A simple form of percussive drilling involves the use of drive pipes. This method is suitable for testing the depth and character of soft material overlying solid rock and as a necessary preliminary to rock boring when some thickness of surface soil must first be passed through The drive pipe consists basically of one or more lengths of wrought-iron pipe open at both ends and one-half to six inches in diameter. Small-diameter pipes are driven by a heavy hammer; for deep and larger holes a light pile driver is necessary.

The lower end of the pipe has an annular steel shoe; the upper end, a drivehead for receiving hammer blows. Successive lengths are added as required. **A** bailer, consisting of a cylinder four to six feet long with a valve at the foot, is used for cleaning. Drive pipes are often sunk by the application of weights at the surface and slow rotation by levers. Two pipes are then used. one inside the other. Water is pumped down the inner pipe to loosen the soil and raise the debris. In a variation of this, for tough soil or hardpan. a drill on a hollow rod is raised and dropped inside the pipe. The water passing down the rod and through holes in the bit raises the debris. The "driven well" for water supply is an adaptation of the drive pipe. These methods are rarely used for depths over 120 ft.

For deep boring the rod method is no longer used. Cable (rope)-operated tools known loosely as cable-tool drills (in the U.S.) or churn or "oil-uell" drills (in Britain) have been widely used for prospecting and oil-well drilling in the past. but for deeper holes. including those over 6.000 ft., the method has been replaced by rotary drilling Less than half the oil wells are drilled by cable tools. although many blastholes in quarries are drilled by this method. In its simplest form the "string of tools" suspended from the rope consists of a chisel bit, jars and rope

FIG. 3.— DRILLING TOOLS

(A) Drilling stem; (B) drilling bit; (C) drilling jars; (D) dart-valve bailer; (E) swivel socket for wire rope

socket. The jars (fig. 3[C]) are a pair of sliding links to produce a sharp shock on the upstroke as the jars come together for loosening the bit if it tends to stick fast. A heavy bar (auger stem) is generally inserted between the jars and bit to increase the force of the blow. The weight of another bar (sinker bar) above the jar keeps the rope taut. The length of stroke and the feed are regulated by a "temper screw" or feed screw which allows the rope to be let out four feet or so as boring progresses. The bits are usually three to eight inches in diameter.

FIG. 4.—BUCKET AUGER

This method of drilling is especially suitable for glacial pebble beds and conglomerates, which often damage rotary bits. A great variety of "fishing tools" is used in case of loss of tools. For mobility the drilling machinery may be mounted on a trailer truck or lorry. It is a cheap method of searching for water supplies.

Rotary Drilling. — The simplest form of rotary drilling is the earth auger operated by hand and resembling the wood auger used in carpentry. It is possible to drill soft materials to a depth of 60 ft.. but deeper holes can be drilled with the assistance of a small motor or a rotary table. There are two forms of auger, the spiral and the pod types. The auger is attached to rods by socket joint, and successive rods are added as the hole is deepened. Horizontal levers are clamped to the rods and drilling proceeds by rotary action which is stopped from time to time so that the debris can be removed from the tool, or the mud collected by a sludge pump lowered into the hole.

Pdd augers are generally from 8 to 20 in. in diameter and are used for drilling sandy soils. A common form consists of two curved plates. one attached to the rod rigidly. the other by hinge and key; a fen revolutions fill the pod. For holes of large diameter the auger is handled nith the aid of a light derrick.

Rotary drilling. unlike some other methods. may be adapted for holes at any angle and therefore is quite suitable for underground work in coal and metalliferous mines.

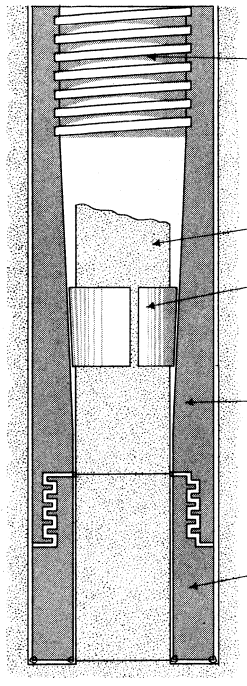

FIG. 5.—CORE LIFTER USED IN DIAMOND DRILL WORK

For diamond drilling from the surface the apparatus consists of a line of hollow rods, coupled by screw joints, and an annular steel bit, set with diamonds. attached to the lower end. By a small engine on the surface the rod is rapidly rotated and fed down automatically as the hole is deepened. The speed of rotation is from 300 to 1,700 r.p.m. depending on the kind of rock and the diameter of the bit. While the boring progresses water is fed down the hollow rods by pump, and returns between the rods and the hole sides. Cuttings are thus conveyed upward leaving the hole bottom clean. Core recovery and inspection of the diamond bit may be carried out every three to eight feet oi depth by raising the rods with the aid of a small rope which operates by the driving engine.

Above the bit are the core lifter and core barrel. The core lifter (fig. 5) grips and breaks off the core and raises it to the surface. The barrel. three to ten feet long, fits closely in the hole and may be spirally grooved for the passage of water and debris. It serves partly as a guide, tending to keep the hole straight. and partly for holding and protecting each core. For coring in coal, a double core barrel is mostly used.

In broken fissured rock diamond loss often is so great that such bits are replaced by steel toothed bits. Another core drill is the Davis calyx drill. For hard rock it has an annular bit. accompanied by a quantity of chilled-steel shot (generally known as shot boring). This method is not suitable for holes at an angle to the vertical.

The feed may be hydraulic or differential. With the hydraulic feed. mostly used with the heavier machines for deep work. the rate of feed is independent of the rotation speed of the rod and can be precisely adjusted. There are either one or two feed cylinders supplied with water from a pump. The rod. while rotating freely. is supported by the feed-cylinder piston and caused to move slowly downward by the water's being allowed to pass from the lower to the upper part of the cylinder. Valves regulate the passage of the water. and hence the rate of feed.

The differential feed usually is adopted only on the smaller units intended for shallow-hole drilling. With this system the driving engine has a hollow left-hand threaded screw shaft to which the rod is coupled. This shaft is driven by a spline-and-bevel gearing and is supported by a threaded feed unit in the lower bearing. Geared to the screw shaft is a light countershaft. The number of teeth in the gear wheels is such that the feed unit revolves a little faster than the screw shaft so that the drill rod is fed downward a fraction of an inch for each revolution. To vary the rate of feed for different rocks, there are three pairs of gears with different ratios of teeth. The screwshaft and gearing are carried by a swivel head, which can be rotated in a vertical plane, for drilling holes at any angle.

FIG. 6.— STRAIGHT ROTARY RIG WITH MAST IN WORKING POSITION

Rotary drilling rigs are built in a wide variety to meet the requirements of depth drilled. loads to be handled and the terrain where the wells or holes are to be located. Drives are from gasoline, diesel engines or electric motors: although steam-driven reciprocating engines are sometimes used. Rods are of wrought-iron or steel tubes in five feet or ten feet lengths. Many rigs for shallow depths are truck-and-trailer mounted for economical mobility and rapid assembly. Fig. 6 shows a mobile type of rotary rig suitable for seismic work or prospecting.

For operating in underground workings of mines, small machines are sometimes mounted on columns. They drill holes $1\frac{1}{4}$ to $1\frac{9}{16}$ in. in diameter to depths of 300–400 ft., cores being $\frac{7}{8}$ to 1 in. in diameter.

Rates of advance for core drilling to moderate depths range usually from two to three feet per hour including ordinary delays, though in favourable rock higher speeds are attainable. In deep holes speeds diminish because of the time consumed in raising and lowering the rods. Solid bits produce faster rates as it is necessary only to raise the rod occasionally for examining the condition of the bit.

Hole Maintenance. — Drilling fluids or compressed air can be used for both cooling the hit and transporting cuttings to the surface. The chief diiadvantage of air flushing is that no support is offered to the hole sides.

It is essential that a hole be kept open during the drilling process and then until it is no longer required for the extraction of water, oil or gas. The method used in nearly all drilling in fissured ground up to about 1930 was by the use of steel casing. A hole

was started at a diameter much larger than the finishing diameter and lined with coupled steel pipes. Each coupling resulted in a decrease in diameter. However. flush jointed casing can be used to maintain a constant diameter. Steel casing is still used in very friable strata and often to prevent loss of mud or drilling fluids in very pronounced fissures or breaks. Often the casing must be set firmly in position by the use of cement between the casing and sides of the hole. Casing is lowered into the hole in the same way as drill rods. and strings of casing are equipped with a casing shoe or hollow bit to remove loose debris adhering to the side of the hole.

In very strong and homogeneous strata it is often possible to drill many thousands of feet without the use of casing. To achieve this the modern method is to use a drilling fluid containing mud. Any drilling mud must have (1) sufficient weight to support the rock by forming a cake around the sides of the hole; (2) sufficient weight also to control the ingress of gases and fluids into the hole; (3) properties to prevent loss of water or oil into the pores or fissures in the rock; (4) properties of cooling the drilling bit; (5j sufficient viscosity to float the cuttings from the hole; and (6) sufficient viscosity to permit separation of the cuttings from the mud over the shaker screens on the surface. With normal rotary drilling, without the use of coring, samples of cuttings are taken at the separating screens and may be as small as one-sixteenth inch.

Another method of hole maintenance was introduced in the U.S. in the 1950s for putting down large-capacity irrigation wells in unconsolidated strata. Known as reverse-circulation rotary drilling, it employed the static pressure of a heavy drilling mud to prevent caving of the hole walls. The drilling mud flowed from a settling pit directly into the hole, which was kept filled at all times; large centrifugal pumps were used t ~draw the mud and cuttings up the drill pipe—the reverse of the standard rotary drilling method.

The chemistry of drilling muds is a very complex subject. The acidity or alkalinity of a mud, its pH value, will obviously be a guide to its possible reaction with chemicals in the strata or with any cements used in the hole. It is also essential to know the pH value of the clays and chemicals used and of the mixing water. The desired characteristics of drilling muds are obtained by careful addition of clays such as bentonic clays, weighting materials and chemicals. Other drilling fluids are prepared with oils and are known as oil-base muds.

Power Plant Requirements.—The type of motive power used for drilling depends largely on the availability of electricity, fuel and water. Choice may be made from steam, internal-combustion engines, gasoline or diesel, natural gas, alternating- or direct-current electricity and compressed air. Gasoline motors are usually expensive to operate. Steam power is attractive in areas remote from other power sources, but application depends on the availability of suitable water supplies. It has been used extensively for the deep soft formations of the U.S. Gulf coast and California.

For holes down to 400 ft.. 20 h.p. is usually adequate in most formations. while diamond drilling down to 4,000 ft. may require 50 h p. It is also necessary, of course, to take into account the load to be put on a rotary bit in order to secure efficient penetration. This may vary from 400 lb. on a $1\frac{3}{8}$-in. bit to 10 tons on a 9-in. roller bit.

U.S. experience has shown that, where fuel and water supplies are costly and drilling is simple, straight power rigs are most efficient. Typical examples are the practices adopted in Texas and New Mexico. Special hydraulic couplings and torque converters have been developed to obtain the maximum efficiency from such rigs.

A full rotary drilling layout for very deep drilling may have up to eight prime movers and generators. Motors of 300 h.p. are necessary to drive the generators, which-may be of 150 kw. output. It also is necessary to have a motor of up to 800 h.p. for driving the reduction gearing and hoisting the rods. A smaller motor of 200 h.p. may be necessary for rotating the bit and rods, two 500-h.p. motors for driving the mud-circulating pumps and one or two small motors for driving the mud-screening plant. The hydraulic coupling has had widespread use in rotary drilling in many oil fields of the world. It has the advantage of reducing shock in the form of torsional vibrations to the drill and reducing slip due to acceleration. Torque converters are also widely used. They govern the torque on the output side of the prime mover. When the load on the drill increases the torque is automatically increased.

For rapid drilling using very little coring, a drilling machine may be mounted on skids. The height of the derrick is dependent on the type of strata. depth of hole, number of bit changes, etc. High derricks are mostly used when coring, necessitating frequent hoisting, is in use.

Other equipment includes controls for operating the rotary table drill fluid pumps, and also hydraulic and electrical controls. Instruments include weight indicators to show the total load on the derrick and weight on the bit, pressure gauges for slush pumps, both indicating and recording, and torque indicators to show rotation losses on drill pipe. There are also tachometers, temperature, air-pressure and oil-pressure gauges and ammeters.

Drilling for water, resulting in artesian wells, can be per-'formed with either the normal percussive method or, in very hard rocks, with rotary methods. Wells may continue to supply water for many years after being drilled, but occasionally have to be rejuvenated. This is carried out by firing explosives, lowered in canisters, in the hole. The operation results in cracks and fissures being opened up so that water is supplied in larger quantities. An example is a well at Rochester, Kent, which yielded 20,160 gal. of water an hour immediately after rejuvenation.

Diamond drill holes are rarely straight; very deep holes may vary even as much as 60° from their true direction. This is because the rod does not fit closely in the hole and therefore bends. Deviation is likely to occur also in drilling through inclined strata, especially when the layers are of different degrees of hardness.

By using a long and closely fitting core barrel deviation is reduced. Nearly horizontal holes always deflect upward because the sag of the rod tilts up the bit. Diamond-drill holes should therefore always be surveyed. This is done by placing into the hole instruments for observing at a number of successive points the direction and degree of deviation. If accurately surveyed a crooked hole may be as useful as a straight one.

(RT. SD.)

DRINKWATER, **JOHN** (1882–1937), British poet, playwright and critic, remembered as a typical "Georgian" man of letters, a successful promoter of the repertory theatre in England and as the author of popular chronicle dramas, was born at Leytonstone, Essex, on June 1, 1882. After 12 years as an insurance clerk, Drinkwater devoted himself to theatrical enterprise, and became manager and producer to the Pilgrim Players, who developed into the Birmingham Repertory Theatre company. His first volume of poems appeared in 1906 and his first play, *Cophetua* (in verse), in 1911.

Drinkwater subsequently published several volumes of verse, critical studies, *William Morris* (1912), *Swinburne* (1913) and others, and several historical plays, of which *Abraham Lincoln* (1918) was produced nith great success both in London and in the United States. In 1923 his *Collected Poems* (2 vol.) were published, and in 1925 *The Muse in Council,* a collection of essays, his *Collected Plays* (2 vol.), and a prose study of Byron, *The*

Pilgrim of Eternity. His autobiography appeared in two volumes, *Inheritance* (1931) and *Discovery* (1932). He died in London on March 2j, 1937. (J. Sp.)

DRIVER, SAMUEL ROLLES (1846–1914). English Semitic languages scholar, co-editor of the Oxford *Hebrew and English Lexicon of the Old Testament* (1906), was born in Southampton on Oct. 2, 1846. Educated at Winchester and New college, Oxford, where he became a fellow (1870) and tutor (1875), in 1883 he succeeded E. B. Pusey as regius professor of Hebrew and canon of Christ Church, Oxford. He was a member of the Old Testament Revision committee (1875–84) for the Revised Version of the Bible. He died in Oxford on Feb. 26, 1914.

Driver devoted his life to the study of the language and text of the Old Testament and to its interpretation. He played a leading part in the communication to British students of the new literary critical approach to the Old Testament which was then current on the continent of Europe, especially in Germany. He also helped to lay secure foundations for research into Hebrew and Semitic philology. which mas then entering upon a fresh stage. His *Introduction to the Literature of the Old Testament* (1891; 9th ed.. 1913) became a standard work, and exercised great influence on younger scholars. Of his numerous commentaries on books of the Old Testament, at least one, *Notes on the Hebrew Text and the Topography of the Books of Samuel* (2nd ed., 1913), has become a classic. A list of his publications is given in an appendix to his selected sermons, *Ideals of the Prophets* (1915), ed. by G. A. Cooke. His son GODFREY ROLLES DRIVER (1892–), professor of Semitic philology in the University of Oxford. was made chairman of the Old Testament translation committee for the New English Bible.

See the appreciation *by A.* Cowley in *Proceedings of the British Academy* (1915–16). (D. W. TH.)

DRIVER'S INSURANCE: **see** MOTOR VEHICLE INSURANCE.

DRIVING AND COACHING. Driving is a word used in a restricted sense for the art, or sport, of controlling and directing draft animals from a coach or other conveyance to which they are harnessed for the purpose of traction. The animal most commonly employed is the horse, but the mule. ass and ox are also much used, while in arctic lands their place is taken by the reindeer and the dog.

The use of horses for driving goes back to remote times. On bas-reliefs of Assyrian and Egyptian origin kings are shown doing battle and hunting in two-wheeled chariots drawn by a pair of horses. Ancient Britons used them for warfare and agriculture. and the Romans and Greeks used them for chariot racing and other sports. Italy and Hungary have been credited with the introduction of the carriage in Renaissance times; about 1550 the first private carriage was in use in England, but for nearly two more centuries the saddle horse remained the usual means of transport. The ponderous, springless stagecoach toiled slowly over the rough and rutted tracks throughout the 18th century, and it was only at the end of that century that the construction of better roads and the Invention of springs for carriages made driving at all pleasurable. In Britain the first mail coach was put on the road in 1784, running from Bath to London at the rate of about seven miles per hour, and the stage and mail coaches existed side by side until the advent of the railways. By the beginning of the 19th century the art of coachbuilding had reached a high degree of perfection and driving as a pastime was becoming fashionable. An important revival of coaching was initiated in 1866, and up to World War I there were numerous stagecoaches running daily in and out of London. On July 13, 1888. J. Selby performed his celebrated feat of driving the "Old Times" coach from London to Brighton and back in 7 hr. 50 min., averaging 13.79 miles per hour (with 8 teams and 14 changes). A number of driving clubs came into existence in England in the 19th century. The Benson Driving club lasted from 1807 to 1854; the Richmond club from 1838 to 184j; and Four-in-Hand Driving club from 18j6 to 1926. The Coaching club was founded in 1870 and in 1958 the British Driving society was formed to encourage people who wish to drive horse for pleasure. In the United States, the Coaching club, founded in 1875, held its last extended drive, from the club's headquarters at the Knickerbocker club in New York to Belair house, Collington, Md., Oct. 11–14, 1916; the club continued in existence, establishing the Coaching Club American Oaks, a stake race for three-year-old fillies. at Belmont park, first held in 1917.

The amateur will do well to visit such shows as the Richmond and International Horse shows, where he will see the finest harness horses and the most skillful drivers or "whips." He will also see fast U.S. trotters and pacers and note the difference in the style of U.S. and English driving. The number of horses driven is usually one, two or four.

When two horses are used they may either be placed side by side: in double harness, or, less commonly, one following the other, in a tandem. Four horses, or a four-in-hand, are harnessed in two pairs, one following the other, and called respectively the leaders and the wheelers. When three horses are used, two wheelers and a single leader. this is known as a unicorn team. In Russia and Hungary three horses are driven abreast, the centre horse trotting and the outside horses galloping; such a team is known as a troika.

Driving is an accomplishment which can be learned only at the hands of a first-class coachman and requires constant practice. The following are a few principles which are common to all branches of driving. whether of one, two or four horses. The driver should have knowledge of horses. He should become acquainted with every part of the harness he uses and with the purpose which each buckle or strap is intended to serve. The indefinable quality known in horsemanship as "good hands" is partly the result of learning the correct position for the left arm and hand, which hold reins. The hand should be kept at about the level of the lowest button of the driver's waistcoat or at belt level, and near the body though not pressed against it; the upper arm should lie loosely against the side, the forearm horizontal across the front of the body, forming roughly a right angle at the elbow joint, the wrist bent inward, and the back of the hand and knuckles facing outward toward the horse. In this position the three joints of the arm form a kind of automatic spring movement that secures the "give" to the movement of the horse's mouth which, in conjunction with firmness, is a large part of what is meant by "good hands." The reins must also be held with the proper degree of bearing on the bit; this depends greatly on the character of the horse and the severity of the bit, but under no circumstances should the reins be allowed to lie slack. The driver should always just "feel the horse's mouth" as lightly as possible; he then has the animal under control, but does not pull on the mouth and cause chafing and fretting.

The driver will learn early that a horse must be kept well in hand going downhill and given its head on an ascent, and that the hand brake should be used sparingly. He must acquire an eye for pace and distance, and the instinctive realization of the length of the carriage behind him, without which he may collide with other vehicles or allow insufficient room in turning a corner or entering a gateway. Special skills are required to drive a tandem or a four-in-hand, and it needs both strength and an instinctive knowledge of the position of the greater number of reins in the hand. It also requires a knowledge of the proper use of the whip, accuracy with which is essential when driving a four-in-hand.

(G. W.; E. E. HN.)

DRIZZLE, a steady light rain in which the drops are very minute (diameter less than $\frac{1}{50}$ in.. approximately) and numerous. Such small drops seem almost to float in, and thereby to follow, even the slightest motions of the air.

Drizzle is distinguished from sprinkles or ordinary light rain in that it falls from thick low-lying stratus or strato-cumulus clouds, rather than from cumulus or alto-stratus, and always causes poor visibility. In theory the precipitation of drizzle is a consequence of turbulence produced by friction of the air with the ground, whereas other rain requires larger-scale vertical motions reaching higher levels in the atmosphere. Freezing drizzle causes glaze (or glazed frostj, a thin: transparent ice crust on the ground and exposed objects; but frozen drizzle (or granular snow) consists of very fine snow or ice grains falling under identical cir-

cumstances as rain drizzle, except at cloud-level temperatures at or below the freezing point.

In the U.S., drizzle is sometimes confused with mist (*q.v.*).

(R. G. SE.)

DROESHOUT, MARTIN (1601–*c.* 1650), English engraver, whose title to fame is his engraved portrait of William Shakespeare. which appeared in the first folio edition of Shakespeare's plays (1623). Born in London, probably in April 1601, the son of Michiel Droeshout, he was probably the pupil of his father and of his elder brother John, both engravers. The Shakespeare engraving mas eulogized by Ben Jonson and called true to life. Since the engraver was only 15 years old at the time of Shakespeare's death, the portrait was probably not done from life. Among Droeshout's more successful mature works are several other portraits: book decorations, and allegorical, mythological and satirical subjects. (C. H. C. B.; X.)

DROGHEDA (DROICHEAD ATHA, "Bridge of the Ford"), a municipal borough and seaport on the southern border of County Lough, Republic of Ireland, lies on the Boyne river about 4 mi. from its mouth in Drogheda bay and 30 mi. N.W. from Dublin by road. Pop. (1961) 17,071. Drogheda was a stronghold and trading post of the Danes and later of the Anglo-Normans, who replaced the ford by a bridge. In 1157 a synod was convened there. Two towns grew up, one on either side of the river, which received separate incorporation in 1228 but were combined by charter in 1412. In the reign of Edward III it was one of the four staple towns of Ireland with Dublin, Waterford and Kilkenny, and was granted the right of coining money. Several parliaments were held there, the most notable being in 1494 when Poynings' law was enacted (see POYNINGS, SIR EDWARD). In the 1641 rebellion the town was besieged by Sir Phelim O'Neill arid was relieved, but in 1649 it fell to Oliver Cromwell and the inhabitants were massacred; after the battle of the Boyne in 1690 it surrendered without a struggle. though garrisoned by King James's army. It ceased to be a parliamentary borough in 1885 and a county of itself in 1898.

The ancient fortifications of Drogheda have disappeared except for the gateway of St. Lawrence on the north side, which remains almost perfect, and the ruins of the West or Butler gate. From the close of the 12th century to some time after the Reformation the primates of Ireland lived in Drogheda. In the Dominican friary founded in 1224, of which the Magdalen tower remains, Richard II received the submission of the O'Neill, O'Donnell and other chieftains of Ulster and Leinster. Of the establishments of the Franciscans, Carmelites and Knights of St. John nothing is left! but there are a tower and a pointed arch of the Augustinian abbey of St. Mary d'Urso founded in 1206. In St. Peter's church, which was erected to his memory, a shrine contains the head of the archbishop of Armagh, Blessed Oliver Plunket (*q.v.*), who was martyred at Tyburn in 1681. The Bluecoat school was founded in 1727 but the present buildings date from 1870. At Mellifont, 6 mi. W., are ruins of the first Cistercian abbey of Ireland.

There are linen and cotton mills, coachbuilding works, flour and sawmills: a brewery, a large cement works and factories making vegetable oil products, clothing, boots, fertilizer and spark plugs. Drogheda is the headquarters of the valuable Boyne salmon fishing. Agricultural produce and coal are traded by sea.

DROGOBYCH, a town of Lvov oblast of the Ukrainian Soviet Socialist Republic, U.S.S.R., and formerly an administrative centre of its own oblast. Pop. (1959) 42,000. On May 21, 1959, Drogobych oblast was absorbed into Lvov oblast. Drogobych lies in the foothills of the Carpathian mountains?about 40 mi. S.S.W. of Lvov. It is an ancient town, known in the 11th and 12th centuries for its salt, which is still mined nearby at Stebnik. Known as Drohobycz, it was in Poland between World Wars I and II, passing to the U.S.S.R. in 1939. It is important as the centre of the Carpathian oil and natural gas field, the principal oil fields being near Drogobych and Borislav. Nearby are potassium and magnesium salt mines and natural gas wells. Ozocerite is also found locally. There are timber and light industries. Drogobych has a pedagogic institute and an oil-electromechanical technical school. (R. A. F.)

DROIT, a right or that to which one has a right; a term used in various legal connections, referring principally to certain rights of a feudal superior, such as droit *du seigneur* (q v.). In English law. the best-known use is in the phrase droits of admiralty, these being rights of the crown to property found upon the sea or stranded upon the shore, including great fish (whales, porpoises, sturgeon, etc), wrecks (*q.v.*), flotsam. jetsam and lagan (*q.v.*), and enemy ships found in English ports. Droits of admiralty are not, as such, recognized in the United States. See also PRIZE COURTS AND PRIZE LAW. (M. C. ME.)

DROIT DU SEIGNEUR, known also as *jus primae noctis* ("right of first night"), a feudal right said to have existed in medieval Europe giving the superior to whom it belonged the right to sleep the first night with the bride of any one of his vassals. The custom is paralleled in various primitive societies, but the evidence that we have of its existence in Europe is almost exclusively of the redemption dues paid by the vassal to avoid enforcement, not of actual enforcement. The one document which appears to present the right actually in operation (decree of the Seneschal ot Guyenne, 1302) has been challenged on several grounds in the course of spirited controversy in France. Remarkable displays of learning have been devoted to the problem, but although it seems possible that such a custom may have existed for a short time at a very early date in parts of France and Italy, it certainly never existed elsewhere. A considerable number of feudal rights related to the vassal's marriage, particularly the lord's right to select a bride for his vassal. but these are almost invariably known only in the form of a money payment, or "avail," for redemption. It seems likely that, in effect, the droit du seigneur was only another tax of this sort.

See L Veuillot, Le *Droit* du *seigneur au moyen age (1854)*; J Delpit, *Le Droit du seigneur* (1873). (*M C.* ME)

DROITWICH, a market town. spa and municipal borough in the Worcester parliamentary division of Worcestershire, Eng.. 7 mi N N.E. of Worcester by road. Pop. (1961) 7,975. The old town, which stands on the Salwarpe river, a tributary of the Severn to which it is connected by a canal, contains many half-timbered black-and-white houses among which are Priory house and the Elizabethan manor house of Wyche (now the Raven hotel). In a former manor house on this site St. Richard, the town's patron saint. was born about 1197 and scenes from his life are depicted in mosaics in the Roman Catholic church at Witton (1909), the suburb at the top of the hill upon which the modern Droitwich is built. A statue of St. Richard stands in Vines park. A bronze tablet in St. Peter's church commemorates Edward Winslow (*q.v.*), one of the Pilgrim Fathers and three times governor of the New Plymouth colony, nho uas born in Droitnich and baptized in the church. The toun has long been famous for the salt obtained from the brine springs or *wyches,* to which it probably owes its name and origin. The brine pumped up is about ten times as salty as sea water and is used for the treatment of rheumatic diseases. The health resort superseded the salt-manufacturing town in 1830 after a cholera patient was dipped into a vat of hot brine and recovered. The salt industry was moved to Stoke Prior in 1922 Besides the Royal baths and the St Andrew's Brine baths with their clinics, there are hospitals and convalescent homes.

A Roman villa has been found at Droitwich and it is probable that the brine springs mere then used as a source of salt. They are mentioned in several charters before the Conquest but at the time of the Domesday survey they belonged to the king nho received a yearly farm of £65; the manor was then divided between several churches and tenants in chief. King John granted the tonn its first charter in 1215 in return for a yearly rental of £100 for the springs. Mary I granted the incorporation charter in 1553–54 and James I granted a fuller charter which remained in force until 1835. The many medieval fairs have been discontinued. Besides catering for visitors and patients, Droitwich has light industries making heating appliances, metal and plastic goods and food products.

DRÔME, a *département* of southeastern France, situated east of the Rhône river, was formed in 1790 from parts of Dauphine and Provence (*qq.v.*). It is bounded on the nest by Ardèche

across the Rhône, north and east by Iskre, east by Hautes-Alpes and south by Vaucluse. Pop. (1953) 275.230. Area 6.560 sq.km. (2.533 sq.mi.). Drôme is crossed by left-bank tributaries of the Rhône from the Alps. including the Iskre, Drôme, Roubion and Aygues. It extends from the outer portion of the north-south ranges of the limestone Préalpes of the Vercors, Diois and the Baronnies to the plains along the east side of the Rhône, which are interrupted by rocky spurs that constrict the valley.

Although winter snow lingers late on the mountains, the lowlands have sunny, warm summers. They are subject, however. to the icy blasts of the notorious north wind, the mistral. funneled by the Rhône valley and emphasized by the constrictions between its basins. Only in sheltered sites in the south of the *département* does the olive appear. On slopes that have a favourable exposure the vine is extensively grown, however, and the vineyards on the schistose hills near Tain-l'Hermitage produce a wine of high quality. The cultivation of fruit, including almonds and walnuts. is widespread, Montélimar being especially well known for its nougat, and the production of market-garden crops was being increased in the 1960s by the extension of irrigation. On the other hand. mulberry cultivation has greatly declined, though textile factories have spread into the *départements,* especially in the northern part, nearest Lyons.

Situated along the historic routeway of the Rhône valley. the old settlements are characteristically perched on defensive sites. At the ancient crossing of the Isère, the twin bridge towns of Romans-sur-Iskre and Bourg-de-Pkage have experienced industrial growth with leather and footwear as well as textile industries at the former and felt-hat manufacture at the latter. Along the Rhône the left-bank towns in Drôme are usually paired with settlements across the river in Ardèche.

The main railway to Marseilles and Route Nationale 7 traverse the *département* from north to south. After a long period of decline the navigation of the river was revived by major improvement works. including that associated with the multipurpose Donzère-Mondragon project. constructed after World War II. From the rocky defile of Donzkre. a deep lateral canal is derived from the Rhône and rejoins the river 18 mi. farther south at Mondragon, after serving the great André Blondel electric power station at Bollène. Besides providing power for the electrification of the railway and for industrial development, including a plutonium factory. the scheme provides water for irrigation and a navigation channel to bypass the most obstructed reach of the Rhône, in the plain below Donzkre. By the early 1960s the project had already resulted in the creation of new settlements. Valence (*q.v.*) is the capital of the *département,* which comprises the three *arrondissements* of Valence; Die and Nyons. It forms the bishopric of Valence and comes under the court of appeal and *académie* (educational division) of Grenoble. Roman remains, medieval castles and the traces of town walls are typical of the old towns in the *département.* Among them the little walled town of Grignan, with its Renaissance château, is well known through the writings of Mme de Sévigné, who died there. (AK. E. S.)

DROMEDARY, the Arabian (one-humped) riding camel, a swift. domestic species not found in the wild. Being longer-legged and slimmer than the bactrian (two-humped) camel, it has been known to carry a man 115 mi. in less than 11 hours. *See* CAMEL.

DRQMICEIDAE, a family of flightless, terrestrial birds comprising one living form: the emu (*q.v.; Dromiceius novaehollandiae*) of Australia.

DROMORE, a market town and urban district of County Down. Northern Ireland. on the upper Lagan, 17 mi. S.W. of Belfast by road. Pop. (1961) 2.125. A bishopric grew out of an abbey of regular canons reputedly founded there by a St. Colman *c.* 600. The town and cathedral were destroyed in the 1641 insurrection and the present structure was built by the Anglican bishop Jeremy Taylor in 1661. Another bishop of Dromore was Thomas Percy (1729–1811), the editor of the *Reliques of Ancient English Poetry;* both bishops are buried in the cathedral.

The diocese was united in 1842 with that of Down and Connor. Dromore is also the name of a Roman Catholic diocese. The 8th- or 9th-century cross of Dromore, formerly in the market place, was restored and re-erected beside the Lagan bridge in 1887. The large mound near the town is a Norman earthwork. The chief induitries are hemstitching bleaching and dyeing.

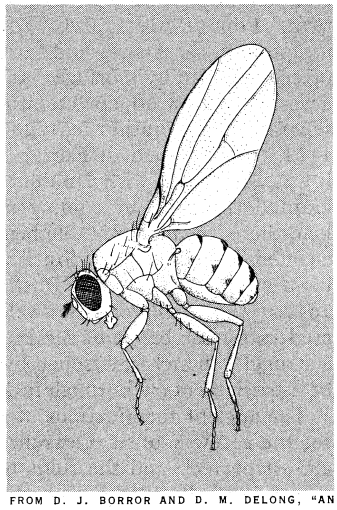
DRONGO, any of about 30 species of old-world tropical perching birds. also known as king crows or drongo shrikes, forming the family Dicruridae. related to the old world orioles. They are handsome, usually glossy black. fork-tailed birds, 10 to 12 in. long, the prolonged outer tail feathers sometimes doubling that length. They are commonest in southeastern Asia, but also occur in Africa. the Malay archipelago and Australia. The drongo cuckoo of India (*Surniculus lugubris*) resembles or mimics the black drongo (*Dicrurus macrocercus*) and lays its eggs in the drongo's nest. (G. F. Ss.)

DROP FORGING: *see* FORGING.

DROPSY: *see* EDEMA.

DROSERACEAE, a family of dicotyledonous plants, remarkable in that all its members are carnivorous. There are four genera and about 90 species. *Drosera* is a cosmopolitan genus including about 85 species, known as sundews (*q.v.*). *Dionaea* is Venus's-flytrap (*q.v.*). *Aldrovanda,* widespread in the old world, is a water plant, lacking roots. *Drosophyllum* (*q.v.*), allied to the sundews. is found in the eastern Mediterranean. *See* CARNIVOROUS PLANTS.

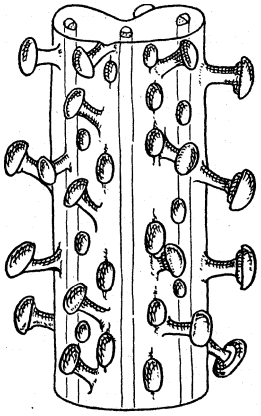
DROSOPHILA, a genus of flies (Diptera). commonly known as vinegar, or pomace, flies and also. popularly but misleadingly, as fruit flies (this last name rightly belongs to flies of the family Tephritidae [Trypetidae; *see* FRUIT FLY], to which vinegar flies are not closely related). The number of *Drosophila* species may be conservatively guessed at no less than 1.000.



FROM D. J. BORROR AND D. M. DELONG, "AN INTRODUCTION TO THE STUDY OF INSECTS," HOLT, RINEHART AND WINSTON, INC., 1959

FRUIT FLY OR POMACE FLY (DROSOPHILA)

Some. though not all, species lend themselves admirably for laboratory and field experiments on heredity and evolution. They are cultured easily and cheaply: their life cycles are short (less than two weeks at room temperature. 25" C.), a pair of parents producing hundreds and even thousands of progeny. Their chromosomes. particularly the so-called giant chromosoines in the cells of the salivary glands of mature larvae, are beautifully clear and accessible for study (*see* CYTOLOGY). About a dozen species. and particularly D. *melanogaster,* have been used in biological laboratories throughout the world, fallowing the pioneer work of Thomas Hunt Morgan and his school (*see* GENETICS).



FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

DROSOPHYLLUM. SMALL PORTION OF A LEAF SHOWING THE TWO KINDS OF GLANDS. STALKED AND SESSILE

The biology of *Drosophila* in its natural habitats is not well known. Some species live in rotting. injured — but not in uninjured — fruits and are attracted to and live on fermenting plant juices. whereas others develop in fungi or in fleshy flowers. *See* also FLY.

See M. Demerec (ed.), *The Biology of Drosophila (1950);* J. T. Patterson and W. S. Stone, *Evolution in the Genus Drosophila (1952).* (T. Du.)

DROSOPHYLLUM, a genus of carnivorous plants allied to the sundews (*Drosera*) and found in the hills of Portugal and Morocco. It is a low. shruhby plant which, in contrast with other carnivorous plants. inhabits

dry soil. It produces numerous long, linear leaves bearing two kinds of glands: stalked, having the shape of minute toadstools, and sessile. lacking the stalk. The former are coloured red, the latter pale green. The stalked glands secrete a stiff mucilage which serves to catch insects as large as houseflies. In struggling, the prey is bedaubed with the mucilage and is asphyxiated. Coming into contact with the digestive glands, which have been stimulated from the stalked glands, the prey is attacked by a digestive enzyme. It is thought that a mosquito can be digested completely in 24 hours.

The common name for the plant in Portugal is "slobbering pine" or den- of the sun (sundew). *See* also CARNIVOROUS *PLANTS*.

(F. E. L.; X.)

DROSTE-HULSHOFF, ANNETTE ELISABETH, BARONESS VON (1797–1848), the outstanding German woman writer of her time. Her parents belonged to the Catholic nobility of Westphalia and she was born on Jan. 10, 1797, at Hülshoff near Münster. With her brothers she was educated by tutors. She learned to love the landscape of her homeland and to understand its people, even sharing some of their superstitions. The impressive cycle of religious poems *Das geistliche Jahr* (begun 1820, completed 1839, first published 1851) reflects both her piety and her doubts. After the death of her father she moved to nearby Rüschhaus and in 1830 she met the novelist Levin Schücking (1814–83) who was to be her only link with contemporary literature and a spur to poetic ambitions such as she lacked in her family circle. He thought of her as a friend, but her feelings toward him were more intense. In 1841–42 she stayed at the home of her brother-in-law Joseph. Baron von Lassberg (1770–1855) in Meersburg where Schucking was librarian. There she wrote a number of her best poems, often inspired by memories of Westphalia. Her lyrics and ballads, first published under her full name in 1844, are distinguished by shrewd and unsentimental observation of nature, originality of approach and virility of tone. Her only completed prose work, *Die Judenbuche,* a penetrating study of a murderer's upbringing. crime and atonement within the setting of Westphalian village life. appeared in 1842. After a lifetime of indifferent health, she died on May 24, 1848. at Meersburg.

DROUAIS, JEAN GERMAIN (1763–1788), French historical painter, was born in Paris on Nov. 25, 1763. His father, François Hubert Drouais, and his grandfather, Hubert Drouais, were !?ell-known portrait painters. Jean studied first under his father, then under N. G. Brenet, and finally under J. L. David, whom he accompanied to Rome. There he was influenced by ancient art and by Raphael. Goethe, who was at Rome when Drouais's "Marius at Minturno" was finished, has recorded the deep impression made by the picture. The last picture he completed was "Philoctetes on the Island of Lemnos." He died on July 15, 1788, at the age of 24.

DROUET, JEAN BAPTISTE (1763–1824), French revolutionary. chiefly remembered for his part in the arrest of Louis XVI, was born at Ste. Menehould in Champagne, where his father was postmaster. The carriages conveying Louis XVI and his family on their flight to the frontier stopped at his door on the evening of June 21, 1791; and the passengers were recognized by Drouet, who took steps which led to their arrest on reaching Varennes. For this service he declined a reward. In Sept. 1792 he was elected deputy of the Convention. He voted the death of the king without appeal, showed implacable hostility to the Girondins and proposed the slaughter of all English residents in France. He was captured by the Austrians at the siege of Maubeuge in Hainault (1793) and imprisoned at Spielberg in Austria until the close of 1795. He then became a member of the Council of Five Hundred! and was named secretary. Drouet was implicated in the conspiracy of Babeuf (1796) and was imprisoned; but he escaped to Switzerland and then to Teneriffe. There he took part in the resistance to Nelson's attempt on the island in 1797. He later visited India. The first empire found in him a docile subprefect of Ste. Menehould. After the second Restoration he had to leave France (1816). Returning secretly, he settled at Mâcon under the name of Merger. He died there on April 11, 1824.

DROUET D'ERLON, JEAN BAPTISTE, COMTE (1765–1844), French soldier whose long career raised him from the ranks of Louis XVI's army to be the first governor-general of Algeria and a marshal of France under Louis Philippe, was born at Reims on July 29, 1765. A volunteer in the regiment of Beaujolais from 1782, he had reached the rank of corporal in 1792, before the fall of the monarchy. Elected captain in 1793, he became aide-de-camp to Gen. P. Lefebvre in 1794 and thenceforward enjoyed rapid promotion. General of division in 1803, he was created comte d'Erlon by Napoleon in Jan. 1809. Having been chief-of-staffof the Bavarian army (from March 1809) and subsequently its commander in chief, in Aug. 1810 he was sent to Spain, where he became governor of Extremadura. He was promoted lieutenant general in 1813. Cnder the first Restoration he was made commander of the 16th military division, but conspired against the regime. Joining Napoleon during the Hundred Days in 181j, he was made a peer of France and given command of an army corps, but in the Waterloo campaign he spent June 16 between Ney at Quatre-Bras and Napoleon at Ligny, failing to support either as required.

On the second Restoration Drouet fled to Bavaria, where, as Baron Schmidt, under King Maximilian I's protection, he set up a brewery near Munich. The death sentence passed on him in France in 1816 was, however, canceled in 1825. Returning to France in 1830, he was reinstated on the active list by the July monarchy. As commander of the 12th military division at Nantes, he was responsible for the arrest of the duchesse de Berry (1832).

In July 1834 Drouet was appointed governor-general of Algeria. Ignorant of the country, he at first let himself be guided by his chief-of-staff, Gen. C. A. Trézel, but on Trézel's being posted to Oran he fell under the influence of the scheming Juda ben Durand, an emissary of Abd-el-Kader (*q.v.*). He disavowed Trézel after the latter's defeat by Abd-el-Kader at La Macta. Weak, lazy and bewildered by intrigues despite his intelligence, he was recalled to France in July 1835. After further years at Nantes, he was made marshal of France in April 1843. He died in Paris on Jan. 25, 1844. His Algerian correspondence is edited by G. Esquer, as volume iii of the *Correspondance générale* in the *Collection des documents inédits sur l'histoire de l'Algérie après 1830* (1926).

(L. G.)

DROUGHT (DROUTH) results from long-continued dry weather and lack or insufficiency of rain which causes exhaustion of soil moisture. suffering of plants from lack of water, depletion of underground water supplies and reduction and eventual cessation of stream flow. Only when the rate of rainfall exceeds the rate of evapotranspiration (evaporation and transpiration combined) is there a surplus of water for soil moisture recharge, ground water recharge and runoff. On the other hand, when the rate of transpiration exceeds the rate of precipitation, moisture in the root zone of the soil will be used up. So long as soil moisture is deficient. water cannot pass through the root zone to replenish ground water, nor does it produce appreciable amounts of surface runoff. Ground water sustains stream flow; but, as long as there is no ground water recharge, the ground water reserves will gradually decline and stream flow will diminish. Thus, the various aspects of drought are interrelated. Absence of rain means utilization and rapid exhaustion of soil moisture with consequent damage to plants and reduction of crop yield; the dry soil prevents addition of water to ground water reserves which are consequently gradually depleted.

Drought is most accurately described as a condition in which the amount of water that is needed for evaporation and transpiration exceeds the amount actually available. Because of the difficulty of determining water needs. however, drought has most often been defined as a period of consecutive days without rainfall. According to a G.S. weather bureau definition a drought exists whenever the rainfall for a period of 21 days or longer is but 30% of the average for the time and place. Tennessee Valley

authority meteorologists defined drought similarly. The British Rainfall organization defined an "absolute" drought as a period of at least 15 consecutive rainless days. Other attempts to define drought restrict the rainfall to a definite percentage of the monthly or annual normal value.

One such definition states that drought occurs when the annual precipitation is 75% of normal or monthly precipitation is 60% of normal; another says that any amount of rainfall less than 85% of normal constitutes drought.

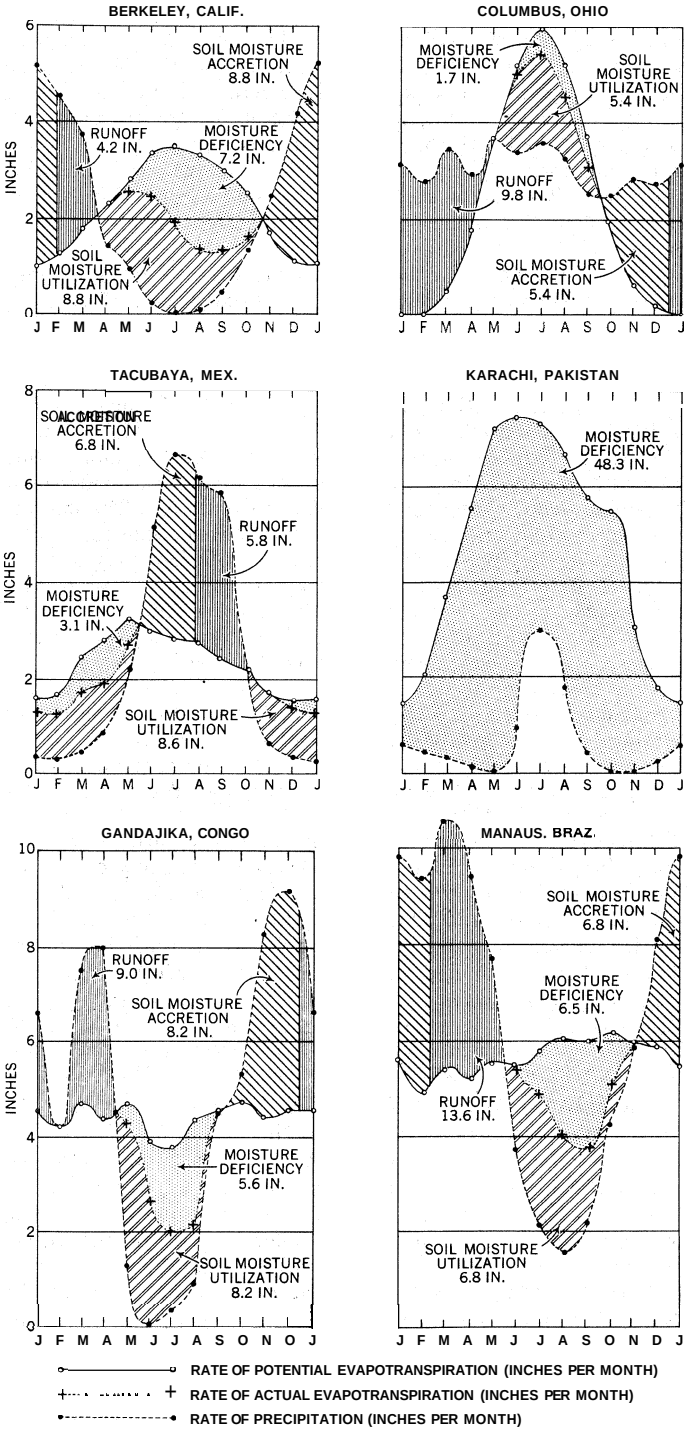
It is evident that drought cannot be defined as a shortage in rainfall alone because such a definition would fail to take into account the amount of water that is needed. Furthermore, the effect of a shortage of rainfall depends on whether the soil is moist or dry at the beginning of the period. Drought begins only when the vegetation can no longer absorb water from the soil rapidly enough to replace that lost to the air by transpiration. It does not necessarily begin on the day that rain ceases but rather only when soil moisture is exhausted.

There are three basic types of drought. The first, called permanent drought, is characteristic of the driest climates. The sparse vegetation is adapted to drought, and agriculture is impossible except by irrigating through the entire crop season. In regions of permanent drought stream flow is absent; there is no runoff except locally when a rare rain occurs. The second, or seasonal drought, is found in the climates that have well-defined rainy and dry seasons. The natural vegetation is made up of plants that produce seeds during the rainy season and then die, and of plants that remain alive but become dormant in the dry season. For successful agriculture, planting dates must be adjusted so that the crop develops during the rainy season. Otherwise, irrigation is necessary. Stream flow is periodic; all but the largest streams may become completely dry during the dry season. The third kind of drought results from the fact that rainfall is irregular and variable everywhere. These are contingent droughts. They are due to the accidental failure of rainfall and are not certain to occur in any definite season. but they are most probable in summer when water needs of plants are greatest. They may occur almost everywhere, even in the areas of seasonal drought. but are most characteristic of subhumid and humid climates. They are usually brief and irregular and may affect a relatively small area. They vary greatly in intensity and time of occurrence and cannot be anticipated.

A fourth type called invisible drought can also be recognized. Even when summer showers are frequent they may not supply enough water to restore that lost by evaporation and transpiration. The result is a borderline water deficiency that cuts crop yields to a small fraction of the potential. When water is supplied to the crops by irrigation to make up the deficiency, crop yields increase twofold and threefold. *(See* IRRIGATION: *Supplemental Irrigation.)*

The amount of water in the root zone of the soil at any time is a result of the interaction of two meteorologic processes—precipitation, which adds water to the soil, and evapotranspiration, which removes it. The meteorologic forces that determine the amount and distribution of precipitation are not the same as those that govern the need for it. The distribution of precipitation in space and time over the inhabited parts of the earth is reasonably well known. On the other hand. almost nothing was known in the second half of the 20th century of the similar characteristics of evapotranspiration. It would be possible to measure actual evapotranspiration as soon as existing methods were perfected. But since potential evapotranspiration does not represent actual transfer of water to the atmosphere but rather the transfer that would be possible under ideal conditions of soil moisture and vegetation, it usually cannot be measured directly but must be determined experimentally.

The many studies that have been made reveal that evapotranspiration depends principally upon four things: (1) climate; (2) soil moisture supply; (3) type of plant cover; and (4) type of land management. Contrary to popular opinion the last two factors are relatively unimportant. The climatic or atmospheric factors determine the rate of transpiration as long as there is no deiiciency



(CENTRE RIGHT AND BOTTOM LEFT) FROM "PUBLICATIONS IN CLIMATOLOGY," VOL. VII, NO 4, 1954 (OTHERS) BY COURTESY OF C W THORNTHWAITE

PRECIPITATION COMPARED WITH EVAPOTRANSPIRATION AT SIX SELECTED WEATHER STATIONS. DROUGHT. OR MOISTURE DEFICIENCY. OCCURS WHEN WATER NEED IS NOT FULLY MET BY PRECIPITATION AND SOIL MOISTURE UTILIZATION

of moisture within the transpiring parts of the plant.

The moisture content of the soil determines the supply of water to the absorbing roots and then to the transpiring parts. Thus, as long as soil moisture is not deficient, temperature and sunshine are the chief controlling factors. The relation between temperature and sunshine and evapotranspiration observed at various places in western United States provides a useful basis for determining potential evapotranspiration elsewhere, at least approximately.

Annual potential evapotranspiration varies from less than 20 in. in the north of the United States to more than 50 in. in the south.

In the arctic tundra it is less than 10 in. and in some parts of the tropics it is more than 60 in.

Except in equatorial climates, the potential evapotranspiration varies systematically from month to month throughout the year; it is quite small or negligible in winter and, even in the polar regions, is large in summer.

This periodic variation between winter and summer which is associated with the apparent motion of the sun gradually diminishes in the tropical regions until at the equator it disappears. Potential evapotranspiration may vary from month to month, however, even in full equatorial climates. For example, in Manaus, Braz., within 3° of the equator, the need for water is highest in August, September and October during the dry season and least in February at the height of the rainy season.

Almost everywhere in the world soil moisture is deficient at some time during the year. The magnitude of the deficiency is the most direct measure of drought and represents, of course, the amount by which the precipitation fails at any time to provide an adequate water supply to the vegetation. It is the amount which should be supplied to crops by irrigation to assure maximum yields.

Even in humid climates such as eastern United States or western Europe droughts are frequent and severe. More often, however, the rains are spaced only a little too far apart in time or are too light to supply needed water at the right time. Soil moisture is deficient and drought results although it may not be recognized by any visible signs until after serious damage has been done to the crop. Water is available for supplemental irrigation in most humid regions The benefits to be secured by adding the right amount of water at the right time are gradually coming to be understood.

Drought is the most serious physical hazard to agriculture in nearly every part of the world. Since both precipitation and the demands for water by crops vary from one year to another. there is a similar great variation in the magnitude of drought. To be able to forecast drought incidence and intensity a season, or even a few weeks, in advance would be of inestimable value to agricultural, industrial and commercial interests. For many years a tremendous amount of effort was expended by official agencies and private individuals all over the world in attempts to develop reliable means of making seasonal drought forecasts. By the second half of the 20th century no method had been found and the possibility of finding one appeared unlikely.

Even more important than the forecasting of drought would be the ability to control it through the artificial production of rainfall. Experiments in cloud seeding with dry ice and silver iodide in the late 1940s were sensationally reported and led to the formation of many firms of rain makers who operated throughout the world. Before the end of the 1950s, it had become clear that the potentialities of rain making were limited and that there was no reason to expect that drought would be controlled or reduced in importance or areal extent.

DROWNING AND LIFESAVING. Drowning means suffocation by immersion in a liquid, usually water. Water closing over the victim's mouth and nose cuts off the body's supply of oxygen. Deprived of oxygen the victim stops struggling, loses consciousness. gives up the remaining tidal air in his lungs and sinks to the bottom. There the heart may continue to beat feebly for a brief interval, but eventually it ceases and death ensues. Lifesaving is the term used for all the methods devised to aid or rescue drowning persons and to revive the apparently drowned.

The number of lives lost by drowning in the world each year totals many thousands (approximately 7 000 in the United States alone) By far the largest number of these are bathers The second largest number of drownings occur in small nater craft accidents More than 90% of the drowning accidents among bathers occur within ten yards of the safety or shore. shallow nater, pier, float or poolside Most drownings occur as nould be expected among nonswimmers although the number of novice swimmers who lose their lives in the water runs a close second Drownings among skilled swimmers are rare.

The commonest causes of drowning among nonswimmers are: (1) stepping off into deep water while wading; (2) being knocked down and swept into deep water by wave action or current; (3) being precipitated into deep water as a result of capsize or sinking of small water craft; (4) falling or being pushed into deep water from an overhanging hank. pier. float or small craft; (5) ill-advised attempts to aid drowning persons. The commonest causes of drowning among novice swimmers arc: (1) exhaustion in deep water because of undue cxpcnditurc of energy: (2) ineffectiveness of newly acquired strokes; (3) ill-fated attempts to aid drowning persons.

There are three ways in which a nonswimmer can he reasonably safe in. on and near the water. The first is to confine his aquatic activities to supervised shallow-water areas. The second is to wear a life vest or other buoying device when venturing into small water craft. The third is to be accompanied by a person skilled in lifesaving who is capable of making a rescue in case of accident. The novice swimmer also has three ways to ensure his safety. First. by staying in water of standing depth until he can use his newly acquired strokes with some degree of ease. Second, by making his first ventures into deep water only under the supervision of a person skilled in rescue techniques. Third. by being able to swim twice as far in shallow water as he proposes to swim outward from shore: also by being able to float or rest in a floating position before taking his place among swimmers. Reasonable safety in the water ior nonswimmer. novice and skilled swimmer alike is to be found only within supervised bathing places. Risk is always involved when bathing or swimming in unknown waters. or when unaccompanied or unsupervised by someone skilled in lifesaving. In the last analysis. however. the safety of a person in, on or about the water under any conditions lies in his ability to take care of himself. The nonswimmer should learn how to swim at the earliest opportunity. He should try to become a skilled swimmer. Then. as a skilled swimmer. he should perfect his skill to the point where he can take care of himself in any but the most perilous situation.

One of the most tragic of water accidents is the double drowning in which a person sacrifices his life. often needlessly. trying to rescue a person in danger of drowning. Contact with a drowning person poses no threat to the trained lifesaver skilled in ways of avoiding or releasing the grip of the victim. For the person unskilled in lifesaving to come within the grasp of a drowning person almost always results in death for both. There are ways. however, in which anyone can give effective aid to the victim whether he is a skilled lifesaver or not, even if he cannot swim at all. Furthermore. there is one form of swimming rescue that may be employed effectively by any reasonably skilled swimmer. with small risk.

So many persons get into difficulty close to safety that the rescuer may aid them without entering the water at all. For those very close to the rescuer, a hand reach is enough. The rescuer must have a firm position or handhold on something to avoid being pulled in himself. and he must grasp the victim, rather than permit the victim to grasp him, for the same reason. To make contact with the victim just beyond hand reach, anything to serve as an extension may be used. An oar, a paddle, a boat hook or even a fishing rod may be held by one end while the other end is thrust into the victim's grasp and he is drawn to safety. A drowning victim beyond reach of extensions may be aided by flinging within his grasp anything that has enough buoyancy to enable him to keep his head above water until he can be brought to safety. King buoys, inflated tubes, floating seat cushions or life vests may

BY COURTESY OF THE AMERICAN NATIONAL RED CROSS

FIG. 1.—REAR APPROACH IN LIFESAVING

be so employed. Ring buoys of the throwing type may be hurled with considerable accuracy to a distance of 50 or 60 it.

A swimming rescue may be made as a last resort by a person who is a strong swimmer even though he may have had no lifesaving training. provided he is willing to take the risk involved. The rescuer should approach the drowning person from the rear even though it involves circling the victim to come at him (fig. 1). Watching his chance, the rescuer should swim to within arm's reach of the victim anti assume an upright position in the water with the legs in stroking position, a little forward of perpendicular. The rescuer should grasp him firmly by the hair, or by the collar if the victim' is clothed. Immediately. the rescuer should turn on the side and start swimming strongly with the legs and the free arm. The holding arm should be kept rigid. No attempt should be made to lift the victim's head above water. because the act of swimming an-ay will not only bring the victim's face above the surface so he may breathe. but it will plane the victim's body to the horizontal position and thus make towing easier. If the

FIG. 2.—HAIR CARRY

victim sinks beneath the surface as the rescuer maneuvers into position, the rescuer should unhesitatingly follow him down, reverse position. seize the hair or collar and pull him to the surface. He may then he towed to safety.

Small craft accidents frequently occur far from shore. Under such circumstances. the only feasible way to aid the victims is to use a rowboat. If the boat is small the safest way to make the rescue is to wind the boat end for end when the victim is reached. and back down upon him in the water. The victim may then grasp the stern and climb or be pulled into the boat with little danger of upsetting or filling the craft.

If a small motorboat is employed to make a rescue. the same technique is used hut the clutch must be released or the engine stopped before contact is made to avoid injuring the victim aith the spinning propeller.

A great many methods of resuscitating the apparently drowned have been devised. The major ones in modern use are described in ARTIFICIAL RESPIRATION. It is all-important that artificial respiration be started promptly and continued without interruption until the victim is breathing spontaneously or until it is determined beyond a doubt that he is dead.

DROYLSDEN, an urban district (1894) in the Ashton-under-Lyne parliamentary division of Lancashire, Eng., 3½ mi. E. of Manchester and 2½ mi. W. of Ashton-under-Lyne. Pop. (1961) 25,457.

Part of the manor of Manchester, Droylsden was an agricultural area until 1784 when a Moravian settlement u-as built at the southern end of the township. In 1785 the congregation was "settled." the church opened and the name Fairfield given to the settlement. Fairfield still retains its late Georgian houses and cobbled streets.

Coal mining began in about 1790 in the area and a dye works was opened early in the next century. The town is now largely industrial with textile (cotton and rayon) mills and factories, engineering (the making of textile machinery), the manufacture of chemicals and the preserving of fruit.

DROYSEN, JOHANN GUSTAV (1808–1884), German historian and politician, developed under the stress of political circumstance, a conception of Prussia's historical vocation which had considerable influence. He was born on July 6, 1808, at Treptow, Pomerania, son of an army chaplain. The War of Liberation against Napoleonic rule made a lasting impression on him, laying the foundation of his ardent attachment to Prussia. After studying at Berlin he became a *Gymnasium* teacher and in 183j professor of classical philology in Berlin. To these years belong Droysen's works on Alexander the Great and on Hellenism (conceived as a distinctive east-west culture). In 1840, however, he accepted an invitation to Kiel as professor of history and there he became interested in the Schleswig-Holstein question. then acute. In 18jo, with Carl Samwer, he published *Die Herzogthümer Schleswig-Holstein und das Königreich Dänemark seit dem Jahre 1806* (Eng. trans., 1850), which was formative of German opinion, and he supported the rights of the duchies so prominently that in 1851, after Holstein passed to Denmark, he thought it prudent to accept an invitation to Jena. It was nevertheless during this agitated period that he worked on his admirable life of Yorck von Wartenburg (1851–52).

Meanwhile the movement for German unification drew him. In 1848 he became a member of the Frankfurt parliament and secretary to the committee for the constitution. Droysen believed in Prussia's vocation to lead Germany and after the king refused the imperial crown in 1849 he retired in disappointment. In spite of Droysen's intense Prussian patriotism, his liberal views brought him disfavour in official circles and it was not until the regency of Crown Prince Frederick that he was called back to Berlin (1859). Droysen took no further active part in politics but devoted himself to his great work, the *Geschichte der preussischen Politik,* 14 vol. (1855–86). The history goes up to 17j6 and was unfinished at his death in Berlin on June 19, 1884. Droysen's belief in Prussia was no unrestrained nationalism, for human individuality and responsibility were for him basic articles of faith.

DRUG: *see* ANESTHESIA AND ANESTHETICS; ANTIBIOTICS; BARBITURATES; DRUG ADDICTION; NARCOTICS; PHARMACOLOGY; PHARMACOPOEIA; POISON; SULFONAMIDES; TRANQUILIZING DRUGS; *see* also under names of specific drugs such as CHLORTETRACYCLINE; HEROIN; OPIUM; PENICILLIN; etc.

DRUG ADDICTION, as defined by the World Health organization study group on the treatment and care of drug addicts in the second half of the 20th century, is the habitual and compulsive use of any narcotic drug in a way that directly endangers the addict's own or others' health, safety or welfare. Abusive use of addiction-producing drugs has been a human problem ever since prehistoric times. Most countries are concerned about drug addiction and are aware that it flourishes particularly among persons of low economic and cultural status. Persons of any nationality, race, colour or class of society may become addicted to the use of narcotic drugs.

Opium and opiates are the predominant drugs in international illicit traffic. Prohibition of opium smoking, however, is gradually reducing addiction in the far east. In 1955 Iran prohibited the production of opium, in 1957 Afghanistan prohibited its production and sale, and the All-India conference of 1956 decided that no opium should be legally available for quasi-medical purposes after March 31. 1959. The United Nations and allied agencies

provide technical assistance to countries to devise means of combating drug addiction. Thailand received technical assistance to suppress opium smoking and illicit traffic of opium and opiates.

Since early in the 20th century, heroin (diacetylmorphine) has been the most widely used drug of addiction. Drugs used by addicts include the groups of which morphine, pethidine. methadone and cocaine are members. Because of the prohability that new addiction-producing compounds of different structure will be developed, the relation of chemical structure to addiction-producing properties cannot be positively stated.

Although some synthetic narcotic drugs may possess less addiction-producing liabilities than some natural narcotics, both should be subject to the same rigid controls. Addiction to natural narcotics has been most prevalent among persons in the lower social groups; addiction to synthetic drugs has been more prevalent among certain professional and subprofessional groups. Addicts generally. however, quickly learn of the qualities of new synthetic drugs and turn to them through thefts and through forged or otherwise illegally obtained prescriptions to satisfy their desire.

Increasing abuse of the drug cannabis (obtained from the resin of the herb *Cannabis sativa),* called also hemp, marijuana. bhang, ganja. hashish and kef in various countries, caused considerable alarm. World Health organization authorities agreed that cannabis and its preparations have no therapeutic use and studied means of developing a strain of C. sativa without harmful resins, or of replacing it with other similar crops for industrial use. Cannabis does not create physical dependence; its effect on different individuals is unpredictable, but prolonged use may lead to a psychosis, and many users quickly become heroin addicts.

Most countries prohibit production and therapeutic use of cannabis. Nonmedical use of ganja was prohibited in India beginning in 1959, and of bhang beginning in 1961. Egypt destroyed cannabis substances in all pharmacies. In the middle 1950s Lebanon destroyed millions of square metres of illicit cannabis plantations. In 1954 Morocco prohibited cultivation, sale and use of cannabis in the southern zone. and conducted a nation-wide educational campaign to fight illiteracy and addiction simultaneously. Mexico and the U.S. co-operated closely to suppress illicit traffic in marihuana.

Cocaine. a stimulant used by some addicts, does not cause physical dependence. Cocaine abuse was not a major problem. but illicit traffic persisted in the far east and middle east, with increased activity in Burma.

Barbiturates, although subject to much abusive use. can best be controlled by local legislation. which should be of a different nature and scope, and therefore independent of legislation for the control of narcotic drugs and cannabis. Control similar to that of barbiturates should be applied to amphetamines.

Kat (*Catha edulis*), a shrub cultivated chiefly in Ethiopia, Kenya. Yemen and neighbouring countries and growing wild in east and south Africa and along the west coast of Arabia, was first discussed by the United Nations commission on narcotic drugs in 1956. Aden. Kenya. Somaliland Protectorate (British) and French authorities considered kat dangerous to public health and adopted control measures against its use. Kat produces stimulating effects similar to those of cocaine or caffein, although it contains neither of these substances.

Indispensable Uses of Drugs. — In the United States prescription for narcotic drugs may be issued only by a duly registered physician for a bona fide patient for medical purposes only, and may be filled by a qualified druggist. Thus both physician and druggist share responsibility for prescribing and dispensing narcotic drugs. An order purporting to be a prescription issued to an addict or habitual user of narcotics. not in the course of professional treatment but to provide the user with narcotics sufficient to keep him comfortable by maintaining his customary use, is not a prescription within the meaning and intent of the Harrison Narcotic act. and the person filling such an order. as well as the person issuing it, may be charged with violation of the law. Nonaddiction-producing drugs should be prescribed whenever possible to alleviate pain.

Causes of Addiction. — Undesirable personal associations are a very important cause of drug addiction. Much addiction is directly related to character and perscnality disorders. Young people may indulge in drugs out of curiosity or for a thrill.

