met on her return trip from Washington in 1855. Their correspondence does not survive. On his part it probably was conducted as that of a solicitous pastor trying to assist a troubled spirit. On hers it may have been a deep emotion, however disembodied; for his departure with his family to accept a pulpit in San Francisco, Calif., coincides with the period in which she mas writing poetry, some of the best. with demonic energy. It is also the time that she began to dress entirely in white, a practice she never abandoned, and that she first wrote to Higginson. Eight years later Higginson called upon her at her earnest insistence, because as she said in her request. "Of our greatest acts we are ignorant. You were not aware that you saved my life. To thank you in person has been since then one of my few requests."

After 1863 the greater part of her poetic energies was spent, though she continued to fashion verses until her death. But they were usually composed for an occasion and for the friends to whom they were sent. Though people continued to be of utmost importance to her, direct contacts so exhausted her emotions that she shrank from all but the most intimate friends. Her seclusion thus became nearly absolute after 1870. But the intensity of her living never abated. and she associated steadily with the friends of her selection through the medium of letters. The care that she lavished on her revised drafts may suggest that letter writing sublimated the creative urge when her poetic drive lost force. In any event. she deliberately chose obscurity. evidently because she was unwilling to be diverted from her own originalities which those capable of evaluating only dimly perceived. Such withdrawal never became necessary in the presence of children, who adored her and for whom her cookie jar was always filled.

Only seven of her poems are known to have been published in her lifetime. Most of them were surreptitiously issued, perhaps by her sister-in-law Susan Dickinson. who from the first encouraged Emily's sense of dedication. and to whom Emily sent some 300 poems, usually in brief notes dispatched next door. Over the years it was by means of letters that Emily Dickinson found private audience for her poems. Higginson received more than 100, which he once acknowledged by thanking her. not for poems, but for the "beautiful thoughts and words." Her friendship with Samuel Bowles, distinguished publisher of the *Springfield Republican*, and with Josiah Holland. Bowles's associate and later founder of *Scribner's Monthly*, endured through the years. In gratitude for kindnesses from them she responded on occasidn with verses which Bowles and Holland concluded (as Higginson had done) could not really be called poetry.

Among her contemporaries only Helen Hunt Jackson unreservedly believed that bliss Dickinson was a poet of genuine stature. Mrs. Jackson by the late 1870s had become a most successful writer, and was then generally acclaimed the best woman poet in America. Both women had been born in the same pear in Amherst, members of the academic community. But Mrs. Jackson had grown up elsewhere. and it was Higginson who brought the poetry of Emily Dickinson to her attention. Only Mrs. Jackson's importunity secured Miss Dickinson's "Success" for inclusion in A *Masque of Poets* (1878), a collection published anonymously. Her later plea for enough poems to fill a separate volume went unheeded, as did her request to be designated Miss Dickinson's literary executor. But the conviction thus revealed of Mrs. Jackson's opinion was an accolade beston-ed by no other. Their acquaintance was slight, but the unexpected death of Mrs. Jackson in 1885 seemed to Emily Dickinson especially distressing.

Otis P. Lord of Salem, Mass., a lifelong friend of Edward Dickinson and a justice of the superior court and later the supreme court of Massachusetts, frequently visited the Dickinson home u-ith his wife until her death in 1877. Soon thereafter a deep attachment became manifest between Judge Lord and Emily. Until his death in 1884 he frequently stopped in Xmherst at the inn with his nieces. and the surviving drafts of her letters to him evidence their mutual love. He may have offered marriage, but the pattern of her life was too firmly established to allow a change. Few of her close friends now survived. Judge Lord, Bowles, Hol-

land and Wadsworth were gone. She continued writing letters and occasional poems to the end, but her finest achievement had long since been consummated. The "nervous exhaustion" which overtook her after the death of Judge Lord was gradually intensified. She was confined with increasing frequency to her room or bed late in 1885, and died on May 15, 1886, in her 56th year.

After her sister's death, Lavinia Dickinson discovered the numerous packets of the many hundreds of poems, neatly placed in a locked box. She had known, of course, that Emily wrote poetry, but she contemplated the large body of verse with genuine astonishment. She set about with determination to find a publisher, and naturally turned first to Higginson. With misgivings whether a public could be reached, and with reservations of judgment whether the poems merited publication, he was finally persuaded to undertake preparation of a slender volume with the help of Mrs. Mabel Loomis Todd, who had become acquainted with the Dickinson family during Emily's lifetime. Together they edited *Poems by Emily Dickinson* (1890), 114 brief lyrics selected with an eye to public taste, and editorially tailored to fit accepted standards of metre and rhyme. Though reviewers were uniformly bewildered and for the most part hostile, the public demand for the volume encouraged Higginson and Mrs. Todd to issue *Poems: Second Series* in the following year. So reassuring was the acceptance that Mrs Todd brought out two volumes of *Letters* (1894). and two years later a further selection. *Poems:* Third *Series* No more appeared until Emily's niece. Martha Dickinson Bianchi, published *The Single Hound* (1914), *Further Poems* (1929) and *Unpublished Poems* (1932). With the appearance of *Bolts of Melody* (1945), edited by Mrs. Todd and her daughter, virtually all of the poetry had finally been brought to light.

Appraisal.— Emily Dickinson had no theory of poetics, and her achievement is confined to the genre of brief lyrical bursts of song uttered aith fleetness and intensity. She wrote as she tried to live. outside of history. She was concerned with universals, and thus the two great sources of her inspiration were the Bible and the phenomena of nature. Through newspapers she had a daily eye on events, and from magazines she culled the first publications of such favourite contemporary writers as Charles Dickens and George Eliot. But her reading always passed through the alembic she distilled, for she believed that form is inherent in the created object. She adopted as the basic pattern for all her poems the hymn metres familiar from her childhood, but her innovations of half- and quarter-rhymes, her combinations of varying poetic feet, metres and rhyme patterns helped to create a new sense of the richness with which language can be used. Her laconic diction scorns the commonplace even as it clings to the homely word. Her outlook remained dualistic in the sense that it juxtaposed the abstract with the concrete, the trivial with the sublime, reverence with satire, the comic with the cosmic. Her flood subjects are the uneasy relation of impermanence to eternity, and her nervous style employs awkwardness of expression as a metaphor of the paradoxes inherent in living and dying.

BIBLIOGRAPHY.—Almost all of Emily Dickinson's poems and a great many of her letters are extant, the bulk of them in the libraries of Amherst college and Harvard university. T. H. Johnson (ed.), *The Poems of Emily Dickinson,* 3 vol. (1955) is a variorum edition, and *The Letters of Emily Dickinson,* 3 vol. (1958), fully annotated. George Frisbie Whicher, *This Was a Poet* (1938); Richard Chase, *Emily Dickinson* (1951); T. H. Johnson, *Emily Dickinson* (1955); *see* also Millicent Todd Bingham, *Ancestors' Brocades* (1945), a full account of the early publications of poems and letters; and *Emily Dickinson's Honze* (1955).
(T. H. JN.)

DICKINSON, JOHN (1732–1808), American statesman often referred to as "the penman of the Revolution," was born in Talbot county (Md.) Nov. 8, 1732. His father acquired large tracts of land in Kent county (Del.) and took the family there in 1740. After receiving his early education under private tutors, and reading law in Philadelphia. John Dickinson went to London in 1753 to study law at the Middle Temple. He returned to America in 1757, beginning the practice of law at Philadelphia. Three years later he entered upon a long career in public affairs, during which he held various offices in Pennsylvania and Delaware. He represented Pennsylvania at the Stamp act congress, and drafted its declaration of rights and grievances.

Dickinson won fame in 1767–68 as the author of the *Letters From a Farmer in Pennsylvania,* which appeared in many colonial newspapers and helped mold American opinion against the Townshend acts. He inveighed against the proposed use of the proceeds of the Townshend duties to pay the salaries of royal officials in the colonies; and he denounced the establishment of the American board of customs commissioners at Boston. Although he condemned the duties themselves, he took a relatively moderate approach toward them. Refusing to appeal to natural rights, he declared that the duties, because they were intended to collect a revenue. had to be classified with the stamp tax. Accordingly. he contended, they violated the rights of Englishmen and were unconstitutional. He admitted the validity of parliamentary taxation to regulate trade. His distinction between such taxation and duties for revenue was not so clear as he believed it to be.

Dickinson was also an active delegate from Pennsylvania in the first continental congress, for which he prepared the "Petition to the King" and the "Address to the Inhabitants of Quebec." In the second continental congress, again representing Pennsylvania, he was the principal author of the "Declaration . . . Setting Forth the Causes and Necessity of Their Taking Up Arms." and he wrote the so-called "Olive Branch Petition." He was also instrumental in preparing the first draft of the Articles of Confederation. However, he vigorously opposed a declaration of independence in the early summer of 1776. calling for delay, notably in a speech made on July 1. When it became apparent that sentiment ran against his views, he absented himself from the congress and was replaced. Dickinson did not sign the Declaration of Independence and temporarily retired from politics. He was unjustly suspected of turning Loyalist and afterward served in the patriot militia.

Because of his cautious attitude toward declaring independence, Dickinson lost much of his influence outside Pennsylvania and Delaware. He was nevertheless elected president of the council (*i.e.*, governor) of Pennsylvania in 1782. and also served in 1786 as the president of the Annapolis conventicn. As a member of the federal convention from Delaware in 1787 he stood for the small states against the large states, but signed the constitution and laboured for its adoption in the two states where he exercised influence. As "Fabius" he defended the document in a series of vigorous letters.

Dickinson college at Carlisle. Pa., chartered in 1783, was named in his honour. He was the first president of its board of trustees, and one of its principal benefactors.

Dickinson died Feb. 14. 1808, and was interred in the Friends' burial ground at Wilmington, Del.

See C. J. Stillé, "Life and Times of John Dickinson," *Memoirs of the Historical Society of Pennrylvania,* vol xiii (1891); P. L. Ford (ed.), "The Writings of John Dickinson," *Memoirs of the Historical Soczety of Pennsylvania,* vol. xiv (1895). (J. R. AL.)

DICKINSON, JONATHAN (1688–1747), American Presbyterian clergyman, one of the foremost of the colonial period, and first president of Princeton university, was born in Hatfield, Mass., April 22, 1688, and graduated from Yale college in 1706. He was settled as pastor of the town church of Elizabethtown, N.J., in 1708. Though moderately Congregational in persuasion, Dickinson and his people tended toward Presbyterianism. In 1717 he joined with the newly founded (1706) Presbyterian body in the Middle Colonies. He quickly became a leader also in theological thought and debate. When in 1721–29 this Presbyterian body, by that time a synod of three presbyteries, came to adopt a constitution, it was largely through Dickinson's efforts that the undefined ecclesiastical powers were given to the presbyteries and not to the central body, the synod. Also, in the matter of creedal subscription by ministers, a distinction was to be allowed between "essential and necessary points of doctrine" and points "extra-essential and not necessary." The synod was made up of a Scotch-Irish group (the Old Side) and a group of members of mixed origins (the New Side), largely of New England origins. The compromise sponsored by Dickinson soon proved unacceptable to the Old Side, and much controversy ensued. The church was further plagued by differences of opinion on the Great Awakening revival movement of the 1730s and 1740s. Though hesitant at first,

Dickinson joined the backers of the Great Awakening. In 1746 the New Side founded the College of New Jersey (later Princeton university), with Dickinson as president. He died Oct. 7, 1747.

DICKSON, SIR JAMES ROBERT (1832–1901), Australian statesman, premier of Queensland in 1898–99 and an advocate of federation, was born in England. at Plymouth, on Nov. 30, 1832. He emigrated to Australia in 1854 and continued the career in banking which he had begun at Glasgow. He later settled in Queensland, became an auctioneer and commission agent in Brisbane in 1862, and was elected to the legislative assembly in 1873. In 1876 he was appointed secretary for public works and mines: and then colonial treasurer. He became leader of the opposition in 1881, was again made colonial treasurer in 1883, and served as acting premier in 1887 during the absence in England of Sir Samuel Griffith. Soon afterward he resigned because of a disagreement over land policy and in 1888 lost his seat in parliament. He was once more returned to the assembly in 1892 and supported the movement in favour of importing Asian labour for work in the tropical regions of the colony. He became secretary for railways and postmaster general in 1897 and home secretary in 1898. In Sept. 1898 he succeeded T. J. Byrnes as premier. He resigned at the end of 1899 and after a short-lived intervening ministry, became chief secretary in the government of Robert Philp.

Dickson had represented Queensland in the federal councils of 1886 and 1887, and supported federation in the referendum of 1899. He was one of the Queensland delegates to England in connection with the passage of the commonwealth bill, and on his return to Australia. was elected to the federal parliament and appointed minister of deiense in the first commonwealth government. He died in Sydney on Jan. 10, 1901, having been knighted a few days before. (J. F. C.)

DICOTYLEDONS, plants of the Dicotyledonae. the larger of the two great groups (the smaller is the Rlonocotyledonae) of. flowering plants, or angiosperms. The majority of common garden plants are dicotyledons. All of the group are characterized by the presence of a pair of seed leaves, or cotyledons. in the embryo contained in the seed. *See* ANGIOSPERMS; SEED: *Structure. See* also PLANTS AND PLANT SCIENCE.

DICTATING MACHINES: *see* OFFICE MACHINES AND APPLIANCES.

DICTATOR, in modern usage, a ruler enjoying extraconstitutional power; in ancient times, an extraordinary magistrate in the Roman commonwealth. The earlier official title was *magister populi,* which may mean "head of the host" as opposed to his subordinate, the *magister equitum,* who was "head of the cavalry." Emphasis was thus laid on the military aspect of the dictatorship and, in fact, the office seems to have been instituted for the purpose of meeting a military crisis too serious for the annual consuls with their divided command. The repression of civil discord was one of the motives for the institution of a dictatorship. This function of the office is attested by the internal history of Rome. In the crisis of the agitation at the time of the Licinian laws (367 B.C.) a dictator was appointed, and in 314 B.C. a dictator was created for purposes of criminal jurisdiction (*quaestionibus exercendis).* The dictator appointed to meet the dangers of war, sedition or crime was described as the "administrative dictator" *(rei gerundae causa).* He held office for six months.

The powers of a dictator were a temporary revival of those of the kings, with some limitations. The dictator was never concerned with civil jurisdiction. His military authority was confined to Italy; and his power of life and death was limited. By the *lex Valeria* of 300 B.C. he was made subject to the right of criminal appeal (*provocatio*) within the limits of the city. But all the magistrates of the people were regarded as his subordinates. The dictator was nominated by one of the consuls. But the senate claimed authority over the magistrates, and suggested not only the nomination but also the name of the nominee. After nomination, the *lex curiata* confirmed the dictator's imperium *(see* COMITIA).

The first dictator is said to have been created in 501 B.C.; the last of the "administrative" dictators belongs to the year 216 B.C. The epoch of the Second Punic War was marked by experiments with the office. such as the election of Q. Fabius Maximus by the people, and the codictatorship of M. Minucius. The emergency office of the early and middle republic has little in common with the dictatorship as revised by Sulla and by Caesar. Ostensibly to prevent its further abuse. M. Antonius in 44 B.C. carried a law abolishing the dictatorship.

Modern dictators. like the ancient ones. have taken over the reins of government in times of emergency. but they have used the powers thus gained to establish a permanent. autocratic and sometimes despotic rule. In this they resemble the ancient tyrants rather than the ancient dictators. Both Benito Mussolini and Adolf Hitler (*qq.v.*) falsely posed as the defenders of popular rights, used democratic institutions and exploited the techniques of mass communication to cement their power; they became heads of the governments in their respective countries formally in accordance with the existing constitutions, and even enjoyed some popular support in spite of their suppression of freedom. The Communist dictatorship in Russia was proclaimed originally as the temporary dictatorship of a political elite to preserve the revolution; it became permanent and, under Joseph Stalin (*q.v.*) was a personal one.

See ABSOLUTISM, POLITICAL; *see* also references under "Dictator" in the Index volume.

Ford (ed.), *Dictatorship in the Modern World,* 2nd ed. (1939).

DICTIONARY, a book listing words of a language, with their meanings in the same or another language, usually in alphabetical order, often with data regarding pronunciation, origin and usage.

The term "dictionary" in one of its Latin forms *(dictionarius,* a collection of words) was used *c.* 1225 by an English scholar, John Garland, as title for a manuscript of Latin words to be learned by heart. The words were arranged not in alphabetical order but in groups according to subject. This *Dictionarius,* used only for the teacher's classroom work in teaching Latin, contained no English except for a few interlined glosses (translations of single words).

15th and 16th Centuries.— In the 15th century English words did appear in dictionaries, but even then they were used only as an aid to the study of Latin, as in the famous *Promptorium Parvulorum* ("Storehouse for the Little Ones"), a pioneer English-Latin wordbook. This important manuscript, completed in Norfolk *c.* 1440, was the work of a Dominican friar known as Galfridus Grammaticus (Geoffrey the Grammarian). He listed about 12,000 English words, mostly nouns and verbs, with their Latin equivalents, and for some time his dictionary held a place of leadership. The *Promptorium* was written several years before the invention of printing, but in 1499 it was published at the London press of Richard Pynson, an early servant and associate of William Caxton.

The custom of giving colourful titles to dictionaries was followed for many years. In the *Promptorium* we had a "storehouse," and later, in 1500, came a "garden of words"; for that is the meaning of *Ortus Vocabulorum,* printed by another of Caxton's assistants, Wynkyn de Worde. *Ortus,* a Low Latin form of *kortus* (garden), shows that even scholars sometimes omitted the aspirate. In the *Ortus,* Latin words come first, translated by English. The book, like earlier ones, was designed for students of Latin.

What has been called the first real English dictionary, printed in 1552, was the *Abcedarium Anglico-Latinum pro Tyrunculis,* compiled by Richard Huloet. Huloet, sometimes addressed as "Maister Howlet," was a native of Wisbech in Cambridgeshire. *Pro tyrunculis* means "for young beginners," but Huloet seems to have intended his book for beginners of all ages, including adults whose main interest was to learn to read English. Latin study, as usual, was probably the goal of this work, but the Latin translation was not given until the English word had been defined in English; hence the *Abcedarium* can be regarded as an English dictionary.

Huloet's style was informal and sometimes humorous, as may be judged from some of his definitions:

Bachiler, or one unmaried, or havyng no wife, *Agamus*, mi.
Black (or blewe) spotte in the face or bodye, made with a stroke, as when a wife bath a blewe eye, she sayth she hath stombled on hir good man his fyste. *Suggilatio, onis; Livor, uoris.*
Trymme wenche gorgiously decked, *Phalerata foemina.*

Huloet doubtless felt that the resplendent young lady needed no further definition in English; and it should be noted that wench, in 1552, was a very proper word; it meant simply a girl or young woman.

The *Abcedarium*, which contained 26,000 words, was popular, but it was expensive. This fact was recognized by a Yorkshire schoolmaster and physician named Peter Levins, who decided to write a smaller work; then, he said, "the price being little, the poorer sorte may be able to bie it." Comparing Huloet's big book with his own little one, Levins wrote, "His is for greater students, and them that are richable to have it; this is for beginners and them that are poorable to have no better." From that day to this, richable and poorable have needed dictionaries, and generations of publishers have tried to serve them all. Following the custom of using a picturesque title, Levins named his book, published in 1570, *Manipulus Vocabulorum*, "a handful of words," the handful comprising about 9,000 entries. He also called it, "A dictionarie of English and Latine wordes, set forth in suche order, as none heretofore hath ben . . . necessary not only for scholars that want variety of words, but also for such as use to write in English meetre." To help the poets, he arranged his words not according to their initial letters, but by the spelling of their final syllables, which resulted in a sort of rhyming dictionary, the first of its kind in English. The final syllables, however, brought together some strange bedfellows such as casket, suet; bell, chisel; madame, surname; and—most confusing—bough, cough, through, tough, which even in 1570 were probably not more than "eye rhymes."

In 1573 John Baret published a dictionary which he called *An Alvearie*, or "beehive." In this work an English word is given an English definition, and the equivalent in Latin, followed usually by French. Baret, an ingenious and doubtless popular educator, tells us how the book was compiled: "About eyghteene years agone, having pupils at Cambridge studious of the Latin tongue," they "perceyving what great trouble it was to come running to mee for every word they missed . . . I appoynted them . . . every day to write English before ye Latin, and likewise to gather a number of fine phrases out of Cicero, Terence, Caesar, Livie, etc., and to set them under several1 tytles, for the more ready finding them againe at their neede." Baret encouraged his pupil-assistants by calling them his busy bees, and "within a yeare or two they had gathered togither a great volume," like "diligent Bees in gathering their wax and hony into their Hive." Here is a sample entry from the *Alvearie:*

A GOAST, an image in man's imagination, *Spectrum, tri,* Cic. Phantasme, vision. La semblense des choses que nostre pensee ha conceue.

17th Century.—The compilers of early dictionaries made no attempt to include all words. They were satisfied to explain or define the hard words of the language, and often so stated. This custom was illustrated in 1604 when Robert Cawdrey issued his dictionary, *A Table Alphabeticall, conteyning and teaching the true writing and understanding of hard usuall English wordes . . . with the interpretation thereof by plaine English words, gathered for the benefit & helpe of Ladies, Gentlewomen, or any other unskilfull persons.* Cawdrey was another schoolmaster, and his explanations of about 2,500 words may have been based in part on his classroom experience. Much of his work, however, was taken without acknowledgment from earlier writers. It was an era of borrowing, adapting and downright plagiarism, often on a scale that by modern standards would seem outrageous. But almost every writer added something of value, and as dictionaries increased in number they tended to increase also in usefulness. Cawdrey, perhaps recalling the informal or complicated groupings of words in some earlier dictionaries, stressed the importance of the word "alphabeticall" in his title. Apparently some "unskilfull persons" in his day (as in ours) had not taken the trouble to learn their ABC's. So, he said, "Thou must learne the Alphabet, to wit, the order of the Letters as they stand."

At long last, in 1623, a work was issued entitled simply ***The*** *English Dictionarie*. The author, or compiler, was "H. C., Gent.," who turned out to be Henry Cockeram. Much of his material was borrowed from Cawdrey and others, but for the use of the intelligentsia he added some weird Latinesque words, such as *"Commotrix,* A maid that makes ready and unready her Mistris; *Glauci-tate,* To cry like a whelpe; *Torvitie,* Sowrenesse of countenance." An amusing definition of a more familiar word was *"Ovalt,* a long round circle like an Egge, wherein pictures are sometimes drawne in." Always dramatic, Cockeram calls his preface a "Premonition" or forewarning, perhaps having in mind the third section of his book, a fearsome "recitall" of "Gods and Goddesses, Giants and Divels, Birds and Beasts" and signs and wonders miscellaneous. Here we are told that the *"Hiena"* is "a subtil Beast, counterfeiting the voice of a man . . . He is sometimes male and sometimes female."

In 1656 a London lawyer named Thomas Blount published a dictionary entitled *Glossographia,* loosely translated as "an expounding of strange words." The author addresses himself to readers of all classes, including "the more-knowing Women and less-knowing Men." Blount did the best he could to provide etymologies, which was commendable; but some of his derivations were more amusing than accurate, as when he says *"Tomboy,* a girle or wench that leaps up and down like a boy, comes from the Saxon *tumbe,* to dance."

The *Glossographia* was followed in 1658 by *The New World of English Words,* "collected and published by E. P." "E. P." was Edward Phillips, a writer of only moderate ability. His *New World* was a pretentious work, largely copied from his predecessors, notably from Blount. The word "collected" on his title page was hardly frank enough; the truth would have been better expressed by "appropriated."

In 1676 Elisha Coles, teacher of shorthand, Latin and English, issued *An English Dictionary* with brief and generally adequate definitions and a small but interesting selection of cant and slang expressions. Coles was ingenious; in his address "To the Reader" he wrote:

I am no friend to vain and tedious Repetitions; therefore you will often meet with words, explain'd in their Dependence and Relation to one another, and the Sense compleated by taking them together: As for example
Lupa, a She-wolf that nourished *Romulus* in the
Lupercal, a place near *Rome,* where they celebrated the
Lupercalia, feasts in honour of *Pan,* performed by the
Luperci, Priests of Pan.

Coles died in 1680, but his dictionary was often reprinted and survived him by many years.

18th Century.—John Kersey, an open-minded and progressive lexicographer, is credited with a good small wordbook, *New English Dictionary,* issued in 1702 "by J. K. Philobibl." He also edited and revised Phillips' *New World of Words,* enlarging it in 1706 and somewhat abridging the enlarged version in 1708. Kersey was a pioneer in introducing and defining words of everyday use, which his predecessors had not troubled to do.

In 1721 was issued the *Universal Etymological English Dictionary,* a comprehensive work "compil'd and Methodically digested" by "N. Eailey, Philologos." This was Nathaniel Bailey, an ingenious and enterprising London schoolteacher. His book contained more words "than any English Dictionary before extant." In 1730 Bailey followed with his great *Dictionarium Britannicum,* a folio volume "containing not only the Words, and their Explications, but the Etymologies," and "Illustrated with near Five Hundred Cuts." This was enlarged in 1736. Bailey was more than a lexicographer; he was a philosopher, an entertainer and a humorist. When he came to an important word, he was seldom satisfied merely to define it; he used it as an excuse for a little lecture; for example: *"Woman* . . . the female of the human race . . . Women have two Qualities, a good and a bad. This is, they are either a blessing or a curse, according to the use we make of them"; then about 30 more lines of amusing commentary. Bailey was one of

the pioneers in indicating pronunciation, or at least marking the stressed syllables. Bailey's work was revised and reprinted for many years, and when Samuel Johnson was preparing his own dictionary, he kept by his side an interleaved copy of Bailey's *Dictionarium*.

Johnson, a sort of lexicographical giant, undertook, with very little aid, a work which in modern times would be entrusted to a corps of editors, subeditors and departmental experts numbered in the hundreds. In France and in Italy learned academies had been established to preserve the purity of the national languages. Academic concepts of purity involved a tendency to oppose change, in spite of the fact that change is essential to the life and growth of language. Johnson, with the approval of many of his contemporaries, was expected to be a one-man academy, to set forth the English tongue in all its glory and, if possible, to crystallize it in a classic form. He hoped to do it all within three years; it took him nearly eight—little enough for such a mighty task. That the task was mighty could be realized by anyone who saw the two folio volumes, published in 1755, of *A Dictionary of the English Language . . . by Samuel Johnson, A.M.* And when it was all done, Johnson admitted in his preface that no scholar "can embalm his language and secure it from corruption," and that "no dictionary of a living tongue can ever be perfect, since while it is hastening to publication, some words are budding, and some falling away."

Johnson was a skilled definer. He had a way of perceiving the essential character and use of a word, and of explaining it clearly. He pioneered in the illustration of definitions "by examples from the best writers," a work involving long and painstaking research. A few of Johnson's definitions became famous for reasons that had nothing to do with scholarship; as when he wrote: *"Lexicographer,* a writer of dictionaries; a harmless drudge"; and *"Excise,* a hateful tax levied upon commodities, and adjudged not by the common judges of property, but wretches hired by those to whom excise is paid." Johnson's services to the science and art of lexicography were substantial and of lasting value. They set a high standard for later workers to keep-in mind.

In 1791 came the *Critical Pronouncing Dictionary and Expositor of the English Language,* by John Walker, a 59-year-old actor with a trained and perceptive ear and a lively interest in all types of English pronunciation. Walker's dictionary is of value even now because of the author's thorough treatment of pronunciation problems. Its influence was felt throughout Britain and America. More than 40 editions were published. Walker, who died in 1807, was regarded as an authority as late as 1837, when Isaac Pitman, himself a famed phonetician, published a system of shorthand "founded on Walker's Principles of English Pronunciation."

In 1794, three years after Walker's first edition, another enterprising Londoner, James Hindmarsh, carried lexicography into a hitherto unexplored field with *A New Dictionary of Correspondences . . . or the Spiritual significations of words . . . in the Sacred Scriptures.* This work, based on the researches of Emanuel Swedenborg, gave meanings not of words but of scriptural persons, places and things, as: *Peter,* faith; *Egypt,* science; *Water,* truth.

Signs of **U.S.** Initiative.— As the 18th century drew to its close, more than 20% of the world's English-speaking people were inhabitants of the United States. Pledged to a policy of universal education, they felt the need of an English dictionary designed specifically for use in their primary schools. In 1798 this need was recognized by a Connecticut schoolmaster, Samuel Johnson, Jr., who issued in New Haven. Conn., a little book entitled *A School Dictionary.* Although this work was admittedly a "collection from previous authors," it was well received; it was the first English dictionary compiled by an American. In 1800 it was followed by another small book, *A selected, pronouncing and accented Dictionary,* of about 10,000 words, published at Suffield, Conn. Samuel Johnson, Jr., shared its authorship with John Elliott, pastor of the church in East Guilford. This Elliott-Johnson work showed signs of Americanization; it included a few words peculiar to America (tomahawk, wampum, Cincinnati), or considered to have American meanings (Capitol, federal, ireshet). It quoted endorsements from 19 educators, clergymen and others, including Noah Webster, then famed as author of a spelling book. The Connecticut pioneers indicated pronunciation, somewhat crudely, by diacritical marks and an occasional footnote.

Now, also in 1800, came *The Columbian Dictionary,* by another New Englander, Caleb Alexander of Massachusetts. In this work, containing about 32,000 entries, American usage was recognized by a few words (cent, dime, dollar, elector, Congress, Congressional, lengthy, minute-man, Presidential, Yanky), and honor, favor, color, Savior, troop, wo, were so spelled. Some alternatives were listed: calendar-kalendar, chequer-checker, screen-skreen, sponge-spunge. Pronunciation was shown by respelling. Whereas the Connecticut pioneers had given much of their space to "choice" or fairly hard terms, Caleb Alexander included also the simple words, providing a vocabulary that could reasonably be called complete.

A few weeks before Alexander's work was published, Noah Webster (*q.v.*), of New Haven, Conn., announced that he was planning a series of dictionaries. The first was published in 1806 as *A Compendious Dictionary of the English Language.* It contained about 40,000 words, with brief definitions. Webster spent years in language study and research to prepare for his masterpiece, *An American Dictionary of the English Language,* published in 1828 in two quarto volumes and thereafter in many revised and improved editions. The 1828 edition, which contained about 70,000 entries, earned general acceptance as an authority, even in England. Some of Webster's definitions were faulty, but many of them were confirmed, years later, when language study had become a science.

Still another New Englander, Joseph Emerson Worcester, issued three reputable dictionaries (1830, 1846, 1860), designed to record and not to reform American usage. Worcester's works were in some quarters preferred to Webster's; but Webster, although he died 22 years earlier than his rival, "had the last word," for he is remembered as America's foremost pioneer lexicographer.

Compilers of British dictionaries in the 19th century availed themselves generously of American aid. Sometimes they acknowledged their indebtedness, notably so in the case of the monumental *New English Dictionary on Historical Principles,* later known as the *Oxford English Dictionary.* This great work, conceived 70 years before its completion in 1928, listed and defined all recorded English words from the 7th century to the 20th. It showed each word in all its traceable forms, with dated quotations and with etymologies determined in the light of modern scholarship. Every possible use of a word was considered, with the result that the little word *set,* for instance, was allotted more than 22 large pages of three columns each. Pronunciation was indicated by scientific respelling.

The project involved years of research by hundreds of volunteers on both sides of the Atlantic. Editor in Chief James A. H. Murray stated that most of the co-operation from "men of Academic standing" came from "Professors in American Universities" and their students. In 1860 supervision of the American workers was in the hands of the Hon. G. P. Marsh of Vermont; in 1879 it was taken over by Prof. Francis A. March of Massachusetts, famed for his 50 years at Lafayette college in Pennsylvania. Both gentlemen were noted philologists, both New Englanders in the pioneer tradition and both were eager to help their British confreres in building a monument to their common tongue.

Historically important is The *Century Dictionary: an Encyclopedic Lexicon of the English Language,* first issued in 1889–91 in six volumes and edited by William Dwight Whitney of Yale. This work, which started as an authorized expansion and Americanization of the English *Imperial Dictionary,* was rich in words, etymologies and literary examples.

Modern American Dictionaries.— Prominent among large modern wordbooks is the *New Standard Dictionary of the English Language,* first published 1893–95 and periodically revised. Outstanding among works using the name of Noah Webster was *Webster's International Dictionary,* published in 1890 by G. & C. Merriam company. Its second edition, with "New" added to the title, appeared in 1934. Both editions were generally accepted as authoritative in legal and literary circles. In 1961, however, on publication of the third edition, a lively controversy arose, con-

cerning a "permissive" editorial policy, which. according to critical consensus, let down the bars that preserve good usage, thereby encouraging or condoning careless diction and writing.

Noah Webster died in 1843, and his name in many dictionary titles today derives from the days nhen "Webster" was almost a synonym for dictionary; even as "Calepin" in Europe is used for some modern wordbooks, in spite of the fact that the lexicographer Ambrogio Calepino (q *v.)* died in 1511.

Popular in the second half of the 20th century are medium-size dictionaries. often described as "collegiate." These are designed for use in business offices. schools and homes. Examples are *Webster's New World Dzctionary of the American Language,* published in 1953 and frequently revised; also *The American College Dzctionary* (1947) and later editions; and Funk & Wagnalls' *New College Standard Dictionary* (1958). Similar in content, but giving more space to derivations and to related words in other languages, is the *Consolidated Webster Dictionary,* new edition (1962). The *Britannica World Language Dzctionary,* published first in 1954 with the *New Practical Standard Dictionary,* has a master list of English words with their equivalents in French, German. Italian, Spanish, Swedish and Yiddish. In addition to the word list proper, this work includes letters of the alphabet, cardinal numbers, days of the week. months of the year and common first names; also data on grammar and pronunciation; there is a separate index for each language. *Wyld's Universal Dictiorzary of the English Language* (1957) gives modern British usage.

America's contributions to the vocabulary are found in *Dictionary of American English* (1936–44; 2nd edition, 1960); also, notably, in Mitford M. Mathews' *Dictionary of Americanisms* (1951; 2nd edition. 1956). The latter contains about 50,000 words and expressions, a large percentage of which have earned acceptance as normal English. Several hundred of the more picturesque of these are discussed informally by Mathews in his *American Words* (1959).

Foreign-Language Dictionaries.— Lexicography as a science owes much to the researches of Jakob Grimm (*q.v.*), one of the world's master philologists, discoverer of Grimm's law, and his hardly less famous brother Wilhelm Grimm. These eminent scholars, who did not think it beneath them to write the stories known as "Grimm's Fairy Tales," collaborated in launching a German dictionary on scientific principles, the great *Deutsches Wörterbuch,* started in 1852 and completed years later by their followers. In many ways the *Wörterbuch* served as an aid to norkers in other languages.

Also of international repute and service in this field was Émile Littré, French dictionarian, philosopher and physician, whose *Dictionnaire de la langue française* (1863–72; new edition, 1958) is one of the monuments of lexicography. The 1958 edition contains the author's useful treatise, *Comment j'ai fait mon dictionnaire.* His work, a one-man task for more than 30 years, is a fascinating blend of science and genius. It served as a treasury on which many later compilers have drawn freely.

Pierre Larousse (1817–75), a distinguished French educator, published the *Grand dictionnaire universel* in 15 volumes, virtually an encyclopaedia. completed in 1876 just after his death. His successors have issued a series of dictionaries to meet varied popular needs such as the *Nouveau Larousse illustré,* the *Larousse universe1* and the *Petit Larousse,* all of them revised from time to time.

Other foreign dictionaries of outstanding value, available in the 1960s, include the following:

Hebrew: H. F. W. Gesenius. *Hebrew and Chaldee Lexicon to the Old Testament* (Ger. original, 1819; Eng. trans.. 1957); M. Jastrow, *Dictionary of the Targumim, Talmud Babli and Yerushalmi, and Midrashic Literature,* 2 vol. (1950).

Gseek: H. G Liddell and R Scott, *Greek-English Lexicon* (first issued 1843; revised 1958); W. F. Arndt and F. Wilbur Gingrich, *Greek-English Lexicon of the New Testament,* revised and adapted from Walter Bauer's German nork (1957).

Latin: C. T. Lewis and C. Short, *Latin-English Dictionary* (1907).

French: J. and W. Bellows, *French-English and English-French Dictionary (1951).*

Italian: B. Reynolds (ed.), *The Cambridge Italian Dictionary,* vol. i, Ital.-Eng. (1962).

Spanish: E. B. Williams, *Spanish aad English Dictionary* (and Eng.-Sp.) (1957); A. Cuyas, *Appleton's New! English-Spanish and Spanish-English Dictionary (1956).*

German: M. Bellows, *German-English, English-German Dictionary* (1956).

Dutch: J. Cauberghe, *Woordenboek* (Dutch-Eng., Eng.-Dutch) (1952).

Swedish: W. E. Harlock *et al., Svensk-Engelsk Ordbok* (Swed.-Eng. only) (1947).

Danish: J. Magnussen *et al., Ordbog* (Eng.-Dan., Dan.-Eng.) (1954).

Icelandic: (of great value in study of all Scandinavian and Germanic languages) R. Cleasby, G. Vigfusson and W. A. Craigie, *An Icelandic-English Dictionary* (1st ed., 1874; rev. ed., 1957).

Russian: M. A. O'Brien, *New Russian-English, English-Russian Dictionary* (new orthography) (1948).

Chinese: Yuen Ren Chao and Lien Sheng Yang, *Concise Dictionary of Spoken Chinese* (1952).

Japanese: O. and E. E. Vaccari, *Concise English-Japanese and Japanese-English Dictionary* (1958).

BIBLIOGRAPHY.—Some of the best essays on the making of dictionaries are found in prefaces of the important modern works of the 19th and 20th centuries mentioned above. Separate works of value are *A Survey of English Dictionaries* by Mitford M. Mathews (1923) and The *English Dictionary From Cawdrey to Johnson* by De Witt Starnes and G. E. Noyes (1946). Important also is a Spanish work, *Introducción a la Lexicografia Moderna,* by Julio Casares (1950). Robert L. Collison's *Dictionaries of Foreign Languages* (1955) is a useful guide to hundreds of wordbooks, some of them little known. (A. McQ.)

DICTUM DE OMNI ET NULLO, the statement that whatever may be predicated (or denied) of all members of a given class may also be predicated (or denied) of all members of any subclass of that class. This statement has often been considered fundamental to the theory of the syllogism, in the sense that the valid moods of the first figure *(Barbara, Celarent, Darii* and *Ferio; see* LOGIC, HISTORY OF: *Ancient Logic),* to which all the others are reducible, may be "validated" by means of it. For example, one may interpret the premisses of *Barbara* to assert that *A* is predicated of all *B* and that *C* is a subclass of *B;* then the *Dictum* justifies the conclusion that *A* may be predicated of all *C*. Similarly, the first premiss of *Ferio* denies *A* of all *B*, while its second premiss says that *Some C* is a subclass of *B*, and thus *A* may be denied of *Sonze C*. The moods *Celarent* and *Darii* are treated analogously. Several rather different versions of the *Dictum* exist. There is also a lack of agreement as to which passage in Aristotle's works, if any, is the ultimate source. Most authorities favour the statement in his *Prior Analytics* I, col. 24 b, 28–30: "We use the expression 'predicated of all' whenever no instance of the subject can be found of which the predicate is not true." Others point instead to col. 25 b. 32–35, in the same book and one common version of the *Dictum* appears to be a translation of *Categories,* 1b, 10–12. There is, however, no evidence that Aristotle himself regarded any of these statements as the foundation of his syllogistic. (B. Ms.)

DICTYS CRETENSIS, according to the prologue of the *Ephemeris belli Troiani* which goes under his name. followed Idomeneus to Troy, and at his instigation composed an account of the Trojan War; the manuscript, written in Phoenician characters. was buried in Dictys' tomb at Knossos. discovered in the reign of Nero. and by Nero's command transliterated into Greek script. The Latin. *Ephemeris,* a supposed translation of this account by Lucius Septimius (probably 4th century A.D.), was a source of medieval versions of the Troy story equal in importance to the *De excidio Troiae* of Dares Phrygius (*q.v.*), which it resembles in its provision of authenticating detail and in its partisanship (Dictys is pro-Greek. Dares pro-Trojan). A papyrus fragment of a Greek version shows Septimius to have been a translator who closely followed his original in books i–v though book vi, on the return of the Greeks, condenses books vi–x. The origi-

nal Greek text probably dates from the 1st or 2nd century A.D.

See edition, with papyrus fragment, by W. Eisenhut (1958).

(D. R. BR.)

DICUIL (fl. 825), Irish monk, grammarian and geographer, whose work, important to the historian of science, is a monument of Irish learning in the 9th century. Much of his astronomical knowledge was gained in calculating dates to regulate the calendar for religious festivals. His *De mensura orbis terrae,* finished in 825, contains the earliest notice of a European discovery of and settlement in Iceland and the most definite western reference to the old fresh water canal beween the Nile and the Red sea, blocked up in 767.

In 795 Irish hermits had visited Iceland, where they marveled at the perpetual day of midsummer. Relics of their settlements were found by the permanent Scandinavian colonists of Iceland in the 9th century. Of the old Egyptian fresh water canal Dicuil learned from one "Brother Fidelis," probably another Irish monk, who, on his way to Jerusalem, sailed along the "Nile" into the Red sea—passing on his way the "Barns of Joseph" or pyramids of Gizeh, which are well described. Dicuil's reading was wide; he quotes from, or refers to, 30 Greek and Latin writers and his contemporary, the Irish poet Sedulius; he professes to utilize the alleged surveys of the Roman world executed by order of Julius Caesar, Augustus and Theodosius.

A short astronomical treatise written between A.D. 814 and 816 was edited by Mario Esposito in the *Proceedings of the Royal Irish Academy,* vol. xxvi, s. C (1907). The best edition of the *De mensura* was made by G. Parthey (1870).

See also *C. R.* Beazley, *Dawn of Modern Geography,* vol. i (1897).

(E. E. E.)

DIDACHE (TEACHING OF THE [TWELVE] APOSTLES), an early Christian document known from references in early writers but not discovered in manuscript until 1875, in Constantinople, by Philotheos Bryennios. It comprises 16 short chapters dealing with morals and church practice. *See* APOSTOLIC FATHERS; CONSTITUTIONS, APOSTOLIC (for the seventh book of which it forms the basis).

DIDEROT, DENIS (1713–1784). French man of letters and philosopher, was one of the most brilliant and original thinkers of his age and the chief editor of the *Encyclopédie,* the magnificent testament of the age of Enlightenment.

He nas born Oct. 5, 1713, at Langres, where he received his early education, and was tonsured at the age of 13, but he did not in fact enter the church. His father, a master cutler, was much respected in his own milieu and by his son. In 1729 Diderot moved to Paris where he attended classes at the Jansenist Collège d'Harcourt, or at the Jesuit Lycée Louis-le-Grand or most probably at both these institutions. It is known that he was awarded the degree of master of arts in the University of Paris on Sept. 2, 1732. He proceeded to study law. as an articled clerk, in the office of Maître Clément de Ris, but he was more interested in mathematics and in languages, in which he showed exceptional proficiency. From 1734 to 1744 he led a penurious existence as a publisher's hack, writing sermons for missionaries at 50 *écus* each and seeking relaxation in the coffee houses, particularly the "Régence" and the "Procope," where he became acquainted with Jean Jacques Rousseau. There is evidence that Diderot intended. about 1741, to take up an ecclesiastical career but none that he actually entered the seminary of St. Sulpice. In 1741 he met Antoinette, daughter of Mme Champion, a linen draper, and in 1743 was married secretly to her, since his father disapproved. The marriage, at first romantic, mas unhappy, since the couple had little in common. Of their four children only Angélique, born in 1753, survived, and she became one of his deepest attachments. He took great pains over her education and later arranged her marriage.

Mme de Puisieux, for whose financial advantage he published the *Pensées philosophiques* (1746) and *Les Bijoux indiscrets* (1748), was his mistress for a time; and with Sophie Volland, whom he met in 1755 or 1756 and to whom he remained attached until her death in 1784, he enjoyed an intimate friendship. His correspondence with Sophie, which has been preserved, forms, with his other letters, one of the most fascinating documents on Diderot's personality, enthusiasms and ideas, as well as on his social connections, the milieu of Mme d'Épinay and his close friend Baron F. M. Grimm, of the baron d'Holbach, the *abbé* Ferdinando Galiani (*qq.v.*) and many *philosophes.* The letters are written in a vivid, colloquial style and are highly prized for their entertaining qualities and for their insight into the life of the period. They reveal the exuberant conversationalist, the gifted narrator and the emotional lover. Through his friendship with Rousseau, which lasted for 15 years, Diderot met the philosopher the *abbe'* E. B. de Condillac (*q.v.*), and for a time the three friends dined together once a week at the "Panier fleuri." Diderot broke with Rousseau in 1758 over the three-cornered entanglement involving J. F. de Saint-Lambert, Mme d'Houdetot and Rousseau, but there is considerable controversy over differing accounts of the quarrel.

In 1745 Diderot was approached by the publisher André le Breton with a view to bringing out an encyclopaedia. It was originally to have been a French translation of Ephraim Chambers' *Cyclopaedia* (which in turn owed much to the Dictionnaire de Trévoux), entrusted in 1743 to John Mills and Godefroy Sellius. But Diderot soon changed the whole nature of the undertaking, turning it into an important organ for mobilizing radical and revolutionary forces. He had already had some experience of translation work, having rendered into French the 3rd earl of Shaftesbury's *Inquiry Concerning Virtue or Merit* (in 1745), Temple Stanyan's *Grecian History* (in 1743) and Robert James's *A Medicinal Dictionary* (in 1746–48). He seized the opportunity of broadening the scope of the project and gathered together a team of active and devoted workers, among them littérateurs, scientists and even priests, some well established, others at the beginning of their careers, but all fired with a common purpose: to further knowledge and by so doing strike a resounding blow against reactionary forces in church and state. Diderot outlined his program in a *Prospectus* (1750), leaving it to his co-editor Jean d'Alembert (*q.v.*) to expand and systematize it in his momentous *Discours préliminaire* (1751). They saw knowledge as an organized whole and stressed the interconnections between the sciences in a genealogical tree which owes something to Francis Bacon. As a *dictionnaire raisonné,* the *Encyclope'die* was to bring out the essential principles and applications of every art and science. The underlying philosophy was rationalism and faith in the progress of the human mind. The history of the *Encyclope'die (see* ENCYCLOPAEDIA), from the publication of the first volume in 1751 to the distribution of the final volumes of plates in 1772, was checkered but ultimate success was never in doubt. Diderot was undaunted by the cabals of enemies and the desertion of friends. A critical moment occurred in 1758 on the publication of the seventh volume, when d'Alembert resigned on receiving warning of trouble and reading Rousseau's attack on his article *Genève.* It was at this time that Helvétius's book *De l'Esprit,* said to be a summary of the *Encyclope'die,* was condemned to be burned by the parliament of Paris and the *Encyclope'die* formally suppressed. Diderot's most devastating experience, however, was to discover in 1764 that Le Breton had secretly removed compromising material from the corrected proof sheets of about ten folio volumes. Three hundred pages of proof, with corrections in Diderot's hand, were found in 1933 by D. H. Gordon in A. Rau's catalogue, the documents emanating from the Leningrad collection of Diderot books and manuscripts. The censored passages, of considerable interest, are not such as to have made an appreciable difference on the impact of the work. In fact, nowhere in the *Encyclope'die* is there an overt attack on articles of faith or on the government. This makes the unbridled wrath of the ecclesiastical party surprising unless one remembers the historical context of polemical controversy. To the 17 volumes of text and 11 volumes of plates (1751–72), Diderot contributed innumerable articles, especially on the history of philosophy (the article "Eclectisme," which is a book in itself), social theory ("Droit naturel"), aesthetics ("Beau") and the mechanical arts. He was, moreover, an energetic general editor and supervised the illustrations for 3,000 to 4,000 plates of exceptional interest.

In addition to his work for the *Encyclope'die,* Diderot published the *Lettre sur les aveugles* (1749), which emphasizes our dependence on sense impressions and marks an important step toward atheism. He was arrested because of its daring and irreligion and imprisoned at Vincennes for three months. His *Lettre* is also important for its proposal to teach the blind to read through the sense of touch and for its presentation of the first step in his evolutionary theory of survival by superior adaptation. In 1751 he published the *Lettre sur les sourds et muets,* which studies the function of language and deals with points of aesthetics, and in 1754 the *Pensées sur l'interprétation de la nature,* acclaimed as the *Discours de la méthode* of the 18th century and herald of the new experimental approach to science. Diderot published few other works in his lifetime. His manuscripts were known only to intimates and the privileged correspondents of Grimm's *Correspondance littéraire.* Among his philosophical works special mention may be made of *Le Rêve de d'Alembert,* the *Entretien entre d'Alembert et Diderot* which precedes it (both written 1769, published 1830) and the *Eléments de physiologie* (1774–80). In all these works Diderot developed his materialist philosophy, foreshadowing the evolutionary doctrine and evolving the first modern theory of the cellular structure of matter. But though his speculations in the field of science are of great interest. it is the dialectical brilliance of their presentation that is exceptional. Diderot successfully exploited a manner initiated by Bernard de Fontenelle, but unlike Fontenelle he was more concerned with deepening and developing his thought for its own sake and giving rein to his astonishing imagination, than with popularizing his argument for the benefit of the contemporary reader. His ideas, often propounded in the form of paradox and invariably in dialogue, stem from a sense of reality and a profound understanding of the complexities and contradictions inherent in human nature. All his works reveal his penetrating mind and show him to be an original thinker with flashes of intuitive insight.

His essays, among them *Regrets sur ma vieille robe de chambre* (1772) and *Entretien d'un père avec ses enfants* (1773), share the same qualities of form and style as his short stories, *Les Deux Amis de Bourbonne* (1773) and *Ceci n'est pas un conte* (1772, published 1798), and his novels: *La Religieuse* (1760, published 1796). *Jacques le Fataliste* (1773, published 1796) and *Le Neveu de Rameau* (written between 1761 and 1774), which Goethe so greatly admired and translated in 1805 (French edition in 1823, authentic text in 1891). *Jacques le Fataliste,* which owes something to Laurence Sterne and has been considered as a kind of *"anti-Candide,"* is in the tradition of the picaresque novel and of the *conte philosophique.* Jacques, who believes in Fate, is involved in an endless argument with his master, who does not, as they journey along retelling the story of their lives and loves. Diderot's philosophical standpoint is ambivalent, as is his ethical standpoint in *Le Weveu de Rameau.* The latter work may properly be called a satire. It challenges the cant of contemporary society and the hypocrisy of conventional morality. It offers a vigorous dramatic sketch of a parasite and an eccentric, a musician who is gifted yet unable to make his mark through insufficient talent and is shamelessly selfish. The dialogue between Diderot and Rameau's nephew is spontaneous and witty, the comments are pungent, bitter and ironic; the arguments are well sustained and wholly convincing because they are related to character, personality and idiosyncrasies of expression and movement. There are digressions, a lengthy disquisition on contemporary musical controversies and diatribes against Diderot's own enemies. This brilliantly conceived, highly original and entertaining *divertissement* cuts deep. It has authenticity and reveals the complexity of Diderot's nature and of his philosophical ideas. In the *Supplément au voyage de Bougainville* (1772, published 1796), Diderot emphasized his conception of a free society based on tolerance and developed his views on sexual liberty.

Diderot, who was deeply interested in the theatre, had many of the qualities necessary for the successful playwright. His delightful play *Est-il bon? Est-il mechant?* (1781, published 1834), nhich was not staged. is a small masterpiece. Yet neither of his major plays, *Le Fils naturel* (1757) and *Le Pkre de famille* (1758), was truly successful. However, his theories, which are to be found in *Entretiens sur le Fils Naturel* (1757) and *De la poésie dramatique* (1758), are important to the history of drama. Taking as his starting point the *comédie larmoyante,* which he admired, he stressed the need for greater realism on the stage and favoured the serious, dramatic, bourgeois drama of real life. Characters should be presented against their milieu and belong to specific professions, so that the moral and social implications of the play. which he considered to be of primary importance, should have greater impact. He urged modifications in stagecraft and décor and was convinced that *tableaux vivants,* reminiscent of canvasses by J. B. Greuze. would deeply move the audience His theories exercised a determining influence on G. E. Lessing, whose *Hamburgische Dramaturgie* appeared in 1767–68. It mas not until the 19th century, however, that certain of Diderot's suggestions were adopted on the French stage by such playwrights as Émile Augier and Dumas *fils.* In his best-known writing on the theatre, the *Paradoxe sur le comédien* (1773–78, published 1830), which is in dialogue form, Diderot argues that great actors, like great poets. are insensitive. The great actor must possess judgment and penetration without sensibility, which would impede his interpretation. His definition of the actor is interesting: "un pantin merveilleux dont le poète tient la ficelle et auquel il indique la véritable forme qu'il doit prendre" ("a fabulous puppet, for whom the poet holds the strings. and determines the essential shaping of his part"). As well as writing on the theatre and his literary criticism—*Réflexions sur Terence* (1762) and *Éloge de Richardson* (1761)—Diderot became an art critic, covering the *salons* or annual art exhibitions of his day for the *Correspondance litte'raire* edited by Baron Grimm (1759–81). His analysis of art, artists and the technique of painting is remarkable for a critic without practical experience of painting, yet his approach is a literary one. and the subject of a canvas. its meaning or message, of primary importance. His *Salons* have set a standard for all subsequent art-criticism, mainly because of the natural excellence of his taste and the vigour of his writing. They were handsomely edited and illustrated in 1957. Diderot's aesthetic, first expressed in the article "Beau" in the *Encyclope'die,* is to be found in *Essai sur la peinture,* which may be read in conjunction with the *Salons.*

The completion of the *Encyclope'die* left Diderot without a regular source of income. To relieve him of financial worry, Catherine the Great of Russia first bought his library for a substantial sum through an agent in Paris, with a request that he retain the books in Paris until she required them; she then appointed him librarian with a yearly salary for the duration of his life. Diderot went to St. Petersburg in 1773 to thank her and was received with great honour and warmth. He wrote for her the *Plan d'une université pour le gouvernement de Russie* (published 1813–14). After his death his books, and copies of all his manuscripts, were dispatched to Catherine the Great by his daughter Mme de Vandeul. The set of manuscripts which the latter retained with a view to their ultimate publication was preserved, because of the prompt action of H. Dieckmann *(cf. Inventaire du Fonds Vandeul et Inedits de Diderot,* 1951) and deposited in the Bibliothèque Nationale.

In 1774 Diderot returned home. Now old and ill, he completed his *Réfutation de l'ouvrage d'Helvétius institulé L'Homme* (published 1875). and in 1778 published an *Essai sur les règnes de Claude et de Néron,* known as *Essai sur Sénèque,* which may be regarded as an apologia. His intimate circle was dwindling. When Rousseau died in 1778 (in the same year as Voltaire) Diderot, who had long been estranged from him, expressed no regret. Mme d'Épinay and d'Alembert died before him. Only Grimm and Baron d'Holbach remained. Slowly Diderot retired into the shell of his own personal and family life. He was now on better terms with his wife and took pleasure in the company of his friend Belle, a jeweler, nhom he visited at Sbvres. The death of Sophie Volland in 1784 was a great grief to him. He survived her by only five months, dying of coronary thrombosis on July 30, 1784, in the house in the Rue de Richelieu which Catherine the Great had put at his disposal. Apocryphally his last words were: "Le premier pas vers la philosophie, c'est l'incrédulité" ("The first step toward philosophy is incredulity"), a ghostly reiteration of a statement

made in the early *Pensées philosophiques*. It was because of the intervention of his son-in-law that he was buried in consecrated ground at St. Roch.

DIDINGA, a small Negro tribe of the southeastern Sudan numbering about 2,000 people. Very little is known about them or their ethnical affiliations except that they are closely related to the Murle, Beir and Longarim (who live in the same locality). Despite difference in language and origin, however, their culture is otherwise very similar to the Nilo-Hamitic peoples who surround them. The Didinga are pastoralists, keeping cattle. The men go naked; the women wear aprons and skin mantles. The tribe has a powerful rainmaker, who also officiates for the Longarim and the Nilo-Hamitic Topotha, but in other matters political and ritual authority is exercised by local elders. The Didinga have a reputation as fierce raiders and are a perpetual cause of disturbance to the Sudan administration.

DIDIUS JULIANUS, MARCUS, Roman emperor in A.D. 193 (March 28 to June 2), came from one of the most prominent families of Mediolanum (Milan). His mother was a close relative of Salvius Julianus, the great lawyer and statesman of Hadrian's reign. Born *c.* 135, Didius Julianus had a long public career of distinction. After commanding the legion at Moguntiacum (Mainz), *c.* 167, he governed northeastern Gaul, Dalmatia, the lower Rhine, Bithynia and his mother's native province of Africa. During the political disturbances of Commodus' reign, he was banished to Milan. He was about 60 yr. old when Commodus was murdered on the eve of Jan. 1, 193. His successor Pertinax was assassinated by the imperial guards at the end of March. Backed by a group of senators with some Milanese connections, Julianus competed with the late emperor's father-in-law, T. Flavius Sulpicianus, in offering the guards a substantial donative (accession bounty), and when Sulpicianus outbid him, he raised his own figure, also promising to restore the memory of Commodus, which the senate had condemned. His offer accepted, he was escorted to the senate house by the guards, to be met by angry demonstrators denouncing the auction and invoking the intervention of the army in Syria. The legions of the Danube, however, marched on Rome and killed him, proclaiming their principal commander P. Septimius Severus as emperor.

DIDO (ELISSA), the reputed founder of Carthage (*q.v.*), daughter of the Tyrian king Mutton, wife of Acerbas. Her husband having been slain by her brother Pygmalion, Dido fled to Cyprus, and thence to the coast of Africa where she purchased from a local chieftain, Iarbas, a piece of land on which she built Carthage.

The city soon began to prosper and Iarbas sought Dido's hand in marriage, threatening her with war in case of refusal. To escape from him, Dido constructed a funeral pile, on which she stabbed herself before the people.

Virgil, in defiance of the usually accepted chronology, makes Dido a contemporary of Aeneas, with whom she fell in love after his landing in Africa, and attributes her suicide to her abandonment by him at the command of Jupiter. Dido was identified with the Virgo Caelestis; *i.e.,* Tanit, the tutelary goddess of Carthage. Timaeus is the oldest authority for the story; the meaning of the name Dido is uncertain.

DIDOT, the name of a family of French printers, publishers, type founders and papermakers. The founder of the family business and its various later ramifications was FRANÇOIS DIDOT (1689–1757), who began business as a printer and bookseller in Paris in 1713. Among his important productions was a collection of the travels of his friend, the Abbé Prévost, published (1747) in 20 volumes. FRANÇOIS AMBROISE DIDOT (1730–1804), son of François, is noted mainly for important improvements in type founding and is thought to have been the first to attempt printing on vellum in 1780. Among the works that he published was a collection of French classics prepared by order of Louis XVI. PIERRE FRANÇOIS DIDOT (1732–1795), his brother, was especially adept at type founding and papermaking. Among the works printed on his press was an edition in folio of the *Imitatio Christi* (1788). HENRI DIDOT (1765–1852), son of Pierre François, is remembered chiefly for his editions of various standard works printed with microscopic types; he engraved these small types when almost 70 years of age. LÉGER DIDOT (1767–1829), second son of Pierre François, was the inventor of a papermaking machine. PIERRE DIDOT (1761–1853), eldest son of François Ambroise, is noted mainly as the publisher of especially beautiful editions of Virgil (1798), Horace (1799), Racine (1801–05) and other classics.

FIRMIN DIDOT (1764–1836), another son of François Ambroise, was credited with inventing stereotyping and was noted as a publisher, printer, type founder and author. He was the author of two tragedies—*La Reine de Portugal* (1824) and *La Mort d'Annibal* (1817). AMBROISE FIRMIN DIDOT (1790–1876), eldest son of Firmin Didot, published many important works with his brother HYACINTHE FIRMIN DIDOT (1794–1880). When the father retired in 1827, the two brothers took over the business. Their most important publishing venture was a new edition of the *Thesaurus Graecae linguae* compiled by Henri Estienne (9 vol., 1855–59). Among numerous other important works published by the two brothers were the 200 volumes forming the *Bibliothèque des auteurs grecs, Bibliothèque latine* and *Bibliothèque française.* In 1875 Ambroise Firmin Didot published a learned, elaborate monograph on Aldus Manutius, Venetian printer of the 15th century. At the time of his death, his collection of manuscripts was said to have been worth 2,000,000 francs.

The Didot business was operating in Paris in the 1960s as F. Didot and Company. (W. V. HA.)

DIDYMA (DIDYMI or BRANCHIDAE), an ancient sanctuary of Apollo in Ionia, *c.* 15 mi. S. of Miletus (by road), in the Aydin *il* (province) of Turkey. The name Branchidae derived from the priestly caste, which claimed descent from Branchus, a youth beloved by Apollo. As the seat of an oracle, the archaic Ionian temple attracted offerings from the pharaoh Necho and the Lydian Croesus, but was plundered and burned either (according to Herodotus) by Darius the Great of Persia or (according to Strabo and others) by Xerxes I early in the 5th century B.C. The Branchidae, willing exiles to Bactria, were massacred there by Alexander the Great. The famous cult statue of Apollo, by Canachus, familiar from reproductions on Milesian coins, was also carried off to Persia, there to remain till restored by Seleucus I. The oracle revived under Alexander, and the extant temple was begun about 300 B.C. Still incomplete under Caligula, who wished

to appropriate it, the structure was never wholly finished. But, even as it was, Strabo considered it the greatest Greek temple, and Pliny placed it among the four most splendid, second only to the Xrtemisium at Ephesus.

The first excavation. by E. Pontremoli and B. Haussoullier. cleared the front parts and discovered some of those building inscriptions now surmised to cover a century and a half of the temple's erection. The whole building was finally cleared by T. Wiegand and H. Knackfuss between 1905 and 1930. The noble remains reveal it as a decastyle dipteral Ionic structure, standing on seven steps and with outer columns 60 ft. high. 21 in each row on the flanks. It is remarkable not only for its great size but also for its large, sunken, hypaethral cella with free-standing *naiskos* (shrine); its complicated *pronaos* (hall), the rear of which is in two stories; the staircases. or labyrinths (a very early example of vaulting), down to the lower *pronaos (prodonzos)* and cella; the elaborate external order, with varied bases, figured "eyes" to the volutes and Medusa heads in the frieze; and the antae and engaged Corinthian columns of the cella.

There survive some carved pieces from the earlier temple, and also some archaic statues removed from the Sacred Way by C. T. Newton and now in the British museum.

Thomas, *Milet et le Golfe Latmique* (1877); E. Pontremoli and B. Haussoullier, *Didymes* (1903); T. Wiegand and others, *Didynta* (1941–58). (WI. H. P.)

DIDYMIUM, originally regarded as a chemical element. was found by C. A. von Welsbach in 1885 to be a mixture of the two elements praseodymium (*q.v.*j and neodymium (*q.v.*). See also RARE EARTHS.

DIDYMUS THE BLIND (*c.* 313–*c.* 398), head of the catechetical school of Alexandria, where he was horn and died, supported the Council of Nicaea and commented on various books of the Bible. His works, but not his person, were condemned at the fifth ecumenical council (553) for teaching Origenist doctrine. His biblical commentaries survive in fragments only; those on the Catholic Epistles are of dubious authenticity. He wrote treatises on the Trinity. the Manichees (his authorship of both has been questioned) and the Holy Spirit (extant in Latin translation).

See J. P. Migne, *Patrologia Grarca,* vol. xxxix (1858) for most of his works; *see* also A. Van Roey in A. Baudrillart (ed.), *Dictiotznaire d'histoire eccltsiastique et de géographie,* vol. xiv (1960).

DIDYMUS CHALCENTERUS (*c.* 83–10 B.C.), Greek scholar and grammarian and one of the chief channels through which ancient learning was transmitted to modern times. Born at Alexandria, he taught there and later perhaps at Rome. His surname, which means "of the brazen guts," came from his industry: he was said to have written more than 3.500 books. most of them compilations from earlier authors. Later commentators, scholiasts and lexicographers drew freely on his vast store of information. His works comprised: (1) an attempt to recover the lost editions of Homer by Aristarchus from later copies and Aristarchus' other Homeric writings; (2) commentaries on many other Greek poets and prose writers which seem to have aimed particularly at illuminating the subject matter; (3) numerous lexicographical works, the most important being his collections of phrases from tragedy and comedy; (4) grammatical writings; (5) miscellaneous contributions to literary history, on myths and legends, the Greek lyric poets, the tablets of the laws of Solon, proverbs, etc.

See M. Schmidt (ed.), *Didymi Chalcenteri grammatici Alexandrini fragmenta* (1854); J. E. Sandys, *A History* of *Classical Scholarship,* vol. *1,* 140–143, 3rd ed. (1921). (E. A. B.)

DIEBITSCH, HANS KARL FRIEDRICH ANTON, COUNT (1785–1831), called hy the Russians IVAN IVANOVICH DIBICH-ZABALKANSKI, Russian field marshal! was born of a German family at Grossleipe, Silesia, on May 13, 1785. He was educated at the Berlin cadet school. but passed into the service of Russia in 1801. He served in the campaign of 1805, was wounded at Austerlitz and fought at Eylau and Friedland, after which he was promoted captain. He distinguished himself in Count P. K. Wittgenstein's campaign, in particular at Polotsk (Aug. 17–18, 1812), and was promoted major general. In the latter part of the campaign he served against the Prussian contingent of Gen. J. D. L. Yorck von Wartenburg. with whom, through Karl von Clausewitz, he negotiated the convention of Tauroggen, serving thereafter with Yorck in the early part of the War of Liberation. After the battle of Lützen he served in Silesia and took part in negotiating the secret treaty of Reichenbach. He fought at Dresden and Leipzig. At the crisis of the campaign of 1814 he urged the march of the allies on Paris. In 1815 he attended the congress of Vienna. and was afterward made adjutant general to the emperor Alexander I, who hsd great confidence in him and showed him special favour. In 1824 he had become chief of the general staff, and in 1825 he assisted in suppressing the rising of the Dekabrists (*q.v.*) in St. Petersburg. He was made count in 1827. His greatest exploits were in the Russo-Turkish War of 1828–29. which was decided by Diebitsch's brilliant campaign of Adrianople, which surrendered to him on hug. 20. 1829; this won him the rank of field marshal and the designation "Zabalkanski" to commemorate his march across the Balkans. In 1830 he was appointed to command the army destined to suppress the insurrection in Poland. He won the terrible battle of Grochow on Feb. 25 and was again victorious at Ostroleka on May 20, but soon after he died of cholera (or by his own hand) at Kleszow near Pultusk, on June 10, 1831.