Classes of Addicts. — The World Health organization addiction study group believes that the best key to classification of addicts may be their amenability to treatment. In countries where narcotics are plentiful and medical care is not readily available. the addicts most amenable to treatment may be those whose addiction is caused by exposure to more or less accidental stresses such as hunger, poverty or physical exhaustion; in other countries, they are likely to be those whose addiction results from group or gang participation or from treatment for illness not due to personality disorder. Many addicts have a history of social maladjustment because of parental neglect or broken homes and are experienced criminals before they become interested in taking drugs. Addicts who suffer from basic character disorders are the most difficult to treat. Even some among this group may become reasonably well adjusted under proper management and not return to the use of drugs, whereas some apparently well-adjusted patients might. under continued stress. develop a fixation to drug use as a means of solving their problems. Progress toward control of addiction in any country may be impeded by lack of co-operation from neighbouring countries.

Known drug addiction in the United States decreased after a high peak during and following World War I. when about 1 in every 400 of the population was a narcotic user. By 1925 the rate of addiction was reduced to 1 in every 1,000, and by 1938 to about 1.53 in every 10,000. Rejections of drug addicts for military service in World War I were 1 in every 1.500. compared with 1 in every 10,000 in World War II. Illicit narcotic traffic arid addiction in the United States during World War II were prohahly the lowest since enactment of federal narcotic control legislation. Resumption of shipping after that war brought an influx of heroin from Europe and the middle east. In 1950 Communist China became the great uncontrolled source of smuggled heroin.

A survey conducted by the bureau of narcotics during the five years 1953–57 enumerated about 44,000 addicts. of whom about 80% were men. About 76% were located in four states: New York. 43%; Illinois, 16%; California. 11%; and Michigan, 6%. About 60% were between 21 and 30 years of age and about 12% under 21 years of age; of the latter group. more than 84% were 18 or older. More thnn 90% of all addicts used heroin.

Symptoms. — In most persons the first nonmedical doses of morphine produce unpleasant symptoms such as nausea. vomiting. pallor. sweating and itching. The eyelids usually droop slightly. and blinking is frequent. Appetite is lessened, sexual drive is diminished and fatigue seems to disappear. Use of the drug facilitates indulgence in fantasy and escapism. As tolerance develops, the pupils remain constricted and constipation is continuous. When a drug addict cannot obtain the increasing quantities of the drug he craves he may become irritable. depressed. moody. asocial and suffer physical torture. He is likely to be preoccupied with himself and his desire for the drug. and may become psychotic. He probably will lie. forge prescriptions. shoplift, steal. embezzle or commit other crimes to obtain drugs. Finally. he neglects physical cleanliness. his skin may be pallid and affected by rashes. he perspires freely upon slight stimulus. suffers sexual disturbances and deteriorates physically and morally.

Treatment. — The simplest and most effective method of withdrawal of opium, opiates or morphinelike synthetic drugs is by substitution of methadone, in decreasing doses. for the drug of addiction. After physical withdrawal, which usually requires about ten days. a prolonged period of institutional rehabilitation under constant surveillance is necessary to prevent access to narcotic drugs. The addict should do useful work daily and engage in occupational therapy to develop his talents and skills. Varied recreational facilities should he provided. Psychotherapy is important during this period to give the addict insight into his problems and the stresses of life that will help him to return to normal life and avoid relapse. Group psychotherapy for the families of some addicts may be necessary.

Treatment should continue until the addict is discharged by a competent medical authority. The goal of treatment is to help the

addict attain a feeling of well-being and reasonable adjustment to life problems without drugs. Maintenance of drug addiction is not treatment. Addicts should not be given drugs for self-administration. The community should co-operate to restore the former addict to his proper place in society and to help him avoid associations that would influence him to return to the use of drugs.

Facilities. — Few addicts submit voluntarily to treatment; thus some coercion is usually necessary to commit them to institutions for medical treatment and psychotherapy. Methods of commitment vary with laws and procedures of different countries. Some civil commitment laws provide for indefinite periods of treatment and for safeguarding of medical and court records. Supervised parole and treatment for long periods with immediate readmission for hospital treatment upon relapse are provided in other laws. A few countries have penal laws to provide for commitment of addicts for treatment.

The United States law authorizes treatment at either of two United States public health service hospitals — Lexington, Ky., and Fort Worth, Tex.—for (1) federal prisoners and probationers; (2) addicts from the District of Columbia by civil commitment without the stigma of a criminal record or by criminal commitment; and (3) voluntary patients addicted to narcotic drugs. Prisoner addicts considered suitable for treatment are sent to these hospitals by the bureau of prisons after conviction in federal courts. Probationers from federal courts and patients committed from the courts of the District of Columbia must remain in the hospital until treatment is completed, and they are supervised folloning discharge from the hospital. Voluntary patients are admitted to the federal hospitals at their own request if beds are available after eligible prisoners and probationers are admitted. Records of admission, treatment and discharge of voluntary patients at these hospitals are confidential.

In 1952 Riverside hospital in New York city was opened for treatment and rehabilitation of addicts under 21 years of age. Rehabilitation services in Chicago help former addicts to obtain employment, provide financial assistance in the interim and encourage them to discuss their emotional problems with professionally trained staff members as an aid to better self-understanding to prevent relapse. Detroit provides limited rehabilitation services, including group psychotherapy and welfare assistance.

The Alameda county rehabilitation centre at Santa Rita, Calif., conducted a pilot study of the therapeutic usefulness and medico-legal aspects of prolonged treatment of addiction under probation in the environment of a county jail farm. California law provides a jail sentence of 90 days to one year for any person convicted of unlawful use of or addiction to narcotics. The court may place such person on probation for not more than five years, and if probation is granted may require jail confinement for at least 90 days, making possible a period of low-cost psychotherapy.

Several countries have expanded facilities for treatment of addiction. Morocco has a central psychiatric centre near Casablanca, several psychiatric hospitals in major cities and other hospitals with psychiatric wards to discover incipient cases of addiction Singapore maintains a rehabilitation centre for opium addicts, who remain an average of six to seven months, and not more than one year After treatment each addict is supervised by a parole officer. This centre has aroused interest in neighbouring countries, and Thailand planned to send medical officers to study techniques there. Macao established an addiction treatment centre in 1956. Egypt has several hospitals for treatment of hashish smokers. Several camps in Iran provide withdrawal treatment and a brief period of rehabilitation for opium smokers. Argentina, Denmark and the Federal Republic of Germany treat addicts in state mental hospitals as beds are available. In Germany psychotherapy is continued after discharge from the hospital.

The United Nations commission on narcotic drugs has suggested that a summarization be made of experiences of various treatment centres with different methods of treatment and that regional seminars be held to exchange information between countries.

Prevention. — Prevention of drug addiction necessitates education of parents, schoolteachers, police officers and other adults in methods of narcotic control; improvement of social conditions, high living standards and greater educational advantages generally; severe penalties for narcotic law violators and rigid enforcement of narcotic laws; compulsory hospitalization of addicts to prevent spread of addiction; and control of production of narcotics.

Large quantities of opium. greatly in excess of world medical and scientific needs, were diverted into illicit channels in several countries. A significant step toward control of world opium production is the International Opium protocol of 1953, which was planned to reduce annual world production from 2.000 to 500 tons, the latter amount being deemed sufficient to supply medical and scientific needs. This protocol would not become effective until ratified by 25 countries, including 3 drug-producing and 3 drug-manufacturing countries. It brought under control dangerous synthetic drugs throughout the world. See also BARBITURATES; COCAINE; HEROIN; MORPHINE; NARCOTICS; OPIUM; etc.

DRUIDISM, according to the traditional belief, was the religion of the Celts of ancient Gaul and the British Isles. The extravagant modern notion of the druids, as members of an esoteric religious order performing secret rites at midnight in oak groves or at such places as Stonehenge, is attributable largely to the antiquarian researches of John .Aubrey and, especially. William Stukely, in the 18th century. In fact, as the following article shows, practically nothing is known about the druids. (X.)

The earliest tolerably reliable evidence concerning the druids comes from Julius Caesar and his sources, which would place them as an established institution in southern and central Gaul at least as early as 100 B.C. How much earlier they existed in Gaul itself and how widely spread their institution was among the other Celtic tribes is a matter of pure conjecture. It is significant that Caesar, who gives the druids a position of great influence in one short passage of his *Gallic* War, never again refers to them, although such reference would have been most apposite if the druids had formed a centre of tribal cohesion and national resistance to the Roman invader. Just as little is heard of the druids in the following two generations. The tradition merely states that they were banned by Tiberius and Claudius, chiefly because of their superstitions and human sacrifices, while Pliny in his *Natural* History merely enlarges on their magical cures. The tradition concerning them stands in need of a critical appraisal.

The main authority for Celtic ethnography, apart from the historians, is the Stoic philosopher Poseidonius, who also, therefore, provides the chief evidence for statements about the influential and cultured classes among the Celts, to whom the druids belonged. His work, which was contained in book 23 of his history, is not extant, but his material on the Celts is reproduced, in summary and with some changes and additions. in three later Greek authors, the historian Diodorus Siculus, the geographer Strabo and the writer of miscellanies Athenaeus. The similar material in Caesar's *Gallic War* is taken from Poseidonius without acknowledgment and with significant omissions and additions.

While Poseidonius may rightly be admired as the most learned man of his day and while his ethnographic digressions may properly be regarded as the high-water mark of ancient ethnography, yet it cannot be forgotten that his history was composed from a Stoic viewpoint, which becomes peculiarly obvious in his discussions of the cultured classes in barbarian nations. This was first hinted at by Karl Reinhardt, who in his book on Poseidonius (1921) said that the druids are stylized by him as representative

of the Logos, the higher power of the soul that holds the instincts in check. This view was next referred to by G. Pasquali in 1931' and elaborated somewhat by a student of Pasquali in 1935. Reinhardt again mentions the topic briefly in his last full-length treatment of Poseidonius in 1953 (see *Bibliography*).

The reasoning runs as follows. For Poseidonius the universe is a pantheistic god whose leading principle is the Logos, the reason which also inhabits the mind of man. The great men of the past who have led humanity on its long road to civilization were the kings and philosophers who, particularly endowed uith reason and fresh from their divine origin, were able to understand the divinity and proclaim his wishes to their people. Such a man was Moses. nho taught the Jews that there was only one God, variously called heaven, the universe or nature; this god bestowed his gifts on the virtuous and gave good counsel to those who practised divination. Such also were the druids of Gaul, who were philosophers and theologians, possessing the highest political authority, and were in charge of divination and sacrifice. They studied theology, ethics and natural science, including the physics of the earth and stars, and were the teachers of the upper-class Gauls. Among their main tenets were that the soul of man is immortal and that the universe is indestructible, although from time to time it would be temporarily consumed by the action of fire or water.

When this account of the druids is examined soberly, it becomes impossible to believe that it is historical. It is known that the Celts at this period, about 80 B.C., were still practising divination by human sacrifice and preserving the skulls of slain enemies by nailing them as trophies to the porches of their houses. The alleged studies of the druids are simply a program of Stoic philosophy including some of their specific doctrines such as that of the periodic destruction of the universe by fire and water. The general position of the druids, with their political and religious authority and their control of divination, confirms this theory of cultural development with its strong Stoic traits. This picture of the druids is no more historical than that of the god of Moses.

It is not, hot\-ever, as a consequence necessary to maintain that the druids were not to some extent both political and religious leaders in Gaul Poseidonius was, after all, one of the most acute observers of antiquity, and whatever factual knowledge he had obtained about the druids prompted him to embroider it with Stoic fiction, for the reasons given above. It is probable that their influence has been exaggerated by Poseidonius for his philosophical reasons, and by Julius Caesar for his own different political reasons. It is difficult to believe that the druids possessed any body of coherent religious doctrine, much less the philosophy so liberally bestowed upon them by Poseidonius. Present knowledge of Gallic religion as detailed by J. Vendryes is rather one of multiplicity and diversity than of anything resembling a system.

What may reasonably be accepted of the tradition about the druids is problematical and depends primarily on the view taken of the relationship of the four secondary sources to Poseidonius. The two chapters in Julius Caesar (De Bello Gallico, vi, 13–14) appear to be an abbreviated rendering of Poseidonius. Ch 13 emphasizes and exaggerates the political importance of the druids, and ch. 14 does the same for their position as teachers, philosophers and theologians. Caesar's interest may be indicated by his omission of the other educated classes in order to concentrate on the druids, and perhaps by addition of detail. Perhaps Caesar changed what had been stated with qualification by Poseidonius merely of a tribe or tribes in the south into the idea of druidism regarded as a national system throughout the whole of Gaul.

The third chapter (De *Bello* Gallico, vi, 16), in which the druids are connected nith the Gallic practice of human sacrifice, is again clearly tdken from Poseidonius, since it illustrates his theory of degeneracy from the primal Golden Age, a degeneracy that leads to superstition and tyranny.

The old problem of whether Poseidonius had described two or three educated classes among the Celts (*i.e.*, whether the seers should be included as a separate class) should be decided in favour of three classes in view of the importance divination possessed in Poseidonius' view of the early history of mankind.

It seems that a critical consideration of the tradition regarding the druids must lead to the conclusion that this priesthood was not in any way a distinguished exception among the priesthoods of the contemporary barbarian nations, but that the Celts were in this respect very like the Germans. According to Strabo (vii, 290). Poseidonius says that the habits and way of life of both peoples are almost the same, but the Germans are somewhat less civilized. Caesar's distinction therefore in regard to their priesthoods cannot be regarded as historically correct. (J. J. T.)

The word *druí* (n. pl. *druid*) is found in Old Irish and may be analyzed as **druuids*, where the second element means "he who knows" and the first may either be an intensive prefix or the word meaning "oak." No genuine tradition of druids exists in the Brythonic languages; the ceremonies of the modern Welsh Gorsedd are a product of 18th-century romanticism (see EISTEDDFOD). In early Irish literature, which comes through Christian sources, the druids (ntagi) are represented as malignant magicians who bitterly opposed the introduction of the new faith. The situation cannot have been so simple, since the *filid* ("seers"), who also practised divination and are often confused with druids in the sagas. assumed an honoured place in early Irish Christian society as literary men and historians. It is probable that the druids represented the learned class in its religious and magical function and were thus replaced by the ecclesiastics in positions of power and authority; it is significant that many of the contests between saints and druids are represented as taking place over possession of land. In later Irish the words draoi, *draoidheacht* come to mean simply "magician, magic." Owing to the nature of the sources it is not possible to construct any coherent account of the beliefs of the druids in pre-Christian Ireland. See also IRELAND: History; IRISH LITERATURE. (D. GE.)

DRUM, HUGH ALOYSIUS (1879–1951), U.S. army officer. was born at Fort Brady, hlich., Sept. 19, 1879. The son of an army officer, he spent his youth at various army posts and studied at St. Francis Xavier college, New York, and Boston (Mass.) college. In 1898, at the age of 19, he was given a direct commission as a second lieutenant in the U.S. army. Drum fought in the Philippines and in 1914 participated in the occupation of Veracruz. He then served as a staff officer along the Mexican border. where he was largely responsible for drafting the defense plans for the area. He accompanied Maj. Gen. John J. Pershing to France in 1917 and served as chief of staff of the services of supply and of the 1st army. Following World War I he held important command and staff positions, including those of assistant chief of staff and deputy chief of staff.

In 1939 he was prominently mentioned for the post of chief of staff, but was passed over in favour of Brig. Gen. George C. Marshall; by 1940 he was the senior ranking officer of the U.S. army in permanent commission. At the start of World War II Drum commanded the 1st army and later the eastern defense command, retiring in 1943 as a lieutenant general. After retirement. he commanded the New York state guard, was chairman of the New York State Veterans commission and president of the Empire State corporation. He died in New York city. Oct. 3. 1951. (S. L. FK.)

DRUM, in music, a percussion instrument common to most nations and ages. Unlike most musical instruments that have their origins in the practice of ritual magic, the drum has never completely lost these associations. In its form the drum is basically either a cylinder or a bowl of nood, metal or earthennare; the "shell" is covered at one or both ends with a membrane. called the "head." that is set in vibration by direct percussion of hand or stick (for primitive drums see PERCUSSION INSTRUMENTS). European drums may be divided into three groups according to the

(CENTRE LEFT) MESSRS. HENRY POTTER & CO., LONDON; (CENTRE RIGHT) PENGUIN BOOKS LTD.; (RIGHT) BOOSEY & HAWKES LTD.

(LEFT) TAMBOURINE; (CENTRE LEFT) MILITARY SIDE DRUM, 17TH CENTURY; (CENTRE RIGHT) MODERN SIDE DRUM, SHOWING SNARES; (RIGHT) MODERN ORCHESTRAL BASS DRUM

nature of their construction: (1) a single head on a shell open at one end, as the tambourine; (2) a single head on a closed shell, as the kettledrum; (3) two heads, one at each end of the shell, as the side drum and tabor. Of the several drums used in the modern orchestra only the kettledrums are designed to produce a note of a definite musical pitch. In oriental and African countries drums are often played by striking them with the hand; in these countries this technique is developed to an astonishing degree of rhythmic intricacy and virtuosity. In Europe the drum—generally played with one or two sticks—is, traditionally, a less sophisticated instrument that fulfills the relatively simple purpose of marking the rhythm for dancing or marching.

Very little is known about European drums and drumming in the middle ages, the only evidence being that of representations in paintings and sculpture and a certain amount of not very helpful information from literary sources. No medieval drums have survived, and it is not until the 16th century that written percussion parts appear, and even then only in instruction books. In fact, before the middle of the 17th century the composer did not feel obliged to notate any percussion parts, knowing that the player's training would have made him thoroughly conversant with what was then a traditional technique. By the 13th century three types of drum appear to be established: the nakers, the tabor (in several forms) and the tambourine.

The Nakers, a 13th-century importation derived from the Arab *naqqara,* were a pair of hemispherical drums like very small kettledrums and were played by one drummer. The shells were made of metal or wood, the head was tensioned by ropes or thongs and sometimes the instrument was equipped with a snare, *i.e.,* a string of gut or silk stretched across the head to cause a rattling sound. They were suspended from the waist and played with two sticks. The pairs of nakers were tuned to a high and a low note of rather indefinite pitch and were used to accompany bands of "loud" instruments—trumpets, shawms, bagpipes, etc.—in ceremonial music.

The Tabor was a small cylindrical drum of variable depth with a wooden shell and a drumhead at each end. It was a rope-tensioned and usually had a snare on both heads. The tabor was always used in conjunction with the "tabor pipe," a long three-holed whistle-flute; both instruments were played by one musician. The pipe was played with the left hand while the tabor, generally suspended from the left wrist, was struck with a stick held in the right hand. The pipe-and-tabor combination dates from at least the 13th century and, despite early pastoral associations, provided court dance music until as late as the 16th century. It is still used in the popular music of Provence.

The Tambourine, a shallow wooden hoop with a single head and metal "jingles" set in the sides, is struck with the hand, rubbed with the thumb or shaken. The tambourine (a similar instrument was the ancient Greek *tympanon*) was a medieval adaptation of an instrument used by the Arabs. Like its Arabic prototype, the tambourine in the middle ages often had a snare. By the end of the 15th century its use seems to have declined except where it survived as a folk instrument. Early in the 19th century the tambourine was introduced to the orchestra via the opera (the usual route to respectability for percussion instruments) for special Spanish or gypsy effects.

The Kettledrum is a large drum with a bowl-shaped shell, usually of copper; the head is tensioned (and tuned) by handles set around the circumference or by a mechanical device. It is the most important of the drums used in the modern orchestra. The standard number in the modern orchestra is three. Although similar in many respects to the earlier nakers, the kettledrums have a completely separate history. In the mid-15th century the pairs of large kettledrums of the Ottoman Turks were brought to Europe by way of Hungary and Germany. Like the modern instrument, the shells—one larger than the other—were generally of copper, and the calfskin heads were tensioned and tuned by screws around the circumference. They were military and ceremonial instruments and formed an important part of the retinue of emperors, kings and noblemen. From the time of their introduction to Europe the kettledrums were associated with trumpets; the players of both instruments belonged to the same exclusive guild. By the beginning of the 16th century trumpet and kettledrum players were established in most important noble households in Europe and the word "dromme" (having the same derivation as "trumpet") first appears in the English language at about this time. Kettledrums were often played on horseback, one drum on either side of the horse, as the Turkish armies used kettledrums on camelback. Although no written drum parts survive from the 16th century, such works as the chanson *La Bataille de Marignon* by Clement Janéquin, in which the voices imitate the calls of the trumpets and drums, give a reasonably clear picture of a technique based on a tonic and dominant tuning of the kettledrums that was not to be substantially altered for more than two centuries. An early example of trumpet and drum music is the *toccata,* or fanfare (the contemporary English word was "tucket"), at the beginning of Claudio Monteverdi's opera *Orfeo* (1607). During the 17th and 18th centuries kettledrumming developed into an elaborate ceremonial and ostentatious art that used complicated drum patterns based on the multiple tonguing technique of the trumpeters. The orchestral use of the instrument was confined to passages that expressed rejoicing, as in J. S. Bach's cantata *Tönet, ihr Pauken! erschallet Trompeten,* or supported the brass in loud passages. The expressive use of the kettledrum in the 19th-century orchestra (played *piano, crescendo* and with the drums not necessarily tuned to the tonic and dominant) was largely due to the innovations of Beethoven. Later Hector Berlioz, who in his *Requiem* (1837) used the formidable number of 16 kettledrums, discussed in his book on orchestration (1843) the use, for the kettledrum, of drumsticks with wooden ends and with ends that were covered with leather or sponge; he said that it was worse than negligence for the composer not to indicate in his score which should be used. For a discussion of modern developments *see* TIMPANI.

The Side Drum, a larger form of the tabor, has a cylindrical

shell. two heads that are tensioned with rope, and snares on the lower head; it is played with two wooden sticks. It mas introduced to the rest of Europe by Swiss mercenaries in the 15th century who brought with them their fife and drum bands. The side drum was the drum of the infantry—as the kettledrums were the drums of the cavalry—and as such were used not only to mark the rhythm for marching but also (to quote Toinot Arbeau. a 16th-century writer) ". . . as a signal and warning to the soldiers to break camp, to advance, to retreat and give them heart, daring and courage to attack the enemy and to defend themselves with manful vigour." The side drum was much in favour in the 17th and 18th centuries with the increase in popularity of the military bands for display and ceremonial occasions. The side drum in the 18th century was a much smaller, more manageable instrument than that of the 16th century and of a higher pitch. As an orchestral instrument it was used to supply special military effects. The modern orchestral side drum has a shallower shell and is screw-tensioned.

The Tenor Drum is similar in size and shape to the 16th-century side drum but has no snares. The military tenor drum is rope-tensioned while the orchestral tenor drum is screw-tensioned. The tenor drum is an important instrument in military fife, bugle and drum bands but is infrequently used in the orchestra.

The Bass Drum is the largest orchestral and military drum. It has a shallow shell and the military instrument has two heads while the orchestral instrument often has only one. The diameter of the head is much greater than the depth of the shell. It has no snares and is usually played with a felt-headed stick. The military bass drum is rope-tensioned while the orchestral one is screw-tensioned. The bass drum has a long history in the east but was uncommon in Europe before the 18th century. when it was used in *Musica alla Turca.* The 18th-century instrument (known in England as the "long drum") had. like its Turkish prototype, a deeper shell and heads of a smaller diameter than the modern bass drum. It was played in the Turkish manner; *i.e.,* it was struck with a padded stick in the right hand and a switch of birch twigs in the left; the drummer often was a Negro in exotic dress. The leopardskin of the British army drummers today is a curious survival of these Negro drummers. The bass drum was first introduced to the orchestra via the opera toward the end of the 18th century in order to supply military or Turkish effects.

Sachs, *The History of Musical Instruments* (1940); F. W. Galpin, *Old English Instruments of Music,* 3rd ed. (1932).

DRUM, in zoology, the name given to certain perchlike, carnivorous fishes belonging to the family Sciaenidae, so called because they make a peculiar grunting noise by rapid contraction and expansion of muscles round the air bladder. The sea drum (*Pogonias cromis*), found along the Atlantic coasts of North and South America, attains a length of four feet. The body, which is oblong. with an elevated back. has large scales except on the breast. The throat is paved with stony teeth adapted for crushing shellfish.. In colour the sea drum is brownish-gray or brownish-red, the young being marked with broad, vertical bands of a darker shade. It is not valued for food and, as it destroys great quantities of oysters, is much disliked by oystermen.

The very similar fresh-water drum (*Aplodinotus grunniens*), called also sheephead and thunder pumper, is a grayish, silvery fish sometimes attaining three to four feet in length and 40–60 lb. in weight. It occurs from Georgia and Texas to the Great Lakes but is especially abundant in the streams and lakes of the Mississippi valley. Its scales are thin and deep, with the larger ones on the breast. The fresh-water drum is a popular food fish (best when it weighs less than three pounds) in the south but is little used in the north. It inhabits muddy waters, feeding on mussels. snails and crayfish. which it crushes in the same manner as its sea counterpart. Of all fishes the fresh-water drum appears to be the most heavily infected with larval mussels (glochidia) which later become planted on the river hed and, after a period of growth, become food for other drum. *See* also *FISH.*

FRESH-WATER DRUM (APLODINOTUS GRUNNIENS)

DRUMMOND, HENRY (1851–1897), Scottish evangelical writer and lecturer, was born in Stirling on Aug. 17, 1851. He was educated at Edinburgh university, and in 1877 became lecturer on science in the Free Church college, Glasgow. He was associated with Dwight L. Moody and I. D. Sankey in their revival mission in England and Ireland in 1874–75. and again with Moody in 1882. Drummond also was known as a geologist and explorer, one of his writings in this field being *Tropical Africa* (1858). His principal work was *Natural Law in the Spiritual World* (1883), the argument of which was that the scientific principle of continuity extended from the physical world to the spiritual. In 1893 he delivered the Lowell lectures at Boston. which were printed in 1894 under the title of *The Ascent of Man.* Drummond died on March 11, 1897.

See the *Life by* Sir G. A. Smith (1898).

DRUMMOND, JAMES (1835–1918), British Unitarian scholar, was born in Dublin on May 14, 1835. and was educated at Trinity college, Dublin. and Manchester New college. London. In 1860 he became pastor of Cross Street chapel, Manchester, but nine years later returned to his old college in London as lecturer in biblical and historical theology. From 1885 to 1906 he held the principalship, moving with the college to Oxford in 1889. Drummond died on June 13, 1918.

As a Unitarian, Drummond advocated doctrinal freedom. He regarded Christ as the highest revelation from God but rejected the Resurrection and the nature miracles. His acceptance of the apostle John as author of the Fourth Gospel is elaborated in his *Inquiry Into the Character and Authorship of the Fourth Gospel* (1903). Among his other chief works are *The Jewish Messiah* (1877), *Philo-Judaeus* (1888), *Via, Veritas, Vita* (Hibbert lectures. 1894) and *Studies* in *Christian Doctrine* (1908).

See the "Memorial Introduction" by his daughter, E. Drummond, and G. D. Hicks, prefixed to his *Pauline Meditations* (1919).

DRUMMOND, WILLIAM, called "OF HAWTHORNDEN" (1585–1649), Scottish poet, translator and man of letters. was the first notable poet in Scotland to write deliberately in English, with almost no admixture of Scots forms. Born on Dec. 13, 1585, at Hawthornden, near Edinburgh, the son of John Drummond. first laird of Hawthornden, he studied at Edinburgh university and took his M.A. degree in 1605. After a few years in France (1606–08), ostensibly in the study of law at Bourges and Paris, he returned to Scotland. and on the death of his father in 1610 settled down on his Hawthornden estate. leaving law for literature, and devoting himself to the life of a cultured and rather detached man of means. A certain natural retiringness in Drummond's character was perhaps confirmed and deepened by the emotional shock of his fiancée's death in 1615 shortly before they were to have been married; certainly his love and grief for Mary Cunningham are deeply interwoven in the poems he wrote at this time. But he had many friends, including Michael Drayton, Sir William Alexander and Ben Jonson; and he found happiness in his marriage to Elizabeth Logan in 1632. He died at Hawthornden on Dec. 4, 1649.

Jonson visited Drummond at Hawthornden at the end of 1618, and the record of their conversations throws light on both personalities. Jonson's mild objection that Drummond's poems, though good. "smelled too much of the Schooles, and were not after the fancie of the tyme" is both a shrewd thrust at the conservative and imitative character of his writing and a tribute to his unusually wide reading in European literature. Drummond enjoyed, adapted and translated poems from French, Italian and Spanish, in addition to making curious mosaic raids into such English poets as Sir Philip Sidney. The chief foreign influences on his verse come from the Renaissance love poetry .of Ronsard, Petrarch. Tasso. Giambattista Marino and Garcilaso de la Vega. Some of his best-known poems are in fact translations, or near translations. This might suggest a mind of little originality or

strength, and it is true that Drummond's poetic effectiveness is limited by the narrow range of literary influence which stimulated him; yet he transforms his borrowings, and he has his own genuine quality, a strange blended glow of warmth and melancholy withdrawal which is of some poignancy.

Apart from his *Poems* (1614, 1616) and *Flowres of Sion* (1623), Drummond wrote *Forth Feasting* (1617), a poem celebrating James I's visit to Scotland in that year, and he was apparently, although surprisingly, the author of *Polemo-Middinia,* a hilarious macaronic piece intermingling Scots and Latin (published 1684). His prose writings include a group of Royalist political pamphlets; a *History of Scotland, from the year 1423 until the year 1542* (1655); and *A Cypresse Grove* (1623; earlier version, *A Midnight's Trance,* 1619), a meditation on death and mutability which combines a rich, cadenced prose with a too commonplace statement of the great inevitables.

(E. G. M.)

DRUMMOND, WILLIAM HENRY (1854–1907), Canadian poet, whose works give a sympathetic but sentimentalized picture of the French-Canadian peasant, was born at Mohill in County Leitrim, Ire., on April 13, 1854. He was the son of an officer in the Royal Irish constabulary who emigrated with his family to Canada about 1864. His father died soon after, and Drummond left school at the age of 15 to help support his family. He worked as a telegraph operator at Bord-à-Plouffe on the Rivière des Prairies near Montreal and afterward attended McGill university, Montreal, and Bishop's college, Lennoxville, Que., where he took his degree in medicine in 1884. After four years in country practice, he moved to Montreal, where he became prominent in the social and athletic life of the city, being much in demand as an after-dinner speaker. He gave public readings with great success of his humorous dialect poems dealing with characters and incidents drawn from the life of the French-Canadian *habitant.* These were collected and published as *The Habitant,* which appeared in 1897. It was followed by *Phil-o-rum's Canoe and Madeleine Vercheres* (1898); *Johnnie Courteau* (1901); *The Voyageur* (1905); and *The Great Fight* (1908). These were collected in 1912, with an introduction by the French-Canadian poet Louis Fréchette and an appreciation by the Scottish novelist Neil Munro. Drummond's verses mingle humour and pathos and are written in a synthetic patois and from the point of view of a British imperialist. After 1905 Drummond made his home in northern Ontario to look after the operation of the Drummond mine, near Cobalt, which he owned in conjunction with his brothers. He died in Cobalt, Ont., on April 6, 1907.

See J. F. Macdonald, *William Henry Drummond* (1923), which contains a bibliography. (A. J. M. S.)

DRUMMONDVILLE. A city in the southeastern part of Quebec, Can., on the St. Francis river, about 60 mi. E. of Montreal; the seat of Drummond county. Its main characteristic is intense industrialization which began during the 1920s when a hydroelectric plant was built on the river. Products are varied, ranging from synthetic textiles to paper, pencils and rubber goods. The main railroad lines and direct roads to Montreal, the Maritime provinces and the United States plus a municipal airport provide distribution of the manufactured products all over Canada and the U.S. Founded in 1815 by Maj. Gen. Frederick George Heriot and incorporated as a village in 1874, as a town in 1888 and as a city in 1936, Drummondville has a population of 27,909 (1961), mostly of French origin and Roman Catholic. The city has many French and English schools where courses leading to university degrees can be followed. (GA. M.)

DRUNKENNESS: *see* ALCOHOLISM; LIQUOR LAWS AND LIQUOR CONTROL.

DRUSUS, MARCUS LIVIUS, the name of two Roman statesmen, father and son. The elder Drusus (d. 109 B.C.) was a colleague of Gaius Gracchus (*q.v.*) as tribune in 122 B.C. The senatorial party, in an attempt to thwart Gracchus' program of reform, put up Drusus to try to outbid him and thus win over popular support. Gracchus had proposed the establishment of colonies, but some at least of the colonists were to be drawn from the middle classes; Drusus now proposed the foundation of 12 colonies in Italy and Sicily, each to comprise 3,000 men with no property qualification. He also proposed that all land that had been distributed since Tiberius Gracchus' bill should be rent-free. Further, he proposed immunity from corporal punishment (even on military service) for the Latins; this was a skilful measure since many Latins wanted protection from Roman magistrates rather than all the other privileges that Roman citizenship would confer. A commission was set up to carry out these *leges Livianae,* but Drusus was not a member (inclusion of the proposer of the law was probably illegal). The laws were certainly not implemented in full, and possibly not at all. This would suggest that Drusus' aim had been primarily to undermine Gracchus' position rather than to carry out genuine economic reform. He was consul in 112 and became governor of Macedonia, where he campaigned successfully against the Scordisci; on his return he celebrated a triumph in 110, and was censor in 109, but died in office.

His son, also named Marcus Livius Drusus, (d. 91 B.C.), tribune in 91 B.C., was a man of great integrity who recognized the need for reform. He sponsored a more generous senatorial policy, and tried to build up sufficient support to achieve his ultimate aim of enfranchising the Italian allies. He supported colonial and agrarian bills, and proposed a judiciary law which aimed at reconciling the senate and equites; its provisions are uncertain, but it probably envisaged that the law-courts, then controlled by the equites, should be empaneled jointly from senators and equites, and that all jurors should be liable to prosecution for corruption. This compromise pleased neither group, and opposition increased when Drusus was known to favour a franchise bill and was alleged to be plotting with the allies. The senate declared his legislation invalid on a technical point, disturbances increased and Drusus was murdered; the assassin was never discovered. If his methods were not prudent, and if his aristocratic manner suggested undue personal ambition, at least his aims were statesmanlike and he had the courage to seek to achieve them. (H. H. SD.)

DRUSUS, NERO CLAUDIUS (38–9 B.C.), younger brother to Tiberius (later emperor), was born in 38 B.C. shortly after his mother, Livia Drusilla, had been divorced from Tiberius Claudius Nero and married to Augustus. Like his brother he was allowed to seek office five years before the legal age, becoming praetor in 11 and consul in 9 B.C. With Tiberius (*q.v.*) he conducted a creditable campaign against the Alpine tribes, the Raeti and Vindelici, in 15, and in 13 he was made governor of the Three Gauls, where he carried out an important census and next year erected the altar of Augustus at Lugdunum (Lyons). In 12–9 B.C. he led expeditions into Germany, based first on Vetera (where the Lippe river joins the Rhine) and then on Moguntiacum (Mainz). The Frisii, Chauci, Cherusci and Chatti were all subdued and a canal, the Fossa Drusiana, was dug from the Rhine to the North sea. In 9 Drusus reached the Elbe river, but he was thrown from his horse and died 30 days later. Tiberius followed the body on foot to Rome, where Drusus was given a public funeral and buried in the imperial mausoleum. A cenotaph was erected in his honour at Moguntiacum, and he was posthumously given the cognomen of Germanicus.

It was believed in antiquity that Drusus' German operations, for which he had been awarded triumphal honours and minor triumph in 10 B.C., were the successful first steps toward creating a Roman province between Rhine and Elbe. There is no adequate reason to doubt this view, though archaeology has not revealed the nature of the Roman occupation. Suetonius (2nd century A.D.) says that Augustus (who was naturally suspected of being Drusus' real father) declared that he would make him his heir along with his own grandsons; but in Drusus' lifetime Augustus chose his

brother Tiberius as his son-in-law; and it is probably a later anti-Tiberian tradition which allows preference to the younger stepson Still less is it possible to substantiate the story that Drusus wanted to restore the "republic" if he came to power.

Drusus married (c. 16 B.C.) the younger Antonia, daughter of Mark Antony and Octavia. Their surviving issue were Germanicus. Livilla and Claudius, later emperor.

See, for ancient sources, E. Groag and *A.* Stein, *Prosopographia Imperii Romani,* 2nd ed., part ii, pp. 194 ff. (1936). (*G* **E.** F C)

DRUSUS CAESAR (c. *13* B.C.–A.D. 23), only son of Tiberius (later emperor) and Vipsania Agrippina. Through his father's adoption by Augustus he entered the Julian house in A.D. 4; but Tiberius had simultaneously to adopt Germanicus and Drusus took second place to his elder cousin. Yet despite faction by their adherents the two were on excellent terms, and Drusus married Germanicus' sister Livilla. He suppressed a dangerous mutiny in Pannonia in 14. and became consul next year: then as governor of all Illyricum in 17–20 he engineered the fall of the formidable king Maroboduus of the Marcomanni. After Germanicus' death Drusus, though reputedly violent and dissolute, showed ability in public business and was clearly designated as Tiberius' successor, becoming consul again in 21 and receiving tribunician power next year. But in *23* he died: eight years later it was alleged to have been revealed that he had been poisoned by his wife Livilla and by Sejanus (*q.v.*). Livilla bore him twin sons (in 19 according to Tacitus though it may have been later); one died in 23, and the other. Tiberius Gemellus, was executed by Caligula in 37. A daughter, Livia Julia, was married to Germanicus' son Nero, and subsequently to Rubellius Blandus.

DRUZE (DRUSE; Anglicized forms of Arabic DURŪZ; sing. DARAZI. colloquial DURZI), the name of a small community of hill people, numbering fewer than 200.000 souls. living in southern Lebanon and neighbouring Syria and Israel, who have a special closed religion of their own. They are interesting because of their cohesion and loyalty (at times politically significant) and because they have managed actively to maintain through almost a thousand years of turbulent history their close-knit identity and distinctive faith. The Druze permit no conversion, either away from or to their religion. and no intermarriage. They practise *taqiyah,* "concealment" or dissimulation, a principle that permits or even enjoins them to profess publicly the creed and to conform externally to the mores of any group among whom they may find themselves, if interest so dictates. In these circumstances the survival of their religion and community across almost a millennium is the more remarkable in that their religious system is kept secret not only from the outside world but in part even from their own numbers; only an elite of initiates, known as *'uqqal* ("knowers") participate fully in their religious services and have access to their scriptures.

It is not known to what extent this people was self-conscious and distinct before adopting their present religion. This was an amalgam promulgated in Cairo in A.D. 1017, by a band of whom the chief was Hamzah ibn 'Ali ibn Ahmad and a subordinate called Darazi, from whom this people take their name. Into the system went elements of messianism, incarnationism, gnosticism, Neoplatonism, transmigration and of other currents then flowing in the near east; they were brought into a pattern under a doctrine of the soteriological divinity of the *khalifah* (caliph) of the then ruling Fatimid dynasty of Egypt, al-Hakim bi-Amri-llah. It is apparently believed that al-Hakim did not die but vanished and will one day return in triumph to inaugurate a golden age. There is some suggestion that a number of people in widely scattered areas accepted this system, but only the Druze have survived. It is known certainly that a great many groups in the near east at that time, most of whom came under the various headings of the heretical Shi'ah Muslim sects and movements, accepted similar notions and joined similar causes (see SHI'ISM). There are no elements in the Druze system, as far as this is discernible, for which more or less exact parallels are not well known from contemporary Shi'ah. Batini, Christian and other systems, except perhaps a calf figure, of which the connections are somewhat more remote and the role is still obscure (some Druze vehemently deny its existence) What is unique is the particular Druze constellation and the fact that they have survived into the 20th century

The Druze people have figured prominently at various periods in the local history: in the Arab stand against the crusades; in the century following the Ottoman conquest (1516 ff.), prospering as powerful vassals (until their leader and early westernizer Fakhr al-Din Ma'n was driven out, to take asylum at the courts of Tuscany and Naples); in the 19th century, with imperialist involvements. under the prominent Shihab family, which has also Sunni Muslim and Christian branches; in the 20th century, in many of the vicissitudes of Arab and Lebanese development.

BIBLIOGRAPHY.—Most general histories, and many travel books, dealing with Lebanon-Syria include something on the Druze, as do most works treating Muslim sects. *See* also Philip *K.* Hitti, *The Origins of the Druze People and Religion, With Extracts From Their Sacred Writings* (1928); N. Bouron, *Les Druzes,* 2nd ed. (1930); F. Massey, *Druze History* (1952), a translation of Bouron with extensive commentary by the translator, who is a member of the community.

(W. C. SM.)

DRYAD (HAMADRYAD), in Greek mythology, one of the nymphs of trees and woods. It is sometimes said by late authors that a dryad is a nymph who lives among trees (Gr. drys, tree, especially oak), a hamadryad the spirit of a tree, living and dying with it. See NYMPHS.

DRYAS, a genus in the rose family, containing five species commonly called mountain avens, dryads and feathers. They are hardy evergreen subshrubs 3 to 12 in. high, with horizontal branches; leaves are small, entire or toothed, smooth or hairy; solitary flowers are on erect scapes; the petals are white or yellow; and the fruits are feathery tailed in heads. Distribution is circumpolar in rocky situations in the northern hemisphere, south to the Gaspé peninsula and Colorado in the new world, to the Pyrenees and Urals in Eurasia.

Propagation is by cuttings, division or seed. D. *octopetala* is suited to rock gardens but should not be moved after planting. Porous calcareous soil, frequent watering in summer and some shade in winter give best results. Plants live many years and form dense mats.

See also *ROSACEAE.* (I. L. W.; X.)

DRY CLEANING. Dry cleaning is the process of cleaning fabrics with liquids other than water. Although methods vary according to the composition of the fabric or article, the basic process removes dirt, stains and spots by immersion and agitation in organic solvents and detergents, in contrast with the laundering of fabrics in soap and water.

For many years the dry-cleaning process was based on the use of highly flammable solvents such as gasoline and naphtha. Initial cost was low, but fire hazards led to a search for other dry-cleaning fluids. In 1925 the Stoddard solvent, a petroleum distillate separated from impurities and odour compounds, was developed, and another petroleum solvent known as "140° F.," with a higher initial boiling point and higher flash point, appeared. Both solvents gained wide acceptance despite the successful introduction of such manufactured chlorinated hydrocarbon solvents as carbon tetrachloride, trichloroethylene and perchloroethylene. The majority of dry-cleaning plants in the Cnited States continued to use petroleum solvents, with the remainder favouring perchloroethylene. Trichloroethylene is widely used in countries other than the United States. The high toxicity of carbon tetrachloride led to its almost complete disuse in commercial dry cleaning.

The conventional dry-cleaning operation begins with the inspection of the garments in the plant for spots, stains, tears, etc. The garments are then tagged for identification by the marker, who also removes buttons, belts, shoulder pads, ornaments and other fragile accessories, and next are sorted into classifications by fabric type and colour. Each garment is accompanied through the operation by special handling instructions for the spotter, dry cleaner, seamstress, finisher, etc. In the fundamental process, a load of soiled clothing is placed in the dry-cleaning washer containing the petroleum or synthetic solvent. The solvent dissolves much oil

and greasy soil. Insoluble soil, consisting largely of lint, earth, dust, ashes and carbon particles, is loosened by agitation. The loosened dirt, as a result of the continuous flow of solvent and detergent that is maintained through the fabric, is flushed out, washed free of the fabric's surface and passed into suspension in the solvent, which is constantly force-filtered.

The dry-cleaning process is followed by extraction, which removes excess solvent from the garments by centrifugal force. Drying takes place in a tumbler, where the last traces of solvents are removed.

One of the most skilled workmen in a dry-cleaning plant is the spotter, who identifies and removes stains by the use of chemicals, steam or tamping and dry brushing. The spotter identifies fibres and combinations of fibres, selects the correct solvent from among 20 reagents for the specific fabric and stain, and knows when to stop the application before the colour or fabric is damaged.

The finishing process applies only to the pressing of cleaned garments. After the garments are pressed on specialized steam-air machines, they go to seamstresses who replace the buttons, trimmings, etc., that were removed in marking, and do minor tailoring repairs. Certain fragile garments are ironed by hand.

The dry-cleaning plant requires high-pressure steam and many highly specialized machines and appliances, including marking machines, washers, stills, pumps, extractors, dry tumblers, wind whips, drying cabinets, presses, puff irons, wet-cleaning and steam tables, sleevers, glove units, steam irons, bagging and assembling racks, and sewing machines. Utility presses in a variety of shapes are used for the finishing of different types of garments.

(V. KR.)

DRYDEN, JOHN (1631–1700), English poet, dramatist and critic, was born on Aug. 9, 1631, into a Puritan family at Aldwinkle, Northamptonshire. He went to Westminster school as a King's scholar; and entered Trinity college, Cambridge, in 1650. Fortified by a legacy of landed property from his father, he left Cambridge after graduation in 1654. "His head," says a contemporary, "was too roving and active, or what else you'll call it, to confine himself to a College life; and so he . . . went to London into gayer company, and set up for a poet." He seems first to have been employed as secretary to his cousin Sir Gilbert Pickering, who was then in the service of Cromwell. After the death of the protector in 1658 he is said to have worked for the publisher Henry Herringman.

Dryden was, on his own testimony, a boy poet; but his earliest surviving verses, a "conceited" elegy on Lord Hastings, belong to his last year at Westminster. His first substantial poem, "Heroique Stanza's" on the death of Cromwell (1659), shows some of the energy of style, the rhetorical assurance and the facility in panegyric, which mark his mature verse. In 1660, with most of his prudent compatriots, he modified his political sympathies and quickly established himself as the poet of the new court in *Astraea Redux* (1660), *To His Sacred Majesty . . . on His Coronation* (1661) and *To My Lord Chancellor* (1662). He allied himself to the royalist family of the earl of Berkshire, first in a friendship with Sir Robert Howard and then in his marriage to Lady Elizabeth Howard (1663). *Annus Mirabilis . . . 1666. An Historical Poem* (1667) was suggested by Sir Robert, and written at the Howard house in Wiltshire. The theme of this, the most ambitious of Dryden's early poems, is heroic—superficially, the Anglo-Dutch naval war and the Fire of London; essentially, the security of the new reign, the maritime power of England and the promise of commercial wealth and scientific achievement. Virgil, says Dryden, "has been my Master in this Poem"; and his influence goes deeper than imitations in language and style. *Annus Mirabilis* is a modern Georgic. It celebrates the material enrichment of the community by native skill and diligence under the guidance of providence and a great king. In 1668 Dryden succeeded James Howell as historiographer royal and Sir William Davenant as poet laureate. He held these appointments until the revolution of 1688.

At the Restoration Dryden turned for a livelihood to the drama, then the only form of literature which offered much security to the professional writer. *The Wild Gallant,* a first attempt in comedy presented at the Theatre Royal in 1663, was overshadowed by *The Adventures of Five Hours,* Sir Samuel Tuke's adaptation from the Spanish at the rival Duke's theatre. In *The Rival Ladies* (1664) Dryden, who had a keen business sense, followed Tuke with a complicated "Spanish" plot in blank verse and couplets and won Pepys's approval for "a very innocent and most pretty witty play." Turning then to a new, more elaborate form of verse drama, he collaborated with Sir Robert Howard in *The Indian Queen. A Tragedy,* acted in Jan. 1664 "so beautified with rich Scenes as the like had never ben seene here" (Evelyn). Dryden set out his arguments for rhymed plays in the dedication of *The Rival Ladies* (published in the summer of 1664), and made his first independent contribution to the heroic drama in *The Indian Emperour,* a sequel to *The Indian Queen,* in 1665. The success of this play put him at once among the leading dramatists of the day and he worked with resourceful energy in the next decade to confirm his place, both in the heroic *mode*—*Tyrannick Love, or The Royal Martyr* (1669), the two parts of *The Conquest of Granada* (1670–71; presented with "very glorious scenes and perspectives") and *Aureng-Zebe* (1675)—and in comedy.

The matter of Dryden's comedies at this time is mainly French. *Secret Love, or The Maiden Queen* (1667), "mightily commended for the regularity of it, and the strain and wit" (Pepys), is a tragicomedy written strictly to the French rules and based on Mlle de Scudéry's romance *Le Grand Cyrus. Sir Martin Mar-all, or The Feign'd Innocence* (1667) draws on Molière's *L'Étourdi* and Philippe Quinault's *L'Amant indiscret. An Evening's Love, or The Mock-Astrologer* (1668) is based mainly on Thomas Corneille's *Le Feint Astrologue.* "'Tis true," says Dryden in his preface (1671), "that where ever I have lik'd any story in a Romance, Novel, or forreign Play, I have made no difficulty. . . to build it up, and to make it proper for the *English* Stage." These comedies depend on plots of intrigue and on the witty dialogue of pairs of lovers which is Dryden's main contribution to the comedy of manners. In his touches of romance and sentiment, however, and in a preference for emotional tensions over intellectual sparkle, he looks back to the early 17th-century tradition rather than forward to the comedy of William Congreve.

Most of Dryden's early criticism, worked into the prefaces and dedications of his plays, deals with problems he had to face as an experimental dramatist in a new theatre. There are important passages on the poetic imagination and on the modern style in English verse in the dedication of *The Rival Ladies;* the preface to *An Evening's Love* is "a cry for a new artist in comedy; it places the Siege Perilous for Congreve to occupy" (W. P. Ker); but the main theme of the early essays is the heroic play, and especially the dramatic use of rhyme. The defense of rhyme in the dedication of *The Rival Ladies* was answered by Howard in the preface to *Four Plays* (1665); Dryden returned to the topic in *Of Dramatick Poesie, An Essay* (1668); Howard replied in the preface to *The Duke of Lerma* (1668); and the dispute ended in Dryden's essay published with the second edition of *The Indian Emperour* (1668)—"as I was the last who took up Arms, I will be the first to lay them down." *The Conquest of Granada* (1672) contains two essays, one on heroic plays and another on the superiority of modern over Jacobean drama in language, wit and conversation.

Dryden's most ambitious piece of criticism on these topics is the essay *Of Dramatick Poesie,* a defense of English drama against the champions of both the classical and the modern French theatre and an attempt to discover general principles of dramahc criticism. It takes the form of a dialogue with four speakers "under borrowed Names": Crites. Lisideius, Neander (who, in a long examen of Ben Jonson's *Silent Woman,* gives one of the earliest critical analyses in English) and Eugenius. Traditionally, these speakers have been identified as Howard, Sir Charles Sedley, Dryden and Lord Buckhurst; but they are primarily vehicles for critical attitudes which Dryden wishes to set against each other. The *Essay* is built round Lisideius' definition of a play as "a just and lively Image of Human Nature, representing its Passions and Humours, and the Changes of Fortune to which it is subject, for the Delight and Instruction of Mankind." Which drama best illustrates this description? Crites argues for, and Eugenius against, the an-

cients; Lisideius argues for the French, Neander for the Elizabethans and Jacobeans; Crites argues against, Neander for, contemporary drama. By deploying his disputants so as to break down the conventional oppositions of ancient and modern, French and English, Elizabethan and Restoration, Dryden deepens and complicates the discussion. This is the first substantial piece of modern criticism—sensible, judicious, exploratory, combining general principles and analysis—in a gracefully informal style. Dryden's approach, here and in all his best criticism, is characteristically speculative and shows the influence of disengaged scientific inquiry: "My whole Discourse was Sceptical, according to that way of reasoning which was used by Socrates . . . and which is imitated by the modest Inquisitions of the Royal Society. . . . it is a Dialogue sustain'd by persons of several opinions, all of them left doubtful, to be determin'd by the Readers in general" *(Defence of An Essay)*.

Aureng-Zebe was Dryden's last rhymed heroic play. Too much has been made of the effect on his career of *The Rehearsal* (1671, by Buckingham and others), which ridicules him and parodies his plays. He was not uncommonly sensitive, and knew the faults of his heroic writing as well as any of his critics; and the plays were still commercial successes. But he was growing dissatisfied: "I desire to be no longer," he wrote in 1675, "the *Sisyphus* of the Stage; to rowl up a Stone with endless labour . . . which is perpetually falling down again. I never thought my self very fit for an Employment, where many of my Predecessors have excell'd me in all kinds; and some of my Contemporaries . . . have out-done me in Comedy" (dedication of *Aureng-Zebe*). He persisted in comedy for a time, gaining a last triumph for a pair of witty lovers in the romantic tragi-comedy *Marriage A-la-Mode* (1672), but declining into sheer indecency and dullness in *The Assignation* (1672), *Tlze Kind Keeper; or, Mr. Limberham* (1678) which "express'd too much of the Vice which it decry'd" and *The Spanish Fryar* (1680). Thereafter there were no comedies apart from *Amphitryon* (1690), which is good entertainment, but offers lewdness for wit and lacks the energy and grace of the early plays. Dryden's first attempt at political satire was made in the theatre, in the deplorable tragedy *Amboyna* (1673); he wrote—with predictable ill-success—a stage version of *Paradise Lost*, *The State of Innocence* (1676), probably for a court performance; but the main interest in his work in the later 1670s lies in his experiment with a form of tragedy which would combine the structural principles of the French theatre with the Shakespearean tradition in character and style.

In *All for Love: or, The World well Lost* (1677) he reshaped the story of Shakespeare's *Antony and Cleopatra*, elaborating the last phase into a five-act tragedy and observing "the Unities of Time, Place, and Action . . . more exactly . . . than perhaps the English theatre requires." This restriction in scope and setting confines him to a much narrower field of emotion—he is concerned only with the culmination of a tragic love. He thus gives us nothing of Shakespeare's earlier, nobler Antony, and his Cleopatra is less vital and magnificent. Shakespeare's tragedy is acted out under "the wide arch of the ranged empire"; the world of Dryden's play is the closer world of love. He has little of Shakespeare's poetry, an imagery integral to the theme and the characters, full of passion and light; his imagery is more simply decorative and the tone of the play more sombre. Yet it is a great play in its kind and the richest illustration of French influence on English tragedy. Dryden's experiment with *Troilus and Cressida* (1679) was less successful. There is the same thinning of Shakespeare's poetic wine but no compensating energy of spirit. The story and characters are recast in the mold of the Restoration heroic convention despite the whole tradition of false Criseyde; and there is "something too nice and fastidious in the critical rule which exacts that the hero and heroine of the drama shall be models of virtuous perfection" (Sir Walter Scott).

All for Love was the last play Dryden wrote for the King's company. *Tlze Kind Keeper; or, Mr. Limberham* was first acted by the rival Duke's company in March 1678 and *Oedipus* (written with Nathaniel Lee) after the following August. The King's company protested in a petition, against conduct which was contrary to Dryden's "promise. and all gratitude to the great prejudice, and almost undoing of the Company"; but since the fire at the Theatre Royal in 1672 they had been in a bad may, and Dryden cannot have got his due share of profit for the plays he wrote between 1672 and 1678. The defection of Drpden and Lee accelerated the decline of the King's company, and they merged with their rivals in Nov. 1682.

Dryden's later plays have little intrinsic interest. He felt more and more that he had no natural bent for drama; a younger generation of comic dramatists was out-pacing him; and he was finding fuller satisfaction in poetry. *Tlze Duke of Guise* (1682) is a political satire on the Whigs, built up in collaboration with Lee from an early draft by Dryden. *Albion and Albanius* (1685) is a slight and unsuccessful opera written to celebrate the political triumph of Charles II and the duke of York. A final series of plays was written under the pressure of poverty, when Dryden's fortune turned with the abdication of James II: *Don Sebastian*, a tragedy (1689), *Amplzitryon*, a comedy (1690), *King Arthur . . . A Dramatick Opera* with music by Purcell (1691; "the last Piece of Service . . . for my Gracious Master, *King Clzarles* the Second"), *Cleomenes*, a tragedy (1692), and *Love Triumphant*, a tragi-comedy (1694).

While *All for Love* was bringing Dryden's work for the theatre to its climax, he began to discover his powers in verse satire. *Mac Flecknoe*, a mock-heroic lampoon on the dramatist Thomas Shadwell, was written in 1678 and circulated in manuscript until its first (unauthorized) printing in 1682. Its immediate occasion is unknown. The basis of the satire, which represents Shadwell as a literary dunce, is the disagreement of the two men over the quality of Ben Jonson's wit. Dryden thought Jonson deficient in "the *Urbana, venusta, salsa, faceta* . . . the Ornaments of Wit," and defended his opinion against Shadwell, who regarded Jonson with uncritical reverence. But in the essays which make up his part in the controversy (1668–73) Dryden shows no personal animosity toward Shadwell; and it seems likely that *Mac Flecknoe*, though its substance is literary, was provoked by some later personal quarrel. It is a concentrated, hilariously comic piece—the first English mock-heroic poem, and the immediate ancestor of Pope's *Dunciad*.

Dryden soon had a chance to display his heroic-satiric art on the grand scale. In March 1681 Charles II dissolved the Oxford parliament and threw the Whig opposition into disorder. Their leader, Shaftesbury, was committed to the Tower on a charge of high treason and tried on Nov. 24. During the months of Charles's triumph Dryden was at work on *Absalom and Achitophel*, a long poem in the heroic mode which summarizes the growth of the opposition party, the fomented scare of the Popish plot, the attempt to exclude the Catholic duke of York from the succession and the king's counterattack. It appeared in mid-November, probably with the design of prejudicing Shaftesbury's trial, and ran to at least three London editions in four months. *Absalom and Achitophel* is not primarily a satire, but a political narrative written to vindicate the king and his court party. It consists of a witty historical introduction leading up to the seduction of Absalom (Monmouth, the "Protestant Duke") by Achitophel (Shaftesbury); a brilliant series of satiric portraits of Whig personalities; a medial discussion of the fundamental political issues behind the crisis of 1676–81; a series of panegyrical portraits of the king's friends; and a statement of Charles's own case. The application of the biblical story of Absalom is not a novelty; but Dryden's use of the Old Testament is wonderfully consistent, complex and witty, and the whole story is beautifully turned to serve his political design. The heroic style, with echoes of the grand seduction in *Paradise Lost* and the exalted debates of the heroic play, is an instrument of both panegyric and satire; and the portraits of the Whigs illustrate the notion of satire as a kind of heroic poetry, gaining its effects by irony and "fine raillery," which Dryden later set out in his essay on Juvenal and Persius. In *Absalom and Achitophel* he lifts the tradition of English satire, as represented in the work of John Oldham, Andrew Marvell and Samuel Butler, to a new level of art and sets the tone of the dominant mode in Augustan verse. A *Second Part* which followed in 1682 is

mainly the work of Nahum Tate, with a number of satiric portraits by Dryden. Dryden's later attack on Shaftesbury in *The Medall* (1682), following the failure of the indictment for treason, has great energy and intensity; but it is on a smaller scale, with neither the variety nor the heroic ironies of *Absalom.*

Dryden turned now to religious controversy—in his day a natural concomitant of politics. *Religio Laici or A Laymans Faith* (1682) is a discussion of authority in religion, written in a plain "Legislative" style: "A Man is to be cheated into Passion, but to be reason'd into Truth." Dryden follows the sceptical Pyrrhonist tradition in rejecting reason as the ultimate guide to truth; but he criticizes both the Papist claim to infallibility and the Protestant reliance on personal interpretations of Scripture with the aid of the inner light. His position is a compromise, accepting the doctrines established by the double tradition of the Bible and the Fathers, and curbing "private Reason" in the interests of "Common Quiet."

His conversion to the Roman Church a few years later has been regarded as an act of expediency following the accession of James II; but there is a logical advance from the troubled antirationalism of *Religio Laici* to the defense of fideism and Catholic authority in *The Hind and the Panther* (1687), Dryden's most ambitious original poem. It is a finely sustained piece of apologetics, in the rather clumsy framework of a beast fable: the animal disputants represent the Roman and Anglican churches. The style ranges from "the Majestick Turn of Heroick Poesie" to the simplicity of "Domestick Conversation," carrying theological argument, historical narrative, vigorous satire on the Reformation and the Protestant sects, and a long satiric allegory (also in beast-fable form) of current ecclesiastical politics. *The Hind* is the culmination of Dryden's religious development: he did not "except in outward profession, abandon the Church of England for that of Rome, but was converted to the Catholic faith from a state of infidelity, or rather of Pyrrhonism" (Scott).

In the 1680s Dryden wrote a substantial amount of political and historical prose—including *His Majesties Declaration Defended* (1681), a life of Plutarch for a translation of the *Lives* (1683), a translation of Louis Maimbourg's *History of the League* (1684) and another of Dominique Bouhours' *Life of St. Francis Xavier* (1688). Some of his best panegyrical verse dates also from this decade. From the "Stanza's:' on Cromwell to his epistle to John Driden of Chesterton (1700) he reflected the ideals of virtue and heroism so inconstantly realized by the great men of his time, in a long series of verse eulogies. The greatest artist in compliment in English literature, he had "all forms of excellence, intellectual and moral, combined in his mind with endless variation . . . He considers the great as entitled to encomiastick homage, and brings praise rather as a tribute than a gift, more delighted by the fertility of his invention than mortified by the prostitution of his judgment" (Dr. Johnson).

But in 1680, in a collaborative translation of Ovid's *Epistles,* Dryden began the work which was to absorb the energies of his last years. To the first three volumes of Jacob Tonson's *Miscellany—Miscellany Poems* (1684), *Sylvae (1*685) and *Examen Poeticum* (1693)—he contributed some of his best criticism, on the Latin poets and the art of translation, and a mass of translation from Ovid, Theocritus, Lucretius, Homer, Horace and Virgil. In 1693 he edited a translation of the *Satires* of Juvenal and Persius, with five of Juvenal's poems and all of Persius by himself, and a long essay on the history and art of satire. In 1697 he completed, singlehanded, a translation of *The Works of Virgil,* with a dedication of the *Aeneis* containing a fine critique of Virgil; and in 1700, just before his death, he published a miscellany of *Fables Ancient and Modern . . . from Homer, Ovid, Boccace, and Chaucer.* In variety and quality this is one of the best books of narrative verse in the language, and the preface is the most delightful of all his critical, essays.

The quality of Dryden's translation is variable. His method was "paraphrase"; he attempted to hold true to the sense and spirit of his authors, and at the same time to make them speak the kind of English they would have used had they "been born in *England,* and in this present Age." The success of this difficult policy must depend mainly on an affinity of spirit and style between original and translator, and Dryden works best with Ovid, Lucretius and the Roman satirists. Within the limits of the method he adopts, and the scholarship of his day (over which he is more conscientious and critical than is often supposed), he manages the rhetorical wit of Ovid, the assertive exposition of Lucretius and the *saeva indignatio* and energy of Juvenal with conspicuous success. He fails with Theocritus, and catches hardly enough of Horace's delicacy and grace. His *Virgil* is a heroic achievement, and one of the monuments of English Augustan verse; but he misses the essence of Virgil's art, its imaginative richness, its feeling and its complexity of style. Chaucer and Boccaccio were not classical authors, and demanded less fidelity from a translator. Dryden rewrites three of Chaucer's *Tales* in a modern romantic style, and boldly recasts three prose stories from the *Decameron* with all the baroque ornament and heroic passion—and a satiric salt—at his command. In his translation as in his original verse, he set the dominant tone of English poetry—its strength, harmony, clarity and pervasive wit—for nearly a century. He died in London on May 1, 1700, and is buried in Westminster abbey.

DRYDEN, JOHN FAIRFIELD (1839–1911), U.S. senator and businessman, was the founder of the Prudential Insurance Company of America, the first company to issue industrial life insurance in the United States. Born at Temple Mills, Me., on Aug. 7, 1839, Dryden made a study, while attending Yale university, of industrial or "workingman's" insurance (small policies usually based on weekly premiums) as developed by the Prudential Assurance company of London, Eng., and by private benevolent societies. In 1873 Dryden and a few backers founded the Widows and Orphans Friendly society in Newark, N.J. It was succeeded in 1875 by the Prudential Friendly society, which took its present name in 1877.

Dryden was secretary of the company (1875–81), and president from 1881 until his death on Nov. 24, 1911. He was U.S. senator from New Jersey, 1902–07. His son Forrest succeeded him as Prudential's president in 1912.

See Earl Chapin May and Will Oursler, *The Prudential* (1950). (W. O.)

DRY DOCK, a structure designed to permit maintenance work on ships too heavy to be lifted from the water. There are two principal types: the fixed dry dock, called a graving dock, is a basin dug into the side of a channel and fitted with watertight gates and pumps to remove the water inside; the floating dry dock is a barge-like structure that can be partially submerged so that a vessel can enter it. The dock is then raised in the water and pumped dry to permit work on the vessel. *See* DOCK.

DRY FARMING. Dry farming is farming without irrigation in areas where the moisture supply is the chief limitation to crop production. Such farming practices have existed approximately as long as man has been an agriculturist, particularly as subsistence farming on desert margins and in areas having dry summers, such as the Mediterranean basin. Dry farming in the

U.S., under that name and as a type of commercial agriculture. began perhaps in Utah in 1863. It became a general practice in many parts of the subhumid and semiarid grasslands of continental interiors of North America, Australia, Asia and. to a lesser degree, South America and Africa. Such areas generally have less than 20 in. of precipitation yearly; but temperature, evaporation and soil characteristics. as well as rainfall season and reliability, are very important. Wind erosion as well as occasional drought and dust-bowl characteristics afflict most of these areas. Yet they have contributed greatly to both the abundance and the variability in commercial food supplies of the 20th century, particularly of wheat, harley and grain sorghums.

Efficient dry farming consists of making the best use of a limited water supply by storing in the soil as much of the rainfall as is possible and by growing suitable crop plants by methods that make the best use of this moisture. Storing water is accomplished by maintaining a surface condition that permits water to enter the soil readily and by preventing its loss by killing weeds and other unwanted plants. Storing moisture in advance of seeding is accomplished in different ways. In the moister portions of the dry-land winter wheat regions of the U.S. and the U.S.S.R., tilling the soil shortly after harvest and keeping the land free from weeds until seeding time in the fall has resulted in better yields through increased moisture storage.

In latitudes where harvest is late and crops are spring seeded, the snow caught by stubble may be more important than fall weed control in storing moisture. In the drier areas, alternate fallow, by which land is cultivated to keep the land free of live vegetation one year and a crop grown the next, may be needed to ensure a supply of water for the crop *(see* FALLOW). This practice is particularly adapted to large-scale operations where it stabilizes yields and reduces costs. In more favourable areas an intertilled crop such as corn (maize) or potatoes may leave a residue of moisture sufficient to help materially in insuring a yield of a small grain crop following. Moisture control while a crop is groning consists largely of prevention of runoff and destruction of weeds. The ideal surface, to absorb water and prevent wind and water erosion. is one that is free from live weeds but has enough clods or dead vegetable matter to hinder runoff and prevent erosion. Cultivation that controls weeds is generally sufficient to maintain such a surface condition. but loosening a packed surface is sometimes necessary. The depth of plowing has little to do with moisture storage, since the quantity of water that enters a soil is governed chiefly by the condition of the immediate surface. In some dryland areas of the world plowing to a depth of eight or nine inches has been more productive than shallower plowing, but usually this is associated with nitrification rather than with moisture storage. Loosening the soil to extreme depths as by subsoiling has not been profitable.