DIE CASTING (PRESSURE CASTING). Die casting is the manufacture of a metal object by injection of molten metal under high pressures into molds (dies) of metal. The molds, or dies, are the inverse shape of the object (casting) being made. Die casting differs from the English gravity die casting and its American counterpart. permanent mold casting. in which reusable molds made of metal are fed by gravity pressure or centrifugal force only *(see* FOUNDING: *Methods of Molding).* Die casting employs injection pressures on the liquid metal up to 100.000 lb. per square inch (p.s.i.) with forces for locking large die faces in position reaching as much as 4.000.000 lb. Although die casting is not a 20th-century development (the Mergenthaler Linotype machine invented in 1884 is one of the earliest applications of this process), it was not used industrially to any great extent until World War I. The process. as well as the casting made. is called die casting in America and pressure die casting in England.

The development and adoption of the automotive assembly-line technique of manufacturing opened up a huge consumer outlet for die castings and provided the necessary stimulus for mass production needed to make die casting an economical method of manufacturing. Castings produced by this process vary from tiny pieces. such as carburetors or sewing-machine parts, to single-piece aluminum engine-block castings weighing up to 45 lb. By means of high injection pressures it is possible to make thin, satin-smooth castings of such well-known items as vacuum-cleaner heads, automobile grills, sewing-machine heads and bases, lawn-mower bodies and thousands of less well-publicized engineering parts. Linear dimensional accuracies of 0.001 in. per inch make it possible to use mating interlocking parts without expensive machining; also, inserts can be used in the metal dies (such as cast-iron cylinder walls or threaded mounting pins) to produce castings requiring little or no machining. The high production rate (up to 500 cycles per hour) and adequately high strength of die castings make the

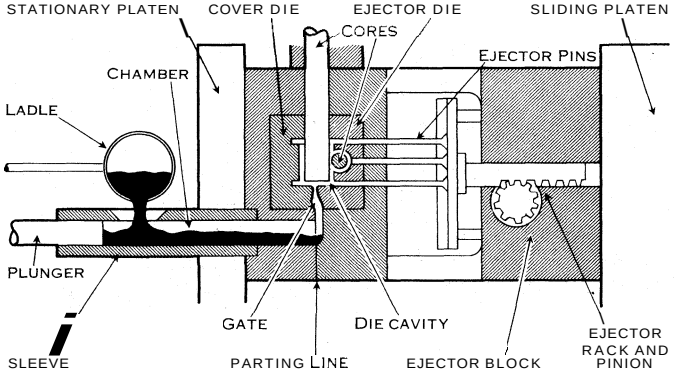

FIG. 1.— CROSS-SECTION VIEW OF A COLD-CHAMBER DIE-CASTING MACHINE SHOWING METAL BEING LADLED INTO A CHAMBER

process attractive to production-minded engineers. One or several die castings can be made for each injection by use of multiple impression dies.

The two basic die-casting processes are identifiable by their names, the cold-chamber machine employs a water-cooled cylinder into which metal is ladled as in fig. 1, and the piston or gooseneck type (submerged plunger) which has the pot of metal mounted directly to the machine. Both types are identical. except for the method of injecting molten metal into the dies. In both, a movable die half opens and closes by hydraulic or mechanical force or by a combination of hydraulic and mechanical mechanisms To each die there are tno main parts nhich separate for removal of the casting One part. called the ejector die (incorporating ejector pins for pushing the casting from the die). and an ejection-pin block with a geared mechanism. is mounted on the movable end of the machine The other part. the cover die, remains stationary and contains the hole, or sprue, through which metal is fed into the casting cavity. It is at this end that the two machines differ fundamentally. The sequence of operations is shown in fig 1–4

The cold-chamber machine provides a cylinder. usually horizontal, into which metal is ladled The close-fitting water-cooled plunger is positioned at rest in the cylinder behind the pouring slot. After the metal is fed into the cylinder, the plunger is forced forward by hydraulic pressure which confines the liquid metal suddenly and forces it into the mold cavity. The liquid metal solidifies quickly because the dies are also water-cooled; the dies are then opened and the ejector pins force the casting from the die. The casting cycle is non complete, and the machine is ready for the next cycle. This sequence is repeated in a cadence regulated by electronic timers. solenoids and limit snitches.

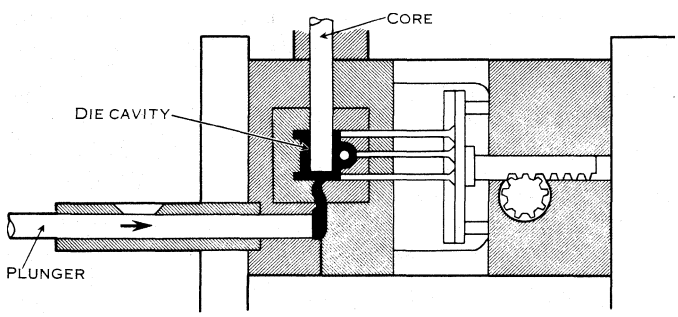

FIG. 2.— LIQUID METAL FORCED INTO THE MOLD CAVITY BY PLUNGER

In the submerged plunger type. both the plunger and the shot cylinder are submerged vertically in the molten metal. With the plunger in the open (retracted) position the metal flows into the cylinder through a hole in its side near the top. On the initial stroke of the plunger the hole is closed by the passing plunger and the metal is forced into the die cavity. The cycle then continues as in the cold-chamber machine. The gooseneck machine may also be designed to dip alternately into the metal and to slide into position against the die sprue before pressure is applied.

The type machine used is usually determined by the metal to be cast; aluminum, magnesium and copper alloys which attack and erode machine parts with nhich they are in constant contact are made in the cold-chamber machine, while tin, lead and zinc die

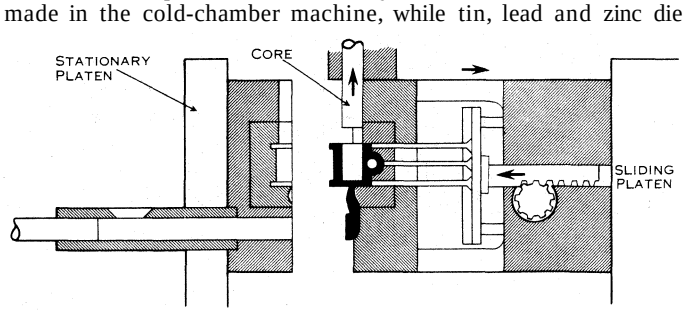

FIG. 3.— CORESWITHDRAWN AND CASTING MACHINE OPENED AFTER SOLIDIFICATION OF LIQUID METAL

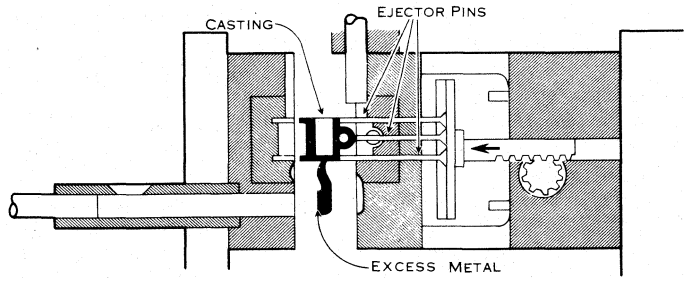

FIG. 4.— CASTING AND EXCESS METAL FORCED OUT OF THE DIE-CASTING MACHINE BY EJECTOR PINS

castings are produced in the submerged plunger or gooseneck type.

Prolonged die life is ensured by elaborately controlled water cooling; this rapid cooling also improves casting properties and accelerates the casting cycle. Metal cores for making precision holes or recesses in the casting may be loose (knockouts) or fixed; positioning and withdrawing cores may be activated manually or automatically. Dies are made of carbon and alloyed steels, and those for higher melting-point castings require heat treatment. The sprue and flash (excess metal, forced between the dies beyond the die cavity) are removed by grinding or by shearing (blanking). Frequently this is the only finishing operation required.

Die design is a highly specialized field, requiring extensive training and experience. Integrating sprues, gates (channels for distributing metal throughout the mold) and ejection mechanisms, with complex design features, is an assignment challenging the ingenuity and empirical knowledge of a capable designer. Each new design presents a new problem. However, by using small dies, mechanically keyed into the cover die or the ejector die like pieces in a jigsaw puzzle, the design may be altered without a major machining operation. Such a procedure reduces die maintenance and alteration expense and facilitates repair.

Since World War II die casting has expanded more rapidly than any other casting process. As metals have been developed for dies that will withstand higher temperatures and that are more resistant to erosion by molten metal, it has become possible to die-cast metals of higher melting points. such as the copper-base alloys. Also as techniques have been improved and problems solved. more intricate and more accurate engineering castings have been made. (H. F. TR.)

DIEFENBAKER, JOHN GEORGE (1895–), Canadian statesman, Conservative party leader and prime minister, was born on Sept. 18, 1895, in Grey county, Ont. He received an M.A. degree from Saskatchewan university in 1916 and, after serving overseas in World War I, returned to acquire a law degree in 1919. While practising law in Saskatchewan he was active in political affairs; elected to the house of commons in 1940, he won the leadership of the Progressive Conservative party in Dec. 1956. His party was returned to the house of commons with the largest group of members in the election of June 10, 1957, in an unexpected victory over the Liberals, who had held power for the preceding 22 years, and on June 21 Diefenbaker succeeded Louis St. Laurent as prime minister. In Sept. 1957 Queen Elizabeth II appointed him a member of her privy council. In the election of March 31, 1958, his party established a clear majority in the house of commons, winning 208 of 265 seats.

DIEFFENBACHIA, a genus of tropical American plants of the arum family (Araceae), much grown indoors for their handsome leaves that are variously spotted with white, cream or yellow markings. They bear minute flowers crowded on an erect fleshy spike fhat is sheathed by the leaflike spathe. *See* also ARACEAE.

DIEGO-SUAREZ, the name of a large bay in northern Malagasy Republic (Madagascar), now applied to Antsirana (pop. [1956] 38,305), the town on a promontory at the south of the bay

which developed as a result of the French naval base there. The climate is very hot, with dusty winds injurious to the lungs. West of the town is the Port de la Nièvre, with wet and dry docks; north is the Dordogne basin; and east (the side that opens to the Indian ocean) is Melville basin.. The town, of an old colonial style. has no buildings of interest but has slowly been modernized. One main street. the Rue Colbert, crosses it from north to south.

A modern road links Antsirana with Majunga on the west coast and runs on to Antananarivo (Tananarive), capital of the Malagasy Republic. The airport of Arrachart ($6\frac{1}{2}$ mi.) is served by internal air services. There is no agriculture, the mountains behind the town being covered with forest. The town's economy is based on the naval yards and on transshipment of cargoes bet een coasters and larger vessels from outside. Industries include ironworks. soap- and brickmaking and rice milling; salt pans supply the island.

The bay was discovered in 1500 by Diogo Dias, the Portuguese navigator. At the end of the 17th century Misson, a French pirate, founded there the short-lived republic of Libertalia. At the time of the first war with the indigenous Hova (Merina) people (1883–85), French naval forces took possession of the bay. which became French by treaty (1885) ten years before the conquest of the island. Col. (later Gen.) J. J. C. Joffre installed the first heavy coastal batteries there. (J. AR.)

DIELECTRIC, a relatively poor conductor, or nonconductor, of electricity. The term now is applied to any electrical insulating material. In alternating-current fields, the dielectric characteristics of some materials vary with the frequency, so that a material may be a poor dielectric at low frequencies. The dielectric constant of any material is the ratio of the capacitance of an electrical capacitor (condenser), with that material as the insulating material between the conducting plates, to the capacitance of the same capacitor with vacuum as the insulating medium. The dielectric constant of vacuum is taken as 1.00; that of air, 1.00060, is so nearly unity that it usually is assumed to be the same as that of a vacuum. See CAPACITOR; ELECTRICITY; INSULATING MATERIAL (ELECTRICAL).

DIELECTRIC HEATING: see HIGH-FREQUENCY HEATING.

DIELS, OTTO PAUL HERMANN (1876–1954), German organic chemist who with Kurt Alder was awarded the Nobel prize for chemistry in 1950 for their joint work on the diene synthesis. Diels was born on Jan. 23, 1876, at Hamburg, Ger. He studied chemistry in the University of Berlin under Emil Fischer (*q.v.*) and after various appointments was made professor of chemistry in the University of Kiel in 1916, becoming emeritus in 1945.

In 1906 he discovered the remarkable and highly reactive substance, C_3O_2, carbon suboxide or malonic anhydride: and determined its properties and chemical composition. He devised an easily controlled method of removing some of the atoms of hydrogen from the molecules of certain organic compounds containing much hydrogen by the use of metallic selenium.

His most important work was concerned with the so-called diene synthesis, in which dienes! organic substances containing two double-bonded carbon atoms, such as for example, 1,3-butadiene, $H_2C{:}CHCH{:}CH_2$, were used to effect the syntheses of many organic substances under conditions that threw light on the molecular structure of the products obtained. This method was developed (1928) in collaboration with Kurt Alder, his pupil, later professor of chemistry in Kiel and afterward in Cologne, and is known as the Diels-Alder reaction.

They had taken simple dienes, such as butadiene or its alkyl derivatives, or cyclic dienes, and had combined them with 1,4-naphthoquinones and had obtained a whole series of homologues of anthraquinone without the intervention of any other reagent; complicated molecules were produced by merely putting the reactants together, no great heat being necessary and no great heat being produced; the reactions proceeded in conditions of temperature resembling those in the living organism. Simple dienes such as isoprene give a synthetic rubber on polymerization, and diene syntheses have proved specially important in the production of plastics. Diels died in Kiel on March 7, 1954. (D. McK.)

DIEMEN, ANTONIO VAN (1593–1645), Dutch merchant and colonial administrator, who, as governor general of the Dutch East Indian settlements, greatly extended his country's influence in the far east. was born at Culemborg, Neth., in 1593. After an unsuccessful start as a merchant in Amsterdam, he went in 1618 to Batavia where he had a highly successful career in the Dutch East India company. He was appointed director of the commercial department in 1626 and became governor general in 1636. His rule saw the crushing of a revolt in the Moluccas, the capture of Malacca and Portuguese possessions in Ceylon, the signature of advantageous treaties with the princes of Atjeh, Ternate and Tidore, and the establishment of commercial relations with Tongking, China and Japan. Van Diemen introduced the legal code known as the Batavian statutes and founded at Batavia a Latin school, several Protestant churches, a hospital and an orphanage. The expeditions of Abel Tasman and F. Visscher in 1642 and 1644, which led to the discovery of Tasmania (at first called Van Diemen's Land), New Zealand and other Australasian islands were due to Van Diemen's initiative. He died at Batavia on April 19, 1645. (E. H. K.)

DIEPPE, a seaport of northern France in the *département* of Seine-Maritime, is on the English channel, 58 km. (36 mi.) N. of Rouen and 167 km. (104 mi.) N.W. of Paris by road. Pop. (1954) 25,983. It stands at the mouth of the Arques river in a valley bordered on each side by steep white cliffs. The main part of the town lies to the west and the fishing suburb of Le Pollet to the east of the river and harbour. The sea front of Dieppe consists of a pebbly beach backed by a handsome marine promenade. The port and docks mere destroyed and one-third of the town was damaged in World War II. Dieppe has a modern aspect; two squares side by side and immediately to the west of the outer harbour form the nucleus of the town. The church of St. Jacques, founded in the 13th century, consists largely of later workmanship and was restored in the 19th century. The castle, overlooking the beach from the summit of the western cliff, was built in 1435; it houses the museum. The church of Notre Dame de Bon Secours on the opposite cliff and the church of St. Remy, of the 16th and 17th centuries. are noteworthy. A well-equipped casino stands near the sea front and there are golf links. Two miles to the northeast of the town is the ancient camp known as the Cité de Limes.

Dieppe has one of the safest and deepest harbours on the English channel. A curved passage cut in the bed of the Arques and protected by an eastern and a western jetty gives access to the outer harbour?which communicates at the east end by a lock gate with the Bassin Duquesne and at the west end with an inner tidal harbour and two other basins. Vessels drawing 20 ft. can enter at neap tide. A dry dock and a gridiron are among the repairing facilities of the port. The harbour railway station is on the northwest quay of the outer harbour.

The distance of Dieppe from Newhaven, Eng., with which there are daily services except in winter, is 64 mi. Imports include bananas. silk and cotton goods, thread, oilseeds. timber, coal, iron, patent fuel, cement, china clay, machinery. tobacco, mineral oil and motorcars; leading exports are wine, silk, woolen and cotton fabrics, vegetables and fruit, and flint pebbles. The industries comprise shipbuilding, oil refining, steam sawing. the manufacture of machinery, rope, textiles, porcelain briquettes and articles in ivory and bone, the production of which dates from the 15th century. The fishermen of Le Pollet, traditionally of Venetian origin. are among the main providers of the Parisian market. The sea bathing attracts many visitors in the summer.

It is suggested that Dieppe owed its origin to Norman adventurers, who iound its diep or inlet suitable for their ships, but it was unimportant till the late 12th century. Its first castle was probably built about 800 by Charlemagne and was called Bathaille. Philip Augustus attacked it in 1195 and in 1197 it was bestowed by Richard I of England on the archbishop of Rouen in return for territory at Les Andelys. In 1339 it mas plundered by the English. but soon recovered and, in spite of opposition from the lords of Hautot. fortified itself. Its commercial activity was already great. It is believed that its seamen visited the coast of Guinea and founded there a Petit Dieppe in 1365; they were in the bay

of New York in 1543. The town was occupied by the English from 1420 to 1435. A siege undertaken in 1442 by John Talbot. 1st earl of Shrewsbury, was raised by the dauphin, afterward Louis XI, and the day of the deliverance continued for centuries to be celebrated by a great procession and miracle plays. In the beginning of the 16th century Jean Parmentier, a native of the town, made voyages to Brazil and Sumatra, and a little later its merchant prince. Jacques Ango, was able to blockade the Portuguese fleet in the Tagus. Francis I began improvements, continued under his successor. Its inhabitants in great number embraced the reformed religion, and they were among the first to acknonledge Henry IV, who fought one of his great battles at the neighbouring village of Arques, now called Arques-la-Bataille. Few cities suffered more than Dieppe from the revocation of the Edict of Nantes in 1685, and this blow was followed in 1694 by a terrible bombardment on the part of the English and Dutch. The town was rebuilt after the peace of Rijswijk, but its modern prosperity dates only from the 19th century, partly because Marie Caroline, duchess of Berry, brought it into fashion as a watering place, and also because the railway. built in 1848, gave an impetus to its trade.

During the Franco-German War the town was occupied by the Germans from Dec. 1870 till July 1871. Dieppe was a hospital centre for British troops in Sept. 1939 and was occupied by the Germans in June 1940. The Dieppe raid. a sea-borne assault across the channel made mainly by Canadian troops on Aug. 19, 1942, was a costly reconnaissance in force with heavy casualties. It taught valuable lessons stressing the need for teamwork. beach reconnaissance, naval support bombardment and improvements in landing craft.

DIESEL, RUDOLF (1858–1913), German engineer noted for his work on the oil-fuel engine that bears his name, was born in Paris on March 18, 1858, and died by drowning in the English channel on Sept. 29, 1913. He spent his early years in Paris and later studied engineering at Augsburg and Munich. Having learned that the thermal efficiency of an internal-combustion engine was very low, he was inspired to carry out many experiments in order to raise it and thereby reduce the running costs. He had in mind an improved engine nith a cycle of operations approaching that of the ideal cycle described by N. L. S. Carnot in 1824. He was convinced by results he obtained that he would arrive at a higher efficiency if he were to compress the air in the cylinder to a greater extent than was customary at that time. The higher temperature thus achieved would suffice to ignite the charge introduced into the cylinder, and no fuel-ignition equipment nould be required. After four years of experimental work he completed in Augsburg his first commercially successful diesel engine (1897), which operated according to the principles stated in his German patent specifications of 1892 and 1893 The success of this 2j-h p four-stroke single-cylinder vertical oil engine attracted world-wide attention. although it was not the first compression-ignition oil engine ever to be constructed; Akroyd Stuart had patented an oil engine which worked at lower pressures in 1890. Diesel published two papers. *The Theory and Construction of a Rational Heat Motor* (Eng trans.. 1894) and *The Geneszs of Diesel Motors* (1913). *See* also DIESEL *ENGINE*. (C. ST. C. B D.)

DIESEL ENGINE, an internal-combustion engine in which the fuel is sprayed into the cylinders after the air charge has been so highly compressed that it has attained a temperature sufficient to ignite the fuel. All other internal-combustion engines induct and moderately compress an inflammable mixture of air and vaporized or gaseous fuel. and then ignite it by an electric spark. The diesel engine compresses a noninflammable charge (usually air) to so small a volume that the resulting temperature is above the ignition point of an appropriate fuel. The fuel is then sprayed into the highly compressed air and ignited by the high temperature of the air. without a spark. No ignition devices are employed in diesel engines and they might be called compression-ignition engines as a more descriptive name than diesel.

The diesel engine is the predominant source of industrial power throughout the world for units up to about 5,000 h p., principally because it can burn a low-grade fuel at a lower rate of consumption per horsepower per hour, thus producing cheaper power than other internal-combustion or steam power plants in this horsepower range Low fuel consumption results principally from the higher compression ratio used. A greater fuel saving is effected at partial load than at full load because it is not necessary to throttle the inlet air, as is the case with spark ignition, in order to maintain an inflammable air-fuel mixture. Approximately two-thirds as much fuel is required.

Relatively unrefined fuels can be burned because of the nature of the fuel-injection system and the combustion process. This economic advantage has lessened because processes for making gasoline from the heavy constituents of crude oil have increased the value of fuel oils. High-speed diesel fuels sell for relatively little less than regular gasoline.

Four broad classes of fuels are burned in diesel engines: crude oil, distillates, residuals and natural or by-product gases. Crude oil can be burned in large slow-speed diesel engines after merely centrifuging it to remove sand and water. The distillates, called gas oils by the petroleum industry, are taken from crude oil after the volatile fractions used in gasoline are removed. They range from light fuel oils, differing little from kerosene, to the heavier distillates that have boiling points within the approximate range of 350° to 650° F.

Residuals include all of the ingredients of crude oil remaining after the gasoline and distillate fuels are removed. They are cheaper than the distillates but cannot be burned in high-speed diesels and may cause operating difficulties in larger engines. Natural gas is burned in practically all large. stationary, power-plant diesel engines. The resistance of gases to self-ignition necessitates pilot injection of fuel oil, but cheaper power is produced than nith any other fuel.

Specifications for diesel fuels include only those restrictions necessary to prevent impaired performance or damage to the engine. Cleanliness is essential to the life of the injection system. Ignition quality or cetane number affects starting and roughness of running in high-speed diesels (cetane number is the measure of ignition quality of diesel fuels; it is derived from the percentage of cetane in a mixture of cetane and alpha-methyl-naphthalene that has the same ignition quality as the fuel being tested). The viscosity or body of the fuel must not be so high that spraying is difficult or so low that the fuel does not provide lubrication for the injection system. A maximum boiling point is specified for distillate fuels to avoid difficulty in vaporizing the heavier components.

Diesel engines are built so ruggedly that operational failures are uncommon. There is less fire hazard in storage and handling of the relatively nonvolatile diesel fuels. These factors are especially important for marine and other transportation applications.

The diesel engine is handicapped by its higher first cost and greater weight per horsepower, by its exhaust smoke and odour under certain load conditions and by its greater operating noise and vibration. Good progress has been made, however, in minimizing these faults.

HISTORICAL DEVELOPMENT

The first diesel engine was built in Germany in 1897. Spark-ignition engines had then been built commercially for 37 years. The possibility of compression ignition appears to have been first mentioned by the French scientist N. L. S. Carnot, who in 1824 published his *Reflections on the Motive Power of Heat,* in which he discussed the possibility of igniting fuel by compressing air to one-fourteenth of its original volume.

The principle on which the modern automobile engine operates nas conceived in 1862 by Alphonse Beau de Rochas. also in France, but was not applied to a practical engine until 1876 when Nikolaus Otto built the first engine in which the charge was compressed in the cylinder before burning. This was the engine that Rudolf Diesel (*q.v.*) undertook to improve when he started the experiments that led to the diesel engine.

After several years of studying the problems involved, Diesel applied for and nas granted a patent in Feb. 1892 under the title "Working Processes for Internal-Combustion Engines," and a second patent, granted a year later, that modified the cycle de-

scribed. These patents were not for engine designs, but merely for a thermodynamic cycle to be followed by the gases in the engine cylinder.

The processes described in Diesel's patent claims made up a cycle differing from the theoretical or ideal cycle followed by existing engines only in the rate of combustion of the fuel-air charge. He proposed to burn the fuel during the first portion of the power stroke of the piston so slowly that no pressure rise occurred., As a means of slowing down combustion to avoid the almost instantaneous explosion of the spark-ignition engine, he proposed to induct air alone into the cylinder, instead of a fuel-air mixture, and compress it so highly that it would attain a temperature sufficient to ignite the fuel that would be gradually sprayed into the combustion chamber during the descent of the piston. This method of igniting the fuel requires that the air be compressed to a pressure of about 500 lb. per square inch, which produces a temperature of about 1,000° F.

Diesel presumably thought that any fuel would be suitable for an engine operating in the manner he described. He proposed to build an engine that would burn pulverized coal, the cheapest conceivable fuel. and obtained financial backing for the venture from the Krupp industrial organization which had extensive interests in the coal-mining industry. The coal-burning project was soon abandoned, but work mas continued at the plant of Maschinenfabrik Augsburg on an oil-burning engine and, after several failures, the engine ran in 1897.

The fuel economy of Diesel's engine proved to be better than that of any other existing power plant. His engine attracted considerable interest at an industrial exposition in Munich the following year, where Adolphus Busch, a U.S. brewer, saw it. Realizing its possibilities, he purchased a licence from Diesel for manufacture and sale in the United States and Canada. A diesel engine built .for his company in 1898 was the first to be placed in regular industrial service.

The diesel engine was not rapidly adopted. Until his death in 1913, Diesel insisted that all engines manufactured under his licences be made to operate with combustion at practically constant pressure, as described in his 1893 patent. This restriction meant that the engines had to run at very low speed and thus possible design improvements were delayed. The early engines were so large and heavy in proportion to their power output that they had no application other than as stationary power plants. The original diesel engine weighed 450 lb. per horsepower.

The first marine installation of a diesel engine mas made in 1910, very successfully, and the diesel engine became the predominant power plant for submarines during World War I. The first diesel engine that was small enough and light enough for automotive application was built in Germany in 1922, and opened up numerous fields of application that had previously been closed to diesel engines because of their low specific power output. The higher-speed diesel engines do not follow the slow-burning cycle originated by Diesel. Fuel is injected into the cylinder near the end of the compression stroke and burned rapidly, with sharply rising pressure, while the piston is near its dead-centre position. Only the compression-ignition and fuel injection of Diesel's original engine are retained in the modern high-speed diesel engine.

Although many diesel engines had been in operation for years in motor ships, highway trucks, farm tractors and as industrial power units, public awareness of diesel engines was first heightened when diesel 'locomotives were introduced on railway trains in 1934. These diesel-powered trains quickly established new records for fast nonstop runs and started a rapid dieselization of all U.S. railroads. Production of diesel engines in the United States the following year. 1933, exceeded 1,000,000 h p. and this figure was doubled in 1937.

The diesel engine was the most prevalent power plant for military equipment on the ground and at sea during World War II. After that war the diesel engine became the conventional power plant for all railway purposes in the U.S., all heavy construction machinery, a large portion of the trucks and buses operating on the highways and most of the higher-powered farm and construction tractors. The diesel engine has had only limited use in passenger automobiles and other applications where its greater weight and cost combine with its less smooth running qualities to partially offset its lower cost of operation.

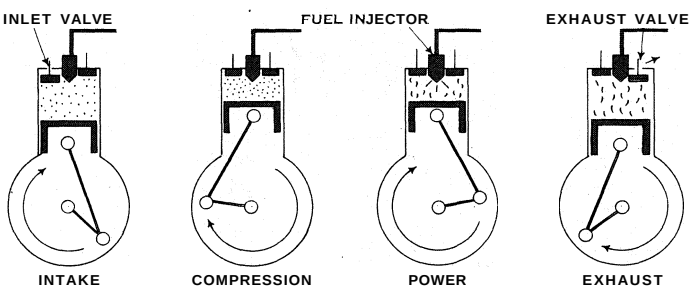

FIG. 1.—SCHEMATIC VIEW OF A FOUR-STROKE-CYCLE DIESEL ENGINE ILLUSTRATING THE SEQUENCE OF CYCLE EVENTS

FUNDAMENTAL PRINCIPLES

Certain operating fundamentals are common to all internal-combustion engines of the reciprocating-piston type. (See INTERNAL-COMBUSTION ENGINE.)

The operating cycle or series of events carried out in succession. over and over again, to make an internal-combustion engine run are as follows:

1. A charge of atmospheric air is introduced into the cylinders through intake valves or ports.
2. A proper amount of fuel is introduced into the air charge, either as the air enters, as in the carburetor engine, or sprayed into the cylinder later, as in the diesel engine.
3. The charge is compressed, ignited and burned.
4. The piston is pushed donnnard by the pressure of the expanding hot gases.
5. The products of combustion are exhausted from the cylinder through the exhaust valves or ports.

These processes require four strokes of the piston if the air is drawn into the cylinder through the open inlet valve by a downstroke of the piston and the exhaust gases are forced out through the open exhaust valve by an upstroke of the piston (fig. 1). The other two strokes: the compression and power strokes, are the basic and necessary strokes of the cycle.

The inlet and exhaust strokes are eliminated in the two-stroke-cycle engine by compressing the fresh charge slightly outside the cylinders so that it will flow in through ports uncovered as the piston approaches the end of the power stroke (fig. 2). Exhaust gases are pushed out through a second set of cylinder ports or valves in the cylinder head by the incoming charge. This process is called scavenging. The two-stroke cycle can be followed more effectively by the diesel engine than by the spark-ignition engine because air alone is used in scavenging the cylinders and no fuel is lost during the process.

Modern two-stroke-cycle diesel engines usually employ Roots-type blowers to supply scavenging air. These are positive-displacement rota y blowers that operate on the principle of the gear-type pump and have two intermeshing impellers with either two or three lobes. Blowers with air capacity considerably exceeding the piston displacement of the engine are used to flush the spent gases thoroughly from the cylinders.

Crossflow and loop-scavenged engines have two sets of cylinder

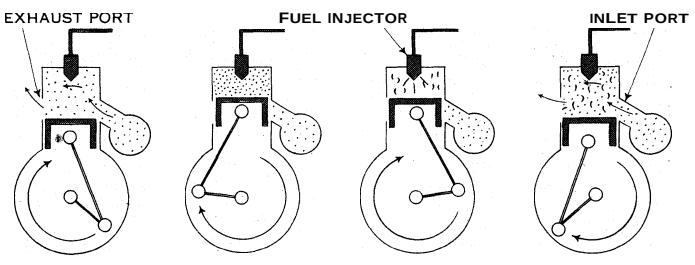

FIG 2— SCHEMATIC VIEW OF A TWO-STROKE-CYCLE DIESEL ENGINE ILLUSTRATING THE SEQUENCE OF CYCLE EVENTS

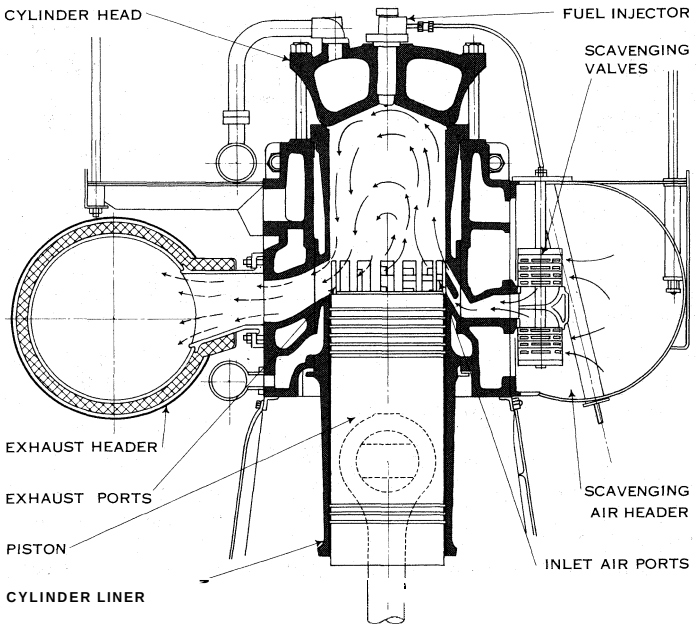

FIG. 3 — SECTIONAL VIEW OF A TWO-STROKE-CYCLE, PORT-SCAVENGED ENGINE. ARROWS INDICATE SCAVENGING AIR PATH

ports, one for entering air and one for the outflow of spent gases. Crossflow ports are on opposite sides of the cylinder and the inlets are inclined upward to oppose the tendency for air to short-circuit across the top of the piston. Loop-scavenged engines have the exhaust ports above the inlets or between two sets of inlets on the same side of the cylinder. Uniflow-scavenged engines have poppet-type valves in the cylinder heads and inlet ports entirely around the cylinder wall. A so-called blowdown period must be provided by timing the exhaust valves to open earlier than the inlet ports to relieve the cylinder pressure and prevent backflow into the air-charging system. Backflow is prevented in the engine of fig. 3 by the use of spring-loaded scavenging valves that permit flow only toward the cylinders.

The size, weight and cost of the engine per horsepower are reduced because the two-stroke engine completes a power stroke during each turn of the crankshaft instead of during each second turn. Most extremely large diesel engines use the two-stroke cycle.

It can be proven by a thermodynamic analysis that the efficiency of an internal-combustion engine operating on either the two-stroke or the four-stroke cycle depends principally upon the ratio by which the charge is compressed before its combustion. The compression ratio is found by dividing the volume in the cylinder when the piston is at its lowest point by the volume of the combustion chamber when the piston is at its highest point. The range of compression ratios at which diesel engines operate is from 12 to 18, which is considerably higher than knock-limited compression ratios for spark-ignition engines.

Analyses also show that combustion should be as rapid as is practical. limited by rough running. and that a high ratio of air to fuel increases thermal efficiency. The diesel engine meets these requirements for maximum efficiency more effectively than other type engines.

Fuel Injection. — The important distinguishing mechanical feature of the diesel engine is the fuel-injection system, consisting of the pumps that meter and place the fuel under injection pressure, the spray nozzles and the governing controls. The functions of the injection system are to measure out the minute quantity of fuel for each injection, to time the instant at which fuel is sprayed into the cylinder in order to establish the timing of ignition and to disperse the fuel throughout the air in the combustion chamber.

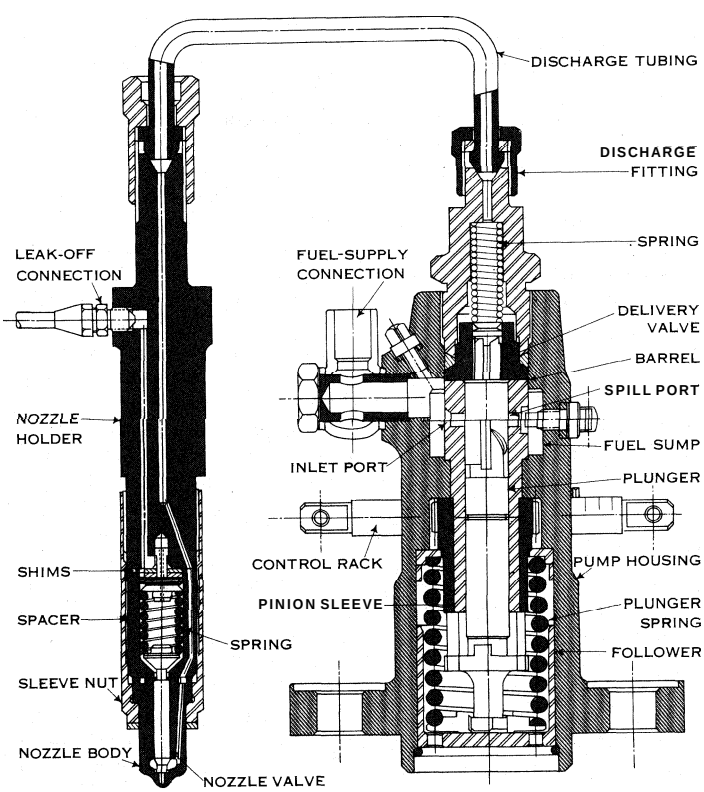
Originally. high-pressure air was used to carry the fuel into the combustion chamber, much as paint is sprayed by a spray gun. This method required a large air compressor and was inherently limited to low-speed-method operations. James McKechnie devised a mechanical or solid injection system in England in 1910 that eliminated the compressed air. This solid-injection principle has been adopted for all diesel engines and has taken two general forms. the common-rail type and the jerk-pump type.

The common-rail system has a continuously operating pump that maintains a pressure of several thousand pounds per square inch on a quantity of fuel in a manifold that serves as a fuel reservoir and connects together all of the injectors. Cam-operated injector valves admit fuel from this manifold to each of the spray nozzles in proper succession, and control the timing and the amount of fuel injected.

The jerk-pump system employs a type of plunger pump that delivers fuel under high pressure for only a brief instant during a small portion of each delivery stroke. Usually there is a separate pump for the injector in each cylinder of the engine, but there are also distributor systems that supply two to four cylinders from a single pump element that completes as many cycles as there are spray nozzles served by it. The pump plunger is rotated to act as a distributor to deliver each successive charge to the proper cylinder.

The various jerk-pump systems differ principally in the relative locations of the pump units and the spray nozzles. The unit injector has the pump and nozzle combined to form a single unit for each cylinder of the engine. Multipump systems comprise as many pump elements in a single central pump unit as there are cylinders to be served. In separate-pump systems each pump is independent of the others and located adjacent to each cylinder head. This type of pump is illustrated in fig. 4.

The most widely used method of fuel metering is by a plunger-controlled spill port. The pump barrel of fig. 4 is filled with fuel through the inlet port on the downstroke of the plunger, and fuel is returned to the supply chamber on the discharge stroke until the upper edge of the plunger covers the port. Fuel is then pushed out through the delivery valve until the helical upper edge of the groove that is cut around the plunger surface uncovers the spill port, thus permitting fuel to return to the supply chamber for the remainder of the stroke. The point in the upward stroke at which the cutaway region on the plunger encounters the spill



BY COURTESY OF AMERICAN BOSCH CORPORATION

FIG. 4. — SECTIONAL VIEW SHOWING THE COMPONENTS OF A JERK-PUMP SYSTEM

port is adjusted by rotating the plunger in the stationary barrel. The relationship between the plunger helix and the spill port is established by the control rack that engages a pinion on the sleeve guiding the plunger. The control rack is moved by a speed-sensitive governor in response to changes in throttle position and load on the engine. The effective portion of the plunger stroke, during which fuel is delivered. may be varied from zero to about the middle one-fourth of the total plunger stroke by rotating the plunger to appropriate positions.

The nozzle holder is an adapter that permits the spray nozzle to be installed in the cylinder head and connects to the injection pump by the discharge tube. Because of the extremely high iuel pressure during injection, the discharge tube must be of heavy-walled steel tubing with an outside diameter usually one-fourth inch or more and an inside diameter of about one-sixteenth inch. A spring-loaded nozzle valve is seated behind the spray tip to prevent fuel flow until sufficient pressure is built up by the pump, thus cutting off initial and final delivery that would otherwise occur at low velocity. Fuel leaking past the valve stem is returned to the fuel system by the leak-off connection.

Theoretically. each volume of liquid diesel fuel requires approximately 10,000 vol. of air to provide the oxygen necessary for complete combustion. Actually, this ratio must be increased to supply about 25% excess air in most diesel engines to avoid exhaust smoke. The dimensions of the fuel-injection-pump plunger and barrel are consequently only a tiny fraction of those of the power cylinders served by the pump. High-speed diesel engines. such as those used in highway vehicles, have injection-pump plungers as small as one-fourth inch in diameter with strokes of perhaps one-half inch.

The fuel-injection system is designed to be capable of delivering more fuel per cycle than the engine requires at its rated output because the rated horsepower is not the maximum horsepower that the engine can develop. A continuous rating is established by the engine builder at the point above which exhaust smoke becomes noticeable and internal temperatures rise. Intermittent-overload ratings permit additional power to be developed for short periods at slightly decreased fuel economy and darker exhaust.

Combustion. — Diesel combustion differs fundamentally from spark-ignition combustion in that the entire air charge is at a temperature sufficient to ignite fuel, and each particle of fuel receives the energy that ignites it directly from the hot air. Ignition occurs at many places throughout the combustion chamber as each tiny droplet in the fuel spray finds oxygen and attains ignition temperature. The spark-ignition engine must have an inflammable mixture of fuel and air that will support a flame front originating at the spark plug and traveling across the chamber. The iuel must be thoroughly mixed with from 12 to 16 times its weight of air to make this possible. The fuel-air mixture is heated to ignition temperature only as the flame front reaches it. This flame travel is not necessary in the diesel combustion chamber because each fuel particle ignites itself, and the mixture proportions need not be maintained within inflammability limits by throttling the intake air at reduced loads. The diesel engine inducts a full charge of air at all times, about 18 lb. for each pound of fuel at full load and about 100 lb. per pound of fuel when idling.

The diesel fuel does not ignite instantaneously because time is required for spray disintegration, heating and vaporizing the iuel, mixing the vapour to the ignition point, and for chemical prereactions that precede the actual combustion of the fuel. The elapsed time after the start of fuel spray until the chamber pressure starts to rise is called ignition lag and is usually about one-thousandth of a second. During this brief interval, the crankshaft of an engine running at 2,000 r.p.m. turns through 12° and at least half of the fuel is injected. Instead of each fuel droplet igniting and burning as it emerges from the spray nozzle. a considerable portion of the fuel charge accumulates during the ignition lag and then may burn almost instantaneously. The resulting rate of pressure rise may be so rapid as to cause rough running or combustion knock in high-speed engines.

The large low-speed diesel engine has no combustion-roughness problem because injection takes a much longer time and the ignition lag occupies so small a fraction of the fuel-injection period that very little fuel accumulates before igniting. After ignition occurs the remainder of the fuel burns as fast as it is injected, and the rate of combustion can be controlled by the injection rate.

All large, slow-speed diesel engines have simple combustion chambers that are called open or direct-injection chambers. The entire combustion-chamber volume is concentrated in a single compartment formed between a flat or slightly concave cylinder head and a flat or recessed piston crown. This type of chamber has been adapted to higher speeds by creating air turbulence to speed up the mixing of fuel and air. The fuel-injection nozzles for these engines are centrally located and of the multihole type with from six to ten holes drilled into the sides of protruding tips so that the paths of the several jets of fuel are along the ordinates of a very flat cone The piston-crown profile combines with that of the cylinder head to form a space that matches the fuel-spray pattern as nearly as is practical.

More elaborate combustion-chamber designs were introduced to ensure smooth and complete combustion when diesel engines were made to run at higher speeds. Divided combustion chambers are employed in some high-speed diesel engines as a means of decreasing the initial rate of pressure rise and providing more positive mixing of fuel and air. The first of these to be used was the precombustion chamber, a small compartment comprising about one-fourth of the total combustion-chamber volume and connected to the main chamber by a small orifice or throat. The fuel-spray nozzle is located in this antechamber and delivers the entire fuel charge into the small portion of the air charge that is located there. Combuition of a small amount of the fuel in the precombustion chamber builds up a pressure and discharges the burning mass of fuel rapidly into the main chamber where it finds the air to complete its combustion. The rate of cylinder pressure rise is not overly rapid because the greater portion of the fuel does not contact air for combustion until it is transferred to the main chamber. Excellent mixing, attained by the violence of the blowoff from the precombustion chamber, assures completed combustion.

A major advantage of this device is the simplification of the fuel-injection system that it permits. The spray nozzle can have a single hole of .025- to .030-in. diameter instead of several holes as small as 005 in. in diameter required in nozzles for open chambers, and fuel pressure can be much lower. The dispersion of the iuel into the air is accomplished by the blonoff process, not by the fuel spray. The precombustion chamber is used extensively in tractor diesel engines because of easier injection-system maintenance, less exacting fuel requirements and more complete combustion.

The turbulence chamber is another of the divided-chamber designs for improved mixing of fuel and air. The cylinder head and piston crown are both flat, with only the necessary mechanical clearance between them at top dead centre. The combustion-chamber volume is largely concentrated in an auxiliary chamber of circular cross section connected to the cylinder by a tangential passage. On the compression stroke, the rising piston forces the air charge through this passage at high velocity and causes it to spin rapidly in the turbulence chamber.

The fuel is sprayed into the swirling air as it moves past the spray nozzle. and each successive portion of the fuel enters a different portion of the air. A spray nozzle of the pintle type is used which has a pin protruding from the end of the spray valve through the nozzle opening to form a narrow circular slit. Pressure built up after ignition forces the burning mass to flow back through the tangential passage and reverses the direction of rotation in the swirl chamber.

Mixing is thus carried out in two stages and is equally effective at all engine speeds because the swirl velocity is proportional to piston speed.

Supercharging. — The amount of fuel that can be burned per cycle and the resulting power produced by an engine are limited by the weight of air inducted into the cylinder. A supercharger supplements the pumping action of the pistons by the use of a blower that increases the inlet air pressure. Blowers of the Roots type,

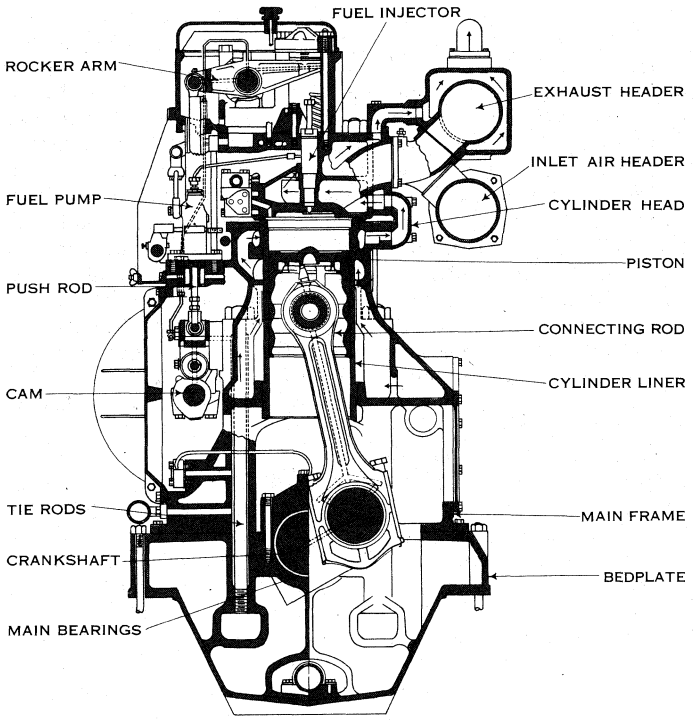


FIG. 5.—SECTIONAL VIEW OF A MEDIUM-SPEED, FOUR-STROKE-CYCLE DIESEL ENGINE

driven from the crankshaft. were used extensively to supercharge automotive-type diesel engines before the development of the gas turbine made the turbosupercharger possible.

The turbosupercharger consists of a centrifugal blower that is driven by a small gas turbine deriving its power from otherwise wasted energy in the exhaust gases from the engine cylinders. The power developed by the engine can be increased 50% to 150% by burning more fuel with the additional air supplied to the cylinders. The air from the supercharger is frequently passed through a heat exchanger to reduce its temperature and specific volume so that a more dense charge results.

Turbosupercharging has done much to overcome the disadvantages of large size, great weight and high cost in proportion to power output of the earlier diesel engines. Supercharging also improves ignition by increasing the air temperature and density. Four-stroke-cycle diesel engines are seldom built unsupercharged because the additional power capacity of the turbosupercharged engine is attained with very little increase in size. weight and cost. The competitive position of the diesel engine has been greatly strengthened by the improved performance attained by supercharging.

Starting. — Automotive diesels for use in highway vehicles are equipped with electric starters similar to those for automobiles except that greater cranking power is needed. The systems operate at a minimum of 12 v., with 24 v. commonly used, and battery capacity must be several times that needed for gasoline engines of the same horsepower.

Engines that are directly connected to electric generators. as in electric power stations. diesel locomotives and ships with electric propulsion. are cranked by motoring the generator; *i.e.*. supplying it with current so that it operates as a motor. Marine and railway units have special generator windings to permit motoring from batteries of 36 to 64 v. Generating-station engines receive their cranking power from other units with which they are electrically interconnected.

Large stationary engines and direct-drive marine engines are started by compressed air. Air pressure of several hundred pounds per square inch is maintained in storage tanks by built-in or separate compressors. Cam-operated valves that open as each piston starts downward distribute the air to the cylinders through check valves in the cylinder heads, and the engine is'motored until the injected fuel ignites.

Diesel engines that must be started at low temperatures are frequently equipped with small rope-start gasoline engines that are geared to the flywheel. The water jackets of the cranking engine are connected to the diesel cooling system to heat it as it is cranked. Cranking can be continued for an indefinite time if necessary under severe conditions.

Some tractor diesels are started by conversion to gasoline fuel and spark ignition. The compression ratio is reduced by opening the poppet valve communicating with the clearance pocket in which the spark plug is located. The engine can then be cranked more easily and should start more readily than with compression ignition. After warming up briefly, the clearance valve is closed and fuel injection started to convert to diesel operation.

Starting aids may be needed to preheat the diesel engine at extremely low temperatures. Electric glow plugs in the combustion chambers or immersion heaters in the cooling jackets may be used. Diethyl ether sprayed into the inlet air from capsules promotes ignition at low temperatures.

DESIGN FEATURES

High-Speed Diesel Engines. — These range in cylinder bore from 3.j to 6 in., in number of cylinders from 1 to 16 and in crankshaft speed from 1,200 to 4.000 r.p.m., but seldom exceed 3,000 r.p.m. The cylinders of these engines were originally arranged in line, but the later trend was toward the V type. The engines are largely intended for use in highway vehicles, farm tractors and earth-moving machinery. Both two-stroke- and four-stroke-cycle designs are built, and divided combustion chambers are sometimes used.

A typical engine of this class is a 12-cylinder, two-stroke-cycle model of 4.25-in. bore and j-in. stroke, with a maximum capacity of 482 h.p. at 2,100 r.p.m. As is customary in all diesel engines, the cylinders are fitted with alloy-iron cylinder liners of the dry type that are pressed into the water-jacketed cylinder block. Air is supplied by a Roots blower located between the cylinder banks, and a unit injector in each cylinder head supplies the fuel. Pistons are cooled by oil sprayed against the crowns from the drilled connecting rods. Aluminum-alloy blocks are available for applications where weight limitation is an important factor, making a 12-cylinder model weigh 6.7 lb. per horsepower at maximum output. Units with from 2 to 6 in-line cylinders and from 6 to 16 cylinders in the V type are built in this size.

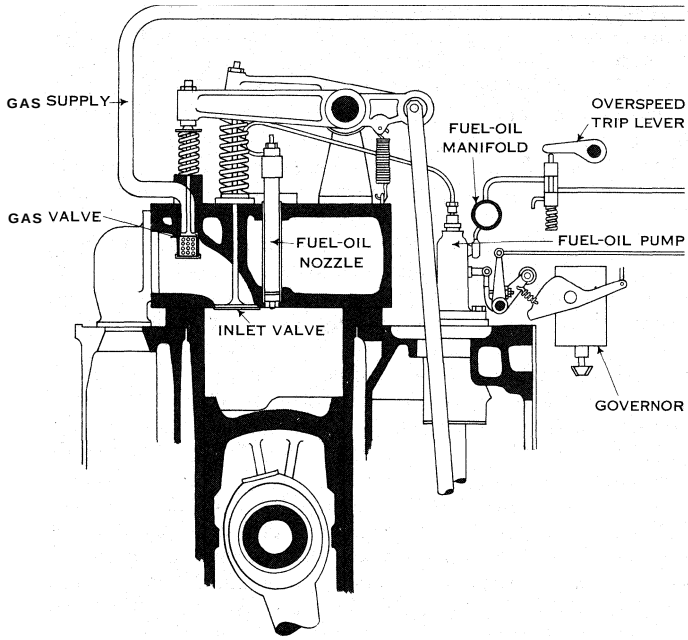

FIG. 7.— -SECTIONAL VIEW OF A FOUR-STROKE-CYCLE, DUAL-FUEL DIESEL ENGINE

Medium-Speed Diesel **Engines.**—Operating at speeds from 500 to 1,200 r.p.m., engines of this class are used extensively for marine, stationary and locomotive applications. Engines delivering about 2,000 h.p. have been developed to meet the severe requirements of railway use. Space limitations favour V-type engines of greater width and less length than the in-line engine. High specific power requirements dictate two-stroke-cycle engines or turbosupercharged four-stroke-cycle engines, and the rough service makes steel frames mandatory. Cylinder bores in the range from eight to nine inches prove adequate at crankshaft speeds up to 800 r.p.m.

The most extensively used locomotive diesel engine is a 45° V-type, two-stroke-cycle engine with uniflow scavenging for which air-inlet ports extending entirely around the circumference of the water-jacketed cylinder liner and four poppet-type exhaust valves in the cylinder head are provided. The pistons are of malleable cast iron and have several distinctive features. The crown thickness is decreased at the outer edge to form a heat dam that reduces the temperature of the piston-ring belt, thereby minimizing the possibility of piston rings sticking. The piston pin is attached to the connecting rod by two cap screws and is carried in an insert that fits into the piston and is retained by a steel snap ring at the bottom. The piston assembly is cooled by lubricating oil sprayed into the cavity between the piston-pin insert and the piston crown.

Fuel is injected by a unit injector in the centre of the cylinder head through a multihole spray nozzle. The unit injector and the exhaust valves are actuated by rocker arms directly from the crankshaft that is carried in bearings above the cylinder heads. These engines are usually built with 12 or 16 cylinders.

Fig. j is a sectional view of a four-stroke-cycle. in-line engine in the same size and speed range. This engine is of conventional construction, with separate fuel-injection pumps located above the camshaft which operates the inlet and exhaust valves in the cylinder heads through push rods and rocker arms.

Low-Speed Diesel Engines.— The low-speed designs are in regular production, both in the United States and European countries, with cylinder diameters up to 29 in. These engines operate on the two-stroke cycle at crankshaft speeds as low as 11j r.p.m. and develop up to 12,500 h.p.

The largest diesel engine ever built is in the H. C. Orsted Central Electricity works in Copenhagen, Den. It has eight double-acting cylinders of 33-in. bore and 59-in. stroke and is rated at 22,500 h.p.

Fig. 6 is a sectional view of a typical low-speed engine. Engines of this size and type are intended for stationary and marine applications. Structurally, they do not employ the cylinder-block castings of the smaller engines but are built up from a bedplate with separate cylinder castings supported by A-frame structural members. A crosshead, operating in vertical slides, is connected to the oil-cooled piston and relieves it of side thrust. A marine-type connecting rod is bolted to a separate lower bearing block. Lubricant is pumped directly to each component of the engine. Wet cylinder liners form the inner walls of the cylinder water jackets.

Gas Diesels.—These engines induct an appropriate amount of gas with the air charge and inject a small amount of diesel fuel, about 5% of the total fuel, at the proper time to act as a pilot charge to produce ignition. The amount of fuel oil injected is the minimum that can be dispersed throughout the lean gas-air mixture in the combustion chamber to ensure ignition at many scattered points, and is constant for all loads. The amount of gas inducted is varied by a governor to meet the load requirement. A second type of gas-burning diesel is called dual-fuel diesel; it differs from the gas diesel in that provision is made to inject more fuel oil and induct less gas when the supply of gas is inadequate.

A governor automatically increases the fuel oil injected from the minimum 5% to as much as 100% of the total fuel as the available gas decreases.

Fig. 7 is a sectional view of a four-stroke-cycle, dual-fuel diesel, showing the timed valve for introducing gas into the air stream just outside the inlet valve and the injection system for spraying fuel oil into the combustion chamber. Two-stroke-cycle gas diesels are equipped with timed gas valves in the cylinder heads to admit the gas immediately after scavenging has been completed, thus preventing its escape with the exhaust gases.

All large stationary-power-plant diesels are built to burn gas because the cost per unit of energy supplied is much less for natural and by-product gases than for even the cheapest fuel oils.

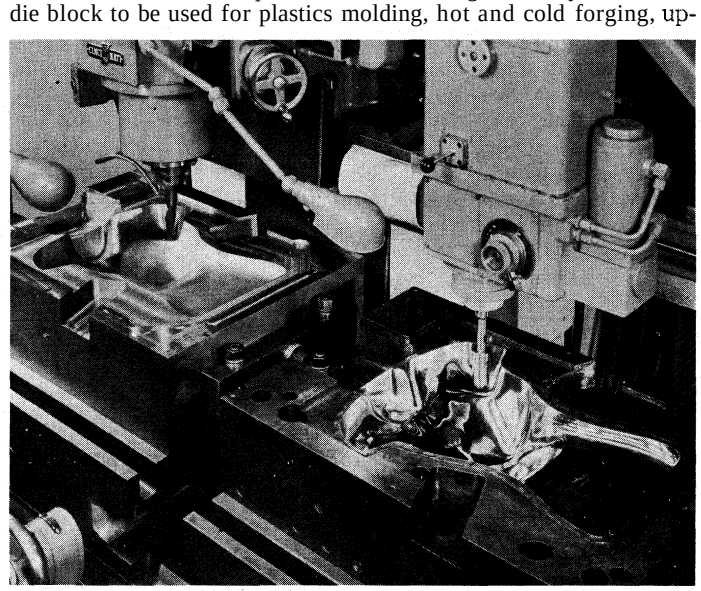
DIESINKING, a process of machining a cavity in a steel die block to be used for plastics molding, hot and cold forging, up-



BY COURTESY OF CINCINNATI MILLING MACHINE CO.

FIG. 1.—HYDRO-TEL, HYDRAULIC-OPERATED DIESINKING AND VERTICAL MILLING MACHINE. SHOWING (LEFT) A SINGLE CUTTER SINKING A FORMING DIE AND (RIGHT) THE PILOT GUIDE AND DIE PATTERN

setting, die casting and coining. The process uses end-cutting milling cutters in a vertical-spindle milling machine with the die block mounted on the table. In some simple machines, the movement of the cutter is controlled by the manual operation of the transverse. horizontal and vertical feeds. A pantograph is sometimes used to cause the cutter to follow a layout. Celluloid or sheet-metal patterns are also used as guides.

Most diesinking is done in machines which operate automatically. The movement of the cutter against the die block is controlled by the tracing of a finger of the cutter size and shape in contact with a previously made model of soft metal, plaster of paris, wood, etc. The model or template is attached to the bed beside the die block. The movement of the finger over the template is transmitted to the cutter by hydraulic or electrical controls. The surface of the sunk die is finished to desired size and surface quality by hand scrapers, files, small grinding wheels and polishing cloth. Large dies for automobile body parts are often cast to the shape of prepared patterns, after which they are ground and polished to size When the die cavity extends through the block it may be roughed out by oxyacetylene torch or jig saw and finished on a slotting machine, shaper or filing machine which reciprocates the tool against the surface of the die as it is held on the table and moved about as required.

Die hobbing (hubbing) is a process of producing the die cavity by pressing a hardened and polished male master plug, called a hob, into the soft steel die block by the slow, forceful stroke of a hydraulic press. This method of diesinking is simpler than that described above, since it is easier to make the male master than to machine the cavity. The hob may be used for producing a number of duplicate cavities or dies. Hob dies are limited in their use to formed parts which can be drawn readily from the cavity. This process is frequently used for making dies for limited production or for making parts of low-strength materials such as molding plastics.

DIES IRAE (Lat., "Day of wrath"), the opening words of a Latin hymn on the Last Judgment, ascribed to Thomas of Celano (d. 1256) and forming part of the office for the dead and requiem mass. The impressive plainsong melody to which it was sung was used by composers of religious works from the 16th century onward, either in its original form or as the basis of a polyphonic composition. Mozart and Verdi were among the composers of religious works who wrote original music on the text of the hymn. The original melody made a strong appeal during the romantic period and was used. often in the form of a parody or to suggest the supernatural or the macabre, in many secular compositions by Berlioz, Saint-Saëns, Vaughan Williams and others.

See R. Gregory, "Dies Irae" in *Music* and *Letters* (April 1953).

DIET, a term denoting an assembly or council in certain countries; *e.g.*, Sweden, Denmark, Poland, Hungary, Japan. This article is concerned with the diet (Reichstag) of the German empire which lasted from the 12th century to 1806, and its later successors from 1871.

To understand what happened to the diet between the 12th century and the 17th century it should be remembered that the period 1100–1500 marks the continuing decline in the powers of the emperor, due, among other causes, to the long conflict between empire and papacy and the rise of sovereign states. The conception of the "Holy Roman empire," used by papal and imperial chancelleries and apologists. had in practice little effective political significance. The Habsburgs, particularly Charles V, revived the conception as useful political propaganda to aid in covering over the diverse political and religious groups in the Habsburg dominions. During the Reformation period, and the ensuing wars of religion, the political weakness of the Holy Roman empire nas abundantly plain, and after the Peace of Westphalia (1648) it ceased to have authority or significance.

The diet of the German empire, the oldest political organization in Europe. rras foreshadowed in the Frankish period when meetings of the nobility had been held at the same time as the assemblies of the people. In the Carolingian empire meetings of the nobility and higher clergy mere held during the king's royal progresses, or court journeys, as occasion arose, to make decisions affecting the good of the state. After 1100, definitively, the emperor called the diet to meet in an imperial or episcopal city within the imperial frontiers The members of the diet were originally the princes, including bishops of princely status, but counts and barons were included later. After 1250 the representatives of imperial and episcopal cities were recognized as members of the diet, and at this time the electoral princes, whose duty it was to elect the emperor. began to meet separately, a division formally confirmed in the golden bull (*q.v.*) of Charles IV (1356) which established the number of the electoral princes as seven.

The declining power of the emperor from the 12th century can be seen in the fact that by 1489 the diet was divided into three colleges which met separately to give decisions on questions presented to them. These three colleges were. the electoral college of seven lay and ecclesiastical princes presided over by the imperial chancellor, the archbishop of Mainz; the college of the princes presided over by the archbishop of Salzburg, or the archduke of Austria; the college of the cities presided over by the representative of the city in which the diet met. This last group was a new departure and was not formally acknowledged until the peace of Westphalia, although it had been prominent since the end of the 15th century. The college of princes consisted of 94 princes, 33 ecclesiastical and 61 lay, who had individual votes (*Virilstimme*), and were divided into six groups which had group votes (*Kurialstimme*). The college of cities was separated eventually into the Rhine and Swabian divisions, the former having 14 towns and the latter 37.

The decisions taken separately by the three colleges were combined in an agreed statement the text of which was sent to the emperor as "the resolution of the empire" (*conclusum imperii*). All the decisions of the diet forming the resolution were called the "recess of the empire" (*Reichsabschied*). The emperor could ratify part of the recess or the whole of it, but he could not modify the words of the recess. The ratification of a recess required in law that all tribunals of the empire should conform to it. Until the 17th century the diet had possessed effective legal power, including the decision of war or peace, but after 1648 this legislative authority disappeared. The last recess was that of Regensburg in 1654; the next diet, that of 1663, was never dissolved and so published no recess.

The peace of Westphalia meant the final breakdown in the conception of one German empire united by its members' common aims. This was replaced by an assembly of sovereign princes, usually represented by envoys, indifferent to the emperor's wishes, divided in religious and political aims, and confined in practice to long-drawn lawsuits. The diet of Regensburg of 1663 prolonged itself indefinitely into permanent session. The emperor was now represented by a prince of the empire as his commissioner, a jurist was appointed as subcommissioner. and the elector of Mainz. arch-chancellor of the empire, had charge 'of the business of the meetings of the diet. This assembly of representatives without legislative power disappeared when the Holy Roman empire collapsed under Napoleon's attack in 1806. After 1806 the diet was succeeded by the *Bundesrat* or federal diet of the German confederation (1815–66) to which came representatives from the various German principalities, but it had no legislative powers and was as ineffective as the diet had been prior to 1806. A new diet or *Reichstag* was constituted under the German empire of 1871–1918. Together with the emperor, and in association with the *Bundesrat* (which resembled the old diet in being a council of representatives from the various states of the empire), it constituted the new unity of the empire. The empire was divided into constituencies where by secret ballot 397 members

were elected for the diet. At first it was called to meet annually by the emperor who alone could adjourn or close the diet, but this brief session was extended first to three then, by 1885, to five years. When the diet dissolved so did the *Bundesrat,* if the emperor had agreed to the dissolution. After the collapse of the imperial constitution in 1518, the new Reich, the Weimar republic of 1919–33, was considered to represent the sovereign people, and voting to the diet was by proportional representation and now included female suffrage. But a major weakness of the republic was that its diet gradually lost political power by its failure to make effective decisions and enforce them. The Reichstag building in Berlin was burned down on Feb. 27, 1933, probably at the instigation of the Nazi party under Adolf Hitler which was victorious in the elections to the diet later that year, disbanded all other parties and made the diet merely a platform for its public declarations.

DIET AND DIETETICS. A diet is the kind of food on which a person or group lives and a dietary usually means the diet supplied in an institution, such as a school, hospital, prison or barracks. Dietetics is defined as the application of the science of nutrition to the feeding of human beings in health and disease and it involves a knowledge of foods, their composition, preparation and contribution in essential nutrients for tissue repair and growth, for heat and energy and for the normal functioning of the body. A dietitian, or dietist, is one who practises in any branch of dietetics. The training of dietitians, their responsibilities and the scope of their work vary widely in different countries. In most countries dietetics started as a therapeutic service, but in many countries it subsequently broadened, as the importance of good nutrition came to be recognized, to the catering, education, public health and research services. In most countries dietetics is a female profession and the existence of suitable basic education for women is a decisive factor in its development.

Functions of Foods.—Food nourishes the body in three ways: it provides the substances necessary for the building and maintenance of the structure and tissues of the body, for oxidation to supply energy for the body's activities and for the regulation of the conditions and processes of the body. The chemical substances that take part in any of these nutritive functions are termed nutrients. The nutrients needed for building and maintaining the body's tissues are, in brief: the proteins, which are essential components of all living cells; mineral elements, such as calcium and phosphorus, which as calcium phosphate are largely responsible for giving bones and teeth their strength, rigidity and relative permanence; and iron, a necessary component of hemoglobin. Those nutrients that are oxidized to provide energy are the carbohydrates and the fats and, to a lesser extent, the proteins. Alcohol can also supply some energy. The nutrients needed for the regulation of the conditions and processes of the body include the vitamins (a chemically unrelated group of substances, each with a specific function) and some mineral elements, such as iodine (necessary for the proper functioning of the thyroid gland) and chlorine, which, in the form of its salts the chlorides, is important in the maintenance of normal conditions in the body, particularly concerning the passage of water into and out of the tissues. In total, the body contains 19 principal mineral elements derived from food. It is not usual to include oxygen and water among the nutrients, although by strict interpretation of the above definition they tvould be so classified.