Crops adapted to dry farming may be either drought resistant or drought evasive. The drought-resistant crops, of which sorghums may be selected as an example, are able to reduce transpiration and may nearly cease growth during periods of moisture shortage and then resume development when conditions again become favourable. Drought-evasive crops make their greatest growth at times of the year when heat and drought conditions are not severe. They may either be crops that are planted in fall or early spring and mature in time to miss much of the hot part of summer or those that are planted late and make much of their growth after the period of greatest summer heat has passed. Crops adapted to dry farming are usually smaller in stature and quicker in maturing than those grown under more humid conditions. Planting rates are also generally lower and the individual plants are given more space. Primitive tribes in many lands have made use of wide plant spacings to help avoid failure of corn and sorghums.

Dry farming of the commercial sort, whether of the family farm or large size. illustrates large-scale, highly capitalized and mechanized agriculture. Special implements have been developed, not only adapted to extensive farming but designed to keep the surface weed-free, water absorbent and yet resistant to wind erosion. Net agricultural incomes per hour of labour in good years are among the highest, yet fixed costs are high; the risk involved may be partly offset by such income supplements as insurance and credit improvements, livestock production and irrigation agriculture where possible. *See* also *AGRICULTURE (ARTICLES ON)*.

DRYGALSKI, ERICH DAGOBERT VON (1865–1949), German geographer and polar explorer who, although his chief interests lay in Antarctic geography, glaciology and glacial geology, in the later years of his life turned his attention to political geography and the methods of regional geography. He was born on Feb. 9, 1865, at Konigsberg. then in East Prussia, and died at Munich on Jan. 10, 1949. In 1891 Drygalski was chosen by the Gesellschaft für Erdkunde in Berlin to lead an expedition to Qarajaks Isfjord in west Greenland. The resulting publications established his reputation. In 1899 he became professor of geography and geophysics in Berlin. Two years later he was selected to lead the German Antarctic expedition in the "Gauss." 1901–03, sent out by the German government as part of an international program of concerted Antarctic exploration. This expedition reached the continent in about longitude 90° E. in what is now called Kaiser Wilhelm II Land, and wintered about 50 mi. east of Gaussberg. The lack of dramatic new land discoveries evoked imperial displeasure. but the scientific merit of the expedition could be measured more truly by the extraordinarily comprehensive series of scientific reports that were published during the next 30 years. On his return. Drygalski published a general account of the expedition. *Zum Kontinent des eisigen Südens* (1904). In 1906 he became professor of geography in Munich, a post which he retained until he retired in 1934. In 1910 he took part in Count Zeppelin's expedition to Spitsbergen, and studied the influence of glaciers on land features.

After World War I, Drygalski devoted himself to the publication of the "Gauss" expedition reports. *Deutsche Südpolar-Expedition,* 20 vol. (1905–31). He summarized his studies of the regional geography of the Antarctic in Fritz Klute's *Handbuch der geographischen Wissenschaft* (1930). His last important work was, in joint authorship with Fritz Machatschek, *Handbuch der Gletscherkunde* (1942), a comprehensive text book of glaciology. (B. B. Rs.)

DRY ICE, the popular name for solid carbon dioxide, a dense, snowlike substance having a temperature of −78.5° C. or lower. Carbon dioxide gas is changed to a liquid when subjected to a pressure more than five times that of the ordinary atmosphere and at −57° C. When this liquid is allowed to expand rapidly from the high pressure to atmospheric pressure, carbon dioxide snow results. This snow is compressed into cakes. Instead of melting, it evaporates to a dry gas that has no corrosive action if moisture free. It makes possible the shipping of perishable products (meats, ice cream) long distances. One pound of dry ice will absorb a little less than twice as much heat as one pound of water ice. A 10-in. cube (1,000 cu.in.) of dry ice weighs about 45 lb. *See* also CARBON, *OXIDES OF: Carbon Dioxide.*

DRYOPITHECUS, the type and European representative of a group of fossil apes, the Dryopithecinae, ranging from early Miocene to late Pliocene (beginning about 21,000,000 years ago and lasting 20,000,000 years) in Europe, north Africa and India, and including at least seven other genera. The Dryopithecinae represent the ancestry of the living anthropoid apes; some students claim that they include the common ancestors of man and the recent apes. *Ser* also MAN, EVOLUTION OF. (G. G. SI.; X.)

DRY POINT. Though generally classed as a variety of etching, and in practice often combined with that process. dry point is. strictly speaking, a kind of engraving.

In etching the needle scratches only through the etching ground and exposes the surface of the plate (usually copper). The plate

is then placed in a bath of acid, and it is the chemical action of the acid that eats out a line of sufficient depth to hold printing ink. In dry point. on the contrary, as in line engraving, the lines are hollowed out by the tool itself in direct contact with the metal as directed by the artist's hand, without the intervention of any chemical action. Zinc can be used instead of copper, but work on this metal wears out quickly under the pressure of the printing press. Celluloid plates have been used, but no heat can be applied during the inking and printing of the plates. (See ENGRAVING, LINE; ETCHING.)

HISTORY

Earliest Work. — The first appearance of dry point was before that of etching. There can be no doubt that the scarce prints of the "Master of the Hausbuch." a painter-engraver. possibly of Dutch origin, who worked in western Germany (probably on the middle Rhine) about 1480, were produced with the dry point or possibly with the burin used in the same way, so as to scratch the surface of the copper (or some softer metal such as lead or tin) and throw up a burr, which was not scraped away. This engraver is also called the "Master of the Amsterdam Cabinet" from the fact that the largest collection of his prints, numbering 82 examples of the 91 subjects (plates) which constitute his known work, is owned by the Amsterdam Print room. He was a very original artist and a keen observer of nature, with a technique quite unlike that of any other 15th-century engraver.

Dürer.—One of the next engravers of importance whom we find employing dry point is Albrecht Durer, who resorted to this process only in or about the year 1512, and probably abandoned the experiment when he discovered how few good proofs a plate engraved in this manner could yield. There are only three dry points by Durer, "The Man of Sorrows" (1512), "St. Jerome Seated Near a Pollard Willow" (1512) and its companion print, the undated "Holy Family" of similar dimensions. Of the two latter dry points very few good impressions are extant, for the burr wore off rapidly, and the majority of extant specimens were taken from the worn-out plates. Of Dürer's first work in this technique. "St. Jerome." two proofs only exist of a first state before the monogram (in the British museum. and the Albertina, Vienna). These are of superb quality; the Albertina impression of the second state is also very fine. A fourth dry point, "St. Veronica," dated 1510, which figures in the older catalogues as one of the great rarities in Durer's work, for only two impressions are known, is discredited. for it was proved to be a copy of an unsigned woodcut published at Nuremberg in a *Salus Animae* of 1503. Hans Sebald Beham alone of the followers of Durer used dry point, and that but sparingly. It is hardly found again in the history of German engraving until a much later date.

Italy. — In Italy also the process was used in early times, chiefy by Andrea Schiavone, or Meldolla (1522?–82), an engraver who worked at Venice, and perhaps also by the monogrammist H. E., for early impressions of his prints show signs of burr which in the usual later prints would not be suspected.

Rembrandt.—In the Netherlands dry point was hardly used, if at all, before the 17th century. Its varied uses, as described below, for the enrichment of the etched plate by the addition of burr to the etched line as well as for the production of pure dry points were first discovered and exploited by the greatest of all painter-etchers, Rembrandt. In his middle period and onward, from about 1639, he used this technique increasingly. in a thoroughly personal manner, for the sake of substituting "colour" and warmth for the drier effect of the pure etchings of his earlier period. From 1640–50 Rembrandt used dry point extensively for retouching his etched plates — "The Death of the Virgin" and "Christ Healing the Sick" (the "Hundred Guilder Print") are examples taken from the beginning and close of this period— while in his last period (1650–61), plates wrought wholly in dry point became more and more frequent. Among the finest of these must be reckoned "The Goldweigher's Field" (1651); "The Vista" (1652); the two large plates, "The Three Crosses" and "Christ Presented to the People," of 1653 and 1655 respectively, and the "Portrait of Arnold Tholi'nx" (1656).

The **18th** Century. — After Rembrandt, little use of the dry point was made by any of the great engravers for a lengthy period. The 17th century was in all countries an age of line engraving and etching, while in the Low Countries, Germany and England, the invention and development of mezzotint were claiming attention. In the 18th century dry point was used here and there by a number of painter-etchers, amateurs in their technique as compared with the professional engravers, who found the medium congenial and probably took hints in their use of it from their study of Rembrandt. A beautiful example of such an 18th-century dry point is the portrait of himself, dated 1739, by Arthur Pond. One of the little subjects illustrating the destruction by fire of the Foire de Saint-Germain in 1762, by Gabriel de St. Aubin, is a dry point which seems in its modernity a precursor of the 19th century. In the period which preceded what is known as "the revival of etching," that is to say, during the first half of the 19th century, several English and Scottish etchers produced dry points of remarkable merit. Among these were D. C. Read of Salisbury (1790–1821), E. T. Daniell of Norwich (1804–42) and especially the two Scottish painter-etchers Andrew Geddes (1783–1834) and Sir David Wilkie (1785–1841). Geddes' "Portrait of the Artist's Mother," his "Peckham Rye" and some other landscapes, and Wilkie's one pure dry point, "The Lost Receipt," are of conspicuous merit if compared with the dry points of any period.

The French etcher Charles Jacque also produced, long before 1850, a number of dry-point landscapes, with figures or horses, of great beauty.

Modern Work. — The etchers of the "revival," both in France and England. soon brought the dry point, as well as etching, into renewed favour. In the hands of Sir Francis Seymour Haden it yielded masterpieces like "Windmill Hill" and "Sunset in Ireland"; in those of Whistler, "Finette." the "Portrait of Axenfeld," "Weary" and many more. Alphonse Legros, soon after 1860, produced "Le Cours de phrénologie," "Les Baigneuses." "Pecheurs d'ecrevisses" and several landscapes. Legros' pupil, William Strang, half a century later, did much fine work in dry point; so did Sir D. Y. Cameron, especially in his work after 1903, and particularly after 1910. Another master of the technique was Theodore Roussel (1847–1926). Of outstanding excellence among French dry points of the late 19th century are those of the sculptor Auguste Rodin, whose portraits of Victor Hugo, of Henri Becque, of A. Proust. and "Allégorie du printemps" and "La Ronde," are among the masterpieces of the medium. The French painter and etcher J. L. Forain produced some superb dry points about 1909–10 and later. Among British engravers, Sir Muirhead Bone became pre-eminent as a master of dry point, in which medium almost the whole of his numerous plates after 1898 were wrought. Another excellent engraver in dry point was Edmund Blampied.

With many other modem artists, dry point found favour, both as an independent medium and an auxiliary to the etching process. It has been used to express talents as divergent as those of Edvard Munch, Pierre Bonnard. Lovis Corinth, Pablo Picasso, Andre Dunoyer de Segonzac. Max Beckmann, Marc Chagall, Stanley William Hayter and Jacques Villon.

TECHNIQUE

The "dry" point is so called because no bath of acid supplements its use. It is a tapering pointed instrument of steel, of stronger build than the point or needle used by the etcher and sometimes sharpened at both ends; many artists have substituted for steel a diamond point. or more rarely a ruby. The artist works directly upon a plate of hard and polished copper. either shiny or blackened, or merely dimmed with grease, producing a line, shallow or deep, according to the amount of pressure used The instrument is drawn toward the artist, like a pencil (in making a line engraving, on the contrary, the burin is pushed forward). Along one edge of this line, if the point is slanting, or along both edges if it is held upright, a raised edge of copper is turned up by the tool, and this ridge is termed the "burr." The burr, when the plate is inked for printing, becomes clothed with ink and produces in' the impression the rich. soft and velvety effect which

DRY POINTS BY ENGRAVERS AND ETCHERS FROM THE 16TH TO THE 19TH CENTURY

1. "St. Jerome Seated Near a Pollard Willow" (1512) by Albrecht Durer, the first of three dry points. From the impression of the second state in the Albertina museum, Vienna
2. "Holy Family" by Albrecht Diirer. Undated, but about 1512
3. "The Man of Sorrows" (1512) by Albrecht Durer. This plate and the two preceding were the only dry points made by Durer
4. "Portrait of Himself" (1739) by Arthur Pond, one of the English painter-etchers of the 18th century who used the dry-point techniaue with success
5. "Spectacle des Tuiieries" (1760) by Gabriel de St. Aubin. Touched up with dry point in 1753
6. "L'Orage" (1848) by Charles Jacque, a French etcher who produced a number of dry-point landscaoes with figures or horses
7. "Portrait of the Artist's Mother" (1822) by Andrew Geddes
8. Trial proof (Oct. 7. 1877) of "Windmill Hill," dry point by Sir Francis Seymour Haden, one of the leading English etchers of the 19th century
9. "Sunset in Ireland" by Sir Francis Seymour Haden, 1863

EXAMPLES OF THE DRY-POINT TECHNIQUE

Dry point is generally classed as a variety of etching, though actually a kind of engraving. In dry points no acid is used on the plate, as in pure etching, but the lines are hollowed out of the copper with a sharp-pointed instrument. The raised edge of copper turned up by the tool is called the burr. This, in printing, produces the soft velvety effect peculiar to dry points

1. "Weary" by James Abbott McNeill Whistler, finished in 1872
2. "Christ Healing the Sick" (the "Hundred Guilder Print") by Rembrandt. An etching of his middle period (1640–50) retouched with dry point
3. "Portrait of Arnold Tholinx" by Rembrandt, 1656
4. "Portrait of Victor Hugo" by Auguste Rodin (1840–1917)
5. "La Ferme des bordes" by Alphonse Legros (1837–1911)
6. "Portrait of Victor Hugo" by Auguste Rodin
7. "The Vista" by Rembrandt, 1652
8. "Wells Cathedral" by Sir Muirhead Bone, 1919

constitutes the peculiar charm of a dry-point proof. If the burr is removed (as it easily can be with a scraper') the somewhat thin line thus produced is less easily distinguished, except by a practised eye, from the characteristic lines produced by the burin in line engraving, or the needle in etching. The burr is delicate and is easily worn out. either by too vigorous wiping with rag or muslin when the plate is inked or by too great pressure in the printing press. In any case the burr does not last long and the "bloom" of the early proofs of a dry point soon wears off. The first two or three proofs, though they may be rough and uneven, often have a charm which can never be replaced by the more even printing of the bulk of the edition; and at some stage, it may be after a dozen proofs. or 20 or 50, according to the manipulation of the plate and the depth to which the lines have been sunk, deterioration inevitably becomes noticeable, unless the plate has been protected from wear by steel facing.

The comparative ease with which changes can be made in dry point results in a multiplicity of states (*i.e.*, stages of development; impressions taken in different states are distinguishable by the changes that the artist has made in the plate). Of a celebrated dry point by Sir Muirhead Bone, "A Spanish Good Friday." there are no less than 39 states, the artist having repeatedly changed his mind about some detail. or thought of a fresh improvement that he could introduce, after he had begun to take proofs.

Dry Point and Etching. — Dry point has sometimes been used by line engravers in the first preparatory stage (outline) of plates which are subsequently to be finished with the burin. However, dry point is much more often used in combination with etching. Such a combination may be made in a second or subsequent state either for the general enrichment of an etched plate, by the addition of the dry-point burr, or for the sake of introducing small corrections. Corrections to an etched plate can be made far more easily (though less permanently) by a few touches with the dry point than by an additional biting of the plate, involving as this does the stopping-out or laying of a fresh ground. Dry-point additions to an etching can, be readily distinguished by a trained eye in early impressions, but they can wear away gradually in the course of the printing until almost every trace of them is lost. It is the presence of the clearly visible dry-point work, lending richness where it was intended, that confers value on such an etching as the second state of Rembrandt's "Hundred Guilder Print." Yet these rich early impressions and the bare-looking late ones after the worn plate has lost its dry-point burr have, it should be remembered, to be described as impressions of the same state. (C. Do.; H. Es.)

Dry point has several striking advantages over etching: (1) the work can be more easily judged on the bare plate. being positive in character. *i.e.*, the lines appearing black (if filled in with black paint) exactly as in the print; (2) corrections are more easily made since the lines are shallower, and the metal. being thrown up in furrows and not removed from the plate, can be forced back into the groove with a burnisher; additions to the work can be easily made since the plate requires no regrounding and rebiting as in etching; (3) a trial print can be easily taken at any stage of the work, though it should be remembered that the fewer trial proofs that are taken the better, since a dry point may easily be worn out in the course of a protracted series of trial proofs.

Materials. — Some dry-point artists use a plate prepared or blackened as for etching. taking care to cut through the varnish to the metal surface underneath. and using the varying emphasis required by their design; in dry point everything must be drawn delicately or strongly by the artist himself as in ordinary drawing. The difficulty of working on the blackened plate is that it is not easy to judge exactly what emphasis has been used in making the lines. so the bare plate is more often used and a little weak black paint rubbed into the lines to mark their progress. Great care should be taken to do such inking of the lines as gently and as sparingly as possible. since the burr is easily injured during the progress of an elahorate plate with the result that the earlier portions of the work may look quite different from the later. Another difficulty will be found in the varying degrees of sharpness of the point used. A steel point requires resharpening frequently, and the sharpening may not be exactly the same each time. This difference will be found reflected in the work. Diamond or ruby points work very smoothly when in good condition. They are. however, somewhat brittleand apt to flake away in strong crosshatching or by striking the edge of the plate.

The point, the burnisher and the scraper are the three instruments used in dry point; the use of the scraper is of much more importance than it is in etching since the burr can be wholly or partly removed by it and the whole significance of the line altered. Some artists even remove the burr altogether and depend on the "nervous" character of the dry-point line for their effect.

Characteristics. — One great disadvantage of dry point is the difficulty of obtaining a large number of prints of equal excellence because of the delicate character of the work compared with etching or line engraving. This was largely overcome by the practice of steel-facing the plate before printing. It led to the mixed plate, where dry point is strengthened and stiffened by engraved lines done with the burin. The result is work obviously clearer and firmer in, character than many pure dry points. but lacking the particular charm of the best dry-point prints where spontaneity and vivacity (not characteristics of the burin) are most important assets. The best qualities of the two mediums are really incompatible. It is difficult to imagine a burin line introduced into the masterpieces of dry point without producing fatal results. Dry point is also used to lend to etched plates a warmth or accent, or simply as the easiest method of making necessary additions. The difficulty then is that the dry-point lines wear out under the pressure of printing much earlier than the etched lines, and it becomes necessary to renew the dry-point work from time to time. From the pictorial point of view dry point has the disadvantage of producing a picture too often out of tone and spotty. because of the somewhat accidental emphasis of the burr. From the point of view of style the dry-point needle is capable of too many different kinds of strokes; yet these difficulties only add to the fascination of trying to overcome them as they have been overcome by the great masters of the art.

Because of its very simplicity. dry point is a peculiarly autographic medium. very sensitive to the display of the temperament of the artist. All etched work bears a strong family resemblance, and still more so work with the burin. But a collection of the best dry points shows an astonishing difference in the mere appearance of the lines. This is the great fascination of the craft, since a peculiarly personal style has been attained in it again and again. It is as responsive to as many styles as drawing itself, to which it is the nearest of all methods of making prints. There is no chemistry to overcome — no accidentals — the old gibe, leveled at etching, of "a blundering art" does not apply. Any artist who draws interestingly can probably with a little practice be a good dry pointer — it is as simple as that. Hence every draftsman should at least attempt the medium and new triumphs of individual method in dry point may yet have to be recorded.

Steel Facing. — The question of steel facing is surrounded by a prejudice in the eyes of collectors because it allows larger editions to be printed. The old steel facing was heavy and clumsy compared with the modern method, and must have injured the dry point on its application. Then, too, editions used to be printed from the copper and only after that steel-faced for a commoner kind of print. And the steel-faced plate being considered foolproof was handed over to unintelligent printing — the fact not being recognized that a steel-faced plate really requires more and not less care in printing; the delicate tones of the printing ink are more difficult to estimate with nicety on the less "sympathetic" surface of the steel. Still. it is true that for certain plates requiring delicate tones of printing ink to supplement the line work, steel facing is not appropriate. If steel facing is determined on, this should be done immediately after the plate is completed. It should be remembered that the cleaner the plate and its lines have been kept during working the better, since the plate has to be made chemically clean before the electrosteeling, and the smaller the amount of cleaning required the better for the preservation of the burr and the delicate lines.

Printing. — Printing dry points is a difficult art, for the line

and its burr lends itself to many different styles of printing. Care should be taken to give a clearness and purity to lines which easily become clogged and heavy. The aim should be, while retaining the ink caught by the burr, to remove all the smudginess and heavy tone between the lines. This can best be done by repeated hand wiping of the plate from all directions while the plate is fairly warm. Dry-point printing—or rather the preparation of the plate for the press—is thus a much slower process than etching printing, as so much more careful hand wiping is required. Retroussage should be sparingly used, since the ink on the burr is easily smudged. A soft paper shows a dry point to best advantage.

DRY ROT, a term applied to a type of wood decay often found in houses and caused by fungi of the class Basidiomycetes, the mushroom group (see FUNGI). The wood becomes lighter in weight, weaker and less elastic, so that when struck it emits a muffled sound and snaps readily. In more advanced stages the wood may warp, show cracks (cross-shakes) at right angles to the grain and tend to soak up available liquids. The causal fungus does not attack living trees.

Merulius *lacrymans* is the common species causing dry rot in Europe, whereas in North America Poria *incrassata* is the common causal agent. These fungi belong to the Polyporales or pore fungi, so-called because the underside of the fruiting body bears a layer in which are thousands of small holes or pores. Most members of the Polyporales are tough to woody, and the pileate forms are popularly called bracket fungi.

The fungus plant is composed of spawn (mycelium) as in a mushroom. In the case of wood-rotting fungi, this spawn lives in the wood and feeds on it by liberating enzymes that digest the materials of which the wood is made. This process goes on outside the threads of the spawn. The digested material is then absorbed by the fungus and used to produce more spawn and, eventually, also a fruiting body. This process goes on until all the food material present in the wood has been used up by the fungus. Then the fungus dies.

The fruiting body varies in its characters, depending on the species to which it belongs. That of Merulius *lacrymans* is pliant to nearly membranous and has broad, shallow cavities (pores) on the undersurface, the edges of which may be beaded with the drops of a liquid that is not pure water but instead a rather well-buffered mineral salt solution (hence the name lecrymans, from the Latin for "tears"). Clavate cells form a palisade over the inside surface of the pore, and these bear spores that are discharged and carried away by air currents. Some alight on surfaces that can serve as a source of food, and here they germinate and initiate the process known as decay.

Dry-rot fungi have an additional means of moving from one place to another. The main body of the mycelium is in the rotting wood, but a second type is produced in the form of ropelike strands, called rhizomorphs, that grow out and away from the parent spawn to some location often several feet away. Such strands have been known to penetrate brick walls, and since they may carry excess water with them, they can attack and decay perfectly dry wood.

Contrasting such "contagious" species, there are many merely "infectious" kinds typically living only in the interior of the wood until they fruit. This internal decay may be difficult to detect unless the wood is bored for a sample.

Treatment.—Two important procedures are used to combat dry rot: sanitation and fungicidal treatment.

Sanitation.—This is the cheapest method of combating dry rot, but is often ineffective if the treatments are not continued. Any process that retards or inhibits the growth of the mycelium, short of applying specific chemicals to kill it, comes under this heading. Since high humidity, a source of adequate moisture and proximity to living mycelium or exposure to infection from spores are the conditions that favour development of the mycelium, it follows that sanitation techniques are devised to produce the opposite conditions; *i.e.,* low relative humidity, lack of adequate moisture, removal of all wood debris to get rid of any potentially harmful mycelia and covering of all wood surfaces so that germinated spores cannot penetrate the wood and initiate decay.

Regulation of moisture is of first importance. In the construction of buildings great care must be used to select well-dried lumber. If there is no basement, there must be good ventilation between the floor and the earth. Wood should never be in direct contact with the soil. This is important both from the standpoint of wood decay and activity of termites. In warm or humid regions untreated wood should not be closer to the soil than 18 in. at any place. Standing water near a building can be a hazard. Wood should never be thrown in the pit around a house as a fill because it will serve as a source for mycelium. Dry-rot fungi can thrive on such material, and their rhizomorphs can grow out and into the wood above the basement masonry.

Plumbing should be watertight; leaks will cause the adjacent wood to take up moisture and hence cause decay. If wood flooring is laid directly on a concrete slab in contact with the soil, sweating will occur and decay can be expected. Fungi causing dry rot may grow luxuriantly on the hidden faces of floor boards, panels and skirting boards without being visible on the exposed surfaces.

Once a fungus is established, merely cutting off the current source of moisture will not kill the spawn. In the process of digesting wood, water is a by-product, and a species such as Merulius *lacrymans* can continue to grow on the water produced by the decay. If infected wood is thoroughly dried at relatively low temperatures, the mycelium may simply remain dormant until moisture conditions again become favourable.

Fungi causing rot are active only within certain ranges of temperature. Low winter temperatures in temperate regions will not kill spores or mycelia of wood-rotting fungi. High temperatures (over 50° C.) are much more effective. Hence local infection in a building may be treated by application of relatively high temperatures for short periods of time; with this method, however, it is difficult to be sure that all the mycelium has been killed.

Antiseptic (Fungicidal) Treatment.—Compounds that render wood unsuitable for fungus growth are classed as preservatives. Compounds that actually kill the fungus already in the wood are called fungicides. The most familiar preservative is the so-called coal tar "creosote oil" used on railway ties (sleepers), paving blocks, telegraph poles, etc.; it is not used on wood in homes because of its odour. The method of treatment is as important as the preservative used. Sapwood, which generally decays more readily than heartwood, should be completely permeated. Heartwood should be permeated with the preservative to a depth of at least $\frac{1}{4}$ in. and preferably more.

Penetration is accomplished by applying the preservative under pressure within a container.

A good preservative should (1) have high penetrating ability; (2) not be dangerous to handle; (3) be odourless (for most uses); (4) not increase fire risk; (5) not leach out readily; (6) not make painting difficult; (7) be inexpensive. Preservatives may be grouped into three general classes: (1) oils or mixtures of oils of low volatility and only slight solubility in water; (2) inorganic salts and similar substances that can be used in water solution; and (3) toxic chemicals dissolved in something other than water. Corrosive sublimate, a fungicide, should not be used in a house because it is highly poisonous. Merely painting a preservative or fungicide on the surface of the wood is seldom effective for any length of time. (AR. H. S.)

DRY TORTUGAS, the last eight in a long string of coral islands, or keys, and sand bars that extend westward from the tip of Florida, U.S., into the Gulf of Mexico. In 1513 Juan Ponce de Leon discovered these islands 65 mi. W. of Key West and named them Las Tortugas because of the numerous tortoises in the area. Later, mariners added the word "dry" because of the lack of fresh water in the group. In 1825 the U.S. government built a lighthouse on Garden Key, and in 1856 the lighthouse on Loggerhead Key was erected. The construction of Fort Jefferson began in 1846. Though building continued for 30 years, the massive fortification that was one-half mile in perimeter and covered most of

Garden Key was never finished. The fort remained in federal hands during the American Civil War and served as a prison until 1873. The Tortugas possess abundant bird and marine life, and in 1935 Fort Jefferson, the islands and a surrounding water area of 75 sq.mi. were proclaimed a national monument. (J. E. D.)

DUALA, a west African, people of Cameroon, who live on the estuary of the river Wuri (earlier known as the Cameroons river). In 1949, I. Dugast quoted an indigenous population of 22,927, of whom the great majority live in the modern town of Douala (total population [1949] 59,899; [1956] 125,000), which grew from their original settlement. They belong to the most northwesterly branch of the Bantu-speaking peoples. Their language is well documented, J. Ittmann's being the definitive grammar. Traditionally they are said to have migrated from the east and south, displacing the Bakoko-Basa, possibly before the end of the 17th century. The Wuri (Oli), Limba and other neighbouring tribes claim relationship. The Wuri estuary supports a fishing and agricultural economy (oil palms, cassava, cocoyam, plantain, maize).

By 1800 the Duala controlled the Cameroons' trade with Europeans. and their concentrated settlement pattern developed under this influence. The Duala have a patrilineal descent system (there may have been an older double-unilineal systemj and are remarkable for a system of chieftaincy partly founded on trading wealth. For much of the 19th century there were two politico-commercial "kingdoms." Bell and Xkwa. By 1884, however, when their kings signed the treaties with the Germans which led to the establishment of the Kamerun protectorate, they were already weakened and under competition from other formerly subordinate lineages. The position of associations ("secret societies") as instruments of social control may be noted. By 1961 the great majority of Duala were nominal Christians. Before Christianity the religious system recognized a "High God" but no further pantheon and no true shrines or priests; other beliefs concerned the power of ancestors, witchcraft and impersonal fetishes; influences from the Ekoi people of the Cross river were strong. Many Duala are now found in various urban occupations. In the 1960s the chiefly houses remained an elite. some members being active in politics, but their influence was waning. See also CAMEROONS.

DUALISM is a term first used by Thomas Hyde in his *Historico-religionis veterum Persarum* (1700) to denote the fact that the ancient Persian religion knew two supreme principles. one good and the other evil. Christian Wolff later applied it in his exposition of Cartesian (*q.v.*) metaphysics. But the words dualism and dualistic are liable to multiple connotations. Generally speaking, they refer to any system which. in the interpretation of the universe as a whole or of some particular aspect of reality. postulates the existence of two heterogeneous and irreducible principles: for example. God and the world, matter and spirit. being and thought, or good and evil. In asserting that certain opposed term.; are dualistic. the intention is not merely to acknowledge their dissimilarity but primarily to insist on the irreducibility of their difference. A dualism is said to be relative if one term is held to be subordinate to, derivative from, explicable by or in any manner dependent for its heing upon the other; if neither term is held to be dependent in any such sense. then the dualism is absolute.

In Comparative Religion. — A certain kind of dualism is implied in every religion by the simple fact that the *sacred* is considered to be radically different from and opposed to the *profane*. Moreover. all polytheistic religions recognize a class of supernatural beings (such as demons, Titans. monsters) which are different from and antagonistic to the gods. Even within a single pantheon of divinities there may be noted a tension and a conflict between the celestial and the terrestial or chthonian gods; such is the case, for instance. in Germanic mythology. with the Asen and the Vanen. A very characteristic type of religious dualism is illustrated by a cosmogonic myth widely diffusedin central and northern Asia and among the North American tribes: a demonic being or a demiurge attempts to collaborate with God in the creation of the world. either finishing the creation or spoiling it by introducing suffering and death. This type of cosmogonic myth, which is a desperate effort to explain the imperfections of the world and the existence of evil, is not dependent upon Iranian dualistic influences.

The extreme form of religious dualism is to be found in ancient Persia, though not so much in the original teaching of Zoroaster as in later Zoroastrianism: and especially in Iranian gnosticism and in Manichaeism (*q.v.*). Zoroaster proclaimed an irreducible opposition between Ahura Mazda, the Wise Lord (or Ormazd, as he later came to be called). and Angra Mainyu. the Evil Spirit (or Ahriman). Ahura Mazda incarnates truth. righteousness and order, while Xhriman represents the lie. unrighteousness and disorder. But Zoroaster also pointed out that Ahriman has freely chosen to do evil, thus bringing misery, illness and death into the world; hence. for Zoroaster, dualism is the result of the free choice of the two supernatural beings. Later Zoroastrianism presented Ormazd and Ahriman as two coeternal principles of good and evil: one is good by virtue of his very mode o being, the other is evil; one is the creator. the other is the destroyer. Manichaeism took over this pessimistic valuation of late Mazdean dualism, and blended it with the gnostic myth of the corrupted creation.

Under the influence of Iranian eschatology, dualistic elements found their way into the Jewish apocalyptic (*see* APOCALYPTIC LITERATURE). The Qumran texts exalt the "Sons of Light" comhating the "Sons oi Darkness." But, unlike the Iranian figures, the two rival angels guiding the human armies are God's creatures. The New Testament utilizes some old dualistic formulas, but in a different sense. Antithetical terms such as new and old. inner and outer man, pneumatic and psychic body are not the expressions of a dualistic anthropology but rather phases in the history of salvation. Christian dogma denounced dualism as a heresy and condemned it repeatedly in Marcion, in Manichaeism, etc. Though Christianity accepts a radical difference between good and evil. it rejects a metaphysical dualism. In Roman Catholic theology, God and creature, Spirit and matter, etc., are only different modalities in the absolute unity of being.

In Philosophy.—The Chinese cosmological conception of *yin-yang* can be interpreted as a presystematic dualism. *Yin* represents the feminine, passive and negative principle and *yang* the masculine, active and creative principle. The interplay of these contrasting but complementary forces engenders and sustains the universe. In India, the irreducible heterogeneity between the body and the self constitutes the central theme of the speculations of the Upanishads. The same problem plays a most important role throughout the history of Indian philosophy. The Sankhya and Yoga systems for instance. have elaborated a radical and very coherent dualism. On the one hand there is *prakrti,* the dynamic and creative Substance; on the other, *purusa,* the autonomous and transcendent Self Both principles are real and eternal. The whole creation of inanimate and animate beings. as well as all psychomental experiences. is the emanation of *prakrti.* Similar views are held by Jainism and Buddhism. with the difference that Buddhism does not recognize the existence of an autonomous spiritual principle. a "Self." corresponding to *purusa.*

A philosophical dualism of a rather Platonic structure mas also elaborated by the Iranian Zervanists, who held that every terrestrial phenomenon has its counterpart in some celestial, transcendent and invisible phenomenon.

Empedocles reduced the totality of existence to two antagonistic principles. love and hate. Anaxagoras tried to explain the world by the interplay of passive Substance and the Logos. This metaphysical dualism survives in the system of Plato and Aristotle; *i.e.,* an eternal and passive Substance confronts the Supreme Intelligence. For Plato, the intelligible world is separated from and opposed to the sensible world; the pre-existent soul is forcibly united with the body. The ideal world, though transcendent. is not hostile to the material one; there is a duality rather than a dualism. Neoplatonism, however, accentuated the opposition between spirit and matter. soul and body. reason and the senses.

For Descartes (*q.v.*), body and mind, res *extensa* and res *cogitans,* are in their intrinsic natures irreducibly heterogeneous. Neither interacts with the other, neither derives from or in any way depends upon or is explicable by the other. Their duality is absolute. Even so, neither mind nor body is self-sustaining: each depends for its existence on something else of quite a different nature — that is to say, on God, who alone is absolutely and unconditionally existent. Spinoza (*q.v.*), while retaining Descartes' absolute duality of the physical and the mental, makes body and mind both depend on an ultimate uncaused existent (*Deus sive Natura*) as a part depends on its whole (in contrast to the Cartesian dependence upon a separate third existent). For *Natura,* Spinoza holds, is itself diversified into innumerable interdependent parts ("modes"), each at once doubly manifested in parallel orders, the physical and the mental. Certain constellations of those parts manifested in one order are bodies, the same manifested in the other are minds. This parallelism involves an absolute dualism which denies interaction between the mental and physical.

Leibniz (*q.v.*) retains the dualism of matter and mind, combining it first with a relative dualism of appearance and reality, then with a final. major dualism of God and the world. A gnosiological dualism of appearance and nonapparent reality ("phenomena" and "noumena") underlies the whole critical philosophy of Kant (*q.v.*). His moral philosophy introduces two further dualisms: those of practical reason and desire, and of reason and faith. *See* BODY AND MIND; OCCASIONALISM; PLURALISM AND MONISM; PRE-ESTABLISHED HARMONY; see also references under "Dualism" in the Index volume.

DUALITY. A statement capable of two different meanings, both of them true, one obtained from the other, by simply interchanging two words, is an illustration of the principle of duality. An important application of the principle is found in projective geometry. In the plane this is accomplished by interchanging the words "point" and "line"; it is well illustrated by the theorem of Pappus, which may be stated as follows:

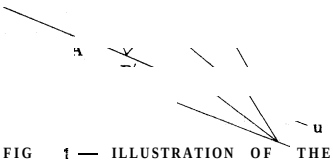

FIG 1 — ILLUSTRATION OF THE THEOREM OF PAPPUS

Given any two straight lines u, u' in the plane; choose any three points A B. C on u. and any three points A′, B', C′, on u'. The three points of intersection AR' A'B:, AC′, A′C; BC', B'C lie on a straight line u″ (see fig. 1). The dual theorem is:

Given any two points U, U′; draw any three lines a, b, c through U and a', b', c' through U'. The three lines joining the points ab', a'b; ac', a'c; bc', b'c all pass through a point U″ (see fig. 2). If the first proof has been established, the second follows by duality, since the determining elements of lines in terms of points are identical with those of points in terms of lines. The principle was first recognized by J. V. Poncelet in the Journal fur *Mathematik* (1829), and by J. D. Gergonne in the *Annales de Mathématiques pures* et *appliquées* (1825–27), and first generally applied by J. Steiner in his *Systematische Entwickelungen* (1832).

In geometry of three dimensions there is a corresponding duality between points and planes. In this case the line is self dual, as it is determined by any two distinct points on it or by any two distinct planes through it.

Many other illustrations of the principle can be given. A geometry can be constructed in the plane by replacing the word "line" wherever it occurs in a proposition by the word "circle," if the circle associated with any given line is constructed as follows: Given a fixed circle C with centre O. Let a given line meet it in A, B. Dram the circle through A, B. O. After this has been done for every line, think of the point O being removed from the plane. The resulting system of incomplete circles furnishes a non-Euclidean interpretation of plane geometry. The line-sphere transformation of Lie is an illustration of a complete duality between lines and spheres in space. Much of higher geometry is concerned with the principle of duality; every new application practically doubles the extent of existing knowledge. See also PROJECTIVE GEOMETRY.

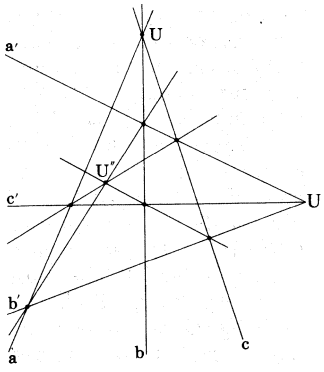

FIG. 2.— ILLUSTRATION OF THE DUALITY OF THE THEOREM OF PAPPUS

DUAL ORGANIZATION. The basic feature of dual organization is the division of a society into two complementary parts called moieties. Often associated with this social division is a wider dualism which relates natural phenomena to the moieties, as among the Cainpang of South America who divide up the entire cosmos and associate the parts with one or the other of the moieties. Dual organization is commonly found in Australia. Melanesia, Indonesia. Xssam, North America and South America. It also occurs in tribal India, western Siberia and in parts of Africa. Dual divisions occur in two basic forms: as a feature of social organization related to but not necessarily determining the regulation of marriage (kinship moieties), and as a ceremonial organization. Usually the two forms are combined, but in some cases only one form occurs or the two forms appear concurrently as separate systems. The Canella of South America have four dual schemes, one of which regulates marriage while the other three are independent ceremonial groupings.

Kinship moieties are ordinarily unilineal exogamous divisions whose members consider themselves to be blood relations. Membership is thus determined by birth and descent, through either the father or mother, and a person must marry outside his moiety. Variant rules occur, such as that among the Fox of North America where the first child belongs to the division opposite that of his father and then membership alternates, each successive child belonging to the moiety opposite that of his preceding sibling. On a world-\vide basis; matrilineal moieties are far more common than patrilineal moieties. In general, moieties are found in association with smaller kin groups such as lineages and clans.

Where exogamous unilineal moieties embody the same rule of affiliation as smaller kin or local groups in the society, as for example. patrilineal moieties and patrilineal clans. the moieties group together such smaller segments into two opposed divisions. If the rule of affiliation in moieties is other than that employed in smaller kin or local groups, as with matrilineal moieties and patrilineal clans. then the moiety divisions crosscut the other groups, as in the section systems of Australia where adjacent generations in any one local descent group belong to opposite moieties.

Occasionally. dual organization with endogamous or nonexogamous moieties is reported. In many but not all such cases where adequate information is available. it appears that the in-marriage possibility is due to a shift from a previous rule of exogamy. Where dual organization is not associated with the regulation of marriage: the principles determining membership vary from group to group.

Certain antitheses linked with dual organization recur in widely separate geographic areas: sun-moon; war-peace; white (or red)-black; upper-lower; male-female. The Creek Indians of the southeastern United States are divided into exogamous matrilineal moieties, phratries and totemic matrilineal clans with the entire tribe dichotomized into upper and lower divisions and a division of tonns into red and white. the former associated with mar and the latter with peace. Often the dual divisions are given geographic expression by localizing the moieties in different sections of the settlement, as among some of the Ge peoples of Brazil.

Moieties may be of unequal status in a given society and reci-

procity may be incomplete. C. Lévi-Strauss has suggested that dual organization should be viewed as a triadic structure in which the two sides are opposed not to each other, but to a centre.

Functions. — The functions of the dual organization vary from society to society, but usually the moieties interact reciprocally. In the case of exogamous kinship moieties, men from one moiety receive their wives from the other. Reciprocity may involve services, as when one division assists in initiations or disposal of the dead for members of the opposite side. Particularly in North and South America, the moieties frequently furnish teams for competitive sports. Rivalry is a common feature of intermoiety relations, and in some areas the two groups may be hostile to one another. In the Banks Islands and in the northern New Hebrides in Melanesia, the members of one division are assumed to be clever and peaceful while those of the other are ignorant and quarrelsome. Dual organization does not generally enter directly into political affairs, but there are numerous exceptions. The council of the Iroquois of North America was organized on a moiety basis, the members of one moiety assembling on one side and those of the opposite moiety assembling on the other. Iroquois moieties adjudicated in disputes as representatives of their respective clans.

In all cases, whether the moieties are exogamous or nonexogamous, unilineal or not, or whether they are aligned on the basis of season, geographic position, name bestowal or other criteria, these dichotomies serve to divide society into two opposed parts which channel reciprocal rights and duties, competition and co-operation, and thus function as integrative devices.

Theories **of** Origin. — A common assumption is that kinship moieties, phratries and clans are kin groups of essentially the same order. Moieties differ from the other groups in that there are only two in the society. Phratries comprise two or more related clans, there being more than two such groupings in the society. This assumption of similarity underlies theories of origin which attribute moieties to the fission or fusion of kin groups such as clans.

However, certain characteristics distinguish moieties from clans. Clan members emphasize descent from a common ancestor. Members of a moiety, while regarding themselves as related, do not stress common descent although this may be implicit. In north Pentecost (New Hebrides) the moieties are named for two culture heroes, Tagaro and Supwe, and members of the respective moieties have traits characteristic of these two heroes. Despite this, it is never suggested that moiety members are descended from these supernatural beings. Individuals trace descent from the mythological founding ancestors of the matrilineal clans within the moieties. Clans function frequently as land-holding units and in co-operative economic enterprises; moieties do so rarely. (See CLAN.)

A second interpretation holds that kinship moieties are only coincidentally descent groups and thus are qualitatively different in origin from kin groups such as clans. According to this view, kinship moieties are structural phenomena automatically produced by the interaction of other features of a kinship system such as localized lineages or clans and symmetrical or matrilateral cross-cousin marriage. This sort of interpretation is employed especially to account for moieties which crosscut local descent groups (as in section systems) and which therefore cannot be attributed either to amalgamation or subdivision of such groups. Moieties of opposite linearity to other kin groups in the society may be implicit in the structure and unrecognized or unformulated by the society. This presumably accounts for some of the so-called implicit moieties in Australia, Melanesia and Indonesia. Where such divisions receive recognition, society may be segmented simultaneously in several ways including local unilineal descent groups divided into two large moieties with these crosscut by moieties of opposite linearity, as occurs frequently in Australia. Whether the moieties comprising local unilineal groups are regarded as descent groups or not, it seems clear that their origin and development differs from that of moieties which crosscut local unilineal groups. See also KINSHIP.

DUARS (DWARS; DOOARS), a tract of country in northeast India divided by the Sankosh river into Western (Bengal) and the Eastern Duars. Both belonged to Bhutan before the Bhutan War of 1864–65, as a result of which they were ceded to the British, The Eastern Duars was assigned to Assam and the Western to Bengal. The Eastern Duars is in Goalpara district, Assam, forming a strip of flat country below the Bhutan mountains. It is only slightly developed and sparsely populated. The Western Duars lies at the foot of the Himalayas in northeast Jalpaiguri district, West Bengal. It is traversed by the North-Eastern railway and is an important centre of the tea industry.

DUARTE, JUAN PABLO (1813–1876), father of Dominican independence, determined to win freedom from Haiti for the Spanish-speaking portion of the island of Santo Domingo while studying in Europe (1828–1833). His first attempt in 1843 collapsed, forcing him to flee the country, but his followers succeeded in ousting the Haitians in Feb. 1844. Returning home, Duarte joined the government but a rift soon developed between his and an opposing faction which sought the protection of a European power. Defeated and exiled by Gen. Pedro Santana (*q.v.*), Duarte eventually established residence in Caracas, Venez., (1845), remaining there until recalled to his homeland in 1864 during the War of Restoration against Spain. Fearing his popularity, the provisional government despatched him on a diplomatic mission to South America. He served for about a year and then resumed his residence in Caracas where he died in 1876.

(K. M. S.)

DUARTE, a province in northern Dominican Republic. Area 499 sq.mi. Pop. (1960) 161,326. It occupies part of a wide alluvial lowland formed by the Camú river in the fertile eastern section of the La Vega Real valley and is one of the nation's most densely populated agricultural regions. Its numerous small farms produce nearly one-half of the nation's cacao, as well as significant quantities of rice, bananas, coffee and corn. Duarte has railroad connections with the port of Sanchez to the east on Samana bay. The province was established in 1936. Its capital, San Francisco de Macoris (pop. [1960] 26,000), was founded in 1777.

(D. R. D.)

DU BARRY, MARIE JEANNE BÉCU, COMTESSE (1743–1793), the last and loveliest of the mistresses of the French king Louis XV, was born at Vaucouleurs on Aug. 19, 1743. Educated in a convent, she became a shop assistant in a fashion house in Paris, where she went under the name of Mademoiselle l'Ange, or Jeanne Vaubernier. There she became the mistress of Jean du Barry, a Gascon nobleman who had made a fortune as a war contractor. She was launched into the artistic world of the capital as the comtesse du Barry, though she had no right to the title, since her protector's wife was still alive. Her beauty captivated a succession of lovers before she attracted the attention of Louis XV in 1768. Du Barry, anxious that she should occupy the place of royal mistress, vacant since the death of Madame de Pompadour in 1764, arranged a nominal marriage for her with his brother Guillaume. This allowed her to be presented at court, after the death of the queen, on April 22, 1769. Apart from helping in the overthrow of the duc de Choiseul in Dec. 1770, Madame du Barry, unlike her predecessor, exercised little political influence at the French court. Louis XV made over to her the crown property of Louveciennes, near Marly, where she became a great patron of the arts. On the accession of Louis XVI (1774) she was banished to this estate, where, till the Revolution, she lived in retirement with the duc de Brissac (Louis Hercule Timoléon de Cossé). In 1792 she made several journeys to England to place her wealth at the disposal of

the *émigrés*. For this, and because she was accused of being in league with the British government, she was condemned to death by the Revolutionary tribunal and executed on Dec. 7, 1793.

DU BARTAS, GUILLAUME DE SALLUSTE, SEIGNEUR (1544–1590), French poet, author of *La Semaine* (1578), a popular and influential biblical epic on the Creation. Born into a prosperous merchant family at Montfort, near Auch, he lived chiefly on his estates, with occasional attendances at the court of Henry of Navarre, who, wishing to profit from James VI's high regard for his poetry, sent him on a diplomatic mission to Scotland and England in 1587. James had published a translation of his *L'Uranie* in 1584, and tried to persuade him to remain at his court. Du Bartas took only a reluctant and late part in the wars of religion and although his *Cantique de la Victoire à Ivry* (1590) has encouraged a belief that he fought there, this is incorrect. He died in July 1590 at Coudon.

A convinced Huguenot, Du Bartas long cherished the idea of writing an epic with a religious theme, to replace the literary paganism lately fashionable. His first epic, *Judith,* appeared in a volume with which he was later dissatisfied, *La Muse Chrétienne* (1574). The publication of *La Semaine* in 1578 made him admirers who placed him on a level with Pierre de Ronsard. His reputation was perhaps greatest abroad, where translations retained the grandeur of his range and vision while omitting his newly coined words and mitigating the many bizarre metaphors and awkward classical constructions which made the original unrestrained and graceless. Sir Philip Sidney began a translation of *Le Semaine;* Spenser, Joseph Hall and Jonson praised the poem highly; and Milton is said to have been influenced by it. *La Seconde Semaine* (1584) was intended to take the narrative beyond the birth of Christ but was never completed: the surviving portion shows more of the faults, particularly the didacticism, than of the merits of his earlier work.

BIBLIOGRAPHY.—The complete works of Du Bartas were printed in 1579 and 1611; two volumes of a critical edition by U. T. Holmes *et al.,* appeared in 1935 and 1938. Among a number of contemporary translations into English is *Du Bartas His Divine Weekes and Workes* (1608) by J. Sylvester. *See* also G. Pelissier, *La Vie et les oeuvres de Du Bartas* (1883); and H. Ashton, *Du Bartas en Angleterre* (1908).

DUBAWNT, a river and lake of Mackenzie and Keewatin districts, Northwest Territories, Can. The Dubawnt river, mapped by J. B. Tyrrell in 1893, rises in Mackenzie district, northeast of Lake Athabasca, at a height of about 1,500 ft. It flows first in an easterly direction to Wholdaia lake before turning northeast to Beverly lake (140 ft.) on the Thelon river, which carries the water via Baker lake and Chesterfield inlet to Hudson bay; its total length is 580 mi.

The river flows through undulating country and connects many lake expansions. The largest one, Dubawnt lake, at 700 ft. above sea level, measures 60 mi. in north-south extent. Its 1,600 sq.mi. are covered with ice for most of the summer. East of the mouth of Kamilukuak river a 20-mi. long peninsula projects north from the south shore. Wholdaia lake (275 sq.mi.), second largest in the river course, is strewn with islands; others are Barlow lake, Carey lake and Wharton lake (180 sq.mi.). (AN. KR.)

DUBBO, a town on the Macquarie river in New South Wales, Austr. It lies 267 mi. by road N.W. of Sydney, with which it is connected by rail and daily air services. Pop. (1954) 12,009. First settled in the 1840s, it is the centre of an extensive wheat and wool-growing district that also yields fruit, vegetables and dairy products. Industries include flour mills and clothing manufacture.

DU BELLAY, GUILLAUME, SIEUR DE LANGEY (1491–1543), French soldier and writer, one of Francis I's cleverest diplomats, was born at the château of Glatigny, near Montmirail, of an Angevin noble family. The eldest of six brothers, he was educated at the Sorbonne, but became a soldier, fought in Flanders and in Italy and was taken prisoner with Francis I at the battle of Pavia (1525). Afterward he was employed by the king as a diplomat. He was concerned with the execution of the treaty of Cambrai between Francis I and the Holy Roman emperor Charles V and was also sent three times to England between 1529 and 1530. On the question of the English king Henry VIII's divorce, Guillaume, with the help of his brother Jean du Bellay (*q.v.*), obtained a decision favourable to Henry from the Sorbonne (July 2, 1530). From 1532 to 1536 he was principally employed in uniting the German princes against Charles V: he signed the treaty of Scheyern with the dukes of Bavaria, the landgrave of Hesse and the elector of Saxony in May 1532 and the treaty of Augsburg in Jan. 1534. During the war of 1536–37 between Francis and Charles, Du Bellay was sent on two missions to Piedmont. Having been governor of Turin for two years from Dec. 1537 he became governor of the whole of Piedmont in April 1540. At the end of 1542, overwhelmed by work, he returned to France and died near Lyons on Jan. 9, 1543. Rabelais, an eyewitness, has left a moving story of his death (*Pantagruel* iii, ch. 21, and iv, ch. 27). Charles V is said to have remarked that Guillaume du Bellay thwarted more of his schemes than all the rest of the French together.

Guillaume du Bellay, without joining the Protestants, defended them against their opponents. In 1534–35 he tried to bring about a meeting between Francis I and Melanchthon, and in 1541 he intervened in favour of the Vaudois. He was also the friend of many writers and scholars, including Rabelais, who stayed with him in Piedmont from 1540 to 1542. Du Bellay wrote, in the style of Livy, a history of the rivalry between Francis I and Charles V from 1521. Of this work, the *Ogdoades,* only fragments remain: the first part, covering the years 1515–21 in Latin (ed. by V. L. Bourrilly, *Fragments de la première Ogdoade,* 1905); and the rest in French (incorporated by Guillaume's brother Martin du Bellay in his *Mémoires,* 1st ed., 1569). The first four books of a preliminary history by Guillaume were published by Martin in 1556 as *Épitome de l'Antiquité des Gaules et de France.* The famous *Instructions sur le faict de la guerre* (1548), formerly attributed to Guillaume, are believed not to be his. There is a modern edition of the *Mémoires de Martin et de Guillaume du Bellay* by V. L. Bourrilly and F. Vindry, 4 vol. (1908–19).

See V. L. Bourrilly, *Guillaume du Bellay* (1905). (RO. M.)

DU BELLAY, JEAN (*c.* 1492–1560), French cardinal and diplomat, one of the chief counselors of Francis I, was a younger brother of Guillaume du Bellay (*q.v.*). He was made bishop of Bayonne in 1526, a privy counselor in 1530 and bishop of Paris in 1532. Francis I also employed him as a diplomat, sending him on five missions to England between Sept. 1527 and Jan. 1534. Du Bellay also went to Rome in 1534 to defend the English king Henry VIII's divorce. He was made a cardinal in May 1535. Returning to France from a second mission to Rome in Feb. 1536, he was appointed lieutenant general of the kingdom during the war of 1536–37 between Francis I and the Holy Roman emperor Charles V. He was sent to the diet of Speyer in 1544 and took charge of negotiations with the German Protestants. During the last years of the reign, Du Bellay was in favour with the duchesse d'Étampes, Francis I's mistress, and received many benefices including the bishopric of Limoges (1541–44), the archbishopric of Bordeaux (1544–53) and the bishopric of Le Mans (1546–56).

On the accession of Henry II (1547), Du Bellay fell into disfavour. He spent the years 1547–50 mainly at Rome. After living in France from 1550 to 1553, he finally retired to Rome, where he became bishop of Ostia and dean of the Sacred College of Cardinals (1555). He died in Rome on Feb. 16, 1560.

Jean du Bellay played an important role as a protector of humanists and reformers. He was a friend of Guillaume Budé, whom he helped to persuade Francis I to found the Collège de France. Rabelais was his secretary and doctor, and other men of letters such as Étienne Dolet and the poet Salmon Macrin were indebted to him for assistance. His own writings include three books of Latin poems (printed with Salmon Macrin's *Odes* by Robert Estienne in 1546), and a defense of Francis I (1542). His correspondence is preserved in the Bibliothèque Nationale in Paris.

Weiss, "Jean du Bellay, les Protestants et la Sorbonne," *Bull. Soc. Hist. Prot. français* (1903, 1904); V. L. Bourrilly and P. de Vaissière, *Ambassades de Jean du Bellay en Angleterre* (1905). (RO. M.)

DU BELLAY, JOACHIM (1522–1560), French poet and critic, member of the Pléiade, who with Pierre de Ronsard (*q.v.*) founded the French school of Renaissance poetry, was born at the chfteau of La Turmelikre, not far from Lirit, near Angers, being the son of Jean du Bellay, seigneur de Gonnor, cousin-german of the cardinal Jean du Bellay and of Guillaume du Bellay. Both his parents died while he was still a child. and he was left to the guardianship of his elder brother, René du Bellay, who neglected his education, leaving him to run wild at La Turmelikre. When he was 23, however, he went to Poitiers to study law, no doubt with a view to obtaining preferment through his kinsman the cardinal. At Poitiers he came in contact with the humanist Marc Antoine Muret, and with Jean Salmon Macrin (1490–1557), a Latin poet famous in his day. There too he probably met Jacques Peletier, who had published a translation of the *Ars poëtica* of Horace, with a preface in which much of the programme advocated later by the Pléiade is to be found in outline.

It was probably in 1548 that Du Bellay met Ronsard in an inn on the way to Poitiers, an event which may justly be regarded as the starting point of the French school of Renaissance poetry. The two immediately became fast friends. Du Bellay returned with Ronsard to Paris to join the circle of students of the humanities attached to Jean Dorat (*q.v.*) at the Collège de Coqueret. While Ronsard and Antoine de Baïf were most influenced by Greek models, Du Bellay was more especially a Latinist and perhaps his preference for a language so nearly connected with his own had some part in determining the more national and familiar note of his poetry. In 1548 appeared the *Art poétique* of Thomas Sibilet, who championed the cause of Clément Marot and his disciples and poured scorn on the sonnet and on newfangled ideas. The famous manifesto of the Pléiade, the *Défense et Illustration de In langue française* (1549), was at once a complement and a refutation of Sibilet's treatise. This book was the expression of the literary principles of the Pléiade as a whole, but although Ronsard was the chosen leader. its redaction was entrusted to Du Bellay. To obtain a clear view of the reforms aimed at by the Pléiade, the *Défense* should be further considered in connection with Ronsard's *Abrégé d'art poétique* and his preface to the *Franciade*. Du Bellay maintained that the French language as it was then constituted was too poor to serve as a medium for the higher forms of poetry, but he contended that by proper cultivation it might be brought on a level with the classical tongues. He condemned those who despaired of their mother tongue and used Latin for their more serious and ambitious work. For translations from the ancients he would substitute imitations. Not only were the forms of classical poetry to be imitated. but a separate poetic language and style, distinct from those employed in prose, were to be used. The French language was to be enriched by a development of its internal resources and by discreet borrowing from the Latin and Greek. Both Du Bellay and Ronsard laid stress on the necessity of prudence in these borrowings, and both repudiated the charge of wishing to latinize their mother tongue. The book was a spirited defense of poetry and of the possibilities of the French language; it was also a declaration of war on those writers who held less heroic views.

The violent attacks made by Du Bellay on Marot and his followers, and on Sibilct, did not go unanswered. Sibilet replied in the preface to his translation (1549) of the *Iphigenia* of Euripides; Guillaume des Autels, a Lyonnese poet, reproached Du Bellay with ingratitude to his predecessors and showed the weakness of his argument for imitation as opposed to translation in a digression in his *Réplique aux furieuses de'fenses de Louis Meigret* (1550); Barthélemy Aneau, regent of the Collège de la Trinité at Lyons, attacked him in his *Quintil Horatian* (1551), the authorship of which was commonly attributed to Charles Fontaine. Aneau pointed out the obvious inconsistency of inculcating imitation of the ancients and depreciating native poets in a work professing to be a defense of the French language. Du Bellay replied to his various assailants in a preface to the second edition (1550) of his sonnet sequence *Olive*, with which he also published two polemical poems, the *Musagnaeomachie*, and an ode addressed to Ronsard, *Contre les envieux podtes. Olive*, a collection of love sonnets written in close imitation of Petrarch, first appeared in 1549. With it were printed 13 odes entitled *Vers lyriques*. Du Bellay did not actually introduce the sonnet into French poetry, but he acclimatized it.

About this time Du Bellay had a serious illness of two years' duration, from which dates the beginning of his deafness. He had further anxieties in the guardianship of his nephew. The boy died in 1553, and the poet, who had up to this time borne the title of sieur de Liré, became seigneur of Gonnor. In 1549 he had published a *Recueil de poësies* dedicated to the Princess Marguerite. This was followed in 1552 by a version of the fourth book of the *Aeneid*, with other translations and some occasional poems. In the next year he went to Rome as one of the secretaries of Cardinal du Bellay. To the beginning of his four and a half years' residence in Italy belong the 47 sonnets of his *Antiquités de Rome*, which were rendered into English by Edmund Spenser (*The Ruins of Rome*, 1591). These sonnets were more personal and less imitative than the *Olive* sequence, and struck a note which was revived in later French literature by the comte de Volney and Chateaubriand. His stay in Rome was, however, a real exile. His duties were those of an intendant. He had to meet the cardinal's creditors and to find money for the expenses of the household. Nevertheless he found many friends among Italian scholars, and formed a close friendship with another exiled poet whose circumstances were similar to his own, Olivier de Magny. Toward the end of his sojourn in Rome he fell violently in love with a Roman lady called Faustine, who appears in his poetry as Columba and Columbelle. This passion finds its clearest expression in the Latin poems. Faustine was guarded by an old and jealous husband and Du Bellay's eventual conquest may have had something to do with his departure for Paris at the end of Aug. 1557. In the next year he published the poems he had brought back with him from Rome—the Latin *Poemata*, the *Antiquités de Rome*, the *Jeux rustiques* and the 191 Sonnets of the *Regrets*, the greater number of which were written in Italy. The *Regrets* show that he had advanced far beyond the theories of the *De'fense*. The simplicity and tenderness specially characteristic of Du Bellay appear in the sonnets telling of his unlucky passion for Faustine and of his nostalgia for the banks of the Loire. Among them are some satirical sonnets describing Roman manners and the later ones written after his return to Paris are often appeals for patronage. His intimate relations with Ronsard were not renewed; but he formed a close friendship with the scholar Jean de Morel, whose house was the centre of a learned society. In 1559 Du Bellay published at Poitiers *La Nouvelle Manière de faire son profit des lettres*, a satirical epistle translated from the Latin of Adrien Turnèbe, and with it *Le Podte courtisan*, which introduced the formal satire into French poetry. These were published under the pseudonym of J. Quintil du Troussay and the courtier poet was generally supposed to be Melin de Saint-Gelais, with whom Du Bellay had always, however, been on friendly terms.

A long and eloquent *Discours au roi* (detailing the duties of a prince, and translated from a Latin original written by Michel de l'Hôpital, now lost) was dedicated to Francis II in 1559, and is said to have secured for the poet a tardy pension. In Paris he was still in the employ of the cardinal, who delegated to him the lay patronage which he still retained in the diocese. In the exercise of these functions Joachim quarreled with Eustache du Bellay, bishop of Paris, who prejudiced his relations with the cardinal, less cordial since the publication of the outspoken *Regrets*. His chief patron, Marguerite de Valois, to whom he mas sincerely attached, had gone to Savoy. Du Bellay's health was weak; his deafness seriously hindered his official duties; and on Jan. 1, 1560, he died in Paris. There is no evidence that he was in priests' orders, but he was a clerk and as such held various preferments.

DUBLIN (ATHA CLIATH), a county of the Republic of Ireland, in the province of Leinster, is bounded north by County Meath. east by the Irish sea, south by County Wicklow. and west by counties Kildare and Meath. The area is 311 sq.mi. and the population (1961 j 180,668, apart from Dublin city (area 44.5 sq.mi.; pop. 535,488). The county includes the borough of Dun Laoghaire (*q.v.*) and, though one of the smallest counties. is among the most populous in Ireland. Of the population the great majority are Roman Catholics. The central and northern portions of the county are 10x1,-lying and composed chiefly of Carboniferous Limestone, with some Millstone Grit to the north and northwest, and some Silurian and Ordovician rocks behind Balbriggan. The peninsula of Howth, connected by a raised beach with the mainland, is formed of old quartzites and shales: crushed and folded. and probably of Cambrian age. The rocks of the county show many signs of ice action, and Leinster granite underlies the whole southern part as far north as Blackrock.

The mountains which occupy the southern border of the county are the extremities of the great group belonging to adjacent Wicklow (*q.v.*). The principal summits are Glendoo (1,919 ft.) and Two Rock (1.699 ft.) within the county, and the border group of Kippure, reaching in that summit a height of 2,473 ft. The mountains are chiefly covered with heath, except where a subsidence in the ground affords a nucleus for the formation of bog, with which about 2.000 ac. are covered. There are also a few small tracts of bog in the northern part of the county. The mountain district is well adapted for timber. The northern coast of the county from Balbriggan to Homth has generally a sandy shore, and affords only the small harbours of Balbriggan and Skerries. But in the promontory of Howth. the coast suddenly assumes a bolder aspect. Between the town of Howth and the rocky islet of Ireland's Eye an unsuccessful artificial harbour was constructed; Dun Laoghaire harbour on the south side of Dublin bay superseded this and is by far the best in the county. The chief river is the Liffey, which rises in the Wicklow mountains about 12 mi. S.W. of Dublin, flows through the city and into Dublin bay. The course of the river is so tortuous that 40 mi. may be traversed and only 10 mi. gained in direction.

Among early remains, raths or domestic earthworks are frequent and there are also dolmens and round towers, notably that of Clondalkin and the example at Lusk. incorporated in a later church tower by medieval builders. The ancient church of St. Doulough's with its stone roof, and the 15th-century castle at Dunsoghly are also noteworthy. Malahide castle, near the coastal resort of Malahide, was founded in the 12th century by Richard Talbot and still remains in the possessions of his descendants. Lord Talbot de Malahide (d. 1948), a great-great grandson of James Boswell (*q.v.*) sold to an American the collection of Boswell manuscripts which were acquired by Yale university in 1950. They contain many passages suppressed by Boswell before publication of his *Life of Samuel Johnson* and other items relating to contemporary figures.

Dublin is among the counties generally considered to have been formed in the late 12th century by King John. It comprised the chief portion of country within the English pale. The limits of the county. however, were uncertain and underwent many changes before they were fixed. As late as the 17th century the mountainous country south of Dublin offered a retreat to the lawless. and it was not until 1606 that the boundaries of the county received definition in this direction, along with the formation of County Wicklow. Although so near the seat of government, much land was forfeited in the Civil War of 1641 and in the revolution of 1688. In 1867 the most formidable of the Fenian risings took place near the village of Tallaght, about 7 mi. from the city. Because of its proximity to the capital, with which its history is closely associated, the county was the scene of much sporadic fighting in the troubled years between 1914 and 1922. The gun-running by Nationalists, in answer to that already carried out by Unionists at Larne, took place at Howth in June 1914, and numerous incidents followed until peaceful conditions returned after the establishment of the Irish Free State.

Administration is by a county council and a county manager. Dun Laoghaire is a borough with its own corporation and Balbriggan is administered by town commissioners. County Dublin returns three members to *dáil éireann*.

Wheat, barley and potatoes are the principal crops, but livestock breeding, especially cattle, receives greater attention. There is manufacture of cotton hosiery at Balbriggan and chocolate and cement goods are made in the west of the county. There are some light industries, mostly established under protective tariffs. Several important railways converge upon Dublin city.

(M. J. CG.; HU. S.)

DUBLIN (BAILE ATHA CLIATH), is a county borough, seaport and the capital of the Republic of Ireland. It lies on the bay of the Irish sea to which it gives its name at the mouth of the river Liffey. about midway on the eastern coast of the island and 64 mi. W. of Holyhead. Wales. The Gaelic name, meaning "Town of the Ford of the Hurdles," is used by the post office. Pop. (1961) 535,488.