Nutrients and Their Sources.—For a more detailed discussion of the biochemistry and metabolism of these nutrients, see NUTRITION.

Proteins.—The proteins (*q.v.*) are widely distributed in nature and no life is known without them. They are made up of relatively simple organic compounds, the amino acids, all of which contain nitrogen and some of which contain sulfur. Man and animals build the proteins they need for growth and repair of tissues by breaking down the proteins obtained in food into their component parts, the amino acids, and then building up these components into proteins of the type needed. Plants, on the other hand. build their proteins from the simpler inorganic materials found in the soil and air. The ultimate source of man's protein is the plant; he may obtain it directly by eating plant foods or indirectly by eating the flesh, milk or eggs of animals, birds or fish that have fed on plants. The protein-rich foods from animal sources contain complete proteins, which supply all the amino acids necessary in the human diet, but vegetable proteins vary in their biological value because they supply varying amounts of the essential amino acids. Combinations of protein of plant and animal origin work well together in supplying man's protein needs. Of the vegetable proteins the chief source is grain, other sources including soybeans. peas, beans and other pulses and nuts. Fruits and vegetables contribute little to the total protein intake.

A protein allowance of one gram per kilogram of body weight per day for the normal adult used to be the widely accepted standard known to provide a good margin of safety. A preliminary attempt has been made by the committee on protein requirements of the Food and Agricultural organization to assess protein requirements in terms of the amino acid composition of the protein consumed: a smaller consumption is required of proteins of high than of those of low biological value. For a country eating a western type of diet the allowance of one gram per kilogram is generous because of the high biological value of the protein consumed.

Carbohydrates.—The most abundant and least expensive food sources of heat and energy are the carbohydrates (*q.v.*), of which there are a great variety. Important dietary carbohydrates are divided into two groups, starches and sugars. The starches, which may be converted into utilizable sugars in plants or in the body, are supplied in the grains (wheat, rice, maize or corn, oats, rye and others), the pulses (such as peas and beans), tubers (such as potatoes) and some rhizomes and roots. The sugars occur in many plants and fruits, the most important as a food commodity being sucrose. which is obtained from the sugar cane or the sugar beet. Sucrose is an isolated nutrient, a pure carbohydrate, which can be oxidized to supply energy but which supplies no other nutrient. In fruits starches tend to be converted into sugars with ripening; *e.g.,* most of the starch originally present in a banana has been changed to sugar by the time it is fully ripe.

Fats.—The fats, which are widely distributed in nature, are a concentrated food source of heat and energy and are glyceryl esters of fatty (carboxylic) acids (see CARBOXYLIC ACIDS). When broken down by hydrolysis fats yield many different fatty acids and glycerol. The so-called essential fatty acids, which are derived in the main from vegetable fats that have not been hydrogenated, are thought to fulfill specific biochemical functions, the precise mechanism of which has not been elucidated. After digestion and absorption, fats are either used as sources of heat and energy or they may be stored in the body. Carbohydrates, if taken in excess, can be converted into fat and likewise stored as fat deposits. The foods that contain fats are—in addition to butter, margarine and other edible fats—milk, fatty fish, eggs, nuts, grains, seeds and some fruits such as olives and avocado pears.

As the standard of living in a population or group rises there is a tendency for fat consumption to increase at the expense of carbohydrate and probably also of protein. In the early 1960s about 40% of the calorie supplies in countries enjoying a western type of diet was derived from fat. Many authorities hold that such a percentage is too high and that this increasing consumption of the types of fat available in western countries is associated with an increasing incidence of ischemic heart disease and other degenerative diseases.

Minerals.—Of the many minerals eaten in foods calcium and iron have received much attention mainly because of the danger of dietary shortage: if these two are in adequate supply, it is likely that other mineral elements will be, too. Thus phosphorus, which, with calcium, is an important component of bones and teeth, is more widely distributed than calcium and is not likely to be lacking in any diet. In all western types of diet milk and its products constitute the chief source of calcium, but in the diets of tropical

or eastern countries the necessary calcium may be obtained from a variety of sources such as the bones of small fish. some cereals such as ragi in India, some vegetables and even by the use of crude sea salt in cooking and by adding lime water to maize (corn) in the preparation of the tortilla of Mexico. Iron is also fairly widely distributed but can be short in some diets. The chief sources are meat, egg yolks, vegetables, high extraction cereals or cereals to which the iron removed in milling has been restored. The dietary intake of iodine depends largely on the consumption of sea foods and of vegetables grown on soils containing sufficient iodine; a common public health measure is the provision of iodized salt where iodine is in short supply. The need for chlorine is usually fully met by adding common salt (sodium chloride) in the preservation, preparation and service of food.

Vitamins.—The foods that contain vitamins (*q.v.*) are often called the "protective" foods. This term was first proposed by E. V. McCollum to mean milk and leafy vegetables. As a result of his early studies he had reached the view that the two nutritional shortages most often encountered in U.S. diets were of calcium and vitamin A and that milk and leafy vegetables were "protective" against these deficiencies. Further research showed that a "protective" diet should also provide other nutrients. H. C. Sherman mentioned, particularly, vitamin C and riboflavin and discussed the confusion on the meaning of the term, which could clearly cover any food that contains protein, mineral salts and vitamins in useful quantities, concluding that the term had become so ambiguous that it was better not to use it.

Probably the simplest classification of vitamins is one based on whether they are soluble in water or fats (oil). Vitamins A, D, E and K are insoluble in uater but soluble in fats and are therefore provided by fatty foods. Milk fat is a good source of vitamin A and contains a little vitamin D; egg yolk contains good supplies of both vitamins; the fat of fish and the livers of fish and animals are abundant sources of both. Vegetable fats, including the fats in grains, usually contain vitamin E but no vitamin A or vitamin D, so that it is usual to fortify margarine made from vegetable fats nith vitamins A and D. Both vitamins E and K occur in green leaves. Vitamin A may be obtained either from foods containing the vitamin itself or its precursor, carotene, the yellow colouring matter of carrots and many other plant materials, such as green vegetables and tomatoes. Both vitamin A and carotene are present in milk fat and egg yolk. Vitamin D is not widely distributed in foods but is produced by the action of sunlight on ergosterol in the body. The vitamins of the B complex and vitamin C are soluble in water and thus can be leached out of foods during processing and cooking and, in addition, vitamin B_1 and vitamin C are both fairly easily destroyed by heat. The vitamins of the B complex are widely distributed among foods. In most countries the most important source of vitamin B_1 (or thiamine) is the germ and the outside parts of the staple cereal and this makes the method of milling cereals a decisive factor in the adequacy of the supply of this vitamin. In many countries the vitamin B_1, which is known to be lost in the milling of wheat, is restored before the flour is baked, and throughout the rice-eating world possible methods of restoring vitamin B_1 to polished rice were under consideration in the early 1960s. Milk and its products, meat. potatoes, and other vegetables also supply the vitamin and are sources of other members of the B complex. Milk is particularly important for riboflavin and meats and the outside parts of cereals for nicotinic acid (or niacin). The only important sources for vitamin C are fresh fruits, particularly citrus and some soft fruits and tomatoes, and vegetables, particularly green vegetables and potatoes. Fresh milk and fresh animal liver supply a little vitamin C.

Energy Requirements.— The caloric need of an individual, supplied largely by carbohydrates in most diets but also by fats and proteins (and also by alcohol), usually in that order of importance, is that amount of energy that will maintain body neight over a prolonged period at an optimal level; for a growing child the caloric need is the amount that will maintain a satisfactory rate of growth.

Nutritional Requirements.— The assessment of the nutritional value of foods is of practical value only in relation to the nutritional needs of the consumers. In the development of any kind of agricultural or food policy it is essential to be able to assess the nutritional needs of the population in quantitative terms and it becomes even more important to be able to check the nutritional adequacy of food supplies when these are restrictec. for any reason. Several tables giving estimates of nutritional requirements or allowances, most of which include generous margins of safety, have been compiled. One, as recommended by the Food and Nutrition board of the National Research council of the United States, may be found in the article NUTRITION. Another is that given in the Report of the Committee on Nutrition of the British Medical association (1950).

Pregnancy and Lactation.— Infants are best fed on their mother's milk, but this alone does not necessarily ensure good growth and development of the baby. H. C. Stuart of Boston, Mass, and F. F. Tisdall of Toronto and their associates independently showed that an adequate diet and good hygiene during pregnancy are essential to the well-being of both mother and baby. The supply of milk can be maintained even if the mother's diet is inadequate, but at the expense of her own stores of nutrients and possibly of her health. During pregnancy and lactation women require a moderate increase in calories and a definite increase in the protein as well as in the vitamin and mineral contents of their diets. For example, the recommended allowance for calcium is 50%–100% greater and that of iron 25% greater than for other adult women and the requirements for vitamins are also increased.

Infants.—Infants need food for rapid growth in addition to their other body needs. On the basis of weight they require about four times as much protein as an adult. During the first year of life milk should be the main food and special methods of feeding are required. When the mother's milk is not available, cow's milk, usually dried or evaporated, is the normal substitute, but goat's milk or a vegetable protein substitute such as soybean milk are used in some places. Extra calories can be supplied by adding sugar to the milk. To ensure an ample supply of vitamin C. orange juice or some other suitable source of the vitamin, in small amounts at first, is started at an early age. To provide an adequate vitamin D intake for the prevention of rickets and for the normal gronth of bones, 400 international units of vitamin D should be supplied daily. A supplementary source of vitamin A is also necessary. As the baby grows, cereals are added to supply extra calories as well as minerals and vitamins and these are supplemented by strained fruits and vegetables. Eggs are a good weaning food, particularly for their content of iron, and strained or scraped meat may be added at about the same time as other solid foods. Meats supply protein, minerals, particularly iron, and vitamins of the B complex.

The protein content of the diet after weaning is particularly important for the child's health, and in countries where milk supplies are sparse or nonexistent a nutritional deficiency disease, usually called kwashiorkor, occurs among toddlers who have been weaned on to a diet of cereals or starchy roots. The disease can be severe and lead to death or so mild as hardly to be noticed. Its prevention and cure are theoretically simple: the provision of an adequate supply of protein at weaning and in early childhood. The most convenient food to supply is milk, but success has been achieved with mixtures of vegetable proteins.

Of particular importance in the feeding of babies is strict cleanliness. Foods, particularly milk, provide excellent media for the growth of bacteria and milk should be sterilized or pasteurized before feeding. (See also INFANCY : *Infant Feeding.*)

Older Children.— As children grow their need for more food becomes apparent. Healthy children need never be forced to eat and it is a good rule never to do so. If an adequate supply of foods that are not too bulky and are of good nutritional value is placed before a child hunger will cause him to eat adequately. Children need concentrated nutritional value.

Adolescents.—During adolescence there is a period of rapid growth and adjustment, both physical and psychological, and the need for food is increased even above that of the average adult.

Adults.— The nutrient needs of adults depend on their body size,

their age and their activity. Energy needs decrease with increasing age and if food intake is not reduced as the pace of energy expenditure slackens weight will increase. It seems that with advancing years appetite is not always an infallible guide to food requirements.

The Aged.—The food needs of the elderly require more study than they have been given. It is likely that the requirements of protein, minerals and vitamins are not less than those of younger adults, but fewer calories are needed. Thus it seems that the composition of the diet should be changed as a person grows older. In addition. lack of teeth, or other similar handicaus, mav make it necessary to pay special attention to the form in which food is supplied.

The Sick.—The use of diet to maintain health or to treat disease is as old as recorded history. The importance of adequate nourishment for the sick was fully recognized by Florence Nightingale, who wrote in her *Notes on* Nursing (1860). "Every careful observer of the sick will agree in this that thousands of patients are annually starved in the midst of plenty, from want of attention to the ways which alone make it possible for them to take food." She then gave her views, surprisingly in accord with modern knowledge, on desirable food for invalids Since then the dietitian has devoted the major part of her skill to providing food for the sick, both by maintaining the nutritional adequacy of hospital meals in general and by designing special diets used therapeutically in certain illnesses. In special diets that may be made from a limited range of foods it is particularly important to guard against the lack of essential nutrients.

Education in Nutrition.— By satisfying hunger with a reasonable variety of foods the normal individual in a country with a varied food supply is provided mith sufficient essential nutrients to maintain the body in a good state of health. If an individual or a family is not taking a nutritionally satisfactory diet this is due either to national or personal poverty or to ignorance. It is generally accepted that proper nourishment is one of the secrets of human well-being and that if the foundations of good health are laid in early life by adequate feeding there will be a greater chance in maturity of living a full and active life. It is not, however. easy for individuals to know what is the nature of a well-balanced diet. It is not even easy to know to what processes foods have been subjected. There is, therefore. a need in all countries for more information among the consuming public on food values and requirements. The view that knowledge of nutrition and dietetics is an essential part of education is slowly being accepted throughout the aorld but the question remains how best to spread this knowledge.

It is generally accepted that no program of nutrition teaching should be started without an assessment of the nutritional value of the food supplies available and of the nutritional needs of the groups or population to be taught, and that a system of teaching that has produced successful results in one country may be quite wrong for a country mith different food problems.

To those with sufficient scientific knowledge nutrition can be taught in chemical and physiological terms, but it often has to be taught to those without scientific education. This can best be done in practical terms, that is, in terms of preparation of attractive well-cooked meals that are dietetically well-balanced and good to eat. Teaching in these terms was being conducted successfully under the South Pacific Health service, and in many countries the practice of serving nourishing and palatable school meals provides another example.

Two basically different systems of teaching simple nutrition are in operation in various countries. One, the more ambitious, aims to teach in terms of the functions of foods and to give the learner a sound enough knowledge of nutrition to enable him to select a well-balanced diet without detailed instructions on precisely which foods to eat. During World War II the United Kingdom used this system and taught that foods belong to three groups—body-building foods, regulating and protective foods and foods for fuel or energy. Subsequently F. J. Stare and his colleagues suggested that. for countries where food supplies are limited and even calories may be short, teaching might be effective in terms of two groups, energy foods and protective foods.

Other countries adopted systems essentially similar to each other, though different in detail. Foods are classified according to their nutritional value but the groups are arranged with the aim of increasing the consumption of nutrients known to be short in the diets of those being taught. Probably the most celebrated system of this kind was the Basic Seven Food Groups of the United States devised during World War 11 as a guide to the selection of protective foods. This was later simplified to a Daily Food Guide. shown in the table, which may be supplemented with other foods

Milk group	Meat group	Vegetable-fruit group	Bread-cereal group
8-oz. cups Children . . . 3—4 Teen-agers . . 4 or more Adults . . . 2 or more Pregnant women. 4 or more Nursing mothers . 6 or more Cheese and ice cream can replace part of the milk	2 or more servings of beef, veal, pork, lamb, poultry, fish or eggs. As alternatives. dry beans, dry peas, nuts	4 or more servings to include: a citrus or other fruit or vegetable important for Vitamin C; a dark-green or deep yellow vegetable for vitamin A, at least every other day; other vegetables and fruits, including potatoes	4 or more servings of whole grain, enriched or restored

to complete meals and to provide additional food energy and other food values. It will be noted that neither fats nor sugars are mentioned in the table. Many other countries have developed variations on this scheme. The simplest are probably those of several Latin American countries and some South Pacific islands; these are divided into three groups—energy foods, animal products and vegetables and fruit—with the animal products sometimes split into milk and other animal products (the grouping into four being very similar to the Daily Food Guide of the United States). The most complicated is probably that of Poland, in which recommendations are made for each of 12 food groups for 11 different groups of the population. Five is the most frequent grouping and is used in Australia, Canada, Indonesia. Israel, the Netherlands, Papua and Puerto Rico, the approach in the last-named country apparently being unique. There the advice is that food is divided into: (1) foods that almost everyone eats routinely (including sugar, fats and rice); and four groups thought to be inadequately eaten; *i.e.,* (2) milk; (3) meat. fish and fowl; (4) yellows and greens; and (5) fresh native fruits. Finally it is interesting to note that in Norway no food group scheme is used, but teaching is concentrated on the nutrients most likely to be short in the Norwegian diet; *i.e.,* calcium, vitamin D and vitamin C. Milk is recommended for calcium. fat fish for vitamin D and potatoes, principally, and fruits and vegetables in season and preserved fruits, such as black currants, out of season for vitamin C.

The Quality of Foods.—Quality depends on the composition and condition of the food eaten and on the reactions of the person eating it but, since nutritive value cannot be detected by taste or smell. it is not a directly nutritional matter. Quality and nutritional value. however. are often related; for example, most fruits and vegetables are richest in nutritive value when freshly picked, when their flavour is also at its most delicious. Efforts are constantly made to improve foods through the selection of better varieties of plants and breeds of animals and by controlling the conditions of food processing, storage and transport. To feed the rapidly growing and increasingly urban population of the world it is necessary to preserve foods in a condition as similar as possible to their fresh state and to retain that condition while they are being stored or transported from the areas of production to the towns.

Cool or cold storage and transport temperatures are important considerations for foods marketed fresh because nutrient losses and adverse changes in quality are accelerated by high storage temperatures, but modern controlled methods aim to conserve the nutritive value and other qualities present in the foods at the time of processing (see Food Preservation).

Foods must be clean. Much contamination usually cannot be

recognized by the consumer, who must thus depend for protection upon the technical ability and vigilance of food manufacturers and government inspectors. Foods must also be free from harmful bacteria. Milk, particularly, is likely to be the carrier of harmful organisms unless especially protected. Some communities require that all cheese either be made from pasteurized milk or aged for a sufficient length of time to ensure that harmful bacteria have been rendered innocuous. In certain parts of the world where the soil is contaminated with the eggs of intestinal parasites it is usually necessary to scrub, wash, peel or cook vegetables carefully to ensure their safety.

Chemical substances may be added to foods either by accident or intent. During and after World War II a large number of pesticides and other chemical aids to agriculture and horticulture have been developed. Similarly, a number of antibiotics and hormones have been used experimentally in animals to improve milk production or the quality of meat. The health hazards of residues of these substances in foods have led to intensive investigation and the establishment of means of control. *See* FOOD PREPARATION; NUTRITION; *see* also references under "Diet and Dietetics" in the Index volume.

DIETRICH, CHRISTIAN WILHELM ERNST (1712–1774). German painter and engraver, was born at Weimar on Oct. 30, 1712. He was taught by his father, Johann George, painter of miniatures to the court, and in 1724 was sent to Dresden to work under Alexander Thiele, the landscape painter, with whom he remained three years. Augustus II, king of Saxony, sent him to the Netherlands where he learned to imitate the masters of the previous century with amazing fidelity. Many of Dietrich's works in the manner of Rembrandt, Ostade, Watteau, Salvator Rosa, Castiglione, Ruisdael and Berghem have been falsely attributed to these artists. In 1741 he was appointed court painter to Augustus III at Dresden, and in 1743 traveled in Italy, where he studied and became closely associated with the painters Ismael and A. R. Mengs. Linck accredits Dietrich with over 180 prints, many of which reveal both spirit and skill. After his return from Italy he generally signed himself "Dietericij."

In 1748 he became keeper of paintings at the Dresden gallery. He was also director of painting at the Meissen porcelain factory and in 1764 became professor at the Dresden academy of arts. He died in Dresden on April 23. 1774.

DIETRICH VON BERN is a heroic figure of Germanic legend, apparently derived from Theodoric the Great (*q.v.*). His exploits are related in a number of south German songs preserved in the *Heldenbuclz* (*q.v.*)—*Dietrichs Flucht, Die Rabenschlacht* and *Alpharts* Tod—and, more fully, in the Icelandic prose *Tlzidrekssaga.* This 13th-century version may be based either on the German sources or represent an independent Gothic tradition. References to Dietrich in the Anglo-Saxon records are few and obscure.

Dietrich's story begins when he was driven by Ermanaric from his kingdom of Berne (*i.e.,* Verona). After years of exile at Attila's court he returned with a Hunnish army and defeated Ermanaric at the battle of Ravenna (Rabenschlacht). Attila's two sons fell in the fight, and Dietrich returned to Attila to answer for their death. Later he had his revenge by slaying Ermanaric (Ermenrichs Tod). Dietrich's long stay with Attila represents Theodoric's youth spent at the Byzantine court. The period of exile was as usual adorned with amazing exploits most of which had no connection with the cycle. Through Attila, Dietrich enters the Nibelung cycle as the avenger of the Amelungs, who finally vanquishes Hagen and delivers him to Kriemhild (*see* NIBELUNGENLIED). There are brief references to him in the *Hildebrandslied* also.

Dietrich typifies the wise and just ruler as opposed to Ermanaric the tyrant. Much of the incident told about him has no basis in the story of Theodoric: some could be related to the experiences of his father Theudemir, but the rest is purely fictional. The chief heroes of the Dietrich cycle are his weaponmaster Hildebrand with his nephews the Wolfings Alphart and Wolfhart; Wittich, who renounced his allegiance and slew Attila's sons; and Heime and Biterolf.

BIBLIOGRAPHY.—The poems of the Dietrich cycle are summarized by L. Uhland, *Schriften zur Geschichte der Dichtung und Sage* (1866–72). *Tlzidrekssaga* is translated into German by F. Erichsen in the collection *Thule,* vol. 22 (1924). A summary of the legend is in T. Hodgkin, *Theodoric the Goth* (1891). *See* also W. Grimm, *Deutsche Heldensage* (1867); O. L. Jiriczek, *Die deutsche Heldensage,* trans. by Bentinck-Smith, *Northern Legends* (1902); H. Schneider, *Germanische Heldensage* (1928) in H. Paul's *Grundriss der gernzanischen Philologie,* which also has a full bibliography; and G. Zink, *Les Légendes Héroiques de Dietrich et D'Ermrich dans les Littératures Germaniques* (1950) which has a select bibliography of more recent works. (W. W. Cs.)

DIEZ, FRIEDRICH CHRISTIAN (1794–1876), German philologist. the founder of Romance philology, was born at Giessen, Hesse-Darmstadt, on March 15, 1794. A visit to Johann von Goethe in 1818 decided the direction to his studies. Goethe had been reading Franqois Raynouard's *Choix de poésies originales des troubadours,* and advised the young scholar to explore the rich mine of Provenqal literature which the French savant had opened up. Henceforth Diez devoted himself to Romance literature. He moved in 1822 to Bonn, where he held the position of *Privatdozent.* His *Poesie der Troubadours* (1826) and *Leben und werke der Troubadours* (1829), of both of which there are later editions edited by Karl Bartsch, were his earliest important studies. In 1830 he became professor of modern literature at Bonn. The rest of his life was mainly occupied with the composition of the two great works on which his fame rests. the *Grammatik der romanischen Sprachen* (3 vol., Bonn, 1836–44; 5th ed., 1882) and the *Etymologisches Worterbuch der romanischen Sprachen* (2 vol., Bonn, 1853; 5th ed., 1887); in these two works Diez did for the Romance group of languages what Jacob Grimm did for the Germanic family. He died at Bonn on May 29, 1876. He also wrote works on the Spanish and Portuguese languages and early literature.

DIFFERENTIAL, in the sense of pertaining to, or involving the difference between, two or more motions, is a term applied to the mechanism that drives the rear (or any pair of powered) wheels of a motor car; *i.e.,* the system of gears (usually situated in the back axle) by means of which one driving wheel may revolve with increased speed while the other is checked (in turning corners. for example). In physics, differential apparatus (*e.g.,* a differential thermometer) is designed in such a manner that extraneous effects which may affect two readings or two different phenomena equally are eliminated and errors thereby are somewhat reduced or avoided altogether. (H. B. LM.)

DIFFERENTIAL CALCULUS, ABSOLUTE: *see* VECTOR ANALYSIS.

DIFFERENTIAL EQUATIONS, ORDINARY. Th any

scientific or technological field. such as astronomy. chemistry, engineering. physics. etc.. the formulation of a natural law is regarded as completely precise and definitive only when it is expressed as a mathematical equation. This equation effectively relates the quantity, or function (*q.v.*), upon which the attention is focused, with the independent variables such as time: position, etc., upon which it may depend. Now it is frequently—even prevalently—the case that the equation which does this involves, besides the function itself, also one or more of its derivatives. (For a definition and discussion of derivatives, see CALCULUS. DIFFERENTIAL AND INTEGRAL.) Such an equation, specifically one in which a derivative or derivatives occur, is called a differential equation. The following are examples of such equations:

$$\frac{dy}{dt} = -ky \tag{1}$$

$$m\frac{d^2y}{dt^2} = -k^2y \tag{2}$$

$$\left[1 + \left(\frac{dy}{dx}\right)^2\right]\frac{d^3y}{dx^3} - 3\frac{dy}{dx}\left(\frac{d^2y}{dx^2}\right)^2 = 0 \tag{3}$$

In these y stands for the function, and either t or x is the independent variable. The symbols k and m are used here to stand for specific constants.

Classification.—Differential equations are classified into several broad categories, and these are in turn subdivided into many subcategories. Of the former the most important are the category of the so-called ordinary differential equations and the category of the so-called partial differential equations. When the function involved in the equation depends upon only a single variable its derivatives are ordinary derivatives, and the differential equation is classed as an ordinary differential equation. If. on the other hand, the function depends upon several independent variables, so that its derivatives are partial derivatives, then the differential equation is classed as a partial differential equation.

Whichever the type may be, a differential equation is said to be of the nth order if it involves a derivative of the nth order but no derivative of an order higher than this. Equations (1), (2) and (3) are all ordinary differential equations. They are respectively of the first. second and third orders. The equation

$$\frac{\partial u}{\partial t} = k^2\left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}\right] \tag{4}$$

is an example of a partial differential equation. It is of the second order. The theories of ordinary and partial differential equations are markedly different. and for this reason the latter are treated separately (see DIFFERENTIAL EQUATIONS, PARTIAL). In almost all respects the former is the simpler.

Instead of a single differential equation. the object of study may be a simultaneous system of such equations. The formulation of the laws of dynamics frequently leads to such systems. In many cases a single differential equation of the nth order is advantageously replaceable by a system of n siinultaneous equations each of nhich is of the first order. (R. E. L.)

Historical Background.—The theory of differential equations is practically as old as the infinitesimal calculus. Sir Isaac Newton started working on differentials (which he called "fluxions") in 1665. He wrote a treatise on fluxional equations in 1671, dividing them into three classes according to the number of fluxions and fluents (flowing quantities) involved. In modern notation his first class contains the equations in nhich dy/dx is a function of x alone or of y alone, while the second class is formed by the equations

$$\frac{dy}{dx} = f(x,y)$$

and the third by the first-order partial differential equations. He developed the method of power series with indeterminate coefficients nith the aid of which he claimed that all equations could be solved. Nenton's treatise, which was published in 1736, had little or no influence on the development of the theory.

A greater share of credit was given to the second discoverer of the calculus, Gottfried Wilhelm Leibniz, who started his work in 1673 and who initiated the basic notation dx and $\int$ by the end of 1675 Leibniz' first publications in the *Acta Eruditorum* (1684, 1686) made no impression in Germany. but he found tno eager followers in Switzerland in the brothers Jakob (Jacques) and Johann (Jean) Bernoulli. This gifted Basel family produced eight mathematicians in the course of a century and several of them took a part in the development of differential equations In May 1690 Jakob Bernoulli published a new method of finding the isochrone; that is, the curve in a vertical plane followed by a mass particle when its vertical velocity component is constant (see CURVES, SPECIAL) These conditions gave him the equation

$$dy\cdot(b^2y - a^3)^{\frac{1}{2}} = dx\cdot a^{\frac{3}{2}},$$

and from the equality of the differentials he concluded the equality of the integrals and found the equation of the curve. This is the first time that the term "integral" occurs in the literature. In the 1690s much work on differential equations was done by Leibniz and by the Bernoullis. In 1691 Leibniz found that a differential equation in which $f(x,y) = f(x)g(y)$ could be solved by quadratures (see *Solutions*, below). A year later Leibniz was able to integrate the so-called homogeneous differential equation of the first order and still later also the linear equation of the first order (see equation [17] below). What later became knonn as the Bernoulli equation was proposed by Jakob Bernoulli in 1695 and solved by Leibniz and Johann Bernoulli using different methods. Thus in a few years most of the known elementary methods of solving first-order equations had been found.

Numerous applications of the new methods to geometrical problems were published prior to 1720, such as the problem of orthogonal trajectories and the problem of finding curves whose curvature is a knonn function of position. Some of these problems led to equations of the second or the third order. Besides the Bernoulli~,the Italian mathematician Count Jacopo Riccati, who solved equations of the form

$$F(y, y', y'') = 0$$

in 1712, should be mentioned. What later became known as Riccati's equation goes back to 1723; some younger members of the Bernoulli family, notably Daniel, participated in the discussion of this equation. Important work on differential equations by A. C Clairaut dates from 1734.

Leonhard Euler. also from Basel, made important contributions to the theory of differential equations starting in 1728. Various methods of lowering the order of an equation; the notion of an integrating factor; the discussion of linear equations; series solutions and the discovery that the equation

$$(1 - x^4)^{-\frac{1}{2}}\,dx + (1 - y^4)^{-\frac{1}{2}}\,dy = 0$$

has an algebraic solution are all due to Euler.

This special case of Xbel's theorem played an important role in the theory of elliptic functions (*q.v.*) created by N. H. Abel and K G. J. Jacobi in the 1820s.

At this time the function concept received its first airing during the debate between Daniel Bernoulli, Euler and Lagrange concerning the solutions of the so-called wave equation and the notion of an '.arbitrary" function. The important questions of what is a function and what constitutes a solution of a differential equation had now been raised; they were often repeated and the answers that satisfied one generation of mathematicians were revised by their successors.

1he first great revision of the principles of mathematical analysis took place in the 1820s, pioneered by Abel and Augustin Louis Cauchy. Cauchy gave an entirely new direction to the theory of ordinary diiferential equations. He showed that. within certain generous limits, all differential equations are solvable and he gave methods of finding the solutions through limiting processes. The theory of analytic functions, also created by him, led to a new theory of differential equations in the complex domain (see FUNCTIONS, ANALYTIC). Subsequent historical developments are relatively specialized and are beyond the scope of the present article. They may be found in several of the works listed in the bibliography. (E. H.)

Formulation of Natural Laws.—The way in which differential equations are utilized for the expression of natural laws' is indicated in some small measure by the following examples.

Radioactivity.—A radioactive material is constantly disintegrating. the rate of this process being at each instant proportional to the amount of the material which is then left. If the amount of material is designated by y, and t stands for the time, the rate of the disintegration is $-dy/dt$. The stated law asserts that this value is always proportional to y; namely, that it is always equal to ky, k being an appropriate constant. The law is, therefore, expressed by the differential equation (1) above.

Mass *Suspended* From a Spring.—If a heavy article is suspended from a coiled spring, the position in which it will hang in a continued state of rest is called its position of equilibrium. On a vertical y-axis this position can be taken as the point y = 0. If the particle is vertically displaced from this position it will be subject to a restoring force that is always proportional to its coordinate of position y, and is opposite to y in sign. The formula for this force is. therefore, $-k^2y$, where k is a constant of the spring. By Newton's second law of motion, the product of the mass m of the particle by its acceleration d^2y/dt^2 is equal to the force. The law of motion in accordance with which the particle oscillates up and down is, therefore, expressed by the differential equation (2) above.

Curvature.—It is shown in the calculus that the curvature K of a curve $y = f(x)$ is given by the formula

$$\cdot K = \left[1 + \left(\frac{dy}{dx}\right)^2\right]^{-\frac{3}{2}} \frac{d^2y}{dx^2}$$

The fact that a certain curve is a circular arc may, therefore, be expressed by the assertion that along it K does not change; namely, by the equation $dK/dx = 0$. This is found to be given explicitly by the differential equation **(3)** above. That equation thus formulates mathematically the law of the circular nature of the given arc.

Solutions.—An ordinary differential equation in which, for example, the function and the independent variable are denoted by y and x, is in effect an implicit summary of the essential characteristics of y as a function of x. These characteristics would presumably be more accessible to analysis if an explicit formula for y could be produced. Such a formula, or at least an equation in x and y (involving no derivatives) which is deducible from the differential equation, is called a solution of the differential equation. The process of deducing a solution from the equation by the applications of algebra and the calculus is called that of solving or integrating the equation. Some methods that serve for the integration of certain classes of differential equations will be explained below. It should be noted, however, that the differential equations which can be integrated form but a small minority. The chances are large, in the instance of a differential equation selected at random, that the equation is itself the simplest mode of summarizing the characteristics of the function, and that even theoretically no solving formula in the usual sense exists. In such instances the function must be studied by indirect methods. Even its existence must be proved when no possibility of producing it for inspection maintains. These subjects find their place in the more advanced theory.

Quadratures.—As an example of ordinary differential equations which are of so simple a type that their integration depends only upon an obvious application of the calculus, consider the equations of the form

$$\frac{dy}{dx} = f(x), \tag{5}$$

in which $f(x)$ is a given function. The solution of this equation, namely

$$Y = \int f(x)dx + c, \tag{6}$$

affords the occasion for some remarks which are of rather general applicability. In the relation (6) the indicated integration calls for some (any) indefinite integral of the function f(x). For many types of functions such integrals are to be found in tables of integrals, which are contained in many mathematics textbooks and in scientific and engineering handbooks. Not all functions $f(x)$, however, and not even all simple ones, have integrals that can be expressed by elementary closed formulas. Hence an indicated integration is not always replaceable by an expression that is more explicit. For this reason a relation in the form (6) is generally regarded as a satisfactory solution of equation (5), just as it stands. The term "quadrature" is frequently used in the place of "indefinite integral," the relation (6) being called a solution in terms of an indicated quadrature.

The *General* Solution; *Other* Solutions.—The final term of the relation (6), being a constant of integration and hence being able to assume any value whatever, is called an arbitrary constant. For each specific value of this constant equation (6) defines a curve in the (x,y) plane. and while the constant remains arbitrary the equation refers to the whole aggregate or family of these curves. This family is the solution of the differential equation. What is thus observed in the simple case of equation (5) is generally true of differential equations. The process of solution brings one or more arbitrary constants into the relations, and these as a result represent a family of curves. A solution which includes the maximum possible number of arbitrary constants is called the general solution of the differential equation. It can be shown that this maximum number is precisely equal to the order of the differential equation; namely, that the general solution of an ordinary differential equation of the nth order involves n arbitrary constants.

For any set of specific values of the constants the solving relation still yields a solution. Such a solution is called a particular solution. Obviously the general solution includes all the particular solutions. In the case of some differential equations still other solutions. called singular solutions, exist. A discussion of singular solutions is contained, for example, in the book by L. M. Kells listed in the bibliography.

Initial *and* Boundary Conditions.—The presence of arbitrary constants in the general solutions of ordinary differential equations is a matter of fundamental significance for the application of these equations to scientific problems; for such problems ordinarily call not merely for a solution of the equation, but for the solution which fulfills also certain other relations that are pertinent to it. These auxiliary relations must, therefore, be fulfilled by the appropriate assignment of values to the arbitrary constants. Some examples mill illustrate this.

It was shown above how the disintegration of a radioactive substance is formulated by the differential equation (1). The general solution of this equation is

$$y = ce^{-kt}, \tag{7}$$

in which the constant c is arbitrary. Now in any specific case the substance is of a definite amount, say 20 g., at some definite time, say at t = 2 seconds. These values, upon being substituted for y and t in the equation, impose upon c the relation $20 = ce^{-k2}$, in accordance with which

$$c = 20e^{2k} \tag{8}$$

The solution which fits the case is, therefore,

$$y = 20e^{k(2-t)} \tag{9}$$

It was also shown above how the motion of a particle suspended from a spring is formulated by the differential equation (2). The general solution of this equation (obtained by a method involving the use of an auxiliary equation, described below) is

$$y = c_1\cos\frac{kt}{\sqrt{m}} + c_2\sin\frac{kt}{\sqrt{m}} \tag{10}$$

Now in any specific case. the particle is at a definite place, say at y = 1, and is moving with a definite velocity, say $dy/dt = -\frac{1}{2}$, at a definite time, say at t = 0. These values substituted into (10) and the equation for dy/dt derived from (10) impose upon c_1 and c_2 the relations $1 = c_1$, and $-\frac{1}{2} = c_2k/\sqrt{m}$. Thus it is required that $c_1 = 1$, $c_2 = -\sqrt{m}/2k$, and accordingly the solution that fits the problem is

$$y = \cos \frac{kt}{\sqrt{m}} - \frac{\sqrt{m}}{2k} \sin \frac{kt}{\sqrt{m}}$$

Auxiliary conditions that are imposed upon the solution of a differential equation at some one value of the independent variable, as in the examples above, are called initial conditions. If the auxiliary conditions apply at two or more values of the independent variable, they are usually called boundary conditions. Problems leading to such conditions are called differential boundary problems. The work by R. V. Churchill listed in the bibliography is primarily concerned with such problems.

FIRST-ORDER EQUATIONS

Equations With Separable Variables.—The ordinary differential equation of the first order, when it is solved for the derivative, is of the form

$$\frac{dy}{dx} = f(x,y), \tag{11}$$

in which $f(x,y)$ is an explicit function. A form which is obviously equivalent to this, but which is in some respects more convenient, is

$$M(x,y)dx + N(x,y)dy = 0 \tag{12}$$

The case to which attention is to be given first is that in which equation (12) is of the more special form

$$P(x)dx + Q(y)dy = 0, \tag{13}$$

or in which it can be brought into this form by multiplying it through by appropriate factors that are functions of x or of y. The salient specialization which distinguishes (13) from the general form (12) is that P, the coefficient of dx, does not involve y, and Q, the coefficient of dy, does not involve x. In equation (13) the variables are said to be separated, and a differential equation which can be reduced to such a form is classed as an equation with separable variables. When the variables have been separated the integration of the differential equation reduces to a mere matter of quadrature. Thus the general solution of the differential equation (13) is given by the relation

$$\int P(x)dx + \int Q(y)dy = c, \tag{14}$$

with c denoting the arbitrary constant.

By way of example consider the differential equation

$$dy + kydt = 0$$

This will be recognized as equation (1) above. In this equation the variables are separable, for upon multiplication by $1/y$ the form is changed to

$$\frac{1}{y}dy + kdt = 0,$$

in which the variables are separated. Integration yields the solution

$$\log y + kt = c$$

The differential equation

$$y^4dx + (4y - 3)\cos^2 xdy = 0,$$

if multiplied through by the factors y^{-4} and $\sec^2 x$, takes the form

$$\sec^2 xdx + \left(\frac{4}{y^3} - \frac{3}{y^4}\right)dy = 0,$$

in which the variables are separated. Integration of this yields the solution

$$\tan x - \frac{2}{y^2} + \frac{1}{y^3} = c$$

The differential equations

$$y^2 + 5y\frac{dy}{dx} = 3 + xy\frac{dy}{dx},$$

$$y^2dx + \sqrt{1 - x^2}\,dy = 4dx$$

are of this type. Their solutions are respectively

$$\log (x - 5) - \tfrac{1}{2}\log(y^2 - 3) = c,$$

$$4 \sin^{-1}x + \log\left(\frac{y - 2}{y + 2}\right) = c$$

Exact Equations.—It is shown in the calculus that if two functions $M(x,y)$, $N(x,y)$ fulfill the relation

$$\frac{\partial}{\partial y}M(x,y) \equiv \frac{\partial}{\partial x}N(x,y) \tag{15}$$

then there exists a function $\varphi(x,y)$ of value such that $\partial\varphi(x,y)/\partial x = M(x,y)$ and $\partial\varphi(x,y)/\partial y = N(x,y)$. In accordance with this it is clear that if the differential equation (12) is one whose coefficients fulfill the identity (15), then the equation can be written in the form

$$\frac{\partial\varphi(x,y)}{\partial x}dx + \frac{\partial\varphi(x,y)}{\partial y}dy = 0$$

This may, however, be more concisely written as $d\varphi = 0$, and thus it must be concluded that $\varphi(x,y) = c$, a constant. This is, then, the general solution of the given equation. It remains only to describe the means by which the function $\varphi(x,y)$ may be found. This may be done as follows: Treating y as though it were a constant, evaluate the integral $\int M(x,y)dx$. Then treating x as though it were a constant, evaluate the integral $\int N(x,y)dy$. The sum of all unlike terms in these two evaluations (*i.e.*, including no repetitions) is the function $\varphi(x,y)$.

As an example consider the differential equation

$$(\cos y - y + 1)dx + (3y^2 - x \sin y - x)dy = 0$$

In this case the two members of the identity (15) are each $(-\sin y - 1)$, and thus the equation is exact. Regarding y as a constant, the first member of the equation integrates into $x \cos y - xy + x$. Regarding x as a constant, the second member integrates into $y^3 + x \cos y - xy$. Setting the sum of unlike terms equal to an arbitrary constant gives as the general solution

$$x \cos y - xy + x + y^3 = c$$

The differential equations

$$y(e^{xy} - \sin x)dx + (\cos x + xe^{xy})dy = 0,$$

$$(2xy^3 - 3)dx + \left(3x^2y^2 + 8y - \frac{1}{y}\right)dy = 0$$

may be shown to be exact. Their solutions are respectively

$$y \cos x + e^{xy} = c,$$

$$x^2y^3 - 3x + 4y^2 - \log y = c$$

Although a differential equation may not be exact in the form in which it is encountered, it is possible to prove that by multiplication with a suitable factor it may be made exact. Thus the differential equation

$$\left(2y + \frac{1}{xy}\right)dx + \left(x - \frac{1}{y^2}\right)dy = 0 \tag{16}$$

is not exact, but if it is multiplied through by the factor x it becomes so. A multiplier, such as x in this instance, which makes a differential equation exact is called an integrating factor. Other integrating factors for equation (16) are $y/(xy^2 + 1)$ and $x^2\left(xy + \frac{1}{y}\right)$. It can be proved that for every differential equation of form (12) an unlimited number of integrating factors exists. In some simple cases it is possible to guess an integrating factor. Many textbooks point out earmarks to be sought in the differential equation as guides to such guessing. In most actual cases, however, integrating factors are not easily found.

Linear Equations.—A differential equation which can be written in the form

$$\frac{dy}{dx} + Py = Q, \tag{17}$$

in which the coefficients P and Q may be constants or functions of x but do not involve y, is called a linear differential equation

of the first order. This is a type of equation which is of considerable importance in many different connections. When the equation is given the alternative form

$$[yP(x) - Q(x)]dx + dy = 0,$$

the remarks of the section just preceding apply to it, and it is, in fact, found that the multiplier $e^{\int P(x)\,dx}$ is an integrating factor. By the method of exact equations outlined above, the general solution of the equation is thus found to be

$$ye^{\int P(x)\,dx} - \int Q(x)e^{\int P(x)\,dx}dx = c \tag{18}$$

As an example consider the differential equation

$$\frac{dy}{dx} + \left(1 + \frac{1}{x}\right)y = \frac{5}{x}$$

The integrating factor is $e^{z + \log x}$, a function which is more briefly written xe^z, and the solution of the equation is

$$xye^x - 5e^x = c$$

The differential equations

$$\frac{dy}{dx} + 2y \tan x = 2x \cos^2 n,$$
$$(xe^{2x} - 2y\sqrt{1 + x^2})dx + \sqrt{1 + x^2}dy = 0$$

are of this type. Their solutions are respectively

$$y \sec^2 x - x^2 = c,$$
$$ye^{-2x} + \sqrt{1 + x^2} = c$$

Solution by Change of Variable. — When no convenient method for the integration of a differential equation suggests itself, a procedure which is frequently resorted to is the following one. Some combination of the variables x and y is taken as a new variable. say s, and the differential equation is then expressed in terms of this new variable and one or the other of the original variables. In its new aspect the differential equation may be of a form quite different from its original one. New possibilities for its integration may thus present themselves. It is not always possible to foretell how such a change of variable may profitably be made.

In some instances certain combinations of the variables are obviously prominent in the differential equation, and the clue as to a desirable change may therein be seen. Some examples will serve to illustrate the procedure.

Consider the differential equation

$$(x + 3y + 2)dx + (2x + 6y + 3)dy = 0 \tag{19}$$

The combination $x + 3y$ appears with some prominence in this equation. Set $s = x + 3y$, namely $x = s - 3y$, so that $dx = ds - 3dy$. On substituting these values for x and dx in equation (19), the latter becomes

$$(s + 2)(ds - 3dy) + (2s + 3)dy = 0$$

This is found to be an equation with separable variables. By the method of same it may be integrated into the relation

$$s - \log(s + 3) - y = c$$

On replacing s by its value in terms of the original variables, it is found that

$$x + 2y - \log(x + 3y + 3) = c,$$

and this is the solution of the given differential equation.

As a second example consider the differential equation

$$2x^2ydx + (xy^2 + x^3)dy = 0$$

In this all terms are of the same degree (the third) in x and y, and a multiplication of the equation by x^{-3} changes it to the form

$$2\left(\frac{y}{x}\right)dx + \left[\left(\frac{y}{x}\right)^2 + 1\right]dy = 0$$

The change $s = y/x$, namely $y = xs$, is strongly suggested. In accordance with this change, $dy = xds + sdx$, and with the substitution of these values of y and dy the equation becomes

$$2sdx + (s^2 + 1)(xds + sdx) = 0$$

This has separable variables, and has the solution $\log x + \log(s^3 + 3s) = c$. Upon replacing s by its value in terms of x and y the solution of the given equation is obtained, namely

$$\log x + \tfrac{1}{3}\log\left(\frac{y^3}{x^3} + \frac{3y}{x}\right) = c$$

A standard form of differential equation which yields to this method of integration is the equation

$$\frac{dy}{dx} + P(x)y = Q(x)y^k, \tag{20}$$

in which the coefficients P and Q do not involve y. If $k = 1$ the variables are separable, and if $k = 0$ the equation is linear. The integration in these cases has, therefore, already been discussed. In the remaining cases, namely $k \neq 0$, $k \neq 1$, the change of variable $s = y^{1-k}$ reduces the equation to the linear form.

SECOND-ORDER LINEAR EQUATIONS

The differential equation of the nth order which is of the form

$$a_0\frac{d^ny}{dx^n} + a_1\frac{d^{n-1}y}{dx^{n-1}} + \ldots + a_{n-1}\frac{dy}{dx} + a_ny = f(x), \tag{21}$$

in which the coefficients $a_0, a_1, \ldots, a_n$ may be functions of x but do not involve y or any of its derivatives, is called the linear differential equation of the nth order. The equation which differs from this only by having zero as its right-hand member in the place of $f(x)$ is called the corresponding reduced or homogeneous equation. Certain facts concerning equations of this type greatly facilitate the construction of their solutions. These are primarily the following: If $y_0(x)$ is any particular solution of the differentialequation (21), and $y_1(x), y_2(x), \ldots, y_p(x)$ are any linearly independent solutions of the corresponding reduced equation, then the relation

$$y = y_0(x) + c_1y_1(x) + c_2y_2(x) + \ldots + c_py_p(x), \tag{22}$$

in which the coefficients $c_1, c_2, \ldots, c_p$ are arbitrary constants, is also a solution of equation *(21)*. If, in particular, the number p is equal to n, the solution *(22)* is the general solution since it involves n arbitrary constants. In view of these facts the integration of an equation of the form *(21)* is achievable by the determination, in any manner, of a particular solution of that equation, and of n functionally distinct particular solutions of the reduced equation.

Insofar as the applications of differential equations to physics and engineering are concerned, the linear type of equation is of extremely great importance. Since by far the largest number of applications lead, moreover, to differential equations of the second order, the remaining discussion will be confined to these. Such equations are solvable by elementary methods, as will be shown, whenever the coefficients are constants. When these coefficients are more general functions of x, on the other hand, explicit solutions in simple closed formulas usually do not exist. Because of their great importance a number of equations of this kind have been endowed with proper names, such as the Bessel equation, the Legendre equation, the Mathieu equation, etc., and volumes have been written about them.

When the differential equation *(21)* is of the second order, it is explicitly

$$a_0\frac{d^2y}{dx^2} + a_1\frac{dy}{dx} + a_2y = f(x), \tag{23}$$

and its reduced equation is

$$a_0\frac{d^2y}{dx^2} + a_1\frac{dy}{dx} + a_2y = 0 \tag{24}$$

If a_0 is a constant, it is assumed to be different from zero, since the equation would otherwise be of a lower order than the second.

Applications to Physics. — In an earlier section the physical problem of a weight suspended from a coiled spring and oscillating in the vertical direction about the point $y = 0$ was shown to be

formulated by the differential equation **(2)**. It will be observed at once that this equation is of type **(24)**. Had the position of equilibrium been chosen to be some value of y different from zero, the resulting differential equation would have been of type **(23)**. In the following, some other formulations from the field of physics are shown to lead to differential equations of these types.

If a body of mass m and weight w is permitted to fall in a vacuum. the pull of gravity exerts upon it a force equal to its weight. By Newton's second law of motion this force is equal to the product of the body's mass by its acceleration, the latter being d^2y/dt^2, where y denotes the distance through which it has fallen. The motion is thus formulated by the differential equation

$$m\frac{d^2y}{dt^2} = w,$$

and this is of the form **(23)**. For the case of a fall not in a vacuum but in a medium such as air, which resists the motion with a force that is at any instant a constant k^2 times the velocity, the efiective downward force is $w - k^2dy/dt$. The law of motion is accordingly

$$m\frac{d^2y}{dt^2} = w - k^2\frac{dy}{dt},$$

and this is again a differential equation of the type **(23)**.

The discharge of an electrical condenser through an inductive coil of wire may also be readily formulated in symbols. The potential difference V between the terminals of the condenser is at each instant proportional to the charge Q upon it, the constant C in the relation $Q = CV$ being called the condenser's capacitance. The current I of the discharge is the rate $-dQ/dt$ at which the charge diminishes, and thus $I = -CdV/dt$. The counter e.m.f. interposed by the coil is equal to the coil's inductance L times the rate of change of current, and thus the effective voltage is $V - LdI/dt$. This is equal to the current times the resistance R; namely, $V - LdI/dt = RI$. Upon substituting the value of **I** above, this equation becomes

$$V + LC\frac{d^2V}{dt^2} = -RC\frac{dV}{dt},$$

and this differential equation is of the form **(24)**.

Solution by Use of Auxiliary **Equation.**—When the coefficients of the equation **(24)** are constants, as in the case of each of the equations which were derived in the section immediately preceding, the substitution

$$y = e^{rx}, \tag{25}$$

with r standing for a constant, leads to the relation

$$(a_0r^2 + a_1r + a_2)e^{rx} = 0$$

This is fulfilled if r is a root of the equation

$$a_0r^2 + a_1r + a_2 = 0, \tag{26}$$

this being called the auxiliary equation of **(24)**. When this auxiliary equation has two unequal roots, say $r = r_1$ and $r = r_,$ formula **(25)** nith either one of these values of r solves the differential equation **(24)**. The same is true of the formula

$$y = c_1e^{r_1x} + c_2e^{r_2x}, \tag{27}$$

irrespective of the values of the constants c_1, c_2. Since the relation **(27)** involves two arbitrary constants, it is the general solution of the differential equation **(24)**.

The reasoning obviously requires some modification when the auxiliary equation **(26)** has a multiple root when, in effect, it has only one root. say $r = r_1$. The exponentials on the right of (27) are then the same, and that relation involves only one arbitrary constant. namely $(c_1 + c_2)$. It is, however, easily verified that in this case the formula $y = xe^{r_1x}$ is also a solution of the differential equation **(24)**. The general solution is, therefore, in this instance given by the relation

$$y = c_1e^{r_1x} + c_2xe^{r_1x} \tag{28}$$

Consider now equation **(23)**. If a particular solution $y_0(x)$ of this equation is in any way obtainable, the general solution is given at once by the addition of this $y_0(x)$ to the right-hand member of the appropriate relation **(27)** or **(28)**. This was observed above, and was formulated in relation **(22)**. The matter at issue is, therefore, only the deduction of a particular solution $y_0(x)$. There are a number of procedures commonly used for achieving this.

One such is the following:

The differential equation **(23)** may be written in the form

$$\frac{d}{dx}\left(\frac{dy}{dx} - r_2y\right) - r_1\left(\frac{dy}{dx} - r_2y\right) = \frac{1}{a_0}f(x) \tag{29}$$

If the symbol $\varphi(x)$ is introduced with the relationship

$$\frac{dy}{dx} - r_2y = \varphi(x), \tag{30}$$

equation **(29)** appears in the form

$$\frac{d\varphi}{dx} - r_1\varphi = \frac{1}{a_0}f(x) \tag{31}$$

This. however, is a linear differential equation of the first order for the value of $\varphi(x)$, and by the relation **(18)** (with $c = 0$) it is fulfilled if

$$\varphi(x) = e^{r_1x}\int\frac{f(x)}{a_0}e^{-r_1x}dx$$

The function $\varphi(x)$ has thus been made known, and, this being so, the solution $y_0(x)$ sought is shown by **(30)** to be obtainable by the integration of that equation. This is again a linear equation of the first order. As applied to it the relation (18) (with $c = 0$) yields

$$y = e^{r_2x}\int\varphi(x)^{-r_2x}dx,$$

and this is the evaluation of the desired particular solution $y_0(x)$.

An example may not be amiss. Consider the differential equation

$$2\frac{d^2y}{dx^2} - 6\frac{dy}{dx} + 4y = e^{-3x}$$

The auxiliary equation has the roots $r_1 = 1$, $r_2 = 2$, and thus the general solution of the reduced equation is

$$y = c_1e^x + c_2e^{2x}$$

Equation **(31)** is in this case

$$\frac{d\varphi}{dx} - \varphi = \tfrac{1}{2}e^{-3x},$$

and a solution of it is $\varphi(x) = \frac{-1}{8}e^{-3x}$. Equation **(30)** is accordingly

$$\frac{dy}{dx} - 2y = \frac{-1}{8}e^{-3x}$$

and this admits as a solution $y = \frac{1}{40}e^{-3x}$. The general solution of the equation considered is, therefore,

$$y = \frac{1}{40}e^{-3x} + c_1e^x + c_2e^{2x}$$

Solution by Method of Undetermined Coefficients.—A procedure for finding a solution $y_0(x)$ of equation **(23)** which is in wide practical use, although it is not always applicable, is the following one. Suppose the right-hand member f(x) is expressible in terms of the functions of a set $\varphi_1(x)$, $\varphi_2(x)$, . . . , $\varphi_p(x)$, in the manner

$$f(x) = k_1\varphi_1(x) + k_2\varphi_2(x) + \ldots + k_p\varphi_p(x), \tag{32}$$

with constant coefficients k_1, k_2, . . . , k_p, the functions of this set being such that the derivative of each one of them can also be so expressed. Then if $y_0(x)$ is assumed to be of the form

$$y_0(x) = b_1\varphi_1(x) + b_2\varphi_2(x) + \ldots + b_p\varphi_p(x), \tag{33}$$

the coefficients b_1, b_2, . . . , b, may be determined. The fol-

lowing example illustrates this method.

Consider the differential equation

$$\frac{d^2y}{dx^2} + 3\frac{dy}{dx} + 2y = 4x + 11\cos x$$

In this case the right-hand member is expressible in the form (32) with $\varphi_1 = x$, $\varphi_2 = 1$, $\varphi_3 = \cos x$, $\varphi_4 = \sin x$, and the derivative of each of these can also be so expressed. Hence if it is assumed that

$$y_0 = b_1x + b_2 + b_3\cos x + b_4\sin x,$$

the result of substituting this into the differential equation is the relation

$$2b_1x + (3b_1 + 2b_2) + (b_3 + 3b_4)\cos x + (b_4 - 3b_3)\sin x = 4x + 11\cos x$$

Equating coefficients of similar terms shows that $2b_1 = 4$, $3b_1 + 2b_2 = 0$, $b_3 + 3b_4 = 11$, $b_4 - 3b_3 = 0$. These equations determine the evaluations $b_1 = 2$, $b_2 = -3$, $b_3 = 11/10$, $b_4 = 33/10$, and thus

$$y_0 = 2x - 3 + 11/10\cos x + 33/10\sin x$$

Solution by Power-Series Method.—When the coefficients of the differential equation (23) are not constants but are continuous functions of x, the character of the solutions near any specific point x depends significantly upon whether the leading coefficient $a_0(x)$ is or is not zero at this point. In the former case the point is called a singular point. It is assumed in the following discussion that for the values of x in question $a_0(x) \not\equiv 0$, and that this and the other coefficients, as well as the function $f(x)$, are either polynomials or are representable in power series (see SERIES). The method is one of assuming a solution to be given by an infinite series

$$y = c_0 + c_1x + c_2x^2 + c_3x^3 + \ldots, \tag{34}$$

and then, by the substitution of this form into the equation, determining the coefficients. The following example elucidates this procedure.

Consider the differential equation

$$(1 - x)\frac{d^2y}{dx^2} - 4\frac{dy}{dx} + \frac{2}{1 - x}y = 0 \tag{35}$$

Since from (34)

$$\frac{dy}{dx} = c_1 + 2c_2x + 3c_3x^2 + 4c_4x^3 + \ldots,$$
$$\frac{d^2y}{dx^2} = 2c_2 + 6c_3x + 12c_4x^2 + \ldots,$$

whereas

$$\frac{2}{1 - x} = 2 + 2x + 2x^2 + 2x^3 + \ldots,$$

the terms of the differential equation (35) are respectively

$$(1 - x)\frac{d^2y}{dx^2} = 2c_2 + (6c_3 - 2c_2)x + (12c_4 - 6c_3)x^2 + \ldots,$$
$$-4\frac{dy}{dx} = -4c_1 - 8c_2x - 12c_3x + \ldots,$$
$$\frac{2}{1 - x}y = 2c_0 + (2c_0 + 2c_1)x + (2c_0 + 2c_1 + 2c_2)x^2 + \ldots$$

The result of substituting the form *(34)* into the differential equation (35) is thus the relation

$$(2c_2 - 4c_1 + 2c_0) + (6c_3 - 10c_2 + 2c_1 + 2c_0)x$$
$$+ (12c_4 - 18c_3 + 2c_2 + 2c_1 + 2c_0)x^2 + \ldots = 0$$

This is fulfilled if the coefficient of each power of x is zero; namely, if

$$2c_2 - 4c_1 + 2c_0 = 0,$$
$$6c_3 - 10c_2 + 2c_1 + 2c_0 = 0,$$
$$12c_4 - 18c_3 + 2c_2 + 2c_1 + 2c_0 = 0,$$

If any choice is made of c_0 and c_1 these equations serve in turn to give evaluations for $c_2, c_3, c_4, \ldots$. Specifically, let the choice $c_0 = 0, c_1 = 1$ be made. The values $c_2 = 2$, $c_3 = 3$, $c_4 = 4, \ldots$ are found to result, and the series

$$y_1 = x + 2x^2 + 3x^3 + 4x^4 + \ldots$$

is accordingly a solution. The alternative choice $c_0 = 1$, $c_1 = 0$, leads to the values $c_2 = -1$, $c_3 = -2$, $c_4 = -3, \ldots$, and the series

$$y_2 = 1 - x^2 - 2x^3 - 3x^4 - \ldots$$

is a second solution. When combined with arbitrary constants as multipliers these yield the general solution. The values of x for which solutions are thus obtained are, of course, only those for which the infinite series are convergent.

DIFFERENTIAL EQUATIONS, PARTIAL. An equation involving several independent variables and one or more dependent variables and their partial derivatives (with respect to the independent variables) is called a partial differential equation. The order of such an equation is the largest of the orders of any of the partial derivatives (of the dependent variables) which occur in the equation. Such an equation is called linear if the dependent variables and their various partial derivatives occur only linearly; the coefficients of these derivatives and dependent variables may, however, be functions of the independent variables. The examples given in equations (1) through (9) and (42) and (44) are all linear.

Applications.— Many physical quantities satisfy partial differential equations, as shown in the following examples:

1. If $u(x,t)$ denotes the lateral displacement at time t of the point of a vibrating string which is at a distance x from one of the fixed ends, then u satisfies the differential equation

$$\frac{\partial^2u}{at^2} = c^2\frac{\partial^2u}{\partial x^2} \quad (c \text{ constant}) \tag{1}$$

2. If $u(x,y,t)$ denotes the vertical displacement at time t of the point at position (x,y) of a horizontal vibrating membrane (such as a drumhead), then u satisfies

$$\frac{\partial^2u}{\partial t^2} = c^2\left(\frac{\partial^2u}{\partial x^2} + \frac{\partial^2u}{\partial y^2}\right) \tag{2}$$

3. If $u(x,y,z,t)$ denotes the temperature at time t and position (x,y,z) within a homogeneous conducting solid, then u satisfies the diffusion equation

$$\frac{\partial u}{\partial t} = a^2\left(\frac{\partial^2u}{\partial x^2} + \frac{\partial^2u}{\partial y^2} + \frac{\partial^2u}{\partial z^2}\right) \tag{3}$$

4. If, in (3), various parts of the surface of the solid are held at various fixed temperatures, the resulting solution of (3) will tend as $t \to \infty$ to the solution u of Laplace's equation

$$\frac{\partial^2u}{\partial x^2} + \frac{\partial^2u}{\partial y^2} + \frac{\partial^2u}{\partial z^2} = 0 \tag{4}$$

that has the given boundary values. The determination of the solution (or solutions if more than one) of (4) with given boundary values is known as the Dirichlet problem. If part of the boundary of the solid is insulated instead of being held at some temperature, then the directional derivative in the direction normal (*i.e.*, perpendicular) to that part of the boundary surface is zero and the problem of determining the solution of (4) with such

boundary data is said to be a mixed problem. The Neumann problem is that of finding the solution of *(4)* with the normal derivative given; this corresponds roughly to prescribing the rate of flow of heat across the various portions of the boundary.

5. The Newtonian gravitational potential $u(x,y,z)$ at a position (x,y,z) away from the celestial bodies which exert the force also satisfies *(4);* at a position within one of the celestial bodies. u satisfies Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = k\rho(x,y,z) \tag{5}$$

where p is the density of matter at (x,y,z) and k is a constant. The electric potential due to the presence of electric charges also satisfies Laplace's equation (4) at positions (x,y,z) away from any charges and satisfies Poisson's equation *(5)* at positions where the distribution of charges has a continuous volume density p; however, electric charges often concentrate on surfaces, in which case the volume density is not defined.

6. If a disturbance (not too large) is propagated through a homogeneous medium, the deviation $p(x,y,z,t)$ of the pressure from normal and the velocity potential $U(x,y,z,t)$ at position (x,y,z) at time t satisfy the so-called wave equation

$$\frac{\partial^2 U}{\partial t^2} = c^2 \Delta U, \ \Delta U = \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} \tag{6}$$

which is the three-dimensional form of the vibrating-string and the vibrating-membrane equations *(1)* and (2) ; here c is the velocity of sound in the medium.

7. The so-called wave functions of quantum mechanics satisfy the Schrödinger wave equation

$$\Delta U + [\lambda + q(x,y,z)]U = 0 \tag{7}$$

in the simplest case. Here ΔU is defined in (6), λ is a constant and $q(x,y,z)$ is a given function; the values of λ for which there are "proper" solutions are called eigenvalues and their totality, together with certain other values of X, form the spectrum of the system being considered. In the case of the hydrogen atom, the negative values of λ are discrete and determine the frequencies of the emitted light.

Systems of partial differential equations, which must be solved simultaneously, arise in the theories of hydrodynamics, aerodynamics, elasticity and electromagnetism. Under special conditions, a problem in elasticity may be reduced to determining plane stresses σ_{xx}, σ_{xy} and σ_{yy} that are proportional to the second derivatives of the Airy stress function $u(x,y)$, which satisfies the fourth-order equation

$$\Delta^2 u = 0; \ i.e., \ \frac{\partial^4 u}{\partial x^4} + 2\frac{\partial^4 u}{\partial x^2 \partial y^2} + \frac{\partial^4 u}{\partial y^4} = 0 \tag{8}$$

The list of applications mentioned above is certainly not exhaustive, but it may serve to suggest the importance to physics and engineering of the study of such equations. But besides the many applications to science of partial differential equations, there are also many applications to other branches of mathematics. First of all, if $u(x,y)$ and $v(x,y)$ are the real and imaginary parts of an analytic function of the complex variable z, then u and v satisfy the Cauchy-Riemann system

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \ \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x} \tag{9}$$

A great variety of systems of partial differential equations arise in the study of differential geometry (*q.v.*). In many of these, there are more equations than unknown functions, so that certain "integrability conditions" must be satisfied in order for there to be a solution. A great deal of progress has been made since *1930* in the theory of differential equations by use of the theory of operators in Hilbert and Banach spaces and some theories in the calculus of variations which were developed during the first half of this century. The many connections of the theory of partial differential equations with other mathematical theories and the solution of several long-standing problems in differential geometry by methods involving differential equations have aroused a renewed interest in this field on the part of mathematicians.

Methods of Solution. — In view of the importance of partial differential equations in science, the technique of finding solutions to such equations has been and still is being studied intensively. It is possible to obtain reasonably simple formulas for the solutions only in a very few cases. The principal techniques are those of separation of variables, combined with the use of Laplace and Fourier transforms.

One of the first equations to be solved was equation *(1)*. First of all, by a change of scale along the x-axis $(x = cx')$, there is obtained a new equation with c = 1. By rotating axes through 45°, setting

$$\xi = \frac{x' - t}{\sqrt{2}}, \ \eta = \frac{x' + t}{\sqrt{2}}, \tag{10}$$

the new equation is seen to be equivalent to the equation

$$\frac{\partial^2 u}{\partial \xi \partial \eta} = 0 \tag{11}$$

which is seen to have only the solutions

$$u = f_1(\xi) + g_1(\eta), \tag{12}$$

where f_1 and g_1 are arbitrary differentiable functions. By retracing the steps, it is seen that all solutions of (1) are of the form

$$u(x,t) = f(x - ct) + g(x + ct) \tag{13}$$

The use of the method of separation of variables in the solution of *(1)* will now be illustrated. In the case of the vibrating-string problem a solution $u(x,t)$ of *(1)* is desired such that $u(0,t) = u(l,t) = 0$ for all t, l being the length of the string; this corresponds to the fact that the string is held fixed at both ends. The method involves looking for a solution of (1) of the form

$$u(x,t) = T(t) \cdot X(x) \tag{14}$$

In order for a function u given by *(14)* to be a solution of (1), the relation

$$T''(t)X(x) = c^2 T(t)X''(x), \text{ or}$$
$$\frac{T''(t)}{T(t)} = c^2 \frac{X''(x)}{X(x)} \tag{15}$$

must hold. Since the left side of (15) is a function of t alone and the right side is a function of x alone, both must be constants. Thus the relations

$$X''(x) = \lambda X(x) \text{ and } T''(t) = c^2 \lambda T(t) \tag{16}$$

must hold for some constant λ. Since the ordinary differential equations in (16) have exponential solutions if $\lambda > 0$, it follows that $\lambda < 0$ if $X(0) = X(l) = 0$. The only solutions of the first equation in *(16)* for $\lambda = -\mu^2 < 0$ are seen from the theory of ordinary differential equations *(see* DIFFERENTIAL EQUATIONS, ORDINARY*)* to be of the form

$$X(x) = A \cos \mu x + B \sin \mu x$$

If $X(0) = 0$, then $A = 0$; if $X(l) = 0$, then $\mu l = n\pi$ for some integer n. Hence any solution u of the desired type must be of the form

$$\sin\left(\frac{n\pi x}{l}\right) \cdot \left(C_n \cos\frac{cn\pi t}{l} + D_n \sin\frac{cn\pi t}{l}\right) \tag{17}$$

Since equation (1) is linear, any finite or convergent infinite sum of such solutions (if the derivatives also converge uniformly) is also a solution. Since any sufficiently regular function which vanishes at $x = 0$ and $x = l$ can be expanded into a Fourier sine series, it is clear that the values of $u(x,0)$ and $u_t(x,0)$, *i.e.*, the initial displacement and velocity at points along the string, may be assigned; the coefficients C_n are just the Fourier coefficients for $u(x,0)$ and the D_n are proportional to those for $u_t(x,0)$ (u_t means $\partial u/\partial t$).