The river Liffey divides the town into two almost equal parts. north and south Dublin, and is crossed by nine road bridges. two railway bridges and a footbridge. Dublin castle was built on a ridge overlooking the Liffey to the north and the low ground to the east. Within the limits of the old walls are found Christ Church cathedral: the city hall, municipal offices and several business premises. John Speed's map of 1610 gives a good idea of this settlement and also shows some buildings to the north of the river. With the exception of some of the churches. however, the buildings in the old centre of the city are themselves later than the 17th century. The castle was originally built in the first two decades of the 13th century, but nearly the whole of the extant structure is early 18th century or later. With the castle as a nucleus, but mainly to the east, the city developed regularly to the first half of the 19th century with wide streets and large squares, the most famous of the latter being Merrion square (1762 onward). To the northwest of Merrion square is Trinity college and to the southwest St. Stephen's green (which became a public park in 1880), while Grafton street: Dublin's chief shopping street, Dawson street, with the Mansion house and the Royal Irish Academy, and Kildare street run between them.

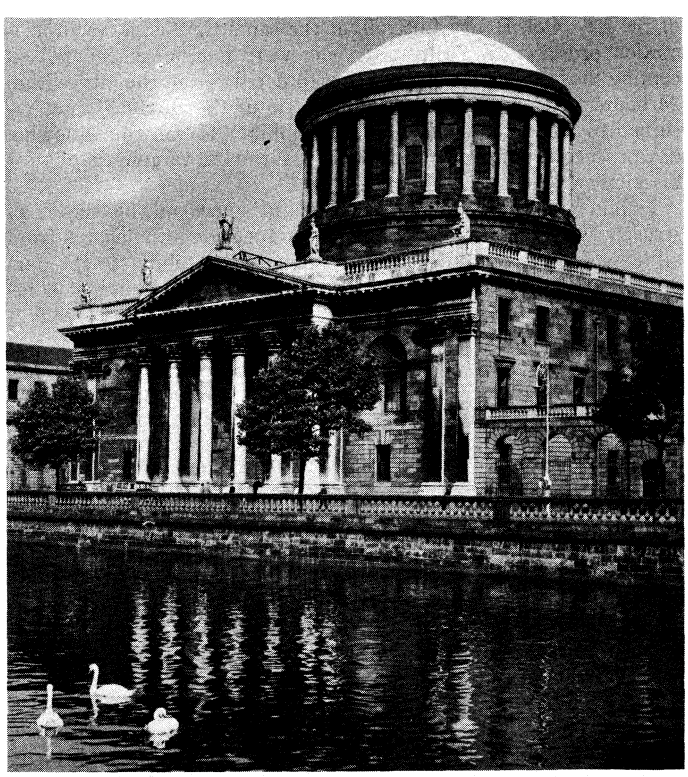
The Protestant cathedral of Christ Church, or Holy Trinity, to the west of the castle was founded by Sigtrygg, a Christianized king of the Norsemen of Dublin. in 1038. It was elevated to a deanery and chapter in 1541. In 1870, at the disestablishment of the Church of Ireland, St. Patrick's became the national cathedral and Christ Church became the diocesan cathedral within the Anglican communion. The building was restored in 1870–78 by G. E. Street. who rebuilt the choir and south side of the nave, following the model of the ancient building. The older parts are Transitional Norman and Early English in style. Among the tombs is that reputedly of Richard de Clare, 2nd earl of Pembroke, called Strongbow, the invader of Ireland by whom the earlier part of the superstructure (1172) was founded. Synods were occasionally held in the church, and parliaments also, before the Commons' hall was destroyed in 1566. There also the pretender Lambert Simnel was crowned in 1487.

A short distance south from Christ Church, outside the walled area. stands the cathedral dedicated to St. Patrick, founded about 1190 by John Comyn, archbishop of Dublin, in an attempt to supersede the older cathedral of Christ Church. However, there was an earlier church dedicated to the same saint. The building was burned about 200 years later, but was rebuilt. It is mainly Early English and has a 14th-century tower. At the Reformation St. Patrick's was deprived of its status as a cathedral. and the building was used for some of the purposes of the courts of justice. Edward VI contemplated changing it into a university but the project was defeated. In the succeeding reign of Mary I, it was restored to its original purpose. The installations of the knights

of St. Patrick were originally held there. St. Patrick's contains the grave and monument of Jonathan Swift, who was dean of the cathedral. Attached is Marsh's library, incorporated in 1707, the gift of Narcissus Marsh; archbishop of Armagh.

In the 18th and 19th centuries there was considerable growth to the north of the river where O'Connell (formerly Sackville) street is one of the principal thoroughfares. It was badly damaged in the Easter Monday rising of 1916 and again in 1922. Down its centre are many statues. among them the Nelson pillar, 134 ft. in height, with a statue of the admiral on the top. In nearby Marlborough street is the Metropolitan pro-cathedral (1816). the principal Roman Catholic church of the city. Farther to the east are the docks below O'Connell bridge. the widest road bridge. Westmoreland street continues to the south of O'Connell street: and where it meets Dame street, which leads up to the castle, are situated the Bank of Ireland and Trinity college. The Bank of Ireland was formerly the house of parliament. Its original portion was designed by Sir Edward Lovett Pearce in 1729. and faces College green as an Ionic colonnade with a central portico and two projecting wings. The eastern portico is by James Gandon, and this and the western portico are connected to the centre by quadrant walls with engaged columns as remodeled by Francis Johnston after 1803, when the bank bought the building. The octagonal house of commons was burned in 1792, but the house of lords survives and remains in its original condition. with tapestries of 1733. The parliament (*dáil éireann*) meets in Leinster house (1745) in Kildare street.

Of the later 18th-century buildings of Dublin the most important are the city hall, formerly the Royal exchange (1769–79), by Thomas Cooley, adjoining the castle, the bluecoat school (1773) by Thomas Ivory and the customhouse and Four Courts by Gandon. on the north bank of the river. The customhouse (1781–91) has a prominent riverside site and four decorated fronts, and is crowned by a slender dome. The Four Courts (central courts of justice) was begun in 1786 and finished in about 1800. Also on the riverside. it has a massive central colonnaded dome and wings enclosing two courtyards open to the river except for triumphal arcaded screens. Both the customhouse and the Four Courts were heavily damaged in the fighting of 1921–22, but were restored. Gandon's last work, the King's Inns (Inns of Court, begun 1795) survives intact. The most important building remaining from the 17th century is the Royal hospital. Kilmainham. in the western suburbs, which preceded the sister institution at Chelsea, London, being designed by Sir William Robinson in 1679, but is no longer devoted to its original purpose. Near the Four Courts is St. Michan's church, with an organ used by Handel. It is notable chiefly for the remarkable manner in which the bodies in the vault are preserved. Another church of interest is St. Werburgh's, which served as the castle chapel until late in the 18th century. Lord Edward Fitzgerald, a leader of the conspiracy of the United Irishmen in 1798. is buried there.



J. ALLAN CASH

THE FOUR COURTS ON THE RIVER LIFFEY, DUBLIN; LATE 18TH CENTURY

Cultural Institutions.— Trinity college. or the University of Dublin. founded in 1591, has a Palladian façade (1759) with statues of Oliver Goldsmith and Edmund Burke by John Henry Foley. Above the gateway is a hall called the Regent house. The first quadrangle. Parliament square, contains the chapel (1798), which has a Corinthian portico; the public theatre or examination hall (1787), where hang portraits of Queen Elizabeth I. William Molyneux, Burke, Bishop George Berkeley and other celebrities; and the wainscoted dining hall. also containing portraits. A beautiful campanile (1853) separates the square from Library square. The library, housed in a building (1712–32) by Thomas Burgh, is one of those scheduled in the Copyright act as entitled to receive a copy of every volume published in the United Kingdom. It has a notable collection of early Irish manuscripts, including the Gospel books of Kells and Durrow. In Library square are the oldest buildings of the foundation. dating in part from the close of the 17th century, and the modern Graduates' Memorial buildings (1904) which contain a theatre, library and reading room and the rooms of the college societies. Other buildings are the provost's house (1760), printing house (1734), the museum by Sir Thomas Deane and Benjamin Woodward (1857). the medical school buildings. including the Moyne Institute of Preventive Medicine (1952), and the 20th-century chemical laboratories. The college (recreation) park and fellows' garden are of considerable beauty. The college observatory at Dunsink, about 5 mi. N.W. of Dublin, was erected in 1785, and in 1791 was placed by statute under the management of the royal astronomer of Ireland. It is administered by the state. The magnetic observatory of Dublin was erected in 1837–38 in the gardens attached to Trinity college. The botanic garden is at Ball's Bridge, 1 mi. S.E. of the college.

In Kildare street stand the National library, with about 500.000 books, and the National museum, which is particularly rich in prehistoric gold ornaments and early Christian metalwork. The National gallery in Merrion square, founded in 1864, has a rich collection of moderate size. The principal learned society is the Royal Irish Academy (1786). The Institute for Advanced Studies (founded 1940) specializes in theoretical and cosmic physics and Celtic philology. The Royal Dublin society, founded in 1731. is known for the annual horse show which it promotes at Ballsbridge in August. The small Abbey theatre (*q.v.*; founded in 1904, burned in 1951) had an influence on world theatre far out of proportion to its size. The other distinguished theatre in Dublin is the Gate. founded in 1928.

Near St. Stephen's green is University college (nonsectarian), which occupies the site of the International exhibition of 1865. It is a constituent college, with Cork and Galway, of the National University of Ireland. Dublin is well known as a medical centre, the Rotunda hospital being the first maternity hospital to be established (1745) in the British Isles. In Phoenix park (1,750 ac.), formed in 1662 and lying west of the city, are the zoological gardens, founded in 1830 and one of the oldest in the world.

Trade and Communications.— Considering its size, Dublin has never been an important commercial or industrial centre. About the time of the English Civil War, the woolen trade flourished there, and Dublin woolens were widely known. The cheapness of labour attracted capitalists, who started extensive factories in that quarter of the town which came to be known as the Liberties. About 1700 the English parliament prevailed on William III to assent to laws directed against the Irish trade. All exportation except to England was forbidden, and the woolen manufacture soon decayed. Nevertheless, at the close of the 18th century there

were about 5,000 persons at work in the looms of the Liberties.

By 1715 parliament had begun to favour the manufacture of linen, and the Linen hall was built. The cotton trade was soon afterward introduced, and silk manufacture was begun by the Huguenots, who had settled in Dublin in considerable numbers after the revocation of the Edict of Nantes. Acts favourable to these enterprises were passed, and they flourished. English opposition arose again in the reign of George I, and in the reign of George III another restrictive act was passed which tended directly to the ruin of the manufacture. Dublin poplins, however, maintained their reputation. Dublin's principal export products are whisky and stout, the Guinness brewery, one of the world's largest. being a major tourist attraction. A considerable export trade, principally in agricultural produce, passes through Dublin from the country. The manufacturing industries of the city include mineral water (soft drink) works, biscuit making, glassmaking, cigarette making, foundries and shipbuilding. Many light industries arose following the tariff protection imposed in 1932.

By continual dredging a great depth of water is kept available in the harbour. The Dublin Port and Docks board, which was created in 1867 as successor to the old Ballast board of 1707, undertook considerable works of improvement at the beginning of the 20th century. These improvements, among other things, enabled vessels drawing up to 23 ft. to lie at low tide alongside the extensive quays which border the Liffey. The Alexandra tidal basin, on the north side of the Liffey, admits vessels of similar capacity. The Custom House docks on the north side have about 17 ft. of water. The Royal and Grand canals. connected with docks ndmed after them, pass respectively to the north and south of the city, the one penetrating the central plain of Ireland on the north, the other following the course of the Liffey. Both join the river Shannon.

The direct route to Dublin from London is by rail to Holyhead from where there are steamers to Dun Laoghaire. Passenger boats also sail to Dublin from Liverpool and Glasgow.

Dublin is the centre of the Irish railway network. There are main lines running north to Belfast, Londonderry and Howth, southwest to Cork and Waterford and west to Galway and Sligo. The airport at Collinstown (5 mi. N.) was considerably enlarged in 1957. There are air services to other European capitals and, via Shannon airport, to New York.

Administration. — The county borough of Dublin is divided into 6 constituencies sending 24 members to *dáil éireann*. Dublin is governed by an elected corporation and a manager. The chief magistrate. originally called the provost and later the mayor, was known after 1665 as the lord mayor. He serves a term of one year and his functions are largely ceremonial. The corporation's powers are restricted to imposing rates, raising loans and making by-laws. Other functions are performed by the manager, a paid official who has power over all municipal officers and whose own removal is subject to central authority. Considerable attention has been devoted by the city government toward slum clearance and the provision of modern housing. More than 100 city charters, the oldest dating from the time of Henry II, are preserved by the corporation.

History. — The name of Dublin is corrupted from *Dubh Linn* and signifies "Black pool" after the colour of the Liffey waters. It is recorded that the inhabitants of Leinster were defeated by the people of Dublin in the year 291. Christianity was introduced by St. Patrick in the 5th century. The Norsemen appeared in the country as early as the close of the 8th century but Dublin was not taken until the 9th, when the first Norse king, Thorkel I (832), established ,himself strongly at Armagh. In 1014 Brian Boru, high king of Ireland, fought the battle of Clontarf against the Norse invaders, and although he, his son and a large number of his followers fell, the Irish won the battle. The Norsemen, however, reoccupied the city. Constant struggles with the Irish resulted in intermissions of the Norse supremacy from 1052 to 1072, at various intervals between 1075 and 1118 and from 1124 to 1136. The Norsemen were finally ousted by the Anglo-Normans in 1170. In 1172 Henry II came to Dublin and held his court there. Prior to his departure for England, Henry bestowed the government on Hugh de Lacy, having granted by charter "to his subjects of Bristol his city of Dublin to inhabit, and to hold of him and his heirs forever. with all the liberties and free customs which his subjects of Bristol then enjoyed at Bristol and through all England." A fresh charter was granted in 1207 by King John to the inhabitants of Dublin. who were constantly feuding with the native Irish. In 1216 Magna Carta was granted to the Irish by Henry III and in 1217 the fee farm of the city was granted to the citizens at a rent of 200 marks per annum. In 1227 the same monarch confirmed the charter of John fixing the city boundaries and the jurisdiction of its magistrates. During most of the medieval period Dublin was less the capital of Ireland than of the pale. a strip of varying width on the eastern seaboard settled by the English. At about this period many monastic establishments were founded.

During the invasion of Ireland by Edward Bruce in 1315–16 some of the suburbs of Dublin were burned to prevent their falling into his hands. The inroads of Bruce had been countenanced by native Irish ecclesiastics. Richard II erected Dublin into a marquisate in favour of Robert de Vere, whom he also created duke of Ireland. Richard entered Dublin in 1394, and after holding a parliament and making much courtly display before the native chieftains, returned to England. Five years later he revisited Dublin, where he remained a fortnight. In 1534 Lord Thomas Fitzgerald, "Silken Thomas," son of the lord deputy, the 9th earl of Kildare, organized a rebellion against the English government and attacked the city of Dublin itself, but later raised the siege.

In 1641, as the English Civil War approached, a conspiracy to seize Dublin castle was disclosed and the city was thus preserved for the king's party. However: there were risings among the Irish outside the city, which in 1646 they unsuccessfully besieged. The city had been put in a state of defense by the marquess of Ormonde, then lord lieutenant, but in the following year, to prevent its falling into the hands of the Irish, he surrendered it to Col. Michael Jones, commander of the parliamentary forces. In 1649 Ormonde was totally defeated at the battle of Baggotrath, near Old Rathmines, in an attempt to recover possession. The same year Oliver Cromwell landed in Dublin, as commander in chief under the parliament.

When James II landed in Ireland in 1689, after his expulsion from England, he held a parliament in Dublin, which passed acts of attainder against more than 3,000 Protestants. The governor of the city, Col. Henry Luttrell, at the same time issued a proclamation ordering all Protestants who were not housekeepers, excepting those following some trade, to depart from the city within 24 hours. After his defeat at the battle of the Boyne, James returned to Dublin for a few hours. William III on the following day proceeded in state to St. Patrick's cathedral to give thanks for his victory.

Dublin was the scene of many disturbances during the Irish struggle for independence. In 1783 a convention of delegates from all the volunteer corps in Ireland assembled in Dublin for the purpose of procuring a reform in parliament, but the house of commons refused to entertain the proposition. In May 1798 a conspiracy planned by the United Irishmen to seize the city was frustrated. The Act of Union of 1800 abolished the Irish parliament and temporarily reduced the status of the capital. The viceregal court, however, continued. In 1803 an insurrection broke out, led by Robert Emmet, but was immediately quelled. There was considerable agitation in 1848, following the famine, but little bloodshed. In 1867 the conspiracy of the Fenian organization came to light. The Habeas Corpus act was suspended at one sitting by both houses of parliament and about 960 arrests were made in Dublin in a few hours. Dublin castle was fortified; and the citizens lived in a state of terror for several weeks.

Although a neutral capital in World War II, the city was bombed by the German air force in May 1941. *See* also IRELAND; IRELAND, REPUBLIC OF.

DUBNOW, SIMON (1860–1941), Jewish historian, social

philosopher and leading protagonist of Jewish autonomism. was born in Mtsislav, Belorussia, Sept. 10, 1860. He received a traditional orthodox Jewish education, but in his early teens he began to waver in his faith and turned to secular learning for authority as well as inspiration. He read avidly the works of the Haskalah and the Russian classics, and pursued the systematic study of western philosophy. history and the social sciences. He was profoundly influenced by the evolutionary positivism of Auguste Comte, H. T. Buckle and Herbert Spencer; the classic liberalism of J. S. Mill determined his political philosophy. In his intellectual maturing he spurned the way of revolutionary radicalism, and his sober realism led him also to reject political Zionism.

Dubnow was largely self-educated. and his professional life was always that of an independent writer. In 1882 he began his long association with the Russian-Jewish periodical *Voskhod,* to which he contributed in serial form many of his most famous scholarly and literary works. He remained in Russia until 1922, leaving because he detested the Bolshevik dictatorship. He settled in Berlin and lived there until the advent of Hitler forced him again into exile. when he went to Riga, Latvia. There he remained until he met his tragic death at the hands of the Nazis when they liquidated the Jewish population of Riga in Dec. 1941.

Dubnow brought to the study of Jewish history in eastern Europe the methods of western Jewish scholarship. He organized and supervised the collection of source materials for the history of the Jews in Russia and Poland. He was the first to subject Hasidism to systematic and objective study based upon source materials from both the Hasidim and their opponents. Dubnow abandoned the spiritualistic philosophy of history held by Graetz and the older Jewish historians for the sociological view. According to Dubnow, the Jews are not merely a religious community hut possess the distinctive characteristics of a cultural nationality and as such create their own forms of autonomous social and cultural life. The history of the Jews is, therefore. a history of the succession of large autonomous centres. The mature fruition of Dubnow's historical studies is found in his monumental *Weltgeschichte des jüdischen Volkes* (10 vol., 1925–29). It was the first secular and purely scholarly synthesis of the whole course of Jewish history, free from dogmatic and theological trappings, fully cognizant of social and economic currents, and sane and realistic in its approach.

In keeping with his philosophy of Jewish history, Dubnow also developed his theory of autonomism, or Diaspora nationalism. As a humanitarian and cultural nationalist he rejected the way of Jewish assimilation, but he was also convinced that political Zionism was messianic and unrealistic. Most of the Jews, he maintained. would remain in the Diaspora. There. he held, they should oppose the political principle of the monolithic nation-state. which identifies state and nationality, and fight for the recognition of the autonomous rights of nationalities within larger multinational federations. The Jews, as such a cultural nationality, would also be entitled to national minority rights. In his famous "Letters on Old and New Judaism." published between 1897 and 1906, he subjcctcd the various current ideologies of Jewish life to critical analysis, and formulated his own doctrine of autonomism. Dubnow's ideas came to be assimilated by almost all groups in Jewish life in eastern Europe and by leading figures in western Europe and the United States: and these inspired the activity in behalf of the minority provisions of the treaty of Versailles after the close of World War I. which granted minority rights to the Jews as well as to other national minorities, and which placed these minorities under the protection of the League of Nations. *(See* also DIASPORA.)

(K. S. P.)

DUBOIS, (MARIE) EUGÈNE (FRANÇOIS THOMAS) (1858–1940), Dutch discoverer of Java man. was born at Eisden, Limburg, on Jan. 28. 1858. He studied medicine at Amsterdam. where he was appointed university lecturer in anatomy in 1886. and investigated the comparative anatomy of the larynx in vertebrates. He was, however, becoming more and more preoccupied with problems of human descent and attempted to obtain a government commission for paleoanthropological work in the East Indies, but without success. He therefore resigned his university post, against all advice, to become in 1887 military surgeon in the East Indies and. while stationed at Pajokumbu in Sumatra. began to excavate caves. first at his own expense. then with government support. Unsuccessful in his search for early human remains. he moved to Java, where in 18'30 at Kedung Brubus near Trinil, he found a jaw fragment, the following year a skullcap and subsequently a thighbone. remarkable in that they represented a small-brained creature intermediate between ape and man which had already attained an erect posture. In 1894 he published his discovery as *Pithecanthropus erectus (see* PITHECANTHROPUS; MAN, EVOLUTION OF: *Pithecanthropus*). He returned to Europe in 1895, subsequently to become professor of geology at Amsterdam. Annoyed at criticism of his material, he withdrew it from all examination: and only in 1923. after an appeal by Henry Fairfield Osborn to the president of the Dutch Academy of Sciences. was Ales Hrdlicka invited to see the original bones. It was not until 1920 that Dubois published the finds he had made at Wadjak in 1889–90. He died at de Bedelaer on Dec. 16. 1940. (D. F. R.)

DUBOIS, FRANÇOIS CLÉMENT THÉODORE (1837–1924), French composer. organist and teacher. known for his technical treatises on harmony, counterpoint and sight reading. Born at Rosnay (Marne), on Aug. 24. 1837, he studied at Reims under the cathedral organist and at the Paris Conservatoire under Ambroise Thomas. After winning the Prix de Rome in 1861 he succeeded César Franck as organist at the church of Ste. Clotilde. In 1868 he was choirmaster at the Madeleine and later succeeded Saint-Saëns as organist there. He was professor of harmony at the Paris Conservatoire (1871–90), elected to the French Institute (1894) and followed Thomas as director of the Conservatoire (1896–1905). He wrote music of all types, including operas and choral and orchestral works. He died in Paris on June 11, 1924.

DUBOIS, GUILLAUME (1656–1723), French cardinal, the leading minister of the regent Philippe, duc d'Orléans, and the architect of the Anglo-French alliance of 1716, was born at Brive. in Limousin, on Sept. 6, 1656, the son of an apothecary. Entering the church, he rose to influence at the French court as a tutor to the families of the nobility. In this capacity he was entrusted with the education of the duc de Chartres, the future duc d'Orléans. When the latter, during the minority of Louis XV, became regent and effective ruler of France, Dubois, at the age of 60, saw his opportunity of rising to high civil and ecclesiastical office. He was a man of great ability and finesse with a flair for intrigue and a settled determination to become a second Richelieu. Unscrupulous in the choice of means and immoral in his private life, Dubois had great foresight and courage and some of the higher qualities of statesmanship. He sought and obtained political power by devoting himself to the promotion of the dynastic interests of his patron the regent, becoming his secret adviser and agent in matters of foreign policy.

Dubois conceived and largely carried out the idea of a diplomatic revolution, uniting France and Great Britain in an alliance which lasted from 1716 to 1731. This *rapprochement* was designed mainly in the dynastic interests of the house of Orléans in France and the house of Hanover in Great Britain. The ground for it was prepared, in July 1716, by Dubois' secret mission to The Hague, where he met the English minister James Stanhope. A further mission to Hanover a month later resulted in the conclusion of the convention of Hanover of Oct. 9, 1716. In this Dubois showed his willingness to sacrifice what were generally regarded as French interests by agreeing to expel James the Old Pretender from French soil, to destroy the fortifications of Mardyck, and to recognize the Protestant succession in England. In return Dubois only obtained the confirmation of the treaties of Utrecht and the guarantee of British support for the pretensions of the regent Orléans to the succession to the French crown, in case of the death of the young and sickly Louis XV. On Jan. 4, 1717,

Dubois induced the United Provinces to adhere to this alliance, which thus became the triple alliance, by reducing French tariffs on Dutch imported cloth.

In reward for these achievements Dubois was admitted as an official member of the French council of foreign affairs. Dubois then assisted Stanhope in associating the emperor Charles VI in the triple alliance in the effort to check Spanish aggressive designs in Italy and Swedish ambitions in Norway. The quadruple alliance of Aug. 2, 1718, concluded at London, once more provided reciprocal guarantees of the dynastic interests and claims of the houses of Hanover and Orléans. It attempted to reconcile Austrian and Spanish claims in Italy by allowing the emperor Charles VI to exchange Sardinia for Sicily and by conceding the duchy of Parma to Don Carlos, the eldest son of Philip V of Spain and his second wife Isabella Farnese. When Cardinal Giulio Alberoni, in control of Spanish policy, attempted to advance Spanish territorial ambitions unilaterally by invading Sardinia and Sicily, Dubois joined Great Britain in attacking Spain and forced Philip V to accept the terms of the quadruple alliance and to dismiss Alberoni in 1720. Also in 1720 the French sent representatives to Stockholm to persuade the Swedes to sign peace with the Russians, which they did at Nystadt in 1721.

Timely calculation and opportunism in the later stages of his career enabled Dubois to fulfill all his material ambitions. With his credit firmly established by his successes in diplomacy, Dubois helped to put an end to the experiment in conciliar government (the so-called *Polysynodie*) and, after the reversion to the secretarial system of Louis XIV, he became minister of foreign affairs in Sept. 1718. When John Law's financial system crashed in 1720 Dubois survived politically by drawing nearer to the representatives of the old court of Louis XIV and by pursuing a more popular pro-Spanish foreign policy, which resulted in the conclusion of the Franco-Spanish treaty of March 27, 1721. He remained, however, faithful to the English connection throughout. His support of the recognition of the papal bull *Unigenitus* against the Jansenists, as well as lavish bribery at the papal curia, made possible further ecclesiastical preferment. Dubois was elevated to the archbishopric of Cambrai in 1720 and became a cardinal in July 1721. In Aug. 1722 he was made *premier ministre*. He died at Versailles on Aug. 10, 1723.

DUBOIS, JEAN ANTOINE (1765–1848), French Roman Catholic missionary in India, was born at St. Remèze in 1765 and ordained in 1792, sailing for India in the same year under the Missions Étrangères. Despite his strongest efforts in many parts of south India. his mission failed, and he returned to Paris in 1823, convinced that the conversion of the Hindus could not be accomplished. In Paris he became director of the Missions Étrangères, and later superior (1836–39). He translated the *Panchatantra* into French (1826), and also a work called *The Exploits of the Guru Paramarta.* His best-known work was his *Description of the Character, Manners and Customs of the People of India,* which was bought and printed by the East India company (1816); an enlarged edition was published in France in 1825 under the title *Moeurs, institutions et cérémonies des peuples de l'Inde.* Abbé Dubois died on Feb. 17, 1848.

DUBOIS, PAUL (1829–1905), French sculptor and painter whose style combined 15th-century Florentine elegance and the academic, detailed naturalism of the mid-19th century, was born in Nogent-sur-Seine on July 18, 1829. He studied with F. C. A. Toussaint, at the École des Beaux-Arts and in Italy from 1859 to 1862. He achieved his first success in 1865 with his statue "A Florentine Singer," which is indicative of the general character of his style. He exhibited a "Virgin and Child" among other works at the Paris exposition of 1867. In 1876–78 he completed his most important commission, the tomb of General Lamoriciere, in the cathedral of Nantes. The work reveals his Renaissance predilections, both Italian and French, with its canopied tomb and four allegorical figures representing Military Courage, Charity, Faith and Meditation in bronze at the corners. His greatest success was the statue of Joan of Arc (1889–95) before Reims cathedral, in which the artist attempted to represent both Joan's role as a military leader and her visionary qualities. A member of the Academy of Beaux-Arts, he became *concierge* of the Luxembourg in 1873 and director of the École des Beaux-Arts in 1878. He died on May 25, 1905, at Paris. (L. W. N.)

DUBOIS, PIERRE (*c.* 1250–*c.* 1320), French lawyer and political pamphleteer in the reign of Philip the Fair, whose most important treatise, *De recuperatione Terre Sancte* (*c.* 1306), while ostensibly outlining the conditions for a successful crusade, actually dealt with a wide range of political issues. Dubois studied at the University of Paris and became a successful lawyer in Coutances (Normandy), probably his birthplace. By about 1300 he was advocate of royal cases and he represented Coutances in the estates-general of 1302 and 1308. His brief career of authorship is significant: not because he expressed or demonstrably influenced royal policies, but because he was one of the more intellectually adventurous of contemporary pamphleteers, and perhaps the earliest of the great French lawyers who sought an active role in politics.. The theme underlying all his works was that of the twofold opportunity of the king: to create peace in Europe by claiming for France the position of leadership traditionally reserved in political thought for the empire, but left vacant by the weakness of successive emperors; and to create peace in France by reviving royal authority in all aspects of administration, and particularly by resumption of the property and jurisdictions of the church. He also recommended replacement of the papal patrimony by an annual pension, abolition of clerical celibacy, and the radical reformation of French education, law and administration.

BIBLIOGRAPHY.—Dubois's treatises include *Summaria brevis et compendiosa doctrina felicis expedicionis et abreviacionis guerrarum ac litium regni Francorum* (1300); *Raciones inconvincibiles* (1302); *Deliberatio* (1302), *La Supplication du pueuble de France au Roy, contre le Pape Boniface le VIII* (1304); and two attacks upon the Templars (1308). *See* also E. Zeck, *Der Publizist Pierre Dubois* (1911); J. Rivière, *Le Problème de l'église et de l'état au temps de Philippe le Bel* (1926); W. I. Brandt, *The Recovery of the Holy Land* (1956).

DU BOIS, WILLIAM EDWARD BURGHARDT (1868–), U.S. author, editor and Negro leader, was born in Great Barrington, Mass., on Feb. 23, 1868. He was proud of his French and Dutch ancestry but identified himself with Negroes. Du Bois received the Ph.D. degree from Harvard university in 1895 and wrote the first monograph in the *Harvard Historical Series,* "The Suppression of the African Slave-Trade to America" (1896). This volume, *The Philadelphia Negro* (1899), and his *Atlanta University Studies* (1897–1911) were his most scholarly publications. *Souls of Black Folk* (1903) established his reputation as a superb stylist and crystallized the revolt of Negro intellectuals against the compromises of Booker T. Washington. The Niagara movement, which he founded in 1905, evolved into the National Association for the Advancement of Colored People by 1910. As editor from 1910 to 1932 of the association's organ, *Crisis,* his invectives against the injustices inflicted upon Negroes created new concern for the shortcomings of American democracy and made him the idol of most of the leading Negro intellectuals of the first half of the 20th century. He was professor of economics and history at Atlanta university (1897–1910) and head of the department of sociology at Atlanta university (1932–44). At the first Pan-African conference, London, 1900, he urged the liberation of African colonies and led this movement in four later Pan-African congresses, 1919, 1921, 1923 and 1927. Du Bois was an authentic American radical until the 1940s when he espoused pro-Soviet doctrines. He and Kwame Nkrumah were co-chairmen of the fifth Pan-African congress in 1945. In 1947 he published *The World and Africa* and, in 1952, *In Battle for Peace.* Du Bois, at the age of 93, joined the Communist party in Nov. 1961.

Although short in stature, his massive head, Van Dyke beard and Prussian-like mustache (a reminder of his student days in Germany), incisive eloquence and encyclopaedic knowledge made Du Bois an almost Olympian public speaker. Somewhat arrogant and

at times bitter in public, his sophisticated wit and charm delighted his few close friends.

See Francis L. Broderick, W. E. *B. Du Bois, Negro Leader in a Time of Crisis* (1959); W. E. Burghardt Du Bois, "My Evolving Program for Negro Freedom" in Rayford W. Logan (ed.), *What the Negro Wants* (1944). (R. W. LN.)

DUBOIS-CRANCÉ, EDMOND LOUIS ALEXIS (1747–1814). French soldier and statesman, eminent as a specialist on military problems during the Revolution, was born at Charleville on Oct. 17, 1747, of an ancient family of Champagne. After attending the college at Charleville, he entered the musketeers of the king's guard in 1762. When this corps was disbanded in 1775, he retired to Châlons-sur-Marne. In April 1789, he was sent to the estates-general as deputy for the third estate of the *baillinge* of Vitry-le-François.

Dubois-Crancé was a resolute defender of the interests of the third estate, and an active member of the Constituent Assembly. He did much to promote the taking of the Tennis Court oath (June 20, 1789). He distinguished himself in the military committee and on Dec. 12. 1789, in the discussion on recruitment, upheld the need for a national army. Having commanded a battalion of the Parisian national guard from May 1791, he returned to the army after the ending of the Constituent Assembly and was promoted to adjutant-general on Sept. 9, 1792. A few days later he was elected deputy to the Convention by the *département* of the Ardennes.

After the opening of the Convention. Dubois-Crancé was sent on missions to the armies of the Midi and of the North. He entered the committee of general defense on Jan. 3, 1793. In the trial of Louis XVI he voted the death of the king without reprieve. On Feb. 21. 1793. he obtained a vote in favour of the *amalgame* or system of *embrigadement* whereby *demi-brigades* were to be formed by joining together two battalions of national volunteers and one battalion of regulars of the former royal army. The purpose of this plan was to combine the revolutionary patriotism of the volunteers with the experience and discipline of the regulars.

One of the most important episodes of Dubois-Crancé's career occurred during his mission to the army of the Alps (from April 30, 1793). When Lyons rebelled against the Convention, Dubois-Crancé, who had the rank of general of division from May 15, prompted F. C. Kellermann to undertake the siege and was largely responsible for the fall of the town on Oct. 9, 1793, though he was recalled to Paris three days earlier.

Recalled to Paris by the Jacobins, Dubois-Crancé resumed his seat on the military committee of the Convention. On Feb. 5, 1791. he was sent to enforce this policy in the armies of the West and Côtes de Brest.

Having been attacked by Robespierre and Georges Couthon in the Jacobin club during the crisis of the spring of 1794, Dubois-Crancé joined the Thermidorians after Robespierre's fall but abandoned them in the spring of 1795. He opposed the suggestion of a bicameral system in the debates on the Constitution of the Tear III. He also called for strong measures against the royalist insurrection of Oct. 1795.

Under the Directory, Dubois-Crancé sat in the Council of the Five Hundred till May 1797. He then returned again to the army and was appointed inspector-general of the infantry of the army of the Rhine in Sept. 1798. He was minister of war in 1799 from Sept. 14 to the *coup d'état* of Brumaire (November), in which he played no part. Dubois-Crancé was then put on the retired list and withdrew first to Balham (Ardennes) and then to Rethel in 1809, where he died on June 29, 1814.

See T. Iung, *L'Armee et la Révolution: Dubois-Crancé,* 2 vol. (1884). (A. So.)

DU BOIS-REYMOND, EMIL (1818–1896), German physiologist and philosopher who conducted important studies of the electrical activity of nerve and muscle at a time when Galvani's work on animal electricity had fallen into disrepute, was born in Berlin, Nov. 7, 1818. Du Bois-Reymond's book on electrophysiology (*Untersuchungen über tierische Elektricität*) appeared in 1818 and created modern scientific electrophysiology. He was a pupil of Johannes Müller, whom he succeeded in the chair of physiology in Berlin. He died in Berlin. Dec. 26, 1896. Du Bois-Reyniond. Hermann von Helmholtz, Carl Ludwig and Ernst von Brücke led a biophysics program that attempted to reduce physiology to applied physics and chemistry. The program did much to purge physiology of vitalistic thinking and also influenced Freud's psychological theories. Philosophically Du Bois-Reymond was a materialist; he was not important among professional philosophers but his lectures had a wide popular audience. He conducted many polemics, both in science and philosophy.

BIBLIOGRAPHY.—Heinrich Boruttau, *Emil du Bois-Reymond* (1922); Siegfried Bernfeld, "Freud's Earliest Theories and the School of Helmholtz" *Psychoanalytic Quarterly,* 13:341–62 (1944); Paul Cranefield. DU BOS, CHARLES (1882–1939), French critic whose work is of particular interest for its understanding of English literature and for its emphasis on the relation between literature and psychology. Born in Paris. Oct. 7, 1882, Du Bos had an English mother and was educated at Oxford. His books on Shakespeare, Shelley and Byron, and many of his stylish *Approximations* (7 series. 1922–39) helped to make English literature better known in France; his *Journal Intime* (3 vol., 1946–49) was written partly in English and is a sensitive account of a spiritual development which brought him into the Roman Catholic Church in 1927. His other books include *Le Dialogue avec Andre' Gide* (1929; 2nd ed., *Lettres de Charles du Bos et réponses d'André Gide,* 1950); *Qu'est-ce que la litte'rature* (1945); and studies of Flaubert, Goethe and Merimée.

Du Bos died at Celle-St. Cloud, Aug. 5, 1939.

See M.-A. Gouhier, *Charles Du Bos* (1951); *A.* P. Bertocci, *Charles Du Bos and English Literature* (1949).

DUBROVNIK (Ital. RAGUSA), a port of Dalmatia, Yugos., is situated on the southern part of the Adriatic coast, 579 km. (360 mi.) S.W. of Belgrade by road. Pop. (1961) 22,961.

Dubrovnik is the most picturesque city on the Yugoslav coast, occupying a promontory jutting out into the sea under the bare limestone mass of Mt. Srdj. The sea fortifications rise directly from the water's edge and a massive round tower dominates the city on the landward side. Beyond the walls. mostly a double line, which have always been the pride of Dubrovnik. are many villas surrounded by gardens. The Stradun (Stradone) or main street, with beautiful late Renaissance houses on either side, runs along a valley which, until the 13th century, was a marshy channel dividing the Latin island of Ragusa from the forest settlement of Dubrovnik (*dubrova* in Serbo-Croat means "woody"). No motor vehicles are allowed inside the walls and, except for the Stradun. the old city is a maze of picturesque narrow streets, many of them steep and twisting. Two 14th-century convents stand at the ends of the city, for the Franciscans were set to guard the western gate while the Dominicans kept the eastern one. The rector's palace is one of the masterpieces of Dalmatian architecture. Lokrum, an offshore island, is famous for its gardens and orange groves.

Dubrovnik is connected to Sarajevo and Belgrade by narrow-gauge railway. From its new harbour at nearby Gruz. ships ply to other Dalmatian ports and to Italy. The main industries are the manufacture of liqueurs, cheese, silk. leather, thread: metalwork and soap, oil refining, slate mining and tourism.

Ragusium was founded by Roman refugees from Epidaurus (mod. Cavtat, 12 mi. S.E. of Dubrovnik) fleeing from the advancing Slav tribes. A colony of Slavs soon joined the Latin settlers at Ragusa and thus from an early date the city formed a link between two great civilizations. During the 9th to the 12th centuries Dubrovnik defended itself against attacks by foreign powers, but from 1205 to 1358 it acknowledged Venetian suzerainty, although keeping much of its independence. To refugees of all nations (one of them was the English king Richard I) the city-republic afforded asylum, and by means of treaty and tribute it enlarged its territory until it stretched from the mouth of Boka Kotorska to the town of Ston about 70 mi. N. It achieved a position of great mercantile power, being conveniently situated at the seaward end of a great trade route which divided at Pljevla to go to Byzantium and the Danube. Ragusan land trade flourished throughout the Balkans and colonies were founded in all the big

BY COURTESY OF YUGOSLAV INFORMATION CENTER

DOUBLE WALLS AND THE TOWER OF LOVRJENAC, 14TH–16TH CENTURIES. DUBROVNIK

towns. Sea trade also developed and in the 16th century had reached to America and India. From 1358 to 1526 Dubrovnik was a Hungarian vassal state; later it had to pay tribute to Istanbul. having great trade concessions in the Ottoman empire. For centuries, however, the inhabitants of Dubrovnik were able to preserve their city-republic by skilful maneuvering between east and west. Having treaty obligations to Spain, they sent their men-of-nar to the Armada of Philip II which tried to invade England in 1588.

A great development of art and literature, beginning in the 15th century and continuing into the 17th, earned Dubrovnik its title of the "South Slavonic Athens." For the first time in the history of the South Slavs the language of the people was introduced into literature by Dubrovnik's poets, among them Ivan Gundulic (1588–1638).

In 1667 an earthquake destroyed a considerable portion of the city and about one-fifth of the inhabitants. Only during the Napoleonic Wars did the republic regain its prosperity. From 1800 to 1805, as the only neutral Mediterranean state, it secured a large share of the carrying trade. Napoleon subjugated Dubrovnik in 1808, and in 1814 it was annexed to Austria. In 1918 it was incorporated in Yugoslavia. In World War II it was in Italian and German hands from 1941 to 1944. (V. DE.)

DUBUQUE, a city in Iowa, U.S., seat of Dubuque county, is on the Mississippi river opposite the boundary line between Wisconsin and Illinois, about 70 mi. N. of Davenport. The business district occupies the lowlands along the river; on the bluffs which rise above it are residential sections The surrounding area, shaped by streams cutting into bedrock. is notably picturesque

The city, one of the oldest in Iowa, was named for Julien Dubuque, a French trader, who in 1788 concluded a treaty with the Fox Indians giving him the right to mine lead in the area. After Dubuque's death in 1810 the Indians refused to give other white men mining concessions. It was only after the Black Hawk treaty of 1832 that settlers 'crossed the river to establish the village of Dubuque.

Municipal government dates from 1837 when the settlement was incorporated. It was chartered in 1841 and a mayor and board of aldermen were elected. The council-manager plan of government was adopted in 1920.

Lead mining and sawmilling were the pioneering industries, but with the development of river and rail transportation, Dubuque became a centre of diversified industry, undergoing expansion at mid-20th century. Among products manufactured are furniture, millwork, tractors, oil-well equipment, pumps and pumping supplies, dry batteries, clothing, packed meats, insecticides, fertilizers, boats and barges. A municipal river-rail terminal is operated by the dock commission.

In the main, residents'are of German, Irish, English and Luxembourgian descent. In 1893 Dubuque was made an archdiocese of the Roman Catholic Church, which maintains Loras college (founded in 1839 as St. Bernard's seminary) and Clarke college (1843). Dubuque university (founded in 1852 as the German Theological School of the Northwest) receives support from the Presbyterian Church. Wartburg Theological seminary (1852) is a Lutheran institution. Old world influences can be seen in New Melleray abbey, 10 mi. S.W., founded in 1849 by Trappist monks from Mount Melleray monastery, Ireland, and in the city market patterned after the market of Luxembourg.

Other points of interest include Julien Dubuque's grave; a shot tower used during the American Civil War; the Fourth street elevator, an inclined cable car built in 1884; and Eagle Point park, covering 165 ac. within the city. Pop. (1960) city, 56,606; standard metropolitan statistical area (Dubuque county), 80,048. For coniparative population figures *see* table in IOWA: *Population.*

(P. W. GL.)

DU CAMP, MAXIME (1822–1894), French writer, a close friend of Gustave Flaubert and a pioneer of amateur photography, was born in Paris, Feb. 8, 1822. He traveled widely with Flaubert (1844–45 and 1849–51), and his *Égypte, Nubie, Palestine et Syrie* (1852) was one of the first travel books illustrated with photographs. In 1848 he was decorated for counterrevolutionary activity. His *Expéditions des deux Siciles* (1861) recounted his experiences as a volunteer with Garibaldi. In 1851 he was one of the founders of the *Revue de Paris.* He also contributed to the *Revue des deux mondes.* His writings included poems *(Chants modernes,* 1855); art criticism; novels; a monograph on Théophile Gautier; and tao volumes of *Souvenirs littkraires* (1882–83), interesting for the light they throw on contemporary literary life, and especially on Flaubert. Du Camp died at Baden-Baden, Ger., Feb. 9, 1894.

DU CANGE, CHARLES DU FRESNE, SIEUR (1610–1688), outstanding lexicographer, one of the group of great French scholars of the 17th century who laid the foundations of modern historical and linguistic criticism, was born on Dec. 18, 1610, at Amiens, where he was educated at the Jesuits' college. Later he read law at Orléans. In 1631 he began practice as an advocate at the parliamentary bar in Paris, but soon returned to Amiens where after some years he succeeded his father-in-law in the office of treasurer (1645–68). A severe epidemic made him leave Amiens in 1688; he spent the rest of his life in Paris where he died Oct. 23, 1688. A person of great charm and modesty, he enjoyed the friendship of many of the best scholars of the age.

He was a polymath and a prodigious worker, equally at home in the study of language, history, law, paleography, numismatics and topography. His contributions to Byzantine and older French history (some still unpublished) are considerable. But his chief works are his dictionaries of medieval Latin and Greek, the *Glossarium ad scriptores mediae et infimae latinitatis* (1678) and the *Glossarium ad scriptores mediae et infimae graecitatis* (1688). They are based on the primary material gathered in the course of reading over many years. Their aim is to treat language historically, that is, to distinguish the Latin and Greek vocabularies of the post-classical ages from their classical counterparts. But they are encyclopaedias rather than dictionaries in that Du Cange tends to illustrate from documents and primary sources not only the words but also the matters described by the words. The diffi-

culty of the task may be gathered from the amount of the material, and from the small number of predecessors Du Cange had in preparing the Latin glossary and the virtually complete lack of them in preparing the Greek glossary. It is a measure of his achievement that scholars were content for more than two centuries to produce either reprints or enlarged editions of Du Cange's works rather than new books. The Greek glossary was reprinted in 1958 and L. Favre's ten-volume edition (1883–87) of the Latin glossary in 1954. Preparations for a new Latin "Du Cange" have, however, been made by the International Union of Academies and the first installment of the *Novum glossarium mediae Latinitatis* appeared in 1959.

See M. Esposito in F. Cabrol (ed.), *Dictionnaire d'archéologie chre'tienne et de liturgie,* vol. 4, col. 1654–60 (1921). (C. O. BR.)

DUCAS (DUKAS or DOUKAS), the name of a Byzantine family which supplied several rulers to the empire. The family first came into prominence during the 9th century, but suffered a setback when Constantine Ducas, the *domesticus* of the *scholae,* son of the general Andronicus Ducas. lost his life in attempting to become emperor in 913. Toward the end of the 10th century there appeared another family of Ducas. which was perhaps connected with the earlier family through the female line. A member of this family became emperor as Constantine X in 1059, and Constantine's son Michael VII ruled from 1071 to 1078. Michael's son Constantine was nominally co-emperor with Alexius I Comnenus from 1081 to about 1090 and was betrothed to his daughter Anna Comnena but did not live to marry her. The Ducas family continued to take an active part in public affairs. In 1204 Alexius V Ducas. called Murtzuphlus, deposed the emperor Isaac II Angelus and his son Alexius IV, and vainly tried to defend Constantinople against the Latin crusaders. In the mid-14th century one Michael Ducas took a leading part in the civil war between the emperors John V Palaeologus and John VI Cantacuzenus, and Michael's grandson was the historian Ducas (*q.v.*). Many of the rulers who arose after the destruction of the Byzantine empire sought to gain prestige by adding the famous name of Ducas to their own.

See C. *Du* Cange, *Historia Byzantina,* pp. 160-166 (1680). (J. M. HY.)

DUCAS (15th century A.D.), Byzantine historian, wrote a vernacular history of the period 1341–1462 in a journalistic style. The dates of his birth and death are unknown but he was the grandson of Michael Ducas (*see* above) and flourished under Constantine XI Dragases. the last Byzantine emperor (1448–53). He strongly supported the union of the Greek and Latin churches and was bitter against those who refused to appeal to the west for assistance against the Turks. After the fall of Constantine, he was employed in diplomatic missions by Dorino and Domenico Gattilusio, Genoese rulers of Lesbos, where he had taken refuge. He survived the annexation of Lesbos by the Turks in 1462, but no more is known of him. His work is often careless and inaccurate. and his value as a source for the closing years of the Greek empire and the cauture of Constantinople has been overestimated.

BIBLIOGRAPHY.—For the history *see* edition by I. Bekker in Bonn *Corpus scriptorum hist. Byz.* (1834), and J. P. Migne, *Patrologia Graeca,* vol. clvii (1866). The Bonn edition contains a 15th-century Italian translation by an unknown author, found by L. Ranke in one of the libraries of Venice and sent by him to Bekker. This version fills in some of the lacunae in the original Greek. *See* also K. Krumbacher, *Geschichte der byzantinischen Litteratur,* pp. 305–307 (1897); G. Moravcsik, *Byzantinoturcica,* vol. i, 2nd ed., pp. 247–251 (1958). (J. M. HY.)

DU CASSE, PIERRE EMMANUEL ALBERT, BARON (1813–1893), French soldier and writer on military subjects, known for his editions of the correspondence of Kapoleon I (1852. 1855, 1887). He was born at Bourges. Nov 16. 1813. educated at St.-Cyr, and in 1849 became aide-de-camp to Prince Jerome Bonaparte, formerly king of Westphalia and then governor of the Invalides. He was attaché to Jerome's son. Prince Napoleon, during the Crimean War and was employed by him to edit the correspondence of Kapoleon I Subsequently *Les Rois frères de Napoléon* (1883) and the *Journal de la reine Catherine de Westphalie* (1893) collected letters nhich had been omitted. They were edited with little care and are not entirely trustworthy, but their publication threw light on Napoleon I and his entourage. Du Casse was also employed by Jerome Bonaparte and his son to compile historical accounts of their lives.

DUCASSE, ROGER JEAN JULES AIMABLE (1873–1954), French composer and teacher known as Roger-Ducasse. Born, Aug. 18, 1873, at Bordeaux, he was a pupil of Fauré at the Paris Conservatoire and won the second Prix de Rome in 1902. He was inspector of music in the municipal schools of Paris and from 1935 to 1940 professor of composition at the Conservatoire. His works include tno operas, *Orphée* (1926) and *Cantegril* (1931), two quartets, the orchestral works *Suite française* (1909) and *Le Joli Jeu de furet* (1920). motets, works for chorus and orchestra and technical studies for the piano. In 1940 he resigned from the Conservatoire and in 1945 retired to his estate in the Gironde. He died at Taillan, near Bordeaux, July 20, 1954.

See L. Ceillier, *Roger-Ducasse* (1920).

DUCCIO DI BUONINSEGNA (c. 1255–*c.* 1318), Italian painter, was the first great master of the Sienese school. He is mentioned in Siena in 1278, when he was employed to decorate 12 cases in which public documents were kept. He was still active in Siena in 1279 and 1280, and in 1285 received a commission from the Compagnia dei Laudesi for an altarpiece in Sta. Maria Novella, Florence. Since his name does not occur in Siena between 1280 and 1285, he may have been active in these years outside his native town Between 128j and 129j he received a number of payments in Siena for painting book covers and other work, and in the latter year was involved (with the sculptor Giovanni Pisano and other artists) in discussions regarding the site of the Fonte Nova. In 1302 Duccio was paid for an altarpiece of "The Virgin and Child With Saints" for the chapel of the Palazzo Pubblico, Siena, and in 1308 received the commission for a second altarpiece of the same subject for the high altar of the cathedral. This was completed by June 9, 1311, uhen, attended by rejoicing crowds, it was installed in the cathedral.

Duccio was still resident in Siena two years after the completion of this altarpiece, and died there probably during 1318, and in any event before Xug. 3, 1319 Duccio was probably trained in the workshop of Guido of Siena. His early activity is conjectural, but is perhaps represented by a "Virgin and Child" from Crevole, now in the Museo dell'Opera del Duomo. Siena.

The altarpiece commissioned from Duccio by the Compagnia dei Laudesi in 1285 is almost certainly identical with the celebrated "Ruccellai Madonna" formerly in Sta. Maria Novella, Florence, and now in the Uffizi gallery. The idiom of this work was profoundly influenced by Cimabue, to whom it uas long ascribed. It reveals a capacity for large-scale composition, a rich and individual sense of colour and a mastery of linear design which distinguished it from other paintings of its time. Strong Cimabuesque elements are also present in the scenes and figures on the rose window at the east end of Siena cathedral nhich has been tentatively ascribed to Duccio and dates from 1287–88 These elements were much reduced in a somewhat later work the small "Madonna of the Franciscans" in the Siena gallery. where the style perhaps reflects that of Byzantine illuminations. In two pictures painted at about the turn of the century. a triptych in the National gallery. London. and a "Madonna" at Perugia, Duccio developed an expressive style which looked forward to that of the "Maestà."

The Palazzo Pubblico altarpiece of 1302 is lost, and the "Maestà," the great double-sided altarpiece painted for the cathedral in 1308–11. is thus Duccio's only fully authenticated work. One of the largest altarpieces of its time, it consisted of a wide frontal panel aith the Virgin and Child adored by the patrons of Siena and surrounded with saints and angels Beneath was a predella with seven scenes from the childhood of Christ and above were pinnacles with scenes from the life of the Virgin. nhile on the back were scenes from the life of Christ betneen the Baptism and the Ascension. It included in all 59 narrative scenes. The main panel and the bulk of the narrative scenes are now in the Museo dell'Opera del Duomo. Siena, but isolated panels from the altarpiece have found their way to the National gallery. London, the Frick collection, New York city. and the National Gallery of Art, Washington, D.C.

ALINARI

"RUCCELLAI MADONNA" BY DUCCIO DI BUONINSEGNA, 1285. IN THE UFFIZI GALLERY. FLORENCE, ITALY

The central panel of the "Maesti" was more solidly constructed than the "Ruccellai Madonna"; a marble throne was substituted for the wooden throne of the earlier panel, and the figures were arranged in depth. There was a new humanity in the relation of the Virgin and Child. In the "Maestà" the Byzantine-Romanesque style of Duccio's early years evolved in the direction of Gothic art, and in the lateral figures the influence of the Gothic sculptures of Giovanni Pisano can be clearly seen. Gothic influences are less evident in the narrative scenes. When contrasted with the contemporary "Scenes From the Life of Christ" by Giotto at Padua these appear archaic and traditional. but they were treated with great intensity and reveal the master as one of the most eloquent narrative artists of all time. By virtue of its prominent position in the cathedral, of the range of scenes depicted in it, and of the beauty of its colour, the "Maesti" dictated the course of Sienese painting throughout the 14th century, and reflections of Duccio's motifs are encountered in Siena for more than 150 years after its completion. Nothing is known of Duccio's style after the completion of the "Maesti," but it is possible that a triptych of "The Crucifixion" in the English royal collection was painted in the artist's workshop after this time. Other works attributable to Duccio or his studio include a small "Madonna" at Berne and two polyptychs in the Siena gallery.

See C. H. Weigelt, *Duccio di Buoninsegna* (1911); C. Brandi, *Duccio* (1951). (J. W. P.-H.)

DUCETIUS (d. 440 B.C.) was a hellenized Sicel from Menae in Sicily who in the middle of the 5th century B.C. welded the native communities of east Sicily for a short time into a powerful force. He seized his opportunity in the general dislocation that followed the collapse of tyranny in Syracuse and other Sicilian states. At first enjoying the good will of the Syracusan democracy, he acted with them in driving out Hiero's colonists from Catana (which Hiero had renamed Etna) and restored it to its former Chalcidian inhabitants. Hiero's colonists went to Inessa about 10 mi. N.W. of Catana, at the foot of Mt. Etna and renamed the town Etna. He then extended his influence over other Sicel communities. founded a new Sicel centre at Palici next to a traditional Sicel sanctuary, and pursued an independent policy, which led to a combination against him of the forces of Syracuse and Acragas. After minor preliminary successes (including the capture of Inessa-Etna from its Greek colonists) he was decisively defeated by their combined forces in 450 and lost the confidence of the Sicels. On the strength of earlier connections he took refuge in Syracuse and was sent to Corinth. In 446 he returned to Sicily. perhaps with the blessing of Syracuse, now at war with Acragas, and colonized Cale Acte on the north coast with Greeks and Sicels. From this centre he attempted to build up again a unified Sicel power, but he died in 440 before his work was complete.

See *Diodorus,* xi, 76, 78, 88–92; xii. 8, 29.

DUCHAMP, MARCEL (1887–), French-U.S. artist, most famous for his paintings but also an important contributor to modern sculpture with his "ready-mades," was born at Blainville (Seine-Infkrieure), on July 28, 1887. His older brothers, Jacques Villon and Raymond Duchamp-Villon (*q.v.*), were also well-known artists. The work by which Duchamp is best known, the "Nude Descending a Staircase," in the Cubist manner, created a sensation at the 1911 Salon des Indépendants show and two years later at the Armory show in New York. In his "ready-mades" (typically, a wine bottle rack, a urinal and cubes of sugar in a cage, titled "Why Not Sneeze?") Duchamp assaulted the traditional preconceptions and values of art. He was in sympathy with the Dadaists and Surrealists, who protested against public taste and reason as the ruling principles of art. Duchamp moved to New York in 1915 (he became a U.S. citizen in 1955) and in 1923 abandoned painting, devoting his time thereafter largely to chess.

See Carola Geidion-Welcker, *Contemporary Sculpture* (1955). (A. E. EL.)

DUCHAMP-VILLON, RAYMOND (1876–1918), French sculptor, whose most important contribution to the art is represented in the series entitled "The Horse" (1914), was born in Paris on Nov. 5. 1876, a member of a highly talented family that included the painter Jacques Villon and the painter-sculptor Marcel Duchamp (*q.v.*), his brothers. Like the Cubists, Duchamp-Villon upheld the sovereignty of the artist's mind over the work of art and rejected descriptive sculpture. His sculpture is of horsepower, and he reconstructs the force and movement of the machine and of a horse with suggestively coiled and pistonlike shapes. His compact, hard and smoothly shaped head of "Baudelaire" (1911) shows his movement away from imitative portraiture and favouring of strong, personally derived shapes. In his "Seated Woman" (1914) and "Head of a Woman," Duchamp-Villon moved toward simple combinations of more abstract shapes which stressed the human head and body as aesthetic objects. His ideas extended into Cubistlike architecture. He died at Cannes on Oct. 7, 1918.

See Carola Geidion-Welcker, *Contemporary Sculpture* (1955). (A. E. EL.)

DUCHENNE, GUILLAUME BENJAMIN AMAND (1806–1875), French physician who was the forerunner of modern neurology, was born on Sept. 17, 1806, at Boulogne. He studied medicine in Paris and in 1833 first tried the effect of electropuncture of the muscles on a patient under his care; from then on he devoted himself to electrophysiology and neurology. His most famous work was *L'Electrisation localisée* (1855), though his Physiologie des *mouvements* (1867) is considered his masterpiece by many. He published the results of his researches on muscular and nervous diseases and on the applications of electricity both for diagnostic purposes and for treatment. His name is connected with the first description of *tabes* dorsalis, progressive muscular atrophy, pseudohypertrophic muscular paralysis, glossolabiolaryngeal (bulbar) paralysis and other nervous troubles. He died in Paris on Sept. 15, 1875.

DUCHESNE, ANDRÉ (Latinized ANDREAS CHESNEUS or QUERCETANUS) (1584–1640), French historian, has been called the

father of French history. He was born at Isle-Bouchard in Touraine in May 1584 and spent his whole life in scholarship. being appointed geographer and historiographer royal through Richelieu's influence. He died in a road accident near Paris on May 30, 1640. The principal works by Duchesne are *Hisforiae Normannorum scriptores antiqui* (1619). now the only source for some of the texts, and *Historiae Francorum scriptores* (j vol., 1636–49). The latter work was projected in 24 volumes as a comprehensive collection of narrative sources of French history. but Duchesne died with only two volumes published; his son François (1616–1693), who succeeded him as historiographer royal, brought it down to the reign of Philip IV in three more volumes. Duchesne's other works include *Les Antiquitez . . . des roys de France* (1609), *Les Antiquitez . . . de toute la France* (1609). *Histoires des papes jusqu'à Paul V* (1616) and numerous family histories and genealogies. He left more than 100 folio volumes of manuscript extracts. 59 of which are preserved in the Bibliothèque Nationale (L. De Lisle: *Le Cabinet des manuscripts de la bibliothèque impériale,* vol. i, pp. 333–334 [1868]).

DUCHESNE, LOUIS MARIE OLIVIER (1843–1922), French priest, was an outstanding historian and a pioneer in the application to early church history of archaeological, topographical, liturgical, theological and social studies. Born at St. Servan, Brittany, on Sept. 13. 1843, he was educated for the priesthood and ordained in 1867, later studying in Rome under G. B. de Rossi. The two theses for his doctorate, *De Macario Magnete* (1877) and *Étude sur le Liber pontificalis* (1877), led to a denunciation to the Holy Office. The nature of his researches was likely'to upset many cherished pious traditions; besides, he had a witty and mordant pen which did not spare the stupid and pretentious. This rather than his conclusions rendered him suspect. But he was fortunate in writing under the pontificate of the enlightened Leo XIII. who made him a monsignor. It was not. however, until 1887, as he himself said, that he fully realized what his life's work was to be—to serve the church through historical research. He became a leading figure in the 19th- and early 20th-century Roman Catholic revival of learning, and his books are still of fundamental importance. In 1878 Duchesne was appointed professor at the Institut Catholique in Paris. where in 1881 he founded the *Bulletin critique de littérature, d'histoire et de théologie.* In 1888 he was elected a member of the Académie des Inscriptions et Belles-Lcttres. While retaining his chair at the Institut he became director of religious studies at the École des Hautes Etudes in 1892. In 1895 R. Poincaré appointed him director of the École Française de Rome. and in 1910 he was elected to the French Academy. He died in Rome on April 21, 1922.

Duchesne's works include the authoritative edition of the *Liber pontificalis,* 2 vol. (1886–92); *Origines du culte chrétien* (1889; Eng. trans.. 1903): *Mémoire sur l'origine des diocèses épiscopaux dans l'ancienne Gaule* (1890), the preliminary sketch for *Fastes épiscopaux de l'ancienne Gaule,* 3 vol. (1894–1915); *Autonomies ecclésiastiques: églises separées* (1896), which treats of the origin of the Greek Church and of the Anglican Church; and *Histoire ancienne de l'église chrétienne,* of which the first three volumes (1905–08) were put on the Index, the fourth volume being published posthumously in 1925.

A close friend of Baron F. von Hügel, Duchesne suffered much from misunderstanding during the days of the Modernist troubles. H. Bremond paid a moving tribute not only to his faith but also to his deep personal piety and loyalty.

See C. d'Habloville, *Grand Figures de l'église contemporaine* (1925); *H.* Bremond, *Discours de réception à l'académie française* (1923).
(M. D. L. B.)

DUCHESNE, (ROSE) PHILIPPINE (1769–1852), French religious of the Sacred Heart who founded the first convents of that order in the U.S.. was born in Grenoble, on Aug. 29, 1769, the daughter of Pierre François Duchesne. well-known legal and political figure, and Rose Perier, member of a prominent family of Dauphiné.

Her education was advanced for a girl of her day. Entering the Visitation order in Grenoble in 1788, she saw the community dispersed by revolution in 1792, devoted herself to works of charity for nine years and tried in vain to re-establish the Visitandines in their old monastery. In 1804 she turned it over to the newly founded Society of the Sacred Heart and mas received into that order by the founder, St. Madeleine Sophie Rarat.

For 14 years Mother Duchesne prepared for a missionary career. In 1818 she headed a band of five nuns, the first to pioneer in the trans-Mississippi west. At St. Charles. Mo., they opened a free school and a boarding academy, moving in 1819 to Florissant, Mo., where they did the same work and also founded an orphanage and a novitiate. Two convent schools were founded in Louisiana, at Grand Coteau (1821) and St. Michael's (1825), and an academy and orphanage in St. Louis (1827); the house at St. Charles was reopened in 1828.

In 1841 Mother Duchesne reached the Indian mission among the Potawatomi at Sugar Creek, Kan. Broken in health, she could remain only one year. She spent the last decade of her life at St. Charles. where she died on Nov. 18, 1852. A memorial church was built there in her honour. She was beatified in May 1940, and her feast is celebrated on Nov. 17.

(L. CN.)

DUCIS, JEAN FRANÇOIS (1733–1816), French dramatist who made the first sustained effort to present Shakespeare's tragedies on the French stage. was born at Versailles on Aug. 22. 1733. His principal adaptations — Hamlet (1769), *Roméo et Juliette* (1772), *Le Roi Lkur* (1783). *Macbeth* (1784) and *Othello* (1792) —had much success. *Hamlet* and *Othello,* in which the acting of François Joseph Talma (1763–1826) aroused great enthusiasm, remained in the repertory of the Comédie Française until 1851 and 1849 respectively, although they were most popular during the 1830s. Knowing no English, Ducis had to depend on the mediocre translations of Pierre Antoine de Laplace (1707–93) and of Pierre Le Tourneur (1736–88). He sought to remodel the tragedies to suit French taste by confining them within the so-called "classical unities" and by introducing Corneille's motive of conflict between passion and duty, together with the sententiousness and sensibility of his own day. Perhaps oversensitive to public opinion, Ducis constantly revised his plays, sometimes providing alternative denouements, often at the expense of the original Shakespearean elements. Although his own moral seriousness made him see in *Hamlet* mainly a lesson in filial piety and in *Macbeth* a treatise on remorse, his style shows a certain vigorous eloquence, and some of his scenes have genuine tragic force, though this is not sustained. Of his original plays, *Œdipe chez Admète* (1778) and *Abufar* (1795) are his best; the first earned him election to the Académie Française in succession to Voltaire (1779). He died at Versailles on March 31, 1816.

The works of Ducis mere published in 3 vol. (1813); his posthumous works were edited by F. N. V. Campenon (1826).

DUCK, the English name for birds forming the Anatinae. one of the two subfamilies of the family Anatidae. Technically. duck is restricted to the female, the male being called "drake." Ducks have long been favourite and important game birds for the sportsman. and millions are shot annually. Aside from some of the fish-eating sea ducks, most species are good eating and are thus much desired.

Ducks comprise the subfamily Anatinae, with seven tribes as follows: (1) the Xnatini or fresh-water ducks; (2) the Tadornini or sheldrakes; (3) the Aythyini or pochards; (4) the Cairinini or perching ducks; (5) the Mergini or sea ducks; (6) the Oxyurini or stiff-tailed ducks; (7) the Merganettini or torrent ducks. The Dendrocygnini or long-legged tropical tree ducks are now considered closer to the geese than to the ducks.

About 115 species of Anatinae are distributed throughout the world, some being confined to small oceanic islands. Males are usually colourful, females duller, but both are dull in some spe-

cies, as, for example, in the American black duck *(Anus rubripes)*.

The Anatini, the typical group, are the ones best known. The mallard *(Anas platyrhynchos)* is the most plentiful and best-known species, and is the origin of the domestic breeds of Europe and the U.S. It inhabits the northern hemisphere, reaching Panamá, Egypt and northwestern India in winter, and the Arctic circle in summer. The nest may be on the ground or even well up in a tree; 9–11 pale green eggs are laid on a lining of down that the mother pulls from her breast. As soon as the young hatch, the mother takes them to the nearest body of water. The male may guard the nest before hatching. but takes no interest in the brood and, indeed, is incapable of rendering active assistance by reason of an additional molt that deprives him of the power of flight until the autumn. In bad weather the ducks resort to tidal waters. It is an interesting point that, whereas the male wild duck is monogamous, the domesticated drake is polygamous.

HUGH M. HALLIDAY FROM NATIONAL AUDUBON SOCIETY

FEMALE MALLARD DUCK (ANAS PLATYRHYNCHOS) ON NEST WITH EGGS

Among some ducks, *e.g.*, the red-headed duck and the ruddy duck, individuals frequently lay some of their eggs in each other's nests, especially early in the breeding season. One South American species, the black-headed duck *(Heteronetta)* is entirely "parasitic" on other marsh-nesting birds.

The Anatinae may be characterized as follows: the tarsus is usually scutellated in front (reticulated in the swans and the true geese and in the so-called tree ducks); there are two annual molts (only one in the swans and geese); the sexes are usually dissimilar in coloration, voice and structure of the voice-producing organ, the syrinx.

The group, world-wide in distribution, is a very ancient one, and has produced many varying types. Both in captivity and in the wild state many ducks, especially of the tribe Anatini, are prone to hybridize. The hybrid offspring, being sterile. do not tend to confuse and to conceal the natural classification of the group, however.

Other species of the group are the pintail, baldpate or widgeon *(q.v.)*, teal *(q.v.)*, shoveler *(q.v.)*, garganey *(q.v.)* and gadwall *(q.v.)*. Allied to the sheldrakes are a number of species commonly but erroneously called geese: Egyptian goose *(Alopochen)*, Orinoco goose *(Neochen)*, Abyssinian blue goose *(Cyanochen)* and upland. kelp and Magellanic geese of South America *(Chloephaga)*. These ducks are as big as large geese, hence their common name. Allied to the pochard *(q.v.)* are the canvasback, scaup *(q.v.)*, ring-necked duck and white-eyed duck. Among the perching ducks are the North American wood duck *(Aix sponsa)*, Asiatic mandarin *(Aix galericulata)*, so-called maned goose *(Chenonetta)*, comb duck *(Sarkidiornis)* and pygmy goose *(Nettapus)*. The sea ducks include the now extinct Labrador duck *(Camptorhynchus)*, scoter *(q.v.)*, eider *(q.v.)*, goldeneye *(q.v.)*, harlequin duck *(Histrionicus)* and old squaw *(Clangula)*. The stiff-tailed ducks comprise only a few species, the masked ducks and ruddy ducks *(Oxyura)* and Australian musk duck *(Biziura)*. The torrent ducks, birds of rushing mountain streams of the Andes, comprise a single genus, *Merganetta*. For domestic breeds of ducks *see* POULTRY AND POULTRY FARMING.

See also references under "Duck" in the Index volume.

See J. C. Phillips, *A Natural History of the Ducks*, 4 vol. (1922–26); J. Delacour, *The Waterfowl of the World*, 4 vol. (1954–). (HT. FN.)

DUCK, a plain fabric, made originally from tow yarns and subsequently from either flax or cotton. It is lighter than canvas or sailcloth, and differs from these in that it is almost invariably single in both warp and weft. The fabric, in its various qualities and colours, is used for an enormous variety of purposes, including tents, wagon and motor hoods. light sails. belting. bicycle tubes, mail and other bags and pocketings, and clothing; the plural form is used colloquially for trousers made of the material. Russian duck is a fine white linen canvas.

The term is probably derived from the Dutch *doeck*, a coarse linen material.

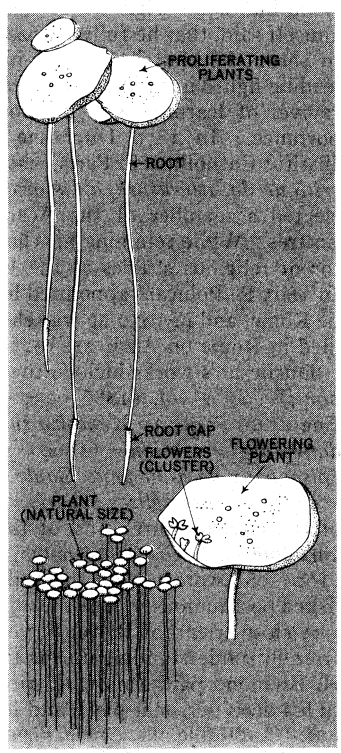
DUCKBILL: *see* PLATYPUS.

DUCKING STOOL, a chair for the punishment of scolds, witches and prostitutes, used in England as late as the beginning of the 19th century. It is sometimes confused with the ancient cucking stool or stool of repentance used by the Saxons. Seated on this stool the person, with head and feet bare, was publicly exposed or paraded through the streets. The cucking stool was used for both sexes and was especially the punishment for scolding women and dishonest brewers and bakers.

The earliest record of the use of the ducking stool is toward the beginning of the 17th century. It was a strongly made wooden armchair in which the culprit was seated, an iron band being placed around her so that she should not fall out during her immersion. The chair was fastened to a long wooden beam fixed as a seesaw on the edge of a pond or river. or was sometimes mounted on a pair of wooden wheels so that it could be wheeled through the streets.

In sentencing a woman, the magistrates ordered the number of duckings she should have. Another type of ducking stool was a chair on two wheels with two long shafts fixed to the axles. This was pushed into the pond and the shafts released, thus tipping the chair up backward.

DUCKWEED, the common name for species of *Lemna* (family Lemnaceae) and for related genera, which form a green coating on fresh-water ponds and ditches. The plants are of extremely simple structure and are the smallest and least differentiated of flowering plants. They consist of a so-called "frond"—a flattened. green. more or less oval structure which emits branches similar to itself from lateral pockets at or near the base. From the under surface a root with a well-developed sheath grows downward into the water. The flowers. which are rarely found, are developed in one of the lateral pockets. The inflorescence consists of one or two male flowers each comprising a single stamen, and a female flower comprising a flask-shaped pistil. The Lemnaceae are regarded as representing a very reduced type allied to the aroids (family Araceae; *q.v.*).



DUCKWEED (LEMNA MINOR), ONE OF THE SMALLEST FLOWERING PLANTS

Besides *Lemnn,* other genera representative of the family are *Spirodela,* with several roots, and *Wolffia* and *Wolffiella,* with no roots. All of the following are distributed widely, nearly throughout the world: the lesser duckweed (L. *minor*), the gibbous duckweed (L. *gibba*), the ivy-leaved duckweed (L. *trisulca*) and the greater duckweed *(Spirodela polyrrhiza)*. In Sorth America 12 duckweeds occur, including many of the same ones found in Great Britain; three are species of *Wolffia* and one is a *Wolffiella. Wolffia punctata,* with fronds only $\frac{1}{50}$ in. to $\frac{1}{35}$ in. long, is one of the most minute of all flowering plants.

In Great Britain the family is further represented by *Wolffia arrhiza,* in which the rootless fronds are only $\frac{1}{20}$ in. long; it is the smallest of British flowering plants. (N. TR.)

DUCOMMUN, ÉLIE (1833–1906), Swiss writer and editor

who won the Nobel peace prize, was born at Geneva on Feb. 19, 1833. At the outset of his career he entered the service of the department of public instruction of his canton, where he rose to a responsible position. He worked also for the *Revue de Genève,* of which he became editor in chief. Later he removed to Berne where he edited *Der Fortschritt.* He became general secretary of the Jura-Simplon railway, retiring in 1903.

Ducommun's chief work lay in studying and preaching the principles of peace to which from an early age he devoted his leisure. He became famous both as an orator and a writer. Most noteworthy of his books were *L'Oeuvre de la paix* (1893), *Le Programme pratique des amis de la paix* (1897) and *Précis historique du mouvement en faveur de la paix* (1899). He took an active part in the movement for European union and conducted *Les États-Unis d'Europe,* the French periodical of the Ligue internationale de la paix et de la liberté, founded in 1867.

In 1889 Ducommun participated in the first of the regular peace congresses, and in 1891 when the International Peace bureau was established he became honorary general secretary. After 1895 he published the *Correspondance bi-mensuelle* relating to the peace bureau's activities. In 1902 he was awarded the Nobel peace prize. He died at Berne on Dec. 7, 1906. (G. P. Es.)

DUDEVANT, A. L. A.: *se* SAND, GEORGE.

DUDLEY, BARONS AND EARLS OF. The holders of these English titles are descended from John de Sutton (c. 1310–59) of Dudley castle, Staffordshire. His great-great-grandson JOHN SUTTON or DUDLEY (1400–87), 1st baron, was born on Dec. 25, 1400. He became lord lieutenant of Ireland (1428–30) and was summoned to parliament as a baron in 1440. He died on Sept. 30, 1487, and was succeeded by his grandson EDWARD (c. 1459–1532), 2nd baron, son of John's eldest son Sir Edmund Dudley (d. 1483). Other sons of the 1st baron included John Dudley, from whom the earls of Warwick and the Dudley earl of Leicester are descended, and William Dudley, bishop of Durham from 1476 to 1483. The 2nd baron's great-grandson, EDWARD (1567–1643), 5th baron, had several illegitimate children, including Dud Dudley (1599–1684), who in 1665 published *Metallum Martis,* describing a process of iron-making, but he died without a legitimate male heir and was succeeded in the barony by his granddaughter FRANCES (1611–97).

Frances married in 1628 Humble Ward (d. 1670), who was created Baron Ward in 1644. Their son EDWARD WARD (1631–1701), 7th Baron Dudley and 2nd Baron Ward, succeeded to both his father's and his mother's title, but after the death of his grandson WILLIAM (d. 1740), 10th Baron Dudley and 5th Baron Ward, the baronies separated.

The Dudley barony passed to the 10th baron's nephew FERDINAND DUDLEY LEA (1710–57), 11th baron, but on his death on Oct. 21, 1757, the title fell into abeyance. It was revived in 1916 in favour of FERDINANDO SMITH (1872–1936), 12th baron, who was the great-great-grandson of the 11th baron's sister Anne. He was succeeded in 1936 by his only son FERDINANDO (1910–), 13th baron.

The Ward barony, in 1757, passed to John Ward (d. 1774), who in 1763 was created Viscount Dudley and Ward. His grandson, JOHN (1781–1833), 4th viscount, was foreign secretary in 1827–28 in George Canning's government and was created in 1827 Viscount Ednam and earl of Dudley. He died on March 6, 1833, when all his titles became extinct. except the barony of Ward which passed to his second cousin William Humble Ward (1781–1835) whose son WILLIAM (1817–85) was made Viscount Ednam and earl of Dudley (in a new creation) in 1860. William's son WILLIAM (1867–1932), 2nd earl of Dudley, was lord lieutenant of Ireland, 1902–05, and governor general of Australia, 1908–11. He was succeeded by his son WILLIAM (1894–), 3rd earl.

DUDLEY, EDMUND (c. 1462–1510), English lawyer and minister of Henry VII, remembered, with Sir Richard Empson (*q.v.*), for his unpopular administration of the crown revenues, was the eldest son of John Dudley of Atherington, Sussex, of the baronial family of Sutton or Dudley. He studied law at Gray's Inn and gave two courses of lectures there. From 1496 to 1502 he was undersheriff of London and two years later was about to be made sergeant-at-law when he bought exemption and became speaker of the house of commons. By 1506 he was called "president of the king's council," but this seems to have been a small body of lawyers and household officials whose work was mainly administrative and financial. He and Sir Richard Empson are the best-known members of this group and became unpopular for their share in re-establishing the payment of the king's feudal dues and of the fines and other penalties of lawbreaking. Dudley was employed also in the Star Chamber, the duchy chamber of Lancaster and on the common-law side of chancery. He amassed a fortune and held land in 13 counties, but evidence of personal corruption or of defrauding the king cannot be proved. After Henry VII's death Empson and Dudley were arrested (April 1509). Dudley was tried at the Guildhall, London, and convicted on a charge of constructive treason on July 18, 1509. A bill of attainder apparently passed "onely the comen house," but the threat of it caused Dudley to plan an escape from the Tower of London. This was betrayed and he was executed on Tower Hill on Aug. 17, 1510.

In prison Dudley wrote *The Tree* of *Commonwealth* (ed. D. M. Brodie, 1948), which is based on the practice of Henry VII's administration and on the theories of the medieval schoolmen. In it Dudley preaches moderation in the use of royal powers as well as the punctual performance of political and social duties by all ranks. The prose is lively, and informed with the irony and wit of a great advocate.

Dudley was twice married. By his first wife, Anne, sister of Sir Andrew Wyndesore, he had a daughter, Elizabeth, who married William, Lord Stourton. His three sons, John, Jerome and Andrew, were born to his second wife, Elizabeth Grey, one of the sisters and coheirs of John, Viscount Lisle.

Cooper in *The Historical Journal,* vol. i, ii and iv (1958–61); Conyers Read (ed.), *Bibliography of British History, Tudor Period,* 2nd ed. (1959). (D. M. RE.)

DUDLEY, SIR ROBERT (1574–1649). English sailor and engineer, titular duke of Northumberland and earl of Warwick, and the author of a famous treatise on navigation, was the son of Robert Dudley, earl of Leicester, and of Lady Douglas Sheffield. He was born in Surrey on Aug. 7, 1574, and based his claim to legitimacy on an alleged marriage ceremony between his parents in 1573; this Leicester later denied, although he recognized Dudley as his heir, sent him to Oxford, and when he died in 1588 left his property to Dudley after the death of his brother, Ambrose Dudley. earl of Warwick, which occurred in 1590.

In 1594 Dudley made a voyage to Trinidad, proposing to explore Guiana, but beyond sending a boat some distance up the Orinoco, he accomplished little. In 1596 he was knighted for his part in the earl of Essex' expedition to Cadiz. On his return he married, as his second wife, Alice Leigh, and attempted to establish his legitimacy and claim to his father's titles. His failure and the disfavour he incurred for his part in the Essex rebellion led him to apply for leave to travel abroad, granted in 1605. He went to Italy, accompanied by his cousin Elizabeth Southwell, whom he afterward married, allegedly by papal dispensation. In 1607 Dudley was ordered to return home to meet charges of unlawfully assuming the titles; he refused and his estates were sequestrated for contempt. Alice, his deserted wife, was created duchess of Dudley for life in 1645. In Italy, Dudley entered the service of the grand duke of Tuscany, and was employed in draining the marshes behind Leghorn and in constructing the port. He was known there as duca di Nortombria and conte di Warwich, and in 1620 Ferdinand II, the Holy Roman emperor, confirmed these titles. He died near Florence on Sept. 6, 1649.

Dudley's chief claim to remembrance is the magnificent *Dell' Arcano del mare,* three volumes (1646–47), a treatise on navigation (particularly on the determination of longitude), ship construction, and naval organization and discipline. It is accompanied by many engraved charts and designs for instruments, often unsuitable for use at sea. Before he left England, Dudley had be-

come a practical navigator, and had learned something from mathematical friends. He clearly had an active and ingenious mind, but his expositions are involved and sometimes superficial. He appreciated the advantages of the Mercator projection, but gave an approximate graphical construction only. The *Arcano* is also remarkable for a scheme for the construction of a navy in five rates, or classes of ship.

See Vaughan Thomas, *The Italian Biography of Sir R. Dudley* (1861); J. T. Leader, *Life of Sir R. Dudley* (1895). (*G.* R. CE.)

DUDLEY, THOMAS (1576–1653), colonial governor of Massachusetts, was born in Northampton, Eng., in 1576, possibly a member of the elder branch of the family to which Robert Dudley, earl of Leicester, belonged. He was the son of a country gentleman of some means and was captain of an English company in a French expedition of 1597. He eventually became the steward of the earl of Lincoln's estates, which he managed with great success for many years. Having been converted to Puritanism, he associated himself with other Lincolnshire gentlemen who in 1629 entered into an agreement to settle in New England provided they were allowed to take a charter with them. This proposal the general court of the Massachusetts Bay company agreed to, and in April 1630 Dudley sailed to America in the same ship with John Winthrop, the newly appointed governor. Dudley himself at the last moment had been chosen deputy governor in place of John Humphrey (or Humfrey), the earl of Lincoln's son-in-law, whose departure was delayed.

Dudley was for many years the most influential man in the Massachusetts Bay colony, save Winthrop, with whose policy he was more often opposed than in agreement. He was deputy governor in 1629–34, in 1637–40, in 1646–50, and in 1651–53, and was governor four times! in 1634, 1640, 1645 and 1650. Soon after his arrival in the colony he settled at Newton (later Cambridge), of which he was one of the founders. He was also one of the earliest promoters of the plan for the establishment of Harvard college. Winthrop's decision to make Boston instead of Newton the capital precipitated the first of the many quarrels between the two. Dudley's sterner and harsher Puritanism being in strong contrast to Winthrop's more tolerant and liberal views. He was an earnest and persistent heresy hunter. Not only the Antinomians: but even such a good Puritan as John Cotton, against whom he brought charges, felt the weight of his stern and remorseless hand. Dudley was an able man with business and managerial ability, and was devoted to the public interest. It mas from him that New England Puritanism derived some of its harshest aspects. He was a strong believer in aristocracy and thought that the state should enforce religious conformity. He was dogmatic, prejudiced, austere and unlovable; he dominated the community by sheer strength of will. He died at Roxbury, Mass., on July 31, 1653.

His son JOSEPH DUDLEY (1647–1720), colonial governor of Massachusetts, was born in Roxbury on Sept. 23, 1647. He graduated from Harvard college in 1665, became a member of the general court, and in 1682 was sent by Massachusetts to London to prevent the threatened revocation of the colonial charter by Charles II. There, with an eye to his personal advancement, he secretly advised the king to annul the charter; this was done, and Dudley, by royal appointment, became president of the provisional council. With the advent of the new governor, Sir Edmund Andros (*q.v.*), Dudley became a judge of the superior court and censor of the press. Upon the deposition of Andros, Dudley was imprisoned and sent with him to England, but was soon set free. In 1691–92 he was chief justice of New York, presiding over the court that condemned Jacob Leisler (*q.v.*). Returning to England in 1693, he became lieutenant governor of the Isle of \Tight and a member of parliament, and in 1702, after a long intrigue, secured irom Queen Anne a commission as governor of Massachusetts, where he served until 1715. His administration was marked. particularly in the earlier years, by ceaseless conflict with the general court. from which he demanded a regular fixed salary instead of an annual grant. He was active in raising volunteers for the so-called Queen Anne's War. He was accused by the Boston merchants, who petitioned for his removal; of being in league with smugglers and illicit traders, and in 1708 a bitter attack on his administration was published in London, entitled The *Deplorable State of New England by Reason of a Covetous and Treacherous Governor and Pusillanimous Counsellors*. He was an able administrator and efficient servant of the crown, but neither of these attributes made for popularity in his turbulent period. He died at Roxbury on April 2, 1720.

Joseph Dudley's son PAUL DUDLEY (1675–1751) graduated from Harvard in 1690, studied law at the Temple in London and became attorney general of Massachusetts (1702–18). He was associate justice of the superior court of that province from 1718 to 1745, and chief justice from 1745 until his death. He was a member of the Royal society (London), to whose Transactions he contributed several valuable papers on the natural history of New England, and was the founder of the Dudleian lectures on religion at Harvard.

See G. E. Koues, *Thomas Dudley, Governor of Massachusetts* (1914); Everett Kimball, *The Public Life of Joseph Dudley* (1911). (**Ra.** Mu.)

DUDLEY, a municipal, county and parliamentary borough of Worcestershire, Eng., forming an isolated enclave in Staffordshire. 9 mi. W N.W. of Birmingham and 117 mi. N.W. of London by road. It is situated on the Birmingham, Stourbridge, and Staffordshire and Worcestershire canals. Pop. (1961) 61,748. Standing on a ridge 370–789 ft. above sea level in what was to become the Black Country. Dudley was conveniently placed over the "ten-yard" coal of the neighbourhood, which formed the richest seam worked in England. and also over limestone and ironstone. The site was of importance from about the 8th century when a Saxon castle was founded on the hill. In medieval times Dudley (Dudelei) depended on the castle. The earthnorks of the Norman castle survive but most of the ruins are of the 16th-century castle built by Sir John Dudley, duke of Northumberland, and burned donn in 1750. The first mention of Dudley as a borough occurs in 1272. Before that time it was governed by a high and low bailiff, appointed every year at the court leet of the manor. Roger de Somery held a market by prescription in Dudley before 1261. Two fairs, on Sept. 21 and April 21, were granted in 1684 to Edward. Lord Ward, lord of the manor. Dudley was represented in the parliament of 1295 but not again until the Reform act of 1832. It was incorporated in 1865.

Mines of sea coal are mentioned as early as the reign of Edward I, and by the beginning of the 17th century mining had become important. The industries of the area thus began early; woodlands were destroyed to supply charcoal for medieval iron smelting. Dud Dudley, a natural son of Lord Dudley, received in 1621 a patent for his method of smelting iron with coal, but no process is known to have been successful until Abraham Darby's method in the 18th century. Dudley played an important part in the Industrial Revolution. Local pig iron production reached a maximum about 1870. The older industries of nail making and glass blowing ceased, but chainmaking continued to prosper. Apart from the collieries, iron and brass founding, engineering and brickmaking predominate with local specialities such as clothing, scales and weights and leather goods. The whole district is set with chimneys, pit buildings and factories, and at night Dudley's glare of furnaces reveals the continuous activity of this "capital" of the Black Country. There are 159 mi. of canals in and around Dudley. An open market is held each weekday in the town.

Despite industry the town has many attractive features. The ruined castle stands above the woods on top of Castle hill, and a zoological garden was opened in the grounds in 1935. In the centre of the town are the ruins of a 12th-century priory (restored by the ministry of works). the grounds of which are a public park. The principal buildings are the council house (1935), the town hall (1928). the technical college (1935), the teachers' training college (1908–09), the Brooke-Robinson museum and the art gallery. The town is noted for its Silurian fossils from the limestone quarries of Dudley castle and Wren's Nest; a Silurian trilobite fossil is in the centre of the tonn's emblem.

DUDO (DUDON) OF ST. QUENTIN (c. 965—before 1043). French chronicler of the first dukes of Normandy, was a canon of St. Quentin in Picardy who was sent by Albert I. count of Ver-

mandois, on a mission to Richard I, duke of Normandy, and became a member of the duke's intimate circle. His *Historia Normannorum,* or Libri *iii* de *moribus* et *actis primorum Normanniae ducum,* is dedicated to Adalberon (*q.v.*), bishop of Laon. Written alternately in prose and verse, it tells the story of the Normans from the 850s to 996, but is of very dubious reliability, especially where Dudo refers to his own private information, which was poor. It is the only source of information on the events culminating in the "treaty of St. Clair-sur-Epte" (probably 911), whereby Charles the Simple authorized the Northmen under Rollo to settle in Normandy, but the narrative is cluttered with fabulous tales (such as that of Rollo's alleged marriage to Charles's daughter) and deserves credence only on a few points. The best edition of the work is by J. Lair (1865).

See J. C. M. R. Steenstrup, *Normannarne* (1876); H. Prentout, Etude critique *sur Dudon de* Saint-Quentin et son *histoire* des *premiers ducs normands* (1916). (J. DE.)

DUDWEILER, a town of Saarland (see SAAR), Ger., which in 1957 was incorporated in the Federal Republic of Germany, is situated in hilly country on the Sulz-bach, 7 km. (4 mi.) S.E. of Saarbrucken to which it is linked by rail and road. Pop. (1959 est.) 27,895. Dudweiler is an industrial town with extensive coal mines and ironworks. Fireproof bricks, electrical equipment, precision instruments and clothing are made. Nearby is the "burning mountain," a coal vein which caught fire in 1648 and smouldered continuously from that time. There are traces of prehistoric and Celtic occupation. The town was the Roman Duodonisvillare.

DUEL, a combat between persons, armed with lethal weapons, which is held according to pre-arranged rules to settle a quarrel or a point of honour. It is an alternative to having recourse to the usual process of justice. Duels. in this sense, were practically unknown in the ancient world. The Greeks and Romans had a different conception of courage: Plato, for instance, defined courage as "the virtue of fleeing from an inevitable danger." Single combats, such as those between Hector and Achilles and between the Horatii and Curiatii, were mostly incidents in local wars.

The Judicial Duel.—The judicial duel or trial by battle mas the earliest form of dueling. Caesar and Tacitus report that the Germanic tribes settled their quarrels by single combat with swords, and with the Germanic invasions the practice became established in western Europe early in the middle ages (it was recognized by the edict issued at Lyons in 501 by Gundobad of Burgundy). The judicial duel was adopted because solemn affirmation, or swearing of oaths, in legal disputes had led to widespread perjury and because the ordeal (*q.v.*) seemed to leave too much to chance or to manipulation by priests. If a man declared before a judge that his opponent was guilty of a certain crime and the opponent answered that his accuser lied, the judge ordered them to meet in a duel. for which he established the conditions as to place, time and arms; both combatants had to deposit sureties for their appearance. The throwing-down of a gauntlet was the challenge, which the opponent accepted when he picked it up. As it was believed that in such an appeal to the "judgment of God" the defender of the right could not be worsted, the loser was usually dragged from the lists by his heels and. if still alive, dealt with according to law. In criminal actions defeated men were hanged and women usually burned; in civil actions a hand might be cut off; and goods and arms were confiscated. Pope Nicholas I declared in 858 that trial by battle was "a just and legitimate combat," and church dignitaries resorted to it in disputes over church property or, in other cases, took their share of the goods seized from a defeated combatant.

This form of trial was open to all free men and even, in certain cases, to serfs. Only ecclesiastics. women. the sick. persons under 20 years of age and men over 60 could claim exemption. In certain circumstances, however, persons under trial could appoint professional fighters or "champions" to represent them. but the principal as well as his defeated champion was subjected to the legal punishment.

In most countries duels also served to decide impersonal questions. In Spain. for example. a duel was fought in 1085 to decide whether the Latin or the Mozarabic rite should be used in the liturgy at Toledo: the Mozarabic champion, Ruiz de Mastanza. won. The procedure of these duels was laid down in great detail. They took place in champs clos (lists). generally in the presence of the court and high judicial and ecclesiastical dignitaries Before combat each participant swore on the cross and the Bible that his case was just and his testimony true and that he carried no weapons other than the stipulated ones and "no stone or herb of virtue, no charm, experiment or other enchantment by which the word of God might be diminished and the devil's power increased." Lest the spectators should influence the combat, strict silence was enforced under penalty, including the loss of a limb or even death. Combats never started beiore noon and might continue until the stars appeared: a defender who resisted until then won his suit. When one of the combatants was wounded or thrown, his opponent usually placed his knee on his chest and, unless he asked for mercy, drove his dagger through a joint in the armour.

England.—William I introduced the judicial duel or trial by battle to England. A notable early example was that in which Godfrey Baynard, count of Beaumont, defeated William of Eu (whom he had accused of treason against William II) on Salisbury plain in 1093. At first the duel was compulsory only for Normans. but this distinction lapsed, and by the reign of Henry II trial by battle was the only method for settling the issue of a writ of right in proprietary suits, though in practice combat rarely occurred. Henry II's reforms provided the alternative of the grand assize on trial by jury and encouraged the use of the jury in appeals of felony, in which trial by battle had also been used. Nevertheless there were later occasions when trial by battle was demanded; for instance in 1571, when a duel over disputed manorial rights was averted at Queen Elizabeth I's behest; and as late as 1818, in the case of *Thornton* v. *Ashford.* In this last case, Abraham Thornton, accused of murdering Mary Ashford, threw down a gauntlet in court and claimed his right to challenge his accuser, Mary Ashford's brother, to wager of battle. His suit was allowed, and as the challenge was refused Thornton escaped. After this, judicial duels were abolished by the law of 1819.

France.—French judicial duels became so frequent and fatal that from the 12th century attempts were made to reduce them. Louis VII decreed in 1168 that certain offenses should no longer be tried in this way. Louis IX *c.* 1254 tried to forbid duels in his domains. A duel which took place in 1385 in the presence of Charles VII profoundly affected the popular belief in the "judgment of God." A Norman gentleman, Jacques Legris. was accused by the wife of Jean de Carrouge of having seduced her when her husband was absent on crusade The *parlement* ordered trial by battle, and Legris, who protested his innocence, was defeated by the husband and hanged. Later a man about to be executed for other crimes confessed that he was the seducer.

Thereafter the number of judicial duels decreased. The last one to be authorized by a French king took place on July 10. 1547, between Guy de Chabot de Jarnac and François de Vivonne de La Châtaigneraie—whose account of a gravely compromising statement by Jarnac was alleged by Jarnac to be untrue. Henry II authorized the duel out of affection for La Châtaigneraie, though his predecessor Francis I had refused to countenance it. In lists prepared with great pomp. the combatants, heavily armoured, met on foot with sword and buckler. When Jarnac felled his opponent with a sudden cut behind the knee (hence the phrase *"un coup* de *Jarnac"* meaning a sly, unforeseen blow). La Châtaigneraie who had been confident of victory, was so mortified that he refused aid and died Henry II now swore never to authorize another trial by battle.

The Duel of Honour.—Duels of honour were private encounters about real or imagined slights or insults. The practice, considerably facilitated by the fashion of wearing a sword as part of everyday dress, seems to have spread over the rest of Europe from Italy from the end of the 15th century. Italy in any case was the great centre of professional swordsmanship and as the duel of honour became prevalent the nobility of Europe flocked to Milan to learn the secret strokes that fencing-masters had to teach.

Men would fight on the slightest pretext and often, at first, without witnesses, but as this secrecy came to be abused (*e.g.*, by ambushes) it soon became usual for duelists to be accompanied by friends or seconds. Later these seconds would also fight! to prove themselves worthy of their friends.

France.—Duels of honour became so prevalent that the estates-general of France at Orléans persuaded Charles IX to issue an ordinance in 1566 which applied the death penalty to anyone taking part in a duel. This ordinance became the model for later edicts against dueling. The rage for dueling persisted nonetheless. In the encounter at the Porte Saint-Honoré on April 27, 1578, between Charles de Balzac d'Entragues and Henry III's favourite, Jacques de Lévis, comte de Quélus, each with two seconds, four of the combatants were killed and the others severely wounded; and it was reckoned that between 1589 and 1608 more than 8.000 gentlemen were killed in duels. Duels, indeed, were fought by the highest in the land. In 1594, Charles de Lorraine, 4th duc de Guise, killed Antoine Montbéton de Saint-Pol in a duel in the streets of Reims after Saint-Pol had criticized his defection to Henry IV's side in the civil war.

It was Henry IV who issued the first strong edicts against dueling, under the influence of the great duc de Sully. The edict of 1602, which declared that those who fought unauthorized duels were guilty of treason, confirmed the powers of the courts of honour which had been set up under Louis XII. In these courts the marshals of France and the governors of the provinces, or their deputies, were to act for the king and to settle points of honour, allowing a duel as the last resort. The edict of 1609 graded punishments according to the degree of participation in a duel and included spectators. Henry's tendency to grant pardons to duelists counteracted this legislation.

Dueling under Louis XIII greatly increased. Lord Herbert of Cherbury, the British ambassador in Paris, reported that "there is scarce a Frenchman worth looking on who has not killed his man in a duel." Then the cardinal de Richelieu. through the edict of 1626, inaugurated a regime of greater severity, which was to be applicable also for duels fought in frontier territories or outside France. Richelieu moreover made no exceptions for any who flouted the laws, however exalted their family might be: when Franqois de Montmorency, comte de Boutteville, fought his 22nd duel (with Franqois d'Harcourt, marquis de Beuvron), Richelieu ordered their arrest and Boutteville was beheaded (June 22. 1627). The edicts against duels were republished in 1634, but after Louis XIII's death were for a time more laxly observed, as when the duc de Beaufort killed his brother-in-law, the duc de Nemours. in 1652. Louis XIV, however, eventually succeeded in putting the duel down through a series of edicts, one of which, in 1679, addressed a special appeal to the nobility. He also made the courts of honour effective and. in 1704. could record his satisfaction at seeing the virtual cessation of fatal duels. During the Regency there was a revival of dueling. which provoked the last royal edict to be issued against it (1723).

Dueling survived the ancien *régime* in France. Furthermore, from the Revolutionary period onward, it came to be a feature of political disputes. In Aug. 1790 Jean de Cazalbs and Antoine Barnave fought a duel after a debate; and, in November, Charles Lameth fought Armand de La Croix, duc de Castries, after the duc had challenged all supporters of the Revolution. According to Barnave. the fact that the aggressors usually favoured the ancien *régime* caused some popular feeling against dueling. In spite of this there was no specific legislation against it. Napoleon's opinion was that a good duelist made a bad soldier, but the code of 1810 'made no mention of dueling.

Political duels were frequent in the 19th century: Paul de Cassagnac was notorious for his duels; Pierre Napoléon Bonaparte shot the journalist Victor Noir when the latter was delivering a challenge to him in Jan. 1870; Léon Gambetta fought the minister of the interior, F. O. Bardy de Fourtou, in Nov. 1877, and Gen. Georges Boulanger came off the worse in a duel with Charles Floquet, president of the chamber of deputies, in July 1888.

In the 20th century duels still took place occasionally in France—often however for form's sake alone, with such precautions that neither sword nor pistol could prove fatal; or even for purposes of publicity. (See also Women's Duels, below.)

England.—Private dueling was never so prevalent in England as in France. Even so, some duels are recorded under Elizabeth I, for example those between the Holles and the Talbot families. Under James I dueling became, in Francis Bacon's words, an "unbridled evil," and, as solicitor-general, Bacon tried to enforce the proclamations against it. Duels were rare under the Commonwealth, but the Restoration brought an increase in their number, and in the 18th century they remained frequent. In George III's reign 172 duels were reported, in which 91 persons were killed, and the custom went on under George IV. Notable encounters were those between Richard Brinsley Sheridan and Maj. Thomas Matthews in 1772; between William Adam and Charles James Fox, who had spoken against Adam in the house of commons in 1779; between William Pitt and George Tierney in 1796; between Henry Grattan and Isaac Cory in 1800; between Sir Francis Burdett and James Paull in 1807; between Lord Castlereagh and George Canning in 1809; and between the duke of Wellington and the 10th earl of Winchelsea (George William Finch-Hatton) in 1829.

Up to the 1840s the British military code authorized dueling. Then two fatal encounters caused public opinion to react: first, the earl of Cardigan shot Capt. Harvey Tuckett on Sept. 12. 1840, for which he was tried by the house of lords and acquitted (Feb. 1841); next, Lieut. Alexander Munro shot his brother-in-law, Lieut. Col. David Fawcett, on July 1, 1843. An association against dueling was consequently formed by members of both houses of parliament and army and naval officers. It presented a memorandum to Queen Victoria and, with Prince Albert's support, succeeded in getting a debate in the house of commons in which Sir Henry Hardinge, the secretary for war, conveyed the Queen's desire for reform. There followed an amendment of the articles of war in 1844, to make dueling a military offense, and this was incorporated into the army act of 1881. Thenceforward duels had to be fought abroad; *e.g.*, at Calais or at Boulogne.

Germany.—In Germany duels of honour were authorized by the military code up to World War I: their conduct was controlled by a council of honour, and an officer who refused a challenge approved by his regiment was compelled to leave the service. Gnder the Weimar republic dueling was punishable with imprisonment, but after the advent of the Nazis to power it was legalized again (1936), under the control of special tribunals, wounds sustained being regarded in the same light as injuries in sport. Under an amendment of 1953 dueling was made punishable with imprisonment.

In a rather different category is the *Mensur,* the student duel still a feature of German university life. Most German universities have long-established *Verbindungen* (fighting corps) with strict rules. distinctive uniforms and great prestige. The meetings of the corps are held in strict secrecy. The Schlager, a heavy basket-hilted sabre is used, and the method of swordplay is quite different from that of normal fencing. In the *Mensur* the combatants take up a position on guard upright and quite close to each other with the sabre held above the head and the forearm in front of the face; it is a point of honour to remain immobile from the top of the head to the rear foot during a bout. The forearm is padded. the eyes are protected by steel glasses and the neck is also protected. Cuts are delivered almost exclusively at the head, inflicting severe wounds. Defense is limited to blocking the strokes with the forearm and the hilt: and the duel continues by timed rounds until loss of blood compels one of the duelists to retire. In this way students can obtain the scars on head and cheek which are prized as marks of courage.

Italy.—Private dueling flourished in Italy in the early 16th century and many books were written about it. Local laws were introduced against it in vain, and it was only after the Council of Trent had decreed against it in 1549 and in 1563 that it became less frequent. In the 19th century dueling became fashionable again (from 1879 to 1889 there were 2,759 duels recorded, but only 50 duelists were killed). Under the Fascist regime dueling was encouraged.

Women's Duels.—Duels have been recorded from time to time among women. Madame Maupin, née d'Aubigny (1673–1707). a singer at the Paris Opéra and the prototype of Theophile Gautier's Mademoiselle de Maupin, learned fencing from her lover and made herself formidable as a duelist. During the Regency in France the marquise de Nesle and the comtesse de Polignac are said to have fought a duel over the duc de Richelieu (L. F. A. du Plessis). In 1868 two young ladies fought a duel with pistols at Bordeaux: one was wounded in the thigh and the principals and seconds were condemned to 15 days imprisonment. In 1892 the princess Pauline Metternich and the Grafin Kilmannsegg fought a duel in Liechtenstein.

DUE PROCESS, a phrase principally associated aith one of the basic guarantees of the U.S. constitution, but with roots in early English common law and constitutional history. The first concrete expression of the due-process idea in Anglo-American law appears in the 39th article of Magna Carta (1215) in the royal promise that "No free man shall be seized or imprisoned or outlamed, or in any way destroyed; . . . excepting by the legal judgment of his peers, or by the laws of the land." In subsequent English statutes purporting to re-enact, and in commentaries elucidating, the principles of Magna Carta, the references to "legal judgment of his peers" and "laws of the land" are treated as substantially synonymous with "due process of law." While American colonial documents frequently reflect the language of Magna Carta, the earliest use of the due-process phraseology in American constitutions occurs in the 5th amendment to the federal constitution, ratified in 1791, in the provision that "No person . . . shall be deprived of life, liberty or property without due process of law."

Since this amendment was held inapplicable to state, as distinguished from federal, action, it was not until the adoption of the 14th amendment in 1867 that a federal due-process clause became applicable to the states. Many state constitutions have similar provisions, but these are enforced only by state courts.

In its first elaboration of the meaning of due process, the U.S. supreme court directed attention to "those settled usages and modes of proceeding existing in the common and statute law of England before the emigration of our ancestors" (Murray's Lessee v. *Hoboken* Land *&* Improvenzent *Co.*, 18 How. 272 [1855]). This test was subsequently restated as embracing only those principles of justice which are "so rooted in the traditions and conscience of our people as to be ranked as fundamental" (Snyder v. *Mass.*, 291 U.S 97 [1934]) or "implicit in the concept of ordered liberty" (Palko v. Conn., 302 U.S 319 [1937]). In determining the procedural safeguards that should be obligatory upon the states under the due-process clause of the 14th amendment, the supreme court has exercised considerable supervision over the administration of criminal justice in state courts, as well as occasional influence upon state civil and administrative proceedings. Its decisions have been vigorously criticized, on the one hand, for interfering unduly with state judicial administration. and on the other hand, particularly in dissenting opinions, for not treating all the specific procedural guarantees of the first ten amendments as equally applicable to state as well as to federal proceedings.

Even more controversial than its application to procedural rights has been the interpretation of the due-process clause to protect substantive rights against arbitrary governmental action, so as to subject to judicial review virtually every type of economic regulation. Perhaps the most famous example was a decision in 1905 invalidating, as an arbitrary interference with "liberty of contract," a New York statute limiting hours of work in bakeries; at least equally famous became the dissent of Justice Oliver Wendell Holmes that "a constitution is not intended to embody a particular economic theory, whether of paternalism . . . or of laissez faire" (Lochner v. N.Y., 198 U.S 45 [1905]). The view expressed by Justice Holmes eventually prevailed. as illustrated by a decision in 1934 sustaining state regulation of milk prices, in which Justice Owen Roberts stated the controlling principle that "a state is free to adopt whatever economic policy may reasonably be deemed to promote public welfare, and to enforce that policy by legislation adapted to its purpose" (*Nebbia* v. N.Y., 291 U.S. 502 [1934]). Since that date the supreme court has rigorously adhered to this principle.

Somewhat later in development, but of more continuing vitality, has been the incorporation into the due-process clause of the 14th amendment of the freedoms of speech, assembly, press and religion which are explicitly protected by the 1st amendment against federal encroachment. Since the first acceptance of this principle of incorporation by the supreme court in 1925, there has been a steady stream of controversial decisions determining the validity of state governmental action regarding such topics as advocacy of violent overthrow of government, holding of mass meetings in public places, distribution of defamatory or salacious literature, newspaper comment upon judicial proceedings, and public support of religious teaching. The distinctions drawn between valid and invalid state action in these areas have frequently been quite technical and not always entirely consistent. but in general they reflect the assumption, though not without occasional questioning by individual justices, that 1st-amendment freedoms are entitled to a "preferred position" in constitutional adjudication, as compared with such economic freedoms as were formerly protected by the doctrine of "liberty of contract."

DUET, a musical composition for two performers or singers. Unaccompanied vocal duets were common in secular music from the 14th to the 16th century. In 17th-century Italian cantatas the accompanied vocal duet was known as the chamber duet. Accompanied duets took on a variety of forms in 17th and 18th-century opera and also in the choral works of Bach and Handel. Unaccompanied instrumental duets, for string or wind instruments, known as duos. were written by French composers of the 18th century and by Haydn, Mozart and Beethoven, while the accompanied instrumental duet led to the development of the trio sonatas of Purcell, Bach, Handel and others. During a short period at the beginning of the 19th century harp duets were common and, when the harp went out of fashion as a domestic instrument, these were replaced in popularity by piano duets for four hands at one keyboard, notably those of Weber and Schubert. Piano duets, either for four hands at one keyboard or for two pianos, are also frequently arrangements of works for orchestra or organ. As orchestral works became more complex piano duet arrangements were particularly useful to students and amateurs, and much of the orchestral repertory became accessible in this form.

See Hans Engel, "Duett," in Die *Musik* in Geschichte und Gegenwart, ed. by F. Blume (1954); Alec Rowley, Four hands—One piano. *A* list of works for duet players (1940).

DUFAURE, JULES ARMAND STANISLAS (1798–1881), French statesman, one of the most notable supporters of Adolphe Thiers during the latter's presidency of the republic, was born at Saujon, Charente-Inférieure, on Dec. 4, 1798. He became a lawyer in Bordeaux and in 1834 was elected one of the deputies for his native *département.* Appointed minister of public works in Marshal Soult's ministry of 1839, he freed railway construction from the obstacles which had hampered it. In 1840 Dufaure became a leader of the opposition, and on the outbreak of the revolution of 1848 he sided with the republicans. On Oct. 13 he became minister of the interior in Gen. L. E. Cavaignac's government, but retired from office on the latter's defeat in the presidential election. During the second empire Dufaure practised at the Paris bar and in 1864 was elected to the Académie Française. In 1871 he was elected to the national assembly, and it was on his motion that Thiers was appointed head of the executive power of the state. Having been minister of justice under Thiers and under

Louis Buffet, he succeeded the latter as premier on March 9, 1876. He resigned office, however, on Dec. *12* but returned to power on Dec. *13, 1877.* Early in 1879 Dufaure took part in compelling the resignation of Marshal MacMahon, but immediately afterward, on Feb. *1.* he himself retired. He died at Rueil, near Paris, on June *28, 1881.*

See G. Picot, *M. Dufaure, sa vie et ses discours (1883).*

DUFAY, GUILLAUME *(c. 1400–1474);* the greatest composer of his time, both of church music and the secular *chanson* (*q.v.*), was born about *1400,* probably in Hainaut, which then was a part of Holland and now is a province of Belgium. He was a chorister at Cambrai cathedral *(1409).* entered the service of Carlo Malatesta of Rimini *c. 1420* and composed a motet for the marriage of Cleophe Malatesta to Theodore Paleologus in *1421.* He joined the papal singers in *1428* and composed motets to mark the election of Pope Eugenius IV (1431), and to celebrate the treaty of Viterbo between Eugenius and the emperor Sigismund *(1433).* In *1436* he wrote a motet for the dedication of Brunelleschi's dome for Sta. Maria del Fiore, Florence. In the same year he was made a canon of Cambrai. After seven years with the duke of Savoy, he lived mainly in Cambrai from about *1445,* and supervised the music of the cathedral. In *1446* he became a canon of Mons. For Philip the Good's brilliant "Feast of the Pheasant" held at Lille in *1454,* and intended to initiate a crusade to recapture Jerusalem, Dufay wrote a *"Lamentatio Sanctae Matris Ecclesiae Constantinopolitanae."* Following the ceremonial motets of his Italian period. he composed a series of masses, which, with those of John Dunstable (*q.v.*) and other English composers, laid the foundation for the rapid development of this form in the second half of the 15th century. For the *cantus firmi* of his masses he used both secular themes, such as his own ballade *"Se la face ay pale"* and *"L'Homme armé"* (which was used by many composers up to Palestrina). and sacred themes, such as *"Ave regina caelorum."* In these and other works of his Cambrai period he perfected the graceful and expressive style, the *contenance angloise,* which, according to Martin le Franc's *Le Champion des Dames (c.* 1440), he and Gilles de Binchois (*q.v.*) had adopted from Dunstable. He died at Cambrai Nov. *27, 1474.*

BIBLIOGRAPHY.—There are modern editions of his music in *Denkmäler der Tonkunst in Osterreich,* vol. vii, xi, xix, xxvii, xxxi and xl *(1849 et seq.);* complete ed., by G. de Van and H. Besseler, for the American Institute of Musicology *(1947–). See* also *J. F.* R. and C. Stainer, *Dufay and His Contemporaries (1898).* (F. L. HA.)

DUFF, ALEXANDER (1806–1878), Scottish missionary in India, who founded schools to promote European science and literature among Indians, was born on April *26, 1806,* at Moulin, Perthshire. At St. Andrews university he came under the influence of Thomas Chalmers, and after being ordained *(1829)* he was sent out by the foreign mission committee of the general assembly as their first missionary to India. On the voyage he was twice shipwrecked and lost all his property before he reached Calcutta in May *1830.* Up to this time Protestant missions in India had been successful only in reaching low-caste and outcaste peoples. particularly in Tinevelly and south Travancore. The Hindu and Moslem communities had been practically untouched. Duff therefore devised the policy of an educational mission. He first opened an English school in which the Bible was the centre of the schoolwork, and along with it all kinds of secular knowledge were taught from the rudiments up to university standard. The school soon began to expand into a missionary college, and a government minute was adopted on March *7, 1835,* which gave official sanction to Duff's aims.

After six years' furlough in England, Duff returned in *1840* to India. In *1839* the earl of Auckland, governor general. had yielded to the "orientalists" who opposed Duff, and adopted a policy which was a compromise between the two. At the Disruption of *1843* Duff sided with the Free Church and had to give up the college buildings. with all their effects, but with unabated courage he set to work to provide a new institution. He had the official support of Sir James Outram and Sir Henry Lawrence: and the encouragement of seeing a new band of converts. including several young men of high caste. In *1844* Viscount Hardinge opened government appointments to all who had studied in institutions similar to Duff's foundation. In the same year Duff took part in founding the *Calcutta Review,* of which from *1845* to *1849* he was editor. In *1849* he returned to England. He was moderator of the Free Church assembly in *1851* and again in *1873.*

In *1856* Duff returned to India, condemning the government's policy in *The Indian Mutiny: Its Causes and Results (1858).* He gave much thought and time to the University of Calcutta. which owes its examination system and the prominence given to physical sciences to his influence. In *1863* Sir Charles Trevelyan offered him the post of vice-chancellor of the university, but his health compelled him to leave India. He continued his work for foreign missions in different parts of the world. and mas the first occupant of the chair of foreign missions at New college, Edinburgh. At his death, on Feb. *12, 1878,* he left his personal property to found lectures on foreign missions at the college.

See his *Life, by* George Smith, 2 vol. *(1879).*

DUFFERIN AND AVA, FREDERICK TEMPLE HAMILTON-TEMPLE-BLACKWOOD, 1ST MARQUESS OF (1826–1902), British diplomat who distinguished himself in several important posts, including those of governor general of Canada and viceroy of India, was born at Florence, Italy, on June *21, 1826.* His father, Price Blackwood, 4th Baron Dufferin, died in *1841.* His mother, Helen, one of the three beautiful Sheridan sisters, lived till *1867,* and influenced him profoundly. He was educated at Eton and Christ Church, Oxford. and married Hariot Rowan Hamilton, an Irish neighbour, in *1862.* He held undersecretaryships in *1864–66* and was Gladstone's chancellor of the duchy of Lancaster, outside the cabinet, in *1868–72;* he was created earl of Dufferin in 1871.

Dufferin was governor general of Canada from *1872* to 1878. Behind his appearance, at once romantic and stately, and his graceful oratory, lay shrewdness and readiness to accept responsibility. He did much to weld the newly formed dominion together. Then, after two years as ambassador to Russia. he was moved in *1881* to Constantinople, where he had to deal with the consequences of Arabi Pasha's rising in Egypt and the resultant British intervention. His diplomatic adroitness assisted British arms in securing a firm foothold in Suez and Cairo; and he spent the winter of *1882–83* in Egypt reporting on government reorganization. He succeeded Lord Ripon as viceroy of India in *1884,* and pursued a domestic policy equally friendly to the Indians without antagonizing, as Ripon had done, the Anglo-Indian community. In foreign policy, he improved relations with Afghanistan and helped to settle the Panjdeh crisis, which resulted from a Russo-Afghan frontier incident in *1885.* By the annexation of Burma in *1886* he consolidated British territories. For his services he was made marquess of Dufferin and Ava when, in *1888,* he retired from India. He spent three years (1889–91) as ambassador in Rome, and then four in Paris, where he established unexpectedly friendly relations with the French. He retired to his estates in Ulster in *1896.*

Dufferin's last years were clouded by his eldest son's death at Ladysmith in *1900* and by business troubles. He died at Clandeboye, his house near Belfast, on Feb. *12, 1902.*

See Sir Alfred Lyall, *Life of the Marquess of Dufferin and* ***Ava,*** 2 vol. (1905); Harold Nicolson, *Helen's Tower (1937).* (M. R. D. F.)

DUFFTOWN, a small burgh of Banffshire, Scot., in the parish of Mortlach and on the Fiddich, *17* mi. S.S.E. of Elgin by road. Pop. *(1961)* 1,555. It dates from *1816* and bears the name of its founder, James Duff, 4th earl of Fife. Although planned in the shape of a cross, with a square and tower in the middle. the arms of the cross are not straight, the constructor holding that, in order to prevent little towns from being taken in at a glance, their streets should be crooked. The leading industry is distilling, the water being good for whisky making. The town is a health resort. The Stone of Mortlach is traditionally believed to have been erected to commemorate the success of Malcolm II over the Danes in *1010.* There are also three large stones known as "The King's Grave," a hill-fort and cairns. A portion of old Balvenie castle) a ruin, is considered to be of "Pictish" origin, but most of it is of the Scots Baronial period.

Three miles southeast of Dufftown is the ruined castle of Auchin-

down, on a limestone crag 200 ft. high, of which three sides are washed by the Fiddich and the fourth was protected by a moat. It dates from the 11th century. and once belonged to the Ogilvies, from whom it passed in 1535 to the Gordons. The Gothic hall with rows of fluted pillars is in fair preservation.

DUFFY, SIR CHARLES GAVAN (1816–1903), Irish-Australian statesman, who was a leading nationalist agitator in Ireland until 1855; when he emigrated to Australia and there embarked on a more successful political career. was born in Monaghan, Ire., on April 12, 1816. Mainly self-educated, he became a vigourous exponent of Irish nationalist views. While studying law in Dublin he met John Blake Dillon and Thomas Davis, and the three decided to found a new Irish weekly journal to express the aims of young nationalists of all classes and creeds. The *Nation,* founded in Oct. 1842. had an immediate popular success. Davis as poet and essayist was its chief inspiration, but Duffy's organization was the basis of its success. The young editors of the *Nation* were largely responsible for arranging the "monster meetings" of Daniel O'Connell (*q.v.*) in 1843. Duffy was imprisoned with other nationalist leaders after the great meeting at Clontarf had been suppressed. After his release Duffy and his colleagues opposed O'Connell's increasingly cautious policy. Known as the "Young Ireland" party, they demanded active agitation. In the famine of 1845–47 they formed the Irish confederation to compel effective measures of relief by the government. They made an abortive attempt at insurrection in Aug. 1848; just before it, Duffy was arrested and the *Nation* suppressed. On his release in 1849 he revived the weekly, but limited his agitation to a program of land reform. He was elected member of parliament for New Ross in 1852. and proceeded to organize an independent opposition of some 50 Irish members at Westminster, which would obstruct any government that did not support the demands of the Irish Tenant league. His parliamentary tactics foreshadowed those of C. S. Parnell, but Duffy's efforts were frustrated by the ambitions of individuals and by ecclesiastical distrust of his political views.

Duffy retired from Irish politics in 1855, declaring that he left Ireland "as a corpse on a dissecting table." In Australia, he was warmly welcomed by Irish exiles in Melbourne, where he practised as a barrister. Elected to the Victoria house of assembly in 1856, he became minister of land and works in 1857; and promoted an important Land act. He was prime minister of Victoria in 1871–72, and was knighted in 1873. He was speaker of the Victoria house of assembly from 1871 to 1880, when he retired to the south of France to write his recollections. which form a principal source of Irish history. His publications include *Young Ireland, 1840–50,* 2 vol. (1880–83). *The League of the North and South, 1850–54* (1886). *Thomas Davis* (1870) and *My Life in Two Hemispheres* (1898). Duffy died at Nice on Feb. 9, 1903.

(D. G.)

DUFOUR, GUILLAUME HENRI (WILHELM HENRICH) (1787–1875), Swiss army officer who was elected four times to the supreme command of the Swiss army and was noted as a civil engineer, was born at Constance on Sept. 15, 1787. He studied in Geneva: at the École Polytechnique in Paris and at the Ecole de Génie at Metz. from which he graduated first in his class. He served in Napoleon's army, defending Corfu in 1813 and taking part in the campaigns in France in 1814. He resigned in 1817 and returned to Switzerland. where he was appointed *ingénieur cantonal* and supervised constructional works which greatly improved Geneva. He helped to form the military school at Thun in 1818, where he became chief instructor. He was appointed chief of staff of the Swiss army in 1831 and commanded a division sent to restore order in Basel in 1833. In the same year, he began his pioneer topographical survey of Switzerland (published 1842–64). Dufour was elected general of the federal army to act against the Sonderbund in 1847 *(see* SWITZERLAND: *The Sonderbund War*) and displayed skill and moderation in its suppression. He was elected general for the second time in 1849 to maintain Swiss neutrality in the face of insurgents from Baden; again in 1856, during the conflict with Prussia over Neuchâtel; and finally in 1859, when the French were about to annex Savoy. He presided over the international congress in Geneva in 1864 which drew up the convention for the wounded in time of war and resulted in the creation of the Red Cross. He sat in the federal assembly as a Conservative. He died at Les Contamines, near Geneva, on July 14, 1875.

BIBLIOGRAPHY.—E. Chapuisat, *Le Général Dufour,* 2nd ed. (1942); O. Keverdin, *La Guerre du Sonderbund, vue par le général Dufour* (1948); *H.* Favre, *Un grand ingénieur suisse* (1932); *T.* Stark, *La Famille du général Dufour et les Polonais* (1955).

DUFRESNOY, CHARLES ALPHONSE (1611–1665), French painter and writer on art, was born in Paris. He learned the rudiments of design under Perrier and Vouet. At the age of 21 he went to Rome. and there studied Raphael and the antique. He went in 1633 to Venice, and in 1656 returned to France. He died at Villiers le Bel, near Paris. His Latin poem, *De arte graphica,* written during his Italian sojourn, was translated into several languages.

DUFY, RAOUL (1877–1953), French painter and designer, known for his scenes of sailboats, bathers, the race course and other themes vibrating with colour juxtapositions, was born June 3, 1877. at the seaport of Le Havre, where he passed his childhood. In 1900 he went to Paris to attend the École des Beaux-Arts. But conventional museum art repelled him; rather he was fascinated by Impressionist and post-Impressionist art. The 1901 Van Gogh exhibition was a great influence on him as was the work of Henri Matisse in the famous 1905 Salon d'Automne exhibition. By 1907 Dufy had broken with the Impressionist idea of pure colour, moving toward the intensified tonalities of the *Fauve* (wild beast) school. During 1908–09 he worked with Georges Braque and Émile Othon Friesz. In 1911 he did a series of woodcut illustrations for Guillaume Apollinaire's *Le Bestiaire.* This. together with a new-found friendship with the fashion designer Paul Poiret, led him to do woodblock designs for textiles and set up his own factory. In 1920 Dufy began to produce pottery and the following year tapestries. His well-known paintings of Nice date from 1927; the Bois de Boulogne scenes from 1929 and those of Deauville from 1930. Although Dufy's life was marked by commercial and semicommercial projects, it is possible to disengage Dufy the sensitive painter from them. He died March 23, 1953, in Forcalquier.

(B. S. Ms.)

DUGDALE, SIR WILLIAM (1605–1686), English scholar and one of England's most distinguished antiquaries. was born at Shustoke. Warwickshire, on Sept. 12, 1605. He attended the Free school at Coventry and from an early age was encouraged by his father to study history and antiquities. At 17 he married Margery Huntbach, daughter of a Staffordshire gentleman, and settled as a small landowner at Blyth hall, Warwickshire.

At this time Dugdale became friendly with William Burton, author of a *Description of Leicesferslzire* (1622). Burton introduced him to Sir Simon Archer of Tanworth, Warwickshire. who was collecting material for a history of Warwickshire. The two subsequently worked together on this project and through Archer, Dugdale obtained access to the records of the Warwickshire gentry. Gradually he became the centre of a scholarly circle and, following an introduction to Sir Henry Spelman in London, he was persuaded to collaborate with Roger Dodsworth in the production of a *Monasticon Anglicanum,* a collection of records relating to monastic foundations. This was subsequently published under Dugdale's name in three separate volumes in 1655, 1661 and 1673. Dugdale's *Antiquities of Warwickshire* appeared in 1656 and was followed by *History of St. Paul's Cathedral* (1658); *History of Imbanking and Draining* (1662); *Origines Juridiciales* (1666); *Baronage of England* (1675–76); and *A Short View of the Late Troubles in England* (1681).

Dugdale was also a professional herald closely associated with the political events of his time. He was appointed a pursuivant extraordinary in 1638 and became Rouge Croix pursuivant in 1640. In 1641. at the instigation of Sir Christopher Hatton who foresaw the approaching Civil War, he undertook a survey of all the monuments and armorial glass in St. Paul's and Westminster abbey and at Peterborough. York, Lincoln and elsewhere. When war broke out he attended Charles I at York and subsequently sum-

moned various castles, including those of Banbury and Warwick, to surrender. He was at Oxford with the king and court from 1642 to 1646 and during his stay collected material for his books at the Bodleian and college libraries. He was admitted an M.A. of the university in Nov. 1642. He compounded for his estates, which had been sequestrated, in 1646 and subsequently resumed his researches in Warwickshire and London. He was created Norroy king of arms in 1660 and undertook a series of visitations to register the coats of arms and pedigrees of the local gentry during the following years. In 1677 he was created Garter king of arms and was knighted. He died at Blyth hall on Feb. 10, 1686.

In the course of a busy working life Dugdale came to be the foremost figure in a small group of medieval scholars whose correspondence, transcriptions and published works laid the foundations of modern English historical scholarship. Pre-eminently a student of charters and an exponent of their use, Dugdale excelled in the field of family history. Yet his interests in history and antiquities in the broadest sense were remarkably diverse. He was a pioneer in the technique of historical research and his work displays an accuracy and insight of an unusual order for his period.

DUGHET, GASPARD (called GASPARD POUSSIN) (1615–1675), French painter, who called himself after his brother-in-law, Nicolas Poussin, was born and died in Rome. He worked chiefly in Rome and its vicinity throughout his life; but his father was French and it is usual to class him among the French school. His activity was exclusively in the field of landscape painting.

Though the chronology of his works is uncertain, his style is familiar, being composed mainly of elements derived in varying proportions from his brother-in-law and from Claude Lorrain. He tended sometimes toward the former's architectonic grandeur, sometimes toward the latter's more lyrical style, but as a rule produced a compromise between them. The landscapes of Paul Bril, Annibale Carracci and Domenichino must also be counted among the influences on his work. Most of his paintings express in an ideal, though not poetic, form, the character of the countryside round Rome. He also made a specialty of land storms. Important series of his works are to be found in the Colonna and Doria-Pamfili palaces in Rome. Many are still in England, where, in the 18th century, they were taken as models for the design of landscape gardens and parks. (M. W. L. K.)

DUGONG, one of the two existing genera of the order Sirenia (*q.v.*), herbivorous aauatic mammals of warm coastal waters. Dugongs (Dugong) are distinguished from the Atlantic-inhabiting ordinal relations the manatees (*q.v.*) by, among other anatomical features, their smaller size (7 to 9 ft. in the adult), broad crescent-shaped whalelike tail, fewer teeth (no more than six flat-surfaced molars on each side of either jaw): tusks in the upper jaw of the male and absence of nails on the well-developed fore flipper. The bones are hard and firm, and the generalized skeleton shows similarities with that of the elephant, though the hind limb bones are practically lost.

Dugongs frequent the shallow waters of far eastern tropical seas where, in small groups, they may be seen basking on the surface of the water, or browsing on submarine pastures of seaweed. for which the thick! fleshy lips and truncated snout pre-eminently fit them. When submerged during feeding the dugong surfaces every five to ten minutes for a fresh supply of air. Although it has poor eyesight, its hearing, despite the lack of external ears: is quite good. The female produces a single calf 12 months after mating, and is remarkable for its great maternal affection; the young is embraced with one flipper while it nurses on one of the two pectoral teats.

One species, with possibly several races: is known as *Dugong* dugong. This is distributed in the Red sea, the Indian ocean and east in the Pacific as far as the Solomon and Marshall Islands; it ranges south along the coast of northern Queensland, Austr., and north into the East China Sea. The islanders frequently hunt it with spears or harpoons, for its flesh is an esteemed delicacy. The oil obtained from its blubber has been of commercial value and a full grown dugong may yield from 10 to 12 gal. In recent years the dugong has been in special danger of extinction. For a discussion of evolutionary history, see UNGULATA.

DUGUAY-TROUIN, RENÉ (1673–1736), French privateer and naval officer who won a great reputation for daring during Louis XIV's wars, was born at St. Malo, on June 10, 1673. A younger son, he was destined for the church, but no college could discipline his turbulent spirit, and it was decided he should become a sailor. Serving on the "Trinité" at the age of 16 and commanding the "Danycan," equipped by his family for privateering, at 19, he had a hard apprenticeship. In 1694, his ship the "Diligente" was overcome by six enemy vessels and he was taken prisoner, but he escaped from Plymouth through the help of a young woman. During the next three years he fought a series of astonishing battles. Louis XIV gave him a sword of honour for the capture of the "Nonesuch" in 1695, and at 24 Duguay-Trouin received a commission as captain of a frigate.

The inferiority of the French navy during the War of the Spanish Succession and then the long period of peace after the treaties of Utrecht prevented Duguay-Trouin from showing the full extent of his ability: he commanded only small ships or small divisions. He attacked the Dutch whaling ships at Spitzbergen in 1703 and a rich fleet of Portuguese galleons in the Atlantic (1706) and, with Claude de Forbin, took part in the famous fight off the Lizard (1707). In 1709 he received letters patent of nobility. In 1711 the king lent several ships to the St. Malo privateers, and the squadron of Duguay-Trouin boldly entered the harbour at Rio de Janeiro and held the town to ransom. This success, although it came too late in the war to help French fortunes, did bring a ray of hope to France during a time of mourning and defeat. After the peace Duguay-Trouin was made a lieutenant-general in 1728. He led his last expedition, against the Barbary pirates, in 1731. He died in Paris on Sept. 27, 1736. His character was complex. Extravagant, prodigal, daring but at the same time calculating and prudent, forceful but kind-hearted, excitable, superstitious and outstandingly brave, he combined a tone of working detachment with a strong sense of honour and of duty: "I give my services only for the pleasure of serving." (L. NI.)

DU GUESCLIN, BERTRAND (*c.* 1323–1380), Breton soldier and constable of France, an outstanding military leader on the French side in the first period of the Hundred Years' War, was born at the castle of La-Motte-Broons, near Dinan. Of his youth nothing is known except what is related in the poem about him by his contemporary Jean Cuvelier, much of which is of doubtful value as history. As a young squire, Du Guesclin learned the art of soldiering in the skirmishes of the War of the Breton Succession between Charles of Blois and John IV (Jean de Montfort). His real military career began when the English under Henry, duke of Lancaster, were besieging Rennes (Oct. 1356–July 1357); it was at this time that his famous duel with Sir Thomas Canterbury took place. Du Guesclin succeeded in forcing his way into Rennes and defended it for several months. He was, on Dec. 6, 1357, rewarded by the dauphin (the future Charles V) with a pension of 200 livres for this action. About the same time (by Dec. 13 at the latest), he was appointed captain of Pontorson for the dauphin's uncle, Philippe, duc d'Orléans. Henceforth he remained in the service of the French royal house of Valois.

Du Guesclin left Pontorson in June 1359 in order to take part in the siege of Melun, but was captured by Sir Robert Knollys on his way back. Set free after the treaty of Brétigny between France and England (1360), he fought against the pillaging *compagnies* (bands of mercenaries) in Normandy, Maine and Perche. He was again taken prisoner at Juigné.

In 1363 Du Guesclin was captain-general in the Norman *bailliages* of Caen and Cotentin, and by the beginning of 1364 his authority extended over the whole of Normandy and over Beauce. In April 1364 he took Mantes and Meulan from the forces holding them for Charles II of Navarre, and in May he defeated the Navarrese at Cocherel, taking prisoner the famous Jean de Grailly,

captal de Buch (*q.v.*). Appointed chamberlain by Charles V on his accession, he relinquished the position of captain-general in Normandy on being recalled to Brittany by Charles of Blois. At the battle of Auray (Sept. 29, 1364), in which Charles of Blois mas killed, Du Guesclin was captured by Sir John Chandos. Having paid 40,000 gold francs for his ransom, Charles V entrusted Du Guesclin with the task of leading the *compagnies* into Spain to fight for Henry of Trastámara against Pedro I the Cruel. Du Guesclin set off in Sept. 1365, going via Avignon, and in 1366 Henry was proclaimed king of Castile. Edward the Black Prince. however. then intervened on Pedro's behalf and defeated and captured Du Guesclin at the battle of Nájera (April 3. 1367). Released after considerable difficulty and in exchange for an enormous ransom, Du Guesclin went to Provence to advance the designs of Louis of Anjou on that country (March–April 1368). He then led a second expedition to Spain, which resulted in Henry's final victory and Pedro's death at Montiel (March 1369). For his services Henry created him duque de Soria y Molina.