It should be noted that the values of λ for which there is a solution of *(16)* of the desired type (in this case $X(0) = X(1) = 0$) are discrete and are all negative; in fact

$$\lambda = -\mu^2, \text{ where } \mu = \frac{n\pi}{l}$$

for some integer n (which may be assumed positive since $\sin(-n\pi x/l) = -\sin(n\pi x/l)$). It is of some interest that the value $n = 1$ corresponds to the fundamental tone emitted by the string and the larger values of n correspond to the harmonics.

In case solutions of (1) for all values of x and t or for all $t \geqq 0$ are desired, the form (13) is more general and more useful than that just obtained; it is easy to see that $u(x,0)$ and $u_t(x,0)$ may be assigned.

The use of the Laplace transform in the solution of (1) with different initial and boundary data will now be illustrated. Let

$$U(x,s) = \int_0^\infty e^{-st}u(x,t)dt, \tag{18}$$

assuming that u does not increase too rapidly with t to prevent the convergence of the integral at least for sufficiently large s; U is called the Laplace transform (in t) of $u(x,t)$. Integration by parts gives

$$\begin{aligned}\int_0^\infty e^{-st}\frac{\partial u}{\partial t}dt &= -u(x,0) + s\int_0^\infty e^{-st}u(x,t)dt \\ \int_0^\infty e^{-st}\frac{\partial^2 u}{\partial t^2}dt &= -u_t(x,0) - su(x,0) + s^2U(x,s)\end{aligned} \tag{19}$$

Equation (1) then becomes

$$U_{xx}(x,s) - s^2U(x,s) = -u_t(x,0) - su(x,0), \tag{20}$$

which is an ordinary differential equation in x for each value of s. If $u(x,t)$ is given along two lines $x = a$ and x = b, for example, then $U(x,s)$ would be given along those lines for corresponding values of s; the desired solution could then be found by finding the solution of (20) for each s which had the given values (depending on s) for x = a and x = b, and then using some "Laplace inversion formula" to solve (18) for $u(x,t)$, this last often being done with the aid of tables of Laplace transforms. In case $u(x,t)$ and $u_x(x,t)$ were given on x = 0 and $u(x,t)$ were desired for $x \geqq 0$ and $t \geqq 0$, then U and U_x would be given along $x = 0$ and it would be possible to solve (20) by introducing the Laplace transform of U with respect to x:

$$V(y,s) = \int_0^\infty e^{-xy}\,U(x,s)dx \tag{21}$$

The methods of separation of variables and the Laplace transform are useful for many other equations with constant coefficients in cases where the region in which the solution is desired is the whole plane, half plane, quadrant, infinite or semi-infinite strip (bounded laterally by a pair of parallel lines!. They may also be useful in corresponding three-dimensional problems. Although the Laplace-transform method has many advantages, the method of separation of variables probably applies in more general situations.

For example, if polar co-ordinates are introduced in the plane, Laplace's equation ($u_{xx} + u_{yy} = 0$) in the plane becomes

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} = 0 \tag{22}$$

Writing

$$u(r,\theta) = R(r)\,.\,\Theta(\theta)$$

and using the argument in the paragraph containing equations (15) and (16), it is seen that R and Θ must satisfy

$$\frac{r^2R'' + rR'}{R} = \frac{-\Theta''}{\Theta} = \lambda, \tag{23}$$

where λ is a constant. If solutions which are regular and single-valued inside the unit circle are desired. Θ must he periodic and of period 2π. The only values of λ which yield such solutions for Θ in (23) are

$$h = n^2, \Theta = a, \cos n\theta + b_n \sin n\theta$$

for some n. The corresponding solutions for R in (23) are

$$R = r^n,$$

where n is a positive integer. Of course 24 = constant is a solution. Thus any convergent series of the form

$$u(r,\theta) = \frac{a_0}{2} + \sum_{n=1}^{\infty} r^n(a_n \cos n\theta + b_n \sin n\theta) \tag{24}$$

(in which the a_n and b_n are constants) is a solution of Laplace's equation; it can also be shown that any solution of Laplace's equation which is regular in the unit circle can be expanded into a series of the type (24), which converges absolutely and uniformly for r < 1. If the series (24) also converges absolutely and uniformly for $r = 1$, the series reduces to the Fourier series for $u(1,\theta)$; if such a convergent Fourier series is given and the factors r^n are introduced as in (24), a solution of Laplace's equation having the function given by the Fourier series as its boundary values is obtained. It can be proved that this is the only solution of Laplace's equation having that property. A similar result holds for solutions of Laplace's equation in a sphere in three-space, but the functions $\cos n\theta$ and $\sin n\theta$ have to be replaced by the so-called spherical harmonics (*q.v.*).

A number of techniques involving the theory of functions of a complex variable are also useful in the solution of partial differential equations. However, all the techniques taken together have only a very limited application. In the many cases where no technique leads to a solution, numerical methods must be resorted to. With the development of high-speed, large-capacity computing machines, the numerical computation of the solution of such equations has become feasible; in fact, a great proportion of the use time of these machines is spent doing just such numerical computations.

Existence Theory.--In many cases where no reasonably simple formula can be found for a solution and a great effort must be made to compute one numerically, it is clearly desirable to know that the equation has one and only one solution which satisfies the given boundary or initial conditions. This is pointed up further by the following example, presented by H. Lewy in 1957, of a pair of linear differential equations of the first order in three independent variables which has no solution defined throughout the interior of any sphere however small; the equations are

$$\begin{aligned}\frac{\partial u}{\partial x} - 2y\frac{\partial u}{\partial t} - \frac{\partial v}{\partial y} - 2x\frac{\partial v}{\partial t} &= \psi'(t) \\ \frac{\partial u}{\partial y} + 2x\frac{\partial u}{\partial t} + \frac{\partial y}{\partial x} - 2y\frac{\partial v}{\partial t} &= 0\end{aligned} \qquad (\psi = u + iv) \tag{25}$$

where $\psi(t)$ is continuous together with all of its derivatives for all t but is not analytic for any t.

The importance of knowing that a given equation has one and only one solution was recognized early during the 19th century, and a first general theorem of this sort was proved by A. L. Cauchy and generalized by Madame Sonya Kovalevski. The simplest form of this theorem states that any equation of the form

$$\frac{\partial z}{\partial x} = f\left(x,y,z,\frac{\partial z}{\partial y}\right), \tag{26}$$

nhere the function $f(x,y,z,q)$ is analytic in its arguments for values near x_0, y,,, z_0, and q,,. say, possesses one and only one solution $z(x,y)$ which is analytic near (x,, y_0) and for which

$$z(x_0,y) = \phi(y), \tag{27}$$

where $\phi(y)$ is analytic at y_0 with

$$\phi(y_0) = z_0 \text{ and } \phi'(y_0) = q_0$$

(A function of two variables is said to be analytic at (x_0,y_0) if it is representable for all points (x,y) near enough to (x_0,y_0) as the sum of a convergent Taylor's series in powers of $(x - x_0)$ and $(y - y_{,,})$; a similar definition holds for functions of more than two variables [*see* FUNCTIONS, ANALYTIC]).

This theorem has immediate generalizations to functions of

more than two independent variables and to systems of such equations. In the case of an equation of the form

$$\frac{\partial^2 z}{\partial x^2} = f\left(x,y,z,\frac{\partial z}{\partial x},\frac{\partial z}{\partial y},\frac{\partial^2 z}{\partial x \partial y},\frac{\partial^2 z}{\partial y^2}\right), \tag{28}$$

where f is analytic in its seven arguments, there is a unique analytic solution z (near (x_0,y_0)) such that

$$z(x_0,y) = \phi(y) \text{ and } z_x(x_0,y) = \psi(y) \quad \left(z_x = \frac{\partial z}{\partial x}\right), \tag{29}$$

where $\phi(y)$ and $\psi(y)$ are given functions analytic at y_0 and having proper values there. The conditions *(27)* and *(29)* are often called Cauchy initial data or just Cauchy data, and correspond to the initial data which can be prescribed at a point x_0 in the case of ordinary differential equations. Of course equation *(28)* could be replaced by a system of equations (with left members $\partial^2 z_i / \partial x_1^2$) in any number of dependent and independent variables.

Equation *(26)* is a special form of the most general equation of the first order, and the determination of the solution with Cauchy data assigned along a segment of the line $x = x_0$ is a special problem. Consider the most general equation of the first order,

$$f\left(x,y,z,\frac{\partial z}{\partial x},\frac{\partial z}{\partial y}\right) = 0, \tag{30}$$

where $f(x,y,z,p,q)$ is required to be analytic wherever defined and where it is desired to assign Cauchy data $z = Z(t)$ along the arc

$$x = X(t),\ y = Y(t) \qquad [(X')^2 + (Y')^2 > 0], \tag{31}$$

where $X(t)$, $Y(t)$ and $Z(t)$ are analytic at t_0 with

$$X(t_0) = x_0,\ Y(t_0) = y_0,\ Z(t_0) = z_0,$$

for example. If there is a solution of *(30)* with the given Cauchy data and if p_0 and q_0 are the values of $\partial z/\partial x$ and $\partial z/\partial y$ at (x_0,y_0), then p_0 and q_0 must satisfy the equations

$$f(x_0,y_0,z_0,p_0,q_0) = 0,\ Z'(t_0) = p_0 X'(t_0) + q_0 Y'(t_0), \tag{32}$$

since in this example it is required that

$$z[X(t), Y(t)] = Z(t) \tag{33}$$

If equations *(32)* have a solution, it is natural to try to reduce the problem to the one described in *(26)* and *(27)* by introducing new co-ordinates (s,t). This may be done in many ways; for example, by setting

$$x(s,t) = X(t) + sY'(t_0),\ y(s,t) = Y(t) - sX'(t_0) \tag{34}$$

It can be shown by using implicit function theorems that the transformation of co-ordinates

$$x = x(s,t),\ y = y(s,t)$$

is one-to-one and analytic from some neighbourhood of (s_0,t_0) to a neighbourhood of (x_0,y_0) and that s and t are analytic functions of x and y near (x_0,y_0) with

$$\begin{gathered} s_x(x_0,y_0) = J^{-1}Y'(t_0),\ s_y(x_0,y_0) = -J^{-1}\cdot X'(t_0), \\ J = [X'(t_0)]^2 + [Y'(t_0)]^2 \neq 0 \quad \left(s_x = \frac{\partial s}{\partial x}, \text{ etc.}\right) \end{gathered} \tag{35}$$

In the new co-ordinates, z satisfies the equation

$$g\left(s,t,z,\frac{\partial z}{\partial s},\frac{\partial z}{\partial t}\right) = 0 \tag{36}$$

where

$$g(s,t,z,\pi,\kappa) = f(x,y,z,\pi s_x + \kappa t_x,\ \pi s_y + \kappa t_y) \tag{37}$$

where, of course, x, y, s_x, t_x, s_y, t_y are to be expressed in terms of s and t; formula *(37)* follows, since p, q, a and κ stand for $\partial z/\partial x$, $\partial z/\partial y$, $\partial z/\partial s$ and $\partial z/\partial t$, respectively, and

$$\frac{\partial z}{\partial x} = \frac{\partial z}{\partial s}\frac{\partial s}{\partial x} + \frac{\partial z}{\partial t}\frac{\partial t}{\partial x},\ \frac{\partial z}{\partial y} = \frac{\partial z}{\partial s}\frac{\partial s}{\partial y} + \frac{\partial z}{\partial t}\frac{\partial t}{\partial y} \tag{38}$$

Now if π_0 and κ_0 are the values corresponding to p_0 and q_0, using equations *(35)* and (38), and if

$$g_\pi(s_0,t_0,z_0,\pi_0,\kappa_0) \neq 0,$$

then equation *(36)* is equivalent to an equation of the form *(26)* in the new variables and the problem is solved. But

$$g_\pi = f_p \cdot Y'(t_0) - f_q X'(t_0), \tag{39}$$

as is seen from equations *(35)* and *(37)*; here g_π, f_p and f_q are to be evaluated at $(s_0,t_0,z_0,\pi_0,\kappa_0)$ and (x_0,y_0,z_0,p_0,q_0), respectively. But, from (39), $g_\pi = 0$ if and only if the pair (X',Y') is proportional to the pair (f_p,f_q); that is, if the direction of the tangent to the arc *(31)* is the same as that determined by the pair (f_p,f_q). This latter direction is called the characteristic direction corresponding to (x_0,y_0,z_0,p_0,q_0) unless $f_p = f_q = 0$, in which case all directions are characteristic.

An entirely similar process for the general equation

$$f(x,y,z,z_x,z_y,z_{xx},z_{xy},z_{zz}) = 0 \tag{40}$$

(f analytic, etc.) shows that analytic values for z and its normal derivative can be prescribed along an analytic arc *(34)* unless the pair (X',Y') (evaluated at t_0) is proportional to one of the two characteristic directions (λ, μ) defined by

$$f_t\lambda^2 - f_s\lambda\mu + f_r\mu^2 = 0, \tag{41}$$

where r, s and t stand for z_{xx}, z_{xy} and z_{yy} respectively. The definition of characteristic directions and the Cauchy-Kovalevski theorem can be extended to very general systems of analytic equations in any number of independent and dependent variables.

In general, the characteristic directions depend on the values of z and its derivatives at (x_0,y_0) as well as on (x_0,y_0). However, this is not the case for linear equations. For example, for the general linear first-order equation

$$a\frac{\partial z}{\partial x} + b\frac{\partial z}{\partial y} + cz = d \tag{42}$$

(a,b,c,d are functions of x and y), the function f is

$$f(x,y,z,p,q) = a(x,y)p + b(x,y)q + c(x,y)z - d(x,y)$$

and the characteristic direction is just (a,b) at each point (x,y). In this case, $x(s,t)$ and $y(s,t)$ may be chosen as the solutions of the characteristic equations

$$\frac{\partial x}{\partial s} = a(x,y),\ \frac{\partial y}{\partial s} = b(x,y),\ x(s_0,t) = X(t),\ y(s_0,t) = Y(t)$$

and *(42)* takes the form

$$\frac{\partial z}{\partial s} + C(s,t)z = D(s,t) \tag{43}$$

In the case of the general linear second-order equation

$$az_{xx} + bz_{xy} + cz_{yy} + dz_x + ez_y + fz - g = 0, \tag{44}$$

the characteristic directions are defined by

$$c\lambda^2 - b\lambda\mu + a\mu^2 = 0 \tag{45}$$

for each (x,y). In case the coefficients are differentiable and the characteristic directions are real and distinct, it turns out to be possible to introduce "characteristic co-ordinates" (s,t) so that equation *(44)* takes the form

$$\frac{\partial^2 z}{\partial s \partial t} + A\frac{\partial z}{\partial s} + B\frac{\partial z}{\partial t} + Cz = D, \tag{46}$$

which can often be solved by successive approximations starting with the solutions in equations (11) and *(12)*.

Although the Cauchy-Xovalevski theorem mas and still is important, the restriction that the equation and Cauchy data have to be analytic is one which is often not met in applications; moreover it is often desired to know the solution in some given domain. However, the example of Lewy cited above shows that difficulties may be encountered if the equation is not analytic. But the fact that any solution of Laplace's equation is analytic in the interior of its domain of definition shows that the values of such a function

along any analytic arc in its domain are necessarily analytic.

However, for first-order equations (30), it turns out that the conclusion of the Cauchy-Kovalevski theorem (without analyticity) carries over if the function j, the arc and the data have continuous second derivatives. Moreover, if the characteristic directions of an equation (43) are real and distinct, the reduction to the form (46) can be carried out, and an equation of form (46) can be solved without requiring analytic coefficients and data. Obviously this reduction cannot be carried out if the characteristic directions defined by (45) are imaginary. This leads to the classification of second-order equations as hyperbolic, parabolic, or elliptic (at a point or set of values) depending on whether their characteristic directions are real and distinct, real and equal, or imaginary. From (45), it follows that equation (1) is hyperbolic with characteristic directions along lines $x + ct = \text{const.}$, Laplace's equation is elliptic and the one-dimensional form of the diffusion equation,

$$\frac{\partial u}{\partial t} = a^2\frac{\partial^2 u}{\partial x^2}, \tag{47}$$

is parabolic (everywhere).

It turns out that the conclusion of the Cauchy-Kovalevski theorem carries over for hyperbolic equations, even nonlinear. ones. A typical problem for equation (47) is the assignment of (possibly nonanalytic) values for $u(x,0)$; this determines $u(x,t)$ for $t > 0$. The situation for elliptic equations is illustrated by the result (24) for Laplace's equation in a circle. This result may be generalized to more inclusive equations (44) which are elliptic over a whole region and on its boundary, which is assumed to consist of several nonintersecting differentiable curves. For such a region, which may be large, the following result is obtained if the coefficient.f is replaced by $j + \lambda$, where λ is a constant. If h does not belong to a discrete set of eigenvalues, the equation has a unique solution which takes on given continuous boundary values; if λ is an eigenvalue, there are finitely many linearly independent solutions of the homogeneous equation ($g \equiv 0$j which vanish on the boundary. The parameter λ is inserted to show the exceptional nature of the case where the equation does not have a unique solution with given boundary values. Similar results hold for other types of boundary-value problems.

It is clear that the variety of types of differential equations increases greatly when systems or equations of higher order are considered, or when more independent variables are involved. Since 1930, great advances have been made in the development of the theories of elliptic, hyperbolic and parabolic equations and systems, and these types have been generalized to cover many additional types of equations. However. even the generalized types do not exhaust all equations of the second order in four variables: the wave equation (6) is hyperbolic, the four-dimensional Laplace's equation is elliptic, the diffusion equation (3) is parabolic but the equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} - \frac{\partial^2 u}{\partial t^2} = 0$$

is not any of these three types. If more than four independent variables are allowed, it is clear that the variety of unclassified equations of the second order will increase. Very little is known (beyond the Cauchy-Kovalevski theorem) about the existence theory for the unclassified types. Moreover. there remain many challenging unsolved problems concerning the solutions of the elliptic, hyperbolic and parabolic types, especially when unbounded domains or nonlinear equations are involved.

Friedman, *Principles and Techniques* of *Applied Mathematics* (1956).

(C. B. M.)

DIFFERENTIAL GEOMETRY, a branch of mathematics concerned with the study of spaces in which differentiation has meaning, so that the too! of differential calculus can be employed. In such space the points must be determined by real numbers as co-ordinates. If the number of co-ordinates is to be equal to the dimension of the space, it is generally not sufficient to use one co-ordinate system throughout the space. For example, this is the case for the $(n - 1)$-dimensional unit hypersphere, which is defined as the set of points at a unit distance from the origin in the Euclidean space of n dimensions. In order to have sufficient generality the space is supposed to be covered by co-ordinate neighbourhoods (at most countably many) in which a point has the real co-ordinates $x^1, \ldots, x^n$ (called local co-ordinates), such that when a point belongs to two co-ordinate neighbourhoods its two sets of local co-ordinates x^i and x'^i, $i = 1, \ldots, n$, are related by a transformation $x'^i + f^i(x^1, \ldots, x^n)$, $i = 1. \ldots, n$, where the functions have continuous first partial derivatives with the Jacobian determinant

$$\frac{\partial(f^1, \cdots, f^n)}{\partial(x^1, \cdots, x^n)} = \det\left(\frac{\partial f^i}{\partial x^j}\right) \neq 0$$

A space with such a covering is said to have a differentiable structure and is called a differentiable manifold or simply a manifold (*see* MANIFOLDS) The manifold is said to be of class k ($= 1, 2, \ldots \infty$) if all the functions $f^i(x^1, \ldots, x^n)$ have continuous partial derivatives of orders $\leqq$ k (or of all orders, if $k = \infty$). It is called analytic if the functions $f^i(x^1, \ldots, x^n)$ are analytic. Since a point may belong to several co-ordinate neighbourhoods, the significant geometrical properties of a manifold are those which remain unchanged under changes of the local co-ordinates.

Tangent Vectors and Tensors.—Consider a differentiable manifold M of dimension n and a point P of M. Let $x^1, \ldots, x^n$ be a local co-ordinate system in a neighbourhood of P such that the co-ordinates of P itself are zero. The equations $x^i = \phi^i(t)$, $i = 1, \ldots, n$, where $\phi^i(t)$ are differentiable functions in t and $\phi^i(0) = 0$, define a parametrized curve through P. Two parametrized curves $x^i = \phi^i(t)$ and $x^i = \psi^i(t)$ are called equivalent if the derivatives $d\phi^i/dt$ and $d\psi^i/dt$, $i = 1, \ldots, n$, have the same values at $t = 0$. Intuitively, equivalent parametrized curves are curves through P having the same tangent vector at P. This geometrical observation makes it possible to define a tangent vector at P to be an equivalence class of parametrized curves through P. If x'^i is another local co-ordinate system in a neighbourhood of P and $x^i = \phi^i(t)$ and $x'^i = \phi'^i(t)$ are the equations of the same parametrized curve relative to the two co-ordinate systems, then

$$A'^i = \sum_j \frac{\partial x'^i}{\partial x^j} A^j, \; i, j = 1, \ldots, n, \tag{1}$$

where

$$A^i = \left(\frac{d\phi^i}{dt}\right)_{t=0}, \; A'^i = \left(\frac{d\phi'^i}{dt}\right)_{t=0}$$

Generally a tangent vector at P is an entity which has n components A^i relative to each co-ordinate system at P such that the components are related by equations (1) under co-ordinate transformations Tno tangent vectors A^i and B^i can be added the components of their sum being $A^i + B^i$. A tangent vector A^i can be multiplied by a real number a, the components of their product being αA^i. Both operations are invariant under co-ordinate transformations. Thus all the tangent vectors at P form a real vector space of n dimensions, called the tangent space at P (see VECTOR SPACES). The existence of the tangent space at every point of a differentiable manifold is a major consequence of its differentiable structure. Roughly speaking, a differentiable manifold can be approximated locally by a linear space.

A tangent vector is called a contravariant vector in contrast to a covariant vector. The latter is defined as having the components

C_i in each co-ordinate system such that under co-ordinate transformations the components are transformed according to the equations

$$C'_i = \sum_j \frac{\partial x^j}{\partial x'^i} C_j, \; i, j = 1, \cdots, n \tag{2}$$

To a contravariant vector A^i and a covariant vector C_i is associated a real number $\sum_i A^i C_i$, which, by equations *(1)* and *(2)*, is independent of the choice of the local co-ordinates. Thus the tangent space and the cotangent space (the latter being the vector space of all covariant vectors at P) are dual vector spaces; one can be considered as the space of all real-valued linear functions of the other. A mixed tensor of contravariant order r and covariant order s has the components $A^{i_1 \cdots i_r}_{i_1 \cdots i_s}$ in each co-ordinate system (see TENSOR ANALYSIS). These components follow the transformation rule

$$A'^{i_1 \cdots i_r}_{i_1 \cdots i_s} = \sum_{k,l} \frac{\partial x'^{i_1}}{\partial x^{k_1}} \cdots \frac{\partial x'^{i_r}}{\partial x^{k_r}} \frac{\partial x^{l_1}}{\partial x'^{i_1}} \cdots \frac{\partial x^{l_s}}{\partial x'^{i_s}} A^{k_1 \cdots k_r}_{l_1 \cdots l_s} \tag{3}$$

The tensor is called contravariant if $s = 0$ and covariant if r = 0. If $r, s \geqq 1$, the components $B^{i_1 \cdots i_{r-1}}_{i_1 \cdots i_{s-1}} = \sum_l A^{i_1 \cdots i_{r-1} l}_{i_1 \cdots i_{s-1} l}$ are those of a tensor of contravariant order r − 1 and covariant order $s - 1$. This process is called contraction. The contraction can be applied to any upper index and any lower index of $A^{i_1 \cdots i_r}_{j_1 \cdots j_s}$, and not necessarily to the last ones. If $C^{k_1 \cdots k_{r'}}_{l_1 \cdots l_{s'}}$ are the components of a tensor of contravariant order r' and covariant order s', then $D^{i_1 \cdots i_{r+r'}}_{j_1 \cdots j_{s+s'}} = A^{i_1 \cdots i_r}_{j_1 \cdots j_s} C^{i_{r+1} \cdots i_{r+r'}}_{j_{s+1} \cdots j_{s+s'}}$ are the components of a tensor of contravariant order r + r' and covariant order $s + s'$. This process is called the multiplication of tensors.

A tensor is symmetric (respectively antisymmetric) in two indices if the components remain unchanged (respectively change sign) on a permutation of the indices. Thus A_{ijk} is symmetric in i,j if $A_{ijk} = A_{jik}$ and antisymmetric in i,j if $A_{ijk} = -A_{jik}$. A covariant tensor is symmetric (respectively antisymmetric) if it is symmetric (respectively antisymmetric) in every pair of two indices. An arbitrary covariant tensor A of order r has a symmetrized tensor SA whose components are

$$(SA)_{i_1 \cdots i_r} = \frac{1}{r!} \sum A_{i_1 \cdots i_r} \tag{4}$$

where the summation is over all the r! permutations $j_1, \ldots, j_r$ of $i_1, \ldots, i_r$. Similarly, its antisymmetrized tensor has the components

$$(KA)_{i_1 \cdots i_r} = \frac{1}{r!} \sum \operatorname{sgn} \begin{pmatrix} i_1 \cdots i_r \\ j_1 \cdots j_r \end{pmatrix} A_{i_1 \cdots i_r} \tag{5}$$

where the summation is again over all the permutations $j_1, \ldots, j_r$ of $i_1, \ldots, i_r$, and the coefficient is $+1$ or -1 depending on whether the permutation is even or odd. The symmetrized (respectively antisymmetrized) tensor of a symmetric (respectively antisymmetric) tensor is itself. An antisymmetric tensor of order greater than n is zero.

As in the case of contravariant vectors. all tensors of a given type form a real vector space, in which addition and scalar multiplication (*i.e.*, multiplication by a real number) are defined. The tensor multiplication introduced above multiplies a covariant (or contravariant) tensor of order r and a covariant (or contravariant) tensor of order s, giving as product a covariant (or contravariant) tensor of order r + s. In the direct sum T of the spaces of covariant tensors of different orders, which is an infinite-dimensional real vector space, this gives rise to an associative multiplication so that T becomes an associative algebra, called the tensor algebra (*q.v.*). Similarly, the product $C_{i_1} \cdots {}_{i_{r+s}} = A_{i_1} \cdots {}_{i_r} B_{i_{r+1}} \cdots {}_{i_{r+s}}$ of two antisymmetric covariant tensors is not antisymmetric, but its antisymmetrized tensor is. The latter is called the exterior product of $A_{i_1 \cdots i_2}$ and $B_{i_{r+1} \cdots i_{r+s}}$. By means of the exterior product the direct sum of the spaces of antisymmetric covariant tensors of orders $0, 1, \ldots, n$ has an associative multiplication and is called the exterior algebra or the Grassmann algebra. The exterior algebra is of dimension 2^n, and plays an important role in the theory of linear subspaces of a vector space. By the use of the symmetrized tensor an associative multiplication can be introduced in the direct sum of the spaces of symmetric covariant tensors of orders $0, 1, \ldots$, which is then called the symmetric algebra.

Tensor' Bundles.—A tangent space has been defined at each point of a manifold M. The collection of all of them forms the tangent bundle of the manifold. The tangent bundle is a space E related to M in a special way: each point of E (*i.e.*, a tangent vector) is attached to a point of M, and all the points of E attached to the same point of M form a vector space. Moreover, the points of E over a co-ordinate neighbourhood of M can be described by the co-ordinates (x^i, A^k). Such a structure is called a fibre space, a fibre bundle or a tensor bundle. The space E itself is called the fibre space, the association of the point of M to every point of E is called the projection and the vector space attached to a point of M is called a fibre, The fibre space E is of dimension $2n$ if M is of dimension n and is a differentiable manifold of class k − 1 if M is of class k. Analogous "fibre bundles" can be formed from the other tensor spaces introduced above. The fibre need not even be a vector space. For instance, it could be the space of all frames (*i.e.*, ordered sets of n linearly independent tangent vectors) at a point P of M. The resulting fibre space, the space of all frames at all points of M, is called the principal fibre space; its dimension is $n^2 + n$. If M is the three-dimensional Euclidean space and the vectors of the frames are supposed to form an orthonormal system, then a frame is an oriented rectangular trihedral, and the corresponding fibre space plays a basic role in the method of moving trihedrals in the theory of curves and surfaces in Euclidean space and in kinematics. The method of moving frames, used extensively by Élie Cartan in differential geometry, is a forerunner of the notion of principal fibre space.

Operations on Tensor Fields.—Let E be a tensor bundle with a definite type of fibre. A tensor field is a differentiable mapping $f: M \to E$, such that the mapping obtained by the successive application of f and ψ is the identity. Geometrically, this means the association of a tensor to each point of M. Analytically, a tensor field is defined by expressing the components $A^{i_1 \cdots i_r}_{j_1 \cdots j_s}$ of the tensor as differentiable functions of the local co-ordinates.

An important problem is to derive new tensor fields from given tensor fields. If f is a real-valued function (*i.e.*, a tensor field of order zero), its partial derivatives are the components of a covariant vector field called the gradient of f. If X is a contravariant vector field with components A^k in the local co-ordinate system x^i, $i = 1, \ldots, n$, then $Xf = \sum A^k \frac{\partial f}{\partial x^k}$ is a real-valued function. It is called the directional derivative of f relative to the vector field X. In this way X can be regarded as a linear operator on functions. If Y is a vector field, it can be shown that $[X,Y] = XY - YX$ is also a linear combination of $\partial f / \partial x^k$ and defines a vector field. This is called the bracket operation of two vector fields. More generally, a vector field X defines an infinitesimal transformation $\delta x^i = A^i \delta t$, $i = 1, \ldots, n$, and the study of the variation of a tensor field under this infinitesimal transformation leads to a new tensor field of the same type. The latter is called the Lie derivative relative to X. The Lie derivative relative to X of the tensor field B^{ij}_k has the components

$$[L(X)B]^{ij}_k = \sum_l \left\{ A^l \frac{\partial B^{ij}_k}{\partial x^l} - B^{lj}_k \frac{\partial A^i}{\partial x^l} - B^{il}_k \frac{\partial A^j}{\partial x^l} + B^{ij}_l \frac{\partial A^l}{\partial x^k} \right\} \tag{6}$$

If A_i is a covariant vector field, then

$$\frac{\partial A_{i'}}{\partial x'^k} = \sum_{j,l} \frac{\partial x^j}{\partial x'^i} \frac{\partial x^l}{\partial x'^k} \frac{\partial A_j}{\partial x^l} + C_j \frac{\delta^2 x^j}{\delta x'^i \delta x'^k} A_j,$$

so that $\partial A_i'/\partial x'^k$ is not a tensor field. But

$$A_{ij} = \frac{1}{2}\left(\frac{\partial A_i}{\partial x^j} - \frac{\partial A_j}{\partial x^i}\right)$$

are the components of an antisymmetric covariant tensor field of order two. This process has a generalization: if $A_{i_1 \cdots i_r}$ is an antisymmetric covariant tensor field of order r, then

$$A_{i_1 \cdots i_{r+1}} = \frac{1}{(r+1)!} \sum \operatorname{sgn} \begin{pmatrix} j_1 \cdots j_{r+1} \\ i_1 \cdots i_{r+1} \end{pmatrix} \frac{\partial A_{i_1 \cdots i_r}}{\partial x^{j_{r+1}}} \tag{7}$$

is an antisymmetric covariant tensor field of order $r + 1$. The latter is called the exterior derivative. It will be more instructive to write these results in terms of differential forms. Under change of local co-ordinates, the differentials are transformed according to the equation

$$dx'^i = \sum \frac{\partial x'^i}{\partial x^j}\, dx^j$$

Define a multiplication of differentials which is antisymmetric: $dx^i \wedge dx^j = -dx^j \wedge dx^i$, so that $dx^i \wedge dx^i = 0$. Then the differential form

$$\omega = \frac{1}{r!} \sum_{i_1, \cdots, i_r} A_{i_1 \cdots i_r}\, dx^{i_1} \wedge \cdots \wedge dx^{i_r},$$

called an exterior differential form of degree r, is independent of the choice of local co-ordinates. Conversely, such a differential form, together with the condition that the coefficients $A_{i_1 \cdots i_r}$ are antisymmetric, define the $A_{i_1 \cdots i_r}$ as the components of an antisymmetric covariant tensor field of order r. Thus the latter notion is equivalent to that of exterior differential forms of degree r. The exterior derivative of ω is then the differential form

$$d\omega = \frac{1}{r!} \sum_{i_1, \cdots, i_r} dA_{i_1 \cdots i_r} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_r} \tag{8}$$

Stokes' Formula; De Rham's Theorem. — Exterior differential forms are the integrands of multiple integrals in manifolds. The integral $\int_D \omega$ over an r-dimensional domain D includes as special cases. for r = 1, $n = 2$ and r = 2, n = 3 respectively, the line integral $\int A dx +$ Bdy in the plane and the surface integral $\int P dydz +$ Qdzdx + Rdxdy in space. If D is the boundary of an (r + 1)-dimensional domain F, then there is the so-called Stokes' formula

$$\int_D \omega = \int_F d\omega \tag{9}$$

This formula includes as special cases the formula for integration by parts and classical formulas of C. F. Gauss, G. Green. G. Stokes and others. In the special cases mentioned above, it gives

$$\int A dx + B dy = \iint \left(\frac{\partial B}{\partial x} - \frac{\partial A}{\partial y}\right) dxdy,$$

$$\iint P dydz + Q dzdx + R dxdy =$$

$$\iiint \left(\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}\right) dxdydz$$

The importance of exterior differential forms and their exterior derivatives lies in the fact that they help in solving problems on manifolds in which local and global properties come into interplay. The link is furnished by De Rham's theorem. An exterior differential form is called closed if its exterior derivative is zero; it is called a derived form if it is the exterior derivative of another. It follows from definition that a derived form is closed. The closed forms can be divided into classes such that two forms belong to the same class if and only if their difference is a derived form. All the classes of closed forms of degree r form a real vector space $\mathcal{H}^r$. This space is manageable, in contrast to the space of all forms of degree r or even that of all closed forms, both of which are "large" and generally infinite-dimensional. If the manifold is compact, *i.e.*, if it can be covered by a finite number of co-ordinate neighbourhoods, De Rham's theorem says that the dimension of the space $\mathcal{H}^r$ is the rth Betti number of the manifold. The latter is an integer and is a topological invariant of the manifold which describes the connectivity properties of the manifold.

Global Problems on Differentiable Manifolds. — The question of tensor fields takes a crucial turn if it is required that the tensors of the field satisfy certain algebraic conditions. The simplest situation of this kind is a differentiable vector field such that the vectors never vanish. Such a field may not exist. In fact, it is not possible to have a differentiable field of tangent vectors on the ordinary sphere without the vectors vanishing at some point. The general problem is so complicated and difficult that it has been found advisable to study only certain special cases. The most important case is when the manifold is the n-dimensional sphere (or the n-sphere); namely, the set of all points in the Euclidean space of n + 1 dimensions at a unit distance from a fixed point. The behaviour of the tangent-vector fields of an n-sphere depends very much on the integer n. While, as mentioned above, the 2-sphere does not have a continuous tangent-vector field which is never zero, the 3-sphere has three such vector fields which are everywhere linearly independent. In general, a manifold of dimension n is called parallelizable if it has n continuous tangent-vector fields which are linearly independent at every point. In 1958 R. Bott, M. A. Kervaire and J. W. Milnor proved that the only parallelizable spheres are of dimensions 1, 3, 7. The study of this and related problems employs methods developed in algebraic topology on fibre spaces, homotopy theory, etc.

Another basic question is whether the same space can be given different differentiable structures; *i.e.*, whether there exist manifolds with the same topological space that are not differentiably homeomorphic. That this is possible was shown by Milnor in 1956, when he proved that the 7-sphere has at least seven distinct differentiable structures. It is not known whether the Euclidean space of n dimensions has, for a given value of n, more than one differentiable structure.

Very little is known about the existence or nonexistence of tensor fields that satisfy a system of partial differential equations (over the whole manifold). A problem of this kind is the complex structure on a manifold of even dimension $2m$. The existence of a complex structure is equivalent to that of a tensor field A_i^k such that $\sum_j A_i^j A_j^k = -\delta_i^k$, $i,j,k = 1, \ldots, 2m$, and such that A_i^k satisfies a system of partial differential equations called the integrability conditions. The latter is a generalization of the Cauchy-Riemann differential equations in the theory of functions of one complex variable. A manifold with a complex structure, or a complex manifold, can be described as one that can be covered by co-ordinate neighbourhoods in which complex local co-ordinates are valid such that when a point belongs to two co-ordinate neighbourhoods the local co-ordinates are related by a holomorphic transformation with a non-vanishing Jacobian determinant. Complex manifolds are natural generalizations of nonsingular algebraic varieties in algebraic geometry and of the domains in the theory of function5 of several complex variables. It is not known whether the six-dimensional sphere has a complex structure. Another problem is the leaved structure (structure *feuilletée*), a global slicing of the manifold by leaves which. in terms of the local co-ordinates $x^1, \ldots, x^n$ can be defined by $x^{k+1} = \text{const.}, \ldots, x^n = \text{const.}$; k is called the dimension of the leaves. A. Haefliger proved that if a compact. real, analytic manifold of dimension n has an analytic leaved structure whose leaves are of dimension n − 1, its fundamental group is not finite.

Among the manifolds, the most important one is the Euclidean space. This is so not only because of its historical significance but mainly because of the fact that it is closest to our geometrical intuition. The question of whether a given structure is equivalent to the induced structure of a submanifold in Euclidean space is called an imbedding problem. H. Whitney proved in 1936 that

every differentiable manifold of dimension n can be imbedded in a Euclidean space of dimension $2n + 1$. That the same is true for compact, real, analytic manifolds was proved by C. B. Morrey in 1958. J. Nash proved isometric imbedding theorems for Riemannian manifolds. If sufficient differentiability requirements are made, the dimension of the Euclidean space needed for the isometric imbedding is higher.

Further Structures.—In the historical development of differential geometry the differentiable structure was studied together with additional structures. The most important of these is the Riemannian metric, which is the geometry based on a positive-definite covariant tensor field of order two (*see* RIEMANNIAN GEOMETRY). It is a natural generalization of Euclidean geometry, because this fundamental tensor field allows the definition of arc lengths of curves and other metrical nations. Its importance is based on the fact that every manifold can be given a Riemannian metric, whereas very few manifolds have a Euclidean metric. Much study has been made on generalizations of Riemannian geometry, and these generalizations were done in several different directions.

An affine connection is a set of components Γ_{ik}^{j} in every co-ordinate neighbourhood such that under change of local co-ordinates the components follow the transformation rule

$$\Gamma_{ik}^{\prime j} = \sum_{l,m,r} \Gamma_{lm}^{r} \frac{\partial x^l}{\partial x'^i} \frac{\partial x^m}{\partial x'^k} \frac{\partial x'^j}{\partial x^r} + \sum_{l} \frac{\partial x'^j}{\partial x^l} \frac{\partial^2 x^l}{\partial x'^i \partial x'^k} \tag{10}$$

These components do not, therefore, define tensor fields. But they can be used to derive from a tensor field $A_{j_1 \cdots j_s}^{i_1 \cdots i_r}$ of contravariant order r and covariant order s a new tensor field of contravariant order r and covariant order $s + 1$. The latter is called the covariant derivative of $A_{j_1 \cdots j_s}^{i_1 \cdots i_r}$ and has the components

$$\begin{aligned} A_{j_1 \cdots j_{s+1}}^{i_1 \cdots i_r} &= \frac{\partial A_{j_1 \cdots j_s}^{i_1 \cdots i_r}}{\partial x^{j_{s+1}}} \\ &+ \sum_{1 \leq k \leq r} \sum_{m} \Gamma_{m j_{s+1}}^{i k} A_{j_1 \cdots j_s}^{i_1 \cdots i_{k-1}\, m\, i_{k+1} \cdots i_r} \\ &- \sum_{1 \leq l \leq s} \sum_{r} \Gamma_{j_l j_{s+1}}^{p} A_{j_1 \cdots j_{l-1} p j_{l+1} \cdots j_s}^{i_1 \cdots i_r} \end{aligned} \tag{11}$$

Geometrically, an affine connection is a generalization of affine geometry. There is no metric in the manifold, but the notion of parallelism of tangent vectors is defined along curves. As a consequence there are curves on the manifold, called the paths, along which their own tangent vectors are parallel. These generalize the straight lines of affine geometry.

Different affine connections may define the same paths. The theory of all affine connections with the same paths is called the projective geometry of paths. Instead of the paths, it is possible to study the geometry arising from a family of submanifolds defined by a system of partial differential equations, which generalize the linear subspaces of a given dimension in projective space. More generally, further extensions include the geometry of systems of ordinary or partial differential equations.

Another direction of generalization of Riemannian geometry lays weight on the metric. Finsler geometry is the theory of an integral of the form

$$\int F\left(x^i, \frac{dx^i}{dt}\right) dt \tag{12}$$

It reduces to Riemannian geometry if the integrand is of the form

$$\left(\sum_{i,k} g_{ik}(x) \frac{dx^i}{dt} \frac{dx^k}{dt}\right)^{\frac{1}{2}}$$

The value of the integral along a curve will be called its arc length. If, instead of a simple integral, a multiple integral of order $n - 1$ is given:

$$\int \cdots \int L\left(x^i, \frac{\partial x^n}{\partial x^1}, \cdots, \frac{\partial x^n}{\partial x^{n-1}}\right) dx^1 \wedge \cdots \wedge dx^{n-1}, \tag{13}$$

the geometry is called Cartan geometry. In Cartan geometry it is possible to measure the area of $(n - 1)$-dimensional domains, but not the lengths of arcs (if $n > 2$).

All these structures in differential geometry can be included in the general notion of a geometric object or a geometric being. The latter is defined by a set of components in every local co-ordinate system, which follow very general transformation laws. More fruitful, however, is the generalization of the affine connection to a connection with an arbitrary Lie group, such as the group of Euclidean motions, the projective group, the conformal group, etc. Such a connection can be defined in an arbitrary fibre space; the connection means geometrically a rule for the parallel transport of the fibre along curves. The problem of associating in an invariant way a connection to a given geometric object leads generally to complicated computations. However, the general theory of a connection in a fibre space can be developed in a simple and satisfactory way.

Homogeneous Spaces and Their Submanifolds.—Another important type of structure on a manifold is a group of transformations. The group is said to act transitively if, to any two points of the manifold, there is a transformation of the group carrying one point to the other. A manifold with a transitive group of transformations is called a homogeneous space. Homogeneous spaces form an important class of manifolds, because they possess in a sense a high degree of symmetry. All the spaces which are involved in the development of geometry—the Euclidean space, the non-Euclidean spaces, the affine space, the projective space, etc.—are homogeneous spaces. Much of the early work in differential geometry was concerned with the geometry of manifolds lying in a homogeneous space. This is the case with the classical theory of curves and surfaces in Euclidean space when the group is the group of motions. The study of submanifolds in affine space and projective space leads respectively to affine differential geometry and projective differential geometry.

Local and Global Problems.—Problems in differential geometry can generally be divided into two types: local problems and global problems. The tangent space at a point and different concepts of curvature are local properties. But the validity of a certain local property throughout the manifold could impose strong restrictions on the manifold as a whole; the determination of such restrictions is a global problem. Thus there are pieces of surfaces in Euclidean space with constant Gaussian curvature, but the spheres are the only surfaces which have constant Gaussian curvature and which are closed. Also, among the orientable, closed, two-dimensional manifolds only the torus can be given a flat affine connection. The latter property can be described by saying that linearity has a sense in the manifold or, more precisely, that the manifold can be covered by co-ordinate neighbourhoods such that if a point belongs to two neighbourhoods its two sets of local co-ordinates are related by a linear transformation. Results of this nature belong to global differential geometry (differential geometry in the large). *See* also ANALYSIS, COMPLEX.

(S. S. CH.)

DIFFERENTIAL PSYCHOLOGY is the branch of psychology that deals with individual and group differences in behaviour. Such differences are quantitative rather than qualitative. Persons do not fall into sharply separated types, such as bright and dull, maladjusted and normal, introvert and extravert. On the contrary, in all psychological characteristics, individuals vary by

degree along a continuous scale. In most traits, the distribution approximates the bell-shaped normal probability curve, with the greatest clustering of cases near the centre of the range and a gradual decrease in numbers as the extremes are approached. Individual differences in behavioural characteristics are not limited to the human species; they occur throughout the animal scale. Investigations of animal behaviour, from unicellular organisms to anthropoid apes, reveal wide individual differences in learning, motivation, emotionality and other measurable traits. So large are these differences that the distributions overlap even when widely separated species are compared. When tested with the same learning problem: for example, the brightest rat in a given sample may excel the dullest monkey.

Heredity and Environment. — The origins of each individual's behavioural characteristics are to be found in the innumerable and complex interactions between his heredity and his environment. Heredity is represented by the genes, minute particles transmitted in the ovum and spermatozoon which unite at conception to form the new organism. To say that a certain factor is hereditary thus means that it can ultimately be traced to the presence of a particular gene or combination of genes. Environment may be defined as the sum total of the stimuli to which the individual responds from conception to death. Environment thus comprises a vast multiplicity of variables, ranging from food and physical habitat to the beliefs and attitudes of associates and the social climate of home and community. It should also be noted that environmental factors begin to operate before birth. Nutritional deficiencies, toxins and other chemical or physical conditions of the prenatal environment may exert a profound and lasting influence upon both physical and mental development. Several varieties of mental deficiency, for example, have been traced to abnormalities of prenatal environment. Such terms as innate, inborn, native and congenital may be misleading since they suggest that all characteristics present at birth must be hereditary, which is not the case. Another common confusion is that between organic and hereditary causation. For instance, mental deficiency resulting from early brain injury may be properly said to have an organic but not a hereditary origin.

The many techniques employed to study the relative contribution and *modus operandi* of heredity and environment in behaviour development may be subsumed under five major approaches.

1. Selective breeding for psychological characteristics has been successfully applied to several species. It has proved possible. for example. from a single initial group to breed two strains of rats comprising good and poor maze learners, respectively.

2. Normative developmental studies, charting the course of behaviour development with age, have been conducted both prenatally and postnatally with animals and human beings. Such studies show the relative influence of learning and maturation, the latter referring to the sudden emergence of a function as soon as the prerequisite stage of physical development is attained. For example, do birds fly and do children walk when they reach certain ages, regardless of prior experience?

3. A closely related approach concerns correspondences between organic and behavioural characteristics. Is there any relation between specific psychological traits and neural, glandular. biochemical and other organic conditions, either from individual to individual or from one developmental stage to another within the individual? To demonstrate an organic basis for a given behavioural difference does not, of course, prove its hereditary origin. Nevertheless, such investigation is a necessary step in tracing possible hereditary factors, since heredity can affect behaviour only through the medium of organic conditions.

4. A fourth approach to the analysis of hereditary and environmental contributions is concerned with the effects of training upon behaviour development. Experimental investigations of this question either provide special training or prevent the normal exercise of a given Function. The large majority of such studies have been made mith animals. a few having been conducted with young children. A less rigidly controlled application of the same general procedure pertains to the effects of schooling upon I.Q. Although many of the results of the latter investigations are difficult to interpret. follow-up studies suggest that education tends to improve intellectual level appreciably.

5. A fifth approach is based on the analysis of family resemblances and differences. Similarity of performance on both ability and personality tests has been investigated in the case of parents and children, siblings, and twins (including fraternal and identical pairs). In general. the closer the hereditary relation, the more similar will be test scores. It should be noted, however, that a family is a cultural as well as a biological unit and that a hierarchy of environmental similarity and mutual influence parallels the hierarchy of hereditary relationships. Special studies of foster children and of identical twins reared apart permit some isolation of hereditary and environmental influences, but varicus uncontrolled factors preclude definitive conclusions. Pedigree analysis, concerned with the genetic mechanisms whereby traits are transmitted from parents to offspring, is an effective technique for analyzing the operation of hereditary factors but is limited in its application to traits having a relatively simple genetic basis, such as colour blindness, deficiency for certain tastes, and a few rare forms of mental deficiency.

Identification of Psychological Traits. — Two persons with the same I Q. may present very different aptitude profiles. The individual's relative standing often varies significantly from trait to trait, and for such purposes as educational and vocational guidance, as well as personnel selection and classification, it is important to know the individual's scores in separate traits, as well as his over-all I.Q. Through specially developed statistical techniques known as factor analysis, psychologists have identified a number of intellectual traits, such as verbal comprehension. numerical skills, arithmetic reasoning. spatial visualization. perceptual speed, associative memory, originality, ideational fluency and logical evaluation. as well as such personality traits as dominance, emotional stability and sociability. Factor analysis utilizes the scores obtained by the same group of persons on a large number of tests. These scores are first intercorrelated and the resulting correlation table is submitted to further mathematical analysis to identify common factors among the different tests.

Age Changes in Psychological Traits. — Longitudinal studies of age changes in performance on traditional intelligence tests reveal a slow rise in early infancy, followed by more rapid progress and eventual slowing donn as maturity is approached. It should be noted, however, that intelligence tests measure a combination of several traits and that the nature of this composite varies mith age. Thus in infancy the I Q is based largely on sensorimotor development, while in childhood it depends increasingly on verbal and other abstract functions.

Contrary to earlier findings, it has been established that intelligence-test performance continues to improve at least into the 20s. Among intellectually superior persons. especially college graduates and those engaged in relatively intellectual occupations, such improvement may continue throughout life In more nearly average samples, tested abilities tend to decline beyond the 30s, the drop being greatest in tasks involving speed, visual perception and abstract spatial relations. Loss in motor skills is slight, especially when the subject is free to introduce compensatory changes in method. Older persons can learn nearly as well as younger but are more seriously handicapped nhen the task conflicts with well-established habits. Cross-sectional studies. based on different samples at each age level. may give spurious results because of lack of comparability of groups in education, cultural milieu and other factors.

Resedrch on age differences has been extended to include a wealth of datd on emotional, motivational and attitudinal changes from infancy to old age. Some popular stereotypes regarding age and personality have been called into question by such findings For example. the "conservatism" of older persons may reflect cultural change between generations rather than age differences.

Extremes of Distribution of Intelligence. — Intellectual deviates, comprising the opposite extremes of mental deficiency and genius, have been singled out for special study. Psychological research on mental deficiency centres around prohlrms of identification, classification, causation, training and rehabilitation. Al-

though a feu rare forms of mental deficiency result from defective genes, many clinical varieties can be traced to environmental factors operating before or after birth and including both physical and psychological conditions. Investigations on the nature of genius have been concerned nith gifted children, living scientists and records of eminent men of the past. Although originally focusing on high I Q.. such research has been broadened to cover creativity and leadership.

Sex Differences. — Sex differences in abilities and personality traits depend upon both biological and cultural factors. The influence of biological conditions may be comparatively direct, as in the effect of male sex hormones upon aggressive behaviour; or it may be indirect. as in the social and educational effects of the more rapid development of girls as compared with that of boys. The contribution of culture is shown by the wide variations in sex roles found in different cultures and epochs. Psychological test surveys in contemporary western cultures indicate that males as a group excel in speed and co-ordination of gross bodily movements, spatial orientation, mechanical comprehension and arithmetic reasoning. but are surpassed by females in manual dexterity, perceptual speed and accuracy, memory, numerical computation, verbal fluency and other tasks involving the mechanics of language. Examples of personality differences include the greater aggressiveness, achievement drive and emotional stability of the male, and the stronger social orientation of the female.

Racial and Cultural Differences. — Other major group differences covered by differential psychology include those associated with social class, occupational level, urban and rural areas, nationality and race. Within the closely related categories of social class. occupation and urban-rural residence. differences have been found in child-rearing practices, sexual behaviour, emotional adjustment, interests and attitudes, as well as in I.Q. and various intellectual traits. In the case of relatively isolated and underprivileged groups, intellectual retardation tends to increase with age. In all groups. differences are specific to the functions tested. Because each of these subcultures fosters the development of its own characteristic pattern of aptitudes and personality traits. comparisons in terms of global or composite ability and personality measures may be fallacious.

Races are populations that differ in the relative frequency of certain genes. They are formed whenever a group becomes relatively isolated, for either geographical or social reasons, so that marriage among its members is commoner than marriage with outsiders. Since isolation fosters cultural as well as racial differentiation, the relative contributions of biological and cultural factors to race differences in behaviour are difficult to separate. A nation is primarily a political unit, not necessarily characterized by either racial or cultural homogeneity. Usually, however, national boundaries tend to encourage race formation, since marriages are more likely to occur within than across such boundaries.

Cultural differences may affect the test performance of diverse races in many ways. The emphasis placed by different cultures on speed, on competitive achievement or on success in abstract tasks. as well as the bilingualism that may handicap children of immigrants, are familiar illustrations. In the case of such minority groups as the American Negro, intellectual development may be retarded by inferior socioeconoinic level, inadequate educational facilities and the adverse motivational effects of social stereotypes. That races differ significantly in mean test performance has been repeatedly demonstrated, but rarely do the results throw any light on the causes of such differences. Some suggestive data are provided by special experimental designs utilizing hybrid (racially mixed) groups, regional differences, infants and young children, or detailed analyses of the operation of cultural factors in personality development. Although the interpretation of race differences in psychological traits is still controversial, what evidence is available points more strongly to cultural than to biological causation. See also PSYCHOLOGICAL TESTS AND MEASUREMENTS.

DIFFRACTION: **see** LIGHT; ELECTROMAGNETIC WAVES; ELECTRON DIFFRACTION.

DIFFRACTION GRATING, a series of parallel straight lines spaced at equal intervals in one plane or on a concave surface. A beam of radiation after falling on such a grating is resolved into a spectrum. See SPECTROSCOPY; LIGHT.

DIFFUSION. In physical science, this term is applied to the random molecular motion by which matter is transported. This definition refers to true or ordinary diffusion, which is sometimes identified as molecular diffusion to distinguish it from thermal diffusion, eddy diffusion, etc. Unless otherwise specified, the term diffusion as used by physicists refers to molecular diffusion.

Diffusion occurs in all forms of matter. In solids the process is as a rule much slower than in liquids and gases. Everyone is familiar with the diffusion of ammonia if a bottle of it is opened in a room. However, if smooth disks of lead and gold are placed in juxtaposition so that their edges meet, the migration of lead into the gold and of gold into the lead will eventually reach the point where it can be readily demonstrated.

The first part of this article is devoted to a general survey of the phenomenon, including some discussion of related effects, and the practical applications of diffusion, particularly in atomic energy. The second part affords a more theoretical treatment, and some diffusion coefficients are given.

General Description of Molecular Diffusion. — Atomic science has demonstrated that the concept of matter in a static condition is merely a relative one. At any temperature above absolute zero. the individual molecules of a substance move incessantly and at random, independently of each other. Frequent collisions occur between particles, so that the path of a single particle is a zigzag one. However, an aggregation of diffusing particles has an observable drift, from places of higher to places of lower concentration. For this reason, diffusion is known as a transport phenomenon.

In liquids, the phenomenon is illustrated by the following experiment: the lower part of a tall cylinder is filled with iodine solution; pure water is added on top of this solution in a manner that carefully avoids convection and stirring. At first only the lower part of the vessel, containing the iodine, is coloured, but then the colour is observed to spread slowly. Thus the upper part becomes coloured too, the intensity of the colour decreasing from bottom to top. After a long time, the entire interior of the cylinder will be uniformly coloured.

Diffusion in gases can be demonstrated by placing a few drops of bromine at the bottom of a closed flask. Bromine, visible by its brown colour, will be distributed through the air in the flask, as the iodine was through the liquid in the previous experiment. In gases the process is much more rapid than in liquids.

While diffusion in solids is in general the slowest type, there are notable exceptions. For example, when cuprous ions are diffusing from solid cuprous iodide into solid silver iodide, diffusion proceeds with a speed comparable to, and even equal to, that exhibited in solutions.

The zigzag path taken by large particles of a diffusing substance was first described by Robert Brown in 1827, and is therefore known as Brownian movement (q v.). The path traveled by a particle in the interval between two collisions is called the free path. Since this differs from collision to collision, an average value, known as the mean free path, is used as the basis of calculations. The mean free path decreases with increasing concentration.

The other quantities characterizing the diffusing substance are the mean velocity and the displacement. By displacement is meant the distance between the original position of a particle and its position after a certain period of time. The mean displacement is zero since, in the absence of a difference in concentration, positive and negative displacement are equally probable. For this reason the mean square displacement is introduced.

Consider a hypothetical horizontal plane passing through the iodine water system described above. Iodine molecules move in both directions through the plane. If one considers all the particles in a layer of a certain thickness on either side of the plane it will be observed that there are more iodine molecules in the same thick-

ness below the plane than above it. Since the same percentage of iodine molecules will cross the hypothetical boundary per second this will result in more iodine molecules moving upward than downward until there is no longer a concentration difference across the plane. There will result an over-all flow from positions of higher to positions of lower concentration. In this way the concentration is equalized. This equalization is macroscopically observable and is called diffusion. It is obvious that the mean square displacement will be a measure for the rate of diffusion. It depends, however, on time and it was found more convenient to introduce another characteristic quantity, independent of time. This is the diffusion *coefficient* D, which is related to the mean square displacement $\bar{x^2}$ as follows: $D = \frac{\bar{x^2}}{2t}$, t being the time. This equation is generally written in the form: $\bar{x^2} = 2Dt$. The mathematical description of the process of diffusion is accomplished with this quantity D, as will be shown below. For the present it is sufficient to note that the process is faster the greater D is and that D for a certain system will increase with temperature since the mean square displacement increases with the mean velocity and the mean velocity increases with temperature.

Diffusion as a Transport *Phenomenon.*—As has been pointed out, diffusion is due to random molecular motion, resulting in a transport of matter from places of higher to places of lower concentrations. Other transport phenomena are heat conduction and viscosity. At least in fluids and gases, these processes are also due to random molecular motion. In heat conduction, heat is transported from places of higher temperature to places of lower temperature, and viscosity is equivalent to a transport of momentum from places of higher velocity to places of lower velocity. Reference here is to the macroscopic velocity of the fluid. Thus the three transport phenomena depend on the same characteristic quantities: mean velocity, mean free path and mean square displacement. Accordingly, the theoretical treatments of all three processes will have much in common. The phenomenological theories of diffusion and heat conduction are similar, and so are the theoretical treatments of diffusion and viscosity in fluids making use of the transition-state theory.

Related Types of Diffusion.—Eddy Diffusion.—In fluid media, mixing by thermal convection and by eddy diffusion may become of importance equal to that of molecular diffusion, or may even predominate. Eddy diffusion, which occurs during the turbulent flow of liquids, is in many ways quite similar to molecular diffusion in still fluids. Unlike molecular diffusion, which is caused by thermal agitation resulting in a random motion of the single molecule, eddy diffusion is the random motion of small quantities of fluid (eddies). Considered in relation to the motion of the fluid as a whole?however, both are random movements.

The change from molecular diffusion to eddy diffusion corresponds to the change from laminar to turbulent flow. A quantitative theoretical treatment of eddy diffusion, comparable to that of molecular diffusion processes, is generally not possible, but considerations of similarity may lead to results of great practical value. Generally speaking, turbulence of a fluid increases with its macroscopic velocity, and so eddy diffusion increases.

Thermal Diffusion.—Ashas been described. ordinary (molecular) diffusion for a homogeneous phase results in an over-all migration of particles from positions of higher to positions of lower concentrations. Thus the concentration gradient may be regarded as the driving force for the diffusion. If a phase, in which there is no concentration gradient, is subjected to a temperature gradient, there may also result a particle flux, which in the case of fluid mixtures leads to a partial demixing (see fig. 1). The separation is much faster in gases than in liquids. Solids exhibit an analogous, though usually very small, effect. In liquids the effect is called the Soret *effect.* The demixing is greatly increased by an appropriate combination of convection and thermal diffusion as obtained in the Clusius separation tube. Such tubes proved most successful in the separation of isotopes. The apparatus consists of a vertical tube, the outer side of which is cooled, and an axis which is heated from within. The temperature gradient usually causes the heavier molecules to move toward the outer wall. Because of thermal convection there is an upward flow of the heated gas as a whole near the centre, while near the outer wall there is a flow downward. The lighter gas may be withdrawn at the top centre and the heavier gas at the bottom periphery. The separation efficiency of such a separation tube is much larger than that of plain thermodiffusion.

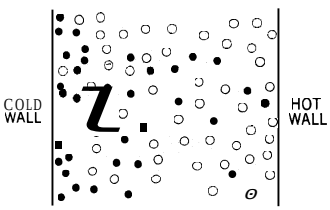

FIG. 1.—SCHEMATIC REPRESENTATION OF THERMODIFFUSION (see TEXT)

Knudsen Diffusion.—Under ordinary conditions the dimensions of a container in which diffusion of gases takes place are such that the mean free path is determined for a certain medium by the number of collisions with neighbouring molecules, the number of collisions with the wall being negligibly small.

For gaseous diffusion at low pressures and in a capillary. however, this is not so.

In this case the number of collisions of one molecule with other molecules is small compared with the number of collisions of the molecule with the wall. Thus the mean free path, in this case to a first approximation. is given by the diameter of the capillary, and is the same for different gases. From the lam of equipartition of energy it follows that mv^2 is proportional to the temperature (m being the mass of the molecule and v its velocity). So for one gas v increases with $\sqrt{T}$, and for two gases at the same temperature the mean velocities are inversely proportional to the square root of their molecular weights. So the lighter gas will traverse the capillary sooner, in accordance with its higher mean velocity. The same effect occurs in the passage of gases through porous solids and may play its part in separation of gaseous mixtures. The gas mixture is made to penetrate a solid diaphragm with sufficiently small pores, by applying vacuum to one side and having the mixture at the other side of the diaphragm. After a certain time a large amount of the lighter gas has penetrated the solid, whereas only a small amount of the heavier gas was able to pass through. So on the low-pressure side of the diaphragm the lighter, and on the high-pressure side the heavier gas is enriched. With both fractions the same process may be repeated. The separation effect for the single process is more pronounced the bigger the difference in molecular weights. This method of separating gases was employed by Lord Rayleigh and Sir William Ramsay in their classical work on the composition of the gases in the atmosphere. It was, however, little more than a laboratory curiosity until 1945, when the giant gas diffusion plant of the atomic bomb project for separating $U^{235}F_6$ from $U^{238}F_6$ went into production. The ratio m_2/m_1 in this case is only 1.0043. It is evident that the separation must be repeated thousands of times to achieve anything like complete purification of the desired isotope, and an elaborate cascading is necessary. In the plant, located at Oak Ridge, Tenn., the largest continuous chemicophysical separation process in the world is performed.

Diffusion in Zeolites.—Zeolites (*q.v.*) are silicate compounds containing water on interstitial sites. Some of them may be dehydrated without their lattice structures being destroyed and they are then capable of taking up other compounds besides water, mainly gases and vapours. These compounds are rather mobile in the zeolite and their rate of diffusion is very high and depends on direction. whereas there is no marked mobility of the constituent particles of the crystal. For details on these rather complex phenomena the reader is referred to the literature on the subject. The properties of zeolites are quite remarkable. They act as molecular sieves and may be used as semipermeable membranes for gases. Such semipermeable membranes are not only of practical importance for the separation of gases but also of theoretical interest. In thermodynamics semipermeable membranes are often postulated. They serve as an auxiliary concept to develop the theory of thermodynamics in its entirety. However, there are very few substances which act, even approximately, as semipermeable membranes. This is especially true for gases: apart from zeolites, the

only well-known semipermeable membrane is palladium metal, which when heated allows for an easy passage of hydrogen but not of other gases.

Diffusion of Neutrons. — The diffusion of neutrons is important for the operation of nuclear reactors, as will be discussed in more detail below. For this reason the diffusion of thermal neutrons through matter has been very intensely studied in recent years. Neutron diffusion differs in some important respects from ordinary gas diffusion. Neutrons, because of their nonelectrical nature, do not interact with the electronic shell of an atom or molecule but pass through it without hindrance. Thus they find matter largely empty. To be deflected they must collide with a nucleus, which is only a minute fraction of the volume of an atom. Consequently, the mean free path of neutrons diffusing through solid matter is about 1,000,000 times greater than the mean free path in gases at ordinary pressures (1 cm. as opposed to 10^{-6} cm.). For this reason boundary effects, which are negligible a few mean free paths away from the boundary, become significant for neutron diffusion, while they usually do not play a part in the diffusion of gases. An even more fundamental complication arises from the fact that neutrons are captured on collision as well as scattered. It will be shown below how this fact may be treated theoretically.

Self-Diffusion.—In diffusion at least two substances are involved. Self-diffusion, as the name implies, refers to the diffusion taking place as result of random motion in a single pure substance. Self-diffusion in the strict sense of the word is not directly observable. There are, however, indirect methods. For only when the substances differ in some respect can flow and concentration changes be detected and measured. When the difference does not exist in any other chemical respect, but only insofar as two different isotopes of the same chemical element are involved, their interdiffusion will, to a good approximation, be equal to self-diffusion. The approximation will be better for a small relative mass difference, *i.e.*, heavy elements, and not so good for isotopes of light elements. Radioactive isotopes are usually used for measurements because of their ease of detection. Radioactive tracers are important in the measurement of other diffusional processes.

Importance and Application of Diffusion. — Diffusion determines the rate of transfer of material across stationary layers of air or liquid. The rate of evaporation of water from a free surface (one with no blanket of gas molecules) at 20° C. is about $\frac{1}{3}$ g. per square centimetre per second, while the diffusion controlled rate of transfer across only 0.1 mm. of stagnant air is 1.000 times less. Consequently, diffusion through the adhering boundary layer of air determines the evaporation of surface waters.

Diffusion is also rate-determining for many chemical reactions, both for natural processes and for technical ones, and is especially important for solid-state reactions, where there is no convection and no stirring. When iron is decarbonized, diffusion of carbon in iron is rate-determining, provided that the iron particles are not too small.

During oxidation of metals the oxide often covers the metal and forms a protective layer. Such reactions are also observed in a halogen or sulfur atmosphere and are known as tarnishing reactions. Once the layer has attained a certain thickness, diffusion of the components through the layer may be rate-determining for the continuation of the reaction.

Importance of Diffusion of Neutrons for the Operation of Nuclear Reactors. — The operation of nuclear reactors depends on the interaction of neutrons with the atomic nuclei of the nuclear fuels. A nucleus of these fuels, after capturing a neutron, splits in two (or more) smaller nuclei. This process is associated with the liberation of large amounts of energies and with the liberation of neutrons. It is called a fission process. Thus in the case of uranium-235 an average of 2.5 neutrons are emitted for each neutron captured, causing a fission process. The number is not an integer because various types of neutron interaction with the atomic nuclei take place. Since more neutrons are created than consumed, a branching chain reaction is possible. In a stationary nuclear reaction just one of the neutrons created by the fission process will cause another fission process, the others being absorbed somewhere or escaping through the boundaries of the pile. The reactor core must have a certain minimum size. called the critical mass, otherwise the fraction of neutrons escaping through the boundaries is too large, and the chain reaction discontinues.

It is evident that diffusion of neutrons is of fundamental importance for any mechanism of liberation of nuclear power, and especially for the operation of nuclear reactors. The neutrons have to migrate from the spot where they were created to the point at which they are utilized. This process of penetrating matter, however, is not merely diffusion, since at first the neutrons possess by their liberation a certain velocity, larger than the velocity caused by thermal agitation. And only the random movement due to thermal agitation is defined as diffusion. But once the neutrons have been slowed down, by means of the moderators in the pile, the migration of these thermal *neutrons* from positions of higher concentration to positions of lower concentration is governed by the laws of diffusion.

The pile may be surrounded by material which acts as a reflector for neutrons. It must have similar properties to that of the moderators; *i.e.*, the rate of absorption of neutrons must be as small as possible, because the neutrons absorbed would no longer be available for the fission process. In pure graphite, for instance, neutrons are mainly scattered and not absorbed.

A neutron which has already left the reactor core and is moving through the material of the reflector may be scattered back into the core because the microscopic process in diffusion is a random movement. So it is possible to define a reflection *coefficient,* or albedo, as the fraction of neutrons entering the reflector which are reflected back to the source medium. By surrounding the core with reflecting material the critical mass of the reactor can be reduced because neutrons. which otherwise would be lost for the chain reaction, are now scattered back into the reacting core.

Separation of Isotopes. — In most cases the separation of isotopes is not possible by chemical means because isotopes have similar chemical properties. Their difference in mass, however, involves a difference in diffusion coefficient. Thus H_2 (hydrogen) and D_2 (deuterium or heavy hydrogen) may be separated by the electrolytic decomposition of water. By this process hydrogen is enriched in the gas and deuterium in the water. This is at least partly due to the fact that the light hydrogen ions move faster; in addition complicated processes at the electrodes are involved.

A separation may also be achieved by diffusion. But even for Knudsen diffusion the separating factor is so small that the process must be applied repeatedly in order to achieve anything approaching complete separation. As early as 1932, G. Hertz described a method involving diffusion through sets of from 10 to 50 clay pipes. By this procedure the isotopes of the light elements neon, oxygen, argon, nitrogen and carbon could be separated. For the separation of heavier elements even more steps are necessary, as already described above for the separation of uranium.

In thermodiffusion, which also proved very useful for the separation of isotopes, increased separating efficiency is achieved through the use of the Clusius and Dickel separation tube as has been described in the preceding material.

THEORY OF DIFFUSION

General Theory. — With regard to the theoretical treatment of diffusion it is necessary to distinguish between two kinds of diffusion theory. The phenomenological theory of diffusion is based upon A. Fick's first law and the equation of continuity. The theory consists mainly in the mathematical solution of the differential equations for various boundary and initial conditions. Thus it is possible to obtain values for diffusion coefficients from measurements of diffusion processes and, once the coefficient is known, to calculate in advance the diffusion in systems with varying boundary and initial conditions. This in no way involves the atomic structure of matter and so the mathematics of diffusion is applicable not only to the diffusion of particles but also to the diffusion (that is, transfer) of heat. The phenomenological theory does not yield any information about the magnitude of the diffusion coefficient. This is the object of the kinetic and atomic theory of diffusion. Starting from the structure of matter it is possible to determine under which conditions and for which properties of the substances

the equations of diffusion in their special forms are valid, and from a sufficiently detailed knowledge of the structure of matter it is possible to calculate the magnitude of diffusion coefficients and discover their connection with other properties of matter.

The Phenomenological Theory (Mathematics of Diffusion).— The laws of diffusion show the relationship between the rate of flow of a diffusing substance and the concentration gradient responsible for this flow. Empirically the following relation is known to exist, which was first postulated by Fick:

$$j = -D\frac{dc}{dx}$$

It is named Fick's first law. The diffusion flow or current per unit cross section of a substance in a mixture is represented by j. It is the amount of this substance passing perpendicularly through a reference surface of unit area during unit time. Then x is the co-ordinate chosen perpendicular to the surface of reference, and c is the concentration of the diffusing substance. Thus $\frac{dc}{dx}$ is the rate of change of concentration in direction of the co-ordinate x. D is the coefficient of diffusion for the substance under consideration and is defined by the above relation. Fick's first law may be interpreted as follows. For a given substance, with nonuniform concentration, there is a flon of substance from positions of higher to places of loner concentrations, which finally results in a uniform distribution of the substance throughout the system The amount of flow is proportional to the concentration difference betueen two points of unit distance. D is the constant of proportionality. If, for a certain substance, D is greater than for another one, this means, provided that the concentration change per unit length is the same for both substances, the flow of the first substance will be greater than that of the second. However. only in limiting cases D is strictly to be considered as a constant for a given medium, temperature and pressure; such limiting cases are diffusion in high dilutions and self-diffusion. In all other real systems D depends more or less markedly on concentration, and the assumption that D is a constant is to be considered as an approximation.

Fick's first law is only valid for homogeneous phases (neglecting the difference in concentration of the diffusing substance). If the medium is not homogeneous there may be a flow in the opposite direction; *i.e.*, from lower concentration to higher concentration. This paradox is called *uphill diffusion* and seems to contradict Fick's first law. The contradiction, however, is not real. To meet such conditions the law is to be generalized. The driving force in terms of chemical thermodynamics is $-\frac{d\mu}{dx}$ when μ is the Gibbs function per mole and is called the chemical potential. μ_0 is a constant, the chemical potential of the standard state. The mean velocity is:

$$\bar{v} = -u\frac{d\mu}{dx} = -\frac{D}{RT}\frac{d\mu}{dx}$$

and the flow is:

$$j = c\bar{v} = -\frac{D}{RT}\,c\,\frac{d\mu}{dx}$$

where u is the mobility and c the concentration. This is the generalized form of Fick's first law, and $u = \frac{D}{RT}$ is known as the Nernst-Einstein relation. For a homogeneous phase with:

$$\mu = \mu_0 + RT \ln c$$

the quantity:

$$j = -\frac{D}{RT}\,c\,\frac{d\mu}{dx}$$

reduces to

$$j = -D\frac{dc}{dx}$$

the original equation ($\frac{d\mu}{dx}$ being $\frac{(d \ln c)}{dx}$; T, temperature; R, gas constant; and ln c the natural logarithm of c). Fick's first law may be formulated independently of a special system of co-ordinates, using vector notation:

$$j = -D \operatorname{grad} c$$

This states that the vector j of the diffusion current is in the opposite direction of the concentration gradient and is proportional to its absolute value. This holds for gases and liquids, but solid crystals. with the exception of those of the regular system, are generally anisotropic and the diffusion coefficient may differ for different directions. Then D is a tensor and the vectors j and grad c may have different directions. In zeolites, for example, there is a marked anisotropy. D in the direction of the planes of the laminated structure is about 20 times greater than D normal to these planes.

The conservation of mass may be expressed mathematically as follows:

$$\frac{\partial j}{ax} = -\frac{\partial c}{at}$$

The equation is called the law of continuity; it means that the difference between the flow that enters a volume element and the flow that leaves it is equal to the change of concentration in this element. This equation may also be forinulated independently of a system of co-ordinates, by means of vector notation, and is of the form:

$$\frac{\partial c}{at} = -\operatorname{div} \boldsymbol{j}$$

From Fick's first law and the law of continuity Fick's second law follows:

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x} D \frac{\partial c}{\partial x}$$

which is called the diffusion equation, or in vector notation:

$$\frac{\partial c}{at} = \operatorname{div} (D \operatorname{grad} c)$$

and for constant D:

$$\frac{\partial c}{at} = D\frac{\partial^2 c}{\partial x^2} \text{ or } \frac{\partial c}{at} = D \operatorname{div} \operatorname{grad} c$$

respectively.

Solution of the Diffusion Equation for Different Cases.—Under steady-state conditions there is no change of concentration with time; *i.e.*,

$$\frac{\partial c}{\partial t} = 0$$

For linear flow and constant D:

$$D\frac{\partial^2 c}{\partial x^2} = 0 \qquad \frac{\partial c}{\partial x} = \text{(constant)} \qquad c = c_0 + c_1 x$$

So the concentration gradient is constant, and a linear distribution exists in the whole sample under consideration. From the fact that $\frac{\partial c}{\partial x}$ is a constant, it follows that j is a constant. So Fick's first law may be integrated and gives:

$$j = D\frac{c_2 - c_1}{l}$$

with l as the length of the system (diffusion length) and c_1 and c_2 as the concentrations at both ends. This relation is very useful for the determination of diffusion coefficients, because a steady state may easily be realized.

If some volatile substance; *e.g.*, ether, is placed in the lower part of a vertical cylinder, which is open at the upper end, a steady state of diffusion will result after a certain time. The concentration at the liquid-gas interface may be determined by measuring the vapour pressure of the substance at the temperature of experiment. Therefore, j, corresponding to the amount of ether evaporating during unit time. can easily be found by weighing or measuring the height of liquid in the cylinder. The concentration at the open end is zero. So from:

$$D = \frac{jl}{c_s}$$

D of the diffusing vapour in the air may be determined. (The above relation, however, is only an approximation since the diffusion length l is not exactly a constant but increases with time, and since the opposing flow of air is zero. The approximation is valid for small concentrations c,.)

A steady state can also be obtained in the case of diffusion through colloidal membranes or through solids. The passage of gases or vapours through membranes by diffusion is called permeation. If corresponding concentrations within the membrane are not available, one defines a permeability constant, which is the value of the diffusion current under certain conditions.

General *Solutions* of the Diffusion Equation. — In many cases the co-ordinates x and t enter into the resulting expression in the combination x^2/t only. As may be verified by substituting into the diffusion equation:

$$c(x,t)=\frac{s}{2\sqrt{\pi DT}}\exp\left(-\frac{x^2}{4DT}\right)$$

is a possible solution with:

$$s=\int_{-\infty}^{+\infty} c\,dx$$

This solution refers to the following physical problem. At $t=0$ the quantity s of the diffusing substance is concentrated in the immediate vicinity of the plane $x=0$, and for $t>O$ the resulting distribution of concentration is given by the above expression. The exponential is Gauss's error curve (see fig. 2). By integrating over $\exp\left(-\frac{x^2}{4DT}\right)$ with respect to x, a solution of the following form is obtained:

$$c(x,t)=\frac{c_0}{2}\left[1-\operatorname{erf}\left(\frac{x}{2\sqrt{DT}}\right)\right]$$

The function erf is called error function and is defined as follows:

$$\operatorname{erf} z\equiv\frac{2}{\pi^{\frac{1}{2}}}\int_0^z \exp(-\xi^2)\,d\xi$$

The corresponding problem is the following. At $t=0$ the concentration profile is such that for $x<0$, c has the constant value c_0 and for $x>0$, c is zero. This uneven profile is gradually smoothed out as diffusion proceeds (see fig. 3).

A class of solutions for finite systems of length 1 is supplied by the Fourier series. Actually this series was introduced as early as 1822 in Fourier's work, *Théorie* analytique de la *chaleur,* as solution for problems of heat conduction. The solution thus obtained is:

$$c(x,t)=\sum_{n=1}^{\infty}\left[A_n\sin\frac{n\pi}{l}x+B_n\cos\frac{n\pi}{l}x\right]\exp\left(\frac{-n^2\pi^2DT}{l^2}\right)$$

The arbitrary constants A_n and B_n must be determined in such a way as to conform with the initial conditions. In this manner diffusion out of a plate may be treated, when the concentration is constant (see fig. 4).

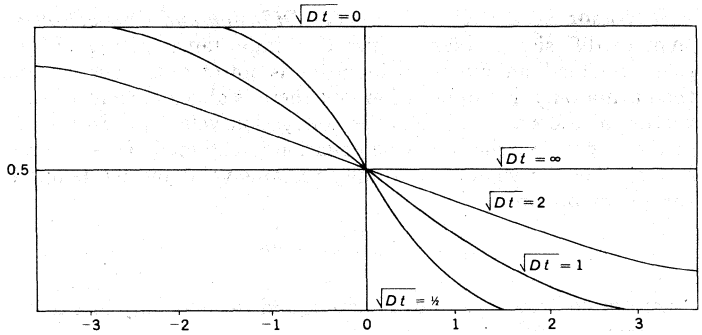
FIG 2.—FUNCTION REPRESENTING SMEARING OUT. BY DIFFUSION. OF SUBSTANCE ORIGINALLY CONCENTRATED AT $X=0$

Treatment of the *Diffusion Equation for D Dependent on c.* The solutions of the diffusion equation considered so far are only valid as long as D is constant or at least approximately constant. The measurement of D as a function of concentration is, of course, possible by choosing such initial conditions that there is only a small difference in concentration throughout the whole system. So a value of D for a mean concentration is obtained, and proceeding in the same manner by choosing other initial concentrations which also are not much apart, it is possible to determine D as a function of c. This procedure is naturally very laborious.

The differential equation for diffusion in the x direction with the diffusion coefficient depending on concentration was:

$$\frac{\partial c}{\partial t}=\frac{\partial}{\partial x}D(c)\frac{\partial c}{\partial x}\quad\text{or}\quad\frac{\partial c}{\partial t}=D(c)\frac{\partial^2 c}{\partial x^2}+\frac{dD(c)}{dx}\left(\frac{\partial c}{\partial x}\right)$$

L. Boltzmann has treated this equation for the following initial



ADAPTED FROM W. JOST, "DIFFUSION IN SOLIDS, LIQUIDS, GASES," ACADEMIC PRESS INC

FIG. 3. — FUNCTION REPRESENTING DIFFUSION OF SUBSTANCE ORIGINALLY CONTAINED IN ONLY ONE-HALF OF SYSTEM

conditions: $c=c_0$ for $x<0$ and $t=0$; $c=c_0$ for $x>0$ and $t=0$. The system is supposed to be infinite in the x direction. Upon the substitution of $y=\frac{x^2}{\sqrt{t}}$ Boltzmann obtained the ordinary differential equation:

$$\frac{d^2c}{dy^2}+\frac{y}{2D}\frac{dc}{dy}+\frac{dD}{dc}\frac{1}{D}\left(\frac{dc}{dy}\right)^2=0$$

This equation, which expresses c as a function of y, defines D arbitrarily as a function of c; however this does not make it possible to integrate D. But for practical purposes one may proceed as follows. Usually the task consists in the determination of $D(c)$ (by this is meant D as a function of c) if c has been obtained from direct experiments as a function of y. The last equation may then be rewritten:

$$\frac{d}{dy}\left(D\frac{dc}{dy}\right)=-\frac{y}{2}\frac{dc}{dy}$$

and upon a first integration:

$$D(c)=-\frac{1}{2}\frac{dy}{dc}\int_{c_0}^{c} y\,dc$$

Since the right-hand side is supposed to be given experimentally, it is always possible to carry through the integration by means of numerical or graphical methods, and thus to evaluate $D(c)$.

FIG. 4. — SOLUTION. BY USE OF A FOURIER SERIES, FOR DIFFUSION OUT OF A PLATE, CONCENTRATION AT BOUNDARIES BEING KEPT AT ZERO

Diffusion in a Field of Force.—Diffusion and Convection.—In many diffusion problems of practical importance, with liquids or gases, the medium under consideration is not at rest. The current then is not only due to diffusion, but there is also a current of convection of the size $\mathfrak{v}c$, if b is the convection velocity. So instead of Fick's first law the following equation is obtained: $j=-D$ grad $c+\mathfrak{v}c$. The equation of continuity remains valid and by its application one obtains:

$$\frac{\partial c}{at} = \text{div D grad } c - \text{div } (bc)$$

which for constant values of D and b, and for flow only in x direction, may be written:

$$\frac{\partial c}{\partial t} = D\frac{\partial^2 c}{\partial x^2} - \mathfrak{v}\frac{\partial c}{\partial x}$$

So in addition to the concentration change, caused by diffusion, there is a concentration change due to convection.

With this equation sedimentation may be treated. Under the influence of gravity, g, $\mathfrak{v}=umg$ (m is the mass of the particle and u is called its mobility: it is the constant of proportionality between a force acting on a particle and the resulting velocity). D and u are connected by Einstein's relation $D=RTu$. So,

$$j=-D\frac{dc}{dx}+cumg$$

At equilibrium, where $j=0$, the equation becomes:

$$RTu\frac{dc}{dx}=cumg$$

This equation may be integrated to give

$$c=c_0 \exp\left(\frac{mgx}{RT}\right)$$

the barometric formula. If c as a function of x is measured. this formula may serve to determine molecular weights. For measurements of practical importance it is usually very tiresome to wait until equilibrium is obtained. So it is more convenient to measure j and determine D or u from measurements at which the external force has been eliminated. This method of determining molecular weights is widely used in organic chemistry and biochemistry, and serves there also for measuring the masses of viruses, etc. The acceleration g is usually supplied by an ultracentrifuge, which gives fields strong enough to make the method useful on molecular weights down to 10,000.

Diffusion of *Charged* Particles.—For ions and electrons there exists, in addition to the diffusion current, a current caused by the electric field which is

$$-cuzF\frac{d\phi}{dx}$$

(u is again the mobility; F, Faraday's constant; ϕ, the electric potential and $\frac{d\phi}{dx}$ the strength of the electric field; z, the electric charge). So Fick's first law is to be replaced by

$$j=-D\frac{dc}{dx}-cuzF\frac{d\phi}{dx}$$

with $D=RTu$ according to the Nernst-Einstein relation. The above equation is known as the equation of motion after Nernst and Planck. It is valid for the transport of ions and electrons, as long as these obey Boltzmann statistics. So the equation is important for the treatment of semiconductors, solid and liquid electrolytic conductors, ion exchangers and for the tarnishing—and similar reactions—of solid metals. It is rather difficult to obtain mathematical solutions of this equation, and so methods of approximation are to be used. In the case of stationary states, however, the problem may be treated more easily and more general solutions may be obtained by assuming a quasi-stationary state.

Diffusion and Chemical Reaction.—For the treatment of diffusion in an external field of force it was necessary to extend Fick's first lay. In other cases the law of continuity no longer holds, and is to be extended. For example, particles may vanish or new particles may be created by a chemical reaction. If the number of particles created by the reaction per second, $f(c)$, is a function of the concentration, the following equation is obtained:

$$\frac{\partial c}{\partial t}-f(c)=\frac{\partial j}{\partial x}$$

or in vector notation,

$$\frac{\partial c}{}-f(c)=\text{div } j$$

Thus for the one-dimensional case and with D a constant the following equation holds:

$$D\frac{\partial^2 c}{\partial x^2}+f(c)=\frac{\partial c}{\partial t}$$

Apart from c, the concentration of the diffusing substance, $f(c)$ may depend on the concentration of other components and on external influences, for instance, illumination as in the case of a photochemical reaction.

The problem thus stated is closely connected with that of heat conduction, coupled with heat production. In the special case where all other influences are independent of the space co-ordinates and of time, and where $f(c)$ is proportional to c; *i.e.*, a reaction of the first order, the equation is as follows:

$$D\frac{\partial^2 c}{\partial x^2}+(\text{constant})\,c=\frac{\partial c}{at}$$

This equation may be integrated by separating the variables.

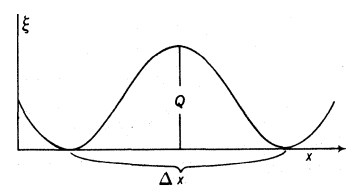
Particles may also vanish or be created because of nuclear reactions. In the case of neutron diffusion, as has been pointed out, neutrons may be captured by the nuclei of the absorbing medium. The rate of capture is obviously proportional to the concentration of neutrons and inversely proportional to the mean lifetime of a neutron. The mean lifetime is $\frac{\lambda w}{\bar{v}}$; λ is the mean free path between two collisions; $\bar{v}$ is the mean velocity; and w is the probability that a capture will result from a collision. The quotient $\frac{\bar{v}}{w}$ is denoted by λ_a, the mean free path for absorption.

The following equation is obtained for the diffusion of thermal neutrons in an absorbing medium:

$$\frac{\partial c}{\partial t}=D\frac{\partial^2 c}{\partial x^2}-c\frac{\bar{v}}{\lambda_a}$$

Solutions of this equation, as given by Enrico Fermi, are necessary for calculating the process of the interaction of matter with neutrons, and to obtain diffusion lengths. Diffusion lengths in paraffin, graphite, water and other common materials for slowing down fast neutrons run between 10 and 50 cm.

Transition-State Theory Applied to Diffusion.—The theory, which is also called absolute reaction rate theory, or theory of the activated state, is applicable to any kind of chemical change, which may be a chemical reaction in the usual sense or a simple displacement of particles, as in diffusion or viscous flow. It is possible to calculate the diffusion constant from other properties of the material involved. The process of diffusion is then regarded as the passage of a particle over a potential barrier when it is moving from one position of low potential energy to an adjacent one. Such an energy barrier is represented schematically in fig. 5. Writing $\dot{n}_{12}$ instead of $\frac{dn_{12}}{dt}$ for the number of particles which cross the potential barrier per unit time, the following equation holds:



TION OF A POTENTIAL BARRIER

$$\dot{n}_{12}=\bar{\nu}n^{\ddagger}$$

(The $\bar{\nu}$ denotes the average frequency with which the particles cross the barrier in the right direction, $n^{\ddagger}$ is the number of particles in the transition or activated state; *i.e.*, on top of the barrier.) From statistical mechanics one gets for the number

of particles in the transition state $n^{\ddagger}$ divided by the number of particles in the ground state n_1: $\frac{n^{\ddagger}}{n_1}=\frac{f'}{f}$ where f and f' are the partition functions for the corresponding states. A partition function is defined by:

$$f=\sum g_i \exp\left(-\frac{E_i}{kT}\right)$$

where g_i is the energy and E_i the weight of a state i. From the partition function the translation states in the direction under consideration may be split off. In doing this, one obtains:

$$f'=f^*\sqrt{(2\pi m kT)}\frac{\delta}{h}$$

where f* is the partition function of the activated state without the contribution of the translational energy in the direction of the x co-ordinate: δ is a certain range on top of the barrier, and h is Planck's constant. The mean velocity in the $+x$ direction is:

$$\bar{v}=\left(\frac{kT}{2\pi m}\right)^{\frac{1}{2}}$$

and consequently the frequency, ν, is $\frac{\bar{v}}{\delta}$. As only half of the total number of particles move in the $+x$ and the others in the $-x$ direction, one obtains for the number of transitions per unit time:

$$\dot{n}_{12}=n_1\frac{f^*}{f}\frac{kT}{h}$$

The factor kT/h has the dimensions of a frequency and is of the order of magnitude of 6×10^{12} per second. Transforming the energies in such a way as to get a summation over energies from $0\rightarrow\infty$ in both partition functions and denoting the partition functions thus obtained by Z one gets:

$$\dot{n}_{12}=n_1\frac{Z^*}{Z}\frac{kT}{h}\exp\left(-\frac{Q}{RT}\right)$$

Q is the height of the potential barrier *(see* fig. 5). It is often referred to as the activation energy of the process. Then j, the current caused by the n particles, expressed in c_1 instead of n_1, is:

$$\overrightarrow{j}=c_1\frac{kT}{h}\exp\left(-\frac{Q}{RT}\right)$$

and in the opposite direction:

$$\overleftarrow{j}=c_2\frac{kT}{h}\exp\left(-\frac{Q}{RT}\right)$$

As long as the concentrations c_1 and c_2 are equal, both currents cancel and, macroscopically, no resulting current exists. For a concentration gradient, however, this is not so. Then c_1 (the concentration at x) is different from c_2 (the concentration at $x+dx$). The resulting current will be:

$$j=\overrightarrow{j}-\overleftarrow{j}=[c(x)-c(x+dx)]\frac{Z^*}{Z}\frac{kT}{h}\exp\left(-\frac{Q}{RT}\right)$$

As a first approximation this equation may be written as:

$$j=\Delta x\frac{Z^*}{Z}\frac{kT}{h}\exp\left(-\frac{Q}{RT}\right)\frac{dc}{dx}$$

(ΔX is a characteristic length, which in case of diffusion in crystals may be expressed by the lattice constant); denoting the factors in front of exp by $-D_0$:

$$j=-D_0\exp\left(-\frac{Q}{RT}\right)\frac{dc}{dx}$$

Comparing this with Fick's first law,

$$D=D_0\exp\left(-\frac{Q}{RT}\right)$$

is obtained. The effect of temperature upon D_0 should be small in comparison with the effect upon exp $(-Q/RT)$. Thus the temperature dependence of D is given by exp $(-Q/RT)$. This relation may be verified experimentally. As stated already, the diffusion increases with increasing temperature.

Some Diffusion Coefficients (D)

Diffusing substance	Solvent	Temp. °C.	D (cm.²/sec.)
Gold	Copper	400	5×10^{-13}
Copper	Silver	650	2.9×10^{-10}
Copper (self-diffusion)		650	2.6×10^{-10}
		850	
		1,030	2.8×10^{-9}
Carbon	Iron	950	10^{-7}
Methanol	Water	18	1.4×10^{-5}
Carbon dioxide	Water	18	1.5×10^{-5}
Tobacco mosaic virus	Water	20	5.3×10^{-8}
Oxygen	Air	0	0.178
Hydrogen	Air	0	0.611
Phosgene	Air	0	0.095

DIGBY, SIR KENELM (1603–1665), English courtier, diplomat, naval commander, philosopher, scientist and author; a man of extraordinary and renowned versatility and energy in almost all fields of action and thought. He combined devoted adherence to the old religion with devoted pursuit of the new science. He claimed. justly, that it had ever been a maxim with him "that one can have no happiness either in this world or the next. but by extreme and vehement love."

He was born on July 11, 1603, the son of Sir Everard Digby, who was executed in 1606 for his part in the Gunpowder plot. After his father's death. Digby was brought up by his mother at Gayhurst, Buckinghamshire, as a Roman Catholic. In 1617 he accompanied his cousin Sir John Digby, later 1st earl of Bristol, to Spain. In 1618 Digby entered Gloucester hall (afterward Worcester college). Oxford, where he studied under the famous mathematician Thomas Allen. He left the university in 1620. traveled to France and Italy and in March 1623 was again with his cousin in Madrid shortly before the arrival of Prince Charles and the duke of Buckingham on their ill-fated mission to obtain a marriage treaty. Digby became a member of the prince's household and returned with him to England in October. when James I knighted him. In 1625 Digby married Venetia Stanley, whom he had known since childhood. To win political favour, in 1627–29 he led a privateering expedition and successfully attacked French ships in the Venetian harbour of Scanderoon. but the government disavowed his actions because of complaints by the Venetian ambassador. Lady Digby died in 1633 and he retired to Gresham college, remaining in seclusion for two years, occupied with chemical experiments.

Digby professed Protestantism after 1630 but had returned to the Roman Catholic faith by 1635. He associated himself with Queen Henrietta Maria and her Roman Catholic friends at court, and supported the king's expedition against Scotland in 1640. for which he was summoned before the bar of the house of commons in 1641 He went to France. where he was pardoned by Louis XIII after he had killed in a duel a French lord who had insulted Charles I Back in England, Digby was imprisoned by the commons in 1642–43. Released. he returned to France. After his arrival in Paris he published his chief philosophical works, *Two Treatises, in the One of Which the Nature of Bodies; in the Other, the Nature* of *Mans Soule; Is Looked Into: in Way of Discovery of the Immortality of Reasonable Soules* (1644). He was appointed Henrietta Maria's chancellor and went to Rome in 1645 to solicit aid for the royalist cause from the pope. A second mission in 1647 was as fruitless as the first. He returned to England in 1649 but was banished by the council. Allowed to return in 1654, he negotiated with and for Oliver Cromwell, hoping to win toleration for Roman Catholics. At the Restoration he returned to England and he was on the council of the Royal society when it was formed in 1660 In Jan. 1664 he was banished from court, and spent the rest of his life in literary and scientific pursuits. He died in London on June 11, 1665.

Among his works were *Observations Upon Religio Medici* (1643) and *Observations on the 22. Stanza in the 9th Canto of the 2d. Book of Spencers Faery Queen* (1643). He also wrote on "the powder of sympathy," which he claimed would cure wounds without touching them. His memoirs were circulated in manuscript in his lifetime and were published, with expurgations, as *Private Memoirs,* ed. by Sir Nicholas H. Nicolas (1827).

(B. H. G. W.)

DIGBY, KENELM HENRY (1797–1880), English writer, author of *The Broadstone of Honour: or, Rules for the Gentlemen of England* (1822), a code of conduct for the upper classes based on an ideal of chivalry as "that general spirit . . . which disposes men to heroic and generous actions." It was later enlarged and issued (1826–27) in four volumes. Digby was born in Dublin, educated at Cambridge and lived as a man of letters in London, where he died. March 22, 1880.

DIGENES AKRITAS, BASILIUS, hero of a Byzantine epic composed probably in the 10th century. His parentage, exploits and death are described in the epic by direct narrative and his own tale of his adventures. He is called Digenes ("of double descent"). his father being Arabian emir, a convert to Christianity, and his mother the daughter of a Greek general, and Akritas as a warrior of the *akrai* ("borders") of the empire. His heroic nature already reveals itself in boyhood. Later, he carries off and marries the daughter of a Greek general, and, with his bride and a small band of followers, wanders in the desolate parts of the border waging war on all kinds of raiders who infest it, all of uhom he exterminates single-handed. He builds a palace on the Euphrates, there to die of illness soon afterwards. The scene of action is the eastern frontier of the Byzantine empire, namely Cappadocia and the 'Euphrates area.

The archetypal version of the epic is lost, but six versions (one being prose) are extant, put together by different redactors and varying in length, date of composition and treatment of the original episodes. There are fragments of a Russian prose version (ed. by M. N. Speranksy, 1922). The earliest version seems to be that in a Grottaferrata 14th-century manuscript. The epic has attracted detailed study, and divergent opinions are held regarding the circumstances of its original composition and the problems, literary and historical, arising from the extant versions and from the relation of the written epic to certain Greek folk songs, the so-called ballads of the Akritic cycle. The background of the poem strongly suggests the rebellions of the Paulician heretics in the 9th century and the campaigns against them of the emperor Basil I (who, it can be plausibly argued, might have been the model for the hero of the epic). The author of the original version drew on Arabic epic material of the 10th century for part of his background, and the poem also contains borrowings from Hellenistic romances, chiefly Achilles Tatius and Heliodorus.

Though lacking in dramatic interest, the *Digenes* is characterized by an "epic comprehensiveness," and its narrative is relieved by descriptions of idyllic scenery of considerable literary merit.

DIGESTION, in physiology and medicine, comprises all the operations to which food is subjected from the time it is eaten until it is absorbed. The materials required for the life of the body tissues are supplied by the circulating fluids, blood, lymph and tissue fluid. This requires that the nutrients be soluble in water or be so finely divided that they can be transported in a liquid medium. Since the food as it is taken into the body is not in this condition, considerable changes must take place before it can be transported in the blood. The food, in addition to undergoing mechanical and chemical digestion, also must be transported along the alimentary tract, and the products of digestion must be transferred through membranes from the lumen of the intestine into the intestinal capillaries and lymphatics.

ORGANS OF DIGESTION

The organs of digestion, known collectively as the digestive or alimentary tract, comprise the mouth (*q.v.*), esophagus, stomach, small and large intestine and various accessory structures associated with these organs.

Esophagus. — The esophagus is a muscular tube connecting the oral pharynx with the stomach. It is lined with a tough mucous membrane similar to that lining the mouth and oral pharynx. The muscle of the upper portion of the esophagus is of the striated variety, similar to voluntary muscle, whereas that of the lower portion is of the unstriped or smooth variety.

Stomach. — The stomach is an expanded portion of the tube designed to serve as a reservoir for food and to initiate chemical digestion. It is connected with the esophagus at its cardiac or upper end, at which point a strong sphincter muscle serves to narrow the tube and to prevent easy passage of gastric contents back into the esophagus. At its lower end the stomach connects with the duodenum, and this junction is guarded by the powerful pyloric sphincter.

Intestines. — The small intestine consists of the duodenum, jejunum and ileum, which together comprise a continuous tube without any clear line of demarcation between the divisions. It is here that the greater part of chemical digestion goes on and absorption takes place. The large intestine in man serves mainly for recovery of the water secreted by the digestive glands and for elimination of undigested residues.

General Structure of the Digestive Tube. — The walls of the digestive tube contain varying amounts of smooth muscle, the activity of which serves the mechanical functions of digestion and transports the digesting mass through the alimentary tract. It is probable that muscular action also aids absorption. The digestive tract is lined with mucous membrane, the cells of which secrete either mucus or enzymes that aid in chemical digestion; in addition it serves as the medium of transport in absorption. Various glands have developed as diverticula from the digestive tract; these likewise secrete fluid containing digestive enzymes. The principal digestive glands are the salivary glands, gastric glands, liver and pancreas.

The entire tract, glands and muscle, is supplied with nerves belonging to the involuntary or autonomic division of the nervous system. It is also influenced by hormones, some developed within the tract itself and some secreted by glands situated elsewhere in the body.

For details of structure of the digestive tract see **ALIMENTARY CANAL.**

MOTOR FUNCTIONS

Chewing (Mastication). — Ignoring cooking, which serves a function in chemical digestion, the digestive process begins when food enters the mouth. Here the food is subjected to the mechanical action of the teeth while being masticated, or chewed. This serves to reduce the size of the food particles and to mix the food with saliva. Saliva serves mainly to moisten and lubricate the food, but it has also some digestive action on starches. The presence of food in the mouth also serves to initiate reflexes that are important in regulation of secretion of gastric juice and, perhaps, other digestive functions.

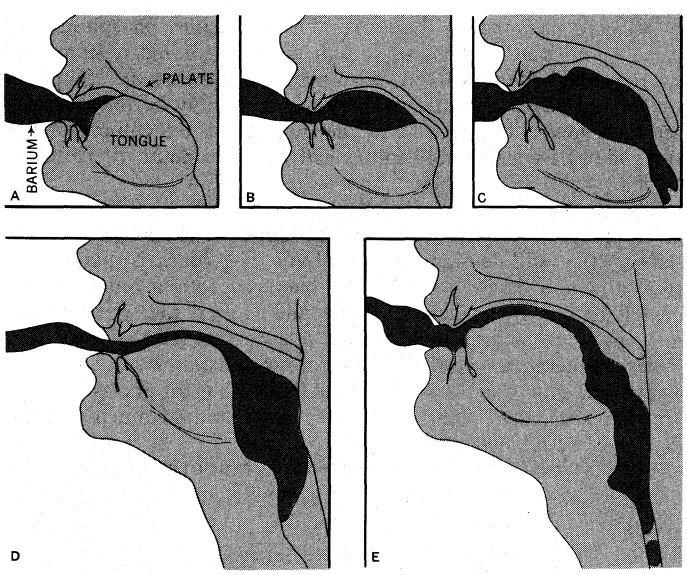
Chewing is accomplished by movements of the lower jaw, which in man can be moved anteroposteriorly, laterally or vertically; any one of these movements may be utilized in chewing. The act may be initiated and controlled voluntarily, but for the most part it is a self-regulating reflex. There is a wide divergence of opinion as to the importance of chewing in the process of digestion; nevertheless it appears evident that food should be chewed enough so that it can be easily swallowed. It is also generally believed that food must be retained in the mouth long enough for its flavour to be enjoyed thoroughly if the succeeding processes of digestion are to proceed optimally.

Swallowing (**Deglutition**). — Swallowing has been described as taking place in three stages: oral, pharyngeal and esophageal. In the oral stage the food is manipulated by the tongue and cheeks into position for swallowing; in the second, or pharyngeal, stage

it is passed rapidly through the pharynx into the esophagus; in the esophageal stage it is carried through the esophagus into the stomach. The mechanics of the oral and pharyngeal stages are so complicated that they are not yet thoroughly understood (fig. 1). The food is manipulated into a bolus and put under pressure by movements of the tongue and contraction of the pharyngeal muscles; consequently it moves toward the esophagus, where the pressure is lower. The combined oral and pharyngeal stages occupy only a fraction of a second, and the solid mass is often caused to move so rapidly that it may be projected halfway through the esophagus without further muscular effort. Liquids are usually projected all the way to the cardia and frequently pass directly into the stomach. Solid food usually has to be propelled, part of the way at least, by the action of the esophageal muscle. This consists of a contraction that develops in the circular muscle at the upper end of the tube and progresses slowly toward the lower end. The longitudinal muscle is also involved, but the mechanism of its action is not fully understood. The effect of the contraction is to narrow the lumen so that whatever may be ahead of the contraction is carried downward and ultimately delivered into the stomach. **As** the contraction wave approaches the stomach there is reflex relaxation of the cardiac sphincter accompanied by relaxation of the stomach itself, known as receptive relaxation of the stomach. This is an important factor in preventing an increase in intragastric pressure as the stomach is filled at mealtime.

Movements of the Stomach.— The muscle of the stomach is seldom completely at rest even when the organ is empty. The contractions of the empty stomach can be recorded with appropriate instruments or observed by means of X-rays. They have come to be called hunger contractions because, when they are very powerful, they give rise to a sensation that, in some people. is interpreted as hunger pain; in others they produce merely a sensation of emptiness or a desire for food. It is probable that the hunger contractions stimulate the search for food in those animals that are governed by instinct. In man they serve as a reminder that mealtime is approaching.

Gastric Peristalsis.— As soon as food is taken, contractions cease and after a variable time are replaced by rhythmic movements called digestive peristalsis. Gastric peristalsis begins as a ring of constriction about the middle of the stomach; this progresses toward the lower or pyloric end, growing deeper as it moves. In man contractions of this sort occur at a rate of about three per minute, and each takes approximately one minute to travel from its origin to the pylorus; consequently, it usually is possible to see with the fluoroscope three waves of contraction simultaneously on the human stomach. If they happen to begin at a higher level, four or more waves may be seen at one time. Contractions of the stomach serve two main purposes. The first is to aid digestion by completing the mechanical disintegration of the food; by far the greatest part of energy expended by the stomach is used for this purpose. The second is to propel the digested material into the duodenum.



ADAPTED FROM MOSHER, "LARYNGOSCOPE," 37:237 (ST. LOUIS, MO., 1927)

FIG. 1.— MOVEMENTSOF THE TONGUE IN THE ACT OF SWALLOWING. (DRAWINGS MADE FROM RETOUCHED TRACINGS OF AN X-RAY FILM)

(A) The tip of the tongue is depressed as the substance ingested (barium meal in this case) accumulates above and in front of the tip and behind the teeth; (B) the tip of the tongue rises and the dorsum sinks; (C) the tip remains up and the dorsum and base sink, forming an inclined plane; (D) the anterior half of the tongue rises as a mass to the roof of the mouth, and the base of the tongue is depressed still further. The mouth is now full. (E) The anterior half of the tongue remains at the roof of the mouth; the posterior half and the base of the tongue rise and shoot suddenly backward, driving the barium meal down the pharynx

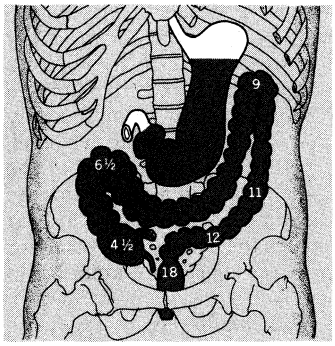
Gastric Emptying.— When liquids are swallowed, passage into the duodenum begins at once. Solid food remains in the stomach until some portion of it is liquefied. In consequence, the chyme, as the evacuated material is called, is fluid or semifluid in consistency, although it may contain small solid particles in suspension. Once emptying begins, it proceeds rhythmically, a small portion of the chyme being projected into the duodenum with each peristaltic wave. The emptying of the stomach is regulated by means of reflexes and hormones. Regulatory reflexes arise in the upper intestine and are caused by stimuli that result from contact of the chyme with the intestinal mucous membrane.

Certain substances in the chyme cause nerve impulses to be initiated that diminish the peristaltic activity of the stomach and thus delay emptying. Substances that act in this manner are products of protein digestion, fat, fatty acids, products of starch digestion and the hydrochloric acid secreted by the gastric glands. Some foreign substances such as alcohol, strong salt solution and other irritants act similarly. Fats and carbohydrates also release from the mucous membrane of the intestine a hormone called enterogastrone, which circulates in the blood and, when it reaches the stomach. tends to slow down its activities. Fats are particularly potent in this regard. and for this reason fats remain in the stomach much longer than do other foods.

Movements of the Small Intestine.— In the small intestine digestion is completed and absorption takes place; the activity of the smooth muscle is appropriate to these functions.

Segmenting Contractions.— The commonest type of muscular action is rhythmic, or segmenting. contractions These are ringlike contractions of the circular muscle, which occur at variously spaced intervals along the intestine. dividing it into segments. The contractions are followed by relaxation and then by contraction of the muscle in the middle of the previously relaxed segment; thus the segments appear under the fluoroscope to be constantly shifting to and fro. These contractions range in frequency from 9 to 18 or 20 per minute. The higher rates occur in small animals and in the upper end of the intestine. The effect of the segmenting contractions is to keep the intestinal contents in motion. so that the portions in contact with the mucous membrane are constantly changing: the contractions also serve a stirring and mixing function and greatly facilitate digestion and absorption.

Intestinal Peristalsis.— The progress of the digesting mass through the intestine depends on the occurrence of intestinal peristalsis. A typical peristaltic movement begins with contraction of a ring of circular muscle. narrowing the lumen of the tube. The contraction is transmitted to adjacent muscle, so that it travels as a wave that progresses in the direction of the lower end of the intestine. Intestinal peristalsis is not rhythmic and occurs only at irregular intervals. The waves appear and disappear without any apparent cause and progress for varying distances. sometimes a few inches, sometimes a few feet, and occasionally over the entire length of the small intestine. The strength of the constriction also varies. at times almost obliterating the lumen so that everything is swept before the wave, at other times causing only a slight indentation of the wall. Usually about six hours are required for an ordinary meal to pass through the small intestine. During this time practically all the usable material in the digesting mass is absorbed into the blood stream or lymph, leaving only water and indigestible residue to be emptied into the large intestine.



ADAPTED FROM STARLING, "PRINCIPLES OF HUMAN PHYSIOLOGY"

FIG. 2.—POSITION OF STOMACH AND LARGE INTESTINE IN MAN

The figures indicate the time in hours of arrival of barium meal at various levels

Movements of the Large Intestine.— In the large intestine, the water that has been used in digestion is recovered and returned to the blood. The undigested food residues, along with a great number of bacteria that inhabit this part of the intestine, are dried out, so to speak. and reduced to the consistency of the feces and propelled toward the anus.

Mixing *Movements.*—In the large intestine occur stirring and mixing movements that appear to be somewhat different in different species and that are not well understood even in human beings. In general they appear to accomplish a to-and-fro movement of the contents between the caecum. which is the large first portion of the large intestine, and the transverse colon. Associated with these are the contractions of the recesses of the colon (haustral contractions), which resemble to some extent the segmenting contractions of the small intestine.

Propulsive Movements.— Propulsive movements occur at infrequent intervals and are usually initiated by the taking of a meal. In some manner the process of filling the stomach stimulates intestinal motility, affecting not only the small intestine but the large intestine as well; this effect is known as the gastrocolic reflex. Since the large intestine is generally quiet between meals, this reflex assumes considerable importance.

In the human subject, follo ing a meal, it is usual to find in the large intestine a type of movement that has been described either as mass peristalsis or mass contraction of the colon. Typical mass contractions start at the caecum, progress over the ascending and transverse colon and terminate in the descending colon. The effect of such a movement is to carry forward the contents of the large intestine and deliver them into the most distal segment, which is known as the sigmoid or pelvic colon. If the contraction wave is strong enough to carry the fecal mass into the rectum, it produces a characteristic sensation that the individual recognizes as a desire to defecate.

Defecation.— In the adult, the act of defecation is preceded by a voluntary effort consisting of relaxation of the external anal sphincter and, usually, compression of the abdominal contents by means of straining efforts. These movements in turn probably give rise to stimuli that augment the visceral reflexes originating primarily in the distended rectum. As a result of these reflexes peristaltic waves appear in the colon while the internal anal sphincter relaxes. The peristalsis of the descending colon carries its contents into the pelvic colon, which in turn transfers them to the rectum, eventually to be evacuated by way of the anus. Hence, the entire distal colon, from the splenic flexure to the anus, may be emptied at one time.

A prominent mechanical feature of the final act of evacuation is contraction of the longitudinal muscle of the distal colon; this muscle is most highly developed in the rectum itself. The shortening of the distal colon tends to elevate the pelvic colon and obliterate the angle it normally makes with the upper end of the rectum; straightening of the passage in this way doubtless facilitates evacuation. Shortening of the rectum itself, assuming that it has a firm grip on its contents at the upper end, may be an important factor in expelling the feces through the anal orifice.

The act of defecation provides another instance of a reflex that is under some degree of voluntary control. Voluntary regulation consists of the ability to inhibit the reflex under normal circumstances and to initiate it voluntarily, provided the necessary visceral stimulus (recent distention of the rectum) is present. Reflex centres for defecation have been located in the brain, namely, the hypothalamus, in the lower lumbar and the upper segments of the spinal cord and in the ganglionic plexus of the intestine.

Formation and Composition of Feces.—Formation.—As food material progresses through the small intestine, practically all the digestible material is absorbed and carried away by the blood or lymph. The residue consists of water, small amounts of undigested and unabsorbed food, the remains of desquamated mucosal cells and the undigestible and unabsorbable fractions of the digestive secretion; in addition, there may be present various species of bacteria and the products of their metabolism. This material is emptied from the terminal ileum into the colon, where it is subjected to further alteration through absorption of water and the action of the bacteria that inhabit the colon. Practically nothing is added in the colon except, possibly, some mucosal secretion.

Composition.—Food residues provide an excellent culture medium for bacteria, and the interior of the colon is a nearly ideal environment for their growth; in consequence they multiply enormously, so that from 30% to 50% of the weight of the feces may be made up of bacterial bodies. The colonic contents are further modified by absorption of water and inorganic salts, so that of the 75 to 180 g. of feces daily excreted only about 70% to 75% is normally water; this proportion varies a great deal, however, according to the consistency of the feces.

Feces normally contain from 5% to 25% of fatty material, including such substances as neutral fats, free fatty acids, soaps and sterols. Fats are present in appreciable amounts even on a fat-free diet, proving that some fat is excreted through the intestine. About one-third of the fecal lipid consists of sterols, chiefly cholesterol. The daily output of feces contains from 0.5 to 1.5 g. of nitrogen as nitrogen compounds. About half the nitrogen represents nitrogenous constituents of the fecal bacteria; the rest represents unabsorbed intestinal secretions and digestive fluids, mucus, desquamated mucosal epithelial cells and a small amount of food residue; some digestive enzymes also may be present. Usually, absorption and digestion of protein are so nearly complete that only small amounts of food protein nitrogen escape into the feces; likewise only small quantities of digestive enzymes are normally present, since they are usually destroyed by other enzymes or by the action of bacteria. Digestive enzymes may be increased in the stool in diarrhea and may then be responsible for severe skin irritations.

Since the pH of the feces is usually between 7 and 7.5, the inorganic constituents are mainly substances that are poorly soluble in alkaline pH ranges; these are chiefly calcium phosphate and oxalate and iron phosphate. Small amounts of magnesium, potassium and sodium salts are also present in the stool. Since, in the human being, cellulose is not digested, it may be found in the feces whenever it is present in the diet; the total volume of the feces may be considerably influenced by the amount of cellulose eaten.

The dark brown colour of the normal stool is due chiefly to stercobilin and urobilin, reduction products of the action of bacteria on the red bile pigment, bilirubin. The odour is due mainly to skatole and indole, produced by bacterial action, but it is also contributed to by hydrogen sulfide and methyl mercaptan; it is more pronounced on a high protein diet because of the formation of larger quantities of these odoriferous substances.

Even when no food is taken, about seven to eight grams of feces are excreted daily. This consists of desquamated mucosal cells, digestive secretions and bacteria.

Regulation of the Gastrointestinal Smooth Muscle.—The organs of digestion are capable of carrying on their function in the absence of the autonomic nerves, but the nerves provide a degree of regulation that presumably increases their efficiency and, in any case, brings their activities into harmony with the needs of the entire body. The muscle is supplied by two sets of nerves called respectively the sympathetic and parasympathetic nerves. The parasympathetic nerves are mainly responsible for regulating the functions of the organs of digestion, and, generally speaking, their effect on the smooth muscle is to increase its activity. The sympathetic nerves. on the other hand, are mainly responsible for diminishing or stopping the activity of the digestive organs when all available energy is needed elsewhere in the body. Thus they diminish or inhibit the activity of the gastrointestinal muscle.

Under normal circumstances a reasonable balance is maintained between these two antagonistic influences, but in conditions of stress or emotional excitement one or another set of nerves may be so stimulated as to seriously impair digestive function; for example, in case of fright or sudden anger, pain, severe exercise or even intense interest, gastric emptying may be slowed and digestion retarded. In some instances the retardation may be so severe as to cause stasis and symptoms of indigestion. Other types of emotional reactions may stimulate the parasympathetic nerves excessively and produce hypermotility, intestinal cramps or diarrhea. When such abnormal situations exist over long periods of time, or reoccur frequently, the disturbance may be so severe that organic changes occur in the digestive organs and chronic disease supervenes. Peptic ulcer and ulcerative colitis are commonly believed to be the result of certain types of stress acting directly through this mechanism or through an associated hormonal mechanism.

Vomiting.—Vomiting is a reflex that relieves the upper gastrointestinal tract of its contents; this may occur either because the contents are irritating or because the organs themselves are not in a normal state. Abnormal stimuli, arising in the irritated stomach or intestine, are conveyed to receptive areas in the brain, where they give rise to the sensation of nausea. They also go to the vomiting centre in the medulla, from which are transmitted to the smooth muscle of the stomach and intestine. and the voluntary muscles of the thorax. abdomen, neck and mouth, nerve impulses that result in a characteristic series of muscular actions.

The first movement to occur is a strong sustained contraction of the upper intestine; next the pyloric sphincter contracts and then the pyloric portion of the stomach. These changes take place during the period of nausea and result in emptying the contents of the jejunum, duodenum and pyloric portion of the stomach into the fundus and body of the stomach, which are relaxed and dilated. Then, following an inspiratory movement, the glottis is closed and the abdominal muscles contract violently, compressing the stomach between the contracted diaphragm and the abdominal organs. The pressure on the gastric contents causes their evacuation through the relaxed esophagus, oral pharynx and mouth.

Vomiting may also be induced by disease or stimulation of the uterus, kidneys. heart, semicircular canals, eyes, nose and mouth, or as a result of direct stimulation of the vomiting centre. Certain of the emetic drugs act on the centre, but most important clinically is the "central" vomiting caused by traumatic stimulation of the centre due to head injuries, increased intracranial pressure, brain tumours or meningeal irritation. This type of vomiting is characterized by the great force with which the contents are ejected (projectile vomiting) and by a minimum of nausea and very little activity of the voluntary muscles.

CHEMICAL ASPECTS OF DIGESTION

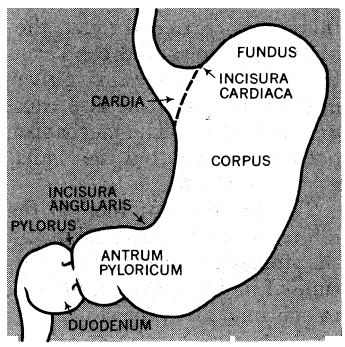
Digestive Secretions.—Saliva.—The first secretion encountered by the food in its progress through the gastrointestinal tract is saliva, which is secreted by three pairs of glands known as the parotid, submaxillary and sublingual glands (see SALIVARY GLANDS). The parotid glands are situated below the ears and behind the ramus of the mandible. They are easily located in a person having mumps, in which disease they become swollen as a result of an acute viral parotitis. The submaxillary glands are located in the floor of the mouth, just internal to the angle of the jaw. The sublingual glands, as the name suggests, are situated under the tongue. The salivary glands empty their secretions through ducts that lead into various parts of the mouth. In addition to the six large salivary glands, there are numerous smaller ones in the mucous membrane of the mouth and pharynx.

Saliva consists of water, inorganic salts and organic solids. The inorganic salts are the salts found in most body fluids, of which sodium, potassium and calcium salts are the most important. The principal organic solids are mucin and the starch-splitting enzyme ptyalin (one of the amylases). The latter is relatively abundant in human saliva but is said to be absent from the saliva of dogs. This fact may have some relation to the normal diet of the species, but since dogs are provided with abundant amylase in other parts of the digestive tract, this interpretation is open to question.

Enough saliva is secreted continuously to keep the mucous membranes of the mouth and throat moist. Changes in the rate of secretion are brought about through secretory nerves that supply the salivary glands; these belong to both the sympathetic and parasympathetic divisions of the autonomic system. The nerves are normally excited through reflexes, which may be inborn or conditioned. Inborn reflexes comprise responses to stimuli associated with the presence of food in the mouth; these include taste, smell and the sense of touch. The act of chewing also probably facilitates the flow of saliva. Conditioned reflexes are acquired; they result from associations experienced during the act of eating. For example, the sight of a lemon will induce salivary secretion in most persons because they have at some time experienced the sour taste of lemon juice. In the absence of such an experience, the sight of a lemon would have no effect whatever on the salivary glands. The salivary glands are unique in that their secretion is not influenced by any specific secretory hormone.

The composition of saliva is influenced to some extent by the type of stimulus causing secretion. For example, acids induce secretion of an abundant watery saliva, whereas alkalies stimulate mainly secretion of mucus. Mucus is also secreted in abundance when the food is dry or hard and also when the food consists entirely of milk. In fact, more saliva and more mucus are secreted in response to milk than to dry solid food. The Russian physiologist I. P. Pavlov, who made these and many similar observations, thought he saw a certain utility in the various modifications of the salivary secretion evoked by different foodstuffs. Acids, for example, require dilution in order to be tolerable. Dry foods need an abundance of secretion, particularly mucus, to enable them to be swallowed. Milk, however, is easily swallowed without saliva but nevertheless receives an abundant secretion; Pavlov was of the opinion that the large amount of saliva, especially mucus, prevented the formation of large curds in the milk when it entered the stomach. According to this interpretation there is a specific teleological relation between the quantity and type of saliva and the food eaten. There can be no doubt that the quantity of secretion and the time when it appears, as well as its composition, are adapted to the needs of the organism.

Gastric Juice.—As soon as the food is swallowed it encounters the gastric juice, a complex fluid secreted by various types of glands situated in different parts of the lining of the stomach. The gastric juice consists of water, inorganic salts, hydrochloric acid, mucin and enzymes. The presence of a strong mineral acid in one of the body fluids is a remarkable phenomenon that has aroused the interest of physiologists for many generations; the exact mechanism of its production remains unknown. The thick, tough, flaky mucus found in the gastric juice is secreted by the surface epithelial cells that constitute the major part of the lining of the stomach; while adhering to the cells that secrete it, it serves to protect them from the abrasive action of various solid substances that may be swallowed, as well as from the corrosive action of the hydrochloric acid.



ADAPTED FROM LEWIS "AMERICAN JOURNAL OF ANATOMY 13 491 (1912)

FIG 3 — SUBDIVISIONS OF THE HUMAN STOMACH

Most of the fluid is formed by the gastric glands. These are small, tubular glands that dip down from the surface of the mucous membrane in the fundus and body of the stomach (*see* fig. 3). These glands are made up of two types of cells, called chief cells and parietal cells. Chief cells line the glands; it is believed that they secrete the pepsin (*q.v.*), rennin and lipase found in gastric juice. The chief cells near the orifice of the gland probably secrete a soluble type of mucus. The parietal cells appear to be applied to the external surface of the gland; they pour their secretion into the lumen through tiny canals between the chief cells. They are believed to secrete the hydrochloric acid of the gastric juice. Although these cells secrete a strong mineral acid, the protoplasm

of the cell is neutral or slightly alkaline in reaction. It is evident that the acid is in some way formed near the surface on the luminal side of the cell.

The pyloric portion of the stomach, which constitutes approximately the distal one-fourth, secretes a neutral or alkaline fluid; besides water and saits its principal constituent is mucus.

A small amount of gastric juice is secreted continuously by most human beings, but by far the greatest amount is secreted after meals. The increased volume of secretion following meals, called the digestive secretion, is the result of stimulation of the gastric glands by nervous and hormonal influence. Nervous stimulation causes what is called the initial reflex, or cephalic, phase of gastric secretion; this is due to the sight, smell and taste of food. The amount and duration of secretion during this phase depends somewhat on the intensity of stimulation, but more particularly upon the psychic response of the individual. The more pleasurable the sensations associated with eating, the more gastric juice will be secreted; thus an individual with little appetite, even though he may smell and taste the food, has little secretory response from his stomach. Gastric juice secreted during the cephalic phase has a high acidity and contains large amounts of pepsin; it is therefore a very active digestive secretion. If an experiment is arranged so that only the initial reflex phase is active — that is, so no food enters the stomach — the secretion ordinarily begins within five minutes after feeding and may last for as much as one hour.

If arrangements are made to put food into the stomach without the individual's knowledge (for example, through a gastric fistula in a sleeping subject), the initial reflex phase does not occur; nevertheless, the stomach will begin to secrete after approximately 15 minutes. Although the secretion is less abundant and less potent than that formed during the initial reflex phase, it lasts for a longer time, indeed for as long as there is food remaining in the stomach. This part of the gastric secretory cycle is known as the chemical or gastric phase and is caused by the presence of food in the distal or pyloric portion of the stomach. The mucous membrane in this region contains a hormone called gastrin, which is capable of stimulating the gastric glands to secrete. In the absence of food the hormone remains in the mucous membrane, but when food is present it is increased in amount and caused to escape from the mucous membrane into the blood that circulates in the submucosa. From there it is carried through the general circulation and, by means of the arterioles and capillaries that supply the stomach, reaches the gastric glands, causing them to secrete. The presence of food in the small intestine also causes some degree of secretion by the gastric glands. The mechanism of stimulation from this source is not fully known, but the available evidence suggests that it is hormonal in nature.

The presence of food in the stomach tends to neutralize and dilute the gastric hydrochloric acid. In consequence, after a meal, the stomach contents are never so acid as is the gastric juice at the time of its initial formation. If for any reason the secretion tends to continue after the stomach is emptied, the acidity of the gastric contents rises to abnormally high levels, and under these circumstances it is possible for the gastric juice to damage the gastric or duodenal mucosa.

One theory of peptic ulcer formation is that gastric and duodenal ulcers are the result of continued secretion of gastric juice after the stomach has emptied itself and the neutralizing effect of the food is no longer present. Some degree of protection against this is provided by a special inhibitory mechanism in the pyloric portion of the stomach. If hydrochloric acid of concentration such as is normally secreted by the fundic portion of the stomach reaches the mucous membrane in the pyloric portion, it brings about, in the normal individual, a cessation of gastric secretion. In this way the secretion of strongly acid gastric juice in the absence of food is prevented.

Pancreatic Juice. — The pancreas (*q.v.*) is a large tapering gland that stretches across the posterior abdominal wall behind the stomach. Its larger end, or head, lies in the curve of the duodenum and its smaller end, or tail, in contact with the spleen. Its secretion is conveyed into the intestine through two ducts, the larger of which, called the duct of Wirsung, enters the duodenum along with the terminal portion of the common bile duct. The other duct, called the duct of Santorini, or accessory duct, empties separately into the duodenum at a slightly higher level. The pancreatic juice contains, in addition to enzymes capable of digesting all the types of food, sodium bicarbonate in a concentration roughly equivalent to the concentration of hydrochloric acid secreted by the stomach. Thus while the stomach is secreting acid, the pancreas is secreting base, an arrangement that helps to maintain the normal acid-base balance of the blood. When the two secretions are mixed in the intestine they neutralize each other, and the products are reabsorbed and restored to the circulation. The quantity of pancreatic juice secreted in 24 hours is probably somewhat less than the amount of gastric juice secreted in the same period of time. It has been estimated that the pancreas secretes about 20 c.c. of fluid per kilogram of body weight in 24 hours. The corresponding figure for the stomach is 25 c.c. This discrepancy partly accounts for the fact that the intestinal contents are normally slightly acid in reaction.

In some species the pancreas secretes continuously, in others only intermittently. It is not known whether or not the human pancreas secretes continuously. In any case, the secretion is greatly augmented during digestion. This increase is due to stimuli associated with the presence of food in the intestine; there is no gastric phase of pancreatic secretion — that is to say, food in the stomach does not influence the pancreas. The substances that act as stimuli comprise various constituents of the chyme, including water, acid, products of protein digestion, products of starch digestion, fat and products of fat digestion. When used singly, each of these substances produces a characteristic type of pancreatic juice; for example, hydrochloric acid produces a large amount of secretion containing a relatively high concentration of sodium bicarbonate but only a small concentration of enzymes; soap and fat and the products of protein digestion cause secretion of a smaller amount of more concentrated pancreatic juice containing a relatively high concentration of enzymes.

The substances mentioned influence secretion of pancreatic juice through nervous and hormonal mechanisms. Secretory nerves are present in both the sympathetic and parasympathetic nerves that supply the gland. The nerves have a profound effect on the enzyme concentration of the pancreatic juice and moderately increase the volume output. The manner in which they are stimulated during digestion is not known, except that the vagus nerves are responsible for an initial reflex phase of secretion corresponding to, but less important than, the cephalic phase of gastric secretion. It is probable that the secretory nerves act synergistically, or cooperatively, with the hormones.

The discovery by William Bayliss and Ernest H. Starling in 1902 of a hormonal mechanism for regulation of pancreatic secretion was an epochal evenf in the history of physiology. They found a substance in the mucous membrane of the duodenum that, when injected into the blood stream, stimulated the pancreas to secrete. This was the first instance in which a specific chemical substance was known to act as a stimulus for an organ at a distance from its site of origin. Bayliss and Starling called their chemical stimulus secretin and coined the word hormone to characterize secretin and similar substances. Secretin is released from the mucous membrane of the intestine by various substances found in the gastric chyme, of which hydrochloric acid is the most effective. After absorption, it is carried by the blood to the pancreas, where it induces an abundant secretion of dilute pancreatic juice. Its principal effect is to stimulate the secretion of water and bicarbonate, although a small amount of enzyme is always present.

Later, two other English physiologists, A A. Harper and H. S. Raper, demonstrated in the duodenal mucous membrane another hormone, which they called pancreozymin, which specifically increases the enzyme output from the pancreas. Normally during digestion hoth hormones are active; consequently, there is an abundant secretion of pancreatic juice with a relatively high concentration of enzymes.

Intestinal Secretion. — The mucous membrane lining the small intestine produces a secretion that aids in the terminal phases of digestion. This is an alkaline fluid somewhat resembling pancreatic

juice in its inorganic composition and known as succus entericus. It contains, in addition to enzymes, much cellular debris resulting from the sloughing of cells from the mucous lining of the intestine. It is not known whether the enzymes present in the juice are actually secreted by living cells or result from the disintegration of cells sloughed from the mucous membrane. In any case, they perform their function of completing carbohydrate and protein digestion within the lumen of the intestine. The intestinal mucosa also secretes enterokinase, which activates the trypsinogen of the pancreatic juice, converting it to trypsin, an enzyme that digests protein.

The secretory activity of the intestine is influenced by nervous, hormonal and mechanical stimuli. The parasympathetic nerves for the most part augment the secretion, which is also increased by mechanical distention and by the presence of food in the intestine. E. S. Nasset demonstrated the presence of a specific hormone, which he called enterocrinin and which has the function of increasing the secretion of intestinal juice. One of the functions of the intestinal mucous membrane is to act as a semipermeable membrane between the blood and the intestinal contents. In consequence, there is a constant interchange of fluid between the intestinal contents and the lymph and tissue fluid. This interchange can be considered as comprising simultaneous secretion and absorption of water.

The net movement of water is determined by the osmotic relation betneen the intestinal contents and the tissue fluids. Hypertonic fluid in the intestine, such as concentrated sugar solution, will cause an outpouring of fluid into the intestine. increasing the volume of the intestinal contents; but it would be a mistake to suppose that physical factors are alone responsible for absorption and secretion.

Formation of **Bile** by *the* Liver. — Bile is an important digestive secretion, but it also serves an essential excretory function having to do with hemoglobin metabolism. The red blood cells, which contain hemoglobin, are constantly being broken down and destroyed in the body, probably as a result of the wear and tear they encounter in the rapidly moving blood stream. The pigment that they contain is excreted by the liver in the form of bilirubin. Bilirubin, while circulating in the blood, is combined with a protein molecule; when it reaches the liver it is conjugated with glycuronic acid and excreted as bilirubin glycuronide. Bilirubin and its derivatives give to the bile, urine and feces their characteristic colour.

The constituents of the bile important for digestion are the bile acids. These are synthesized in the liver and comprise various modifications of cholic acid. The important bile acids in the human bile are glycocholic and taurocholic acids, which appear in the bile as their sodium salts. Bile is secreted continuously, but in those species equipped with a gall bladder (*q.v.*), including human beings, it does not enter the intestine continuously but only in response to specific stimuli. Effective normal stimuli are, in general, connected in some way with the process of digestion, so that the bile is usually delivered to the intestine during the digestion of food.

Bile secreted in the intervals between meals is diverted into the gall bladder, where it undergoes various changes, the most important of which is loss of water and inorganic salts, which are absorbed through the mucous lining of the gall bladder and returned to the blood stream. As much as 90% of the water may be absorbed, resulting in a tenfold increase in concentration of unabsorbed solids. In this way the gall bladder is able to store the typical biliary solids secreted during about ten hours, although its capacity is equal only to the volume of the bile secreted by the liver in one hour. Apparently water and salts are absorbed in approximately equal molecular proportions; at any rate, no significant change in the total salt content ratio has bren reported.