In 1370 Charles V recalled Du Guesclin and appointed him constable of France. The constable then de'feated his old opponent Knollys at Pontvallain and occupied Poitou and Saintonge. Against the great cavalry raids across France by the English, he recommended careful tactics designed to contain and exhaust the enemy.

Expeditions against the English and against the mercenary bands occupied most of Du Guesclin's last years. It was against his advice that Charles decided, in 1378, to confiscate the duchy of Brittany from John IV, whom Du Guesclin had already effectively expelled from the country in 1373. Sent into Languedoc in 1380 to suppress disorders, Du Guesclin was taken ill while laying siege to the castle of Chbteauneuf-de-Randon and died on July 13, 1380. After the death of his first wife, Tiphaine Raguenel. whom he had married in 1364, he had married Jeanne de Laval, dame de Tinténiac. in 1374.

DUGUIT, LÉON (1859–1928), French jurist, one of the most revolutionary legal thinkers of his generation, was born at Libourne, Gironde, Feb. 4, 1859. He studied law at the University of Bordeaux and was appointed professor in the faculty of law at Caen in 1883. In 1886 he returned as professor to Bordeaux, where he became dean of the faculty of law and remained until his death. Dec. 18, 1928. A brilliant teacher and an authority on constitutional law, he gained a world-wide reputation as a legal philosopher. Discarding the traditional theories of law and the state, he found the basis of law in the fact that man was a social animal endowed with a sense of social solidarity. Out of this sense came the recognition of certain rules of conduct as essential for life in society.

In his view the state had neither personality nor sovereign power; governments, like individuals, were bound by the rules of law derived from social necessity. Despite subsequent criticism, Duguit's work remains an important and original contribution to legal thought.

Duguit's more important works include: *Des Fonctions de l'état moderne* (1894); *Les Constitutions et les principales lois politiques de la France depuis 1789,* with *H.* Monnier, 3rd ed. (191j); *Les transformations générales du droit privé,* etc. (1912); *Traité de droit constitutionnel,* 5 vol., 2nd ed. (1921); *Jean Jacques Rousseau, Kant et Hegel* (1918); *Law in the Modern State* (Eng. trans.: 1921). (L. N. B.)

DUHAMEL, GEORGES (1884–), French author and novelist who sought to uphold traditional values and to safeguard individual liberties. was born in Paris on June 30, 1884. He took a science degree in 1908, and qualified as a doctor of medicine in 1909; his interest in science and medicine. and in music and the theatre, was reflected in his writings. Extensive travels provided a further source of material. He was a prolific writer on many subjects.

Duhamel began by writing poetry, plays and literary criticism, and as a critic was one of the first to draw attention to the works of Paul Claudel. In 1906, he joined in founding a small community at Créteil-sur-Marne, known as the Abbaye. It was there that he met Blanche Albane, an actress, whom he married in 1909. The members of this group hoped to earn their living as printers and to combine manual and intellectual pursuits. but the experiment proved unsuccessful, and after 14 months they went their separate ways. Nevertheless, this association promoted the sense of fraternity and social responsibility which several of them were to express, notably Duhamel himself; and Jules Romains (*q.v.*), who was connected with them.

Duhamel served as a front-line surgeon during World War I. He was deeply moved by the sufferings which he witnessed, and oppressed by the futility of war. His experiences were recorded in two notable books: *Vie des martyrs* (1917; Eng. trans. 1918) and *Civilisation* (1918; Eng. trans. 1920).

In 1920, he decided to make writing his career. Henceforth. he chiefly wrote novels. and a great variety of essays and miscellaneous works discussing social and moral issues. Duhamel was an agnostic, and based his philosophy on human values, particularly moderation, tolerance and kindliness. He sought to preserve what was best in civilization. and to maintain individual freedom in an age of growing standardization. His distrust of mechanical or material progress, his misgivings about the future of mankind and his compassion for human misfortunes inspire much of his writing. His views were expressed in such works as La *Possession du monde* (1919); *Le Voyage de Moscou* (1927); *Scènes de la vie future* (1930), describing his impressions of the United States; *Défense des lettres* (1937); *Civilisation française* (1944): *Problèmes de l'heure* (1957). He also wrote memoirs, records of World War II *(Lieu d'asile)*, stories for or about children and works expressing his feeling for nature *(Les Plaisirs et les jeux, Fables de mon jardin)*.

His reputation as a novelist rests mainly on two novel-cycles. Both contain many reflections of his own experiences. The first, entitled *Vie et aventures de Salavin,* j vol. (1920–32; Eng. trans. *Salavin,* vol. i–iv, 1936). describes the frustrations and perplexities of a "little man" of the 20th century, trying to work out his own salvation with no religious faith to sustain him. In the second cycle, *Chronique des Pasquier,* 10 vol. (1933–44; Eng. trans. 1937–46), Duhamel relates the history of a French middle-class family, from the 1880s to the 1920s. His gifts of humour. sympathy and observation are here particularly apparent. Other novels include *La Pierre d'Horeb* (1926); *Le Voyage de Patrice Périot* (1950); *Le Complexe de Théopile* (1958).

Duhamel became a member of the Académie Française in 1935. He was president of the *Alliance française* from 1937 to 1949, and subsequently its first honorary president.

DUHRING, EUGEN KARL (1833–1921), German philosopher and political economist. standing with Ernst Mach and Richard Avenarius as one of the most notable German positivists. was born at Berlin on Jan. 12, 1833. After practising as a lawyer (until 1859), he turned to free-lance studies because of incipient blindness and became *Privatdozent* at Berlin university in 1864; but in 1877 his licence to teach was withdrawn in consequence of a quarrel with the professors there. His work includes histories and systematic treatises in the fields of mathematics, physics and literature, but he is chiefly remembered for his contributions to philosophy and economics.

Dühring's most important books are: *Kapital und Arbeit* (1865); *Der Wert des Lebens* (1865); *Natürliche Dialektik* (1865); *Carry's Umwälzung der Volkswirtschaftslehre und Sozialwissenschaft* (1865); *Kritische Geschichte der Philosophie* (18'69); *Kritische Geschichte der allgemeinen Principien der Mechanik* (1873), one of his most successful works; *Cursus der National- und Sozialökonomie* (1873–92); *Sache, Leben und Feinde* (1882), an autobiography: and *Der Ersatz der Religion durch Vollkommeneres* (1883). Duhring died at Nowawes (Potsdam) on Sept. 21. 1921.

In his theory of knowledge Diihring proceeds from a concept of

reality expressed in strongly scientific terms: our intellect is capable of comprehending the whole of reality, since the laws of the intellect and those of reality are the same. In his early work Diihring concerned himself with the analysis of the epistemological problems raised by this thesis, but in his later writings his concept of reality stiffened into a dogmatic materialism. In the place of the mystical metaphysics current in his day Diihring sought to erect a world system characterized by the antagonism of different powers: with a "law of difference" ruling both the physical world and the consciousness. Yet he held that nature aims generally at a combination of powers. Diihring maintained this optimistic view in his ethics: the origins of morality lie in our naturally "sympathetic" instincts. Individualism and socialism belong inevitably together.

As an economist Diihring placed sociological factors above economic ones. He rejected the Darwinian struggle for existence and put in its place the idea of a "free society" in which all relations based on power are abolished and all human relations are socialized. Following H. C. Carey and F. List, he emphasized the "national" character of economics.

Friedrich Engels. in his famous textbook of Marxism, *Herrn Eugen Dührings Umwälzung der Wissenschaft* (1878; later and more familiarly known as *Anti-Dühring*); Eng. trans. by E. Burns. ed. by C. P. Dutt (1943), dissociated himself from Diihring's "vulgar materialism" and from his utopian socialist ideas: whereas Diihring had contested the importance of Hegel, Engels argued that Hegel's "revolutionary side" had always been misjudged and that the discovery of dialectic was an immortal service distinguishing Hegel from all "metaphysicians." Nevertheless. Engels' own position with regard to the theory of knowledge does not differ from Diihring's naïve realism.

See E. Doll. *Eugen Diihring* (1893); Gerhard Albrecht, *Eugen Diihrings Wertlehre* (1914) and *Eugen Duhring* (Jena, 1927); and H. Lamberz, *Carey und Diihving (1926).* (M. O. G.)

DUIKER (DUIKERBOK, DUIKERBUCK), small African antelopes of forest and brush country. The popular names (derived from the Dutch) allude to the animal's habit of diving into and threading its way through thick bush. *See* ANTELOPE: *Subfanzily Cephalophinae;* BOVIDAE.

DUILIUS (DUELLIUS), **GAIUS** (3rd century B.C.), Roman general during the First Punic War. In 260 B.C., when consul in command of the land forces in Sicily, he superseded his colleague Gnaeus Cornelius Scipio Asina. nho was captured, as commander of the fleet. Recognizing that for the unskilled Romans the best chance of victory lay in fighting under conditions as similar as possible to those of a land engagement, he invented boarding bridges with grappling irons *(corvi),* and gained a brilliant victory over the Carthaginian fleet off Mylae on the north coast of Sicily. He was granted the first naval triumph in Rome's history, and a memorial column adorned with the beaks of the captured ships *(rostra)* was set up in the forum. In 258 he was censor. *See* also PUNIC WARS.

See Corpus, *Inscriptionum Latinarum* i², 2, 25; Polybius, *History,* i, *22–23.*

DUISBURG, an industrial town of Germany which after partition of the nation following World War II was located in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It stands at the junction of the Rhine and the Ruhr. One of Germany's great iron and steel towns, and one of the largest inland ports in the world. Duisburg is connected with the north German ports by the Rhine-Herne canal which links it with Dortmund and thus with the Dortmund-Ems canal. Pop. 11950) 110.783; (1959 est.) 502,028.

The present town was formed by the incorporation of a number of other centres—Ruhrort (which includes the harbour) and Meiderich in 1905 and Hamborn (the chief industrial area), Hochfeld. Neudorf and Düssern in 1929. From 1929 until 1934 it was called Duisburg-Hamborn. It is divided into three main districts. The heart of the town lies south of the Rhine-Ruhr junction, with suburbs and a garden city spreading up the surrounding wooded hills and well-planned industrial areas. To the north is the port area, and to the northwest the sprawling industrial area of Hamborn. There are a number of bridges over the river. The centre of the town is formed by three shopping streets near which lie the Burgplatz. site of the 8th-century Frankish court and of a foundation (1253) of the Teutonic order (*q.v.*). Although many of Duisburg's medieval buildings were destroyed in World War II, the 13th-century Gothic Salvatorkirche (which contains the grave of Mercator) and the 12th-century Romanesque Premonstratensian abbey in Duisburg-Hamborn are still standing. There are a Municipal Arts museum and a local history museum. The zoo contains the largest aquarium in western Germany.

Duisburg is connected by helicopter with Brussels, Belg., and thus with international air services. Its port has 23 docks, over 31 mi. of quays and one of the biggest grain-loading conveyors in Europe, handling an average of 10.000 tons a day. In the mid-1950s Duisburg produced about 25% of the German Federal Republic's steel and 30% of its iron. It is also a centre of coal mining, and manufactures foodstuffs, textiles, wood and metal products and chemicals.

Known to the Romans as Castrum Deutonis and to the Franks as Diuspargum. Duisburg became a free imperial city in the 12th century. In the 17th century it was acquired by Brandenburg. and the elector Frederick William founded a Protestant university in 1655, which flourished until 1802. Its most important period of development came with increasing industrialization after 1880. It was occupied by Belgian troops during 1921–25, and was heavily bombed during World War II.

DUJARDIN, FÉLIX (1801–1860), French biologist and pioneer in cytology, was born at Tours on April 5, 1801, and died at Rennes on April 8, 1860. He forsook art and engineering for natural science, and in 1839 was appointed professor of mineralogy at Toulouse. He was subsequently dean and professor of zoology at Rennes university.

In 1835 Dujardin distinguished protoplasm from other viscid substances. designating it "sarcode" and assigning to it all the qualities of life. He made detailed studies of rhizopods and of oceanic foraminifera and was the first to recognize Infusoria as a special unicellular group.

Dujardin's writings include *Histoire Naturelle des zoophytes infusoires* (1841), *Manuel de l'observateur au microscope* (1843) and *Histoire naturelle des helminthes* (1844). (W. J. BP.)

DUJARDIN, KAREL (1622–1678), Dutch painter and etcher, best known for his spirited representations of Italian peasants and shepherds with their animals. Born in Amsterdam in 1622, he was a son of the painter Guilliam Dujardin and a pupil of Nicolaes Berchem. After a trip to Italy, he worked in Amsterdam and The Hague from 1652 until 1674; after that he returned to Rome where he stayed until shortly before his death in Venice on Nov. 20, 1678. He also painted religious, mythological and allegorical subjects, various genre scenes and a number of excellent likenesses! notably a large group portrait (Rijksmuseum, Amsterdam). (W. Sw.)

DUKAS, PAUL ABRAHAM (1865–1935), French composer whose fame and popularity rest on a single orchestral work, *L'Apprenti sorcier,* was born in Paris on Oct. 1, 1865. and studied at the Paris conservatory under T. Dubois, G. Mathias and E. Guiraud. After winning a second Grand Prix de Rome with his cantata *Velléda* (1888), he established his position among the younger composers with the overture to Corneille's *Polyeucte,* first performed in 1892, and the Symphony in C major (1896). The remainder of his output (never large because of his own strict censorship of his works) consisted mainly of dramatic and program music and compositions for piano. Dukas. who was a master of orchestration, was from 1910 to 1913 professor of the orchestral class at the Paris conservatory and, from 1913 till his death in Paris on May 17, 1935, professor of composition there. Dukas also contributed musical criticism to several Paris papers and his collected writings, *Les Écrits de Paul Dukas* 11948), include some of the best essays ever published on Rameau, Gluck and Berlioz.

Dukas' *L'Apprenti sorcicr* (1897, based on Goethe's *Der Zauberlehrling*) was a piece of descriptive music written at the same time and in much the same style as Richard Strauss's *Till*

Eulenspiegel. Yet Dukas' musicianship was of a considerably wider range than this brilliant period-piece attests. His *Sonate* (1901) is one of the last great works for piano that prolong the tradition of Beethoven, Schumann and Liszt; his Variations, Interlude et Finale pour piano *sur* un *thème* de Rameau (1903) represent an elegant translation into French musical idiom and style of Beethoven's formidable Diabelli Variations, op. 120. The ballet, La *Péri* (1912), on the other hand, displays consummate mastery of impressionist scoring; and in Dukas' opera Ariane et *Barbe-Bleue* (1907), on the play of Maurice Maeterlinck, poetic atmosphere and perfection of musical texture make up for lack of dramatic impact.

After 1912 Dukas ceased publishing his compositions — except for a piano piece written in memory of his admirer Claude Debussy (d. 1918), the evocative La *Plainte* au loin *du Faune* (1920), and a song setting, the charming Sonnet de Ronsard (1924) — and a few weeks before his death, he destroyed all his musical manuscripts. Dukas collaborated with the Paris publishing firm of Durand in preparing modern editions of some of the works of Rameau, Couperin and D. Scarlatti and of the piano works of Beethoven.

An admirable pedagogue (Manuel de Falla was among his disciples and Oliver Messiaen was one of his pupils), a shrewd observer of the musical scene, a tireless reader of every score ancient and modern and of every literary work he could lay hands on, Dukas was that rare man among modern musicians: a 20th-century humanist.

See G Favre, *Paul* Dukas, *sa vie, son oeuvre (1948).* (F. E. **G.**)

DUKE, JAMES BUCHANAN (1856–1925), U.S. tobacco manufacturer and philanthropist, was born on a farm near Durham, N.C., on Dec. 23, 1856. His father, Washington Duke, entered the tobacco business after the Civil War. James. who with his brother Benjamin Duke (1855–1929) entered the business at an early age, became president in 1890 of a combination of major cigarette manufacturers, the American Tobacco company. He also came to control several other tobacco manufacturing combinations. In 1911 the United States supreme court ordered the dissolution of the American Tobacco company, and James Duke bore the chief responsibilities in arranging the dissolution. The Duke family contributed heavily to Trinity college in Durham, which was expanded into a university and named Duke university under provisions of a fund created by James Duke (Dec. 1924). By the indenture of 1924 and by his will, James also provided funds for other educational and charitable purposes in North and South Carolina. He died on Oct. 10, 1925. (H. J. SG.)

DUKE, a European title of nobility: Lat. dux (cf. ducere, "to lead"), It. duca, Fr. *duc,* Sp. and Port. duque, Ger. Herzog.

Origins. — Under the early Roman empire, when the regular army groups were commanded by the governors (legati Augusti pro praetore) of the provinces in which they were stationed, the title dux was normally applied only to generals of special expeditionary forces; the title was followed by a description of the force and often of the campaign for which it had been assembled. When Diocletian and Constantine I separated the military command of a province from its civil administration, they gave to the military commander the title of dux. The Notitia *Dignitatum* records 25 duces, distinguished by their provinces, all round the frontiers of the empire from the dux *Britanniarum* to the dux Armeniae. Some district commanders were dignified with the then higher title of comes (see COUNT); *e.g.,* the comes Aegypti and, in Britain. the *comes littoris Saxonici,* or "count of the Saxon shore."

The title of dux was taken over in the Visigothic, Ostrogothic and Merovingian kingdoms that succeeded the Roman empire in the west: a *dux* provinciae is recorded in Spain, a *dux* Raetiae in Italy, and duces commanding a group of civitates or municipalities in Gaul. As the title comes was in these kingdoms normally given to the military governors of a single *civitas,* a duke came naturally to rank higher than a count.

Tacitus, in his account of the ancient German tribes in the 1st century A.D., states that they chose "their kings for their noble lineage, the leaders [duces] for their prowess." These early Germanic dukes, then, were "leaders of the host" (Old Ger. *herizogo;* cf. Heer, "army"), elected originally by their tribes for the conduct of a campaign but ready when occasion arose to establish themselves permanently — as for instance when the Lombard dukes of Benevento and Spoleto made themselves independent of the Lombard kings in Italy from the end of the 6th century. In Merovingian France likewise in the 7th and 8th centuries dissident and outlying peoples such as the Basques (Gascons) and the Aquitanians set up tribal dukes of their own.

The early Carolingian sovereigns in France and in Germany continued to appoint dukes, but their weaker successors found themselves constrained to free the dukes more and more from royal control in the areas that they had to defend.

Germany. — Franconia, Swabia, Bavaria and Saxony (*qq.v.*), originally the homes of distinct tribes, emerged as the great "stem-duchies" of Germany as the dukes appointed by the Carolingians as military governors made themselves increasingly independent. In the first 100 years of the post-Carolingian period the tribal character of these duchies disappeared: in Franconia from 939, when the emperor Otto I took that duchy into his own hands. They retained their old boundaries, however, even when new men took advantage of the political turmoil to set themselves up as dukes.

The earlier emperors of the 11th century, especially Henry III, were able to assert their authority over the dukes, but the troubles of the Investiture contest weakened this control (see INVESTITURE). In the 12th century the Hohenstaufen emperors, who created the new duchies of Austria (1156) and Styria (1180) and even deposed such a magnate as Henry the Lion of Saxony, seemed likely to succeed in building a strong central authority around the growing royal principality of Franconia and in reducing the dukes to genuinely obedient vassalage; and at the same time the lesser noble families began to consolidate their own holdings and their ancient allodial jurisdiction at the expense of the ducal authority, gradually acquiring various new rights such as criminal jurisdiction and direct taxation. The growth of these smaller territorial principalities (countships, etc.) naturally diminished the real prestige of the dukes. Despite the collapse of the Hohenstaufen design after 1250 and the success of the dukes in securing their independence in their own principalities, their title came to denote no longer greater power under the king, but only a higher rank than that of the princely counts. By the end of the 15th century Brunswick (1235), Mecklenburg (1348), Jiilich (1356), Berg (1380), Cleves (1417), Holstein (1474) and Wdrttemberg (1495) had been raised to the rank of duchies. Furthermore, with the extensive privileges accorded the electors (only one of whom was a duke) by the Golden Bull of 1356, the duke had ceased even in theory to be the highest-ranking of the princes of the empire; the Austrian dukes indeed assumed the new title of archduke (*q.v.*), claiming equal rights with electors.

In the 16th, 17th and 18th centuries, therefore, the Habsburg emperors were ready to accord the title of duke quite readily for honorific purposes to the lords of comparatively small territories. In 1805, the year before the Confederation of the Rhine and the dissolution of the Holy Roman empire, there were ten sovereign dukes in the empire (apart from duchies held by the Habsburgs or by the electoral princes); namely those of Oldenburg, of Brunswick, of Mecklenburg-Strelitz, of Mecklenburg-Schmerin, of Saxe-Weimar, of Saxe-Gotha-Altenburg, of Saxe-Coburg-Saalfeld, of Saxe-Hildburghausen, of Arenberg and of Croy-Dülmen; and there were also the "dukes in Bavaria," as the Wittelsbachs of the Birkenfeld-Gelnhausen line were styled from 1799. The counts of Nassau took the ducal title in 1806, the princes of Anhalt in 1807. The Napoleonic grand duchy of Berg disappeared at the Restoration settlement, but Oldenburg. the two Mecklenburgs. Saxe-Weimar (as the grand duchy of Saxony), Baden and Hesse-Darmstadt were grand duchies (see GRAND DUKE) and Anhalt, Brunsmick, Saxe-Xltenburg, Saxe-Meiningen and Saxe-Coburg and Gotha sovereign duchies till the end of the German empire in 1918.

France. — The dukes of Normandy, Aquitaine and Burgundy (*qq.v.*) were practically independent of the French crown in the early feudal period, as also was the duke of Brittany, though the

French royal chancellery at first accorded him only the style of count. Gradually, however, these great fiefs were reunited to the French crown. Thereafter they were granted only in appanage, as *duchés-pairies,* or peerage duchies, to princes of the blood royal, The first authentic list of "the 12 peers" of France (1257) cites three ecclesiastical dukes (the archbishop-duke of Reims and the bishops-dukes of Langres and Laon) and three lay dukes (Normandy, Aquitaine and Burgundy). In 1297, however, Brittany was "erected" into a *duché-pairie.* Thereafter these erections became frequent. At first reserved for legitimate princes of the blood, *duchés-pairies* were accorded from the 16th century onward to bastard princes of the blood, to foreign princes and to other noble subjects of the French king. The royal letters erecting a *duché-pairie* had to be registered in one of the parlements, after which the holder could sit and vote in the parlement of Paris (bitter quarrels about precedence might arise through delays between erection and registration, where one duchy's letters antedated those of another that had been registered earlier). *Duchés-pairies* were hereditary, but there were also hereditary duchies which were not peerages, as well as life duchies (*à* brevet or par lettres). By an edict of 1711, succession to hereditary duchies was confined to male descendents; for succession by marriage to duchies already created with female succession in default of males, royal approval had to be obtained. Apart from those in the royal house of France, there were 34 ducal titles dating from the ancien *régime* still being borne in the 1960s, the premier duchy of France being that of Uzès (1565; registered 1572).

After the Revolution, Napoleon I bestowed 35 ducal titles (with names nearly all taken from outside France proper), the Restoration monarchy 17, the July monarchy 4 (one of them not ratified) and Napoleon III 14.

Italy. — The great territorial duchies of Italy which survived into modern times were those of Milan, Florence (as the grand duchy of Tuscany), Lucca, Mantua. Modena and Parma-Piacenza (*qq.v.*); the use of the title of doge (*q.v.*) for the head of the Venetian and Genoese republics is a different matter. The popes, the emperors and the kings of Naples, however, could all bestow the ducal title as they wished and did so often enough, with the consequence that it is now fairly widespread. The kings of the house of Savoy gave the title of duca occasionally to their offspring: apart from the titles in that house before the formation of the Italian kingdom (Savoy, Aosta, Genoa, etc.), four such duchies were conferred on members of the royal house in 1904 (Puglia, Spoleto, Pistoia and Bergamo) and one more in 1906 (Ancona).

Spain. — The Visigothic duchies of Spain disappeared under the Muslims. During the Christian reconquest the title duque was revived for honorific purposes. The duchy of Gerona (1351), created by Peter IV of Aragon for the future John I, provided a regular title for the heir apparent to the Aragonese throne. Apart from the Castilian duchy of Soria y Molina, created in 1370 for Bertrand du Guesclin, the title was at first usually reserved for royal princes, but from the middle of the 15th century onward it was accorded more and more frequently to other nobles. Of these latter creations, the premier surviving is that of Medina Sidonia (1445). The Spanish kings also created duchies very liberally in their Neapolitan and Sicilian dominions. As a result of female succession many ducal titles may be accumulated by one person (in the 1960s the duque de Medinaceli, for instance, had seven other ducal titles), and the practice of "rehabilitating" titles long in abeyance (on payment of a fee) makes the number of existing duchies very fluid. In fact the importance of the title depends on the number of grandezas attached to it (see GRANDEE); hence the use of the style conde-duque for the Benavente and the Olivares titles, as the countships of Benavente and of Guzman were already of conspicuous grandeza when their holders were raised to ducal rank. By virtue of the right accorded to him by the Cortes, General Franco created three duchies in 1948: those of Calvo Sotelo, of Mola and of Primo de Rivera.

Portugal. — John I of Portugal created the duchies of Coimbra and of Viseu for his sons Dom Pedro and Dom Henrique after their capture of Ceuta from the Moors (1415), and in 1442 the duchy of Braganza was created for his illegitimate son Afonso. Six more duchies were created for branches of the royal house before the Spanish annexation of Portugal. Thereafter duchies were accorded outside the royal house, but the total number of creations was far less than in Spain.

The British Isles. — In Anglo-Saxon times an ealdorman was sometimes described in Latin as dux till his function was equated with that of earl (*q.v.*). Thereafter there were no English ducal titles (the duchies of Normandy and Aquitaine held by the English kings being of course French fiefs) until 1337, when Edward III erected the county of Cornwall into a duchy for his son the Black Prince. There followed the duchies of Lancaster (1351), Clarence (1362), York (1385), Gloucester (1385), Bedford (1st creation; 1413) and Somerset (1st creation; 1443), all for descendents of the royal house in the male line. In 1444, however, Humphrey Stafford, of royal blood only through his mother, was made duke of Buckingham (1st creation). From the creation of the dukedom of Norfolk (1483) onward, the ducal title was quite regularly bestowed outside the royal house, though creations were not frequent.

In Scotland the title was first bestowed in 1398 by Robert III on his eldest son David, who was made duke of Rothesay, and on his brother Robert, duke of Albany.

In the 1960s. apart from royal dukedoms, there were ten dukedoms in the peerage of England (Norfolk, 1483; Somerset. 1546; Richmond, 1675; Grafton, 1675; Beaufort, 1682; St. Albans, 1684; Leeds, 1694; Bedford, 1694; Devonshire, 1694; and Rutland, 1703); eight in that of Scotland (Hamilton', 1643; Buccleuch, 1663; Lennox, 1675; Queensberry, 1684; Argyll, 1701; Atholl, 1703; Montrose, 1707; and Roxburghe, 1707); six in that of Great Britain (Marlborough, 1702; Brandon, 1711; Portland, 1716; Manchester, 1719; Newcastle, 1756; and Northumberland, 1766); two in that of Ireland (Leinster, 1766; and Abercorn, 1868); and six in that of the United Kingdom (Wellington, 1814; Sutherland, 1833; Westminster, 1874; Gordon, 1876; Argyll, 1892; and Fife, 1900). However, the duke of Richmond was also duke of Lennox and duke of Gordon; the duke of Buccleuch was also duke of Queensberry; the duke of Hamilton was also duke of Brandon; and the dukedom of Argyll belonged to two peerages. Thus the 32 peerages provided only 27 dukes.

DUKE UNIVERSITY, a privately operated coeducational institution of higher learning, established in 1924 at Durham, N.C., and built around Trinity college (1851), founded as Union institute in 1838. See DURHAM.

DUKHOBORS, "spirit wrestlers," a Russian peasant religious sect first known in the 18th century. The majority (about 20,000) now live in Canada. They are distinguished by the rejection of all external authority, even that of the Bible. Dukhobors believe in direct individual revelation, supplemented by a growing body of canticles and proverbs called the "Book of Life," which is handed down orally. They hold that men's souls fell before the creation of the material universe; some believe in reincarnation. Priesthood and sacraments they despise, their only ceremony being the meeting (sobranya), at which they chant round a table laid with bread, salt and water. The leader, often hereditary, is regarded as a reincarnation of Christ. Egalitarian and pacifist, the Dukhobors have varied their attitude to communal ownership and resistance to government with their leaders. The intermittent persecutions they suffered under the tsars were due to their rejection of authority in church and state, to their proselytizing activities and to their refusal to accept conscription. In Canada their clashes with the government turn on their noncompliance with land, tax and education laws. (The Dukhobors strive to avoid schooling on the ground that "the letter killeth" and that "schools teach war.")

Numerous sects of mystical—orgiastic or rationalist—evangelical type sprang up in Russia after the great 17th-century schism (see NIKON) and the opening of the country to western influences by Peter the Great. The Dukhobors, combining features of both types, lived mainly in southern Russia. They were sporadically persecuted from 1773 onward, but in 1801 the majority (about

4.000) was settled by the tsar Alexander I on the Molochnaya river near the Sea of Azov. Prosperous for a time, the sect degenerated on the death of its leader. S. Kapustin (*c.* 1820). A government investigation of 1834 revealed a state of corruption (admitted by the Dukhobors themselves), and in 1840–41 they were nearly all deported to the Caucasus.

Under the leadership of Kapustin's descendants, the Kalmykovs, the Dukhobors, abandoning their earlier communism, enjoyed 30 years of prosperity and peace. On the death in 1886 of the last Kalmykov (a woman), a so-called "large party" followed a fanatical young leader, Peter V. Verigin, who claimed Kalmykov descent. Banished to Siberia in 1887, he instructed his followers in the Caucasus, on principles derived from Tolstoian fellow exiles, to adopt vegetarianism and stricter pacifism and to return to communism. A "small party" of moderates retained individual ownership of property. After disturbances culminating in a solemn burning of arms in 1895 the "large party" was deported to scattered villages in Georgia.

Tolstoi successfully petitioned the tsar to allow the persecuted Dukhobors (renamed in 1886 the Christian Community of Universal Brotherhood) to emigrate. Funds uere collected by English Quakers, and after an unsuccessful attempt at settlement in Cyprus about 7.500 reached Canada by 1899; 12,000 remained in Russia. The Canadian government granted land on easy terms in Saskatchewan and exemption from conscription, Some settled well, but a group of fanatics, who thought to have escaped all government. started a series of nudist protest pilgrimages. Verigin. arriving in 1903, restored order. In 1908 he founded a communal settlement of 6,000 in British Columbia which prospered until his death in 1924. The incompetence of his son, P. P. Verigin, allowed to emigrate from the U.S.S.R. in 1927, and the depression of the 1930s ruined the communal enterprises, which mere not restarted. Verigin, who had given the sect the new name of Union of Spiritual Communities of Christ, died in 1939. The leadership of his nephew. J. J. Verigin. was not fully accepted until 1958, on confirmation of the death of an uncle in the U.S.S.R.

With the demand for labour and the rise in prices after World War II, the Union of Spiritual Communities of Christ became more prosperous, but a certain spiritual disorientation led some to join the extremists, who came to form a distinct group known as Sons of Freedom. The Sons of Freedom has continued nudist parades, arson. dynamiting, etc. (to show contempt for material goods they burn their own property as well as that of their neighbours and the government). A third group of Dukhobors, known as independents. are generally well assimilated to life in Canada.

DULAC, EDMUND (1882–1953), British illustrator. was born at Toulouse. Fr.. on Oct. 22. 1882. and became a British subject in 1912. His best-known illustrations were for traditional fairy tales. but his work also included pictures for *The Tempest* (1908), *The Rubaiyat of Omnr Khayyam* (1909), *Treasure Island* (1927) and *The Marriage* of *Cupid and Psyche* (1951). He designed stamps for the coronation of King George VI and bank notes and stamps for the French government in exile during World War II. He was a successful portraitist. Dulac died in London on May 25, 1953.

DULCIMER, a musical instrument with strings stretched over a flat. shallow soundbox. In Britain, the word denotes the beaten form of the instrument, known in European folk music as the Alpine *Hackbrett,* the Hungarian *cimbalom* (*q.v.*), the Rumanian *tsambal* and the Greek *santouri.* These have a trapeze-shaped soundbox and two or more metal strings for each note; the notes are sounded by striking the strings with a pair of light beaters. often made of cane. There are two long bridges. which are perforated so that the strings bearing on one bridge can pass freely under the other, which they do on alternate sides. Thus the strings slope alternately to right and left, and are struck where they rise toward their respective bridges. This greatly facilitates rapid technique. Tunings vary regionally, being fully chromatic

in the elaborate concert *cimbalom* of Hungarian gypsy orchestras; these instruments are built on legs and fitted with a damper pedal. The simpler varieties are placed on a table or carried on a sling. They are used chiefly to accompany the violin or other instruments. Historically. these dulcimers appear to be beaten versions of the plucked psaltery and to have entered central Europe from Persia about the 15th century A.D.

The "Appalachian" or "mountain" dulcimer of the United States is different, being a true zither (*q.v.*) with stopped melody strings running over a fretted fingerboard. (A. C. BA.)

DULLES, JOHN FOSTER (1888–1959), U.S. secretary of state in the Republican administration of Pres. Dwight D. Eisenhower, also held diplomatic positions under three Democratic presidents, Woodrow Wilson, Franklin D. Roosevelt and Harry S. Truman. His grandfather John W. Foster and his uncle Robert Lansing had both served as secretaries of state.

Born in Washington, D.C., Feb. 25, 1888. Dulles attended Princeton university and George Washington university law school. graduating with highest honours in both. and studied at the Sorbonne in Paris. While he was a student at Princeton he attended the second Hague conference with his grandfather. Entering the international law firm of Sullivan and Cromwell in 1911, he became a partner in 1920 and head of the firm in 1927.

A Republican. Dulles was legal counsel at the Versailles conference at the end of World War I and President Wilson appointed him a member of the reparations commission. In World War II he helped prepare the United Nations charter at Dumbarton Oaks and served as a senior adviser at the San Francisco UN conference. In 1949, while Dulles was attending a Paris conference of foreign ministers, Gov. Thomas E. Dewey named him senator for New York, to fill an unexpired term.

Appointed a state department consultant in 1950, he was assigned to negotiate the peace treaty with Japan. He traveled 125,000 mi. to the various capitals to avoid calling an international conference. The result was a brilliant diplomatic success.

Named secretary of state in 1952 and sworn into office in Jan. 1953, Dulles determined to lead rather than follow public opinion. He stood against Communist China in defending Quemoy and Matsu. When France vacillated in accepting the European Defense community he declared that the U.S. must make an "agonizing reappraisal" of its policies and France compromised. He refused to support France, Great Britain and Israel in attacking Egypt in violation of the UN charter.

His insistence helped to bring about an Austrian peace treaty and a settlement of the Trieste problem. In the Berlin crisis Dulles was adamant against Communist dictation. His determination not to yield to U.S.S.R. or Chinese threats was widely attacked in the U.S. and abroad as "inflexible" and "stubborn"; he was also sharply criticized when he wrote in a magazine article in Jan. 1956 that "the ability to get to the verge [of war] without getting into the war is the necessary art. . . . If . . . you are scared to go to the brink, you are lost." Many leading statesmen of the non-Communist nations. however, credited his firmness with having checkmated Communist "cold war" strategy.

Seriously ill with cancer, Dulles resigned April 15, 1959, and died May 24. President Eisenhower characterized him as "one of the truly great men of our time."

Dulles wrote *War, Peace and Change* (1939) and *War or Peace* (1950).

See John Robinson Beal, *John Foster Dulles* (1957). (G. H. S.)

DULONG, PIERRE LOUIS (1785–1838), French chemist and physicist who helped formulate the Dulong-Petit law of specific heats, which subsequently proved useful in determining. atomic weights although it is now known to be only approximate (see QUANTUM MECHANICS: *Specific* Heats; LOW-TEMPERATURE PHYSICS: Energy Levels and Order). Dulong was born at Rouen on Feb. 12 (or 13), 1785. After acting as assistant to Berthollet, he became successively professor of chemistry at the faculty of sciences and the normal and veterinary schools at Alfort, and then (1820) professor of physics at the École Polytechnique, of which he was appointed director in 1830. He died in Paris on July 18 (or 19), 1838.

His earliest work was chemical in character. In 1811 he discovered nitrogen trichloride. Dulong's important research work in physics was carried out in conjunction with Alexis Thérèse Petit (1791–1820), professor of physics at the École Polytechnique. Their first published research (1816) dealt with dilatation and with the exact measurement of temperature, and it was followed by one in 1817 in which they showed that Newton's law of cooling was only true for small differences in temperature, and one in 1818 on the measurement of temperature and the transference of heat, which was crowned by the French academy. In another. "On some important points in the theory of heat" (1819), they stated the "law of Dulong and Petit" dealing with atomic weights. Subsequent papers by Dulong were concerned with "New determinations of the proportions of water and the density of certain elastic fluids" (1820, with Berzelius); the property possessed by certain metals of facilitating the combination of gases (1823 with Thénard); the refracting powers of gases (18263; and the specific heats of gases (1829). In 1830 he published a research. undertaken with François Arago for the Academy of Sciences, on the elasticity of steam at high temperatures. In his last paper, published posthumously in 1838, Dulong gave an account of experiments made to determine the heat developed in a chemical reaction, together with a description of the calorimeter he employed.

DULSE (Rhodymenia *palmata*), one of the red seaweeds or algae, consisting of flat solitary or tufted purplish-red fronds, fan-shaped in general outline and divided into numerous segments,. which are often divided in a forked manner. It varies much in size and degree of branching, ranging from 5 to 12 or more inches long. It grows on rocks, shellfish or larger seaweeds. and is used by the poor in Scotland and Ireland as a relish with their food. It is commonly dried and eaten raw, the flavour being brought out by long chewing. In the Mediterranean dulse is used cooked in ragouts and other dishes. See also ALGAE: *Rhodophyta.*

DULUTH, a city of Minnesota, U.S., the most western terminus of the St. Lawrence seaway. seat of St. Louis county, is situated on Lake Superior at the mouth of the St. Louis river opposite Superior. Wis. Elevation is abrupt, rising 600 to 800 ft. above the level of the lake in high rock bluffs, once the shore line of glacial Lake Duluth. Along the crest a 30-mi. sky-line boulevard commands an excellent view of both city and harbour. The combined Duluth-Superior harbour results from a natural breakwater formed by deposits left where river and lake meet. This resulting 9-mi. strip. Minnesota point, or Park point, extends toward Wisconsin point, separating St. Louis bay from Lake Superior. The narrow channel between the two points forms the Superior harbour entrance, and a dredged 300-ft. ship canal across Minnesota point, spanned by an aerial lift bridge, forms the Duluth harbour entrance.

The combined harbour ranks second only to New York, among U.S. ports, in tonnage handled. Through it is shipped in order of importance: iron ore from the Mesabi, Cuyuna and Vermilion ranges, coal from Lake Erie ports. grain from the Red river valley, Manitoba and the Dakotas, and crude oil from Canada refined at Wrenshall, Minn., and at Superior. Harbour facilities include coal docks. grain elevators and iron-ore docks, which receive ore and taconite arriving from processing plants in northeastern Minnesoia. Main industries include a steel and wire mill, a blast furnace, a cement plant, an oriental food processing plant, and the manufacturing of electrical appliances, paint, beer, wood and dairy products.

Duluth is the centre for a branch of the University of Minnesota, established in 1947, the Benedictine College of St. Scholastica, founded in 1912, the St. Louis County Historical society, Chisholm museum, Tweed Art gallery and a locally supported symphony orchestra and playhouse. Added attractions are the zoological park, Enger Memorial tower, the scenic North Shore drive and the Jay Cooke State park.

The Duluth area, occupied originally by the Sioux and then by the Chippewa Indians. was visited about 1660 by the French *coureurs de bois:* Pierre Esprit, Sieur de Radisson; Médart Chouart, Sieur de Groseilliers; and in 1679 by Daniel Greysolon, Sieur du Lhut (sometimes spelled Dulhut, Derhaut and du Luth), for whom Duluth was named. The fur-trading post of Fond du Lac, on the banks of the St. Louis river, was controlled by the Hudson's Bay company in 1692, the Northwest company in 1793 and by John Jacob Astor's American Fur company from 1817 until 1854. Another post on Minnesota point was established in 1852 by George R. Stuntz, surveyor of the Minnesota-Wisconsin boundary. The following year brought many settlers to the north shore area in search of copper deposits. Duluth was platted in 1856 and incorporated as a city on March 5, 1870, with a population of 3,131; was relegated to a village in 1877; and was reincorporated in 1887. The extension of railways into the northwestern wheat region, increased lake commerce following the cutting of the Duluth ship canal in 1871, and the development of the Vermilion and Mesabi ranges brought increasing prosperity. Pop. (1960) 106.884. The population of the Duluth-Superior standard metropolitan statistical area, comprising St. Louis county in Minnesota and Douglas county in Wisconsin, was 276,596 in 1960. For comparative population figures see table in MINNESOTA: Population.

(E. F. GR.)

DULWICH, a residential suburb in the metropolitan borough of Camberwell (*q.v.*), London, Eng. Pop. (1951) 54,736. It comprises most of the southern end of the borough from Denmark hill. Peckham, Nunhead and Peckham Rye to the boundary. West Dulwich, in which the college is situated, with its toll gate and its wooded lanes descending from Sydenham hill, is on one side; on the other is Dulwich park (75 ac.), given by the governors of the college for a public park in 1885. The district retains much of its rural character and is spoken of as Dulwich village. The manor, which Henry I gave to the Cluniac monks of Bermondsey, passed through various hands to Edward Alleyn (*q.v.*) in 1605. His foundation of the College of God's Gift, commonly called Dulwich college. was opened with great state on Sept. 13, 1619, in the presence of Lord Chancellor Francis Bacon, Inigo Jones and other distinguished men. According to the letters patent a master, a warden, 4 fellows, 12 poor scholars, 6 poor brethren and 6 poor sisters were to be chosen equally from the parishes of St. Giles (Camberwell), St. Botolph without Bishopsgate, St. Luke's (Old street) and St. Saviour's (Southwark). The master and the warden were to be unmarried and were always to be of the founder's surname. In 1857 the foundation was entirely reconstituted. It now comprises three schools, called respectively Dulwich college. Alleyn's school and James Allen's Girls' school. Dulwich college was built in 1866–70 by Charles Barry in the north Italian Renaissance style. Among many famous pupils was Ernest Shackleton. The college possesses one of the leading private picture galleries in the country, the bequest mainly of Sir Francis Bourgeois. a member of the Royal Academy, in 1811, with later additions and a separate endowment. The Dutch and Flemish schools in particular are well represented, 'together with some fine examples of the Spanish. French and British. Dickens' Mr. Pickwick, after his retirement to Dulwich village, was "frequently seen, contemplating the pictures in the Dulwich Gallery." The Dulwich library was founded in 1896 in memory of Edward Alleyn.

DUMA (properly GOSUDARSTVENNAYA DUMA; *i.e.*, "state deliberative assembly"), the lower house in the imperial Russian legislature during the brief constitutional era (1906–17; see RUSSIA: History). The product of one revolutionary upheaval, it perished in another. The duma always had enemies to the right and left; its very existence was resented by the champions of unlimited autocracy, while democrats objected to its inadequate

powers and indirect unequal franchise. Despite its many failings, however, it acted as a check on arbitrary rule and helped to familiarize a section, at least, of Russian society with constitutional ideas and practices. Liberals in particular valued it as a symbol of Russia's progress toward parliamentary government on the western model.

The promise of a legislative assembly was contained in the October manifesto reluctantly granted by the tsar Nicholas II on Oct. 30 (new style; 17, old style), 1905. The duma's constitutional status was formally established by the revised fundamental laws of May 6 (N.S.; all dates N.S. henceforth), 1906, and certain supplementary acts; the electoral procedure was determined by a decree of Dec. 24, 1905, issued by Count S. Y. Witte, the prime minister, but was subsequently revised (June 1907; see below). The majority of deputies were elected at provincial conventions of "electors" chosen by the voters, who were segregated into four *curias:* landowners (subdivided into two categories), peasants, townspeople and industrial workers. Lesser landowners and townspeople elected deputies in two stages, peasants in three; of the workers, only those employed in larger enterprises in certain industrial areas were represented.

In general the duma enjoyed autonomy in matters of internal organization, although the duration of its sessions was prescribed by the emperor; deputies had personal inviolability; debates were public. and were reported in the press. The duma could not control ministers, who were responsible only to the emperor; it could address questions to them, but ministers were entitled to delay for one month before replying. The duma's rights of budgetary control were limited by the exclusion of certain items, such as the imperial court and the armed forces (except additional estimates); expenditure which it did not approve automatically continued at the previous rate. The duma could initiate legislation, but to take effect this required the assent of the state council (the upper house, a partly elective and partly nominated body with a standing conservative majority) and the sovereign; in practice no bill from the duma surmounted both these hurdles. According to the constitution no law was valid without the duma's assent; but the emperor still called himself an autocrat and retained extensive prerogatives. Under art. 87 of the fundamental laws he could issue decrees while the duma was not in session, subject to its subsequent approval; but this loophole, designed for use only in a genuine emergency, was in practice frequently used by the administration to circumvent the assembly.

*First session. †Approximate

First Duma. — The first duma. which met from May 10 to July 21, 1906, expressed the popular mood of frustrated revolutionary turbulence. The numerous peasant deputies, whom the authorities had hoped would prove a moderating force, supported, or even stood to the left of, the Constitutional Democrats (Kadets), who dominated the assembly (see Table). The Kadets sought to use the duma as a platform from which to appeal for popular support, thereby forcing the government to grant a constituent assembly. But the prime minister. I. L. Goremykin, rejected outright their bold declaration of legislative intentions, particularly their plan for compulsory expropriation of estates where necessary to assuage peasant land hunger. After exploratory talks for a Kadet ministry had broken down, the duma was charged with having exceeded its powers, and was dissolved.

Second Duma. — Despite administrative interference in the elections, the second duma, meeting from March 5 to June 16, 1907, was from the government's viewpoint even more intractable than the first. The Socialists, most of whom had hitherto boycotted the duma, were strongly represented, and there was a vociferous anticonstitutional right wing. The Kadets, who held the balance between the extremes, vainly tried to preserve the duma by scrupulous adherence to the law. P. A. Stolypin, the new prime minister, was readier than his predecessor to collaborate with the assembly, but only on his own terms; once convinced that it would not support his policies, above all his scheme for agrarian reform, he too resolved on dissolution.

Dissolution was announced on June 16, 1907, and simultaneously, in violation of the constitution, the electoral law was revised to the detriment of socially underprivileged groups and non-Russian minorities. In most provincial conventions the number of landowners' electors was arbitrarily augmented to give them an overall majority, and they were also enabled to influence the choice of peasant deputies. The proportion of deputies elected by landowners rose from 34% to 51%, while those elected by peasants declined from 43% to 22%, and by workers from 3% to 2%; representation of national minorities was cut by two-thirds.

Third Duma. — The virtual coup *d'état,* justified by Stolypin on grounds of expediency, yielded an assembly which, though grossly unrepresentative, had a workable majority. The left was much reduced; power lay with the Octobrists, a conservative constitutionalist party, which at first allied with the right but later, resenting administrative obstruction, adopted a more liberal position. The third duma (Nov. 14, 1907, to June 22, 1912) survived for its full five-year term and accomplished much solid legislative work, particularly in the fields of agrarian reform and army reorganization.

It often reacted sharply to bureaucratic abuses, so that its relations with the government were far from cordial. Nicholas II was still at heart unreconciled to the constitutional regime, and in 1912 revelations in the duma about Rasputin (*q.v.*) earned it the lasting enmity of the empress Alexandra.

Fourth Duma. — Administrative pressure in the elections to the fourth duma (Nov. 28, 1912, to March 11, 1917) helped the right-wing parties to increase their strength at the Octobrists' expense, but did not create a stable majority upon which the government could rely. When World War I broke out all parties rallied to the regime; but soon public dissatisfaction became widespread at the incompetence and negligence shown by the administration, particularly in supplying the army, and at the suspicious hostility with which it greeted efforts by duma members to mobilize the country's resources for the efficient prosecution of the war. In Aug. 1915 all groups except the extreme left and right united in a Progressive bloc. demanding the formation of "a ministry enjoying public confidence" and other essential reforms. The emperor replied on Sept. 16 by proroguing the assembly till Feb. 1916. Capable ministers responsive to the pressure of public opinion were dismissed and replaced by worthless creatures of Rasputin and the court camarilla; the duma was convoked only at infrequent intervals and could exercise no influence over policy. Though its inherent conservatism made it shrink from a bold effort to seize power, its debates attracted nation-wide attention; by the autumn of 1916 the duma — somewhat unexpectedly, in view of its unrepresentative character — found itself the focal point of opposition to the discredited regime. On Nov. 14 the Kadet leader P. N. Milyukov (*q.v.*) threw down a challenge to the government by suggesting that those in power were guilty of treason. The empress urged dissolution. When the order for dissolution (as from March 11, 1917) was finally given, Petrograd was already in the grip of a revolution which quickly swept away the imperial regime and the duma as well. The collapse of the monarchy deprived the duma of its legal authority; generally condemned as an undemocratic anachronism, it lapsed into oblivion. (J. L. H. K.)

DUMAS, ALEXANDRE (ALEXANDRE DAVY DE LA PAILLETERIE) (1802–1870), French novelist and dramatist. author of The Count of Monfe Cristo, The Three *Musketeers* and other famous romances, was born at Villers-Cotterêts (Aisne) on July 24, 1802. His father, General Dumas (Alexandre Davy de la

Pailleterie), the natural son of Antoine Alexandre Davy, marquis de la Pailleterie, and Marie Cessette Dumas, a Negress of San Domingo, offended Napoleon by his staunch republicanism and left his family in straitened circumstances on his death in 1806. Alexandre received the rudiments of education from a priest, and in July 1816 entered the office of a local solicitor. His chief friend was Adolphe de Leuven, the son of an exiled Swedish nobleman, and the two collaborated in various vaudevilles and other pieces which never saw the footlights. Leuven returned to Paris and Dumas became a junior clerk in the office of a solicitor at Crépy, where. however, he did not remain long. He visited Leuven in Paris and was received by the actor F. J. Talma. He then determined to seek his fortune in Paris. An introduction to General Foy procured for him a place as clerk in the service of the duc d'Orléans. He has left jocular and humorous memories of his mishaps as a record keeper in the service of the future king. At the same time, he began to collaborate with Leuven in the production of vaudevilles and melodramas. Mme Dumas presently joined her son in Paris, where she died in 1838. Soon after his arrival Dumas had entered on a liaison with a dressmaker, Marie Catherine Labay (1794–1868), and their son. the famous Alexandre Dumas *fils* (*q.v.*), was born in 1824. Dumas acknowledged his son in 1831 and obtained the custody of him after a lawsuit with the mother.

His Plays. — The first piece by Dumas and Leuven to be staged was *La Chasse et l'amour* (Ambigu-Comique, Sept. 22, 1825), and in this they had help from other writers. Dumas had a share in another vaudeville, *La Noce et l'enterrement* (Porte Saint-Martin, Nov. 21, 1826). It was under the influence of the Shakespeare plays produced in Paris by William Charles Macready, Harriet Smithson (later Mme Berlioz) and an English company that the romantic drama of *Christine* was written. The subject was suggested by a bas-relief of the murder of Giovanni Monaldeschi exhibited at the Salon of 1827. The piece was accepted by the Comédie Franqaise, but its production was deferred. Meanwhile Dumas had written, in prose, *Henri III et sa cour,* which was immediately accepted by the Comédie Franqaise and produced on Feb. 11, 1829. It was the first great triumph of the romantic drama. The brilliant stagecraft of the piece and its admirable historical setting delighted an audience accustomed to the decadent classical tragedy, and brought him the friendship of Victor Hugo and Alfred de Vigny. His patron. the duc d'Orléans, now gave him the librarianship of the Palais Royal. *Christine* was recast as a romantic trilogy in verse in five acts with a prologue and epilogue, with the title of *Stockholm, Fontainebleau, Rome,* and was produced by F.-A. Harel at the Odéon in March 1830.

The revolution of 1830 temporarily diverted Dumas from writing. The account of his exploits should be read in his *Mémoires,* in which it is difficult to sift the truth from the boasts of the author. The pages where Dumas tells how he took possession all by himself of the Soissons powder-magazine are an amusing specimen of preposterousness and ingenuity. He finally alienated himself from the Orléans government by being implicated in the disturbances which attended the funeral of General Lamarque in June 1832 and he received a hint that his absence from France was desirable. **A** tour in Switzerland furnished material for the first of a long series of amusing books of travel. Dumas remained, however, on friendly and even affectionate terms with the young duc d'Orléans until the duke's death in 1842. Meanwhile he had produced *Napolkon Bonaparte* (Odéon, Jan. 10, 1831). his unwillingness to make a hero of the man who had slighted his father having been overcome by Harel. who put him under lock and key until the piece was finished. His next play. *Antony,* had a real importance in the history of the romantic theatre. It was put in rehearsal by Mlle Mars, but so unsatisfactorily that Dumas transferred it to Pierre-Franqois Bocage and Mme Dorval, who played it magnificently at the Porte Saint-Martin theatre on May 3, 1831. The Byronic hero Antony was a portrait of himself in his relations with the authoress Mélanie Waldor, except of course in the extravagantly melodramatic *dénouement,* when Antony, to save his mistress' honour, kills her and exclaims, *Elle me résistait, je l'ai assassinée.* He produced a score more plays alone or in collaboration before 1845, as well as dramatizations from his novels. *Richard Darlington* (Porte Saint-Martin, Dec. 10, 1831), the first idea of which was drawn from Sir Walter Scott's *Chronicles of the Canongate,* owed part of its great success to the admirable acting of Frédérick Lemaitre. *La Tour de Nesle* (Porte Saint-Martin, May 29, 1832), announced as by MM. X X X and Gaillardet, occasioned a duel and a law-suit with the original author, Frédéric Gaillardet, whose manuscript had been revised, first by Jules Janin and then by Dumas. In rapidity of movement and in the terror it inspired, the piece surpassed *Henri III* and *Antony.* A lighter drama, *Mademoiselle de Belle-Isle* (Théâtre Français, April 2, 1839), long held the stage. Of the 91 plays for which Dumas was wholly or partially responsible, 67 have appeared in successive collective editions.

In 1840 Dumas married, for ill-defined reasons, the actress Ida Ferrier (1811–59), whose liaison with him was eight years old, about whom he had few illusions and whom he had imposed on stage-managers who produced his plays. The couple soon parted and Mme Dumas went to Italy to live.

His Novels. — Dumas' happy collaboration with Auguste Maquet, which began in 1839, led to the admirable series of historical novels in which he proposed to reconstruct the whole course of French history. In 1844 he produced, with Maquet's help, that most famous of "cloak and sword" romances, *Les Trois Mousquetaires,* the material for which was discovered in the *Mémoires de M. d'Artagnan* (1700–01) by Giles de Courtilz de Sandras. The adventures of d'Artagnan and the three musketeers —the gigantic Porthos, the clever Aramis and the melancholy Athos, who united to defend the honour of Anne of Austria against Richelieu and the machinations of "Milady" — are brought down to the murder of Buckingham in 1628. Their admirers were gratified by two sequels, *Vingt ans après* (1845) and *Dix ans plus tard, œr le vicomte de Bragelonne* (1848–50; Eng. trans., *The Man in the Iron Mask),* which opens in 1660, showing a mature d'Artagnan. a respectable captain of musketeers, and contains the magnificent account of the heroic death of Porthos. The three musketeers are as famous in England as in France. Thackeray, who could read about Athos from sunrise to sunset with the utmost contentment of mind, was one of those who have paid tribute to the band. Before 1844 was out Dumas had completed a new great romance, *Le Comte de Monte-Cristo,* in which he had help from P. A. Fiorentino as well as from Maquet. The idea of the intrigue was suggested by J. Peuchet's *Mémoires . . . de la police de Paris* and the stress laid on the earlier incidents, Dantès, Danglars and the Chbteau d'If, is said to have been an afterthought. Almost as famous as these romances is the set of Valois novels of which Henry IV is the central figure, beginning with *La Reine Margot* (1845), which contains the history of the struggle between Catherine de Medicis and Henry of Navarre; the history of the reign of Henry III is told in *La Dame de Monsoreau* (1846), generally known in English as *Chicot the Jester,* from its principal character; and in *Les Quarante-cinq* (1847–48), in which Diane de Monsoreau avenges herself on the duke of Anjou for the death of her former lover, Bussy d'Amboise.

The Valois novels and the musketeers series brought French history down to 1672. Contributions to later history are: *La Dame de volupté* (1864), being the memoirs of Mme de Luynes, and its sequel *Les Deux Reines* (1864); *La Tulipe noire* (1850), giving the history of the brothers De Witt; *Le Chevalier d'Harmental* (1853) and *Une Fille du rkgent* (1845), the story of two plots against the regent, the duc d'Orléans; two books on Mme du Deffand, *Mémoires d'une aveugle* (1856–57) and *Les Confessions de la marquise* (1857), both of doubtful authorship; *Olympe de Clèves* (1852), the story of an actress and a young Jesuit novice in the reign of Louis XV; five books on the beginning of the Revolution down to the execution of Marie Antoinette. the *Mémoires d'un médecin,* including *Joseph Balsamo* (1846–48), in which J.-J. Rousseau, Mme du Barry and the dauphiness Marie Antoinette figure, with its sequels; *Le Collier de la reine* (1849–50), in which Balsamo appears under the alias of Cagliostro; *Ange Pitou* (1852; Eng. trans., *The Takzng of the Bastille*); *La Comtesse de Charny* (1853–55), describing the artempts to save the monarchy and the

flight to Varennes; and *Le Chevalier de Maison-Rouge* (1846), which opens in 1793 with the hero's attempt to save the queen. Among the numerous novels dealing with the later revolutionary period are *Les Blancs et les bleus* (1868) and *Les Compagnons de Jéhu* (1857). *Les Louves de Machecoul* (1859) deals with the rising in 1832 in La Vendée. Other famous stories are: *Les Frkres corses* (1845); *La Femme au collier de velours* (1851); *Les Mohicans* de *Paris* (1854–55), detective stories with which may be classed the series of *Crimes célèbres* (1839–41), which are however, of doubtful authorship; and *La San Félice* (1864–65), in which Lady Hamilton played a prominent part, with its sequels *Emma Lyonna* and *Souvenirs d'une favorite.*

Of his numerous historical works other than fiction the most important is his *Louis* XIV *et son siècle* (1845). *Mes Mémoires* (1852–54; annotated edition by P. Josserand, vol. i–ii, 1954–57), fascinating in spite of some padding and rigmaroles, is the account of his life until about 1832, with important chapters on the life of General Dumas, his father. There are abridged English translations by A. F. Davidson (2 vol., 1891) and J. E. Goodman *(The Road* to *Monte Cristo;* 1956).

His Collaborators.—Much has been written about the exact share which Dumas had in the novels which bear his name. Equivocating maliciously on his fecund productivity and on the number of his collaborators (or *"nègres"*), Charles Hugo once said: "No one has ever read the whole of Dumas, not even himself." August Maquet was his chief collaborator; others were Paul Lacroix (the bibliophile "Jacob"), Paul Bocage, J. P. Mallefille and P. A. Fiorentino. The Dumas-Maquet series is undoubtedly the best, but Maquet alone never accomplished anything to approach them in value. The manuscripts of the novels still exist in Dumas's handwriting, and the best of them bear the unmistakable stamp of his unrivaled skill as a narrator. The chief key to his enormous output is to be found in his untiring industry and amazing fertility of invention, not in the system of wholesale collaboration which was exposed with much exaggeration by J.-M. Quérard in *Les Supercheries litteraires dévoilées* (1845–60) and by "Eugène de Mirecourt" (C. J. B. Jacquot) in his misleading *Fabrique de romans, Maison Alexandre Dumas et Cie* (1845). His assistants, in fact, supplied him with outlines of romances on plans drawn up by himself and he then rewrote the whole thing. That this method was never abused it would be impossible to say. Before passing judgment, an exhaustive study of the work is necessary; thus *Les Deux Diane,* a prelude to the Valois novels, which mas said to have been written entirely by Paul Meurice, although Dumas's name appears on the title-page, is in all probability by Dumas, as Aksel J. Nielsen, the compiler of a bibliography of Dumas's works translated and printed in Scandinavia, has shown.

Later Years.—The latter part of Dumas's life is a record of excessive toil to meet prodigal expenditure and accumulated debts. His disasters began with the building of a house in the Renaissance style, with a Gothic pavilion and an "English" park. at Saint Germain-en-Laye. This place, called Monte-Cristo. was governed by a crowd of hangers-on of both sexes, who absorbed his large earnings and left him penniless. He also founded the Théâtre Historique, chiefly for the performance of his own works, under the patronage of the duc de Montpensier. Dumas had never changed his republican opinions and greeted the Revolution of 1848 with delight, but the change was fatal to his theatrical enterprise, for the failure of which in 1850 he was made financially responsible. His son, Alexandre Dumas, was at that time living with his mother Mlle Labay, who was eventually reconciled with the elder Dumas. Father and son, though always on affectionate terms when they met, were too different in their ideas to see much of one another. After the *coup d'état* of 1851 Dumas crossed the frontier to Brussels, not as an exile, as he cleverly pretended, but in order to escape from his creditors. Two years of rapid production, and the economy of his secretary, Noel Parfait, restored something like order to his affairs. On his return to Paris at the end of 1853 he established a daily paper, *Le Mousquetaire,* for the criticism of art and letters, wherein he published the final chapters of his *Mémoires,* of which over two-thirds had already seen the light in *La Presse* while he was in Brussels. It survived until 1857 and was succeeded by a weekly paper, the *Monte-Cristo* (1857–60), with a revival in 1862. In 1868, he launched another paper, *Le Dartagnan, journal d'Alexandre Dumas,* which died five months after its birth.

In 1858 Dumas journeyed through Russia to the Caucasus, and in 1860 he joined Garibaldi in Sicily. After an expedition to Marseilles in search of arms for the insurgents, he returned to Naples, where Garibaldi nominated him keeper of the museums. After four years' residence in Naples he returned to Paris. In 1866 he visited the battlefields of the Austro-Prussian War and published the novel *La Terreur prussienne.* But his powers were beginning to fail and in spite of the 1,200 volumes which he boasted he had written, he was at the mercy of his creditors. During this period he also fell a prey to adventuresses and minor theatrical ladies in quest of crude publicity. His liaison with Adah Menken, an American circus girl, created a great scandal. Now and then, an unexpected visit of Dumas fils would, for a time, restore a normal state of things. He was finally rescued by his daughter, Mme Petel, who came to live with him in 1868; and two years later, on Dec. 5, 1870, he died in his son's house at Puys, near Dieppe.

BIBLIOGRAPHY.—The complete works of Dumas were issued by Michel Lévy *frères* in 277 vol. (1860–84). R. W. Plummer published a bibliography of English translations in *The Dumasian, the Magazine of the Dunzas Association* (1957). Among the many translations into other languages, a vernacular version of *La Tulipe noire* has been issued in Samoa. The more important French authorities are: his own memoirs, already cited; C. Glinel, *Alexandre Dumas et son oeuvre* (1884), of use chiefly for the documents published therein; H. Parigot, *Dumas père,* "Grands Ccrivains français" series (1902) and *Le Drame d'Alexandre Dumas* (1899); *H.* Blaze de Bury, *Alexandre Dumas* (1885); Philibert Audebrand, *Alexandre Dumas à la maison d'or* (1888); G. Ferry, *Dernières Années d'Alexandre Dumas* (1883); *M.* L. H. Lecomte, *Alexandre Dunzas* (1904); *J* Lucas-Dubreton, *La Vie d'Alexandre Dumas père* (1928); Henri Clouard, *Alexandre Dumas* (1955); and André Maurois, *Les trois Dunzas* (1957; Eng. trans., *Three Musketeers, a Study* of *the Dumas Family*). Of the English lives of Dumas perhaps the best is that by Arthur F. Davidson, *Alexandre Dunzas Père His Life and Works* (1902). *See* the lives by P Fitzgerald (1873) and H. A. Spurr (1902) and essays by Andrew Lang *(Letters to Dead Authors)* and *R.* L. Stevenson, *Memories and Portraits. See* also Herbert Gorman, *The Incredible Marquis, Alexandre Dumas* (1929). (M. Bt.; P. Jo)

DUMAS, ALEXANDRE (DUMAS FILS) (1824–1895), French dramatist and novelist, chiefly remembered for the dramatized version of his first novel, La *Dame aux camélias,* was the natural son of Alexandre Dumas (*q.v.*). He was born in Paris on July 27, 1824. Like his father, he early turned to letters. *La Dame aux camélias,* written in 1848, and another novel, *Diane de Lys* (1851), from both of which he extracted plays, first performed in 1852 and 1853 respectively, drew largely on his own experience; the former, which paints an idealistic picture of his mistress. Marie Duplessis (Marguerite Gautier in the play), won him instant success and became one of the best known plays of the 19th century, fortunate in having for its interpreters such renowned actresses as Sarah Bernhardt, Eleonora Duse and, later, Edwige Feuillhre. Nor was this play merely lucky in attracting such actresses: it contains intrinsic merits—the humanity of the central figure, the courtesan, and the authenticity of the picture of contemporary Parisian life. A modified version served Verdi as a libretto for his opera *La Traviata* (1853).

A steady stream of plays and novels followed, the novel *L'Affaire Cle'menceau* (1866) containing a bitter account of his sufferings at school. But it was the plays that kept his name alive: *Le Demi-monde* (1855), in which he defended the institution of marriage against the assault of adventuresses, provided the language with a name for the class it portrayed; *Le Fils naturel* (1858) was irreverently called by some *"Le Fils surnaturel,"* because it showed how society went out of its way to recognize a gifted young man, despite the stigma of his irregular birth; *Un Père prodigue* (1859) contained a fine picture of the dashing Dumas *père; L'Ami des femmes* (1864) showed how helpless women are without the assistance of a disinterested man; *Les Idées de Mme Aubray* (1867) was based on the parable of the lost sheep; *Une Visite de noces* (1871) exposed the shabbiness of free love; *Monsieur Alphonse* (1874) described the regeneration of an

unmarried mother by marriage. The two so-called "symbolist" plays, the hysterical *La Femme de Claude* (1873), showing how France was suffering from the depredations of impure women, and the extravagant *L'Étrangère* (1876), warning against the lure of an exotic adventuress in the highest circles of French society, were failures. But Dumas returned to the subject of unfortunate women in *Denise* (1885) and *Francillon* (1887), which brought him much success. From 1867 onward he wrote long and often tedious prefaces to all his plays, coupled with pamphlets on the questions of the day, such as *L'Homme-femme* (1872), *Les Femmes qui tuent et les femmes qui votcnt* (1880). He had warned against prostitutes and impure women generally and now he became the champion of all honourable women by proclaiming their right to divorce and to vote.