Bile contains, in addition to the constituents already mentioned, quantities of cholesterol (*q.v.*). This relatively insoluble substance is concentrated along with the other bilary constituents nhen water and salts are absorbed from the gall bladder. In certain circumstances, the cholesterol may precipitate and form stones, uhich, once started, have a tendency to increase in size. It is not uncommon to find a gall bladder solidly packed with stones, the chief constituent of which is cholesterol.

Normally the gall bladder fills during the interdigestive period and empties during digestion, although some degree of spontaneous emptying may occur if the fast is prolonged. Effective stimuli for contraction, hence emptying, of the gall bladder are provided by various foods and irritant substances present in the duodenum. These include, among others, hydrochloric acid, protein in solution, proteoses, peptones, fats and concentrated salt solutions. One salt that has been widely used for inducing emptying of the gall bladder for therapeutic purposes is concentrated magnesium sulfate. Mechanical stimulation of the duodenum is also effective. Of the food substances, fat has the most pronounced effect. Probably emptying of the gall bladder is usually initiated by reflexes over the vagus nerves, with food in the intestine acting as an effective stimulus. The sustained contraction normally seen during digestion, however, is maintained by a hormone known as cholecystokinin, which is liberated from the intestinal mucous membrane by the action of hydrochloric acid and also by fat.

After entering the intestine the bile salts serve an important function in digestion and absorption of fat, as mentioned above; they are then reabsorbed into the blood and returned to the liver to be used again, with the exception of about 10% that is lost in the feces. This loss has to be replaced by the synthesis of bile acids in the liver.

The bile pigments and other constituents of the bile are normally excreted in the feces, although a small amount of the pigment is reabsorbed and has to be excreted by the kidney.

Digestion of the Various Food Substances. — Chemically, digestion consists of the breakdown of complex food molecules into simpler substances, essentially a reversal of the growth process. In the growth and development of plant and animal tissues that are used by man for food, protein molecules are synthesized from the simpler amino acids; carbohydrate molecules are built up from simple sugars; and fats are made from fatty acids and glycerol. During digestion this process is reversed, the food being reduced to amino acids, simple sugars, glycerol and fatty acids. The process is known chemically as hydrolysis, which means a breakdown by means of water.

In hydrolysis a water molecule is used to split a more complex molecule; in the process the water itself is split. part of the water molecule joining with one fragment of the complex molecule and the other part with the other fragment. In this way. by the addition of the elements of uater, a protein molecule, for example, which may be made up of 50 to 100 different amino acids, is broken down into the original "building stones" from which the molecule was constructed. It is apparent, too, that a certain amount of water is used up in the process. Similarly, carbohydrates and fats are split, utilizing water in the process. By this means the organism is able to reduce its food to soluble, easily distributed forms; furthermore, since human proteins, fats and carbohydrates are not necessarily the same as those that exist in plants and in other animals, human beings are able to build their own characteristic materials from these simple building stones.

Carbohydrates. — Most carbohydrate is taken into the body as either sugar or starch, so starch digestion may serve as a model for the description of carbohydrate digestion in general. The hydrolysis of starch is accomplished by enzymes known as amylases, which are sometimes given special names depending upon the source; for example, the amylase of human saliva is called ptyalin. Ptyalin is a relatively weak enzyme, and the amount of digestion that goes on in the mouth is not quantitatively important; however, since the food becomes thoroughly mixed with saliva in the process of chewing, digestion may go on in the stomach for a period of time after the food is swallowed.

Probably most of starch digestion occurs in the intestine, where the powerful enzyme pancreatic amylase is able to attack the starch molecules. The amylases reduce starch to maltose, a disaccharide sugar. a small amount of glucose being released at the same time. Amylases are also found in the liver and in the intestinal mucous membrane. The maltose produced by starch digestion, and the other disaccharides that may be present in the

food — notably sucrose (table sugar) and lactose (milk sugar) — are broken down to simple sugars, monosaccharides, by the action of appropriate enzymes in the intestine; the monosaccharides are glucose, levulose and galactose. The monosaccharides are absorbed by the intestinal mucous membrane, whereas the disaccharides are not readily absorbed.

Proteins. — Protein digestion begins in the stomach, where the food encounters pepsin and hydrochloric acid. Since pepsin acts only in an acid medium, the presence of hydrochloric acid in the gastric juice is essential for optimal protein digestion. Pepsin has a unique capacity to digest native protein (that is, protein that has not been altered by the action of other reagents or by heat), in contrast with most of the other proteolytic enzymes of the body, which act best on denatured or partly digested protein. Peptic digestion serves to make the protein constituents of the food soluble and also to render them more readily digested by the proteolytic enzymes encountered in the intestine.

Pepsin also has the capacity to coagulate milk, though in young animals another enzyme known as rennin fills this specific function.

After passing from the stomach into the intestine the products of peptic digestion as well as any undigested protein remaining in the chyme encounter the proteolytic enzymes trypsin and chymotrypsin, secreted by the pancreas. As secreted in the pancreatic juice, neither of these enzymes has any proteolytic activity; they are then known as trypsinogen and chymo-trypsinogen, respectively. Trypsinogen is altered to trypsin by the action of enterokinase. Chymo-trypsinogen on the other hand is activated by trypsin. These enzymes are less active in the digestion of native protein than pepsin, but they carry the digestion farther; that is to say, their products are of lower molecular weight than are those of peptic digestion. Both these enzymes, like pepsin, release a certain amount of free amino acids.

The peptones and polypeptides produced by pancreatic digestion are further digested by a group of enzymes known as peptidases. of which there are several. At least one of these. carboxypeptidase, is found in pancreatic juice. Others are found in the mucous membrane and the secretion of the small intestine The end products of protein digestion are amino acids, all of which are absorbable through the intestinal mucous membrane.

Fats. — Fats are digested by lipases, which occur in gastric, pancreatic and intestinal secretions. The only one of importance in digestion of food fat is pancreatic lipase. These enzymes split neutral fats into glycerol and fatty acids; since each glycerol molecule combines with three fatty acid molecules, products of fat digestion may be monoglycerides, diglycerides or free fatty acids and glycerol. The mono- and diglycerides are probably important in emulsification of fat in the intestine. Pancreatic lipase is active as secreted, but its activity is greatly accelerated by the presence of surface-active agents, the normal activating agent being bile.

It is probable that some fat is absorbed undigested; in order for this to take place the fat must be divided into extremely minute particles, hence emulsification by the action of the bile salts and the mono- and diglycerides is an important step in fat digestion and absorption.

Absorption of Food From the Intestine. — Absorption of the products of digestion occurs almost exclusively in the small intestine. Absorption of food from the stomach is negligible, and absorption from the large intestine is limited largely to water and inorganic salts.

The ability of the small intestine to absorb the various products of digestion depends in part on the enormous surface presented by the mucous membrane; this is many times greater than the outer surface of the intestine because of the superabundance of the mucosa, which forms many circular folds called plicae circulares. A still greater surface is provided by the intestinal villi, which are nipplelike projections of the mucous membrane about one millimetre in length that are present over the entire inner surface of the intestine; macroscopically they resemble the pile on a piece of velvet. Each villus is provided with a little strip of muscle that runs its length and that under appropriate circumstances imparts to it a characteristic movement: In a fasting animal, the villi lie flat on the mucosal surface and are inactive, but when exposed to the intestinal contents during digestion they become erected and either perform a lashing movement or exhibit rhythmical shortening and lengthening. These movements accelerate the flow of blood and lymph and aid mechanically in absorption.

The mechanisms of absorption are complex and include such physical factors as osmosis, filtration and diffusion as well as the active intervention of the epithelial cells involving expenditure of energy. Physical processes account for considerable absorption, especially when a favourable concentration gradient exists, but active intervention of the epithelial cells is indicated by the fact that some substances can be absorbed when their concentration is lower in the intestinal contents than it is in the blood; also by the fact that different sugars are absorbed at different rates, even though their physical properties are similar.

Carbohydrates. — The carbohydrates are absorbed as simple sugars, of which glucose, levulose and galactose are the most important. These sugars on entering the epithelial cells combine with phosphate to form hexosephosphates. which are broken down in the cells, releasing the original sugar molecule into the interstitial fluid. In the process, a certain amount of energy is released; it is believed that it is this energy that accelerates the absorption of these sugars as compared with sugars that are not phosphorylated.

Absorption of sugars takes place chiefly in the upper portion of the small intestine; *i.e.,* the duodenum and upper jejunum.

Proteins. — Of the products of protein digestion, only the amino acids or very simple polypeptides are absorbable The possibility of occasional absorption of a whole protein molecule, however, cannot be excluded. This fact provides the basis for the development of certain allergies involving food protein. There is evidence that the amino acids are absorbed more readily than would be accounted for by physical diffusion, even though the concentration of amino acids in the blood is usually low.

Fats. — Absorption of fat presents special problems, since even the products of digestion are not completely soluble. Considerable neutral fat appears in the intestinal lymphatics, suggesting that it was absorbed without digestion or that it was resynthesized in transit through the cells; the available evidence indicates that some neutral fat is absorbed as such into the lymphatics, the remainder being digested and absorbed into the portal blood as fatty acids and glycerol.

Before absorption, fatty acids are made soluble by combination with bile salts. Some experimental evidence indicates that fat is absorbed more rapidly from the ileum, of the small intestine, than from the duodenum or jejunum.

Salts, Water and *Other Nutrients.*—Diffusion and osmosis play a large part in the absorption of water and salt. Water is constantly being transferred in and out of the intestine by osmotic forces, and such water is always accompanied by a certain amount of inorganic salt; however, there is conclusive evidence for the selective absorption of inorganic salts For example, sodium chloride is absorbed selectively from a mixture of sodium chloride and magnesium sulfate.

Absorption of other nutrients presents special problems. The fat-soluble vitamins are not absorbed when the absorption of fat is interfered with, as in pancreatic insufficiency. Adequate absorption of iron and calcium is dependent upon the presence of hydrochloric acid in the gastric juice. Vitamin B_{12}, which is essential for the formation of red blood cells, is absorbed only when a certain unknonn substance called intrinsic factor, which is normally secreted by the mucous membrane of the stomach, is present. Absorption is favourably influenced by the internal secretions of the pituitary, thyroid and sex glands. *See* NUTRITION; ENZYMES; HORMONES; GASTROINTESTINAL TRACT; see also references under "Digestion" in the Index volume.

DIGGERS, the name given to a group of agrarian communists who flourished in England in 1649–50 and were led by Gerrard Winstanley and William Everard. In April 1649 about 20 poor men assembled at St. George's hill, Surrey, and began to cultivate the common land. They held that the Civil War had been fought against the king and the great landowners; now that Charles I had been executed. land should be made available for the very poor to cultivate. (The price of food had reached record heights in the late 1640s.) The numbers of the Diggers more than doubled during 1649. Their activities alarmed the Commonwealth government and roused the hostility of local landowners—rival claimants to the common lands. The Diggers were harassed by legal actions and mob violence, and by the end of March 1650 their colony was dispersed. The Diggers themselves abjured the use of force, but hoped that their example in seizing waste lands for communal cultivation would be followed elsewhere. Winstanley's pamphlets and the dispatch of emissaries from the colony won supporters in Kent, Buckinghamshire, Northamptonshire and Essex. The Diggers also called themselves True Levellers, but their communism was denounced by the leaders of the Levellers (*q.v.*).

See L. H. Berens, *The Dzgger Movement* (1906). (J. E. C. H.)

DIGGES, LEONARD (d. 1571?), English mathematician and land surveyor, who experimented with the optical effects of lenses, has been credited with anticipating the invention of the telescope. He studied at University college, Oxford, but did not take a degree.

In the first book of his *A Geometricall Practise, named Pantometrza,* a work in three books published by his son Thomas Digges (d. 1595) in 1571 (2nd rev. ed., 1591), is included a discussion of "the marvellous conclusions that may be performed by glasses concave and convex, of circular and parabolical forms." He said he had dealt with "these conclusions . . . at large in a volume . . . [which] opened the miraculous effects of perspective glasses," but such a book was not published.

Leonard Digges began the work entitled *An Arithmeticall Militare Treatise, named Stratioticos: compendiously teaching the Science of Numbers.* The book was completed and reworked to some extent by Thomas, who published it in 1579. A second edition appeared in 1590.

Sir Dudley Digges (1583–1639), the son of Thomas, was a judge, diplomat and member of parliament. Sir Dudley and his father jointly wrote *Foure Paradoxes or Politique Discourses* (1604).

DIGITALIS, in pharmacy, the dried leaf of the common foxglove (*q.v.*), *Digitalis purpurea.* It was first introduced into medicine as a diuretic (stimulant of urine secretion) in dropsy in 1775 by William Withering of Birmingham, Eng., who recognized it as the active ingredient of an old woman's secret formula.

Three cardiac glucosides have been isolated in crystalline form from *Digitalis purpurea:* digitoxin, gitoxin and gitalin. All three have essentially similar pharmacological actions, although they differ in the rate in which they are absorbed and eliminated in the body and also in their solubilities in various solvents. In addition, digitalis also contains a number of saponins (*see* SAPONINS AND SAPOGENINS), which probably modify the effect of the cardiac glucosides aithout producing cardiac effects themselves.

The beneficial actions of the cardiac glucosides in heart disease include a tonic effect on the heart, with diminution of the volume of the organ and increased cardiac output; a slowing of the pulse; and a slowing of the conduction of nerve impulses throughout the heart. These effects are produced at near toxic doses and are frequently accompanied by gastrointestinal upsets, caused probably by a stimulation of the vomiting centre by reflexes set up by the cardiac effects. The diuretic effect of digitalis is secondary to its improvement of the circulation.

Digitalis is indicated in congestive heart failure from any cause, being most effective in cases of auricular fibrillation. Prolonged use leads to cumulation of the drug in the body because of its slow excretion and destruction. Because of this cumulation and because of the small margin between therapeutic and toxic doses. untoward effects are not uncommon and may consist of mild gastrointestinal upsets and visual disturbances or more alarming cardiac irregularities. (F. O. K.)

DIGNE, chief town of the *département* of Basses-Alpes, southeastern France, lies on the left bank of the Bléone river, 190 km. (118 mi.) E.S.E of Grenoble by road. Pop. (1954) 8,098. The Ville Haute stands on a mountain spur, dominated by the present cathedral of St Jérôme (late 15th century, largely restored). The majestic old cathedral of Notre Dame du Bourg (13th century, part earlier) is disused. The Boulevard Gassendi, the chief artery of the town, separates the Ville Haute from the Ville Basse. other main thoroughfares being the boulevards Victor-Hugo and Gambetta. The hot and cold springs (3 km.) are valued for rheumatism and other illnesses. Digne is on the Nice branch of the Grenoble–Marseilles railway and has good road connections. Tourism is the chief industry. Agriculture includes sheep rearing and the cultivation of lavender and of orchards which have made Digne famous for its preserved fruits and confections, honey and yellow wax. The annual lavender fair is held in September. The Dinia of the Romans, Digne was the capital of the Bodiontii. From the early 6th century at least it has been an episcopal see, in the province of Embrun until 1790 but in Avignon after 1802. It suffered in the religious wars of the 16th–17th centuries.

DIGOEL, a large river of southwest Netherlands New Guinea. Length *c.* 326 mi. It rises in the Star mountains, part of the main east-west mountain system of central New Guinea, and flows southaard across an extensive, low and forested plain, in which there are many broad swamps in the rainy season. The river is navigable for small ocean vessels as far as Tanahmerah, the chief settlement, founded in 1927 as an internment camp for political prisoners from the Netherlands Indies. (D. W. F.)

DIJON, a city of eastern France, capital of the *département* of Côte-d'Or, lies at the foot of the Burgundian plateau where the valley of the Ouche river opens out into the Saône plain, 323 km. (208 mi.) S.E. of Paris by road. Pop. (1956) 106,267.

Despite the development of new districts. where large blocks of flats alternate with houses, the commercial centre is still in the old city. Along the narrow winding streets are wooden 15th-century houses together with bourgeois dwellings of the following century, with sculptured façades, and the magnificent town houses of members of the *parlement* dating from the 17th and 18th centuries. There are many outstanding buildings. The cathedral of St. Bénigne in the west of the old city, originally an abbey church, was rebuilt in the 14th century but preserves an 11th-century crypt. The church of St. Philibert, close by, has a Romanesque nave, an early 16th-century steeple and a doorway of the 16th and 18th centuries. Notre Dame church is famous for the grace of its interior and for the magnificent carvings on the western faqade with its triple doorway. The faqade of St. Michel's church is 16th and 17th century and it, too, has a finely sculptured doorway. The former Jesuit church (now the city library), the Carmelite church (now Brune's barracks) and the chapel of Ste. Anne are examples of 17th-century religious architecture.

In the centre of the old city stands the splendid group of buildings which was the palace of the dukes of Burgundy and is now the *hôtel de ville.* This former ducal palace was built in the 14th and 15th centuries and extended in the 17th and 18th centuries; two towers. the guardroom and the kitchen survive from the original building. The *hôtel de ville* contains the city archives and the Musée des Beaux-Arts (founded 1785); in a very rich collection are the magnificent tombs of Philip the Bold and John the Fearless, dukes of Burgundy, and also the Master of Flémalle's picture "The Nativity." The two tombs were transferred to the museum from the Chartreuse (Carthusian monastery) of Champmol founded by Philip the Bold so that its chapel might provide a mausoleum for his dynasty. The Chartreuse was destroyed in 1793 and a lunatic asylum built on the site in 1840; the only surviving parts of the original building are the doorway of the chapel and the *puits* de *Moïse,* a pedestal that once supported a great

calvary, by Claus Sluter. The Palais de Justice, to the south of the ducal palace, contains the "golden" room in which the *parlement* of Burgundy met in the 16th century. The archaeological museum is near the cathedral in the dormitory of the former Benedictine monastery.

The park was laid out in the 17th century at the end of the mile-long Cours du Parc south of the town. On the west the Jardin le l'Arquebuse adjoins the botanic garden.

Dijon university (founded 1722) has faculties of law, science and letters and a school of medicine. From being scattered in the centre of the city, it mas, in the late 1950s and early 1960s, gradually being moved to great buildings outside, the new faculty of sciences having been opened in 1957. There are also a higher school of commerce, a school of fine arts and a conservatory of music. The city library and the archives of Côte-d'Or and the former province of Burgundy are particularly important. Several learned societies exist in Dijon. the best known being the Académie des Sciences-Arts et Belles-Lettres, founded in 1740.

Dijon is an important communications centre. The road from Paris to Geneva there crosses that from Nancy to Lyons and the Mediterranean. The station is one of the chief ones on the Paris–Lyons–Marseilles railway and there the line branches to Lausanne and Milan. The Burgundy canal, joining the Saône and Seine, formerly was much used. There is an airfield for tourist traffic.

Dijon possesses a large number of industries, most of them of only secondary importance: metalwork, autocycles (motor-assisted bicycles) and bicycles, electrical and optical material, shoes, tobacco and pharmaceutical products; and there are railway works. Celebrated foods produced in Dijon are gingerbread, mustard and a black currant liqueur called cassis. The city is important as a tourist and market town, an administrative and intellectual centre, and the seat of a bishop (from 1731).

The name of Dijon (Divio, Castrum Divionense) does not appear until the 6th century but the city is much older as the site has always been a great road centre. Many traces of Roman occupation have been discovered and show that the place was then important; it was fortified against the Germanic invasions. The accounts of St. Bénigne's martyrdom have no historical foundation; indeed, the very existence of the saint is doubtful. As soon as the Capetian duchy of Burgundy was founded in the 10th century (see CAPET) Dijon became the Burgundian capital, but it was not until the second ducal dynasty, that of Valois (*q.v.;* 1364–1477), that Dijon really took on the character of a provincial capital, which it retained after Burgundy was reunited to the French crown. (See BURGUNDY.) The annexation of the then Spanish Franche-Comté (*q.v.*) by France in 1678 extended the distance from Dijon to the French frontier and thus began an especially brilliant epoch in the history of the city. Many fine buildings were put up and by the 18th century it had become one of the chief intellectual centres in France. This prosperity was brought to an end by the Revolution, which suppressed all provincial institutions, and thereafter the city declined. It was occupied by the Austrians in 1814 and 1815. The coming of the railway in 1851 brought Dijon to life once more—the citizens had insisted that the line from Paris to Lyons should make a detour to pass through their city. From that day onward Dijon grew steadily—at the beginning of the 19th century it had 20.000 inhabitants, in 1939 there were 95,000. In the Franco-German War the city was occupied by the Germans on Oct. 30, 1870, but recaptured by Garibaldi a few days later and unsuccessfully attacked from Jan. 21 to 23, 1871. In World War II Dijon was in German hands from June 1940 until Sept. 11, 1944. (P. Gs.)

DIKE (DYKE), a trench dug out of the earth for defensive and other purposes (cf. Dutch *dijk*, Ger. Teich). Water naturally collects in such trenches, and hence the word is applied to natural and artificial channels filled with water, as appears in the names of many narrow waterways in East Anglia. "Dike" is also used of the bank of earth thrown up out of the ditch, and so of any embankment. dam or causeway, particularly the defensive works in the Netherlands, the Fen district of England and other low-lying districts which are liable to flooding by the sea or rivers. (See HOLLAND; FENS; RIVER AND RIVER ENGINEERING.) In Scotland any wall, fence or even hedge used as a boundary is called a dike.

In geology the term is applied to wall-like masses of rock (sometimes projecting beyond the surrounding surface) which fill up vertical or highly inclined fissures is the strata. See GEOLOGY: Physical Geology.

DIKRAN: see TIGRANES.

DILAPIDATION, the process of falling into a state of decay or disrepair. In English law, the word is usually used in the plural to mean the disrepair of premises let under a tenancy or occupied by the incumbent of an ecclesiastical benefice.

At common law a tenant is liable for waste (*q.v.*), but in most cases the lease or tenancy agreement expressly provides for liability for repairs. The duty of repairing may be placed wholly on the landlord. wholly on the tenant or partly on each: and sometimes some or all of it is placed on neither. In short tenancies (*e.g.,* for three years or less) and in tenancies of offices and apartments, the landlord is usually made liable for external and structural repairs and the tenant for internal decorative repairs, these conditions being sometimes subject to an exception of fair wear and tear. For longer tenancies, especially of entire buildings, the tenant is usually made liable for most or all of the repairs. But since the Housing act. 1961. the landlord of any dwelling house let for less than seven years is liable, despite any contrary agreement, to repair the structure and exterior and most of the service installations Subject to this, liability depends on the terms of the lease negotiated.

If a landlord considers that his tenant has failed in his obligations to repair. he usually instructs a surveyor to prepare a .'schedule of dilapidations," which itemizes every defect alleged to constitute a breach of covenant, usually by stating the action required to remedy the defect. This schedule is then served on the tenant, accompanied by a notice requiring him to make good the breaches of covenant and to compensate the landlord. After allowing a reasonable time for compliance, and subject to any negotiations as to the propriety of any items, the landlord may proceed against the tenant for outstanding dilapidations. If the lease was granted for not less than seven years and has at least three years still to run, the Leasehold Property (Repairs) act, 1938 (as amended), protects the tenant against unreasonable pressure from the landlord. Within 28 days of the landlord's notice being served on him, the tenant must serve on the landlord a counter-notice claiming the protection of the act. Thereafter, the landlord can neither sue for damages nor proceed to forfeit the lease without the leave of the court; and leave can be given only on certain specified grounds; *e.g.,* that the cost of immediate repair mould be small in comparison with the cost of repair in the future. Subject to the act, the landlord can usually sue the tenant for damages or (subject to the power of the court to grant relief) for forfeiture or for both. Damages are limited to the diminution in the value of the landlord's reversion, and no damages are recoverable if at the end of the tenancy the premises are to be demolished or to be altered structurally in such a way as to make repairs valueless. The court may also grant relief against unreasonable claims with respect to internal decorative repairs.

Under ecclesiastical law, the liability of the incumbent of a benefice for keeping in repair the rectory, vicarage or other house of residence, together with certain other property, was modified by the statutory provisions contained in the Ecclesiastical Dilapidation-measure. 1923, as amended. This establishes an elaborate system, under the church commissioners, providing for inspection and report every five years by a surveyor appointed by the diocesan dilapidations board. Willful dilapidations have to be made good by the incumbent forthwith, but other dilapidations are paid for out of a repair account maintained by a repair rate charged on the revenues of the benefice; and the church commissioners may lend money for repairs. (R E. My.)

United States.—In the United States the term dilapidation is not often used, but some statutes provide that the lessor of any building intended for the occupation of human beings must, in the absence of an agreement to the contrary. place the premises in a condition fit for occupation and repair all subsequent dilapi-

dations. Wherever used, the term refers to a state of partial ruin resulting from a failure to make necessary repairs.

See also LANDLORD AND TENANT. (H. H. LR.)

DILATATION, a term used in medicine to denote the widening or enlarging of a cavity, orifice or hollow organ beyond its normal dimensions. Dilatation may arise pathologically from obstructions in hollow organs such as those of the gastrointestinal tract and the urinary and biliary tracts. Fluid accumulates above the obstruction, leading to dilatation. This usually causes an increased muscular activity above the obstruction, which produces a sensation of pain and may ultimately lead to a thickening of the muscular wall. Following the removal of the obstruction the organ may or may not assume its original dimensions, depending on the elasticity of its muscular layers. In dilatation of the ventricles of the brain, expansion of the brain is limited by the rigidity of the skull, hence hydrocephalus (*q.v.*) results. The term is used in connection with hedrt disease when the muscle is weakened and one or more cavities dilated. thus causing interference with normal circulation. Digital dilatation is employed in diagnosis, and "dilatation" also refers to operative procedures when an orifice or passage is dilated with an instrument. (F. L. A.)

DILEMMA. In traditional logic, a *dilemma* is any one of several forms of inference in which there are two major premisses of hypothetical form and a disjunctive minor premiss; *see* the full list in the article LOGIC.

It is not necessary that a dilemma should have an unwelcome conclusion. But this was often the case in illustrations, the dilemma having been originally a device of rhetoric for confuting an opponent. Hence in common usage the word has come to mean a situation in which each of alternative courses of action that are open leads to some unsatisfactory or ill consequence.

Some traditional logicians have used the term *polylemma* for a generalization of the dilemma in which the minor premiss is a disjunction that is more than twofold and the number of major premisses is correspondingly increased. For example, the constructive trilemma: $A > D, B > D, C \supset D, A \vee B \vee C$, therefore D.

In mathematics, this form of inference is more usually known as *proof by cases.* (AO. C.)

DILIYIANNIS (DELYANNES), **THEODOROS** (1826–1905). Greek statesman, five times prime minister and for many years the exponent of a resolute anti-Turkish policy, was born at Lankadia, Peloponnese, on Jan. 14 (new style; 2, old style), 1826, and studied law at Athens. In 1862 he became minister for foreign affairs. From Jan. 1867 to Feb. 1868 he was minister in Paris. In the ministry of 1877 he voted for war with Turkey, and on its fall entered the cabinet of Alexandros Koumoundouros as minister for foreign affairs. He was a representative of Greece at the Berlin congress in 1878. From this time forward, and particularly after 1882, when Kharilaos Trikoupis again came into power, the duel between 'these two statesmen dominated Greek politics. Diliyiannis first formed a cabinet in 1885, but resigned the following year when his warlike policy ended in failure. He returned to power in 1890, with a radical program, but did not tackle the financial crisis. This led to a conflict with the king, who dismissed him in 1892. In 1895, however, he again became prime minister. He was thus at the head of affairs during the Cretan crisis and the opening of war with Turkey. The humiliating defeat which ensued caused his fall in April 1897, though this time the disastrous war policy had been forced on him somewhat against his will. He kept his own seat at the election of 1899, but his following dwindled. He was again prime minister in 1902–03 and finally returned to power in Dec. 1904. On June 13, 1905, he was murdered for his measures against gambling houses.

DILKE, SIR CHARLES WENTWORTH (1843–1911), British statesman whose highly successful political career was tragically broken by involvement in a notorious divorce case, was born in London on Sept. 4, 1843. the son of the 1st baronet of the same name. He was educated privately and at Trinity hall, Cambridge, where he was senior legalist, president of the Union and a notable rower. After leaving Cambridge he made a world tour and recorded his impressions in *Greater Britain* (1868), a highly successful work in which he developed one of the dominant ideas of his life—the view that the English race, freed of the trappings of a monarchical and hierarchic society, would exercise an increasingly powerful role in the world.

Dilke was elected to parliament in 1868 as Radical member for Chelsea. In 1869 his father died and he succeeded to the baronetcy and to substantial family property. Throughout his first parliament Dilke took up an extreme left-wing position, and in the winter of 1871–72 he delivered a series of speeches strongly critical of the monarchy. He was always a theoretical republican, but except for this brief and unsuccessful foray he took no action in this direction. After 1874, with the Liberals in opposition, Dilke moved closer to his official leaders, and he was entrusted with many important speeches on foreign policy. Extensive travel and a good mind for detail had by this time given him an encyclopaedic knowledge of the minutiae of foreign policy. He also established a close partnership with Joseph Chamberlain (*q.v.*). When Gladstone formed his second government in 1880, Dilke and Chamberlain fought hard to secure two cabinet seats, but they had to compromise, and it was Dilke who got the worst of the deal, remaining outside the cabinet as undersecretary for foreign affairs under Lord Granville. After declining an offer to be chief secretary for Ireland outside the cabinet, Dilke was finally promoted to the cabinet as president of the local government board in 1882. He was responsible for the setting up in 1884 of the royal commission on the housing of the working classes, and himself presided over a membership which included the prince of Wales and Cardinal Manning. He failed to promote a government of London bill, but he was highly successful in negotiating with the Tories a redistribution bill which passed into law as an agreed measure in 1885 and which gave the basic shape to the modern electoral map.

Apart from these departmental activities Dilke was eager, with Chamberlain, to press the general Radical point of view within the cabinet. This eagerness led him to submit frequent resignations to Gladstone. It also led him to a position of great political promise. By the end of the government, in June 1885, Disraeli's prophecy of 1879 that Dilke would be prime minister looked plausible. Gladstone could not long continue, and the leadership of the party would probably then go to the Radicals. Although less well known and with smaller powers of political impact and decision than Chamberlain. Dilke would have been more acceptable to the house and to the bulk of the Liberal party.

The issue was never put to the test, for, a month later, Dilke was cited as corespondent in a sensational divorce suit. Virginia Crawford, the 22-year-old wife of'a Scottish Liberal lawyer. told her husband that she had been Dilke's mistress since 1882. Dilke strenuously denied the story and when the case was heard, in Feb. 1886, there was adjudged to be no evidence against him. although Crawford got his divorce. A press campaign, in which W. T Stead of the *Pall Mall Gazette* took the lead, made this an inadequate victory for Dilke. To try to clear his name he got the queen's proctor to reopen the case, and a second hearing took place in July 1886. This went heavily against Dilke. One of his public difficulties was that. although he rebutted Mrs. Crawford's allegations, he was forced to admit to having been her mother's lover.

Dilke never again held office. Six years later, however, he returned to the house of commons as member for the Forest of Dean and held that seat until his death. He mas active in the house of commons as a military expert and as an exponent of advanced labour legislation. He did much to encourage trade unionists in politics. and in 1894 it was suggested that he should become leader of the Independent Labour party. Much of his energy, however, was devoted to gathering evidence that might clear his name. He was assisted by his second wife, formerly Mrs. Mark Pattison, who had married him immediately after the scandal broke and who retained complete faith in his innocence. The evidence they accumulated showed decisively that much of Mrs. Crawford's story was a fabrication; whether there was a substratum of truth remains uncertain. Dilke died in London on Jan. 26, 1911.

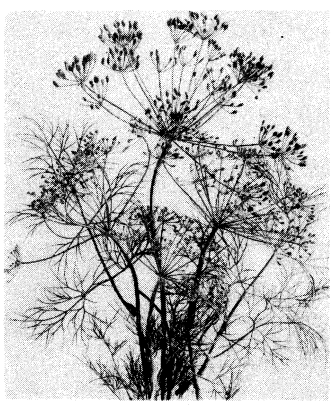
Apart from *Greater Britain,* Dilke's principal works were: *The Fall of Prince Florestan, a Satire* (1874), *The Present Position of European Politics* (1887), *The British Army* (1888), *Problems of Greater Britain,* 2 vol. (1890), *Imperial Defence* (with S. Wil-

kinson, 1892), *Army Reform* (1898) and *The British Empire* (1899). (R. J.)

See S. Gwynn and G. M. Tuckwell, *Life of Sir Charles Dilke,* 2 vol. *(1917);* Roy Jenkins, *Sir Charles Dilke, a Victorian Tragedy* (1958).

DILL, SIR JOHN GREER (1881–1944), British field marshal, a leading figure of World War II, was born at Lurgan, N. Ire., on Dec. 25, 1881, and was educated at Cheltenham college. After service in the South African War and World War I he became successively commandant of the British army staff college and director of military operations. Recognized as the foremost British strategist, he would have been the natural choice for chief of the imperial general staff in 1937 or 1939; but when war broke out in the latter year he remained in command of the 1st corps in France until brought home in April 1940 to become chief of the imperial general staff in the following month. As such he was the government's chief military adviser until the end of 1941, and was largely responsible for the decisions to reinforce Egypt with 150 tanks in Aug. 1940, in spite of the shortage at home. and to send the expedition to Greece in March 1941. Perhaps Dill's greatest services were rendered as the prime minister's military representative and head of the British joint staff mission in Washington, D.C. (1941–44). His clear mind, charm and integrity won the admiration and affection of soldiers of both nations, and his friendship with Gen. George C. Marshall did much to cement Anglo-U.S. solidarity. He died at Washington on Nov. 4, 1944, and his monument stands in the national cemetery at Arlington, Va. (J. R. M. B.)

DILL *(Anethum graveolens),* a fennellike annual or biennial herb of the family Umbelliferae, native to the countries bordering the Mediterranean and widely cultivated in Europe, India and North America. The entire plant is aromatic and the leaves, small stems and immature umbels are used for flavouring soups, sauces and particularly pickles. The seed is employed as a condiment and drug. Dill herb oil, distilled from the plant at early fruiting stage, has largely replaced the whole herb in commercial uses as a flavouring and seasoning agent. The United States—Oregon and Idaho—and Hungary are the principal producers of dill herb oil. The whole seeds and the seed oil have carminative properties and have been used in treating flatulent colic. (Q. J.)



J. HORACE MCFARLAND COMPANY

DILL (ANETHUM GRAVEOLENS)

DILLENIUS (DILLEN), **JOHANN JAKOB** (1687–1747), German botanist, author of several descriptive works on plants, was born at Darmstadt in 1687 and educated at the University of Giessen. In 1721 he moved to England. He became professor of botany at Oxford where, on April 2, 1747, he died. His most notable works are *Hovtus Elthamensis,* 2 vol. (1732), containing descriptions and 324 plates of illustrations of plants in the Sherard garden at Eltham, and *Historia Muscorum* (1741), describing and illustrating over 600 species of "mosses," including true mosses, liverworts, lycopods, algae, lichens, etc. An account of the life and works of Dillenius is given in *The Dillenian Herbaria* by G. Claridge Druce (1907). (J. W. Tt.)

DILLMANN, (CHRISTIAN FRIEDRICH) AUGUST (1823–1894), German orientalist and biblical scholar, to whom in large part the 19th-century revival of interest in Ethiopic studies is attributable, mas born at Illingen on April 25, 1823, and studied at Tubingen. He held chairs of theology at Tübingen (1853), of philosophy at Kiel (1854), and of theology at Giessen (1864) and Berlin (1869). He died on July 4, 1894.

Dillmann was author of an Ethiopic grammar (1857) and lexicon (1865), and he also prepared editions of Ethiopic texts of a number of books of the Old Testament, as well as of some noncanonical books. His commentary on Joh (1869) stamped him as one of the foremost Old Testament exegetes. His renown as a theologian was mainly founded on a series of commentaries on other Old Testament books.

DILLON, HAROLD ARTHUR LEE, 17TH VISCOUNT (1844–1932), antiquary and authority on arms and armour, was born in London on Jan. 24, 1844. He entered the Rifle brigade, served in India and Canada, and retired from the army in 1874. Thereafter he devoted himself to antiquarian studies and produced a long and valuable series of papers. The most considerable of these was a study of Calais and the Pale under the English occupation during the Hundred I-ears' War (*Archaeologia,* 1893). In 1895 he was appointed as the first curator of the armouries of the Tower of London. He reorganized the armouries, swept away false traditions and conducted valuable research among the state papers. In 1904 he published in facsimile the Jacobe album, which had been acquired on his advice by the Victoria and Albert museum, and he was able to connect its drawings with many surviving armours. He served as secretary and later president of the Society of Antiquaries of London, and he mas appointed to the boards of trustees of the British museum, the Wallace collection and the National Portrait gallery. He died on Dec. 18, 1932.

See an obituary notice and a bibliography of his writings in the *Proceedings of the British Academy,* vol. xviii, p. 335 (1932). (J. G. MN.)

DILLON, JOHN (1851–1927), Irish nationalist politician, one of the leaders of the Irish parliamentary party in the struggle for Home Rule! was born near Dublin on Sept. 4, 1851. the son of John Blake Dillon, a leader of the Young Ireland movement. John Dillon was educated at Cniversity college, Dublin, and qualified as a surgeon. He became one of C. S. Parnell's most dynamic young colleagues and accompanied him to the United States in 1879; while abroad, he was elected member of parliament for Tipperary (1880).

Dillon was one of the most vehement of the leaders of the Land league, and in 1881 he was imprisoned, his health being seriously impaired by his prison treatment. He had to resign his seat in parliament in 1883, but was in 1885 elected member for East Mayo, which he represented until 1918. He was closely associated with the "plan of campaign" of William O'Brien (*q.v.*) and was several times prosecuted in 1886–87 and was imprisoned for six months in 1888. After his release he went to Australia to raise funds for Parnell. Again arrested on his return in 1890, he escaped with O'Brien to France and thence to the U.S. Both men returned when the crisis of Parnell's involvement in Capt. W. H. O'Shea's divorce case arose in 1890; after inconclusive conferences with Parnell they declared against his continuance as leader. When the Irish party then split, the anti-Parnellite majority formed the Irish National federation, of which Dillon became chairman in 1896. In 1897 he organized a convention of the Irish people from all parts of the world which about 2,000 delegates attended.

After years of confusion and bitter recrimination, the party was reunited in 1900 under the Parnellite, John Redmond. Dillon showed great magnanimity in accepting service under his former rival. Although he was a staunch upholder of Parnell's strategy of independent Irish opposition in parliament, Dillon became increasingly distrustful of conciliatory efforts by the Conservatives. He declined to enter the Land conference promoted by George Wyndham in 1902, and believed that Conservative policy under A. J. Balfour was directed to allay any discontent by constructive reform and "killing Home Rule by kindness." In 1905 Dillon advised Irishmen in Great Britain to vote Liberal and he supported all the reforms of the Liberal governments. On the outbreak of World War I he was tortured by divided loyalties. He had been keenly apprehensive when the Irish Volunteers were organized in 1913, considering them a threat to the discipline and cautious guidance of the official party, and he gave positive, though reluctant, consent to Redmond's appeal for whole-hearted resistance in Ireland to German aggression. But he vehemently opposed the extension of military conscription to Ireland, both because it would strengthen the Sinn Fein agitation, and because he never accepted the view that Irish and imperial interests must coincide. As the party became more deeply committed to the imperial war effort, the relations between Redmond and Dillon grew

increasingly strained. Dillon refused to take part in the Irish convention set up by Lloyd George in 1917 to reach a settlement. On Redmond's death in 1918 he became leader of the party, but it was widely discredited in Ireland, and Sinn Fein won an overwhelming victory in the general election of Dec. 1918, Eamon de Valera defeating Dillon in East Mayo. Dillon died Aug. 4, 1927

See F. S. L. Lyons, *The Irish Parliamentary Party, 1890–1910* (1951); D. Gwynn, *Lije of John Redmond* (1932). (D G.)

DILTHEY, WILHELM (1833–1911), German philosopher, who devoted himself mainly to literary criticism and to the history of ideas, was born at Biebrich on Nov. 19, 1833. He was successively professor at Basle (1866), at Kiel (1868), at Breslau (1871) and at Berlin (1882; in succession to R. H. Lotze). He died at Seis, near Bolzano, on Oct. 1, 1911.

Dilthey's philosophy is of Kantian inspiration, but deeply influenced by British empiricism and by French positivism. He believes that the central place once held in philosophy by metaphysical speculation must now be given to the theory of knowledge which. however, must learn to give due recognition to the part played in cognition by the will as well as by sensation and thought. Several fundamental concepts (*e.g.,* reality, causality) can only be defined by reference to volitional experience. We must also distinguish between cognitive statements, which refer to existing things. and value judgments and imperatives, which express attitudes of feeling or will. Metaphysics, while it cannot claim to be knowledge of reality, has importance as expressing a total attitude to life (Weltanschauung), a function which it shares with religion and art; and the great metaphysical systems may still be profitably studied from this point of view. Dilthey holds that there are three main types of Weltanschauung (naturalism, the idealism of freedom and objective idealism) which constantly recur in religion, art and philosophy alike and represent three fundamentally different ways of reading experience.

His greatest philosophical project, which occupied him throughout his career, was to write a "Critique of Historical Reason" which might do for the historical and social studies (*Geisteswissenschaften*) something like what Kant had done for the natural sciences. In the course of this work he broke new philosophical ground by his study of the relations betneen lived experience, expression and understanding (Erlebnis, Ausdruck and *Verstehen*); the interdependence of self-knowledge and knowledge of other persons; and the logical development from these to the understanding of social groups and historical processes. The subject matter of the historical and social studies is the human mind. not as it is enjoyed in immediate experience nor as it is analyzed in psychological theory, but as it manifests or "objectifies" itself in languages and literatures, actions and institutions. Dilthey holds that the historical consciousness, the consciousness of the historical relativity of all ideas, attitudes and institutions. is the most characteristic and the most challenging fact in the intellectual life of our time. It shakes all belief in absolute principles, but it thereby sets us free to understand and appreciate all the diverse possibilities of human experience.

Dilthey's chief publications were: Leben *Schleiermachers* (1870); *Einleitung* in die Geisteswissenschaften (1883); Die *Jugendgeschichte Hegels* (1905); Das *Erlebnis und* die *Dichtung* (1905); Das *Wesen* der *Philosophie* (1907); and *Der Aufbau* der geschichtlichen Welt in den *Geisteswissenschaften* (1910). Much other valuable material. both philosophical and historical, previously unpublished or published piecemeal. was brought together posthumously in his *Gesammelte Schriften,* 12 vol. (1913–36).

See H. A. Hodges, *The Philosophy of Wilhelm Dilthey* (1952).

(*Hr. A.* H.)

DIMENSION, a term used in geometry to denote a magnitude measured in a specified direction, as, for instance, along a diameter or a principal axis or an edge. A point is said to be without dimension; a line has the one dimension of length, a surface has the two dimensions of length and breadth, while a solid has the three dimensions of length. breadth and thickness. Since the lengths of lines, the areas of surfaces and the volumes of solids are represented respectively by linear, quadratic and cubic algebraic expressions, the term dimension has been carried over into algebra. Thus quadratic, cubic, biquadratic algebraic expressions (*e.g.,* x^2, x^3, x^4) or equations are said to be respectively of two, three, four dimensions (or degree or order). Similarly, the term dimension is used in mechanics with reference to the units of time, length and mass and various derived units (see DIMENSIONAL ANALYSIS), and it occurs in many other parts of physics, notably in the theory of electricity and magnetism (see PHYSICAL UNITS).

The fundamental descriptive proposition concerning space, as we are accustomed to it in experience, is that space is a continuum (a continuous or unbroken distribution of points) having three dimensions. The intuitive basis of this proposition may be elucidated as follows. If on a curve (or line) we mark certain points (elements without dimension), we separate the curve into parts bounded by the points in such a way that we cannot pass along the curve from one part to another without encountering and passing over one of these marked points. Since the curve may be separated into parts by elements without dimensions, it is itself said to be a figure having one dimension. But a surface cannot be thus separated into parts by marking isolated points on it; for, in going from one place to another on the surface, we can always avoid passing over these marked points by going around them. If we draw in the surface a suitable closed curve (a figure of one dimension), then the surface is separated into parts in such a way that we cannot move over the surface from one part to another without encountering and passing over a point on the curve. Since a surface cannot be separated into parts by points (figures without dimension) but can be separated into parts by a suitable figure of one dimension, we say that a surface itself has two dimensions. Similarly space cannot be separated into parts by isolated points or curves or both taken together, while it can be so separated into parts by means of a closed surface (a figure of two dimensions). For this reason we say that space has three dimensions. This, according to Henri Poincaré, is the fundamental qualitative ground for ascribing three dimensions to the usual space of experience.

The mathematician introduces three co-ordinates to represent the points of ordinary space and much of his analysis of its properties is carried out algebraically. Now the algebraic analysis is competent to deal with sets of any number n of co-ordinates. Thus algebraic geometry leads readily to the conception of spaces of any number n of dimensions; and these have been extensively treated, though no one has a lively mental picture of spaces having more than three dimensions. Popular interest in these higher spaces (as opposed to the interest of mathematicians in them) has been centred principally around the concept of the "fourth dimension." the designation often given to time in Einstein's theory of relativity. But the number of dimensions of these higher spaces is unlimited; and. in fact, several kinds of space with an infinite number of dimensions have been investigated.

That the higher spaces may be given a concrete representation in terms of experience is shown by the fact that the totality of straight lines in our usual space of three dimensions constitutes a veritable space of four dimensions (see PROJECTIVE GEOMETRY). This arises from the fact that four independent co-ordinates are necessary to define completely the position in space of a line of unlimited Extent. Therefore a geometry in which the elements are the lines of ordinary space is a geometry of four dimensions.

(R. D. CA.)

DIMENSIONAL ANALYSIS. The principal use of dimensional analysis is to deduce from a study of the dimensions of the variables in any physical system certain necessary limitations on the form of any possible relationship between those variables. The method is of great generality and mathematical simplicity. The name dimensional analysis is comparatively new; Lord Rayleigh, one of the earliest and principal exponents of the method, called it the principle of similitude.

This method is not capable of completely determining the unknown functional relationship. In the simplest cases it can give everything except a numerical factor of proportionality; for example. it can show that the time of siring of a simple pendulum is independent of its mass and proportional to the square root of its length, but cannot determine the constant of proportionality.

In more complicated cases, where there are a larger number of variables, it can show that the variables must enter the function in certain definite combinations, thus reducing the number of the undetermined functional relations. Perhaps its most important use is in connection with problems so complicated that not only may an exact solution by purely mathematical methods be impossible, but also it may be impossible even to give a precise and detailed formulation of the fundamental equations from which the solution is to be found. Many problems of airplane or ship design are of this nature. In these cases a knowledge of the necessary limitations on any possible functional relationship makes it possible to cover completely the range of all possible experimental relationships with a much smaller number of experiments than would be necessary otherwise. In this capacity it now receives the widest application in engineering. Other uses of dimensional analysis are: as a simple check against error in writing out equations or their solutions; in changing units from one system to another; and in theoretical investigations in making preliminary orienting surveys to explore promising lines of attack.

The methods of dimensional analysis depend to an important extent on the properties of the systems of measurement in ordinary scientific use and presuppose the use of such systems. These systems are subject to certain definite limitations. It is a matter of extensive past experience that all the physical systems ordinarily encountered can be completely described in terms of measurements of the restricted and conventional scientific sort. It is this past experience, the mere existence of which is not always obvious to an uncritical glance, that is capitalized on in obtaining the results of dimensional analysis. For, since the system of measurement is subject to limitations and has definite properties, the fact that it can be applied to such a wide variety of situations implies the possession of certain properties by those situations; it is these properties which are brought explicitly to light by dimensional analysis. In respect to this degree of dependence on past experience dimensional analysis differs from no other scientific enterprise; for it is never possible to obtain factual information about any concrete physical situation by pure ratiocination, but any factual information which emerges in the final mathematical formula had to be explicitly inserted into the mathematics at an earlier stage.

Since it is basic to everything that follows, we begin our detailed argument with an examination of such properties of the systems of scientific measurement as are necessary for our purpose. Many different systems of measurement are in general possible, the desirability of any particular system depending on the purpose in hand and on the physical system to which the measurement is applied.

The primary purpose of a system of measurement may be taken to be precise description. In practice one method of securing precision has proved to be so overwhelmingly superior to any other that it alone survives in serious scientific usage; this is by the specification of numbers. Measurement, then, in a very broad sense means description by the assigning of numbers. Given a concrete physical system, it is possible to assign various numbers to it by performing various sorts of physical operation upon it. The number obtained by any particular kind of physical operation constitutes a particular kind of measurement. Different aspects of the system are dealt with by employing different sorts of measuring operation. If one were dealing with only a single isolated physical system a high degree of arbitrariness would be permissible in the measuring operations by which the system is described. In practice, however, a large part of this arbitrariness disappears because of the fact that we desire to deal with large numbers of physical systems. This leads to the requirement not only that the physical operations back of the measurements be easily applicable to the widest variety of systems, but also that they be such that it is possible to express in relatively simple mathematical terms correlations between the results of measurements on different systems. The discovery of measuring operations which satisfy these requirements came only after hundreds of years of experience and experimenting, and demanded a wide acquaintance with the factual content of our environment.

The requirements of convenient application to many systems and of adaptability to .mathematical correlation are not sufficient, however. to determine uniquely the measuring operations; a great deal of flexibility remains. As a matter of fact, a wide variety of systems and methods of measurement are in scientific use today.

We now consider in some detail the properties of the systems of measurement in actual physical use, starting from the general point of view that a physical measurement is a number obtained by a particular kind of physical operation. The sort of measurement that it is, is determined by the sort of operation that it is.

Length, Weight and Time.—Consider, for example, length. We may define this as the number obtained by the operation of applying a metre stick to successive positions on a body, counting the number of applications, and reading the fractional part from the divisions inscribed on the metre stick. This procedure is applicable to a wide variety of physical systems. From the point of view of maximum precision, once having defined length by this single definite procedure, the name length should be applied only to numbers obtained by this one procedure. In practice, however, there prove to be whole families of operations giving numbers which are either undistinguishable from the numbers given by the defining operation or else are related to them by a constant of proportionality: so that in practice the term length is given the extended meaning of a number obtained by any one of the family of operations.

The family of operations which is at present accepted as defining length may be divided into various subfamilies. Some of these subfamilies involve drastic physical changes in the measuring operations: such, for example, as measuring lengths by optical methods of triangulation, or by counting interference fringes. It is particularly necessary to subject the equivalence of widely different types of operation to fresh experimental check whenever the field of application is extended. Other subfamilies of operations, however, may be specified with very slight verbal changes. By far the most important of these involve the use of some fundamental measuring stick other than the one of the fundamental definition. For example, instead of specifying the metre stick as basic to the operations of measuring length, we may substitute a foot rule, keeping all the other verbal instructions the same. Strictly, it requires experimental confirmation to show that the verbally specified operations are still physically performable when foot rule is substituted in the specifications for metre stick. The recognition that the operations are performable with either is so deeply ingrained in all our experience that we usually do not realize, unless we stop to think about it, that we are saying something about the structure of the world when we say that a length may be measured either with a metre stick or with a foot rule. Dimensional analysis involves some of the consequences of the world being constructed in this way.

We designate the results of operating according to the specifications for measuring length as length in metres or length in feet. An inspection of what we do now shows that there is a simple invariant relation between the two sorts of length. The metre stick itself is an object whose length in feet can be determined, and similarly the length of the foot rule may be measured in metres. We express this by saying so many feet make a metre or a certain fraction of a metre makes a foot. Due consideration of this, together with an examination of the details of any concrete measuring operation, shows that the ratio of the length of any concrete object in metres to its length in feet is a constant, independent of the object, and equal to the number of metres in a foot or the length of the foot in metres. A generalization of this consideration evidently applies to measurement of length with any other primary standard of length, parasang, verst or what not. An immediate mathematical consequence of this application is that the ratio of the lengths, that is, the ratio of the length numbers, of any two concrete objects, both measured with the same primary standards, is the same, independent of what primary standard is used. We may express this by saying that relative length has absolute significance. This is only a special case of a general requirement exacted of any method of making any sort of physical measurement which is to be accept-

able for scientific use, namely: the requirement of the absolute significance of relative magnitude.

The possibility of maintaining the requirement of the absolute significance of relative magnitude has to be determined by fresh examination of the details of the measuring process for each new kind of measurement with which we are concerned. For instance, the measurement of weight is obviously an entirely different sort of measurement from the measurement of length. The operations for weighing may be specified in terms of an equal arm balance. It is not the place here to expand the details of the weighing process. It is evident, however, that certain of the same general results hold for measuring weights as for measuring lengths. We may measure weights in terms of different standards of weight. The weights of the same object in terms of different standards bear a fixed ratio depending on the relative magnitude of the standards, and the ratio of the weights of two different concrete objects is independent of the standard of weight. The requirement of the absolute significance of relative weight is satisfied. Detailed examination shows that the fact that it is satisfied involves the physical law of the conservation of weight—the total weight of all the little weights into which we cut up a standard in order to make a new standard is the same as before it was cut up. There is no immediate, obvious connection between the physical property of conservation of weight and the geometrical properties of lengths placed end to end. We could not have predicted the possibility of the absolute significance of relative weight from the known absolute significance of relative length; but a fresh appeal to experiment is necessary.

Equally fundamental with length and weight is the measurement of time. The physical operations are again basically different: time does not recur; we pass over it only once. We cannot ask whether two intervals of time are equal by placing one interval in juxtaposition with another and comparing them, as we do two lengths or two weights. The operations are different; they are performed with clocks, according to rules which we shall not attempt to formulate in detail. However, the same results that we have found previously carry over to the new situation. In particular, we can specify operations by which the same interval may be measured in terms of different standard intervals. The ratio of the time numbers obtained for any specified time interval by operating with different standard intervals is always the same and depends only on the standards. Furthermore, the relative value of any two different concrete intervals is independent of the interval adopted as fundamental, or in other words, the requirement of absolute significance of relative magnitude is still met. A proof of this can be given by observation of the details of the measuring process with clocks, and involves the properties of the angles swept over by the hands of the clock. There is no immediate connection with the physical situation involved in the absolute significance of relative length or of relative weight.

The measurements of length, weight (or mass) and time are similar in that the operations make direct reference by one physical process or another to standards of length, mass or time. This involves the existence of different physical operations for mass, length and time analogous to the mathematical operation of addition for numbers. Furthermore, other properties of these physical operations are involved; for the resulting mass numbers, or length numbers, or time numbers are combinable according to the commutative or associative rules for mathematical addition. These requirements are obviously definitely restrictive; not every sort of simple physical operation satisfies them, for example, successive rotations through a finite angle about different axes. It required long experience to find such operations. There are still other sorts of physical operations which may be made the basis of other sorts of physical measurement which have similar properties. For example, forces may be measured by direct comparison with a standard force given by a definite deflection on a spring balance, and the physical operation for the addition of forces exists and consists in simply applying two spring balances in parallel to produce twice the force.

Secondary Measurements.—When we make a measurement in this way by direct reference to some concrete standard by means of a physical addition law, we may be said to be making a primary measurement. Most physical measurements are, however, more complicated, and are compounded of simple primary measurements. Such may be called secondary measurements. A simple example is velocity, which is ordinarily defined as the quotient of distance by time, or more exactly the quotient of a distance number by a time number. To measure the velocity of any concrete moving object, we measure the time required by it to traverse a known measured distance, and divide the distance by the time. The distinction between primary and secondary measurement is not absolute; in some cases either method may be used. An example is force. We have indicated above how to measure force as a primary quantity by reference to a spring balance. If we wish to define it as a secondary quantity we may utilize Isaac Newton's first law of motion, defining force as equal to mass times acceleration. In this case we obtain the force on any body by measuring the mass of the body and its acceleration, which in turn is obtained by measuring the change of velocity in a known time interval, the velocities themselves being obtained from measurements of distance and time. That is, when force is defined as a secondary quantity it is measured by making certain primary measurements (mass, length and time), which are then combined by mathematical rules. Other instances may be given of the possibility of either a primary or a secondary definition. Thus, velocity may be measured as a primary quantity by methods which have been described in detail. Or density, which ordinarily is treated as a secondary quantity and defined as mass divided by volume, may be treated as a primary quantity. In this latter case the difficulties of the necessary physical manipulations would obviously be prohibitively great except when dealing with gases at comparatively low pressures. Whether a given quantity is to be treated as primary or secondary is to a certain extent a matter of convenience, depending on the particular situation. In certain problems, for example, force is best treated as secondary, while in others more information is obtained by treating it as primary.

A certain aspect of the measurement of secondary quantities which is significant for our purposes is singled out and specified by giving the dimensional formulas of these quantities. Since the numerical magnitude of any primary quantity changes when the size of the corresponding primary standard is altered, the numerical magnitude of secondary quantities also changes when the size of the primary standards is changed. It is with this aspect that we are chiefly concerned in setting up dimensional formulas. Thus, the dimensional formula of velocity, defined as above, is LT^{-1}, or $[V] = [LT^{-1}]$, where the square brackets denote "dimensions of," and the equation stands for the verbal expression: the dimensions of velocity are the dimensions of length divided by time. This is merely a shorthand statement for: the number which, in the given system of measurement, measures the velocity of any concrete object, is obtained by multiplying the number which measures some distance associated with the object by the reciprocal of another number which measures some time associated with the object. In future applications the square brackets will usually be omitted as unnecessary. In the formula, T^{-1} indicates the reciprocal of a number obtained by the process for measuring T; the exponent -1 is to be associated with the number, not with the T: that is, the existence of another physical operation, the analogue of the mathematical operation of taking the reciprocal, is not involved or implied by this notation. The dimensional formula is obviously only a partial statement: it does not, for example, contain the detailed specifications for associating the measurements of length and time. The dimensional formulas apply to the primary quantities as well as secondary quantities. For instance, we denote the dimensions of length by L. The significance of this is that the number which measures a length is obtained by a definite physical procedure and the L recalls this procedure. Whenever L occurs in a dimensional formula, the connotation is that a number was obtained by the procedure specified for measuring length. By recalling this pro-

cedure we are in a position to find how the numerical magnitude changes when the size of the standard changes.

Dimensional Formulas.—Let us examine other examples of dimensional formulas What is the dimensional formula for acceleration? By what procedure do we obtain the number which measures acceleration? This is given by definition: acceleration is change of velocity in a given time so that the first result would be, [Acceleration] $=[(V_1-V_2)T^{-1}]$, where V_1 and V_2 apply to the final and initial velocities. In use this expanded dimensional formula is at once contracted; the first contraction is to write $[\mathrm{Acc}]=[VT^{-1}]$. That is, our purpose does not demand that we continually remind ourselves that a certain number was obtained by taking the difference of two velocities; but it is sufficient to remember only that the procedure for obtaining velocity entered our operations. This contraction obviously implies a very important restriction, which indeed is contained in the definition; we must measure the initial and final velocity in the same system of units. The reason that the contraction of the dimensional formula is permissible is that under the conditions the difference of two concrete velocities changes by the same factor as do each of the velocities separately when the fundamental units are changed. The dimensional formula for acceleration may now be contracted further by writing $[\mathrm{Acc}]=[LT^{-1}T^{-1}]$. Here we have expressed the fact that the number measuring a velocity is obtained by dividing a length number by a time number. A further contraction at once suggests itself: to combine the two T^{-1}'s into a single term, writing $[\mathrm{Acc}]=[LT^{-2}]$. But this contraction obviously involves another implication that the unit of time used in measuring velocity is the same as the unit of time used in measuring change of velocity. If this is not the case, we have left out a factor which determines how the number changes when we change the fundamental units. In practice, hybrid units are not uncommon. The performance of the brakes of an automobile might be described by saying that the car is brought to rest from a velocity of 30 m.p.h. in five seconds. Acceleration measured in this way is not covered by the dimensional formula above.

In all our analysis it is expressly supposed that all measurements of secondary quantities are such that the same primary units are consistently used at all stages of the measuring process. Under these restrictions we are justified in contracting $T^{-1}T^{-1}$ to T^{-2} because the number obtained by multiplying the reciprocal of a number obtained by measuring a concrete time interval by the reciprocal of another number measuring another concrete time interval, changes by the same factor as the inverse second power of the number measuring any other concrete time interval when the fundamental unit of time is changed. It appears, in general, that addition or subtraction of simple dimensional symbols is without significance for our purpose and may be ignored (as in the formulas for acceleration), and products may be combined by the simple algebraic rules for exponents.

The dimensional formulas of the simple secondary quantities, velocity and acceleration, examined thus far are of the same simple type; that is, products of powers of the primary quantities. This is true of a number of other such quantities, now given for illustration. The dimensions of force, defined as mass times acceleration, are MLT^{-2}; the dimensions of momentum, defined as mass times velocity, are MLT^{-1}; the dimensions of work or energy, defined as the product of force and distance (parallel to the force), are ML^2T^{-2}; the dimensions of moment of force, defined as product of force and distance (perpendicular to force), are also ML^2T^{-2}; and the dimensions of viscosity, defined as force per unit area per unit velocity gradient, are $ML^{-1}T^{-1}$. All these secondary quantities are seen by inspection to have the same important property which, as we have seen, is enjoyed by the primary quantities—that is, the property of absolute significance of relative magnitude. This property follows at once from the construction of the dimensional formulas as products of powers.

The Property of Absolute Significance of Relative Magnitude.—It is easy to give a formal proof that any quantity whose dimensional formula is composed of products of powers has the property of absolute significance of relative magnitude. It will be sufficient to consider systems in which the fundamental quantities are taken as mass, length and time—the extension to other systems involving only trivial modifications.

Consider any secondary quantity of the specified type, the dimensional formula of which may be written as $M^\alpha L^\beta T^\gamma$. Consider two concrete examples measured in a certain system of concrete units, and denote by $M_1^\alpha L_1^\beta T_1^\gamma$ and $M_2^\alpha L_2^\beta T_2^\gamma$, the numbers obtained by combining the component measures of mass, length and time in the way specified by the definition of the secondary quantity. Then the ratio of the two magnitudes is $M_1^\alpha L_1^\beta T_1^\gamma / M_2^\alpha L_2^\beta T_2^\gamma$. Now consider a second system of measurement in which the unit of mass is smaller in the ratio μ than in the first system; the unit of length is smaller in the ratio λ; and the unit of time is smaller in the ratio τ. Then the number which measures any concrete mass will be larger by the factor μ in the second system than in the first, and similarly for the numbers which measure length and time. Hence, the numerical magnitude of the secondary quantity for the first concrete example will now be $(\mu M_1)^\alpha (\lambda L_1)^\beta (\tau T_1)^\gamma$, and for the second concrete example $(\mu M_2)^\alpha (\lambda L_2)^\beta (\tau T_2)^\gamma$. On taking the ratio of these, the μ, λ, and τ cancel, leaving the same result as at first. That is, the ratio of the numerical measures of any two concrete examples is independent of the size of the fundamental units for secondary quantities constructed on the scheme of products of powers of the primary quantities; this is what is meant by absolute significance of relative magnitude. The converse is also true; the dimensional formula of any quantity which satisfies the principle of the absolute significance of relative magnitude is constructed of products of powers of the primary quantities (the proof will not be given here).

The property of absolute significance of relative magnitude has proved to be of such very great convenience in application that no secondary quantities are in present scientific use which do not satisfy this principle, and whose dimensional formulas therefore are not products of powers. *It is an express presupposition of all the following discussion that the dimensional formulas of all quantities have the form of products of powers.* The formulas of primary quantities already have this form identically.

The Formula as Definition.—The dimensional formula may serve as a signpost suggesting the underlying definition. There is obviously no rigorous and exact correspondence between the dimensional formula and the definition, as shown by the example above in which energy and moment of force have the same dimensions. However, in a great many practical cases the dimensional formula permits a decision between conceivable alternatives and is therefore useful as a mnemonic device. In fact it is not uncommon for the system of measurement to be specified by listing the dimensional formulas of various quantities. This method is much used with reference to the various systems of electrical units. Such a listing of dimensional formulas is often entirely adequate; but obviously it presupposes an initial specification more formal and more precise.

Assume that we have developed a system of physical measurement, with measuring procedures and fundamental units specified, secondary quantities defined and all dimensional formulas written out. We address ourselves to apply this system of measurement to some physical system or set of systems. Our problem is to find relationships between various measurcable quantities. We proceed at first on a purely empirical basis, by plotting certain quantities or combinations of quantities against others to find whether the points lie on curves or surfaces. The existence of such curves or surfaces means a relationship: having found such, we then try to find a mathematical equation which shall reproduce the curve or surface within experimental error. Having found this we believe that we have acquired the power to predict the results of any new experiment or measurement on the system, because if we substitute into the equation (or plot on the graph) an independent variable as yet not realized experimentally, the corresponding dependent variable as determined by the equation or the graph will correspond to what we will find when we make the experiment. Of course there is no

logical necessity in this. The assumption is made in virtue of our past experience that interpolation is usually smooth.

Consider a very simple example. We use for our fundamental primary units the pound, the foot and the second, and make application to all systems of weights falling freely from rest under the action of gravity near the surface of the earth. We collect data for the widest range of conditions and find that all our observations satisfy certain equations, namely:

Distance of free fall = 16 × (square of time of fall)
Velocity of fall = 32 × (time of fall).

These equations are a complete and adequate description in the sense that given the time or distance or velocity we can predict what the other two quantities will be for any new experiment in the future or recall what they were at any time in the past. But this may not satisfy us; we notice that there has been an element of arbitrariness in our procedure in that we chose the pound, foot and second as fundamental units. We might have chosen the gram, centimetre and minute as fundamental. If we had, would we have to make our physical measurements all over again? We suspect that we would not, and that there must be some relation between measurements in the two systems, because each system is constructed on the same pattern, and the principle of absolute significance of relative magnitude holds for measurements in the two systems. In fact, substitution of the concrete values for two examples shows that for any other such system satisfying the principle of absolute significance of relative magnitude we must have:

Distance of free fall is proportional to square of time of fall.
Velocity of free fall is proportional to time of fall.

The factors of proportionality obviously depend on the system of measurement. We now have the answer to our question: given a relationship between quantities in any scientific system of measurement, we can at once find corresponding relationships in any other system for which the principle of absolute significance of relative magnitude holds. The change from one system to the other is to be made by changing certain factors of proportionality. Precisely how shall we change the factor of proportionality? We have seen how to change the numerical value of a physical quantity given its dimensional formula. Can we perhaps assign dimensional formulas to our factors of proportionality in our present problem? Inspection shows at once that if we assign to the factor in the first equation the dimensions of LT^{-2} and to the factor in the second equation the dimensions of VT^{-1} our problem is solved, because through the compensatory action of the factor of proportionality the numbers which we substitute into the equation when we measure in pounds, feet and seconds combine so as to give identically the same final result as when we measure in grams, centimetres and minutes.