He was nothing if not categorical. He attacked the creed of *"l'art pour l'art"* ("three words utterly devoid of meaning"), and he naïvely believed that a dramatist, by punishing wickedness and rewarding virtue. could contribute to social health: "To save from transgression, to attempt to reform, that has been the eternal theme for which I have been reproached and of which I am proud." This formula, despite its sincerity and even nobility, has not preserved his plays (with the exception of *La Dame aux camélias*) from oblivion. Nonetheless, Dumas counts as one of the most successful dramatists of the 19th century. He was admitted to the Académie Française in 1875 and received many other honours. He died at Marly-le-Roi on Nov. 27, 1895.

DUMAS, JEAN BAPTISTE ANDRE (1800–1884), French chemist who pioneered in organic chemistry and particularly in organic analysis, was born at Alais (now Alès) on July 16, 1800. He was apprenticed to an apothecary and when he moved to Geneva in 1816 he worked in a pharmacy there. In Geneva he attended the lectures of Raoul Pictet (physics), Charles de la Rive (chemistry) and Augustin Pyrame de Candolle (botany). Before he was 21 he engaged in original work on problems of biochemistry and embryology. In 1818 Dumas and Charles Coindet introduced the use of iodine for the treatment of goitre. As a result of other work done in his early years, Dumas, together with J. L. Prévost, published a paper in 1826 describing segmentation in the frog ovum.

In 1523 Dumas moved to Paris, where he lived the rest of his life. He joined the faculty of the École Polytechnique and founded a research laboratory there in 1832; in the same year he became professor at the University of Paris and the College of France. In Paris, Dumas completed a series of chemical triumphs that made him one of the world's leading chemists by 1840. He originated a method for determining the nitrogen content of organic compounds (1830); isolated anthracene from coal tar (1831); discovered the formula for camphor (1832); showed that halogens could replace hydrogen in organic compounds (1834); conducted, with E. M. Peligot, experiments on the methyl radical and isolated methyl alcohol (1834); obtained and named chloroform (1834); presented a classical paper, together with Justus von Liebig, to show that in organic chemistry groups of elements (radicals) can act as single elements (1837). By using vapour densities, Dumas demonstrated that the atomic weights of certain elements differ from those previously established by J. J. Berzelius, whose theories came to be replaced by the ideas of Dumas and Liebig. Dumas' method is still valid for determining the molecular weights of gases and low-boiling liquids.

Although Dumas continued to be active in chemistry throughout his life, his interests between 1848 and 1870 were in politics. He became a member of the national legislative assembly in 1849, acted as minister of agriculture and commerce for a few months in 1850–51 and later became a senator, president of the municipal council of Paris and master of the French mint. He died at Cannes on April 11, 1884.

DU MAURIER, GEORGE LOUIS PALMELLA BUSSON (1834–1896), an eminent British illustrator and caricaturist who, in late middle life, wrote three successful novels based on vivid memories of his early years, was born on March 6, 1834, in Paris. His happy childhood at Passy is recalled in *Peter Ibbetson* (1891). His full-blooded enjoyment of student life in the Latin quarter of Paris is reflected in *Trilby* (1894). In *The Martian* (1897), there is a poignant episode based on his own tragic experience of losing the sight of his left eye. This misfortune. which occurred in Antwerp during his student days, obliged him to abandon painting and devote himself to drawing. In 1860 he came to London where, thanks to his skilled draftsmanship and engaging personality, he quickly established himself. In a notable period of English illustration, du Maurier's achievement was considerable. His "society pictures" in *Punch* were acute commentaries on the Victorian scene, but his many beautiful illustrations for books and for such periodicals as *Once a Week* and *The Leisure Hour* were the truer measure of his artistic qualities. He died in London on Oct. 6, 1896. His younger son was Sir Gerald du Maurier (*q.v.*).

BIBLIOGRAPHY.—Thomas Armstrong, *A Memoir* (1912); Felix Moscheles, *In Bohemia With du Maurier* (1896); Daphne du Maurier, *Gerald; a Portrait* (1934), *The du Mauriers* (1937) and *The Young George du Maurier* (1951); Derek Pepys Whiteley, *George du Maurier: His Life and Work* (1948) and du Maurier's illustrations for *Once a Week* in *Alphabet and Image* (Sept. 1947). (F. W. W.-S.)

DU MAURIER, SIR GERALD HUBERT EDWARD BUSSON (1873–1934), British actor-manager, a son of the artist and novelist George du Maurier (*q.v.*), was born at Hampstead, London, on March 26, 1873. He was the chief British exponent of an exactly and delicately realistic style of acting, which sought to imitate the surface of life and to suggest rather than to state the deeper emotions. He won immense popularity, but the fact that he presented characters in terms of his own personality, in contemporary plays, led many to underrate him. Among the plays in which he appeared were: *The Admirable Crichton, Raffles, Peter Pan, Dear Brutus* and *Bulldog Drummond.* He joined in the management of Wyndham's theatre in 1910, and then of the St. James's in 1925 with *The Last of Mrs. Cheyney.* He was knighted in 1922. Du Maurier died in London on April 11, 1934. His daughter DAPHNE DU MAURIER (1907–), a successful novelist and playwright, published a life of her father, *Gerald; A Portrait,* in 1934. (W. A. DN.)

DUMBARTON, a royal, large and parliamentary burgh, seaport and the county town of Dunbartonshire, Scot., on the river Leven, near its confluence with the Clyde, 14 mi. W.N.W. of Glasgow by road. Pop. (1961) 26,335. The Alcluith ("hill of the Clyde") of the Britons, and Dunbreatain ("fort of the Britons") of the Celts, it was the capital of the district of Strathclyde. There the Romans are said to have had a naval station. The history of the town, however, practically centres in the successive fortresses on the Rock of Dumbarton, a twin-peaked hill, 240 ft. high and a mile in circumference at the base. The rock, of basalt with a tendency to columnar formation, overlooks the Clyde as well as the Leven. The higher of the two peaks is called Wallace's seat. The Picts seized the hill in 736 and the Northmen in 870. It was the chief stronghold of the earl of Lennox in the time of William the Lion and as a royal fortress it was alternately in the hands of the Scottish and the English for many years. Sir William Wallace (*q.v.*) was in 1305 imprisoned there before he was removed to London. Thomas Crawford of Jordanhill on the night of March 31, 1571. in the interests of James VI scaled the walls and seized the castle from Lord Fleming who had held it for Queen Mary for nearly three years.

Dumbarton was of old the capital of the earldom of Lennox, but was given up by Earl Maldwyn to Alexander II, by whom it was made a royal burgh in 1222 and declared to be free from all imposts and burgh taxes. Later sovereigns gave it other privileges, and all were finally confirmed by a charter of James VI. It had the right to levy customs and dues on ail vessels on the Clyde between Loch Long and the river Kelvin. "Offers dues" on foreign ships entering the Clyde were also exacted. In 1700 these rights were transferred to Glasgow by contract, but were afterward

vested in a special trust created by acts of parliament.

Most of the town lies on the left bank of the Leven. but there is communication with the suburb of Bridgend on the right bank by a five-arched stone bridge. The Glencairn Greit house, which dates to 1623 and has fine dormer windows. mas acquired by the town council and scheduled as an ancient monument in 1923. The principal industries are shipbuilding, engineering, distilling and the manufacture of tubes. aircraft and aluminum houses. The old staple trade of the making of crown glass, begun in 1777, lapsed some 70 years aiterward when the glass duty was abolished. There are quays, docks and a harbour at the mouth of the Leven, and a pier for river steamers runs out from the Castle rock. but is not used. The first steam navigation company was established in Dumbarton in 181j, when the "Duke of Wellington" (built in the town) plied between Dumbarton and Glasgow. But it was not till 1844. consequent on the use of iron for vessels. that shipbuilding became the leading industry. The famous clipper "Cutty Sark" was completed by a Dumbarton firm in 1869.

DUMBARTON OAKS CONFERENCE, a meeting of diplomatic experts of the "big four" powers (U.S., U.K., Soviet Union and China) held during World War II (1944) at Dumbarton Oaks, an estate in Washington, D.C. Newspapers named it the World Security conference, for it was called to draw up basic proposals for a postwar security organization to succeed the League of Nations. The discussions were officially designated "conversations" to indicate that they were held below the foreign ministers' level and would constitute recommendations only, not binding commitments. They constituted the first important step taken to carry out paragraph 4 of the Moscow Declaration of 1943. which recognized the need for a general international organization to maintain world peace and security.

Because the Soviet Union was still neutral in the war with Japan, it would not meet with China. The talks were therefore arranged in two phases: (1) from Aug. 21–Sept. 28. the U.S., the U.K. and the Soviet Union drafted "Proposals for the Establishment of a General International Organization," known as the Dumbarton Oaks proposals); (2) from Sept. 29–Oct. 7, the British and U.S. experts considered the proposals with the Chinese, who then endorsed them.

Unfortunately, the proposals did not represent a complete plan of organization, the U.S. and the U.K. being stalemated with the Soviet Cnion on two essential points: first, on the voting system of the proposed Security council, which later became famous as the "veto problem"; second, on membership, because the Soviet Union demanded seats in the general assembly for all of its 16 constituent republics. Roosevelt. Churchill and Stalin finally resolved these two issues at the Yalta conference (*q.v.*), and the Dumbarton Oaks proposals then formed the basis for negotiations at the San Francisco conference. which drafted the charter of the United Nations in 1945. The text of the Dumbarton Oaks proposals was published in the department of state *Bulletin,* XI, no. 276. Oct. 8, 1944. *See* SAN FRANCISCO CONFERENCE.

(R. B. RU.)

DUM-DUM, a town in Twenty-four Parganas district, West Bengal. India, lies 7 mi. N.E. of Calcutta. It is divided into three municipalities, North Dum-Dum (pop. [1961] 38.451). South Dum-Dum (pop. [1961] 111,507) and Durn-Durn cantonment (pop. [1961] 20.159). North Dum-Dum still contains large rural enclaves. South Dum-Dum forms the northern fringe of the built-up area of Calcutta and has a college. Founded in 1783. Dum-Dum cantonment was the headquarters of the Bengal artillery until 1853. It is now an industrial subutb of Calcutta, having an ammunition factory (where the dumdum expanding bullet was first made) and a large number of engineering concerns. It contains a college affiliated to Calcutta university and a Protestant church (St. Stephen's). The airport of Calcutta is also located there. (S. P. C.)

DUMDUM BULLET (or DUM-DUM), the name applied (about 1897). from its manufacture at Durn-Dum arsenal. Benyal. to a modification (Mark IV) of the Lee-Metford bullet. Its peculiarity consisted in its expanding on impact and thus causing an ugly wound. and it was adopted in Indian frontier fighting because of the failure of the ordinary bullet. making a clean perforation, to stop the charges of fanatical tribesmen. In the dumdum. expansion was obtained by leaving the lead core exposed at the tip and weakening (by making thin) the cupronickel casing round the shoulder of the bullet. Improvised forms of expanding bullets were used in lndia and the Sudan. the commonest method of securing expansion being to file down the point until the lead core was exposed and to make longitudinal slits in the nickel envelope. XI1 these forms of bullets came to be described colloquially. and even in diplomatic correspondence, as "dumdum bullets." The "soft-point" or "soft-nose" bullet for medium and large game works on the same principle as the dumdum.

An international declaration was made at the second Hague conference. July 29, 1899, forbidding the use of expanding bullets. The United States, however, did not subscribe to this declaration. The alleged use of dumdums by the British in South Africa (1899), by the Russians against the Japanese (1904 05) and by both sides in World War I formed the substance of accusations and protests.

DUMESNIL, MLLE (MARIE FRANÇOISE MARCHAND) (1713–1803), French actress. was born in Paris on Jan. 2, 1713, and made her debut in 1737 at the Comédie Française as Clytemnestre in Racine's *Iphigénie* en *Tauride.* She played Cléopâtre in Corneille's tragedy *Rodogune* and Racine's Phèdre. Xthalie and Hermione with great effect. When she created Yoltaire's Mérope (1743), he said that she kept the audience in tears for three successive acts. She retired in 1775 and died on Feb. 20, 1803.

She authorized in 1800 the publication of a *Mémoire* dc *Marie Françoise Dumesnil,* in reply to an attack by her rival. La Clairon (*q.v.*).

DUMFRIES (*Dum Fres,* "the fort of the Frisians"). a royal and large burgh and the county town of Dumfriesshire. Scot.. on the left bank of the Nith, 8 mi. from the Solway firth and 33 mi. W.N.W. of Carlisle by road. Pop. (1961) 27.275. Durnfries is an attractive border town, picturesquely situated, with mild climatic conditions. On the crest of the main street stands the Mid Steeple, built in 1705–08 by Tobias Bnchup. Formerly the town hall, it is occupied by shops but its dignity still forms an appropriate background for traditional ceremonies. particularly those of Guid Nychburris day celebrated annually in June, during which the marches are ridden by the cornet (cavalry officer carrying the standard) and his cavalcade and a schoolgirl is crowned "queen of the south." A competition for "the siller gun" (a small silver gun originally presented as a trophy by James VI [James I of Great Britain] to encourage the use of firearms) which took place annually until 1831 has now been revived as part of the annual Guid Nychburris celebrations. The Theatre Royal, which dates from 1787, was frequently attended by Robert Burns. The Nith is crossed by four bridges and a railway viaduct: of the two bridges used for vehicular traffic. the New bridge dates from 1790–94 and St. Michael's bridge from 1927. The Old bridge, built of nine arches (later reduced to six) in the early 15th century and traditionally known as Devorguila's bridge. is used for foot passengers only, as is the suspension bridge erected in 1875. Maxwelltown, on the opposite side of the Nith, was amalgamated with Dumfries in 1929. World Wars I and II changed the character of the burgh's industry. The traditional occupations. hosiery and knitwear, continued to absorb a proportion of female labour and to command a rich export market, but the weaving of tweed. which fell victim to the depression following World War I. was totally superseded by large-scale industries including the processing and manufacture of articles from rubber, the production of nitrocellulose and man-made fibre, and the dehydration and canning of milk. In Dumfries are the Dumfries academy: Crichton Royal. an extensive hospital for the treatment of mental disorders; the Gracefield arts centre (1950); and the Dumfries Burgh museum. formerly a windmill, which contains a camera obscura.

Although Dumfries was the site of a camp of the Selgovian Britons, nothing is known of its early history. William the Lion td. 1214) made it a royal burgh. but the oldest existing charter was granted by Robert II in 1395. The town became embroiled in the struggles that ended in the independence of Scotland. It

favoured the claims to the throne, first of John de Baliol and then of John Comyn (d. 1306) called the "red", as against those of Robert the Bruce, who drew his support from Annandale and who reputedly murdered "red Comyn" in the chapel of Greyfriars. Until the close of the 16th century the burgh was exposed to frequent raids, both from freebooters on the English side and from partisans of the Douglases, Maxwells and Johnstones. In Covenanting times the martyr roll of Dumfries was heavy and is commemorated by the martyrs' monument in St. Michael's churchyard. There also stands the mausoleum to Robert Burns, who lived in Dumfries (his house is now a museum) from Dec. 1791 until his death on July 21, 1796, and whose remains were reinterred on this site in 1815. The union with England was so unpopular that not only did the provost vote against the measure in the Scottish parliament, but the articles were burned (Nov. 20, 1706) at the market cross by a body of Cameronians. In the Jacobite rebellions of 1715 and 1745 Dumfries remained apathetic.

Lincluden abbey, the ruins of which lie 1½ mi. N.W., was founded in the 12th century and later converted into a collegiate church by Archibald, earl of Douglas; it enshrines the tomb of Princess Margaret, daughter of King Robert III. Caerlaverock castle, 8 mi. toward the estuary of the Nith, is one of the finest examples of early 15th-century military architecture in Scotland.

(M. D. McL.)

DUMFRIESSHIRE, the second largest county of southern Scotland, is bounded on the north by the shires of Lanark, Peebles and Selkirk, west by Ayrshire and Kirkcudbrightshire, east by Roxburghshire and south by the Solway firth and Cumberland.

Physical Features. — The county's 1,075 sq.mi. occupy a roughly oval area facing the Solway firth between Dumfries and Gretna and with a rather irregular, high northern boundary including most of Nithsdale in the west, all of Annandale in the centre and all of Eskdale in the east (with a small part of lower Liddesdale). The northern boundary belt includes many high points like White Coomb (2,696 ft.), Hart Fell (2,652 ft.) and the isolated cone of Queensberry (2,286 ft.); it is largely a watershed: the south-flowing streams are relatively short and vigorous, flowing only 40–80 mi. to the sea, and therefore gouge deep into the Ordovician and Silurian slaty shales, grits and greywackes of the Southern uplands dissected plateau, as in the spectacular Devils's Beef Tub north of Moffat,and extend their basins at the expense of the less vigorous headwaters of Clyde and Tweed, sometimes by actual river capture. These northern heights look south across lower dissected plateaus planed across similar rocks, with summit planes successively at about 1,500, 1,000 and 500 ft.

To the south, Carboniferous lavas and tuffs give a belt reaching about 900 ft. as in Birrenswark. There is a gradual change to the coastal lowlands of the Solway, planed across Carboniferous rocks, and red Triassic sandstones, all usually drift-covered. Of the three major river-basins, the Nith and the Annan particularly carry pockets of lowland into the heart of the upland, gorgelike stretches alternating with partly structural basins in softer, more recent rocks, Carboniferous or Permian. At the maximum glaciation the valleys and lowlands were swept by glaciers from the major centre of ice dispersal just south of the headwaters of the Nith. Valleys were smoothed and a few rock-basin lakes carved, like Loch Skene; lower hillsides and lowlands were plastered with boulder-clay, often in the drumlin pattern; pre-glacial drainage was upset, as in the diversion of the lower Nith to its present course past Dumfries from a broad valley now occupied by Lochar Moss. During retreat phases the hills were notched by drainage channels marginal to standing ice in the Solway area; meltwater gave many valleys a flat gravel floor and spread kames and deltas perhaps with kettlehold lakes, as around Lochmaben; and the higher sea level of post-glacial times left raised beaches at 50 and 25 ft. of which latter the lower Lochar Moss was an embayment, with its peats over shelly gravels.

The climate is mild and genial, the strongest prevailing wind being westerly. Rainfall varies from 35 in. in the south to 60 in. in the north. Because of the nature of the soil. peat plants are largely represented. There are some fine planted beechwoods, often on glacial sands flanking the dales. (A. T. A. L.)

History. — The early populations have left hill forts in the north, stone circles (as in Dunscore and Eskdalemuir), camps (Dryfesdale), tumuli and cairns (Closeburn) and sculptured stones (Dornock and Hoddom). At Holywood, which derives its name from a grove of sacred oaks, is a stone circle known locally as "the twelve apostles." The British inhabitants were called Selgovae by the Romans who built many forts in the upper basin of the Annan. There are traces of Roman roads which ran by Dalveen pass into Clydesdale and up the Annan to Tweeddale, and at Birrens is a well-preserved Roman camp. Roman altars, pottery and coins have been found in many places and much important material on excavations carried out at Milton near Beattock, Dalswinton, and other sites is recorded in the Transactions (3rd series, Dumfries, 1913 et seq.) of the Dumfriesshire and Galloway Natural History and Antiquarian society. Upon the withdrawal of the Romans, the Selgovae were conquered by Scots from Ireland. In the parish church of Ruthwell (pron. Rivvel; the "rood," or cross, "well") is preserved an ancient cross which tells in Runic characters the story of the Crucifixion. The Saxon conquest of Dumfriesshire does not seem to have been thorough, the people of Nithsdale and elsewhere maintaining their Celtic institutions up to the time of David I (1084–1153). Edward I besieged Caerlaverock castle, and the factions of the second Robert Bruce (who was lord of Annandale), John Comyn and John de Baliol were at constant feud. The border clans were continually at strife until the 18th century. In 1680, persecuted Covenanters published at Sanquhar their declaration against the king. Although Prince Charles Edward Stuart passed through Dumfries in 1745, at no time were Jacobite sympathies particularly marked. Robert Burns farmed at Ellisland on the Nith for three years and spent the last five years of his life at Dumfries where he is buried. Thomas Carlyle was born at Ecclefechan, in a house still standing, and is buried in the churchyard. Among other famous men of Dumfriesshire were Thomas Telford, civil engineer, and William Paterson, founder of the Bank of England.

Population and Administration. — The population enumerated in the 1961 census was 88,423. The chief towns are Dumfries (*q.v.*), the only large burgh (pop. [1961] 27,275), and the small burgh of Annan (pop. [1961] 5,572). The other small burghs, which have populations of less than 2,800, are Langholm, Lockerbie, Moffat. Sanquhar and Lochmaben. The last two, together with Dumfries and Annan, are royal burghs. Gretna Green (*q.v.*), once famous for runaway marriages, is near the Cumberland border. There are eight county districts.

The county returns one member to parliament. Dumfries forms a sheriffdom with the shires of Kirkcudbright and Wigtown and there is a resident sheriff-substitute at Dumfries. Senior secondary education is provided at Dumfries academy and by the early 1960s was extended to Annan. There is a farm school at the Barony, Parkgate, and a technical college at Dumfries.

Agriculture and **Industry.**—Dumfriesshire is essentially an agricultural county. During the 18th century farmers began to raise stocks for southern markets and within 100 years 20,000 head of cattle, formerly Galloways, later mostly shorthorns and Ayrshires, were sent annually to England. Cheviots are bred in the hill country, the richer pastures of the Solway plain being reserved for half-bred lambs, mainly a cross of Cheviots with Leicesters or Suffolks. Horse-breeding has declined. Poultry rearing and pig-keeping are carried on. Agricultural holdings occupy about 85% (more than half of which is rough grazing or woodland) of the total area of the county. Oats is the largest crop followed by turnips, barley and potatoes. A big afforestation scheme was established around Ae village in 1947.

Sandstone and to a lesser degree limestone are quarried and coal mining is carried on at Kirkconnel. The oldest-established industries of Dumfriesshire are hosiery and tweed manufacture, at Dumfries and Langholm respectively. Modern industries near Dumfries include plants for the dehydration and canning of milk; the manufacture of flooring and footwear from rubber; the production of nitrocellulose for industrial and military use; and the manufacture of plastics and cellulose ethers. At Annan, in addi-

tion to hosiery and engineering works, is a factory for the manufacture of chip boards; and at Chapelcross, near Annan, is a plutonium and nuclear power generating plant. The salmon fisheries of the Nith and Annan and the Solway firth are of value.

The main railway line between Glasgow and Carlisle runs through Kithsdale and lower Annandale over the border and another line from Edinburgh to Carlisle passes through Beattock and Lockerbie. From Dumfries westward there is also rail communication with Castle Douglas, Kirkcudbright, Newton Stewart and Stranraer. (M. D. McL.)

DUMKA, a musical term of Ukrainian origin borrowed by Dvořák from popular literature as a title for some of his compositions. 'The Dumkn and Furiant. Op. 12. and the Dumka. Op. 35. are the tno examples from his piano works. The term signifies a lament in slow tempo of passionate character. Dvořák's piano trio. Op. 90, known as the "Dumky" trio (*dumky* is the plural of *dumka*), consists of a series of short movements in this form.

DUMONT, the name of a family of prominent French artists. François Dumont (1688–1726), a sculptor. best known for his figures in the church of St. Sulpice, Paris. was the brother of the painter Jacques Dumont, known as "le Romain" (1701–81), whose chief success was gained with a great allegorical composition for the Paris *hôtel de ville* in 1761. François's son Edme (1720–75), the latter's son Jacques Edme (1761–1844) and the son of the last named, Augustin Alexander (1801–84), were famous sculptors Jean Joseph Dumons (1687–1779), sometimes called Dumont, is best known for his designs for the Aubusson tapestries.

DUMONT, FRANÇOIS (1751–1831), one of the greatest miniature painters of France, was born at Lunéville (Meurthe), studied for a time under Jean Girardet, and in 1788 was accepted as an academician and granted an apartment in the Louvre. He married the daughter of Antoine Vestier, the miniature painter, and had two sons, Aristide and Bias, both of whom became painters. He painted portraits of Louis XVI and Marie Antoinette, Louis XVIII and Charles X, and of almost all the important persons of his day. His own portrait was engraved both by Audouin and by Tardieu. He spent the greater part of his life in Paris. and there he died A younger brother. known as Tony Dumont, was also a miniature painter, a pupil of his brother, a frequent exhibitor and the recipient of a medal from the Academy in 1810. Each artist signed with the surname only, and there is some controversy concerning the attribution to each of his own canvases. Many of Dumont's finest paintings came into the collection of J. Pierpont Morgan, but others are in the Louvre, presented by the heir of Bias Dumont.

DUMONT, JEAN (1666–1726), French writer, author of *Corps universelle diplomatique du droit des gens; contenant un recueil des traitez d'alliance, de paix,* etc. *faits en Europe depuis le regne de Charlemagne jusques à present,* 8 vol. (1726–31), continued after his death by J. Rousset Before settling in the United Provinces of the Netherlands, where his early works included a number of pamphlets attacking the government of Louis XIV, he had been a soldier and had traveled in Europe and Turkey. Subsequently he was appointed historiographer to the emperor and became baron de Carlscroon. He died in Vienna.

Dumont's books include *Mémoires Politiques . . . de l'histoire de la paix de Ryswick,* 4 vol. (1699); *Recherche modeste des causes de la presente guerre* (1703); *Nouveau recueil de traitez . . . depuis la paix de Munster,* 2 vol. (1710). He was founder-author (1692–1710) of the periodical *Lettres Historiques; contenant ce qui se passe de plus important en Europe;* it was continued until 1736 by H. Basnage and others.

DUMONT, PIERRE ÉTIENNE LOUIS (1759–1829), Swiss writer and statesman, was author of the valuable *Souvenirs de Mirabeau* and literary collaborator with Jeremy Bentham. He was born in Geneva, July 18, 1759, and ordained pastor in 1783; but after the hostile reception of his first sermon, he went to St. Petersburg. In 1786 he arrived in London as tutor to the sons of Lord Lansdowne. Of many later travels the most interesting was the period from Jan. 1789 until March 1790 when he was in Paris, taking part in Revolutionary events by assisting Mirabeau with the journal *Courier de Provence* and with his speeches. In 1814 Dumont returned to Geneva and later became leader of the representative council. He died in Milan, Sept. 29, 1829. Dumont's relationship with Jeremy Bentham was unusual in kind and far-reaching in effect. Shortly after their first meeting (1788) at Bowood, Bentham agreed that Dumont should take Bentham's chaotic papers to prepare a French edition of his work: during 40 years' intermittent work, Dumont made a compilation, using Bentham's ideas and illustrative material but abridging, arranging, interpreting and translating them into readable French. *Traités de législation civile et pénale,* 3 vol. (1802; Eng. trans., *Theory of Legislation,* by R. Hildreth, 1864; ed. by C. K. Ogden, 1931) was drawn from Bentham's *Introduction to the Principles of Morals and Legislation* (1789) and other manuscripts and made Bentham's reputation, particularly outside England. *Tactique des assemblées le'gislatives,* 2 vol. (1815), drew upon *Essay on Political Tactics* (1791); and *De l'organisation judicaire et de la modification* (1828) upon many writings, including the *Codification Proposal* (1822); but *The'orie des peines et des recompenses,* 2 vol, (1811; Eng. trans., 1825–30), and *Traité des preuves judiciares,* 2 vol. (1823; Eng. trans.. 1825), first appeared in French. Bearing in mind Bentham's lack of interest in publication and his turgid style, Sir Samuel Romilly's comment on his two friends may be justifiable: "But for Mr. Dumont Bentham's reputation might never have emerged from obscurity."

BIBLIOGRAPHY.—Bentham's *Oeuvres,* 2 vol (1829–30); Dumont's *Souvenirs de Mirabeau* (1832; new ed by J Bénétruy, 1951; Eng. trans. 1832 and 1904) *See* also biography by J Martin (1942); B. Gagnebin, *Jeremy Bentham et Étienne Dumont* (1,948).

DUMONT D'URVILLE, JULES SEBASTIEN CÉSAR (1790–1842), French navigator who made a notable voyage of discovery to the antarctic, was born at Condé-sur-Noireau Calvados, on May 23, 1790 He went to sea in 1807 as a *novice* on board the "Aquilon." During the next 12 years he gradually rose in the service, and added a knowledge of botany. entomology, English, German, Spanish, Italian and even Hebrew and Greek to his professional studies In 1820, while engaged in a hydrographic survey of the Mediterranean. he was fortunate enough to recognize the Venus of Milo (Melos) in a Greek statue recently unearthed and to secure its preservation by his report to the French ambassador at Constantinople. In 1822 he served in the circumnavigating expedition of the "Coquille"; on its return in 1825 he was promoted *capitaine de frégate* and commissioned to discover traces of the lost explorer, J. F. La Pérouse, in which he was successful. The "Astrolabe," as he renamed the "Coquille," left Toulon on April 25, 1826, and returned to Marseilles on March 25, 1829, having traversed the South Atlantic. coasted the Australian continent from King George's sound to Port Jackson, charted various parts of New Zealand and visited the Fiji Islands, the Loyalty Islands, New Caledonia, New Guinea, Amboina, Van Diemen's land (Tasmania), the Caroline Islands. Celebes and Mauritius. In 1829 D'Urville was promoted *capitaine de vaisseau* and in Aug. 1830 he conveyed the exiled king Charles X to England. On Sept. 7, 1837, he set sail from Toulon with "L'Astrolabe" and "La Zélée" on a voyage of exploration in the south polar regions, with the object of passing the "furthest south" (74° 15′ S.) reached by James Weddell in 1823. After surveying in the Strait of Magellan, D'Urville's ships reached the ice pack in 63° 29′ S., 44° 47′ W., on Jan. 22, 1838. Ill-equipped for ice navigation, they failed to penetrate the pack, which they coasted for 300 mi. to the east. Returning westward they visited the South Orkney Islands and part of the New Shetlands, and discovered Joinville Island and Louis Philippe land, but were compelled by scurvy to seek succour at Talcahuano in Chile. Thence they proceeded across the Pacific and through the Asiatic archipelago. visiting the Fiji and the Pelew (Palau) islands, coasting New Guinea and circumnavigating Borneo. In 1840 they returned to the antarctic region, hoping to discover the magnetic pole in the unexplored sector between 120° and 160° E., and in Jan. 1841 discovered Adélie Coast in 140° E., 66° 30′ S. Nov. 6 found them at Toulon. On May 8, 1842, D'Urville was killed, with his wife and son, in a railway accident near Meudon. An island (also called Kairu) off the north coast of New Guinea and a cape on the same coast bear his name.

BIBLIOGRAPHY.—D'Urville's principal works are *Enumeratio plantarum quas in insulis Archipelagi, aut littoribus Ponti Euximi,* etc. (1822); *Voyage de la corvette "l'Astrolabe," 1826–1829* (1830–35) and *Voyage au pôle sud et dans l'Océanie, 1837–1840* (1841–54), in each of which his scientific colleagues had a share; *Voyage autour du monde: résumé général des voyages de Magellan,* etc. (1834 and 1844). See also G. Day, *Dumont d'Urville* (1947). (R. A. SN.)

DUMORTIERITE, an uncommon aluminum borosilicate. is one of the aluminum silicate minerals important in the manufacture of refractories. It is an especially desirable raw material because it transforms into the crystalline substance mullite (*q.v.*) at a lower temperature (approximately 1,200° C.) and aith a smaller volume change than most other aluminum silicates. The resulting mullite body has a high degree of thermal, mechanical and chemical stability at high temperatures. Dumortierite is used chiefly for spark-plug and laboratory-ware porcelain. The only known commercial deposit in the world is one near Oreana. Nev.

Dumortierite occurs in aluminum-rich metamorphic rocks such as schists and gneisses and in pegmatites associated with such rocks. In addition to the deposit near Oreana some of the best-known localities are: near Lyons. France. where it was discovered; near Schmiedeberg, Silesia; the Island of Madagascar; near Rio de Janeiro, Braz.; near Vallenar. Chile; Nacozari, Mex.; near Quartzite. and Yuma, Ariz.; and at Dehesa. Calif.

Small amounts of ferric iron (Fe^{3+}) generally are present in dumortierite in solid solution in place of some of the aluminum. the chemical formula being represented by $(Al,Fe)_7BSi_3O_{18}$. The mineral occurs most characteristically in fibrous to columnar aggregates of orthorhombic crystals. The colour ranges through blue, greenish blue, violet and pink. The specific gravity is approximately 3.3. The mineral is difficult to identify with certainty except by careful optical, X-ray or chemical determinations.

(D. M. H.)

DUMOURIEZ, CHARLES FRANÇOIS DU PÉRIER (1739–1823), French general and statesman who deserted the cause of the Revolution after winning for it the victories of Valmy and Jemappes, was born at Cambrai on Jan. 25, 1739. The son of a war commissary, he followed his father to Hanover during the Seven Years' War and volunteered for service in a cavalry regiment (1758). Twice wounded. he was promoted captain in 1761 and made a knight of St. Louis in 1763. Having been discharged from the French army in 1762, he went to fight first for the Genoese against the Corsican rebels. then for Pasquale Paoli and the Corsicans against the Genoese. After a secret mission to Madrid (1767), he took part in the French expedition to Corsica (1768) and was promoted *mestre de camp* in the cavalry (1769). In 1770 he was sent on a mission to the Poles of the Confederation of Bar (*q.v.*). Recalled in 1772, he was next entrusted with a mission to Gustavus III of Sweden in connection with Louis XV's secret diplomacy (1773), but was arrested in Hamburg on the orders of the duc d'Aiguillon and imprisoned first in the Bastille, then in Caen. On his release he was sent to Lille with the rank of colonel (1775). In 1778 he was appointed commandant at Cherbourg, where for 11 years he supervised the development of the port. In 1788 he was promoted *maréchal* de *camp.*

The Revolution opened a new career to Dumouriez. On a visit to Paris he came to terms with La Fayette and with Mirabeau, whom he had previously opposed. He joined the Jacobin club in 1790. In 1791, he was appointed to the command of the 12th military division at Nantes, where he co-operated with Armand Gensonné. the future Girondin, but at the same time made overtures to Louis XVI. He favoured the scheme for declaring war against Austria so that after a short and successful campaign the army could be brought back to Paris to restore the king's power and set up a government in his name. Appointed minister of foreign affairs. on March 1j, 1792, in a government that included Girondin ministers, he was largely responsible for the declaration of war (April 20).

Dumouriez's hopes of an early victory were disappointed, as the French sustained a number of reverses at the start of the campaign. He was made minister of war on June 12, 1792, but resigned on June 15, fearing impeachment by the Legislative Assembly. He then took La Fayette's place as commander in chief of the army of the North (Aug. 16). Together with F. C. Kellermann, he defeated the Prussians in the battle of Valmy (*q.v.*) on Sept. 20, but he then allowed the enemy to withdraw. As commander in chief in Belgium, he next defeated the Austrians in the battle of Jemappes (*q.v.*) on Nov. 6, which delivered Belgium into his hands, but again allowed the enemy to withdraw.

Dumouriez resumed command of the army of the North on Feb. 2. 1793, to direct the invasion of Holland. This began on Feb. 26, but an enemy thrust toward Liège (March 1) forced him to retreat from Holland, and he was defeated at Neerwinden on March 18. He then made two agreements with the Austrian colonel. Karl Mack: under the first, he was to evacuate Belgium; under the second, he was to march on Paris, with Austrian support. Dumouriez failed to take Lille, Condé or Valenciennes, which he had meant to give as pledges to the Austrians, but he did deliver the Convention's war commissaries and the marquis de Beurnonville (Pierre de Ruel), minister of war, into the enemy's hands on April 2, 1793. Outlawed by the Convention and deserted by his troops, he went over to the Austrian army on April 5, 1793.

After living in Germany and Switzerland, Dumouriez went to England, where he enjoyed a pension of £1,200 from 1800. He went to Spain to advise the Spaniards on guerrilla warfare in 1808. Wellington also consulted him—in particular before the invasion of southwestern France (1814). Louis XVIII, however, refused to let Dumouriez return to France. Dumouriez died at Turville Park, in Buckinghamshire, on March 14, 1823.

See A. Chuquet, *Dumouriez* (1914). (A. So.)

DUNANT, JEAN HENRI (1828–1910), Swiss humanitarian, founder of the Red Cross and one of the founders of the World's Young Men's Christian association, was born in Geneva, Switz., May 8, 1828. An eyewitness of the battle of Solferino, in June 1859, where there were nearly 40,000 casualties, Dunant organized emergency aid services for Austrian and French wounded. In the book *Un Souvenir de Solférino* (1862) he proposed the formation in all countries of voluntary relief societies, ior the prevention and alleviation of suffering in war and peace without any distinction of race or creed, and an international agreement regarding those wounded in war. In 1864 the first societies and the first Geneva convention came into being.

Because of bankruptcy, arising from neglect of business affairs, Dunant left Geneva in 1867 and spent most of the remainder of his life in poverty and obscurity, though he fought unceasingly to promote interest in the treatment of prisoners of war, the abolition of slavery, international arbitration, disarmament and a Jewish homeland. In 1895, after being "rediscovered" by a newspaperman at Heiden, Switz., Dunant received many honours and annuities. including, in 1901, the first Nobel peace prize (with Frédéric Passyj. He died on Oct. 30, 1910, at Heiden. *See* also RED CROSS.

See Ellen Hart, *Man Born to Live* (1953). (R. C. Dw.)

DUNASH, the name of two Jewish scholars of the 10th century.

1. DUNASH BEN LABRAT, grammarian and poet, belonged to the brilliant circle attracted to Cordóva by Hasdai, and took a large share in promoting the Jewish "golden age" under the Moors in Andalusia.

Dunash not only helped in the foundation of a school of scientific philology, but adapted Arabian metres to Hebrew verse, and thereby gave an impulse to the neo-Hebraic poetry, which reached its highest level in Spain.

2. DUNASH IBN TAMIM was, like the preceding, a leader in the critical study of language among Arabic-speaking Jews. Bacher says of him: "In the history of Hebrew philology Ibn Tamim ranks as one of the first representatives of the systematic comparison of Hebrew and Arabic."

DUNBAR, PAUL LAURENCE (1872–1906), U.S. author, whose reputation rests upon his verse and short stories written in Negro dialect, was born in Dayton, O., June 27, 1872, the son of an escaped slave. He was a popular student in high school, where he was the only Negro enrolled, and was the editor of the school paper.

While earning his living in various occupations, including work as an elevator boy in Dayton and later as an assistant in the Library of Congress (1897–98), he continued to write, publishing some poems in Dayton newspapers. His first two volumes of verse, *Oak and Ivy* (1893) and *Majors and Minors* (1895), were privately printed. A favourable notice of the latter by William Dean Howells in *Harper's Weekly* made it a considerable success. Howells also wrote a sympathetic introduction to *Lyrics of Lowly Life* (1896), and Dunbar was established as a popular poet.

In 1898 he married Alice Ruth Moore, also a writer, and began to devote his full time to writing. With *The Uncalled* (1898) he turned his attention to the novel form, and produced three other novels in rapid succession: *The Love of Landry* (1900), *The Fanatics* (1901) and *The Sport of the Gods* (1902). His health began to fail at the turn of the century and he finally succumbed to tuberculosis in Dayton on Feb. 8, 1906. His *Complete Poems* was published in 1913.

With charm and simplicity, Dunbar succeeded in portraying both the essence of the old plantation life and the new restlessness of the emancipated Negro in his poems and short stories in Negro dialect. His novels and verse in literary English, however, are generally artificial and unconvincing.

See Benjamin Brawley, *Paul Laurence Dunbar* (1936); V. Cunningham, *Paul Laurence Dunbar and His Song* (1948).

DUNBAR, WILLIAM (*c.* 1460–*c.* 1520), Scottish poet at the court of James IV. He came probably of the family of the earls of Dunbar and March, and may have been the William Dunbar who graduated B.A. in 1477 and M.A. in 1479 at St. Andrews. His life between 1480 and 1500 is without record. It has been suggested on the unsatisfactory evidence of possibly autobiographical allusions in his poems that he was a Franciscan novice, and traveled into England and France as a preaching friar and later in the king's service. In 1501 he was certainly in England, probably in connection with negotiations of the marriage between James IV and Margaret Tudor which took place in 1503. (The poem associated with this Scottish embassy, "London, thou art the flour of cities all," cannot safely be ascribed to Dunbar.) In 1500 he was granted a life pension of £10 by the king, to be paid "quhil he be promouit be oure soverane lord to a benefice of xl lib. or abone." By 1504 he was in priest's orders. By 1507 his pension had been increased to £20, and in 1510 he received a clear mark of royal esteem in a pension of £80. In 1511 he accompanied the queen to Aberdeen, and celebrated in verse the entertainments provided by the city. It seems unlikely that he went with the king to Flodden (1513); but it is likely that he survived into the new reign and received the benefice for which he had so often asked in verse, as there is no record of his pension after 1513.

With few exceptions, the 100 and more poems attributed to Dunbar are short and occasional, written out of personal moods or events at court. His long pieces are *The Goldyn Targe* (an allegory of love) and *The Thrissil and the Rois* (an allegorical prothalamium for the marriage of James IV); his *flyting* (abuse) of his professional rival Walter Kennedy; the alliterative *Tretis of the tua mariit Wemen and the Wedo,* a dramatic *débat* on love which exposes selfish and insatiable sexuality in women against a background of natural beauty and grace; and (if it is his) the comic tale of *The Freiris of Berwik,* the finest *fabliau* after Chaucer. Dunbar's versatility is astonishing. He handles a great variety of stanza forms, the couplet and the old alliterative measure, with assurance. He is splendidly at ease in hymn and satire, morality and obscene comedy, panegyric and begging complaint, elegy and lampoon. His poetic vocabulary ranges from "anamalit termis celicall [divine]"—the Latinate language of the *rhétoriqueur* tradition—through the alliterative abuse of the *flyting* (verbal artifice of a different sort) to colloquial Scots of tavern and street, and he moves freely from one level of diction to another for satiric effect. He is strikingly individual, not only in the expression of his personality in everything he writes with (for his time) uncommon frankness and wit, but in the originality with which he manipulates old themes, devices and forms. Dreams, tournaments, allegorical processions, love dialogues in the tradition of the *chanson d'aventure,* complaint and satire in the tradition of the *chanson à mal mariée,* verse testament, romance and even the offices of the church, are all turned to fresh account. Like other Scots poets after him—notably Robert Burns—he is a vigorously creative traditionalist. Too much has been made of his whimsicality and daftness. He shows the fantastic humour common among pre-Reformation Scots poets, but he has a superb sense of form, a control of his medium and of himself, which set him apart. In sheer artistry and range, though not in humanity, he is the finest of Scotland's poets.

BIBLIOGRAPHY.—*Manuscripts:* Dunbar's poems are preserved in 16th-century prints and mss. The prints, mainly the work of the Edinburgh printers Walter Chepman and Androw Myllar *c.* 1508, survive in apparently unique copies in the National Library of Scotland. The manuscripts collections containing poems ascribed to Dunbar are: (1) the Asloan manuscript (written in the reign of James V) in the possession of the Talbot de Malahide family in Dublin; (2) the Bannatyne manuscript (1568) in the National Library of Scotland; (3) the Maitland Folio manuscript (*c.* 1580) in the Pepysian library, Magdalene college, Cambridge—with the Bannatyne manuscript preserving most of Dunbar's extant work; (4) the Aberdeen Minute Book of Seisins, vol. ii and iii; (5) the Reidpeth manuscript (1622), a transcript of the Maitland manuscript preserving a number of pieces lost from the original and in Cambridge university library; (6) the Howard manuscript (16th century) in the British museum, London (Arundel manuscript 285); (7) an early 16th-century collection of songs in the British museum (appendix to royal manuscripts 58).

Editions: The Bannatyne manuscript was edited by W. T. Ritchie in four volumes (1928–34), the Maitland Folio manuscript by W. A. Craigie in two volumes (1919–27), the Asloan manuscript by W. A. Craigie in two volumes (1923–25), all for the Scottish Text society. A facsimile of the Chepman and Myllar prints was edited with a note by W. Beattie for the Edinburgh Bibliographical society (1950). The standard edition of the poems is by J. Small and others, 3 vol., Scottish Text society (1884–93); others are by W. M. Mackenzie (1932) and J. Kinsley (1958).

Biography and Criticism: Full accounts of Dunbar's life and work are in J. Schipper, *William Dunbar. Sein Leben und seine Gedichte* (1884) and J. W. Baxter, *William Dunbar: a Biographical Study* (1952). For the political and social background *see* R. L. Mackie, *King James IV of Scotland* (1958). Critical discussions are: R. A. Taylor, *Dunbar: the Poet and his Period* (1931); A. M. Mackenzie, *An Historical Survey of Scottish Literature to 1714* (1933); J. Kinsley (ed.), *Scottish Poetry: a Critical Survey* (1955); C. S. Lewis, *English Literature in the Sixteenth Century* (1954). *See* also E. Morgan, "Dunbar and the Language of Poetry," *Essays in Criticism,* ii (1952); J. Kinsley, "The tretis of the tua mariit wemen and the wedo," *Medium Ævum,* xxiii (1954). (J. KY.)

DUNBAR, a royal burgh and seaport in East Lothian, Scot., lies on the southern shore of the entrance to the Firth of Forth, 36 mi. E.N.E. of Edinburgh by road. Dunbar (Gaelic, "the fort on the point") is a favourite vacation town, with a sand and pebble beach and a golf course. Pop. (1961) 4,003.

A castle was built on the cliffs at least as early as 856. The fortress was an important bulwark against English invasion, and the town, which was created a royal burgh by David II, grew up under its protection. The castle was taken by Edward I and it afforded shelter to Edward II after Bannockburn. In 1336 it was besieged by the English, but was successfully defended by "Black Agnes" of Dunbar, countess of March. In 1479, after his escape from Edinburgh castle, the duke of Albany concealed himself there before sailing for France, and Mary Queen of Scots (*q.v.*) sheltered there in two crises. The regent Moray dismantled it in 1568. The remains of the castle, on the hill above Victoria harbour, are a nesting place for kittiwakes. A Franciscan monastery founded in 1218 stands in ruins at the west end of the town. The early 16th-century Town house, with a heeling clock steeple and massive doors to the police cells, is still in use. Lauderdale house, a Georgian mansion in High street, was formerly a residence of the earls of Lauderdale.

There are two harbours, the Old harbour, extended by Oliver Cromwell before the battle of Dunbar, and the Victoria harbour; both are difficult of access because of sunken rocks and reefs. As part of the redevelopment of the ancient part of the town, which is the harbour area, cottage-type dwelling houses were built after 1951 to the special design of Basil Spence, the architect of the new Coventry cathedral.

Apart from tourism the chief industries are fishing, agriculture, and brewing and malting. (X.)

Battle of Dunbar.—This battle was fought on Sept. 3 (Sept.

13), 1650, between the English army under Oliver Cromwell and the Scots under David Leslie, afterward Lord Newark. It took place about 3 mi. southeast of the town, on a plain between the hills and the sea, through which runs the road from Dunbar to Berwick. Plain and road are crossed at right angles by the Spott water (Brocks burn or Broxburn), which at first separated the hostile armies. Rising from the right bank of the Spott is Doon hill (582 ft.), overlooking the whole field. For the events preceding the battle *see* CIVIL WAR. ENGLISH.

Cromwell, worsted by Leslie in a war of manoeuvre near Edinburgh, was compelled by want of supplies to withdraw to Dunbar; Leslie pursued him and occupied Doon hill, commanding the English line of retreat toward Berwick. Cromwell's situation was perilous, and some officers were for attempting to withdraw by sea. He chose to hold his ground, though sickness had weakened his forces and he estimated the Scots numbers as double his own. Leslie, however, likewise short of provisions and perhaps subject to pressure from the civil and ecclesiastical authorities, descended from the heights on Sept. 2 in order to confront and attack his opponent. With the Spott water on their left, his forces now occupied the forward slopes of Doon and the plain below it.

If Leslie had thus placed himself on Cromwell's line of retreat, he had also placed Cromwell on his own; all would then depend on the skill of the commanders and, still more, on the discipline and fighting qualities of the troops. In the evening Cromwell disposed his army along the ravine and issued orders for a dawn attack on Sept. 3. His advance troops crossed the ravine very early and without meeting much opposition. His artillery was posted on the Dunbar side of the burn, to engage and pin down the Scottish left, while the infantry and cavalry, having made the crossing, deployed in a line south of and roughly parallel to the Berwick road.

Attacked on their right. the Scots at first repulsed both the horse and the foot, but soon Cromwell himself came up with his reserve, and the whole English line advanced again. The fresh impetus enabled it to break the Scottish resistance, and Leslie's line of battle was quickly rolled up from right to left. Oliver was heard to exclaim, "Now let God arise, and let His enemies be scattered," and, in a little while, "I profess they run."

Driven into the broken ground between Doon hill and the ravine, where their left wing was useless, the Scots "routed one another after we had done their work on their right wing," wrote one English officer. Cromwell reckoned that the Scots lost 3,000 killed and 10,000 prisoners, while he put his own casualties as low as 20.

DUNBARTONSHIRE, a county of western Scotland, is bounded north by Perthshire, east by Stirlingshire, southeast by Lanarkshire, south by the Clyde and its estuary, and west by Loch Long and Argyll. The detached parishes of Kirkintilloch and Cumbernauld, which are enclosed between the shires of Stirling and Lanark, formed part of Stirlingshire until the 14th century when the earl of Wigtown, to whom they belonged, became heritable sheriff of Dunbartonshire. Excluding fresh and sea water as well as foreshore, the area of Dunbartonshire is 241.2 sq.mi.

Physical Features.— The Highland boundary faults traverse the country northeastward from Kilcreggan through Loch Lomond near Luss. To the north and west lie heavily glaciated block mountains with a summit plane at about 2,200 ft. above which rises the highest hill. Ben Vorlich (3,092 ft.); this tract is mainly of Dalradian schists and grits, but there is a large granite intrusion straddling the county boundary west of Ben Vorlich. The mean annual rainfall exceeds 120 in. in the north; with snow evident for 10–30 days in the winter. This was doubtless an area of high precipitation during the Ice Age and it was a major centre of ice dispersal of which the rock-basin lakes of Loch Sloy and Loch Lornond (*q.v.*) and the fiord of Loch Long bear witness. There is much bare rock. Acid grassland (fescue-purple moor grass with bracken on deeper well-drained soils) dominates the vegetation with birch on protected slopes, oak in the valleys and alder by the streams. The area is within the range of the golden eagle, capercaillie, ptarmigan, great spotted woodpecker, red deer and wild cat.

South and east of the fault line the other half of the county lies in the mid-lowland but includes much hill country. First comes the Old Red Sandstone giving some conglomerate foothills and islands in Loch Lomond, then Carboniferous rocks over the rest of the county; first the Calciferous Sandstone series in which are intercalated basalt lavas especially in the Kilpatrick hills with a summit plane at about 1,200 ft., while Dumbarton Castle rock is a volcanic plug. The east of the county, including the detached portion, is on the Carboniferous Limestone series which as elsewhere in Scotland contains important coal seams, though broken by dolerite dykes which cross the whole of this tract from east to west. The lowland areas are largely covered by boulder clay dumped by the Highland glaciers and including many schistose rocks. The post-glacial rise in sea level which drowned the Clyde estuary and the sea-lochs caused an arm of the estuary to run north from Dunbarton into what is now Loch Lomond, and there are many raised beach deposits of sand and gravel on coastal shelves as also in this tract, along with recent silts of the river Leven meander-belt. The hills have over 50 in. mean annual rainfall, with peat-bog vegetation and wet flying bent grassland (used for sheep grazing), sedges, etc. The true lowlands, with under 50 in., present a landscape of whitewashed dairy farms where oats, turnips and kale are grown, and short leys (pastures) to feed Ayrshire cattle in pleasant rolling country with planted woodlands for amenity and shelter. (A. T. A. L.)

History.— Prehistoric peoples have left rude forts and tumuli, and there are several remains of the wall of Antoninus, built from Forth to Clyde and running along the north of the detached portion of the shire and through the southeastern corner of the county to Kilpatrick *(see* ANTONINE WALL). Other Roman relics have been found at Duntocher, Cumbernauld and elsewhere. The shire formed part of the old Scottish territory of Lennox (Levenachs, "fields of the Leven") which embraced the vale of the Leven and the basin of Loch Lomond, or all modern Dunbartonshire, most of Stirling and parts of the shires of Renfrew and Perth. It gave its title to the earldom created in 1174 by William the Lion and of the dukedom conferred by Charles II on his natural son, Charles, duke of Richmond and Lennox. Robert Bruce is said to have mustered his forces at Dullatur before the battle of Bannockburn, and died in the county at Cardross castle in 1329. In 1603 Glen Fruin was the scene of the conflict between the Macgregors and the Colquhouns in which the latter were almost exterminated. This encounter led to the proscription of the Macgregors, including Rob Roy. The Covenanters in their flight from the field of Kilsyth, where in 1645 the marquess of Montrose had defeated them, made their way through the southern districts. The clans of Macgregor and Macfarlane made their home in this highland fastness and raided their lowland neighbours.

Population and Administration.— The population in 1961 was 184,546; Gaelic and English were spoken by 1,190 persons. The principal towns are Clydebank (pop. [1961] 49,654) and Dumbarton (26,335; a royal burgh and the county town), both large burghs, the small burghs Helensburgh (9,605), Cove and Kilcreggan (877), Milngavie (8,894), Bearsden (17,022) and, in the detached portion of the county, Kirkintilloch (18,257). There are five county districts. The county returns two members to parliament, one representing East Dunbartonshire and one West Dunbartonshire. Dunbartonshire forms a sheriffdom with the counties of Stirling and Clackmannan, and a resident sheriff-substitute sits at Dumbarton.

Industries and Communications.— The arable lands extend chiefly along the Clyde and the Leven and are composed of rich black loam, gravelly soil and clay. Farmers have markets on the Clyde for all kinds of stock and produce, and high farming and dairying prosper. Black-faced sheep and Highland cattle are pastured on the hilly lands and Border Leicesters and Ayrshires

on the low grounds. Oats is the principal crop; potatoes, turnips. swedes and some wheat are also grown.

Agriculture, orientated to the Glasgow market, is altered locally by intensification in the shape.of market gardening (including rhubarb-growing) with considerable areas of glasshouses. and also by the spread of suburban and week-end residences from Glasgow. The great quantities of pure water in the Leven. traditionally used by textile trades and by dye-works and cleaners. are associated with new industrial development including some in the Vale of Leven industrial estate. The Clyde shores, lined at first with shipyards and engineering works, including the sewing-machine works at Clydebank. give sites downstream for suburban and resort development as at Helensburgh and Garelochead, while beyond lies tourist country, naval developments and the new oil port at Finnart. Manufactures include office equipment, elastic garments, alarm clocks, lenses and textile finishing.

The more populous districts are served by British railways. From Craigendoran to Inverarnan, the West Highland line runs through beautiful scenery. Portions of the Forth and Clyde canal. connecting with the Clyde at Bowling. and opened for traffic in 1790, pass through the shire. There is a regular steamer communication between Craigendoran, Kilcreggan, and the south side of the Firth. During the summer months a steamer service on Loch Lomond operates from Balloch. (RT. C.)

DUNBLANE, a small burgh of Perthshire. Scot., mainly on the left bank of Allan water, a tributary of the Forth, 6 mi. N.W. of Stirling by road. Pop. (1961) 2.922. It is a place of great antiquity. with narrow streets and old houses and a 15th-century bridge. later widened. The chief industry is wool spinning and there is also silk dyeing. The agricultural area around Dunblane traditionally produced beef. but dairy farming now predominates while on the arable land seed potatoes are mostly grown. There is good fishing in the Xllan. A large hydropathic hotel stands on a hill. The cathedral by the side of the river, now the parish church, escaped injury at the Reformation. The first church is said to have been erected by St. Blane in the 6th century. but the cathedral, founded by David I. was almost entirely rebuilt about 1240 by Bishop Clemens. The tower is early Norman. The building was neglected for a long period after the decline of episcopacy, but there was extensive restoration in the 19th century. In the cathedral are 1 jth-century carved oak stalls and an old Celtic cross, 6½ ft. high. Of the bishop's palace only a few ruins remain. Leighton library. built in 1687 to house Bishop Robert Leighton's books, was expanded in the following centuries. Queen Victoria school for the sons of Scottish servicemen mas opened in 1908. The battlefield of Sheriffmuir (*q.v.*) lies about 2½ mi. E. of Dunblane.

DUNCAN, the name of two Scottish kings.

DUNCAN I id. 1010). king of the Cumbrians, and king of the Scots from 1034 to 1040. was the son of Bethoc. daughter of King Malcolm II, by her husband Crinan, lay abbot of Dunkeld (in whose family the name Duncan probably ran). Malcolm II made him king of Strathclyde when that kingdom ceased to be independent, probably not long before 1034, when he succeeded his grandfather as king of Scotland. He besieged Durham in 1039. and in 1040 "at an immature age" was killed by Macbeth, mormaor of Moray. Two of his sons, Malcolm III and Donaldbane, became kings of Scotland.

DUNCAN II (d. 1094) was king of Scotland for a few months in 1094. He was the son of Malcolm III and his first wife Ingibiorg, who were related, so that Duncan's legitimacy was later questioned. He was a hostage in England from 1072 to 1087. He went north as William II's vassal in April 1094, and drove out King Donaldbane; but he was forced to dismiss his Anglo-Norman following and fell victim to Donald in Nov. 1094. The earliest known Scottish charter runs in his name and bears his seal; in it he styles himself, like John Balliol, but unlike all other Scottish kings, *rex Scotie* not *vex Scottorum.* Claims to the Scottish throne were made by his descendants until 1215. (A. A. M. D.)

DUNCAN, ADAM DUNCAN, 1ST VISCOUNT (1731–1804), British admiral, who gained a famous victory over the Dutch at Camperdown in 1797, was born on July 1, 1731, at Lundie, Scot. He entered the navy in 1746 and served under Augustus (later viscount) Keppel in the Seven Years' War. He became lieutenant in If 55, captain in 1761 and rear-admiral in 1787. He was present with Xdm. George (later Lord) Rodney at the relief of Gibraltar (1780) and at the battle of the Saints (1782). On the outbreak of war with France in 1793 he was made vice-admiral. In 1795 he was appointed admiral in command of the North sea fleet to blockade the Dutch in the Texel. Though in May 1797 all his ships except two joined the mutiny at the Nore. Duncan maintained his blockade by deluding the enemy with signals to imaginary ships over the horizon. That summer Gen. Lazare Hoche planned an invasion of Ireland with the assistance of the Dutch fleet under Adm. Johann Wilhelm De Winter. On the former's death in September the troops disembarked. but the Batavian government (contrary to the advice of the admiral) ordered the feet to sea. Duncan was informed by his cruisers that 16 line-of-battle ships had left the Texel on Oct. 7. On Oct. 11, as De Winter tried to regain his base, Duncan attacked with 15 ships five miles off Camperdown. In order to engage before the enemy had time to reach shoal water, he bore up in two groups without waiting to form line of battle. The enemy line was broken in two places. De Winter himself surrendering to Duncan's flagship, "Venerable." After a particularly hard-fought action, nine ships (excluding frigates) were captured. The remainder, which escaped under cover of darkness, surrendered to Duncan in 1799, when he covered the landing of an Anglo-Russian force under Frederick, duke of York, at the Helder. For his services at Camperdown Duncan was created a viscount in 1797. In 1800 he retired because of ill-health and died at Cornhill, Northumberland, on Aug. 4, 1804. A man of imposing build, 6 ft. 4 in. tall, he had a modest and genial temperament that made him universally popular. His resolution in adopting tactics similar to those used later at Trafalgar was rewarded by one oi the most complete victories in naval history.

See Earl of Camperdown, *Admiral Duncan* (1898). (C. C. L.)

DUNCAN, ISADORA (1878–1927), U.S. dancer. was a great revolutionary of the dance who repudiated artificial technical restrictions; she returned to nature itself for her inspiration. seeking a form of dance as natural as the rhythmic movement of the waves. She liberated the dance from dependence on worn-out formulas, paving the way for the development of modern expressive dance.

Born in San Francisco, Calif., May 27, 1878, she danced as a child, but, after a few lessons in ballet, determined to study only natural movement. She toured with Augustin Daly and gave her first tentative concerts in Chicago and New York before persuading her family (mother, sister Elizabeth and brother Raymond) to accompany her to Europe in a cattle boat.

Her first substantial success followed a concert in Paris in 1902. Appearances in Budapest, Berlin and Bayreuth focused serious attention on her art. When she visited Russia in 1905, Michel Fokine (*q.v.*) was profoundly impressed by her dancing. She made several American tours, the last in 1922–23. She founded schools in Germany, Russia and the Cnited States, but none survived.

One of the first dancers to interpret symphonic music. Duncan was deeply influenced by Gluck, Brahms, Wagner and Beethoven. Her dancing barefoot in a loose tunic, suggested by Greek sculpture. furthered the 20th-century emancipation of women's dress.

Unmarried. she bore two children. who were accidentally drowned in 1913. Her later marriage (1922) to the Russian poet Sergei Esenin (*q.v.*) ended in separation. She died in Nice, Sept. 14, 1927, accidentally strangled by a long scarf which became caught in a rear wheel of the open automobile in which she was riding.

See her autobiography, *My Life* (1927). (LN. ME.)

DUNCKER, MAXIMILIAN WOLFGANG (1811–1886). German historian and politician. was one of the scholars diverted to political interests by the movement toward German unity. He was born at Berlin on Oct. 15, 1811, and studied at Bonn and Berlin until 1834, when he was imprisoned for six months for belonging to students' corporations. This imprisonment retarded his advancement, but in 1842 he became professor at Halle.

In 1848 Duncker was a member of the Frankfurt assembly, there becoming the friend of J. G. Droysen (*q.v.*). German unity was Duncker's ruling idea and his deepest ambition was directed toward public, not academic. life. His liberal views prevented his advancement in the Prussia of the time and in 1857 he accepted an invitation to Tiibingen. Two years later (under the regency) he was called to a chair at Halle but accepted instead the post of chief press officer in Berlin. In the same year he became assistant in the foreign office and a member of the Prussian lower house. In 1861 he was appointed occasional adviser to the crown prince. In the Bismarck period his position became difficult and he resigned, although he subsequently worked for Bismarck. In June 1867 at his own wish he was appointed director of the Prussian archives, holding the post until 1874. He died at Ansbach, July 21, 1886. In spite of his political career Duncker's reputation rests mainly on his *Geschichte* des *Altertums,* 9 vol. (1852–86); Eng. trans, by E. Abbott, *History of Antzquity,* 6 vol. (1878–82).

DUNDALK (DUN DEALGAN, "Dealga's fort"), a seaport and urban district and the administrative centre of County Louth, Republic of Ireland, lies 22 mi. N. of Drogheda by road, near the mouth of the Castletown river, Dundalk bay. Pop. (1961) 19,706. The town has had a turbulent history, from the legendary exploits of Cu Chulainn and his knights, through the period of Norse attacks in the 10th century, the Anglo-Norman invasion to the invasion of Edward Bruce who was killed (1318) in the neighbourhood. There is a record of sieges after it was walled by Henry IV to the burning during the disorders of 1921–23. Dundalk was a borough by prescription and received charters from King John and other monarchs. It is a junction, with large railway shops, of the Great Northern railway. There are distilleries, breweries, bacon. shoe. clothing, cigarette and tobacco factories, and flour mills. Trade is in livestock and agricultural produce, including barley, and there are sea and salmon fisheries. Coal is imported. Notable buildings include the churches of St Patrick (Roman Catholic) and St. Nicholas (Church of Ireland).

DUNDEE, JOHN GRAHAM OF CLAVERHOUSE, VISCOUNT (1648–1689), Scottish soldier, known as "Bonnie Dundee," who led the first Jacobite rising in Scotland (1689) but was killed at Killiecrankie in the moment of victory. He was the elder son of William Graham and Lady Magdalene Carnegie and succeeded to his father's estates in 1653. Educated at St. Andrews university. he served as a volunteer in France and the Netherlands from 1672. becoming a captain in 1676. He returned to England in 1677 and had settled in Scotland when, on Sept. 23, 1678, he was appointed captain of one of three troops of horse commissioned in view of the situation caused by the militant conventicles of the southwest. In Feb. 1679 he was named a sheriff-depute for the southwestern shires.

After the murder of Archbishop James Sharp (May 3, 1679), rebels published a manifesto at Rutherglen (May 29). Graham, pursuing the disaffected, came upon a large armed conventicle in a well-protected position upon the marshy ground of Drumclog (June 1). The rebels, galled by fire which they could not effectively return, advanced in an impetuous attack which routed the royal cavalry, Graham himself having a narrow escape. The enthusiasm raised by this action was the beginning of a serious rebellion. On June 22 Graham was present at the head of his troop when the covenanters were defeated at Bothwell bridge. He was then commissioned to search the southwestern shires for rebels, but acted for only a very short period. He was in London in July 1679, establishing himself in the favour of James, duke of York, in whose train he probably returned to Scotland in October. But he was in London again by Feb. 1680 and seems to have remained there until late in 1681, except for a brief visit to Scotland.

It was only in Jan. 1682, when Graham was appointed sheriff of Wigtown, that he resumed operations against the covenanters. He retained his commission in the army and was promoted colonel on Dec. 25, 1682. Both then and later. the wide powers given to him were sparingly used, and his systematic proceedings against ringleaders and men of substance who countenanced the rebels were more effective than the haphazard brutalities of other commanders. On his return from another visit to London, he was sworn a privy councilor (May 1683) and in June he was present at the sittings of a circuit court of justiciary instituted for the imposition of the oath required by the Test act and for the punishment of rebels. He was rewarded for his services when, by charter of April 23, 1684, he obtained the lands and castle of Dudhope, with the office of constable of Dundee. From April to Sept. 1684 Graham was again at his old employment of inspecting the southern and southwestern shires; in May 1685, at the time of the earl of Argyll's rising, he was ordered with his cavalry to guard the borders and to scour the southwest in search of rebels. It is to 1684 and 1685 that his alleged atrocities are mostly assigned; but careful investigation has reduced the number of lives he took to no more than ten. From 1685 he spent three uneventful years, mainly at Dundee, of which he became provost in 1688.