The Dimensional Constant.—We see then that we may pass back and forth between equations for different systems of measurement, provided the systems satisfy the principle of absolute significance of relative magnitude, by the device of assigning suitable dimensions to various factors of proportionality. A factor of proportionality which varies when the units change according to a scheme which can be specified by giving to it a dimensional formula is called a dimensional constant.

The equations for the falling body, written with the appropriate dimensional constants, obviously hold for any system of units in which mass, length and time are taken as fundamental. An equation of this sort, which holds without formal change when the size of the fundamental units changes, is called a complete equation. In the problem of the falling hotly there are two dimensional constants, one for the first and one for the second equation. We notice, however, that the dimensions of the second constant, VT^{-1} reduce to those of the first constant, when we substitute for V its dimensions LT^{-1}. That is, in this problem we have essentially only one dimensional constant, instead of the two which are given formally by the two equations. What is the significance of this?

The problem of the falling body is a problem over which we have adequate theoretical mastery; it is a problem in mechanics, and the motion of the body can be obtained by an integration of the equations of motion. We should, therefore, be able to obtain the relations between distance and velocity and time of fall by purely mathematical operations performed on the fundamental equations of motion. An inspection of the nature of any purely mathematical process, such as is involved in solving the equations of motion, shows that if the initial equation is complete the final equation resulting from the mathematical manipulation is also complete. Furthermore, no new dimensional constants can be introduced by any mathematical manipulation. Any dimensional constants in the final result must have been present in the original equations from which the final result was deduced. The equation of motion for a falling body is:

Acceleration of falling body = constant.

The constant acceleration is usually denoted by g, and it is obviously a dimensional constant because its numerical magnitude changes with the size of the fundamental units. In other words, the fundamental equation of motion contains only one dimensional constant, and any relationships implicit in the equation and deducible by mathematical manipulations can contain only the same constant. Of necessity the dimensional constant in the two empirical equations first written must be the same. In fact, the explicit relations are:

$$s = \tfrac{1}{2}gt^2, \text{ and } v = gt$$

It is obvious that any empirical equation whatsoever expressing a relation between various physical parameters can be written as a complete equation by the device of introducing dimensional constants as factors multiplying each parameter, the numerical values of the constants being so adjusted as to be unity in the original system of units. This device demands as many constants as parameters. However, if the relationship can be deduced theoretically, that is by mathematical manipulation of fundamental equations, which by construction are always complete equations, then the relationship will be complete and will involve only those dimensional constants which enter the fundamental equations. The number of such constants, in general, will be smaller than the number of physical parameters, so that an advantage has been gained as compared with the purely empirical method of treatment.

Scientific achievement has now reached such a state of progress that the nature of the fundamental governing equations is known for practically all situations of ordinary occurrence, so that in these situations we know that there are relationships which can be expressed in the form of complete equations between the physical parameters of the system and certain specifiable dimensional constants, that is, the constants which appear in the fundamental equations.

The Pi Theorem and Dimensional **Homogeneity.**—Any mathematical relationship between parameters x_1, x_2, x_3, etc., can be written by a rearrangement in the form of an equation $f(x_1, x_2, x_3, \ldots) = 0$. If the physical system to which this equation applies is one of the very large number in which the nature of the fundamental governing equations is understood, then this equation can be so rearranged as to appear to be a complete equation, because it might have been deduced by mathematical manipulation. There are important restrictions on the mathematical form of any complete equation. Dimensional analysis is essentially a study of the restrictions on the form imposed by the requirement of completeness. There is a fundamental theorem here, the so-called pi theorem, apparently first explicitly enunciated by E. Buckingham, although used implicitly ever since the time of Baron Jean Baptiste Fourier, who was the first to apply dimensional considerations. All the parameters which enter into the functional relationship are given. These will include both physical parameters and dimensional constants, and both physical parameters and dimensional constants are similar in that they have dimensional formulas expressible as products of poners of the fundamental units.

The pi theorem states that, subject to an important restriction, the functional relationship must be expressible in such a form that it contains as arguments only such products of powers of the physical parameters and dimensional constants as have zero dimensions in all the fundamental quantities. The restric-

tion is that there be not more than one independent functional relationship between the quantities. The pi theorem may be rephrased to express the principle of dimensional homogeneity. which is often taken as the fundamental theorem of dimensional analysis. Let us express the function which satisfies the pi theorem, as

$$F(\pi_1, \pi_2, \ldots) = 0$$

where the a's are the dimensionless products formed from all the parameters. We may solve the equation for one of the arguments, say π_1, and express π_1 in terms of the component parameters, say as $p_1^{\alpha} p_2^{\beta} p_3^{\gamma} \ldots$, and then solve for the first, writing the equation as

$$p_1^{\alpha} = p_2^{-\beta} p_3^{-\gamma} \ldots f(\pi_2, \pi_3, \ldots)$$

The function f, having only dimensionless arguments, contributes only dimensionless terms. By construction of π_1, the dimensions of p," (which stands on the left-hand side of the equation) are the same as the dimensions of $p_2^{-\beta} p_3^{-\gamma} \ldots$ which multiplies the f on the right, all the terms of which are dimensionless. Hence, every term on the right-hand side has the same dimensions as the single term on the left; or, in other words, the equation expressing the relationship is dimensionally homogeneous.

Attempts have often been made to prove the principle of dimensional homogeneity by vague intuitive arguments. The following is an example: "Every equation which expresses an 'essential' physical relation must be independent of the size of the fundamental units, and in such an equation every term must have the same dimensions because it is meaningless to add together terms with different physical dimensions, as for example a length and a time." That such an argument is not valid in general can be seen by considering such equations, for example, as the equation for a falling body $(v - gt) + (s - \frac{1}{2}gt^2)^3 = 0$. This is a true equation, since it is always satisfied whenever the simultaneous values of v, s and t for any falling body are substituted into it; furthermore, it is a complete equation, because it holds without change no matter what the size of the units of length and time. It is, however, obviously not dimensionally homogeneous.

The restriction that there is only one functional relationship is essential to the pi theorem and to the principle of dimensional homogeneity. The equation just given obviously falls apart into two equations: $v = gt$ and $s = \frac{1}{2}gt^2$. In practice the requirement of only one functional relationship is no essential restriction because we are alnays interested in reducing the relationships until only one remains. If there should be two relationships, one of the arguments may be eliminated betneen the two, leaving a single relation between a smaller number of arguments.

The functional relation as it first comes from the pen of the mathematical analyst may not obviously satisfy the pi theorem, but some rearrangement may be necessary. The pi theorem states that such rearrangement is always possible. This has particular application to the so-called logarithmic constants which often present themselves in thermodynamic analysis.

The pi theorem places no restrictions whatever on the form of the functional relationship; the restriction is only on the arguments. The importance of the restriction consists in the fact that the number of possible independent dimensionless arguments is in general less than the full number of physical parameters. The number of experiments necessary to find the form of an unknown function is obviously less if we are dealing, for example, with a function of only one argument instead of with one of three.

Consider a system of measurement in which there are m kinds of fundamental units whose magnitude may be changed and in terms of which any equation of relationship must be a complete equation. Suppose this system of measuremrnt is being applied to a physical system in which there are n parameters, including all dimensional constants. Then in general, unless there is some special relationship, the n parameters can be combined into only $n - m$ independent dimensionless products, and any possible functional connection is a function of only $n - m$ arguments instead of the full n. If there are special relationships between the exponents in the dimensional formulas of the parameters, the number of independent dimensionless arguments may be either greater or smaller than n—m. It is possible to include these special exceptional cases in a general formulation, but in practice they are usually immediately obvious to inspection, so that we shall avoid here the complication of a perfectly general formulation.

Since products of powers of dimensionless products are themselves dimensionless products, there is no unique way of writing the $n - m$ dimensionless products—it is only the number which is determined. The precise form in which these products are to be written must be chosen with discretion, to suit the purposes of the application.

Making the Dimensional Analysis.—The steps in a dimensional analysis of any concrete problem are as follows. We first have to decide what sort of physical system we are dealing with in the sense that we have to decide what is the nature of the fundamental governing equations. For example, it may be a mechanical system governed by the equations of mechanics, or it may be an electromagnetic system governed by the equations of electrodynamics. We then have to decide on the system of measurement, which involves fixing the sort of quantities that are to be treated as primary and setting up the definitions of the secondary quantities. This will involve setting up the dimensional formulas; in cases of doubt it will pay to write out the definitions explicitly. We then imagine the fundamental equations written for this system of measurement, paying especial attention to any dimensional constants that may be used in writing the equations. We then make a list of all the parameters entering the particular problem, including both so-called physical quantities and dimensional constants. We write the dimensional formulas of all these parameters. We next form all the independent dimensionless products of these parameters; this is to be done by a method of solution of simple algebraic equations in the unknown exponents, as will appear from a study of the detailed examples. If necessary, the dimensionless products which first present themselves are to be rearranged so as to be more convenient for the particular problem. An arbitrary function of these dimensionless products is then to be set equal to zero, and this function is to be rearranged to suit the special exigencies. This is as far as dimensional analysis proper can go. An additional step is often taken by further restricting the form of the function by applying any special information that one may have: as, the effect of a certain parameter on the function disappears if the parameter is very small (or very large). Lord Rayleigh was especially successful in supplementing the dimensional analysis proper with other sorts of general physical information.

It is especially to be noticed that no detailed solution of the governing equations is assumed—in fact, if we were in a position to give the detailed solution we could get the complete relationship, and dimensional analysis to that extent would be superfluous. All we need to know about the fundamental equations is what goes into them—in particular, what dimensional constants. It follows that we can apply the method to situations so complicated that it would be hopeless to attempt a detailed writing out of the equations, much less to obtain a solution; and in fact the most important applications of dimensional analysis are precisely to such complicated situations.

It is important to notice that a great deal of flexibility is possible in the form in which the governing equations are written, both in the system of measurement and in the definitions for the secondary quantities. The governing equations do not have to be written in any unique canonical form, but may be specially adapted to the particular problem. This flexibility is to be utilized so as to reduce the number of independent dimensionless products to a minimum. The larger the m, other things being equal, the smaller the number of dimensionless products. Special problems often permit an increase in m. For example, a problem in mechanics or hydraulics will ordinarily be set up with conventional mechanical units, mass, length and time, as primary. But if the physical situation is of such a special character that the connection between force, mass and acceleration does not enter, as in a problem of steady motion like the Sir

George Gabriel Stokes problem of the fall of a sphere in a viscous medium where accelerations are zero, then force may be used as an independent primary unit, and the problem may be set up with four independent primary units: force, mass, length and time, instead of three. The result is a reduction in the number of dimensionless arguments, and hence more highly specialized information. If one chooses, any problem in mechanics may be set up in these four primary units; but in most problems the equation connecting force, mass and acceleration will be necessary; and this equation, written in four primary quantities, demands a new dimensional constant, the factor of proportionality between force and mass times acceleration. In general, then, the gain in increasing the number of primary quantities is nullified by an increase in the number of dimensional constants, so that the number of independent dimensionless products is unchanged.

It obviously requires experience and insight to know when the special situations arise; dimensional analysis yields an amount of information dependent on the skill and experience of the analyst. Positive errors are never introduced by failure to recognize these special situations—it is only that less than the maximum information is obtained. In the limiting case, where one has nothing whatever to contribute to a knowledge of the nature of the physical system, dimensional analysis does not give incorrect results, but only trivial results.

We have seen that any empirical connection whatever can be thrown into complete form by introducing an appropriate dimensional constant as a factor multiplying each physical parameter. If there are n' physical parameters, in this case there will be $2n'$ dimensional parameters altogether, including the dimensional constants, and hence $2n'-m$ dimensionless products. The result is some undetermined function of $2n'-m$ arguments. But in general $n'>m$, so that $2n'-m>n'$, and we know less by applying the analysis than before, because we knew in the beginning that there was some functional connection between the n' parameters. Although positive errors are not introduced by using an unnecessarily large number of independent quantities, it is obviously fatal to omit from the analysis any parameter which should actually enter the results. Experience and understanding are required of the analyst in order to ensure this. Consider now several typical applications.

(1) The Simple Pendulum.—This is the conventional introductory problem. The physical parameters defining the simple pendulum may be taken to be the mass of the bob and the length of the suspending rod. The problem is obviously one in mechanics, and we may take as the fundamental units, mass, length and time. A detailed solution of the equations of motion will give the time of any complete oscillation, and this oscillation may be characterized by its angular amplitude. Our physical command of the situation is sufficient to show that the time of oscillation for any particular amplitude must be uniquely determined, since the bob starts from rest at the extreme point of the oscillation and the boundary conditions and the equation of motion determine a unique solution. The equations of motion will involve the force on the bob, and this will involve the acceleration of gravity; that is, in the equations of motion will appear the dimensional constant g. The detailed solution should therefore give a relationship between mass of bob, m, length of pendulum, l, angular amplitude of oscillation, θ, acceleration of gravity, g, and the period of oscillation, τ. This is a complete relationship, being deduced by mathematical manipulations from a complete equation, and therefore the pi theorem applies. We write the parameters which enter:

Parameter	*Dimensional formula*
m	M
l	L
θ	0
g	LT^{-2}
τ	T

The pi theorem instructs us to form all the independent dimensionless products. There will in general be 2, because n, the number of parameters, is here 5, and m, the number of primary units, is here 3. One of these products, θ, is obvious on inspection. We then must form one dimensionless product from the four remaining parameters. The exponents in the dimensionless product are unknowns which we write as $\alpha, \beta, \gamma, \delta$. We must now find these four quantities so that $m^\alpha l^\beta g^\gamma \tau^\delta$ is dimensionless. Substitute the dimensional formulas for the parameters. $M^\alpha L^\beta (LT^{-2})^\gamma T^\delta$ must be dimensionless, or the total exponents of M, L and T must vanish. This condition gives three algebraic equations:

$$\left.\begin{aligned} \alpha &= 0 \\ \beta+\gamma &= 0 \\ -2\gamma+\delta &= 0 \end{aligned}\right\}$$

There are three equations and four unknowns, which means that one unknown may be assumed arbitrarily. Take δ as the arbitrary one. Then the solution is: $\alpha=0$, $\gamma=\frac{\delta}{2}$, $\beta=-\frac{\delta}{2}$. The dimensionless product is $l^{-\frac{\delta}{2}} g^{\frac{\delta}{2}} \tau^\delta$. The pi theorem states that the solution is some functional relationship between the two independent products, or:

$$F[(l^{-\frac{1}{2}} g^{\frac{1}{2}} \tau)^\delta, \theta] = 0$$

where F is completely undetermined.

This equation may be rearranged by solving for the quantity in parenthesis, giving:

$$l^{-\frac{1}{2}} g^{\frac{1}{2}} \tau = f(\theta)$$

where f is completely undetermined. This again may be rearranged as:

$$\tau = f(\theta)\sqrt{\frac{l}{g}}$$

That is, the time of swing is independent of the mass, proportional to the square root of the length, and inversely proportional to the square root of the acceleration of gravity. As far as this analysis goes it may be any function of the amplitude. The detailed solution would show that for small amplitudes f has approximately the constant value 2π.

Even in this simplest of all problems we have had to make approximations and utilize special knowledge. For example, friction has not entered our result, yet every actual pendulum experiences friction, both from the resistance of the air and from imperfect elasticity of the supports. A precise formulation of the equations of motion would have involved the coefficient of viscosity of the air and an internal damping coefficient for the material of the supports. There would have been two more parameters, and the final result would have involved an arbitrary function of three arguments instead of one. Furthermore, we would have lost the information that we now have that time varies as the square root of the length. Suppose, for example, that we consider the effect only of the damping of the air. We would have had one more parameter, the viscosity of air, μ, of dimensions $ML^{-1}T^{-1}$, and one more argument of the function. Our result would have had the form

$$F[(l^{-\frac{1}{2}} g^{\frac{1}{2}} \tau), (ml^{-\frac{3}{2}} g^{\frac{1}{2}} \mu^{-1}), \theta] = 0$$

In this solution l cannot be isolated, and the dependence on l is tied up with that of the other parameters. Our original simplified analysis can be justified only by the additional knowledge, acquired either by experiment or by other considerations, that the effect of viscosity of the air on the period is vanishingly small. This sort of supplemental information is almost always necessary to make dimensional analysis yield useful results.

(2) The problem *of* the resistance experienced by some body *of* definite shape moving at constant velocity through *a* body of *fluid of* dimensions indefinitely large compared with those *of* the moving body. Special cases of this problem are: the resistance encountered by a projectile, by a submarine in deep water, by an airplane, or by a falling raindrop. The case of the ship is not included because for a ship, part of the resistance to motion arises from the creation of surface waves against gravity. The converse problem obviously is covered also; that is, the problem of the force exerted on a stationary obstacle by an infinite mass

of fluid streaming past it. The problem is evidently one of mechanics, involving for its formulation the equations of hydrodynamics (see HYDROMECHANICS). These equations involve no dimensional constants if written in terms of units of mass, length and time as primary. The parameters are therefore the physical parameters only. These will include the resistance to motion, the velocity through the fluid and the other parameters defining the physical setup. We may divide the latter into two groups: parameters defining the body and parameters defining the fluid. The fluid has density, viscosity and compressibility, the last of which may be specified by giving the velocity of sound in it. The body influences the result only through its geometry and through its surface properties. the interior being supposed rigid, so that the specific properties of the material of the body do not enter.

If we suppose that there is no surface slip between body and fluid, which corresponds to a very wide range of experimental conditions, the surface condition reduces merely to the condition that the velocity of the fluid is zero at the surface, and this condition can be stated without the help of any parameters. There remain the geometrical properties of the body. The geometry of the body may be specified by giving its shape and its absolute size; the latter may be specified by giving the numerical measure of some critical dimension and the former by giving the ratio to it of other determinative dimensions. For example, if the body is ellipsoidal in shape, its geometry may be specified by giving the major axis and the ratio to it of the minor axis. The latter are called shape factors and are obviously dimensionless.

We now formulate the problem by listing the quantities as follows:

Name of Quantity	*Symbol*	*Dimensional Formula*
Resistance	R	MLT^{-2}
Velocity	v	LT^{-1}
Density of fluid	d	ML^{-3}
Viscosity of fluid	μ	$ML^{-1}T^{-1}$
Velocity of sound in fluid	v'	LT^{-1}
Fiducial dimensions of body	l	L
Shape factors	$r_1, r_2, \cdots$	0

This list of properties of the fluid is evidently not complete. By leaving out certain properties we are drawing on our experience that these properties have no appreciable effect on the resistance. Obviously there can be little doubt of the propriety of omitting such properties as the electrical, magnetic or optical. But the omission of other properties limits the applicability of our results. Thus we have not included the boiling point or the latent heat of vaporization. This means that the solution is restricted to velocities so low that frictional resistance does not produce enough heat to vaporize the fluid.

Within the limitations imposed by our assumptions we now apply the pi theorem, and form the independent dimensionless products. The shape factors are already in this form; another one is obvious on inspection, namely v'/v. This leaves five parameters, R, v, d, μ, l. In general there should be two dimensionless products, and each of the products will involve four of the five parameters. We have therefore considerable latitude in choosing the precise form of the products. Since we are interested primarily in R, we will do well to include this in only one of the products, so that it may be isolated in the final solution. It will be convenient to omit μ from the other product. Following the procedure illustrated in detail in connection with the pendulum problem, we find that $Rv^{-2}l^{-2}d^{-1}$ and vld/μ are dimensionless. The solution is therefore:

$$F(Rv^{-2}l^{-2}d^{-1}, vld/\mu, v'/v, r_1, r_2, \cdots) = 0$$

where F is unrestricted. This may be rewritten as:

$$R = v^2l^2df(vld/\mu, v'/v, r_1, r_2, \cdots)$$

with f unrestricted.

This general solution covers a range of special conditions. At low velocities the problem is one of the steady state under the viscous resistance of the liquid; under these conditions the density of the liquid and the velocity of sound in it do not enter. If the density is to drop out, f must be linear in the reciprocal first parameter, and the solution is:

$$R = \mu vl\varphi(r_1, r_2, \cdots)$$

where φ is unrestricted. Therefore at small velocities the force of resistance is proportional to velocity, to viscosity and to the linear dimensions of the body. This is the solution for a falling raindrop.

In a higher range of velocity the motion loses its "laminar" character and becomes turbulent. In turbulent motion the microscopic momentum of the liquid enters, so that the density enters. In this range the fluid may be treated as incompressible, and the velocity of sound in it does not enter. These requirements give the specialized form of the result:

$$R = v^2l^2df'(vld/\mu, r_1, r_2, \cdots)$$

This equation is applicable to airplanes at velocities low compared with the velocity of sound.

The transition from the first solution, where the motion is laminar, to the second solution, where the motion is turbulent, occurs in the range where the deviation of the function $f(vld/\mu, v'/v_1r_1, \ldots)$ from linearity in the argument vld/μ becomes important. That is, when vld/μ reaches some critical value, the character of the motion alters. The dimensionless combination vld/μ is known as the Reynolds number, and is of great significance in discussing the flow of fluids.

The equation

$$R = v^2l^2df'(vld/\mu, r_1, r_2, \cdots)$$

is of wide applicability. The important matter is to determine the form of the function f'. If we restrict ourselves to geometrically similar bodies (constant shape factors), f' is a function of a single parameter, and may be determined by varying the parameter vld/μ over a wide enough range. This means that we do not have to study the effect of varying v, l, d and μ separately, but it is sufficient to vary any one of them. This obviously will result in an enormous saving of experimental manipulation.

The theory of model experiments is contained in dimensional equations like this. Suppose we wish to determine the behaviour of an airplane from model experiments. The model airplane must in the first place be made geon~etrically similar to the actual example; that is, the shape factors must be kept constant. If the experiment with the model is made in air, then in order to have the same values of f', vl for the model must have the same value as vl for the full-scale example. If the model is one-tenth size, this would mean that the model must travel at ten times the velocity of the original, an impossible requirement. At first glance this would seem to preclude the possibility of making model experiments on airplanes. The situation is saved by the special form which the function f' is found to have. Above a certain value of the argument vld/μ the function is found by experiment to be asymptotically constant. If vld/μ for both model and full-scale example can be got into this range, resistance is then proportional to v^2l^2, and this gives the information we seek. In practice, the asymptotic constant can be reached with the model, and model experiments are feasible.

At still higher velocities the velocity of sound enters. This is the case for projectiles. An analysis on the lines above would show that if we tried to make model experiments for projectiles by using water as the medium instead of air, a velocity of the model projectile in water five times as great as the velocity of the original in air would be demanded. The requirement is impossible to meet, and model experiments on projectiles cannot be made by changing the medium from air to water. Model experiments on projectiles are usually made in air; in this case the model must be geometrically similar to the original and it must travel at the same speed. That is, the model itself must be projected by some explosive mechanism. Under these conditions the formula shows that the resistance varies as the cross-sectional area.

(3) *The Problem of Heat Transfer.*—A body of given shape is surrounded by an infinite stream of liquid flowing past it at uniform velocity. The body is maintained at a given temperature higher than that of the remote parts of the stream. It is required to find the rate of heat interchange between body and stream. A complete solution of this problem would be excessively complicated; we shall make several essential simplifications. The heat convected away by the stream is known if we know the velocity distribution in the liquid and know the rate of heat transfer into each element of its volume. We assume that the velocity is so low that the flow is nonturbulent; in this region the distribution of flow velocity is independent of the viscosity of the fluid, although the forces are not. Further, the preceding problem shows that in this range the density of the fluid does not affect the velocity distribution. At the surface of separation of liquid and body there is no surface slip. The rate of heat transfer into the liquid at the surface depends on the temperature gradient in the liquid at the surface, and this will depend on the thermal conductivity of the liquid, its thermal capacity, and the rate at which new liquid is brought up by the motion, that is, on the velocity of the liquid. We suppose that the thermal conductivity of the solid body is so much higher than that of the liquid that the thermal conductivity of the solid offers no restriction on the rate of heat transfer from solid to liquid, and therefore the heat conductivity of the solid will not enter.

The conditions in this problem are sufficiently special so that it is advantageous to use a special set of primary units. We have the following table of parameters and dimensions:

Name of Quantity	*Symbol*	*Dimensional formula*
Rate of heat transfer	h	HT^{-1}
Velocity of fluid	v	LT^{-1}
Temperature difference	τ	τ
Thermal conductivity of liquid	k	$HL^{-1}T^{-1}\tau^{-1}$
Heat capacity of liquid per unit volume	c	$HL^{-3}\tau^{-1}$
Linear dimensions of body	l	L
Shape factors	$r_1, r_2, \ldots$	0

Here we use new kinds of fundamental unit, quantity of heat, H, and temperature, τ, while mass does not appear. The justification is in the details, as outlined above. This is a problem in static flow; that is, as far as the velocity of flow is concerned it is a problem in statics and masses do not enter. The equations deal directly with the flow of heat as such; and, since there is no transformation of heat into mechanical work, we are not concerned with the fact that in other kinds of systems heat and mechanical energy are mutually transformable. It is therefore sufficient to treat heat as a primary unit. Furthermore, temperature enters only through temperature differences and through those properties of the body which determine the behaviour when there are temperature gradients. Temperature may, therefore, be treated as a primary unit, in spite of the fact that there are other kinds of physical systems whose behaviour involves the fact that absolute temperature is proportional to kinetic energy per degree of freedom.

Disregarding the shape factors, we have six parameters expressed in terms of four primary units. Unless there is something exceptional in this situation the pi theorem leads us to expect two dimensionless products. Since we are interested in h, we choose one of the products without h. Detailed carrying through of the solution shows that there is nothing exceptional here, and the two independent dimensionless products are found to be $h/lk\tau$ and lvc/k. The solution is:

$$F[h/lk\tau, lvc/k, r_1, r_2, \cdots]=0$$

where F is arbitrary. The solution may be rearranged and solved for h, giving:

$$h=lk\tau f[lvc/k, r_1, r_2, \cdots]$$

where f is arbitrary. The rate of heat transfer is therefore proportional to the temperature difference. In a model experiment, identical values of the function f can be kept only by increasing the velocity in proportion as the linear dimension of the body is decreased. In the range in which the transfer is proportional to the velocity, it is also proportional to the square of the linear dimensions; that is, to the area and independent of the thermal conductivity of the liquid. This means that under these conditions the transfer is entirely a convective phenomenon. In this range the effect of increasing the velocity of flow is the same as decreasing the heat capacity by the same factor.

The importance of a judicious choice of units adapted to the particular problem is particularly apparent here. If we had taken temperature to be a secondary quantity, and defined it as proportional to the kinetic energy of the atoms (as we might in perfect consistency with kinetic theory), the dimensional formulas and all the parameters would have been expressed in terms of three instead of four primary units, we would have had one more dimensionless product; the arbitrary function would have involved one more argument, and the relationships that we could have deduced would have been correspondingly less restricted, although not actually incorrect. The point is that the phenomena of kinetic theory do not enter this problem, and we are only handicapping ourselves unnecessarily if we try to bring them in by way of the definitions. A problem in which the connection between temperature and energy has to be brought in by way of the units is, for example, the very simple problem of the pressure-volume-temperature relation for a perfect gas.

(4) Electromagnetic Problems.—In dealing with problems in electrodynamics the question of the most suitable system of primary units is likely to prove more troublesome than in mechanical problems, because of the much larger number of alternative systems which have been proposed and which are in actual use. From the point of view of dimensional analysis the only requirement is that the system is consistent and adapted to the particular problem in hand. This requirement does not fix the system of measurement uniquely, and alternative definitions and corresponding alternative sets of dimensional formulas are possible in dealing with most of the problems of electrodynamics. There has been much controversy and misunderstanding in this connection; at one time an engineering society tried to determine the correct point of view by majority vote. The view has been very common that a dimensional formula expresses the essential physical nature of a quantity. From this point of view the present indeterminateness in dimensional formulas is an expression of our present incomplete knowledge of the complete physical mechanism, and the time is anticipated when we shall be able to write the correct dimensional formula for the dielectric constant and the magnetic permeability of empty space. The thesis is often defended that when this occurs all fractional exponents will disappear from all dimensional formulas. This attitude has a partial explanation as a historical survival from the time when the displacement current of Maxwell's equations was thought to indicate a movement of an electrical fluid which pervaded all space and which was everywhere elastically tethered to a second all-pervading rigid framework. This point of view has outlived any usefulness it may ever have had in suggesting experiment; it appears not to be unusual for a point of view to survive in its effect on philosophical attitude after it is dead in its original significance.

As an illustration of the application of dimensional analysis to a problem of electrodynamics, consider the classical problem of the electromagnetic mass of the electron. The electron is conventionalized by specifying its total charge, e, and its equivalent radius, a. To find the electromagnetic mass the electron may be placed in a constant electric field, and the resultant acceleration determined. If this acceleration should prove to be constant, independent of the velocity of the electron, then its behaviour is similar to that of a mechanical particle with ordinary mechanical mass, and it is proper to speak of electromagnetic mass. However, until the solution has been carried through one cannot say whether the electron has an electromagnetic mass or not. In carrying through the solution the field equations of

electrodynamics will be used, and into them will be substituted the parameters characterizing the electron. For the solution of theoretical problems of this nature the Gaussian system of units is often regarded as most convenient, and we shall suppose this to be the system used. In the field equations written in this system one dimensional constant occurs, c, of the dimensions of velocity, and numerically equal (by experiment) to the velocity of light. Our problem is then to build up a quantity of the dimensions of mass from the three quantities: electronic charge, e, electronic radius, a, and c. In the Gaussian system e^2 has the dimensions ML^3T^{-2}. Inspection shows that ae^2/c^2 is of the dimensions of mass, so that the point of view which anticipated an electromagnetic mass is to this extent justified and the mass is proportional to ae^2/c^2. The constant of proportionality can be found only by a detailed solution and will depend on the manner of distribution of the charge.

Applications to Theoretical Physics.— The general scheme of applying dimensional analysis to theoretical physics is not different from that in the applications already considered, provided the underlying mechanisms of the system are sufficiently understood. The method may, however, be applied as a tool of preliminary exploration in situations which are not yet completely understood, in order to find whether certain lines of attack are sufficiently promising to justify more detailed and elaborate development. A well-known example is the application by Albert Einstein to a discussion of the infrared characteristic frequency of solids. Before Einstein, no connection had been envisaged between the mechanism responsible for the ordinary elastic behaviour of a solid and that controlling its optical behaviour. Einstein suspected that the forces resisting the ordinary elastic deformations in a solid were the same in character as those responsible for the characteristic optical frequency in the infrared. An exact working out of the point of view would obviously have demanded detailed and laborious calculations, which one would not lightly enter upon. A preliminary dimensional analysis was therefore made. A connection is sought between characteristic frequency, ν, compressibility, K, the mass of the atom, m, and the number of atoms per cm^3, N. The dimensions of these quantities in ordinary mechanical units are respectively T^{-1}, $M^{-1}LT^2$, M, and L^{-3}.

There is in general one dimensionless product, and the result is obtained that

$$\mathrm{K} = \text{numerical const.} \times \nu^{-2} N^{-\frac{1}{3}} m^{-1}$$

A connection of the suspected sort is therefore possible. However, in its present form very little significance can be attached to this result, because in general a dimensionless product may be formed with any four quantities chosen at random. If the exponents in the dimensional formulas of the parameters had proved to have such a special relationship that the dimensionless product was impossible, then the result mould have been of immediate significance, but it would have been negative, and the line of inquiry would have been dropped as impossible. However, in the actual situation further argument is required to find whether the existence of this dimensional relation is significant, and this'further argument was supplied by Einstein from an examination of the numerical value of the constant of proportionality.

Substituting actual numerical values for the physical parameters of a representative solid, copper,

$$7\times10^{-13} \text{ for K, } 7.5\times10^{12} \text{ for } \nu$$
$$7.5\times10^{22} \text{ for } N$$
$$1.06\times10^{-22} \text{ for } m$$

and gives the value 0.18 for the numerical constant. a value neither very large nor very small. Einstein's argument is based on the empirical observation that any very large or very small numbers which appear in equations of physics derived theoretically have their origin in physical parameters; such as the charge on the electron or the number of atoms per cm^3. On the other hand, any numbers which are the result of purely mathematical manipulations are likely to be neither very large nor very small. In the analysis above a number was found, 0.18, neither very large nor very small, so that it might have been the result of mathematical operations on certain fundamental equations containing the physical parameters. The point of view therefore appears to be worth further investigation. It is well known that detailed analysis did justify the general point of view, and the whole modern theory of specific heats at low temperatures has come out of it. The method is admittedly far from rigorous, nor can it be made rigorous; it is intended only to be suggestive, as a tool for preliminary exploration.

Use in Checking Equations.— Another use of dimensional analysis, which often saves much time, is in checking the correctness of a theoretical derivation of a formula. An equation derived from theoretical considerations should in general be a complete equation; the terms should then all have the same dimensions. Simple errors in manipulation are often discoverable by observation of a failure of dimensional homogeneity, and the place of origin of the error may be quickly traced. Consider, for example, a formula in thermodynamics for the adiabatic thermal expansion in terms of the isothermal expansion and other quantities, which might appear as:

$$\left(\frac{\partial v}{\partial \tau}\right)_s = \left(\frac{\partial v}{\partial \tau}\right)_p + C_p\left(\frac{\partial v}{\partial p}\right)_\tau \Big/ \left(\frac{\partial v}{\partial \tau}\right)_p$$

We ask whether this expression is dimensionally homogeneous? The dimensions of thermodynamic quantities are often expressed most conveniently in terms of pressure (p), volume (v), and temperature (r) taken as primary. The dimensions of $\left(\frac{\partial v}{\partial \tau}\right)_s$ in the formula are $v\tau^{-1}$, as also are those of $\left(\frac{\partial v}{\partial \tau}\right)_p$. The dimensions of C_p, defined in this case as the heat required to raise the temperature one degree, are $pv\tau^{-1}$, pv having the dimensions of heat or energy. Substitution gives v for the dimensions of

$$C_p\left(\frac{\partial v}{\partial p}\right)_\tau \Big/ \left(\frac{\partial v}{\partial \tau}\right)_p$$

This differs by τ^{-1} from the dimensions of the other terms, so that there must be some error. Consideration would show that a factor τ^{-1} had been lost, and the correct formula is:

$$\left(\frac{\partial v}{\partial \tau}\right)_s = \left(\frac{\partial v}{\partial \tau}\right)_p + C_p\left(\frac{\partial v}{\partial p}\right)_\tau \Big/ \tau\left(\frac{\partial v}{\partial \tau}\right)_p$$

Use in Changing Units.—By writing out the dimensional formulas of various quantities a method is afforded of finding how the numerical magnitudes of any concrete examples change when the size of the primary units of measurement change. The method is so simple that no elaborate or formal exposition is necessary; it will be sufficient to give several illustrative examples. The method has already been applied in an earlier discussion in this article.

Suppose that a given body is moving with a velocity of 60 m.p.h. and we wish to find what its velocity would be in feet per second. Since 1 mi. contains 5,280 ft. and 1 hr. contains 60×60 sec., we may write:

$$60\ \frac{\text{mi.}}{\text{hr.}} = 60\ \frac{5{,}280\ \text{ft.}}{3{,}600\ \text{sec.}} = 88\ \frac{\text{ft.}}{\text{sec.}}$$

Or, what is the pressure of the atmosphere, which we may take as 15 lb. per square inch, expressed in kilograms per square centimetre? One pound is equal to 0.4536 kg., and 1 in. equals 2.54 cm. Hence, $15\ \frac{\text{lb.}}{\text{in.}^2} = 15\ \frac{0.4536\ \text{kg.}}{(2.54\ \text{cm.})^2} = 15\ \frac{0.4536\ \text{kg.}}{(2.54)^2\ \text{cm.}^2} = 1.054\ \text{kg./cm.}^2$

The method illustrated is obviously general. In fact it may be extended to much more complicated sorts of examples in which the conversion is between systems of units different in general nature, as from a system with mass, length and time as fundamental to one with force, velocity and energy as fundamental.

In applying the method the symbolic and abbreviated character of the notation is especially not to be lost sight of. We do

not, for example, divide a mile by an hour, but we divide a number obtained by the physical operation for measuring a distance in miles by a number obtained by the physical operations for measuring a time interval in hours. Our question is, what number would we have obtained if we had operated on the same physical system with the operation for measuring a length in feet and the operation for measuring a time in seconds?

Critical Comments.— While there is general agreement as to the details of the application of dimensional analysis to any concrete problem, and also with regard to the specific form of the results, there has not by any means been agreement with regard to the philosophy of the subject, and many questions are still controversial. The view presented here is one which apparently is increasingly accepted in the U.S. The crux of this point of view is that dimensional analysis is an analysis of an analysis: that is, an analysis of the implications of the fact that methods of analyzing experience have been found profitable which employ certain types of measuring process and certain methods of mathematical treatment of the results of the measurements. There is nothing absolute here, but a great deal of flexibility.

On the other hand, there has been a view, widely held by British authors and also on the continent, that the dimensions of a physical quantity have a much more esoteric significance; that dimensions refer to its essential physical nature, and that the correct dimensions are unique and sometime perhaps may be discovered. Examples of this point of view have been given in the text; this opinion leads, for example, to an intuitive proof of the necessary dimensional homogeneity of all physical equations, and also to an aversion for fractional exponents in dimensional formulas, the occurrence of which is supposed to indicate that certain essential dimensions have been suppressed. Somewhat connected with this point of view is the feeling, held by many contemporary writers, that it is necessary to distinguish two different sorts of operation in our handling of physical situations: that is, ordinary mathematical or arithmetical operations with numbers, and corresponding operations with physical quantities. Thus, according to this view, a velocity is the quotient of a physical length by a physical time.

Contrasted with these points of view, the point of view of this article may be characterized as a minimum point of view. The thesis is: whether or not it is possible to give satisfactory meaning to operations with physical quantities, or whether or not there is reason for thinking that things have an ultimate essential physical nature. for present purposes it is not necessary to settle these questions, but everything that we actually need or use in applying dimensional analysis is contained in the considerations set forth in this article. In particular, the various symbols in a dimensional formula perform the function of indicating the different sorts of physical operation that give rise to certain numbers that ti-e use in our calculations.

See PHYSICAL UNITS.

BIBLIOGRAPHY.—The bibliography is very extensive, particularly that of applications to model experiments and other problems of engineering. Only a few of the references to more fundamental aspects will be indicated here.

DIMINISHING RETURNS. If, in the production of a commodity, all inputs are increased, output is apt to rise in the same proportion. If only one input is increased, the output is likely to rise, but after a certain point is reached it is likely to rise only at a progressively diminishing rate. This relationship is known as the law of diminishing returns, or the principle of diminishing productivity.

A farmer, for example, who owns a given acreage of land will find that a certain number of labourers will yield the maximum output per worker. If he should hire more workers the combination of land and labour would be less efficient because the proportional increase in the over-all output would be less than the expansion of the labour force. The output per worker would therefore fall. In the extreme, as workers crowd the land they are meant to work, output might fall to zero. This rule will hold in any process of production unless the technique of production also changes.

Early economists, neglecting the possibility of technical progress, used the law of diminishing returns to predict that as population expanded in the world, output per head would fall, until misery kept population from increasing further. In stagnant economies. where techniques of production have not changed for long periods, this effect is clearly exemplified. In progressive economies. on the other hand, technical progress has succeeded in more than offsetting diminishing returns as population increases. In these economies, the standard of living has risen in spite of rising population density on the land.

See also ECONOMICS. (H. O. Sc.)

DIMITRI DONSKOI (1350–1389), grand prince of Moscow, succeeded his father Ivan II when only nine. His advisers' first task was to establish the supremacy of Moscow over the other independent Russian principalities. Only Tver was strong enough to offer effective opposition, and that only because of Lithuanian support. Thrice the Lithuanians under Algirdas, urged on by his brother-in-law Mikhail Aleksandrovich of Tver, invaded Muscovy (1368. 1370, 1372). Each time they were forced to withdraw. In 1375 Dimitri, supported by most of the Russian princes, marched on Tver. Receiving no help from Lithuania. Mikhail made peace. agreeing to recognize Dimitri as his "elder brother," to support him militarily and to renounce his friendship with Lithuania. Moscow's supremacy in northeastern Russia was now undisputed, and Dimitri was able to concentrate on the Tatars. Though the power of the Golden Horde was being sapped by internecine feuds, the Tatars, held together by Mamai during the 1370s. kept up their raids on Russian lands. The Russians, however, were able to hold their own; they even inflicted defeats on the enemy. In 1380 Mamai, determined to avenge a defeat by the Russians in 1378 on the Vozha river, collected a vast force and allied himself to Jogaila (Jagiello) of Lithuania and Oleg of Ryazan, who both failed him. Dimitri mustered an equally large army consisting of troops from most of the northeastern principalities. On Sept. 8, the twb armies met on Kulikovo plain at the confluence of the Nepryadva and Don rivers. The Tatars were routed. Russian morale received a great fillip; the Tatars were no longer considered invincible; Dimitri Donskoi ("of the Don") was now recognized as the national leader. It was not, however, the end of the Tatar yoke, for in 1382 Khan Tokhtamysh invaded Russia and sacked Moscow; and Mongol control over Russia was once more restored. (J. L. I. F.)

DIMITRI, FALSE (PSEUDO-DIMITRI), the name given to three pretenders to the Muscovite throne who, during the "Time of the Troubles," claimed to be Dimitri, the son of the tsar Ivan IV the Terrible *(see* RUSSIA: *History)*. The tsarevich Dimitri died in mysterious circumstances while still a child in 1591, in Uglich, his widowed mother's appanage. The tsarevich's sudden death has been attributed to Boris Godunov, but historians are at variance on this point *(see* GODUNOV, BORIS FEDOROVICH).

First Pretender.— The first pretender was YURI OTREPIEV, a member of the lesser nobility who had taken the name of Grigori when he became a monk. He was a habitué of various princely and boyar houses in Moscow, particularly that of the Romanovs. As a result of various treasonable utterances he was banished to the Solovetski monastery in the White sea, but forewarned, fled

to Poland, where in 1603 he announced to Prince Adam Wisniowiecki that he was the tsarevich Dimitri. This was accepted as fact, and Otrepiev's cause was taken up by the Polish magnate Jerzy Mniszek, with whose daughter, Maryna, Otrepiev had fallen in love and whom he was to make his tsaritsa. Mniszek, whose reputation was that of a lover of intrigue, presented him to the papal nuncio Claudio Rangoni. who in turn presented him to King Sigismund III. Otrepiev was converted to the Roman Catholic faith and received support from the Jesuits. Although Polish and Catholic interest lay in supporting the False Dimitri's claim, public opinion, on the whole, was against a war with Russia. The king, however, allowed him to recruit an army privately. In exchange for Polish help, Otrepiev promised to encourage the growth of Roman Catholicism in Russia, to pay a large sum of money to Poland and to cede to Poland territory along the Russian frontier including Novgorod, Pskov and Smolensk.

In Aug. 1604 Otrepiev advanced into Russia with an army of 4,000, of whom fewer than 2.000 were Poles. After a few early successes, he suffered a severe reverse and could have been completely routed had it not been for the animosity of the boyars to Tsar Boris (Godunov) and their resulting unwillingness to destroy his rival. The sudden death of the tsar supervened on Jan. 23 (new style; 13, old style), 1605, and the principal Russian army then declared its allegiance to the pretender. On June 20 (N.S.; 10, O.S.) Boris' widow and son were murdered, and on June 30 (N.S.) the pretender entered Moscow to the acclamation of the mob, who were convinced that he was Ivan's son. On July 4 (N.S.) he appointed a new patriarch, a Greek, Ignati, who crowned him on Aug. 9.

Subsequently, the pretender declined to honour his bargain with Poland, hiding his conversion, refusing to allow Catholic propaganda in Russia and offering money in place of a cession of territory. He made himself suspect to his subjects by his dislike of ceremony and by his predilection for western manners and for his Polish friends. His marriage to Maryna Mniszek, which brought a non-Orthodox bride and many foreigners to Moscow, infuriated the Muscovites. Plotters led by Prince Vasili Shuiski, whose life the False Dimitri had reprieved in June 1605, killed the pretender (and more than 2,000 foreigners in Moscow) in the Kremlin on May 27 (N.S.), 1606. Of his political actions, the most important were his efforts to secure the title of emperor for himself and his plan for an alliance between the Holy Roman emperor, the pope, Venice, Poland and Muscovy against Turkey.

Second Pretender. — The second pretender, called the "Thief of Tushino," first appeared on the scene about 1607 at Starodub. His origins are unknown. Although nobody believed his assertions, he became a focal point for malcontents and opponents of the tsar Vasili Shuiski's unpopular government. Reinforced by the Poles, he advanced on Moscow in the spring of 1608, routing the tsar's army at Bolkov on his way. He entrenched himself at the village of Tushino, a few miles from the capital, which he converted into an armed camp. In the course of the year he captured Maryna Mniszek, who acknowledged him to be her husband (subsequently quieting her conscience by privately marrying this impostor, who in no way resembled Otrepiev). This marriage brought him the support of the Lithuanian magnates, including Lew Sapieha. He raised another captive, Philaret Romanov, to the rank of patriarch. In the spring of 1610, however, when the tsar's armies received reinforcements, the pretender fled to Kaluga. Moreover, Sigismund III of Poland, making war on his own account, recalled all the Poles to the army in Smolensk. The pretender made another attack on Moscow, which failed, but the support of the Don Cossacks confirmed his hold over all southeastern Russia. He was killed on Dec. 21 (N.S.), 1610, by a servant while hunting.

Third Pretender. — The third Pseudo-Dimitri, supposed to have been a deacon called Sidorka, appeared in Ivangorod (Narva) on April 7 (N.S.; March 28, O.S.), 1611. The Cossacks, ravaging the environs of Moscow, acknowledged him as tsar on March 12, 1612.

The rebels forced the inhabitants of Pskov to swear allegiance to him; hence he is called the "Thief of Pskov." Betrayed on May 28, 1612, he was later executed in Moscow.

DIMITRIJEVIC, DRAGUTIN (1876?–1917), Serbian army officer. mas born in Belgrade in Aug. 1876 or 1877. He entered the military academy in 1892, was commissioned three years later and was appointed lecturer in strategy in 1910. From 1913 he was chief of the general staff intelligence and became colonel in 1915. From 1901 he was a member of the conspiracy which ended in the assassination (1903) of King Alexander Obrenovich. Its ringleaders then brought the army under their rule. Dimitrijevic — brave, patriotic and energetic, but inconsiderate and uncompromising—was surnamed "Apis" because of his strength. He became omnipotent in the army and began to interfere in politics. In 1911 he founded the Black Hand secret society *Ujedinjenje ili* smrt ("Union or Death"). which aimed at uniting all the Serbs, and he was one of the inspirers of the Sarajevo assassination of the archduke Francis Ferdinand.

During World War I, in Aug. 1916, two shots fired in Salonika near the regent Alexander's car were alleged to have been an attempt upon his life. Dimitrijevic and a group of his supporters were arrested in Dec. 1916 and prosecuted as promoters of the Black Hand. which was alleged to aim at overthrowing the government, and therefore plotting against the regent. Although his guilt mas not fully proved, a court martial, sitting in Salonika in May 1917, sentenced him and his friends Ljubomir Vulovic and Rade Malobatic to death. The regent. carried away by desire to regain for the king the supreme authority in the army and persuaded that he was acting justly, refused the reprieve. The irregularities of the trial, however, could not have escaped the notice of the government, especially after its Independent and Progressist members had resigned. The coalition was broken up, and the Radical ministry did not oppose the execution, which took place on June 27 (new style; 14, old style), 1917. At a staged retrial of the case in Belgrade in 1953, all the condemned were found not guilty by the supreme people's court and rehabilitated.

See R. W. Seton-Watson, *Sarajevo* (1927); M. Ž. Živanović, *Pukovnik Apis* (1955). (K. ST. P.)

DIMITROV, GEORGI (1882–1949), Bulgarian Communist leader and statesman, was born at Kovachevtsi, near Radomir, on June 18, 1882. He became a militant Socialist at the age of 20 and played a major part in organizing and inspiring the left-wing ("narrow") Socialists who in 1919 became the Bulgarian Communist party. Both at home and at international conferences Dimitrov took a firm stand against any concessions to moderate Social Democracy: he wanted Bulgarian Socialism to be a revolutionary movement. Ideological rejection of war and militarism led him and his party to persistent opposition to Bulgaria's mobilization and entry into World War I, After brief imprisonment in 1918 he went abroad and in 1921 became a member of the Comintern's executive committee. Dimitrov was one of the principal leaders and organizers of the armed risings in Bulgaria after the overthrow of Aleksandr Stamboliski's Agrarian government in Sept. 1923 and narrowly avoided capture during the fighting. Sentenced to death in absentia, he resumed his international activities abroad. The Reichstag fire trial (see GERMANY: History) in 1933 brought to Dimitrov world-wide fame for his fearless and able defense against the accusation of being the instigator of the arson. Soon after his acquittal, on Dec. 23, he was granted Soviet citizenship and settled down in Moscow where, from 1935 to 1943, he was secretary-general of the Comintern's executive committee and deputy to the supreme soviet of the U.S.S.R. After the German invasion of the U.S.S.R., Dimitrov devoted all his energy to inspiring and directing the resistance movement in Bulgaria, in which the Communist party played a leading part. On Nov. 6, 1945, he returned to Bulgaria, reverted to Bulgarian nationality, became prime minister on Nov. 22 and presided over the drawing up of the constitution of the Bulgarian People's republic.

Dimitrov died on July 2, 1949, in the Barvikha sanatorium

near Moscow, where he had gone for medical treatment. (N. I M.)

DIMITROVGRAD, a town in southern Bulgaria, in the upper Thracian lowlands of the Maritsa river, is located 82 km. (50 mi.) E. of Plovdiv. It is a railway junction on the Belgrade-Sofia-Istanbul railway line. Pop. (1956) 34,162. A modern town, built in 1947 and uniting the neighbouring villages Rakovski and Mariino, it was named after Georgi Dimitrov, Bulgarian political leader and well-known international Communist figure. Until World War II vegetables, cotton, sesame and grain were grown there. There was a lignite colliery near the Rakovski railway station, as well as a small thermal power station, a vegetable cannery and lime kilns. After the war a plant for the production of chemical fertilizers was built, as well as the biggest cement works in Bulgaria and a factory for earthenware products. Dimitrovgrad provides electric power for the Rhodope mining district.

DIMITROVO (PERNIK), a town in southwest Bulgaria, lies in a small valley of the same name 30 km. (19 mi.) S.W. of Sofia. Pop. (1956) 59,930. Dimitrovo produces about one-half of Bulgaria's coal output; there is a 100.000 kw. thermal power station, steel, engineering, glass. cement and pectin works, the last the only one in the Balkans.

During the middle ages Pernik was strongly fortified and after repeated attempts by the emperor Basil II to seize it, it fell into Byzantine hands (1018) and in 1204 was captured by the Bulgarian king Kaloyan. Under the Turks Pernik was a small agricultural village, but after the liberation it developed as a mining centre in the 1890s, when brown coal was found and worked in the neighbourhood. It was given the status of a town in 1929. Developing rapidly after World War II, Pernik was renamed Dimitrovo in 1949 after Georgi Dimitrov, Bulgarian prime minister from 1946 to 1949. (L. DI.)

DIMITY (from the Greek *dimitos*, "of double thread"), a fabric with two or more warp threads thrown into relief, forming fine cords. Originally it was made of silk or wool but since the 18th century it has been woven almost exclusively of cotton. The term was applied to two types of corded cottons: a heavy material used for bedcovers, drapery and the like; and a lightweight, almost sheer fabric either corded or made in check effects. Dimity now refers primarily to the latter. It may be dyed or printed and is a popular, lightweight, staple cotton goods. (G. E. L.)

DINAJPUR, a town and district in the Rajshahi division of East Pakistan. The town, the headquarters of the district, is situated on the east bank of the Punarbhaba just below its junction with the Dhepa. Pop. (1961) 37,711. Dinajpur proper is the northeastern quarter of the town where the maharaja of Dinajpur formerly had his residence; this quarter, as the original seat of government, gave its name to the town and district. Rajgarh is the central portion of the town containing shops and markets; Kanchanghat, on the west close to the river, is an upper-class residential suburb; Paharpur, the southern portion, contains the railway station, courts, circuit house (for senior government officials on tour) and other public buildings. The area south of the railway line has a fine maidan with handsome trees. There is a college (Surendra Nath) affiliated to Rajshahi university. The town is connected by rail with Kurigram in the east and Katihar (India) in the west. Roads radiate from it in all directions.

DINAJPUR DISTRICT, in the northwestern corner of the Rajshahi division, has an area of 2,609 sq.mi.; 1,418 sq.mi. were taken from it at the 1947 partition to make the Indian district of West Dinajpur. Pop. (1961) 1,709,917. It is a flat alluvial plain broken in the south by a slightly elevated tract known as the Barind and in the northwest by low hills. It is an important rice-growing district and stands first in both production and acreage of sugar cane in East Pakistan. Tradition associates Tarpan Ghat in the Nawabganj thana with Valmiki, the author of the Ramayana. In the 9th century Dinajpur came into the possession of the Pala kings who left their traces in numerous pillars and inscriptions, (K. S. AD.)

DINAJPUR, WEST, a district of West Bengal, India, was created in 1947 at the time of the partition of Bengal. Pop. (1961) 1,330,346. Area 2,115 sq.mi. The southern part is composed of older alluvium, dissected into rolling plains. The principal rivers are the Tangan, Punarbhaba and Atrai. Rice, jute, oilseeds, sugar cane and tobacco are the principal crops. Cotton weaving is the main industry. Balurghat (pop. [1951] 18,121), the headquarters of the district, stands on the Atrai river. It has an airport. Raiganj (15,473), about 80 mi. W. of Balurghat, has considerable trade in jute and oilseeds. Hili on the Pakistan border is a rice-trading centre. (S. P. C.)

DINAN, a town of northwestern France in the *département* of Côtes-du-Nord, stands in a dominating position on a height above the left bank of the Rance river, 22 km. (14 mi.) S. of Dinard by road. Pop. (1954) 11,550. The walls of the 11th-century town, with 15 towers and 4 gates, have survived the fire of 1257. the storming of the town by Thomas d'Agworth in 1342 and by the duke of Lancaster about 20 years later, when Bertrand du Guesclin defended it, and the plundering by Olivier de Clisson in 1380. In the southern side of the walls Duke John IV of Brittany began building a castle (1382) which became a fortress when Dinan was a stronghold of the dukes of Brittany. Later the castle was used as a prison and it is now a museum. The walls surround the original streets where medieval timbered houses stand side by side with 18th-century granite buildings, the whole town being dominated by the Tour de l'Horloge, a 15th-century belfry. St. Sauveur's church is partly Norman and St. Malo's is late Gothic. The Jardin Anglais overlooks the deep valley of the Rance where it is crossed by a Gothic bridge and a modern viaduct (1852). Small boats ply down the Rance to Dinard and St. Malo, and there is an airport at Trelivan (4 km. [2$ mi.] E.S.E.). Dinan is an administrative and tourist centre and a market town trading in grain. cattle. honey, butter and agricultural machinery. The annual fair, the Liège, is held during Lent. In World War II the town was in German hands from June 1940 until Aug. 1944. (J. UR.)

DINANT, a town of southern Belgium, province of Namur, is strung out along the east bank of the Meuse below high limestone cliffs. 28 km. (17.4 mi.) by road S. of Namur city and 15 mi. from the French border. Pop. (1955 est.) 6,843. The 11th-century citadel on the cliff, 300 ft. above the river, can be reached by a cable railway or by a stairway of 408 steps. It contains a museum of weapons and historical objects among which is the carriage of the marquise de Maintenon. second wife of Louis XIV. Behind the citadel is the French military cemetery. Over 1,400 years old, the town has many ancient buildings, among them the Collegial church on the site of a chapel founded in 934 and restored in 1697. "La Merveilleuse" grotto is famous for its transparent calcareous stalactites, while above it on the cliff is the 13th-century Montfat tower. There is a summer boat service on the Meuse northward to Namur and southward to Givet in France. The town is a tourist centre with its casino, swimming baths and sports facilities. Dinant has produced fine copperwork (dinanderic) since the middle ages, and decorated biscuits, known as *couques de Dinant*, are also made there.

A dependency of the bishop of Tongres in the 7th century, Dinant was a fief of the prince-bishopric of Liège from the 10th century until the French Revolution. In the 15th century it was a flourishing copper-manufacturing town until stormed by Charles the Bold in 1466. In 1675 it was taken by Louis XIV and remained French for nearly 30 years. It mas again in French hands during the Napoleonic Wars. It was almost destroyed during the German invasion in World War I, and was again damaged in World War II. (E. M. A. R.)

DINAR, the monetary unit of Serbia and, from the end of World War I, of Yugoslavia, equal to 100 paras. Before its conquest by the Turks in 1389 the kingdom of Serbia had a silver coin. derived from the Roman denarius, which was called dinar. This coin mas struck by King Vladislav (1234–41) at the rate of 144 dinars to one pound of silver. When Serbia became independent of Turkey in the 19th century it reintroduced its former currency and, in 1868, the dinar was revived as the national money of account. Although Serbia officially had a gold currency, only paper money circulated and gold coins were sold at a premium. After 1890 Serbia followed the example of Austria-Hungary and

maintained up to the outbreak of World War I a fairly successful gold exchange standard.

During World War I Serbia was occupied by the Central Powers and its own monetary system was suspended. After the war the dinar was reintroduced. At first Austro-Hungarian and Serbian currencies circulated side by side but in 1920 the former was converted at a rate of four kronen for one dinar while, at the same time, rapid inflation of the new Yugoslavian currency took place. Finally, in 1925, the dinar was stabilized; its exchange value was maintained at 9.15 dinars per Swiss franc or 56.70 dinars per U.S. $1.

In 1931 Yugoslavia redefined the dinar in terms of gold as .00275 g. of gold. These measures kept the exchange value of the dinar essentially stable until the occupation of Yugoslavia by Germany in 1941. When Yugoslavia regained its freedom in 1945 the dinar was again reintroduced and its official gold value defined at .0017773 g. of gold—an exchange rate of 2 cents per dinar. This constituted a serious overvaluation of the dinar and on the free market the dollar rose to between 400 and 600 dinars by 1951–52. On the advice of the International Monetary fund a new exchange rate of 300 dinars per U.S. $1 (.002962 g. of gold) per unit was fixed on Jan. 1, 1952, but free market rates of the dollar continued somewhat above that value. By Jan. 1960 the official rate of 300 dinars applied only to some government transactions. such as foreign debt service. All other transactions occurred at a large number of administered rates according to country and commodity. The system included a "settlement" rate of 632 dinars per U.S. $1 and its equivalent at internationally agreed par values for convertible currencies; reductions of 1% to 5% for most clearing currencies. and larger reductions for Egyptian and Turkish currendies; and a set of "coefficients" for all export and import commodities used to multiply the settlement rates. The tourist rate was 400 dinars per U S. $1 and that for emigrant remittances and other gifts to Yugoslav citizens 600 dinars.

(B F H.; Jo. M. L.)

DINARCHUS (DEINARCHUS) (*c.* 360–after 292 B.C.). a professional speech writer at Athens whose work reflects the incipient decline of Attic oratory. He was a native of Corinth. but as a young man settled at Athens where he is said to have studied under Theophrastus. About 336 B.C. he started his career as a professional writer of forensic speeches. Not being an Athenian citizen he was unable to speak himself in the law courts or assembly. He first became prominent in connection with the scandal which followed the flight to Athens in 324 B.C. of Harpalus, treasurer of Alexander the Great. who brought with him considerable wealth derived from Alexander's eastern spoils (see ALEXANDER III, THE GREAT). When Demosthenes and other well-known politicians were accused of misappropriating some of this money, Dinarchus was employed to write speeches for the prosecution. The three extant works ascribed to him—Against Demosthenes, Against Aristogiton, Against Philocles—are all concerned with these trials.

Under the pro-Macedonian oligarchy at Athens which followed Alexander's death in 323 B.C. Dinarchus had considerable success in his profession, but on the restoration of democracy in 307 B.C. he was forced to retire to Euboea. He returned to Athens in 292 B.C. through the influence, it is said, of his former teacher Theophrastus. It is not known when he died.

Dionysius of Halicarnassus (whose work On *Dinarchus* survives), records the titles of 87 speeches ascribed to Dinarchus, 20 of which he considered genuine. Further titles are mentioned by other ancient writers. Three speeches which have survived in the Demosthenic corpus (Against Boeotus, Against Theocrines and Against *Mantitheus*) have been ascribed to him. The three speeches extant under Dinarchus' name, *i.e.*, those connected with the Harpalus scandal, are now generally regarded as genuine. They provide no reason for dissenting from the low opinion of Dinarchus held by Dionysius. He has the conventional rhetorical accomplishments, but lacks taste, individuality and creative skill. Violent abuse takes the place of reasoned argument; plagiarism from other orators, particularly Demosthenes, is frequent.

BIBLIOGRAPHY.—*Speeches* ed. and trans. by J. O. Burtt, Minor Attic Orators II, "Loeb Series" (1954). Index to Andocides, Lycurgus and Dinarchus: L. L. Forman (1897). See also F. Blass, Die attische Beredsamkeit iii (2), 2nd ed. (1898). (H. L. H.-W.)

DINARD, a fashionable French seaside resort, in the *département* of Ille-et-Vilaine, Brittany, is situated on a rocky promontory on the Bay of St. Malo, 73 km. (45 mi.) N.N.W. of Rennes by road. Pop. (1954) 7.325. It is renowned for its mild climate, magnificent scenery, sandy beaches where bathing is safe and invigorating, and spectacular tides of 40 ft. which uncover thousands of rocks. There are numerous hotels and villas, a casino, a Breton museum and an aquarium. Small boats cross to St. Malo and in summer go up the Rance to Dinan. From Pleurtuit airport (5 km. [3 mi.] S.) there are summer services to Paris, London, Bristol, Exeter, Southampton, Jersey and Guernsey, and there are regular steamer services from St. Malo to Southampton. (RT. M.)

DINDIGUL (DINDU KAL, "Demon's rock"), a town in Madurai district, Madras state, India, on the Southern railway, lies 268 mi. S. of Madras city. Pop. (1951) 78,361. It is located at the foot of the Palni and Sirumalai hills at a height of 943 ft. above sea level, commanding the passes leading to Madurai from Coimbatore. It is famous for the manufacture of cigars from locally grown tobacco, and also of locks and safes. Because of its strategic position the small fort, now in ruins, mas keenly contested in the 18th century, several times falling to the Mysore armies and the British before its final cession to the latter in 1792.

(G. KN.)

D'INDY, (PAUL MARIE THÉODORE) VINCENT (1851–1931), French composer and teacher who aas remarkable for his attempted, and partially successful, reform of French symphonic and dramatic music along the lines indicated by César Franck (*q.v.*). Born in Paris on March 27, 1851, of an aristocratic family, he studied under Albert Lavignac, Antoine Marmontel and Franck (for composition). In 1874 he was admitted to the organ class of the Paris conservatory and in the same year his second Wallenstein Overture was performed at one of the Pasdeloup concerts. In 1876 D'Indy visited Bayreuth—an experience that confirmed and completed his musical creed: he considered French 19th-century music and the tradition of the Paris Opéra (Meyerbeer, Gounod, Massenet), of the Paris conservatory and of French "decorative" symphony (Saint-Saens) to be superficial, frivolous and unworthy to compete with the teutonic Bach-Beethoven-Wagner tradition. Yet, paradoxically, this conviction meant, in D'Indy's case, not musical cosmopolitanism but musical nationalism: French musicians should revert to French and "Latin." Roman Catholic, medieval and Renaissance traditions; the serious and uncompromising principles of German symphony and of Bayreuth should be applied to French music, inspired by French legends and true to the spirit of French folklore. And, handled by a French composer, even the German Wallenstein should turn French—just as Celtic Tristan, handled by Wagner, turned unmistakably German. This dogmatic idealism made D'Indy a stimulating theorist and pedagogue, a convincing interpreter and a composer of undeniable though limited creative powers. He codified the practice of early 19th-century sonata form and of Franck's late 19th-century *principe* cycliqzte (unity of thematic material throughout the different sections of a sonata or symphony); yet he was among the first to promote the revival of Monteverdi; and if Wagner was his god, he nevertheless welcomed Debussy's pointedly anti-Wagnerian *Pelléas* et *Mélisande* (1892–1902). The music D'Indy wrote never lacks style, and moments of grandeur are to be found in almost every one of his compositions. On the other hand. even his warmest admirers cannot deny that there is often something unimaginative and naïve about his melody; that his harmony is too systematically Wagnerian and Franckist to be original; and that lack of charm is a price this composer has been too ready to pay for the unrelenting and almost puritanical seriousness and single-mindedness of his art.

D'Indy's most important stage works were Le Chant de *le Cloche* (1883), *Fervaal* (1895), *Le Légende* de Saint *Christophe* (1915) and Le *Rêve* de Cinyras (1923). Among his symphonic works *Symphonie sur un* Chant *montagnard* (1886), with solo

piano, based entirely on one of the folk songs D'Indy had collected in the Ardeche district, and *Istar* (variations, 1896) represent his highest achievement. His 105 scores also include keyboard works, secular and religious choral writings and chamber music. Among the latter are some of his best compositions: *Quintette* (1924). suite for flute, string trio and harp (1927) and the Third String Quartet (1928–29). He also made arrangements of the hundreds of folk songs that he collected in the Vivarais.

In 1894 D'Indy became one of the founders of the Schola Cantorum in Paris and it was through courses at this academy that he spread his theories and initiated the revival of interest in Gregorian plain chant and in the music of the 16th and 17th centuries (*see* his *Cours de Composition*, four volumes 1897–1907). D'Indy also published studies of Franck (1906), Beethoven (1911) and Wagner (1930). In France Paul Dukas. Albert Roussel and D. de Sévérac were among his disciples. Outside France his influence has been great and lasting. in Greece, in Bulgaria, in Portugal and in Brazil he has been the counselor of all those who from 1900 onward endeavoured to shape folk music into symphony.

D'Indy died in Paris on Dec. 1. 1931.

See L. Vallas, *Vincent d'Indy,* 2 vol. (1946, 1950). (F. E. G.)

DINES, WILLIAM HENRY (1855–1927), British meteorologist and designer of meteorological instruments, was born in London on Aug 7. 1855, son of the meteorologist George Dines, inventor of the dew-point hygrometer. After serving an engineering apprenticeship he entered Corpus Christi college, Cambridge. and graduated as wrangler in 1881. Dines was an outstanding meteorologist of his generation, combining theoretical insight with remarkable practical inventiveness and experimental skill. Much of his work was concerned with the design of instruments. his contributions to anemometry being especially noteworthy.

Dines was also a pioneer in the investigation of the upper air by means of kites and free balloons and designed a remarkable meteorograph for upper air soundings weighing only about 2 oz. and costing about £1. This became the standard British instrument and gave much information on pressures, temperatures and humidities up to heights well into the stratosphere. His classical analysis of the data revealed striking correlations between the properties of the upper atmosphere and gave valuable insight into the dynamics of cyclones and anticyclones. Important contributions were also made in studies of terrestrial and solar radiation. His collected scientific papers with a full bibliography were published in 1931 by the Royal Meteorological society, of which he was president in 1901–02. In 1905 he was elected a fellow of the Royal society. He died at Benson, Oxfordshire, on Dec. 24, 1927. (RD. C. S.)

DINGELSTEDT, FRANZ FERDINAND, FREIHERR VON (1814–1881), German poet, playwright and theatrical producer, who became known for his biting political satires, was born at Halsdorf, Hesse-Kassel, June 30, 1814. He joined the liberal Young German movement and wrote satires against the princes (*Lieder eines kosmopolitischen Nachtwächters,* 1841): after his political conversion he was made intendant of the court theatres at Munich and Weimar and, finally, director of the opera and the Hofburg theatre at Vienna, and was ennobled. A founder of the German Shakespeare society, he produced the whole cycle, and translated many of Shakespeare's plays. He also wrote novels (*Die Amazone,* 1868; *Künstlergeschichten,* 1877); an autobiographical sketch. *Münchener Bilderbogen* (1879); and a tragedy (1850). He died in Vienna, May 15, 1881.

DINGHY: *see* BOAT.

DINGO (WARRIGAL), the Australian wild dog (*Canis dingo*), was introduced by the aborigines from Malaya when they first settled the continent. It is of the same genus as the wolf, coyote, jackal and domestic dog, which last-named canid it closely resembles in structure and habits. The dingo is a stout animal about the size of a small collie, with short soft fur, a bushy tail and erect pointed ears; its colour is generally tan, with white markings on the belly, feet and tip of tail. Its skull structure is much like that of the earliest domestic dogs of Europe.

Wild dingoes, which yelp and howl but do not bark, can, in domestication, learn to imitate the bark of dogs. They are suspicious. fierce and bold, and have a high degree of cunning. However, they can be tamed and are easily bred in captivity; those raised from puppies may become affectionate ,pets. Wild dingoes hunt singly, or in pairs or small packs of five or six. Kangaroos were once their principal prey. Through competition they contributed to the extermination of the native Tasmanian wolf and Tasmanian devil (both marsupials) on the Australian mainland.

W. SUSCHITZKY

DINGO (CANIS DINGO), THE WILD DOG OF AUSTRALIA

With the settlement of Australia by white men, the dingo became very destructive of sheep and poultry, and man's hunting nearly eliminated it in some areas. Near settlements it interbred with domestic dogs, and pure dingoes became rare in many regions. The introduction of the rabbit afforded it a staple food supply; the dingo then increased in numbers and again became a serious liability.

Fossil remains of the dingo from the Australian Pleistocene (beginning about 1,000,000 years ago) are mingled with those of giant marsupials. (R. H. MA.)

DINGWALL, a royal and small burgh and the county town of the shire of Ross and Cromarty. Scot. Pop. (1961) 3,752. It is near the head of Cromarty firth where the valley of the Peffery unites with the alluvial lands of Easter Ross at the mouth of the Conon, 22 mi. N.W. of Inverness by road. Its name, derived from the Scandinavian *Thingvöllr,* "field or meeting place of the *thing* or local assembly," preserves the Norse origin of the town; its Gaelic designation is Inverpefferon, "the mouth of the Peffery." The 18th-century townhouse (largely rebuilt in 1905) and some remains of the ancient mansion of the once powerful earls of Ross still exist. A tower on Mitchell hill commemorates Maj. Gen. Sir Hector Macdonald (1853–1903), born at Muir near Dingwall. The town is the centre of a wide and fertile agricultural country. Some shipping is carried on at the harbour at the mouth of the Peffery, about a mile below the burgh. Alexander II created Dingwall a royal burgh in 1226, and its charter was renewed by James IV. On the top of Knockfarrel, a hill about 3 mi. to the west, is a large and very complete vitrified fort with ramparts. *See* VITRIFIED FORTS.

DINIS, JÚLIO (pseudonym of JOAQUIM GUILHERME GOMES COELKO) (1839–1871), the first great novelist of modern Portuguese society, was born in Oporto of a middle-class family on Nov. 14, 1839, and completed a brilliant career as a medical student there in 1861. Four years later he was selected as demonstrator in the medical school and in 1867 he was promoted deputy professor and appointed secretary and librarian. He had already experienced the first attacks of tuberculosis, which had claimed his mother and some of his brothers and was to claim Dinis himself at the age of 31.

In 1862 his first tales had begun to appear in the *Jornal do Pôrto:* they were later collected in one volume, *Serões da Província* (1870). In Ovar, where he spent some time in search of relief from the disease which was sapping his strength, he wrote his famous novel of country life, *As Pupilas do Senhor Reitor,* which appeared in the *Jornal do Pôrto* in 1866 and as a book in the following year. It was a resounding success: 14 editions had been published by 1900. Encouraged, he published first as a serial, then in book form (1868) *Uma Família Inglêsa,* on which he had begun work before 1860.

In 1868 Dinis began to publish, also in the *Jornal do Pôrto, A Morgadinha dos Canaviais,* which appeared as a book in the same year. During 1871, the year of his death (at Oporto, Sept. 12) he was revising the proofs of his last novel, *Os Fidalgos da Casa Mourisca* (1872; Eng. trans. by R. L. Dabney, 1891), which was based on his sojourns in Madeira. His poems were edited posthumously, *Poesias* (publ. 1873, dated 1874). Other posthumous

publications included *Inéditos e Esparsos, Cartas e Esbôços Literarios* and *Teatro Inédito.*

Dinis devoted himself as a writer to stressing the superiority of the middle class and its work over the aristocracy and its prejudices. His novels reflect a simple, kindly, grateful nature, prone to good works and self-sacrifice. One of his critics (Sampaio Bruno) wrote that his novels were amplifications of a moral theme in which the thesis dominates the narrative simplicity. Reading the English sociological novelists decisively influenced his outlook. His village tales, which express his love for the simple life, for loyal and sincere characters and for gentle scenes, were written in a style within the comprehension of a large public and retain the invigorating qualities which made him one of his country's most popular writers.

DINIS DA CRUZ E SILVA: *see* CRUZ E SILVA, ANTONIO DINIS DA.

DINIZ (DENIS) (1261–1325), king of Portugal from 1279 to 1325, was born on Oct. 9, 1261, the son of Afonso III and of Beatriz. an illegitimate daughter of Alfonso X of Castile. In 1282 he arranged his marriage with Isabella, daughter of Peter III of Aragon: she was canonized in 1625. Educated at a court subject to both French and Castilian cultural influences, Diniz was a competent poet. He encouraged the use of the vernacular by making Portuguese the language of the judiciary, and he arranged for the translation of the *Siete Partidas,* the famous legal code of his grandfather Alfonso X. He founded the first university in Portugal—in Lisbon in 1290. A skilled negotiator. Diniz was able to establish with Castile a definitive frontier for Portugal. At home, he made the authority of the crown supreme, intervening in local government, reducing the power of the nobility and combating the supremacy of the clergy. particularly in regard to their territorial wealth (laws of disentail in 1286, 1291 and 1309). Concordats with the papacy (1289 and 1290) ended the struggle with the church. Diniz took a special interest in the land, encouraging forestry plantation and the fuller development of the country's agricultural resources. He also showed great concern for shipbuilding, and for the extension and protection of commerce, and under Diniz Portugal developed close economic relations with France, Italy Flanders and England. The last years of the reign were disturbed by a rebellion of his son, the future Afonso IV, who succeeded to the throne on his father's death on Jan. 7, 1325.

(V. R. R.)

DINKA, a Nilotic-speaking people, closely related to the Nuer (*q.v.*), who live in the savanna country surrounding the central swamps of the Nile basin in the south of the Republic of the Sudan. They number about 900,000 and are divided into independent tribes of between 1,000 and 30,000 persons. These are grouped on a regional, linguistic and cultural basis into congeries, of which the best known are the Agar, Aliab, Bor, Rek and Malual. The Dinka are primarily transhumant pastoralists, moving their herds of cattle to riverain pastures during the dry season (December to April) and back to permanent settlements in savanna forest during the rains, when their food crops, principally millet, are grown. Each tribe is internally segmented into smaller political units with a high degree of autonomy. By tradition, certain of their patrilineal, exogamous and totemic clans provide priest-chiefs ("masters of the fishing spear") who are spiritual leaders of tribes and sections and whose position is validated by elaborate myths. The Dinka have been receptive of modern education, and the Gogrial rural-area council, the first notable experiment in local government in the southern Sudan, was established successfully in 1946. *See* also NILOTES.

(Go. L.)

DINOCRATES (DEINOCRATES), a famous and original architect of the 4th century B.C., flourished under Alexander the Great. He tried to captivate the ambitious fancy of that king with a design for carving Mouth Athos into a gigantic seated statue.

This plan was not carried out, but Dinocrates designed for Alexander the plan of the new city of Alexandria (*c.* 330 B.C.), and constructed the vast funeral pyre of Hephaestion. Alexandria was, like Piraeus and Rhodes (*see* HIPPODAMUS), built on a regular plan in contrast to the narrow and irregular streets of most earlier towns.

DINOFLAGELLATE, any of certain one-celled aquatic organisms bearing two flagella and having characteristics of both plants and animals. Most are microscopic and most are marine. Botanists consider them a class, the Dinophyceae, of the Algae (*see* ALGAE: *Pyrrophyta)*; whereas zoologists claim them as an order, the Dinoflagellata, of the Protozoa (*see* PROTOZOA). The size range is from about 5 to 2,000 microns. Nutrition among dinoflagellates is plantlike. animallike or mixed. Many species are parasitic in, or commensal with, marine animals (the zooxanthellae of many sea anemones, corals, jellyfishes, etc.). The group is an important component of the phytoplankton in all but the colder seas and is responsible for much of the luminescence in the sea. Fossil dinoflagellates are known from the Carboniferous (beginning about 285.000.000 years ago). Those species that are most plantlike (holophytic) contain a stigma and yellow, orange, brown or green pigment bodies. Noncontractile, coloured vacuoles called pusules are characteristic of marine forms. Many species have trichocysts and some have stinging bodies called cnidoblasts.

Around the body is a median or coiled groove, the annulus. which contains a bound flagellum. A longitudinal groove. the sulcus, extends from the annulus posteriorly to the point where a second flagellum is attached. There are variations of this basic pattern. Armoured dinoflagellates are covered with heavy cellulose plates, which sometimes have long spiny extensions; unarmoured species are naked or have a thin pellicle.

Sexuality has been demonstrated for only one genus; reproduction is largely by binary or multiple fission. Under favourable conditions their numbers may increase quickly to 60,000,000 organisms per litre of water. Such outbreaks, called "blooms" by biologists, result in the "red tides" that discolour the sea. Dinoflagellates produce a water-soluble poison, and heavy blooms result in vast kills of fishes and other marine animals; occurrences of this sort off the Florida Gulf coast (due to *Gymnodinium breve)* and off California (due to *Gonyaulax polyhedra)* are notorious. Certain mollusks become poisonous, and unfit for food, from feeding on toxic dinoflagellates.

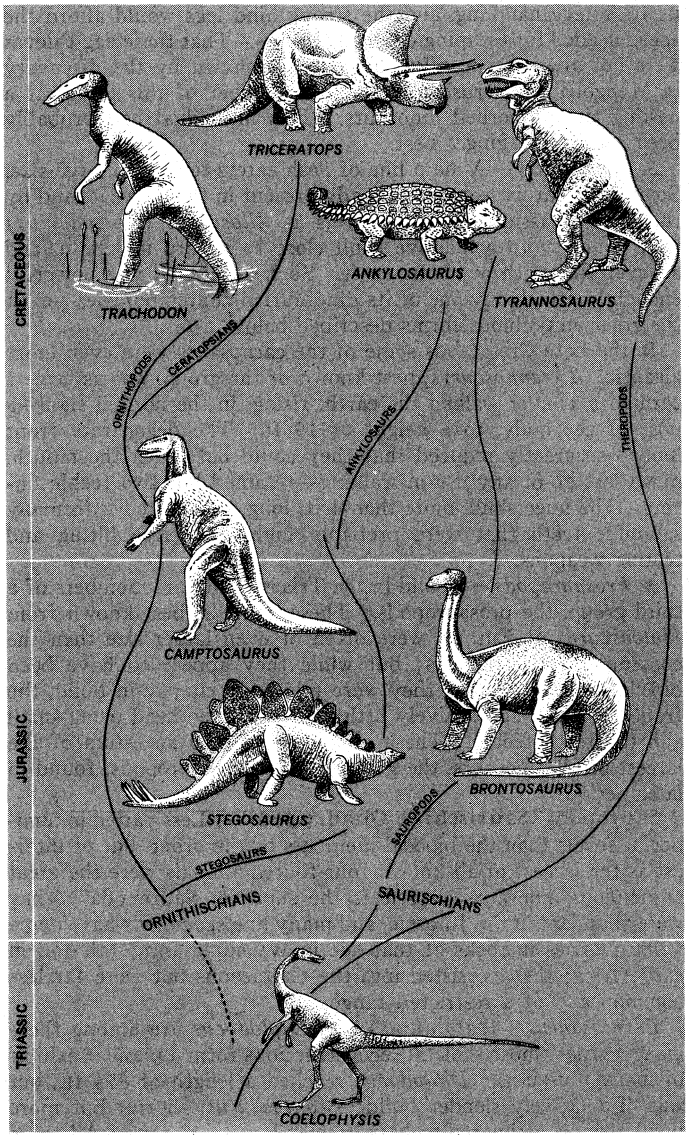
(G. GU.)

DINOSAUR, a term popularly used for the members of a great series of reptiles that were the dominant land animals during most of the Mesozoic era, the age of reptiles, but became extinct at its close. The term, derived from the Greek meaning "terrible lizard," refers to the gigantic proportion of these beasts; but although some of them were in fact the largest animals that ever walked the earth, the earlier or more primitive ones were of small size. Dinosaurs, commonly thought of as constituting a single natural group, actually belong to two distinct but related orders—the reptilelike Saurischia and the birdlike Ornithischia—that were akin to the crocodilians. flying reptiles and bird ancestors. A considerable number of dinosaurs were flesh eaters but a majority abandoned this primitive reptilian mode of life for a herbivorous diet. The early dinosaurs were bipeds, and many forms remained bipedal throughout the history of the group; in both orders however many plant-eating forms reverted to a four-footed gait.

The Mesozoic. the geologic scene in which the dinosaurs played the most important part, extended over a period of more than 100,000.000 years and ended about 70,000,000 years ago. The era is divided into three periods—Triassic, Jurassic and Cretaceous—of



ADAPTED FROM E. H. COLBERT, "DINOSAURS," E. P. DUTTON AND CO., 1961

FIG. 1.— EVOLUTION OF THE DINOSAURS

approximately equal length. Dinosaurs first appeared in the latter third of the Triassic, and are common in red rock deposits of that age in Europe, North America, western China and south Africa. For most of the following Jurassic period the sediments are dominantly marine and dinosaur remains consequently rare. At the end of the Jurassic, however, continental Morrison beds, widespread in the western United States, were laid down with a major dinosaur fauna; a comparable bed is found in the Tendaguru formation of Tanganyika. Early phases of the Cretaceous are, again, mainly marine, but Lower Cretaceous dinosaurs are present in the Wealden beds of southeastern England and adjacent parts of the continent. In the later Cretaceous continental dinosaur-bearing strata are widespread; Alberta and the Rocky mountain states in North America and Mongolia in the old world have yielded abundant remains.

Dinosaur Characters.— The dinosaurs belong to a major subdivision of the reptiles termed the Archosauria, or ruling reptiles. Like the lizards and snakes, and *Sphenodon* of New Zealand, the archosaurs differed from various other reptile groups (such as the ancestors of mammals) in the diagnostic construction of the temporal region of the skull, in which the surface is pierced by two openings (fenestrae), each bounded below by a bony arch—the diapsid condition. In addition, however, archosaurs showed characteristic features of the limbs and limb girdles associated with the fact that early members of the group tended strongly toward bipedal habits. Not only certain dinosaurs but some other archosaurs, notably the crocodilians, tended to revert from incipient bipedalism to a four-footed gait; on the other hand, other dinosaur "cousins," pterosaurs (flying reptiles) and birds, progressed onward from bipedalism to flight.

The bipedal trend was responsible for a series of changes in body build that may have persisted even in a dinosaur that became secondarily quadrupedal. (The front legs are not used, of course, in fully bipedal animals and tend to become more slender and shorter, with, frequently, a trend for reduction in the number of digits). In most four-footed dinosaurs a clue to the preceding bipedal stage is readily seen in the fact that the front legs remained much shorter than the hind. The entire weight of the body came to be supported on the hip girdle (the pelvic girdle) and the hind legs. The girdle was powerfully constructed and had specializations which, however, differed in the two dinosaur orders. In primitive reptiles the limbs sprawled out widely to the side; in dinosaurs the powerful hind legs were rotated to a position directly underneath the body, thus giving more effective support and, since the main limb motion was a fore-and-aft one, giving a more efficient and speedy gait. In many bipedal dinosaurs there was a tendency for the loss of both inner and outer digits in the hind foot, with the development of a three-toed foot closely comparable to that of many of their avian relatives. In consequence it is not to be wondered at that. far back in the last century, when dinosaur skeletons were unknown. footprints of dinosaurs found in the Triassic rocks of the Connecticut river valley and other areas were attributed to gigantic extinct birds.

Dinosaur Stocks.—The names for the two dinosaurian orders, Saurischia and Ornithischia, although not too well chosen, do refer to the most obvious differences between the two groups—differences in the construction of the pelvic girdles. In both groups the ilium, the upper of the three bones forming the girdle, was stoutly built and firmly bound to the backbone. As in all reptiles, there were two lower elements, termed pubis and ischium. In primitive reptiles these two formed a ventral plate. In dinosaurs and related types they were much modified, and more or less rodlike in form, in relation to changed limb posture and consequent change in muscle attachments.

In the Saurischia the pubis extended downward and forward from the limb socket, the ischium ran down and back thus giving (with the ilium) a triradiate appearance to the girdle. In the Ornithischia the structure was still more modified to a tetraradiate pattern. The pubis swung backward to parallel the ischium (as in birds), but developed a paddle-shaped anterior process as an aid in belly support. This contrast in girdle structure is so marked that members of the two groups can be readily observed in casual inspection of mounted museum skeletons or even figures of skeletal reconstructions. Although pelvic build is the most obvious diagnostic feature, the two orders may be contrasted in other regards. For example, saurischians (as is true of reptiles generally), had pointed teeth of simple construction that were generally present the length of the jaws; in ornithischians the front teeth were generally lost and presumably replaced in life by a birdlike bill, and the cheek teeth were leaf-shaped structures. These differences

are to be associated with differences in diet. The majority of saurischians were flesh eaters; all ornithischians were plant eaters.

REPTILELIKE DINOSAURS (SAURISCHIA)

Saurischian Bipeds.—The saurischians were the first of the two great groups to assume prominence. In the earlier Triassic there appeared small bipedal archosaurs called thecodonts, of relatively primitive build. From certain of these forms the saurischians were definitely derived. By the time of formation of the red beds of the Late Triassic a large series of saurischians had made their appearance. All of them were bipeds, as were the majority of later members of the order. and to these and later bipeds as a whole the subordinal term Theropoda is applied. Even at their first appearance, horn-ever, there were clearly distinguishable three types of bipeds; the later history of the three types may be followed in turn.

1. *Coelurosaurs.*—These were a series of relatively small flesh-eating bipeds that are found in every major dinosaur-bearing bed from the Late Triassic to the Late Cretaceous. The coelurosaurs as represented by the Triassic *Coelophysis,* mere slender-limbed, lightly-built (even many of the bones are hollow) and obviously fast-running forms that appear to have preyed upon their smaller reptilian contemporaries. Most members of this group were persistently tiny; for example, a well-known Jurassic form, *Compsognathus,* was no bigger than a rooster. Hoaever. Late Cretaceous coelurosaurs followed to some degree the dinosaurian trend for increased size, although retaining the light build characteristic of the group.

An Interesting end form is *Ornithomimus* (*Struthiomimus*), the "ostrich dinosaur" of the Late Cretaceous. This reptile was about the size of an ostrich and resembled a bird of this sort in such features as the presence (unusual in this order) of a horny bill rather than teeth, small head, long slender neck and powerful legs. It was, however, obviously different from its avian analogue in the presence of a long reptilian tail and of long arms with a clutching power in the fingers. The probable habits of this creature have been a subject of consideable debate. It appears, however, that the animal probably lived by eating the eggs of other dinosaurs. Although teeth would not be needed in eating the egg contents, a beak would help in breaking the shell. The grasping powers of the arms would be useful in egg handling, and the strong hind legs would afford the speed needed for escaping enraged parents. That these egg thieves were not always successful, however, is shown by the discovery in Mongolia of a crushed skull of a member of this group at a nesting site of horned dinosaurs. This individual had probably been caught pillaging a nest.

2. *Carnosaurs.*—A main line of flesh eaters tended to large size. Some large carnivores were already present in the Triassic, and by the Late Jurassic such large forms as *Allosaurus* (*Antrodemus*) were iound, with a massive skull close to a yard in length, and an over-all length of about 34 ft. Such an animal was powerful enough to attack any one of its dinosaurian contemporaries—even the great amphibious forms described below.

In the Late Cretaceous some of the carnosaurs were even more gigantic. *Tyrannosaurus,* best known of the group, was as large a carnivore as ever walked the earth, rising, in the normal slanting pose of the body, to a height of 19 ft. The degenerate front limbs—so greatly reduced that they could not reach the mouth, much less be of any use in walking—retained but two feeble fingers. The huge skull, more than 4 ft. long, was armed with many sabrelike teeth that were probably highly effective biting and tearing weapons.

3. *Prosauropods.*—Found in the Triassic only are members of a third group, the prosauropods. These animals, best known from *Plateosaurus* of Europe, were often of even larger size than the contemporary carnosaurs; but while they appear to have been bipedal to some degree, they were relatively clumsy in build, the front legs showing relatively little reduction, the head being small and the teeth feeble. These animals were the ancestors of the largest of all dinosaurs, the great amphibious sauropods, found in later periods.

Sauropods (Saurischian Quadrupeds).—Less varied in number of forms than the bipedal members of the order, but of interest as the largest of all known four-footed animals were the great amphibious dinosaurs classed as the suborder Sauropoda. They were abundant in the Jurassic. and many fine specimens have come from quarries in rocks of that age in Wyoming and Utah and in east Africa; they persisted into the Cretaceous but were far less common and of a restricted range.

Brontosaurus (Apatosaurus) and Diplodocus are among these giant reptiles whose skeletal reconstructions form a popular exhibit of many museums. *Diplodocus* reached a length of 87½ ft., but was of relatively slender build; Brontosauuus, shorter but more ponderous, is estimated to have weighed up to 35 tons. All these forms had a massive body, powerful limbs with a secondarily acquired four-f ooted pose (honever, the forelegs were usually much shorter than the hind), a long tail and a long neck. The head was preposterously small in proportion to the body, the jaws short and weak, the teeth feeble and few in number; it is difficult to believe that such an apparatus could have served to feed such a great body unless the fodder was very soft water vegetation that could be cropped with little effort. The brain was tiny. Eyes and nostrils were high up toward the top of the skull. one of many reasons for believing that these giant reptiles were water dnellers—the animal could see and breathe with only the top of the head above the surface.

In keeping with sound engineering principles—necessary to carry

FIG. 5.—BRONTOSAURUS, A SAURISCHIAN QUADRUPED, IN A JURASSIC SWAMP

the tons of weight of the enormous body and transfer it to the legs—the backbone was built as an arch, strongest at its centre above the supporting columns formed by the massive hind legs. As a weight-reducing measure, the elements of the vertebrae were hollowed out at the sides, leaving only the essential framework of the bones. But even with such adaptations, it is difficult to imagine how such ponderous animals ever could have walked on land. It is reasonable to believe that these animals were amphibious, spending much of their lives in lowland swamps and lagoons where, buoyed up by the water, problems of support and locomotion were greatly simplified. The largest sauropod was *Brachiosaurus,* known both from North America and east Africa, which may have reached a live weight of 50 tons. Unusual among dinosaurs, the front legs were long, and the neck appears to have stretched almost directly upward. Were it alive today, this dinosaur could look over the top of a three-story building; it was probably adapted for living in waters of considerable depth.

BIRDLIKE DINOSAURS (ORNITHISCHIA)

Ornithischian Bipeds.—The Ornithischia, like the saurischians, are surely descended from primitive thecodont ancestors of the earlier Triassic, but connecting links are as yet unknown. Reported remains of the order in the Late Triassic are few in number, fragmentary and dubious in character. It is not until late in the Jurassic period that any adequate representation of the order is to be found. By that time several distinct types were present, the more primitive of which belong to the suborder Ornithopoda. As in the case of the primitive saurischians, these were bipeds; however, since there was relatively little reduction of the front legs, they probably could amble about on all fours when at leisure. Like all members of the order, these bipeds were herbivores.

In Jurassic and even Cretaceous times certain ornithopods remained relatively small in size. But as in other groups there was a trend toward gigantism. Well known from the Early Cretaceous of Europe is *Iguanodon,* which reached about 15 ft. in height in standing pose. In the Late Cretaceous there flourished a series of large forms technically called the hadrosaurs, the duck-billed dinosaurs.

Numerous fine skeletons of hadrosaurs have been recovered from North American rock beds, particularly from the plains of western Canada. The hadrosaurs. exemplified by Trachodon, owe their popular name to the fact that the toothless front ends of both upper and lower jaws were broadened to form a ducklike bill. It is probable that their diet consisted of some hard type of vegetable material; for although individual cheek teeth (small leaf-shaped structures) nere present, as in other ornithischians, each cheek contained, in both upper and lower jaws, large numbers of such teeth cemented together to form a powerful grinding plate. It is estimated that a duck-billed dinosaur's mouth may have contained as many as 2,000 teeth.

A curious evolutionary trend among the hadrosaurs was the development of crested-beaked forms. In some the crest had merely the curve of a "Roman nose"; in another form this bony crest was a thin high swelling in the shape of a rooster's comb over the top of the head. In others the crest grew farther back to form a sort of horn extending over the neck region. It is uncertain what the function of these curious structures was, but it is of interest that they were formed of the bones that usually lay about the animal's nose, which had been, so to speak, pulled backward over the top of the head. In one instance dissection of a fossil skull shows that these bones contained a long, looped air passage between the nostrils and the back of the mouth. Possibly these structures were an adaptation for underwater feeding. This suggestion is reinforced by the fact that in several hadrosaur specimens in which skin impressions are preserved, the feet are seen to be webbed, indicating amphibious habits.

Armoured and Horned Dinosaurs.—Although bipedal members of the ornithischians flourished throughout the latter part of the Mesozoic, many others reverted to a quadrupedal condition. For a herbivore, speedy running is useful only as a means of escape from enemies, and if defensive measures of other sorts were developed, reversion to a more leisurely four-footed gait could take place. In the remaining three suborders of ornithischians defense against carnivorous dinosaur contemporaries was developed in the form of armour or horns.

Characteristic of the Late Jurassic and Early Cretaceous was a group of which *Stegosaurus* is typical. The general body proportions of stegosaurs were most unusual. The front legs (no doubt reduced during an earlier bipedal phase) were very short; in consequence, the contours of the back rose steeply from the small head to a considerable height above the long and powerful hind legs before sloping downward to the tail. The flanks appear to have been unprotected except, it is assumed, for a stout and leathery skin. Down the back u-as present a double row of large vertical bony plates, and the tail was armed with two pairs of long, pointed, bony spikes.

In the Cretaceous, Stegosaurus and its relatives were replaced by a second type of armoured dinosaur of which Ankylosaurus was representative. The ankylosaurs were at one time grouped as armoured dinosaurs with their stegosaurian predecessors. but they are now known to have been very different in basic structural characters as well as in protective adaptations and body proportions. These dinosaurs have been not inaptly termed "reptllian tanks." In these forms the head was massive and covered with extra bony plating in addition to the normal skull bones. The body, in contrast with that of the stegosaurs was low and broad. The entire back was solidly covered with stout bony armour which in some areas was made up of a mosaic of small bones. and in others was principally formed of large oval flat-lying plates. The tail, further, was armoured, and although the limbs had no bony covering, they were protected from attack by stout

spines extending out from the dorsal armour shield.

A final type of four-footed ornithischian was that of the horned dinosaurs, such as *Triceratops,* which abounded in the Late Cretaceous. In them the trunk appears to have been barren of any defensive structures; everything was concentrated on head development. A broad frill of bone extended out from the back of the head and protected the neck from attack. In addition large bony horns were generally developed on the skull. Two were usually present above the eyes, much as in modern cattle, and a third above the nose. The face terminated in a powerful parrotlike beak.

Ceratopsians, best known from North America, were generally large and ponerful animals; from the Cretaceous of Mongolia, however, comes *Protoceratops,* a small and primitive form only a few feet in length with a well-developed neck frill but almost no trace of horns.

DECLINE AND EXTINCTION OF DINOSAURS

Most types of dinosaurs continued to flourish until the very latest phases of the Cretaceous, last of the Mesozoic periods. Then they disappear completely from the geologic record; the earliest beds of the Cenozoic, the age of mammals, which appear to follow closely in time, show not the slightest trace of a dinosaur. What caused this sudden extinction? The answer is not at all clear. Temperature changes, epidemics, eating of dinosaur eggs by early mammals, have all been suggested but are far from satisfactory.

It appears probable that a major cycle of mountain building that began in the Cretaceous may have been a major factor. Higher land levels would tend to reduce the lowland areas where dinosaurs flourished; new mountain chains would change climates and may have been important in stimulating evolutionary changes in the plant life upon which dinosaurs fed. Decline of herbivorous dinosaurs would have been disastrous to the flesh eaters that fed upon them. The decline of dinosaurian life can, thus, be reasonably accounted for. However, there is no really satisfactory explanation for the sudden and complete extinction of the most spectacular animal fauna the earth has ever known. *See* PALAEONTOLOGY; REPTILE; *see* also references under "Dinosaur" in the Index volume.

DINOSAUR NATIONAL MONUMENT, in northwestern Colorado and northeastern Utah, part of which was set aside in 1915 to preserve rich fossil beds, including remains of dinosaurs. The monument was enlarged from its original 80 ac. to approximately 200,000 ac. in 1938 in order to protect the spectacularly beautiful canyons of the Green and Yampa rivers which cut through 21 tilted and highly coloured geological formations of the Uinta plateau, representing at least 20,000 vertical feet, in deeply incised meanders. The rivers join near famous Steamboat rock, near the centre of the monument, and flow westward as the Green. The colourful canyon walls, rising nearly 2,000 ft. from the water, sometimes vertically and sometimes in varicoloured terraces and steps, can best be seen from the rivers. A 90-mi, river trip, alternating peacefully flowing current and exhilarating white water, can be made under the guidance of concessionaire boatmen in five or six days. Wildlife seen in the monument include deer, beaver, bighorn sheep, antelope, Canada geese, and many others. Pictographs and other evidences of prehistoric Indian life are found in the canyons. Nature trails, campsites and picnic grounds are provided for visitors. The fossil quarry and museum. both open to the public all year, are located at the monument headquarters in the southwestern corner of the monument.

The proposed construction of dams in the monument at Echo park and Split mountain gorge as a part of the upper Colorado river basin storage project resulted in delay from 1950 to 1956 of congressional authorization because of opposition by conservationists and an aroused public opinion on the basis that the dams would destroy the unique features of the monument and set a precedent for similar invasions of other national parks and monuments. The controversy was finally resolved when the bill was so amended as to ensure that no violation of a national park or monument unit would be permitted.

DINWIDDIE, ROBERT (1693–1770), British colonial administrator and lieutenant governor of Virginia during the French and Indian War. He was born in 1693 at Germiston. a few miles from Glasgow, Scot., and was trained in the countinghouse of his father. He later attended Glasgow university. In 1721 he was appointed Britain's representative on the island of Bermuda in charge of admiralty affairs. There he gained experience as a colonial administrator, and in 1738 assumed the post of surveyor general of customs of the southern district in America, which included the continental colonies from Pennsylvania southward and the Bermudas and Jamaica. During the 1740s Dinwiddie made at least two detailed reports on the state of the colonies which exhibited his ability as a governmental statistician on economic and military affairs. In 1751, two years after Dinwiddie resigned from the customs service, he accepted the appointment as lieutenant governor of Virginia. (Dinwiddie was in fact governor, since the titular governorship was a sinecure belonging to William A. Keppel, the second earl of Albemarle.) In Williamsburg, Va., where Dinwiddie made his home with his wife and two daughters, he quickly immersed himself in the affairs of the colony, especially the problems relating to Indian diplomacy and threats of French occupation in the west. Even before assuming the governorship Dinwiddie had become a member of the Ohio Company of Virginia which hoped to bring settlers to occupy a large tract of land that included the area of the forks of the Ohio river where the city of Pittsburgh now stands. Alarmed at what he believed to be encroachments on Ohio company lands. Dinwiddie in 1753 sent young George Washington to warn the French that they were occupying lands claimed by the English. After learning of French plans for further occupation of the Ohio area, Dinwiddie in Feb. 1754 sent Washington back to the frontier with troops, and following Washington's capitulation to the French at Ft. Necessity, he made efforts

to obtain Virginia financial support for another expedition against the French.

After the defeat of Gen. Edward Braddock's army in July 1755, defense against marauding Indians on the wide Virginia frontier devolved on Dinwiddie. He raised ranger companies and a regiment under Washington, built fortifications and with little success sought intercolonial co-operation for defense. Finally after extended negotiations. he brought together about 400 southern Indian tribesmen for a conference at Winchester in 1757 which resulted in temporary pacification'on the Virginia frontier.

Because of failing health Dinwiddie left Virginia at his own request on Jan. 12, 1758, and died on July 27, 1770. in Bristol. Eng. He has often been called one of the ablest governors in the American colonies.

DIO CASSIUS (CASSIUS DIO) **COCCEIANUS** (*c.* A.D. 150–235), Roman administrator and historian. was the author of *Romaika,* a history of Rome, which is a most important authority for the last years of the republic and the early empire. It was written in Greek. He was born at Nicaea in Bithynia, the son of Cassius Apronianus, governor of Dalmatia and Cilicia under Marcus Aurelius, and on his mother's side he was the grandson of Dio Chrysostom. After his father's death Dio Cassius went to Rome (180) and became a member of the senate. During the reign of Commodus, he practised as an advocate and held the offices of aedile and quaestor. He was raised to the praetorship by Pertinax but did not assume office till the accession of Septimus Severus with whom he was for long on intimate terms. By Macrinus he was entrusted with the administration of Pergamum and Smyrna, and on his return to Rome he was made consul. After this he obtained the proconsulship of Africa. and again on his return was sent as legate successively to Dalmatia and Pannonia He was granted a second consulship by Alexander Severus, in 229, but soon afterward retired to Nicaea, where he died. Before writing his history Dio Cassius had dedicated to Severus an account of various prodigies which had presaged his elevation to the throne (perhaps the *Enodia* attributed to him in the Suda lexicon), and had also written a biography of his fellow-countryman Arrian. The history of Rome consisted of 80 books beginning with the landing of Aeneas in Italy and ending in the reign of Alexander Severus (222–235). Books 36–60 (68 B C.–A.D. 47) have survived; books 36 and 55–60 are imperfect. Part of 35 and 36–80 are included in the epitome of Joannes Xiphilinus, an 11th-century Byzantine monk. For the earlier period the loss of Dio's work is partly supplied by the history of Zonaras, who followed him closely. Numerous fragments are also contained in the excerpts of Constantine Porphyrogenitus. Dio's industry was great and the various offices he held gave him opportunities for historical investigation. His narrative shows the hand of the practised soldier and politician; the language is correct and free from affectation. But his work, although far more than a mere compilation, is not remarkable for impartiality, vigour of judgment or critical historical faculty.

DIOCESE, the territorial area administered by a bishop. The original use of the word was entirely secular. The completion by Constantine I in the 4th century of the administrative reforms of the Roman empire begun by Diocletian divided the four prefectures of the empire into 13 dioceses governed by imperial vicars. The church, in its progressive expansion, adapted this secular pattern to its own requirements The secular diocese was subdivided into provinces each under its own governor, but in the ecclesiastical adaptation the province became the larger territorial unit, administered by a metropolitan bishop and subdivided into dioceses. The original unit of ecclesiastical administration was the parish (Gr. *paroikia),* which in the Orthodox Eastern Church still remains the designation of the area administered by the bishop, the diocese being the area administered by the patriarch. The use of these terms was still fluid in the west in the 9th century. when Hincmar, archbishop of Reims. referred to the province as his diocese and his immediate bishopric of Reims as his parish. But by the 13th century "diocese" had settled down to mean the bishop's territorial area.

In the Roman Catholic Church only the pope can divide or merge dioceses, or create new ones (*e.g.,* in missionary territory). All dioceses are divided into parishes, and some large ones into rural deaneries also. The clergy share in diocesan administration and normally attend a diocesan synod once a year.

In the Church of England new dioceses have been created by statute as a result of dividing existing ones in the 16th, 19th and 20th centuries. To give effect to the spiritual charge which the bishop has over all the inhabitants of his diocese, the diocese is subdivided into parishes in each of which is a priest who has the "cure of souls" under licence from the bishop. Parishes are grouped in rural deaneries, and rural deaneries in archdeaconries.

(J. W. L.)

DIO CHRYSOSTOM (DION CHRYSOSTOMUS, the "golden-mouthed") (C. A.D. 40–after 112) also called Dio Prusaeus and Dio Cocceianus, Greek rhetorician and philosopher, won fame in Rome and throughout the empire for his writings and speeches. Born at Prusa in Bithynia of well-to-do parents *c* A.D. 40, he was banished in A.D. 82 on political grounds both from Bithynia and Italy, and wandered for 14 years through the lands near the Black sea, adopting the poverty-stricken mode of life advocated by the Cynics. With the death of the emperor Domitian his exile ended and he made a new career as a public speaker and philosopher.

A collection of 80 "orations" with fragments of others survives, but some are dialogues or moral essays, and two (xxxvii and lxiv) are spurious, being probably the work of a pupil, Favorinus of Arelate (Arles). Four are speeches addressed to Trajan *On Kingship* (i–iv); the *Olympicus* (xii) shows the sculptor Phidias explaining the principles followed in his famous statue of Zeus, one passage being supposed by some to have suggested the German dramatist G. E. Lessing's *Laocoon; On Aeschylus, Sophocles and Euripides* (lii) compares the treatment of the story of Philoctetes by each tragedian. Best known is the *Euboicus* (vii), depicting country life on the island of Euboea, an important document for social and economic history.

A patriotic Greek who accepted Roman rule, Dio typifies the revival of Greek self-confidence under the Roman empire which marks the beginning of the new or second sophistic movement in the and century A.D. In style he belongs to the archaizing Atticist school. As a philosopher he was not original, but blended elements from Stoicism and Cynicism.

DIOCLES (fl. 4th century B.C.), of Carystus in Euboea, Greek physician. second only to Hippocrates in reputation and ability according to tradition, was a pioneer in more than one department of medicine. He resided at Athens and was the first to write medical treatises in Attic Greek, breaking with the tradition of using Ionic for such writings; only fragments, however, of his works survive. He is usually regarded as the chief representative of the "dogmatic" school, but this description is scarcely informative. He wrote on a variety of subjects, including animal anatomy (the first systematic textbook on this subject. in connection with which he practised dissection), dietetics (zoological questions were also discussed in the same work), physiology, embryology and medical botany (here again his book was probably the first work of its kind and may have been used by Theophrastus).

It was once supposed that Diocles was a contemporary of Plato, but W. Jaeger, interpreting the evidence in relation to the philosophical background, has shown that he must have been a contemporary, perhaps a slightly younger contemporary, of Aristotle;

Valentin Rose, however, had already stated (*Aristoteles pseudepigraphus*, 1863. p. 380) that there was no ground for dating Diocles earlier than Aristotle. His most probable dates are 375–300 B.C. (Jaeger's subsequent arguments for a date 30 to 40 years later are less cogent).

In doctrine. Diocles shows a "synthetic" tendency. combining the influence of Hippocratic medicine and that of the Sicilian school, of which Archidamus. his father, had been an adherent; and in his terminology and methodology there are clear indications of Aristotelian influence. It seems certain that he had at his disposal some sort of corpus of Hippocratic writings; it may have been put together by him. He was. however, much more than a compiler and systematizer, although his work in reorganizing medicine on the theoretical side was of the first importance; on the practical side he undoubtedly struck out on original lines. His work on zoology may have been used by Aristotle.

(1940); W. Jaeger, "Vergessene Fragmente des Peripatetikers Diokles," *Abhaadlungen der Preussischen Akademie der Wissenschaften: philosophischhistorische Klasse,* 3 (1938). (A. L. PK.)

DIOCLETIAN (GAIUS AURELIUS VALERIUS DIOCLETIANUS), Roman emperor A.D. 284–305, effected an administrative and financial reorganization of the Roman empire and also ordered the last great persecution of the Christians. Originally called Diocles, he was a Dalmatian of very humble birth who rose by military service to be commander of the *protectores* under the emperor Numerian. When it was discovered that Numerian had been murdered, the army at Nicomedia (Izmit, on the sea of Marmara near the Bosporus) proclaimed Diocletian emperor (Nov. 20,234). His first act was to kill with his own hand the alleged assassin, the praetorian prefect Aper. He then marched against Numerian's brother. Carinus (*q.v.*), who was ruling in the west. They met at the Margus river (Morava in Yugoslavia) in 285 and Carinus was killed in the battle. Diocletian ruled for over 20 years, abdicating on May 1, 305, and during his long reign carried through a great reorganization of the empire which gave it a new lease of life after the disastrous civil wars and invasions of the mid-3rd century.

The Tetrarchy.—The most crying need of the empire was to check the succession of military pronunciamentos which had produced usurper after usurper in the past 30 years. Diocletian did something to this end by emphasizing the divine sanctity of the emperor's person and introducing a more dignified court ceremonial, derived from the Persian monarchy. In this: however, he was merely developing tendencies long current — indeed his immediate predecessors had claimed divinity more expressly than he did — and it is doubtful if these measures would by themselves have protected him against rebellions and mutinies any more than they did his predecessors and successors. More important was his creation of a team of emperors to share the rule of the empire. Immediately after the battle of Margus he appointed a trusted friend, Maximian (*q.v.*), as Caesar to take charge of the Gauls where the peasant Bagaudae had revolted, and early the following year he made him his full colleague as Augustus. Constitutionally the two Augusti were equal, Diocletian being merely the senior of the pair, but in practice he dominated his colleague. Their relation was symbolized by the divine surnames which they adopted. Diocletian was Jovius, the representative on earth of Jupiter, king of the gods, Maximian Herculius, the counterpart of Hercules who by his heroic labours fulfilled Jupiter's will. Seven years later on March 1, 293, Diocletian created two Caesars, Galerius (*q.v.*) to serve under himself and Constantius I Chlorus (*q.v.*) under Maximian. The Caesars were adopted into the Jovian and Herculian families and married to daughters of their respective chiefs. In theory the four emperors ruled the empire as colleagues, all official pronouncements being made in their joint names. In practice they administered separate zones with their own governments and armies. Maximian ruled Italy and the western provinces, and Constantius took over Gaul and Britain from him. Diocletian ruled Illyricum, Egypt and the east; his Caesar, Galerius, seems to have been assigned various tasks in this area according to the needs of the moment.

This tetrarchy produced the desired stability. Four emperors could more effectively maintain touch with the widely separated army groups than could one, and in the event of a rebellion or other crisis one of the colleagues could deal promptly with it while the others held the fort elsewhere. In fact there were only two serious revolts. that of Carausius (*q.v.*) and Allectus in Britain (286–296), ultimately suppressed by Constantius, and that of Domitius Domitianus (or Achilleus) in Egypt (296–297), promptly crushed by Diocletian himself. The success of the tetrarchy, however, depended on the concord of its members, and this was ensured by Diocletian's dominating personality. This was demonstrated by the course of events after his retirement, when the emperors soon quarreled among themselves and another series of civil wars followed.

The tetrarchy was also designed to solve the problem of the succession. When Diocletian abdicated he forced Maximian to do so simultaneously: the two Caesars were proclaimed Augusti, and two new Caesars were nominated. There would thus always be two experienced rulers ready to take over. The succession would go by appointment and adoption; the claims of sons of emperors mere ignored The scheme was too artificial to work and broke down at once. It made no allowance for accidents, such as the death of Constantius after one year's rule as Augustus. It did not take into account the natural ambition of emperors' sons or the strong preference of the army for them: Constantius' son Constantine I and Maximian's son Maxentius (*qq.v.*) had no difficulty in getting the armies to proclaim them.

Diocletian was no more than a competent general and left most of the fighting to his colleagues. The only war in which he is known to have personally taken command after the nomination of the Caesars is that against Domitius Domitianus and when hostilities with Persia broke out in 296 he entrusted the command to Galerius. In military affairs he was somewhat conservative. He greatly increased the size of the army, perhaps doubling its numbers, but maintained in principle the traditional policy of stationing it along the frontiers, which he greatly strengthened with roads and forts. Each emperor had a field army *(comitatus)* at his disposal, but these armies seem to have been very small, and for any major compaign had to be strengthened by detachments drawn from the frontier forces.

Reorganization of the Empire. — It was as an administrative and financial reformer that Diocletian made his mark upon the empire. He approximately doubled the number of the provinces, subdividing the largest into as many as six, as he did in Asia. The object was not to weaken over-powerful governors — the proconsul of Asia. who had no troops, was no danger — but to increase the efficiency of the administration. To lighten the work of the central governments the provinces, now numbering about 100, were grouped into twelve large divisions, called dioceses, each controlled by a deputy (*vicarius*) of the praetorian prefects, and by representatives of the two financial ministers, the *rationales rei summae* ("general treasurers") and *magistri rei privatae* ("masters of the privy purse"). In many of the frontier provinces he separated the military command from the civil administration, appointing a *dux* to command the forces of a province or group of provinces. Here again his object was probably to increase efficiency rather than to guard against rebellion; the *dux* of the three provinces of Egypt, the Thebaid and Libya commanded a very substantial army. The division of power was not extended to the praetorian prefects (and their *vicarii*), who combined military with administrative, judicial and financial functions.

Economic Reforms. — Diocletian found the currency hopelessly debased: the old silver *denarii* had been replaced by silver washed copper *nummi* and gold had gone out of circulation. He issued gold coins (at 70 and later 60 to the pound) and from 296 silver *denarii* (at the old rate of 96 to the pound) and larger and superior *nummi.* But he could not issue enough coins of gold and silver — which had vanished into hoards — and flooded the market with *nummi.* The result was that *nummi* depreciated in relation

to the gold and silver coins and prices continued to rise. In 301 Diocletian issued his famous edict on prices, whereby he endeavoured to fix maximum prices in detail for all varieties of goods (including gold and silver, whether in bar or coin), and maximum wages, by day or piece. for all kinds of services. The penalty for exceeding these prices or withholding goods from the market was death, but though there were many executions the edict proved unenforcible. Nevertheless, although he failed to stabilize the currency Diocletian put the state finances on a sound basis. During the inflation the government had come to pay its employees mainly in kind, obtaining the necessary foodstuffs and clothes by compulsory purchase or requisition (*indictio*). Diocletian organized these indictiones, hitherto irregular. into a system. By a series of censuses all landed property was assessed in fiscal units, generally known as *iuga,* which were of uniform value in each diocese (complete uniformity throughout the empire was no doubt unattainable for practical reasons). and the animal and human population was similarly assessed in fiscal units known as capita. It was the duty of the praetorian prefects to estimate the quantities of goods required in each year, and to issue an annual *indictio* stating how much would be required from each *iugum* and *caput* The burden was thus (in theory at any rate) equitably distributed over all the land of the empire (including Italy, which thus lost its old fiscal immunity). The burden could moreover be adjusted annually according to the needs of the empire. Other levies were imposed on the same assessment of *iuga* and capita, of conscripts for the army and of forced labour for public norks (Diocletian was a great builder; impressive remains survive of his huge baths at Rome and his vast palace at Split). It may be noted that house property and the urban population were not entered in the census and thus remained untaxed.

Religious Policy. — It is somewhat surprising that having for many years maintained his predecessors' policy of tacit toleration of the Christians. Diocletian should have taken drastic action toward the end of his reign, and it seems likely that as stated by Lactantius, Galerius, who was undoubtedly a rabid pagan and whose influence increased in Diocletian's latter years, was the prime mover of the persecution. It is unlikely. however, that Diocletian acted contrary to his own convictions. He seems to have been a religious man of rather old-fashioned piety. There is extant a law of his against incestuous marriages uhich is strongly religious in tone: in it he declared that the continued favour of the immortal gods to the Roman empire nas dependent on his subjects' leading pious, religious and chaste lives. In another law he enacted the severest penalties against the new sect of the Manichees, partly because they derived their doctrines from the hostile race of the Persians, but more on the general ground that the established religion was inspired by the immortal gods and that all innovation was impious. Diocletian is therefore unlikely to have viewed with favour a sect which denied all the gods in favour of a newfangled deity, but it nas apparently with reluctance that he undertook the formidable task of trying to extirpate it.

According to Lactantius he was first roused to action when at an official sacrifice the priests. unable to obtain omens, declared that Christians present, by making the sign of the cross, had offended the gods. Infuriated by this contumacious obstruction of public worship, Diocletian ordered that all Christians be discharged from the army and civil service unless they sacrificed. This probably happened about 298, and it was not until about five years later that Diocletian. having consulted the oracles, issued his first general edict against the Christians (Feb. 23, 303). It enacted that all copies of the scriptures should be surrendered and burned. that all churches should be closed and meetings of Christians banned. Two fires in the palace at Nicomedia — alleged to have been engineered by Galerius — were imputed to Christian incendiaries, and a second edict was issued. ordering the arrest of all the clergy. Some months later the imprisoned clergy were all forced to sacrifice, and then, nith the exception of a few obstinate recusants released. Finally in the spring of 304 an edict was issued. ordering all the inhabitants of the empire to sacrifice. The persecution ceased in the west after Maximian's abdication, but in the east continued intermittently until 313.

Retirement. — In 303 Diocletian paid what was probably his first visit to Rome to celebrate his *vicennalia* (the twentieth anniversary of his accession). During his return journey in the following year he suffered a very severe and prolonged illness, and on May 1, 305, he abdicated at Nicomedia. He spent his last years in the magnificent palace which he built for himself near Salona in Dalmatia, now the town of Split (Spalato). Though pressed by Galerius to resume the throne in 308 he refused. The date of his death is uncertain (probably 313).

Diocletian was evidently a dominating personality, who commanded the implicit loyalty and obedience of his colleagues and ministers. He was ruthless in enforcing his will, and reserved, not to say secretive, in temperament, and was respected but not beloved by his contemporaries. He distrusted and disliked the senate. whose members he almost entirely excluded from the administration. but in many other ways he upheld Roman traditions, notably in religion and in the law. On the other hand he was a bold innovator where circumstances required it. He greatly strengthened the military and administrative structure of the empire, but the increased size of the army and civil service imposed a heavy strain on its manpower and financial resources. To fill the ranks of the army conscription was ruthlessly enforced and the sons of soldiers compelled to serve. To pay and feed it the taxes in money and kind were increased, and to make sure that the peasants paid their poll tax and produced the foodstuffs required they were compelled with their children to remain in the places where they were registered in the census. Diocletian has been much criticized for thus regimenting society. But in so doing he was only accentuating certain basic principles of Roman law and reinforcing existing social tendencies. Under Roman law every man owed certain obligations to the community to which he belonged by birth; in practice service in the army had long been largely hereditary; and in Egypt at any rate it was an old rule to recall the peasants to their place of origin at every census. To support the increased burden of defense against the barbarians every citizen had to play his full part, and the simplest and, to contemporary thinking, the most natural way of achieving this object was to insist that every citizen fulfilled the function to which he was born. *See* also references under "Diocletian" in the Index volume.

BIBLIOGRAPHY.—Original sources for Diocletian's reign are scanty. Apart from papyri and inscriptions, notably the edict on prices reproduced in T. Frank, *An Economic Survey of Aizcient Rome,* vol. v, pp. 301–421 (1940), and laws preserved in the *Codex Justinianus* and elsewhere, the only contemporary sources are the last part of Eusebius' *Ecclesiastical History,* which describes the persecution, and Lactantius' *de mortibus persecutorum,* a highly Biased but informative pamphlet. Among later historians there are only brief chapters in Aurelius Victor, Eutropius and Orosius. Modern studies are also few. The reign is treated in the *Cambridge Aizcient History,* vol. xii, pp. 323–408, 661–667 (1956): there are good monographs on Diocletian by G. Costa in E. de Ruggiero, *Dizionerio epigrafico,* vol. ii, pp. 1797–1888 (1912), and by W. Ensslin in Pauly-Wissowa, *Real-Encyclopiidie der classischen Altertumswissenschaft,* 2nd series, vol. vii, 2419–2495 (1948).

(A. H. M. J.)

DIODATI, GIOVANNI (1576–1649), Swiss Calvinist pastor known for his translation of the Bible into Italian, was born in Geneva, June 6, 1576, of a refugee Protestant family from Lucca. He became a pastor at Geneva in 1608, and professor of theology in 1609. He was a leader of the reformers. being an eloquent, bold and fearless preacher, and a rigid Calvinist. Me conducted a mission to France in 1614 and was appointed to record the proceedings of the synod of Dort (1618–19). His Italian translation of the Bible was first published in 1603. He was also the author oi a translation into French and of biblical annotations and polemical treatises. Diodati died on Oct. 3, 1649.

See E. de Budé, ***Life*** *of* G. *Diodati,* trans, by M. Betts (1905).

DIODORUS CRONUS (fl. 4th century B.C.), Greek philosopher of the Megarian school, born at Iasus in Caria, was a pupil of Apollonius of Cyrene; the surname Cronus, of uncertain meaning, was applied both to him and to his teacher. Through Apollonius he is linked with Eubulides (*q.v.*), and these three represent that branch of the Megarian school which was strong in formal logic. Diogenes Laertius has a story that, at the court of Ptolemy Soter. Diodorus failed to solve a logical problem propounded by Stilpo and died of shame at his failure (c. 307 B.C.).

Diodorus raised difficulties about movement that resemble those of Zeno, but was prepared to admit that it is true to say that a thing has moved from *A* to B: it is the process of moving that is unintelligible. In connection with this, he maintained that there are atomic minima of physical substance. Departing from the earlier Megarian doctrine, he asserted that the possible is that which either is real now or will be real. His view of the meaning of conditional propositions *(see* LOGIC, HISTORY OF) was defended by a famous argument (the so-called *kurieuon logos)* the precise form of which is uncertain.

See I. M. Bocheński, *Ancient Formal Logic* (1951). (D. J. A.)

DIODORUS SICULUS (fl. 1st century B.C.), Greek historian, was the author of a universal history *Bibliotheca historica.* Born at Agyrium in Sicily, he lived in the time of Julius Caesar and Augustus, and his own statements make it clear that he traveled in Egypt during 60–57 B.C. and spent several years in Rome. The latest event mentioned by him belongs to the year 21 B.C. His history consisted of 40 books and was divided into three parts. The first treats of the mythic history of the non-Hellenic and Hellenic tribes to the destruction of Troy; the second ends with Alexander's death; and the third continues the history as far as the beginning of Caesar's Gallic War. Of this extensive work there are extant only the first five books, treating of the mythic history of the Egyptians, Assyrians, Ethiopians and Greeks; and also the 11th to the 20th books inclusive, beginning with the Greco-Persian War of 480–479, and ending with the history of the successors of Alexander, before the partition of the Macedonian empire (302). The rest exists only in fragments preserved in Photius and the excerpts of Constantine Porphyrogenitus.

The faults of Diodorus arise partly from the nature of the undertaking and partly from his use of an annalistic form which sets him chronological problems beyond his powers. He lacks the critical faculty: he repeats and contradicts himself: and his simple diction. intermediate between pure Attic and the colloquial Greek of his time. makes it possible sometimes to detect undigested fragments of his materials. Yet the *Bibliotheca*, invaluable where no other continuous historical source has survived. is of considerable value. too. as supplying to some extent the loss of the works of earlier authors. from nhich it is compiled. He does not always quote his authorities, but in the books which have survived his most important sources for Greek history were certainly Ephorus (for 480–340 B.C.) and Hieronymus of Cardia (for 323–302).

In particular sections (*e.g.*, for Sicily, or the reign of Alexander) Diodorus followed special authorities. who cannot always be named for certain. For chronology he used probably Apollodorus of Athens and Castor of Rhodes, and for geography Megasthenes (perhaps at second hand). Xgatharchides and Artemidorus.

DIODOTUS, the name of a satrap of the Seleucid province of Bactria in the 3rd century B.C. who, together with his son of the same name, may be reckoned as having founded the Greek kingdom of Bactria. In the later period of his life he was acting the part of an independent ruler. Indeed. Justin (3rd century A.D. or later) declares that he took the title of king after revolting against the Seleucid' house. If this is correct, there is unfortunately no means of dating the occurrence. On the other hand, it has been conjectured on numismatic evidence (by W. W. Tarn) that the Seleucid king Seleucus II, in order to secure his friendship, married one of his sisters to Diodotus at a time (246) when the Seleucid empire was in chaos and Bactria one of its few stable parts. The death of Diodotus belongs shortly before the expedition of Seleucus II against the Parthians. the date of which is uncertain (possibly 228). He was succeeded by his son Diodotus II who unquestionably ruled as a king, since he coined in his own name; he was overthrown by the rebel Euthydemus (*q.v.*).

Diodotus I had been the enemy of the Parthians, which is consistent with the supposition that he remained on friendly terms with the Seleucid kings; in contrast. his son, by joining hands with the Parthians against Seleucus II, proclaimed unmistakeably the independence of Bactria. Diodotus I was called after his death by the cult-name *Soter* ("saviour"). It is not clear whether there is in this name the commemoration of any historical event. *See* also BACTRIA. (*R.* H. SI.)

DIOGENES (fl. 4th century B.C.), originator and archetype of the sect of the Cynics (*q.v.*), was born at Sinope on the Black sea, and died as an old man about 320 B.C., probably at Corinth, where his monument was surmounted by a marble dog, the emblem of the sect. A picturesque figure, he became the centre of a legend, some of which seems attributable to the invention of Menippus (*q.v.*). Many of the best-known stories about him are apocryphal: for instance, how the only boon that he would beg of Alexander the Great was that he should stand out of his light; and that, sold into slavery, he declared his trade to be that of governing men and was appointed tutor to his master's sons. It is virtually certain that he was exiled with his father from Sinope; he had probably already adopted his life of asceticism when he reached Athens (at an unknown date); and not later than 330 B.C. Aristotle refers to him as a familiar figure, nicknamed "the Dog." He made it his mission to "deface the currency." perhaps meaning "to put false coin out of circulation"; *i.e.,* to expose the falsity of most conventional standards and beliefs. In so far as he had a positive ideal, it was one of a self-sufficiency unshaken by fear, pain or desire. to be won by an unremitting discipline of body and mind. Tradition. untrustworthy in detail. cannot be wrong in portraying him as the possessor both of a biting wit and of showmanship. exemplified by the story of his going out in broad daylight with a lantern "in search for an honest man." He relied on example as well as on words, and his actions mere designed to show how few were man's needs. His dress, later to be Cynic uniform, was that of a vagabond beggar. with a stick. a wallet for alms and a cloak. which, when doubled. served at night as a blanket. He needed no roof over his head but what he could find in public buildings, or made (as familiar legend has it') his home in a tub. His famous claim to be a "citizen of the world" is another aspect of the same denial of supposed necessities; the ordinary Greek could not imagine a good life except as a member of the exclusive community that he called a *polis.* The authenticity of the writings (now lost) attributed to him—dialogues, plays and the *Republic*—was disputed; one reason was that they contained shocking passages in defense of cannibalism. incest, etc., appropriate to the historical Diogenes but embarrassing to later followers. The Re*public* at least can hardly be doubted: it described an anarchist Utopia, in which men lived "natural" lives. (F. H. SH.)

DIOGENES APOLLONIATES (jth century B.C.). Greek eclectic philosopher, interesting for his cosmology and for his physiology. was born at Apollonia (whether the Cretan Apollonia or the Phrygian is uncertain), but moved to Athens. In Athens his opinions once caused his life to be in danger; and they were derided, as those of Socrates, by Xristophanes in *The Clouds.* He wrote in Ionic Greek, and considerable fragments of his work are extant. His most important book was On *Nature;* writings *Against the Sophists* and *On the Nature of Man* may have been sections of it. Diogenes is notable for his reconciliation of the doctrines of Xnaximenes of Miletus with those of Xnaxagoras (*qq.v.*), which he achieved by taking the former's theory that air is the one source of being and attributing intelligence to it as well. Aristotle in his *Historia animalium* quotes a long passage from Diogenes on veins.

Weygoldt, "Zu Diogenes von Apollonia," *Archiv für Geschichte der Philosophie,* i, pp. 161 ff. (1888); E. Krause, *Diogenes von Apollonia* (1908); H. Diller, "Die philosophiegeschichtliche Stellung des Diogenes von Apollonia." *Hermes,* pp. 359–381 (1941); J. Zafiropulo, *Diogène d'Apollonie* (1956); and general histories of early Greek philosophy.

DIOGENES LAËRTIUS (3rd century A.D.) is best known

as the author of a history of Greek philosophy, which. being the only one of its kind the bulk of which is extant. constitutes the most important single secondary source of our knowledge in this field. One of its traditional titles, *Lives and Opinions of Famous Philosophers,* is indicative of its scope. A compilation, it is often analyzable into its original excerpts, many of which are inserted in the wrong place (whatever the explanation of this may be). These excerpts range from insignificant gossip to valuable biographical and bibliographical information, competent summaries of doctrines and reproductions of important documents (*e.g.,* wills) or philosophical writings (*e.g.,* three letters of Epicurus). Diogenes quotes hundreds of authorities, but most of them he knows from second hand only; his true sources (some of which must themselves have been compilations) have. with some exceptions, not been ascertained. The whole work, in ten books, after a kind of introduction (book i), presents Greek philosophy as divided into an Ionian and an Italic branch (books ii–vii; viii) with "successions," that is to say schools, within each and with "stray" philosophers appended (books ix–x). In all extant manuscripts (the oldest belongs to the 12th century) part of book vii is missing.

BIBLIOGRAPHY.—There are useful editions of Diogenes Laërtius by C. G. Cobet (1850) and by R. D. Hicks, 2 vol. with Eng. trans. and bibliography (1925); the Ger, trans. by O. Apelt, 2 vol. (1921), is also of some importance. *See* further *R.* Hope, *The Book of Diogenes Laertius: Its Spirit and Its Method* (1930); M. Dal Pra, *La Storiografia filosofica antica* (1950); P. Moreaux, "La Composition de la 'Vie d'Aristote' chez Diogène-Laërce," *Revue des études grecques,* 63 (1955), on a special topic but illustrative of certain methodological problems. (PP. M.)

DIOGNETUS, EPISTLE TO, an early Christian apologetic work, of unknown authorship (though once attributed erroneously to Justin Martyr), dating probably from the 2nd or 3rd century. It survived antiquity in one 13th–14th-century manuscript, which perished by fire at Strasbourg in 1870. *See* APOSTOLIC FATHERS.

DIOMEDEIDAE, the albatross family of large, stout-bodied birds remarkable for their almost exclusively oceanic life and their seemingly effortless flight. *See* ALBATROSS.

DIOMEDE ISLANDS, two small islands in the Bering strait, lying about 2½ mi. apart and separated by the international boundary between the United States and the Union of Soviet Socialist Republics, which coincides there with the international date line. They were discovered by Vitus Bering on Aug. 16, 1728 (St. Diomede's day) and are icebound six to seven months of the year. The larger, Big Diomede or Ostrov Ratmanova (Ratmanov Island), belongs to the U S.S.R. and is the site of an important Soviet weather station. Little Diomede is part of Alaska. Its population in 1960 was 88; that of Big Diomede is somewhat larger. (L. D. BL.)

DIOMEDES, the name of two figures in Greek legend. Diomedes, son of Ares. king of the Thracian Bistones, was the owner of mares to which he fed human flesh. Hercules, as his eighth labour, killed Diomedes and captured the mares,

Diomedes, the son of Tydeus. whose death at Thebes he avenged, was commander of 80 Argive ships and one of the most respected leaders in the Trojan War. Homer represents him as younger than other leaders, entirely devoted to the heroic ideals of warfare; as such, he constitutes a perfect foil for the behaviour of Achilles. Diomedes' famous exploits include the wounding of Aphrodite, slaughter of Rhesus and his Thracians, seizure of the Trojan Palladium (*q.v.*) and concealment in the Trojan horse. After the war Diomedes returned to Argos, to find that Aphrodite had vengefully made his wife Aegialea unfaithful. He sailed to Italy and founded Arpi in Apulia, eventually making peace with the Trojans (*Aencid,* 11, 243 ff.). Before or when he died. his men became herons (Ovid, *Metamorphoses,* 14, 457 ff.). Diomedes was worshiped as a hero in Argos and Metapontum. (WM. S. A.)

DION (c. 408–354 B.C.), the son of Hipparinus. and brother-in-law of Dionysius the Elder, was intermittently master of Syracuse between 357 and 354. He combined serious intellectual interests with considerable military and administrative ability. When the younger Dionysius, who was weak and inexperienced, succeeded, Dion assumed control and persuaded Plato, whose friendship he had acquired when Plato visited the court of the elder Dionysius, to return to Syracuse and to train the new tyrant in the practical application of his philosophical principles. The experiment failed, and roused hostility among the supporters of the tyranny. The historian Philistus set Dion at variance with the tyrant, and procured his banishment on a charge of intriguing with the Carthaginians. Dion remained for a while at Athens but in 357, assembling a force of 1,500 mercenaries at Zacynthus, he sailed to Sicily and was received with demonstrations of joy. Dionysius, who was in Italy, returned to Sicily, but was defeated and obliged to flee. Dion himself was soon after banished through the intrigues of Heraclides (356). But the incompetence of the new leader soon led to Dion's recall; Heraclides submitted. and soon afterward the supporters of Dionysius surrendered. Dion retained his position as *strategos autocrator* (commander with unlimited powers) but suspected of aiming at tyranny, in 354 he was assassinated by Callippus, an Athenian who had accompanied him in his expedition. *See* also SYRACUSE and SICILY: *History.*

See Lives of Dion by Plutarch and Cornelius Nepos; Diodorus Siculus, xvi, 6–20. (R. ME.)

DION (DIOON): *see* GYMNOSPERMS.

DIONAEA: *see* VENUS'S-FLYTRAP.

DIONE, in Greek mythology, was the cult-partner of Zeus of Dodona. The partner and wife of Zeus is normally Hera, so Dione was variously described: in the *Iliad* as mother by Zeus of Aphrodite; in Hesiod's *Theogony* as a daughter of Oceanus.