On the invasion of England by William of Orange, Graham, who had been promoted major general in 1686, was second-in-command in the Scottish army ordered to England to aid King James; he was created Viscount Dundee on Nov. 12, 1688. After James's flight, Dundee returned to Scotland, where he attended the meeting of the convention. The convention proving hostile to James, Dundee left it. and as he retired from Edinburgh (March 18. 1689) at the head of about 50 dragoons he conferred with the duke of Gordon and encouraged him to hold the castle for James. On March 30 he was publicly denounced as a rebel. Gen. Hugh Mackay took the field against him, but the secrecy and speed of his movements outwitted his pursuers as he retreated to the north and into the central Highlands. Dundee expected substantial help to arrive from the exiled king, but little came. By June 11 a kind of stalemate had been reached, but in July many Highland clans assembled round Dundee and both sides took the field again. On July 18 a high price was set on Dundee's head. Mackay, in his march toward Blair castle, entered the pass of Killiecrankie, the battleground selected by Dundee and his officers. There, on July 27, 1689, was fought the battle of Killiecrankie (*q.v.*). The Highlanders were completely victorious, but their leader was shot and fell dying from his horse.

BIBLIOGRAPHY.—C. S. Terry, *John Graham of Claverhouse, Viscount Dundee* (1905); Mark Napier, *Memorials and Letters of Graham of Claverhouse, 3* vol. *(1859–62)*; *Letters of the Viscount Dundee,* Bannatyne Club (1826). (GN. D.)

DUNDEE, a royal and parliamentary burgh, county of a city and seaport of Angus (Forfarshire), Scot. Pop. (1961) 182,959. It lies on the north shore of the Firth of Tay, 51 mi. W.N.E. of Edinburgh by road and ferry. Railway approach from Edinburgh is either by way of Perth or across the Forth and Tay bridges. The town has a frontage on the water of more than 8 mi. and rises gradually from the river to Dundee Law (571 ft.) and Balgay hill. The estuary to the east of Tay bridge (more than 2 mi. long) is 1½ mi. wide and the docks—accessible from it at all stages of the tide—are within 12 mi. of the sea. At the 1961 census Dundee was the fourth largest city in Scotland, but second in respect of commerce.

The new city chambers, forming two sides of a large open square, were opened in 1933. The Caird hall, with a fine classic portico, which forms the southern end of the square, was erected largely from a bequest of Sir James Caird (d. 1916) and contains a big concert hall and a banquet hall (the Marryat hall). The Mercat cross, a shaft 15 ft. high, bearing a unicorn with the date of 1586, once stood in High street, but was reconstructed in the southwestern corner of the grounds of the City churches. A library and sculpture galleries in Ward road were finished in 1915 and the Albert institute in Meadowside contains the art gallery, museum and central library. In Dock street stands the Royal arch. erected to commemorate the visit of Queen Victoria in 1844. Dudhope castle, once the seat of the Scrymgeours. hereditary constables of the burgh (one of whom, Sir Alexander, was a companion-in-arms of Sir William Wallace) was granted by James VII of Scotland (James II of England) to John Graham of Claverhouse. On his death it reverted to the crown and was later clubrooms for various organizations. Though Dundee was once a walled town, the only relic of its walls is the East port in Cowgate, preserved because it was said that George Wishart, the Scottish reformer who

was burned as a heretic in 1546 at St. Andrews, preached from the parapet during the plague of 1544.

Of the many churches and chapels the most interesting are the City churches—St. Mary's, Old St. Paul's and St. David's, and St. Clement's. the three parish churches being under one roof. At the west end of the building stands the noble square tower (St. Mary's tower) 156 ft. high, commonly called the old steeple, which was once the belfry of the church erected on that spot by David, earl of Huntingdon, as thanksgiving for his escape from shipwreck on the shoals at the mouth of the Tay (1193). The church perished, but the bell tower remained and was restored in 1871–73 by Sir George Gilbert Scott. Bishop Alexander Forbes (1817–75) transferred the Anglican see of Brechin to Dundee.

Hospitals include the Royal infirmary, Maryfield hospital, King's Cross hospital, the Dundee Royal mental hospital and Ashludie sanatorium. The Baldovan institution for the mentally sick was founded in 1884.

The University of St. Andrew's act (1953) dissolved University college, Dundee. which was endowed in 1881 by Miss M. A. Baxter of Balgavies (1801–84) and John Boyd Baxter (1796–1882), and united with the University of St. Andrews in 1897. Following the 1953 act it combined with the University Advanced Medical school (1898) and Dental school (1914) to form Queen's college, a constituent college of the university. There is a fine technical college and school of navigation, while the Duncan of Jordanstone College of Art was opened in 1954. The high school stands on the site of the old public seminaries. Morgan hospital, in Scots Baronial style, immediately to the north of Baxter park was founded for poor boys in 1858 by John Morgan, a native of Dundee. but is now under the jurisdiction of the local education authority as a secondary school. A training school for teachers was opened in Park place in 1920.

Dundee is well endowed with public parks, a total of 1,150 ac. being available. In one of them, Balgay park, is Mills observatory, open to the public. The large Camperdown park (500 ac.) was opened by Queen Elizabeth II when Princess Elizabeth in 1946. It contains the mansion house of the former earls of Camperdown. Along the shore of the estuary is the esplanade running west from Craig pier and linking with the main road to Perth at Ninewells, thus forming a useful bypass.

With modern changes. some picturesque but unsanitary buildings, narrow winding streets and unsavoury courtyards disappeared, along with a few structures of more or less historic interest, like the castle. the mint and numerous convents. But the large factory population, together with the number of high tenement buildings, gave ,rise to slum conditions, which had been considerably improved by the early 1960s.

Dundee returns two members to parliament. The city council consists of the lord provost, bailies and councillors, there being 36 elected members, plus the dean of guild.

Suburbs.— Broughty Ferry lies on the Firth of Tay, 34 mi. E. of Dundee. The name is a corruption of Brugh or Burgh Tay, in allusion to the fortress standing on the rock that juts into the firth. It is believed that a stronghold has occupied this site since Pictish times. The later castle, built in 1498. fell into the hands of the English in 1547 and was held by them for three years. Gradually growing more or less ruinous it was acquired by the government in 1855, repaired, strengthened and converted into a Tay defense, mounting several heavy guns. Because of its healthful and convenient situation, Broughty Ferry became a favourite residence of Dundee merchants. To the northwest lies Benvie. Fowlis, 5 mi. N.W., is remarkable for its 15th-century church, with carved ambry and rood screen (curious representation of the Crucifixion), decorated font, crocketed door canopy and several paintings. The ruined castle adjoining the church ultimately became a dwelling for labourers. Lundie, 3 mi. farther out in the same direction, contains several small lochs, and its churchyard is the burial place of the earls of Camperdown. Tealling, 4 mi. N. of Dundee, was the scene of the ministry of John Glas before he was deposed for heresy. Newport and Wormit, on the opposite bank of the Tay, are connected with Dundee by ferry.

Industry and Commerce.— Dundee is noted first for its large-scale jute industries; the raw materials are imported from Pakistan and fabrics in jute range from the roughest sacking to beautiful carpets. Linen is also manufactured in quantity while the chief textile products are canvas (for which the Royal Navy is the largest customer), ropes, sheetings, sackings, carpets, etc. Dundee is also celebrated for its confectionery and preserves, especially marmalade. Other industries are bleaching and dyeing, engineering, shipbuilding. linoleum manufacturing, foundries, breweries, corn and flour mills, electrical transformers, cash registers, watches, refrigerators. counting devices, batteries and expanded rubber.

On the front wharves and harbour works extend for approximately $2\frac{1}{2}$ mi. The docks cover an area of 354 ac. including Earl Grey dock, 5 ac.; King William IV dock, 39 ac.; Tidal basin, $4\frac{3}{4}$ ac.; Victoria dock, $10\frac{3}{4}$ ac.; Camperdonn dock, $8\frac{1}{2}$ ac., and Fish dock, $1\frac{5}{8}$ ac. There are also graving docks, the ferry harbour and timber ponds. There is regular communication by steamer with London. Kingston-upon-Hull, Newcastle-upon-Tyne. Liverpool, Southampton, Portsmouth, Manchester. Leith and Aberdeen, also with Rotterdam, Amsterdam, Hamburg and other continental ports. There is a steady trade with Calcutta. Bombay and Karachi.

History.— The name of the city is derived most probably from the Gaelic *Dun* Taw, "the fort of the Tay." of which the Latin Taodunum is a transliteration—the derivation pointing to the fact of a Pictish settlement on the site. Its earliest authentic mention is in a deed of gift by David, earl of Huntingdon. younger brother of William the Lion, dated about 1200, in which it is designated as "Dunde." Shortly afterward it was erected into a royal burgh by William the Lion. Edward I is said to have removed its charter but Robert Bruce and successive kings confirmed its privileges and rights, and Charles I finally granted it its great charter in 1641.

In 1291 the town fell into the hands of the English, and while engaged in besieging the castle in 1297 Sir William Wallace withdrew to fight the battle of Stirling bridge. In their incursion into Scotland under John of Gaunt the English captured and partially destroyed the town in 1385. but retreated to meet a counter invasion of their own country. The English seized it again for a brief space during one of the first earl of Hertford's devastating raids in the reign of Edward VI. Dundee bore such a prominent part in propagating the Reformed doctrines that it was styled "the Scottish Geneva." The marquess of Montrose sacked it in 1645 and then burned a considerable portion of it. Charles II spent a few days in the castle after his crowning at Scone, Jan. 1, 1651. In the same year Gen. George Monk captured it after an obstinate resistance and put more than one-sixth of the inhabitants and garrison, including its governor Robert Lumsden, to the sword. Sixty vessels were seized and filled with plunder; but the ships, says Thomas Gumble in his Life *of* Monk, "were cast away within sight of the town and that great wealth perished." In 1684 John Graham of Claverhouse, to the north of the town, became constable and in 1688 provost, in which year James II created him Viscount Dundee (see DUNDEE, JOHN GRAHAM OF CLAVERHOUSE, VISCOUNT). Other famous men who were born or lived in Dundee include Hector Boece (*q.v.*), James Halyburton. the reformer, Sir George MacKenzie (*q.v.*), known as "the bloody MacKenzie," Adm. Adam Duncan, the victor of Camperdown, James Bowman Lindsay, a pioneer of wireless telegraphy, George Constable of Wallace Craigie, the prototype of Jonathan Oldbuck in Sir Walter Scott's *Antiquary*, who lived in Seagate, William Thom (1798–1848). the writer of The *Rhymes* of a *Handloom* Weaver, who was buried in the Western cemetery, and Sir Richard Claverhouse Jebb (*q.v.*), the classical scholar.

Queen Victoria granted a charter to Dundee dated Jan. 25, 1889, raising it to the status of a city, and since 1892 its chief magistrate has been styled lord provost. In 1894 it was created a county of a city. (G. S. WN.)

DUNDERLANDSDAL, a valley of northern Norway, draining southwestward from the neighbouring glaciers to the Ranafiord (latitude 66° 20' N.). Valuable deposits of iron ore (magnetite and hematite) occur there. They were worked during interrupted periods from 1902 to 1939 by a British company.

After 1947 they were state owned. In the early 1960s the mines were reconstructed and modernized to supply an iron- and steel-works in Mo, a town at the mouth of the river. The valley is remarkable for caverns in the limestone, some of the tributary streams flowing for considerable distances underground. The North Norway railway and the North Norway highroad follow the valley. (L. H. Hg.)

DUNDONALD, THOMAS COCHRANE, 10TH EARL OF (1775–1860), British admiral, who ranks among the greatest of British seamen for his brilliant and unconventional career, was born at Annesfield, Lanarkshire, on Dec. 14, 1775. He was the eldest son of the 9th earl whose scientific experiments on his Scottish estates impoverished his family. In 1793 Thomas joined the ship commanded by his uncle, Alexander Cochrane. In 1800 he was appointed to the command of the brig "Speedy." His brilliant capture of the Spanish frigate "El Gamo" (1801) brought him fame, and his subsequent cruises in command of the frigates "Pallas" and "Impérieuse" won him a fortune in prize money. His fame as a frigate captain is immortalized in the novels of Capt. Frederick Marryat, who served under him.

Cochrane was elected member of parliament for Honiton in the radical interest in 1806, and for Westminster in 1807. He led a hazardous fireship attack on the French fleet in the Aix roads in April 1809, but the fruits of his courage were thrown away by the commander in chief, Lord Gambier. Cochrane's ill-advised criticisms of Gambier resulted in the latter's court-martial, at which he was acquitted. This, together with Cochrane's unpopularity in government circles in consequence of his demands for parliamentary and naval reform, resulted in his not being employed again at sea. In Feb. 1814 Cochrane and others were involved in a plot to make money on the stock exchange by spreading false rumours about the abdication of Napoleon. In the trial which followed Lord Ellenborough sentenced him to a period of imprisonment; he was expelled from parliament and deprived of the order of the Bath, which had rewarded his exploit in 1809.

At this lowest point of his fortunes Cochrane accepted (May 1817) the invitation of Chile to command its fleet in the war of independence against Spain. His capture of the Spanish flagship "Esmeralda" in Callao harbour contributed largely to the independence of Chile and Peru. From 1823 to 1825 he transferred his services to Brazil in its war against Portugal. Soon after his return to Europe he was employed by the Greeks in their war of independence, but resigned in 1828 on account of factional disputes and delays in the delivery of steamships, which he proposed to use in war for the first time. At home he campaigned vigorously for reinstatement in the navy, which he achieved in 1832, the year after he succeeded his father as earl of Dundonald. From 1848 to 1851 he commanded the American and West Indies station, where he drew attention to the importance of Trinidad Pitch lake. Only his advanced age of 79 prevented him from commanding a fleet in the Crimean War. He died in London on Oct. 30, 1860, and was buried in Westminster abbey. Throughout his life he occupied himself with inventions, particularly in connection with gas and tar, tubular boilers and screw propulsion. The plans which he put forward in a letter to the prince regent on March 2, 1812, for the use of sulfur gas and smoke screens in war remained secret for nearly a century. Few men have had such an adventurous, turbulent and versatile career, Cochrane was the author of *Autobiography of a Seaman,* 2 vol. (1860–61) and *Narrative of Services in the Liberation of Chili, Peru and Brazil,* 2 vol. (1939).

See the *Life,* 2 vol. (1869) by his son Thomas and H. Fox Bourne; C. C. Lloyd, *Lord Cochrane* (1947). (C. C. L.)

DUNE, a mound or hill and ridge of sand heaped by wind. Dunes are numerous in (1) deserts, particularly in low-lying areas; (2) on sandy coasts with onshore winds; and (3) near rivers of which the volume varies, leaving sandy beds exposed during the dry season. The *areg* of the Sahara and Arabian desert are characterized by vast expanses of dunes, as are the *koums* of the deserts of Iran and Turkistan and the plateaus of Gobi and other Mongolian deserts. Few such desert dunes are found in America or Australia, but the sand hill region of western Nebraska affords a good illustration. In Europe the coasts of Brittany, Cornwall, the Landes of France and the shores of the Baltic; in North America the whole eastern coast from Cape Cod southward, and at places along the Pacific coast; and in Africa, Australia and Asia numerous leeward coasts—these serve as examples of oceanic coastal dunes. Lacustrine dunes are admirably developed on the east shore of Lake Michigan, the south shores of Lake Superior and Lake Erie, the shores of former Lakes Lahontan and Bonneville in the Great Basin of the United States, and on the east shores of the Caspian and Aral seas in western Asia. Examples of river bank dunes are found in almost every land, as. for instance, along the east banks of the Mississippi, Missouri and Rio Grande rivers in the United States.

Dunes migrate constantly unless the sand of which they are composed is prevented from blowing by grass or other vegetation. The rate at which dunes move varies. depending upon the velocity of the wind and the height of the dunes, small dunes migrating the faster. In Denmark the rate is from 8 to 20 ft. a year; in France, on the Bay of Biscay, the sands have advanced at a rate estimated from 15 to 105 ft. a year, burying in their progress forests, farms, vineyards, churches and whole villages, some of which may in course of time be exhumed as the dunes migrate onward. On the south side of Lake Michigan forests which were buried by sand dunes have been uncovered as the dunes moved on. Hundreds, perhaps thousands of square miles of towns and cities in central Asia are buried under dunes. Moving dunes constantly encroach upon the Suez canal. Nor are dunes merely a contemporary geologic feature. Sand dune deposits are recognizable by the character of their bedding in sandstone rocks of many geologic periods, indicating that aeolian action has been prevalent throughout geologic history. Fossil dunes are widely distributed.

(W. E. E.)

DUNEDIN, the fourth largest city of New Zealand and capital of Otago provincial district, lies on the southeast coast of South Island. Pop. (1961) 73,226 (105.053 with urban area). Area 21.8 sq.mi.

Dunedin is situated at the head of a 14-mile-long harbour. The deep-water Port Chalmers is on the northern shore and wharves at the city end are able to accommodate medium-sized ships. The site of the town is hilly, the higher suburbs commanding views of the ocean and harbour. The city was planned in Edinburgh, Scot., and many of the streets are named from Edinburgh streets. The main thoroughfare, Princes street and George street, runs southwest and northeast from the central Octagon, a park area. Important public buildings include the municipal chambers, the Anglican cathedral and the impressive stone-built University of Otago, which was founded in 1869 and has schools of medicine, dentistry, mines, home science and physiotherapy. The Otago Boys' high school and Otago Girls' high school are both the oldest of their kind in New Zealand.

Dunedin is notable for its "green belt" planned by the original settlers and surrounding the inner area with 500 ac. of native forest. The botanical gardens display a fine collection of New Zealand and exotic plants and their Ellen Terry garden contains all the kinds of plants mentioned in Shakespeare's works. The Otago museum has a fine Polynesian section and the Otago Early Settlers' museum contains many records of the pioneering days.

Passenger transport within the city is provided by diesel buses and electric trolley buses. Dunedin is on the main railway and is linked with other New Zealand cities by road services and by air services from Momona airport, 18 mi. S.W.

Dunedin is an important industrial centre. The leading industries are wool spinning, the manufacture of clothing, woolen goods and footwear, flour milling, brewing, frozen meat, engineering and ship repairing. Other factories produce foodstuffs. chemicals, fertilizers. soap, cement and building materials, paper and furniture. The chief exports are wool, frozen meat and dairy produce and the chief imports petroleum products, iron and steel, sugar, phosphates and sulfur.

Capt. James Cook in 1770 observed that the coastal region appeared uninhabited. An English settlement arose in 1840 from a whaling station at Waikouaiti, 20 mi. N., and Dunedin was founded in 1848 as a Scottish Free Church settlement by Capt. William

Cargill, a Peninsular War veteran, and the Rev. Thomas Burns, nephew of the poet Robert Burns. The original intention was to name the town New Edinburgh, but later the Gaelic name for Edinburgh, Dunedin, was adopted. The city has strong Scottish associations; kilts and pipe bands are in evidence at public functions and the Dunedin Burns club is the largest outside Scotland. The discovery of gold in central Otago in 1861 brought prosperity and increased population to Dunedin and led to the settling of much hitherto unexplored country in the vicinity by farmers and graziers. Dunedin was constituted a city in 1865.

BIBLIOGRAPHY.—R. Gilkison, *Early Days in Dunedin* (1938); A. H. McLintock, *History of Otago* (1949); A. H. Reed, *Story of Otago* (1947). (J. MACG. E.)

DUNES, BATTLE OF THE, was fought on June 14 (new style; June 4, old style), 1658, near Dunkerque, then on the Spanish side of the frontier of France and the Netherlands, between the French and English army under the command of the marshal de Turenne and the Spanish army under Don John of Austria and the Great Condé. The severest part of the fighting was borne by the English contingents on either side. Six thousand English infantry under Gen. William Lockhart had been sent by Oliver Cromwell to join Turenne's army, and several English royalist corps under the command of the duke of York (afterward James II) were serving in the Spanish forces. The object of the Spaniards was to relieve Dunkerque, which Turenne was besieging. Don John had a strong superiority in cavalry, but left behind his artillery so not to delay his advance. He took up a position on the dunes with his right on the sea and his left on the Bruges canal, and there Turenne at once attacked him. Condé's cavalry on the left wing charged with great resolution and despite heavy losses gained the upper hand, but their success was nullified by the failure of the Spanish right and centre to resist the pressure of Turenne's infantry and of Cromwell's veterans in particular. When the rest of the Spanish army was in rapid retreat, the one small corps of English royalists. about 300 strong, held out stubbornly and laid down their arms only on terms that they be allowed to rejoin their king, Charles II, at Ypres. From this corps, the royal regiment of guards, are descended the Grenadier guards of the British army. The surrender of Dunkerque by the Spaniards speedily followed (it was left to the English by France), and the peace of the Pyrenees between France and Spain was signed the next year. (D. M. SC.)

DUNFERMLINE, a royal and parliamentary burgh and city of Fifeshire, Scot., 14 mi. N.W. of Edinburgh by road and ferry. Pop. (1961) 47,159. The burgh includes Rosyth (*q.v.*), which was added to it in 1911. It is situated on high ground 3 mi. from the shore of the Firth of Forth, with two railway stations. The town is intersected from north to south by Pittencrieff glen, a deep, picturesque ravine, from which the town derives its name (Gaelic, "the fort on the crooked linn") and at the bottom of which flows Lyne burn.

The early Celtic monks known as Culdees had an establishment there; but its fame dates from the marriage of Malcolm Canmore and his queen, St. Margaret, solemnized in the town about 1067. The king lived in a tower on a mound surrounded on three sides by the glen. A fragment of this castle exists in Pittencrieff park, a little west of the later palace. Under the influence of Queen Margaret the foundations were laid about 1072 for the Benedictine priory which was raised to an abbey by David I. Robert the Bruce gave the town its charter in 1322.

With the exception of Iona, Dunfermline abbey has received more of Scotland's royal dead than any other place in the kingdom. Within its precincts were buried Queen Margaret and Malcolm Canmore, their sons Edgar and Alexander I, with his queen; David I and his two queens; Malcolm VI; Alexander III, with his first wife and their sons Edgar, David and Alexander; Robert the Bruce, with his queen Elizabeth and their daughter Matilda; and Annabella Drummond, wife of Robert III and mother of James I. Bruce's heart rests in Melrose, but his bones lie in Dunfermline abbey, where (after the discovery of the skeleton in 1818 during excavations for the New church) they were reinterred below the pulpit. In 1891 the pulpit was moved back and a monumental brass inserted in the door to indicate the royal vault. The tomb of St. Margaret and Malcolm, within the ruined walls of the Lady chapel, was restored and enclosed by command of Queen Victoria. When the Reformers attacked the abbey church in March 1560, they spared the nave, which served as the parish church till the 19th century, and later formed the vestibule of the New church (1821). The old building was a fine example of simple and massive Norman work with a beautiful doorway in its west front. Another rich Norman doorway was exposed in the south wall in 1903. On the south side of the churchyard are the early 14th-century ruins of the frater (refectory) and dorter (dormitory), connected by a gatehouse with the remains of the kitchen and guest house, which was later the palace.

The palace was a favourite residence of many of the kings as the famous lines in the ballad "Sir Patrick Spens" recall,

> The king sits in Dunfermline town
> Drinking the blude-red wine.

It occupied a striking position near the ravine and was of considerable size, judging from the southwest wall, which is all that is left of it. James I. king of Scots, and Charles I were born there and the last royal tenant was Charles II, who occupied it just before the battle of Inverkeithing or Pitreavie (July 20, 1651). which took place 3 mi. to the southwest, and there also he had signed the National League and Covenant.

The staple industry is the manufacture of table linen. The weaving of damask was introduced in 1718 by James Blake, who had learned the secret of the process in the workshops at Druinsheugh near Edinburgh. Other industries include dyeing and bleaching, the manufacture of natural and artificial silk, engineering and the making of soap, rope and fireclay; there are numerous collieries, notably Comrie, in the immediate vicinity.

The high school was founded in 1560. Andrew Carnegie (1835–1919) was a well-known benefactor of Dunfermline. He gave to his birthplace the free library and public baths, and. in 1903, the estate of Pittencrieff park and glen, rich in historical associations as well as natural charm, together with bonds worth £500,000 (increased by £250,000 in 1911), in trust for the maintenance of the park, the support of a theatre for the production of plays of the highest merit, the periodical exhibitions of works of art and science, the promotion of horticulture among the working classes and the encouragement of technical education in the district. A statue of Carnegie was placed in the park, where also stands the music pavilion and where, after 1950, a model traffic area was opened for instruction in road safety. Dunfermline became the headquarters of all the Carnegie trusts. (See FOUNDATIONS, PHILANTHROPIC.) The Carnegie memorial hall was built in Tudor style near his birthplace. The town is the seat of the sheriff-substitute for western Fife; it is governed by a provost, bailies and council.

DUNGANNON, a market town and urban district of County Tyrone, N. Ire.. 8 mi. W. of the southwest shore of Lough Neagh, and 43 mi. W.S.W. of Belfast by road. Pop. of the urban district (1961) 6,494. Its early history is that of the O'Neills, earls of Tyrone, whose chief residence was there, and a large rath or earthwork north of the town was the scene of the inauguration of their chiefs; but of the family castle and abbey there are no remains. In Dungannon the independence of the Irish parliament (to which the town returned two members) was first proclaimed in 1782. The town was formerly corporate and was a parliamentary borough until 1885. The Royal school, founded in 1614, was moved to new buildings at the end of the 18th century. The main industries produce textiles, glass fabrics and bricks.

DUNGARPUR, a town and district of Rajasthan, India. The town, headquarters of the district, is 90 mi. N.E. of Ahmedabad. Pop. (1951) 9,814. It was founded late in the 14th century and named after Dungaria, chief of an independent Bhil tribe. It has road links with Baroda, Ahmedabad and Indore via Godhra.

DUNGARPUR DISTRICT (area 1,460 sq.mi.; pop. [1961] 407,382) includes a large hilly area inhabited by Bhil (*q.v.*) peoples. In the southwest the country falls away to the valley of the Maki river, which forms the district boundary and flows into the Gulf of Cambay. The majority of the population is engaged in agricul-

ture; wheat and millets are the main crops. The district corresponds with the former princely state of the same name which fell to Moguls and Marathas in turn and was taken under British protection in 1818. Under British rule it was controlled through the Rajputana agency. In 1948 it was merged with Rajasthan.

(S. M. T. R.)

DUNGARVAN (DUN GARBHAIN), a market town, seaport and urban district of County Waterford, Republic of Ireland, lies 29 mi. W.S.W. of Waterford by road. Pop. (1961) 5,188. The administrative centre of the county, it is situated on the Bay of Dungarvan, at the mouth of the Colligan, which divides the town into two parts. Dungarvan derives its name from St. Gorvan, who founded a monastery there in the 7th century. Under King John walls were built, also a castle, now in ruins. The eastern suburb of Dungarvan is called Abbeyside, where remains of an ancient keep, erected by the M'Graths, still exist, together with portions of an Augustinian friary, founded by the same family in the 13th century. The town has a tannery, a glue works, a factory producing various dairy products and a fruit packing station.

DUNGENESS, a promontory and fishing village on the south coast of Kent, Eng., lies within the borough of Lydd, 11 mi. E. of Rye. This expanse of shingle, triangular in shape and covering about 9 sq.mi., forms the seaward apex of the Romney marsh. Shingle erosion on the southern flank averages about six feet a year, with a corresponding build-up on the eastern flank. For centuries there has been a lighthouse on Dungeness point, and a new structure (50° 53" N., 0° 59' E.), entirely automatic in operation, was opened in June 1960. On a site west of the lighthouse work on the fifth nuclear power station in England and Wales started in 1960. On the promontory there is also a lifeboat station, a Lloyd's signaling station, a bird sanctuary and the terminus of the Romney, Hythe and Dymchurch light railway. (CL. L. W.)

DUNHILL, THOMAS FREDERICK (1877–1946), English composer and author, was born Feb. 1, 1877, in London and was educated at the Royal College of Music, where he studied composition with C. V. Stanford. From 1899 to 1908 he was assistant music master at Eton college. He wrote a good deal of educational music, some chamber and some orchestral music, including a symphony, which he conducted in Belgrade in 1922, but his fame is likely to rest on two songs, "The Cloths of Heaven" and "The Fiddler of Dooney," to poems by W. B. Yeats. In his comic opera, Tantivy Towers (1931) to a libretto by A. P. Herbert, the fun turns on a meeting of bohemian artists with the sporting fraternity. His vein of melody affiliated him with Sullivan, of whom he wrote the first serious critical study (Sullivan's *Comic* Operas, 1928). He died at Scunthorpe, Lincolnshire, on March 13, 1946.

(F. S. H.)

DUNKARDS: see BRETHREN, CHURCH OF THE.

DUNKELD, a civil parish of Perthshire, Scot., is on the left bank of the Tay, 15 mi. N.N.W. of Perth by road; the railway station is at Birnam on the right bank. Pop. (193'1) 841. The river is crossed by a bridge (1808–09) of seven arches designed by Thomas Telford.

Dunkeld is one of the most historic places in Scotland. At an early date it emerged as an important centre of the Celtic Church, though whether the first religious community was established there by St. Adamnan about the year 700 or by some earlier missionary is still uncertain. After 800 the story becomes more clear. About the year 815, Constantine, king of the Picts, rebuilt the abbey for the Celtic monks from Iona who had been driven out by the Norsemen. About 850 Kenneth MacAlpine brought relics of St. Columba from Iona to Dunkeld, which was made the head church of his kingdom. Although this dignity passed before long to St, Andrews, Dunkeld continued to be a major religious centre. The church was converted into a cathedral by David I in 1127 and in the 14th and 15th centuries grew into a stately building. The most famous of the bishops was Gavin Douglas (*q.v.*), translator of the Aeneid. After the Reformation the cathedral and canonry fell into partial decay, but the cathedral was restored after 1815 and in 1908; there are some traces of the 12th-century building though most of the remaining fabric dates from the 14th and 15th centuries. In 1587 a presbytery of the Reformed Church was established with Dunkeld at its centre. The Royal school was founded in 1567.

Shortly after the battle of Killiecrankie (1689) Dunkeld was held by the Cameronian regiment under the poet Col. William Cleland. An attacking force of 5,000 Highlanders was repelled but Cleland was killed.

To promote its growth the town was made a royal burgh in 1704, but with little effect, and it was not until the building of Telford's bridge that it began to prosper. The coming of the railway to Birnam in 1856, however, again lessened the importance of Dunkeld and by the 20th century the old heart of the town had begun to fall into a half-derelict state. The National Trust for Scotland undertook the renovation of the houses around the old market place and cathedral. The oak and sycamore in front of the demolished Birnam house, 1 mi. S., are believed to be a remnant of Birnam wood which Shakespeare immortalized in *Macbeth.*

DUNKERQUE (DUNKIRK), a seaport of northern France in the Nord *département,* lies on the Straits of Dover between Calais and the Belgian frontier and is 78 km. (48.5 mi.) N.W. of Lille by road. Dunkerque was almost completely destroyed by bombs in World War II (1940) but was rebuilt on a spacious plan. Pop. (1954) 20,735. The chief thoroughfares converge on the Place Jean Bart, in the centre of which is a statue by David d'Angers of Adm. Jean Bart (*q.v.*), who was born in Dunkerque in 1650. Close by is the 213-ft. belfry built by the Spaniards in the 16th century and once the western tower of the Gothic church of St. Eloi, from which it is now separated by a street. St. Eloi, partly destroyed in World War I and severely damaged by fire in World War II, was largely rebuilt. In 1960 the town hall (built 1897–1901 and burned down in 1940) was being reconstructed for the ninth time since 1233. The museum, although partly destroyed in 1940, preserved most of its collection of paintings and other works of art. There are a school for navigation, a school of fine arts and a stadium. The statue of victory commemorates the raising of the siege in 1793 and there are monuments to those killed in World War I and to the British dead of World War II.

The harbour of Dunkerque is approached by a fine natural roadstead entered on the east and west and protected on the north by sandbanks. The roadstead is indicated by lightships, and the entrance channel to the port by a lighthouse 193 ft. high and visible for 19 mi. There are 7.5 mi. of quays, berths for 50 vessels of all sizes, three locks, three dry docks, one floating dock, a large basin for oil tankers, sheds and warehouses and 120 electric cranes. There are also 155 mi. of railway lines and a silo for storing grain. There is a daily ferry service between Dunkerque and Dover. Canals connect the docks with Belgium, the coal basins and industrial towns of Nord and Pas-de-Calais and the rich agricultural regions of Flanders and Artois. There is an oil refinery to the west of the docks and a vast shipbuilding yard for naval vessels. Dunkerque is the industrial centre of the region, and its chief industries, which are situated in the suburbs, are oil refining and the production of oil, chicory, chocolate, beer, jam, biscuits, flour, rice, soap, fertilizers, cotton, flax, hemp, jute and fishing tackle. The large chamber of commerce was founded in 1700. The main imports are fuel oil, coal, phosphate, minerals, pyrites, textiles, wine and early fruit and vegetables. Exports include metal products, sugar, cement, cereals, flour, chemical products, fruits and vegetables, cloth and thread, glass, earthenware and china.

Dunkerque derives from the Flemish Dunkerk, "the church of the dunes." The first mention of a town situated there in 1067 is found in a gift of the tithe by Baldwin V, count of Flanders, to the abbey of St. Winoc at Bergues. At the end of the 12th century Philip of Alsace armed a fleet at Dunkerque against the Norman pirates. In 1558, after the French had taken Calais, Dunkerque was besieged and burned to the ground. It was seized by the duke of Anjou in 1582 and retaken in 1583 by the duke of Parma in the name of the king of Spain. The Spanish fleet of Dunkerque was beaten in 1639 by the Dutch admiral Martin Tromp and the following year the Spaniards built new ramparts round the town. It fell, however, to the French in 1646 but was retaken by the Spaniards in 1652. After the battle of the Dunes (*q.v.*) in 1658 the town was given to the English, but four years later it was re-

deemed by Louis XIV. The port and the fortifications were rebuilt and the town prospered until 1713 when by the terms of the treaty of Utrecht the port was demolished and an English garrison installed because of the damage done by Jean Bart and other corsairs of the port. The Mardyck canal was built to compensate for the obstruction of the channel. It was not until the treaty of Paris was signed in 1783. after the American Revolution. that the port was allowed to be rebuilt. The whole region was liberated in 1793 during the French Revolutionary Wars (*q.v.*) after the French victory of Hondschoote.

The 19th century saw the building of the railway in 1838 and the enlargement of the port in 1880. In World War I Dunkerque, close to the Flanders front. was very badly damaged. In World War II (*q.v.*) it was the place from which the British expeditionary force and some other Allied troops were evacuated in 1940 (May 26 to June 3) just before it was occupied by the Germans. The town. almost destroyed. was liberated on May 10, 1945, the last French town to be freed.

See also references under "Dunkerque" in the Index volume. (JA. P.)

DUNKIRK: *see* DUNKERQUE.

DUN LAOGHAIRE (KINGSTOWN), a seaport of County Dublin. Republic of Ireland, lies at the southeastern extremity of Dublin bay. 8 mi. S.E. of Dublin by road. Pop. of coastal borough (1961) 47.803. Originally called Dunleary (Leary's fort), after the fortress built there by Laoghaire. a 5th-century Irish king, its name was changed to Kingstown after the embarkation of George IV at the port in 1821, and again changed in 1921. The town was a fishing village. but after the construction of an extensive harbour, designed by Sir John Rennie and begun in 1817, enclosing about 250 ac. with a varying depth of from 10 to 28 ft.. it grew into a large ribbonlike residential town, with some attractive early- to mid-19th century terraces. but generally lacking in character except for the waterfront. In 1852 the present Carlisle pier. a short pier near the east of the harbour, was begun, but controversies delayed its completion until 1859 when it was opened; it has been used ever since both by the boat trains from Dublin and the mail packets from Holyhead. Wales. This service, begun by the London and North-Western railway and the City of Dublin Steam Packet company, is now operated by British railways in conjunction with Coras Iompair Eireann (Irish transport board).

Dun Laoghaire is the headquarters of the Irish Lights service which operates the lighthouses and lightships round the Irish coasts. and the harbour is also much used by yachtsmen. There are three principal yacht clubs and many hotels and boarding houses. (M. J. CG.)

DUNLIN, *Erolia (Calidris) alpina,* one of the commonest of the sandpipers (*q.v.*), often called oxbird. It breeds on elevated moors in Europe, northern Asia and North America and in winter, haunts the mud flats and sandbanks in large flocks. A smaller race, E. *a. schinzii* occurs in Great Britain and Baltic Europe. In the breeding season, the male utters a peculiar whistle.

A subspecies of the dunlin, the red-backed sandpiper (E. *a. pacifica*) breeds chiefly in the arctic and is migrant throughout the U.S., usually being seen near the Great Lakes and along the coasts.

DUNLOE, GAP OF (DÚN LOIE) in County Rerry, Republic of Ireland, is a deep ravine between Purple mountain (2.739 ft.) on the east and the fine ridge of the Macgillycuddy's Reeks (highest point. Carrauntuohill, 3,411 ft.) on the west. The gap is said to have been cut by a single stroke of Finn MacCoul, an ancient giant. and many other legends are provided for visitors: in fact it was cut by ice which deepened by several hundred feet the gap that existed before the glacial period. The summit point is 795 ft. above sea level and the grandeur of the scene is due to the towering cliffs with large areas of hare rock. The Gap of Dunloe is entered 6 mi. W. of Killarney (*q.v.*) and the journey is made in jaunting cars in which passengers sit facing the roadside, over the wheels. Mr. and Mrs. Samuel Carter Hall, who traveled through Ireland in the 1830s and 1840s. spoke of the gap as "a scene rarely paralleled for wild grandeur and stern magnificence," with "bleak and barren rocks. of forms as varied and fantastic as they are numerous" and a "brawling and angry stream rushing onwards . . . here a creeping rivulet—here a broad lake, and there a fierce cataract." From the summit of the pass, after three slow miles of ascent, the road bends round the hillside into the upper valley of Killarney and the return journey is made by boat through the small Upper lake which merges into a channel several miles long through a steep-sided, wooded valley of great beauty, with famous echoes, and finally through the larger Muckross lake and Lough Leane. For more than 200 years tourists have visited this remarkable area which during the summer can now be covered in a single day from Dublin. (T. W. FR.)

DUNLOP, JOHN BOYD (1840–1921), Scottish inventor who developed the pneumatic rubber tire, was born on Feb. 5, 1840 at Dreghorn, Ayrshire. In 1867 he settled in Belfast as a veterinary surgeon. There in 1887 he constructed a pneumatic tire for his son's tricycle. The invention was patented in 1888 and production on a commercial scale began in 1890 with Dunlop holding 1,500 shares in the Belfast company. It was discovered that the principle of the pneumatic tire had been patented in 1846, but the company held various accessory patents which enabled them to establish their position. Dunlop himself did not make a great fortune by the invention. He died in Dublin, Oct. 23, 1921.

See Jean McClintock (his daughter), *History of the Pneumatic Tyre* (1923). (W. H. D.)

DUNMORE, JOHN MURRAY, 4TH EARL OF (1732–1809). royal governor of Virginia on the eve of the American Revolution, was born in 1732. A Scottish noble descended from the house of Stuart, he sat in the house of lords from 1761 to 1770. He was appointed governor of New York in 1770, then of Virginia in 1771. Personally interested in western lands as well as officially concerned with protection of the Virginia (western) frontier, he raised 3.000 militiamen to subdue the Shawnee Indians in the upper Ohio valley in 1774. an action known as Lord Dunmore's War.

As the revolution approached, Dunmore's power declined rapidly, especially through his own rashness. He dissolved the Virginia assembly for revolutionary sentiments in 1772, 1773 and 1774. In April 1775 he seized the colony's store of powder, thereby bringing about an armed uprising. Taking refuge aboard an English warship, he shortly declared martial law, proclaimed freedom to slaves who would join the British and proposed to Lord Dartmouth use of Indians against the rebels. Defeated at Great Bridge near Norfolk on Jan. 1, 1776, he ordered his ships to bombard Norfolk, thereby setting it afire. Effective royal government in Virginia having ended, he returned to England in July 1776. After serving again in the house of lords, he was royal governor of the Bahamas from 1787 to 1796. He died at Ramsgate, Eng., early in 1809.

See T. J. Wertenbaker, *Give Me Liberty; the Struggle for Self-Government in Virginia* (1958). (W. R. SL.)

DUNMORE, a borough of Lackawanna county, in northeastern Pennsylvania. U.S., adjoining Scranton on the northeast and a part of the Scranton standard metropolitan statistical area. Anthracite mining and railroading were once the principal occupations. Industries include the manufacture of silk, shoes and fabric gloves. The Pennsylvania State Oral School for the Deaf is located between Dunmore and Scranton. The city was settled in 1787 as Buckstown and renamed (1840) for a son of the earl of Dunmore in a fruitless effort to interest him in a railroad project. It was incorporated as a borough in 1862. The population reached 23.086 in 1940, after which it declined. For comparative population figures *see* table in PENNSYLVANIA: *Population.* (R. D. WI.)

DUNMOW (GREAT DUNMOW), a market town in Essex, Eng.. lies on the river Chelmer, 38 mi. N.E. of London and 24 mi. W. of Colchester by road. Pop. (1961) 3.904. The town was incorporated in the 16th century but the charter, confirmed by Queen Elizabeth I. was withdrawn in 1886. Both charters are preserved in the church of St. Mary the Virgin (14th century) where the register of baptisms dates from 1538 and of marriages and burials from 1558. The town hall, in the centre of the town, was built in 1578. In 1570 Flemish refugees introduced the manufacture of "bays" and "says," the former being

a coarse woolen cloth and the latter a fine thin cloth. The industry became extinct about 1800. Lionel Lukin (1742–1834), inventor of the lifeboat, born in the adjoining parish of Little Dunmow, carried out his experiments on Doctor's pond, Dunmow.

At LITTLE DUNMOW, 2 mi. E. (pop. [1961] 376). an Augustinian priory was established in 1104. The existing remains form part. of the parish church of St. Mary's Priory founded by Robert Fitzwalter, leader of the barons who negotiated Magna Carta at Runnimede on June 15, 1215, who lies there in an unknown grave.

The ceremony of the "Dunmow flitch" originated there when Robert Fitzwalter, lord of the manor, offered a flitch of bacon to the man who had not repented of his marriage for a year and a day, the man having to take an oath to that effect before the prior, the monks and the townsmen. The custom survived the dissolution of the monastery and records of the court awarding the flitch in the 18th century hang on the walls of the church, which also contains the original 13th-century oak chair used in the ceremony. A document in the British museum, London, has the names of three men to whom the flitch was awarded in 1445, 1467 and 1510. The first date is the earliest known award, although there are earlier references in *Piers Plowman* and Chaucer. The original manorial court records are in the Essex record office. The ceremony of the Dunmow flitch is now carried out in Great Dunmow.

DUNNE, FINLEY PETER (1867–1936), U.S. humorist and creator of Martin Dooley, homely philosopher, was born in Chicago. Ill., July 10, 1867, of Irish immigrant parents. He was educated in the public schools and in 1884 began working for various Chicago newspapers, specializing eventually in political reporting and editorial writing.

In 1892 he began contributing Irish dialect sketches to the *Chicago Evening Post* and five years later moved them to the *Chicago Journal.* In these Dunne introduced Martin Dooley. an engaging character in the tradition of Benjamin Franklin's "Poor Richard" and James Russell Lowell's "Hosea Biglow." They did not attract a national following until Mr. Dooley's observations on Dewey's victory at Manila in 1898 became a sensation. National syndication followed and soon Dunne's witty penetration of shams and hypocrisies made Mr. Dooley a force for clear thinking and tolerance in public affairs.

No other American humorist, perhaps, exercised as great an influence upon public life as did Dunne between 1898 and 1910. Many remarks such as "the supreme court follows the election returns" became part of American lore. While the dialect in which they are written became dated, a substantial influence continued. Dunne continued to write irregularly until his death in 1936. He republished about a third of the essays in eight volumes. beginning with *Mr. Dooley in Peace and War* (1898) and ending with *Mr. Dooley on ;Making a Will and Other Necessary Evils* (1919).

See Elmer Ellis, *Mr.* Dooley's *America* (1941). (E. Es.)

DUNNET HEAD, a round. cliffed headland of Old Red Sandstone. some 3 mi. across, is in northeastern Caithness. Scot. It is 12 mi. E.N.E. from Thurso to the northern tip, as the crow flies. Dunnet Head forms a plateau at about 100 ft., with hills rising to 422 ft. and 10 small lochs, and is the northernmost part of the mainland of Britain. A road from Brough (6 mi. S.E.) reaches the lighthouse (built 1831) on the northern tip. Dunnet village is 2 mi. south of Brough by road. See also JOHN O'GROATS HOUSE. (A. T. A. L.)

DUNNOCK, a name for the European hedge sparrow *(Prunella modularis). See* HEDGE SPARROW.

DUNOIS, JEAN, COMTE DE (G. 1403–1468), French military commander and diplomat, the famous BASTARD OF ORLEANS. who played so great a part in his country's final victory over the English in the Hundred Years' War, was born in Paris, the natural son of Louis, duc d'Orléans, and Mariette d'Enghien. Brought up by his father's widow Valentina Visconti, he entered the service of his cousin the dauphin, the future Charles VII, in 1420, became his trusted adviser and was appointed grand chamberlain of France. His first notable success was the defeat of the English at Montargis (1427). During 1428–29 he defended Orléans until Joan of Arc arrived to raise the siege. He then took part in the battle of Patay (*q.v.*) and accompanied Charles VII to Reims for his coronation. He captured Chartres and Lagny in 1432 and engaged in a series of campaigns culminating in a triumphal entry into Paris in 1436. He shared in the negotiations with the English at Gravelines (1439) and helped to obtain the release of his half brother, Charles, duc d'Orléans, who gave him the countship of Dunois. Momentarily involved in the Praguerie (*q.v.*) in 1440, he soon returned to the king's service and was given the countship of Longueville (1443). He negotiated the truce of 1444 with the English and was a member of the embassy (1447–49) sent to persuade the antipope Felix V to abdicate. At the end of the truce, he served in the reconquest of Normandy (1449–50) and of Guienne (1451). Charles VII later entrusted him with the arrest of the duc d'Alençon (Jean II) in 1456 and with measures against intrigues of the dauphin. After the dauphin had become king as Louis XI, Dunois joined the rebellious League of the Public Weal, but made his peace, negotiated the treaty of St. Maur (1465) and recovered his confiscated titles and possessions. He died on Nov. 24, 1468, and was buried in Notre-Dame de Cléry, near Orléans. He had been married twice: in 1422 to Marie Louvet; in 1439 to Marie d'Harcourt, from whom the future ducs de Longueville descended. (Y. M. L.)

DUNOON, a small burgh of Argyll, Scot., lies on the west shore of the Firth of Clyde, on the Cowal peninsula, opposite Gourock, with which there is frequent steamer communication. Pop. (1961) 9,211. Including Kirn and Hunter's quay, at the entrance to Holy Loch to the north, Dunoon presents a continuous front of seaside villas with a two-mile esplanade. Picturesquely situated between the Cowal hills and the firth, it is one of the chief holiday resorts on the Scottish west coast and a centre for excursions into the west Highlands. On a bluff above the pier stand the remains of Dunoon castle, of which Sir Colin Campbell of Lochow, an ancestor of the duke of Argyll, was made hereditary keeper by Robert I the Bruce. At Rilmun, on the northern shore of Holy Loch, are the ruins of a collegiate chapel founded in 1442 by Sir Duncan Campbell and used as the burial ground of the Argyll family. The Lamont memorial near Dunoon pier marks the site of a massacre of the local clan by the Campbells in 1646. Hunter's quay is the headquarters of the Royal Clyde Yacht club. The Cowal Highland Gathering takes place at Dunoon at the end of August. In Nov. 1960 a United Kingdom-United States agreement permitted U.S. Polaris (missile) submarines to be based in Holy Loch, an event of considerable economic importance to Dunoon.

DUNS, a small burgh and the county town of Berwickshire, Scot., lies 15 mi. W. of Berwick-upon-Tweed by road. Pop. (1961) 1.838. Trade is agricultural and there is excellent fishing. On Duns Law (713 ft.) the Covenanters, under Alexander Leslie (afterward earl of Leven), were encamped in 1639, an event commemorated there by the Covenanters' stone. Duns castle. adjoining the town on the northwest, includes the tower said to have been erected by Thomas Randolph, earl of Moray, in 1314. The town, originally on Duns Law, was destroyed by the English in 1545 and 1558; the present town dates from 1588. Each July the town's history is re-enacted during festival week. It was the birthplace of John Duns Scotus (*q.v.*), the medieval philosopher.

DUNSANY, EDWARD JOHN MORETON DRAX PLUNKETT, 18TH BARON (1878–1957), Irish dramatist and storyteller, who combined imaginative power with intellectual ingenuity to create a convincing world of fantasy, was born in London. July 24, 1878. Educated at Eton and Sandhurst, he succeeded his father in 1899. He served in the Coldstream guards in the South African War and in the Royal Inniskilling Fusiliers in World War I. and spent most of his life in soldiering and sport. His first book of short stories. *The Gods of Pegana,* appeared in 1905; his first play. *The Glittering Gate,* was produced by the Abbey theatre. Dublin, in 1909; and his first London production, *The Gods of the Mountain,* at the Haymarket theatre in 1911. Like his many later stories and plays they explored in a richly coloured poetic prose what he himself called "the mysterious kingdoms where geography ends and fairyland begins." introducing also a characteristic element of the macabre. Among his most im-

portant works were the plays *The Tents of the Arabs, The Laughter of the Gods* (1910) and *A Night at an Inn* (1911); *A Dreamer's Tales* (1910); *Travel Tales of Mr. Joseph Jorkens* (1931); a novel, *The Curse of the Wise Woman* (1933); collections of verse (1929 and 1938); and three autobiographical volumes, *Patches of Sunlight* (1938), *While Sirens Slept* (1944) and *The Sirens Wake* (1945), the last of which gave some account of his early wartime experiences, when he was Byron professor of English literature at Athens. He died in Dublin. Oct. 25, 1957.

DUNSINANE, a peak of the Sidlaw hills, in the parish of Collace, Perthshire, Scot., 8 mi. N.E. of Perth. It is 1,012 ft. high and commands a fine view of the Carse (alluvial land) of Gowrie and the Tay valley. Its chief claim to interest, however, lies in its association with Birnam wood, about 12 mi. northwest, near Dunkeld (*q.v.*), mentioned in two well-known passages in Shakespeare's *Macbeth*. An old fort on the summit, of which faint traces are still discernible, is traditionally called Macbeth's castle.

DUNS SCOTUS, JOHN (*c.* 1265–1308), called *Doctor Subtilis,* was the greatest medieval British philosopher and theologian.

Born in the village of Duns, Berwickshire. Scotus entered the Franciscan Order about 1280; he studied for the priesthood in Scotland (Haddington, Dumfries), Oxford and Paris and was ordained on April 17, 1291, in the church of St. Andrew, Northampton, by Oliver Sutton, bishop of Lincoln. Scotus studied at Paris probably between 1291 and 1296 under the master Gonsalvus of Spain, and subsequently lived at Cambridge, Oxford and Paris, teaching several times in the latter two cities. On June 25, 1303, because he refused to sign the petition of Philip IV of France against Pope Boniface VIII, he had to interrupt his teaching at Paris, apparently continuing it at Oxford. In 1305 he obtained the doctorate at Paris and became *magister regens* there (1305–07), holding a solemn disputation called "de Quodlibet." Toward the end of 1307 he became professor at Cologne, where he died prematurely on Nov. 8, 1308. He lies buried in the church of the Franciscans at Cologne. His name is included in the Franciscan martyrology and he is venerated in many places.

Works.—The Vatican's complete critical edition, *Ioannis Duns Scoti Opera Omnia,* began to appear in 1950. The only authentic works of Scotus are: (1) commentaries on Peter Lombard's four books of *Sentences,* namely the *Ordinatio* (commonly called *Opus Oxoniense),* the *Lectura Oxoniensis* and several "Reportationes" preserved in various versions (book i has six, book ii three, book iii five, book iv two), of which the chief are *Rep. Parisiensis* (*i.e., Examinata)* and *Rep. Cantabrigensis;* (2) *Quodlibet* and *Collationes (Oxonienses* and *Parisienses)*; (3) the *Tractatus de Primo Principio* and *Theoremata;* (4) commentaries on Aristotle's *Metaphysica, De Anima, De Praedicamentis, 1–11 Perihermeneias* and *Liber Elenchorum;* and (5) a commentary *Super Porphyrium.*

The principal work, the *Ordinatio,* preserved in hundreds of codices and published in more than 30 different editions from 1472 onward, is a summary by Scotus from different expositions of his on the *Sentences* of Peter Lombard. As the work was still incomplete when he died, the edition completed by his pupils immediately set off the discussion as to what was the original text, A version close to the original edition, however, was checked with the autograph or "Liber Duns," and this medieval critical edition survives in the codex 136 of the Communal library at Assisi. The *Ordinatio,* dictated or written and carefully revised by Scotus, enjoys the highest authority, while certain of the "Reportationes" and, above all, the *Theoremata* and *De Anima,* are very unreliable.

Character.—Duns was sharp and subtle of intellect, sharing the Oxford school's taste for mathematical argumentation and the study of the positive sciences; deeply religious, he followed the Franciscan school which gave the primacy to love and to Christ as "centrum omnium scientiarum." Faced with the ecclesiasticai condemnations of Averroistic and Thomistic theses at Paris (1277) and at Canterbury and struck by the energies consumed in the dual task of assimilating Aristotle while preserving traditional doctrine, he felt the need for an impartial weighing-up of results to date. He did not initiate opposition to St. Thomas Aquinas, who was neither his contemporary nor his rival and whom he rarely cites. Scotus rather aims at Godfrey of Fontaines, Giles of Rome and, especially, St. Thomas' great adversary Henry of Ghent, whose Platonic-Augustinian theories he combats strenuously, while attempting a synthesis with Aristotle. Scotus therefore criticizes constructively, holding that his researches should agree, not with the doctrine of St. Thomas or any other doctor, but with right reason and the *magisterium* of the Church.

Critical study beginning in the late 19th century has dissolved earlier attributions to Scotus of all sorts of theological and philosophical leanings. Eminent medievalists now hail him as the last great scholastic in the orthodox tradition, He did not use dogma for his philosophy, but in his efforts to penetrate the mysteries of faith he sought, like all the scholastics, to form for himself an *intellectus fidei.* Since Scotus states many of the fundamental tenets found throughout scholasticism (*q.v.*), it will suffice to note some of the more characteristic theses in the *Ordinatio.*

Philosophy.—Univocity of being, formalism, hylomorphism, the principle of individuation, the form of corporeity, the primacy of the will—these are the themes of Scotist philosophy. The primary object of the intellect is neither the divine essence (as the Augustinians taught) nor the essence of material things (as the Aristotelian-Thomist current affirmed), but *esse,* being as such, coming before any determination implicit in every reality. This being can be predicated univocally of all things, and without it nothing is comprehensible. Pantheism is thus avoided because being does not mean to have being, as it does for St. Thomas. Being is posited as such in reality always and everywhere. Infinite being and finite being are not specific determinations but intrinsic modes of being.

Yet this unity of being does not imply absolute simplicity. In every concrete, individual being there exist metaphysical elements which, while in reality identical, remain "formally distinct." This formal distinction, which pervades the whole of Scotism, is intermediate between a real distinction, (*i.e.,* between things) and a purely logical distinction (*i.e.,* one made by the intellect alone between aspects of the same thing).

Though Scotus rejects universal hylomorphism, for him too material things arise from the union of matter and form, two really distinct principles. Matter, however, though undetermined, is a positive existing unity, distinct from nothing: it is not pure potency, but has its own act. The unity of the compound is saved because matter and form are ordained to one another not accidentally but essentially.

Furthermore, in every concrete being we must distinguish a common nature, indifferent as to being universal or singular and therefore demanding a principle which determines it to become this or that reality. This is the principle of individuation, a particular positive reality making inherently undetermined natural compounds into this or that individual, this or that essence.

The form of corporeity is the disposition that enables matter to receive the soul; it constitutes the individual in his corporal being as the soul constitutes him in his living being. After death it stays in the corpse a while, causing the body to remain substantially identical with what it was in the living being.

The metaphysical character of transcendent being is the key to Scotus' philosophy, and especially to his proofs for the existence of God, who is known not in himself, but only through the metaphysical properties revealed in creatures—through efficient, final and exemplary causes.

Finally, as the primacy of being characterizes his metaphysics, so the primacy of the will characterizes Scotus' ethics. The will is essentially free and represents the summit of man's perfection and essence. Between intellect and will there is a formal distinction: intellect and will are the sole causes of their respective operations, but this does not exclude their necessary, real and conrinuous interdependence. While God has absolute liberty as the fundamental attribute of his nature, the divine will, in its essentially rational and infinite nature, finds love as its essential norm of action. While it is the source and origin of created things, including moral values, it is this in sign of the divine wisdom and of the essential order of things established by absolute goodness.

Theology.—The primary object of theology is God or the

divine essence as such. Our theology, as distinct from God's, which embraces all things knowable, treats only of those things "which are contained in Scripture or of what can be derived from these." It is the highest science, but not in the Aristotelian sense "through discourse from the cause to the known"; and since it tends to a right loving of God and the reaching of our ultimate end, it is practical rather than speculative, and more rightly called "wisdom."

That God is one in essence and three in persons can neither be demonstrated by natural reason nor clearly known once revealed, although this mystery is not contrary to natural reason or even altogether impenetrable to it. Between the essence. the personal properties and the attributes of God, there is a formal distinction *a parte rei* quite compatible with divine simplicity.

Because God is formally love he liberally communicates his goodness and love. Because God's will operates in an infinitely rational and ordered way, he wills first the end and then those things immediately ordered to it; thus he first predestines the elect, then wills whatever they need to reach their end, namely the goods of grace, and finally whatever serves them toward it, namely the sensible world. In this plan, in which Scotus differs from St. Thomas and many other doctors, Christ and his mother Mary, love on earth and beatific vision in heaven, are prominent.

Scotus praises the Incarnate Word as the first and absolute term *ad extra* of the infinite love which is God himself. Since therefore Christ is predestined as the exemplary and final cause of all creation and enjoys primacy over all things. Scotus rejects the teaching that the greatest of all works, namely the Incarnation, should have been occasioned by a good of a lower order, namely the redemption of mankind. Only as a consequence of the Fall is Christ, the glorifier of the blessed Trinity, destined to redeem us by his death. in virtue of which he became our one and only mediator, so that remission of sin, grace and salvation are obtained only in and through him.

The excellence and perfection of Christ's mediation demand that in at least one case redemption should take the form of preserving rather than subsequently freeing from the stain of original sin, and this case could be none other than that of his mother. Following the principle that to Mary must be attributed "whatever is more excellent," thereby giving greater honour to the Son from whom the mother has received everything, Scotus attributed to her among other privileges that of the Immaculate Conception.

Because God, who is formally love and infinite perfect in the love which he is, has made all things for himself, wanting others who can to share in that love, it is necessary for man by love to tend toward God, his happiness. Nor is this difficult, for the roots of this love are profoundly embedded in man's soul. and this natural inclination finds its crowning perfection in charity, which is not really distinct from grace or from "wisdom," the gift of the Holy Ghost, so that contemplation consists beiore all else in love or charity.

But it is Christ who, having perfected the understanding by faith as he perfected the will by charity, is the way to the finding, knowing and loving of God. Of the sacraments instituted by Christ, the Eucharist is the centre of all spiritual life and worship. In it is manifested in the highest possible degree the love that Christ bears for men, whose eternal happiness will consist in an act of the will, an act of the love of benevolence or friendship, toward the supreme good for himself.

Influence.——Many admirers of Scotus' doctrine began to teach it even during his lifetime and so he became and has remained the leader of the Franciscan school, called after him "Scotist." In the 16th–18th centuries, Scotism rivaled Thomism and was expounded side by side with it in nearly all the universities of Europe. Many Thomist thinkers, at times forgetting their own positions, came to Scotist conclusions. On the problem of the immortality of the soul, the Thomist Cajetan before his death "followed the way of Scotus." The Immaculate Conception once called "a Scotist opinion," today is a dogma of the Roman Catholic Church. Scotus' highly developed critical method and his rigorous rational argumentation have created a doctrinal system that continues to exercise great influence.

DUNSTABLE, JOHN (c. 1385–1453). is one of the very few English composers who can fairly be said to have had any influence on the development of European music. This was recognized by his contemporaries, including the French poet Martin le Franc, who wrote in his *Champion des Dames (c.* 1440) that the two leading composers of the day, Guillaume Dufay and Gilles Binchois, owed their superiority to what they had learned from Dunstable's "English manner."

Information about Dunstable's life is extremely scanty. In 1419 he was presented to a secular canonry of Hereford cathedral, but this carried no obligation of residence, being in the nature of a financial gift by some royal patron — probably the duke of Bedford, in whose service he was at some time. The Mass sections on the plainsong *Da gaudiorum premia* and the famous motet *Veni sancte Spiritus—Veni creator Spiritus* were almost certainly written in 1431 for Henry VI's French coronation; in fact, Dunstable may well have spent the years 1423–35 in France, where the duke of Bedford held his court as regent. although there is no documentary evidence for this. About his later life nothing is known beyond the fact that he died in London on Christmas eve, 1453, and was buried at St. Stephen's. Walbrook. His epitaph, recorded before its destruction in the Great Fire. referred to him as skilled in mathematics and astronomy as well as in music, and this is confirmed by the existence of manuscript treatises on astronomy which belonged to him and are now preserved at libraries in Oxford and Cambridge.

Although the fact of Dunstable's influence on French music was widely admitted by musical historians, its nature remained obscure and misunderstood until it was elucidated by Manfred Bukoizer, the editor of his complete works (*Musica Britannica,* vol. viii, 1953). It is to be seen above all in the relaxation of harmony (by a new regulation of dissonance) and of rhythm (by the cultivation of a flowing, gently asymmetrical triple metre). These characteristics of the English school Dunstable combined with a thorough understanding of the French structural principles of isorhythm, displayed in many of his larger motets and Mass sections. His surviving compositions are almost entirely ecclesiastical, but both this and the fact that scarcely any of them are preserved in English manuscripts are probably mere accidents. It is unfortunate that his only recorded five-part composition has been torn out of the Eton college choirbook, written in the last decade of the 15th century. Three of his compositions are to be found in elaborated keyboard settings in a 15th-century German manuscript, the Buxheim organ book.

See M. F. Bukofzer, "John Dunstable: a Quincentenary Report," *Musical Qunrterly* (Jan 1934); F. L. Harrison, *Music in Medieval Britain* (1938). (J. J. N.)

DUNSTABLE, a municipal borough (1864) and market town of Bedfordshire. Eng.. lies 20 mi. S.S.W. of Bedford by road. Pop. (1961) 25,618. It lies at an elevation of about 500 it. on the north slope of the Chiltern hills known as the Dunstable downs. The

main part of the town extends for a mile along the wide Roman Watling Street, while the highroad from Luton to Tring, which crosses it in the centre of the tomn, represents the ancient Icknield Way. Dunstable contains several old coaching inns. Many prehistoric remains are in the area and it seems probable that there was a Romano-British village on the site corresponding to the Forum Dianae of the Romans. About 2 mi. W. is the camp called Maiden Bower, consisting of a circular earthen wall enclosing about ten acres. Dunstable (Dunestaple. Donestaple) appears as a royal borough in the reign of Henry I, who granted a charter to the Augustinian priory he had built. The priory church of St. Peter and St. Paul embodies a fine fragment of the original church. Priory house. once part of the priory. and five acres of land belong to the corporation. Foundations of a palace of Henry I are traceable near the church.

About 1100 a miracle play of the life of St. Catherine was produced at Dunstable. The Dunstable Annals deal exhaustively with the history oi the monastery and town in the 13th century. The Eleanor cross that once stood in the market place was probably destroyed in the 17th century. At Dunstable Archbishop Thomas Cranmer in 1533 declared Catherine of Aragon's marriage to Henry VIII invalid.

The former straw-hat industry moved to Luton. which is contiguous, but there are printing works and iactories making chains, plastics, motor vehicles and accessories. In Houghton Regis. adjacent to the north, is an extensive cement and lime plant. Dunstable has always been an agricultural town and its annals abound with references to the two staple products, wool and grain. The municipal boundaries were extended in 1933 and 1954.

Whipsnade, the country branch of the London zoological gardens. was opened in 1931, occupying 500 ac. It lies 3½ mi. S.S.W. of Dunstable by road. At the foot of the downs to the west is the headquarters of the London Gliding club.

DUNSTAN, SAINT (c. 909–988), archbishop of Canterbury and reformer of monastic life. the son of a West Saxon noble, was born near Glastonbury. where he was educated by the Irish monks oi that abbey. He entered the household of King Aethelstan, but his love of books and of song and his mechanical skill soon excited the dislike of his kinsfolk at the court. Accused of practising the black arts, he took refuge with his kinsman Alphege, bishop of Winchester. whose persuasion. seconded by a serious illness, induced him to become a monk. Dunstan then lived as a hermit until Aethelstan's successor, Edmund, recalled him as one of his counselors. His enemies again procured his expulsion. but Edmund soon revoked the sentence and about 943 made Dunstan abbot of Glastonbury. Under him the abbey became a famous school. monastic life was revived and St. Peter's was re-erected. Edred. the successor of Edmund, left the administration of the realm largely in the control of Dunstan, who sought to establish royal authority, to conciliate the Danish section, to uproot heathenism and to reform clergy and laity. On the accession oi Edwy. however. in 955, Dunstan's fortunes underwent a temporary eclipse. Having given offense to the influential and unprincipled Aelfgifu, the king's wife, he was outlawed and driven to Flanders. But in 957 the Mercians and Northumbrians revolted and chose as their king Edgar, who at once recalled Dunstan and made him bishop of Worcester and London. In 959 Edwy died and Edgar became sole king. Dunstan was appointed archbishop of Canterbury. On Edgar's death in 975 the archbishop secured the crown for Edgar's elder son, Edward, who was murdered three years later. On the accession of Aethelred Dunstan's public career came to an end; he retired to Canterbury, where he died on May 19. 988. His ieast day is May 19.

Dunstan reiormed monasticism according to the strict observance of the Benedictine rule, which he had seen at the abbey of Blandinium, near Ghent, during his exile under Edwy. Among his foundations were Peterborough. Ely and Thorney. By the rebuilding of churches and the; promotion of education he endeavoured to uplift the people. In political matters his policy was one of unification and of respect for law.

DUNSTER, HENRY (1609–1659), American clergyman, first president of Harvard college. was born in Bury. Lancashire, Eng.. where he was baptized on Nov. 26, 1609. He was educated at Cambridge university (B.A., 1631; M.A., 1634) and then taught school and served as curate of Bury. He had a reputation for learning, and three weeks aiter his arrival in Massachusetts he was installed as president of Harvard (Aug. 27, 1640). The college was all but extinct, instruction having been given for one disastrous year and then suspended, so Dunster had to make a fresh beginning without students, faculty. buildings, income, curriculum, statutes or charter. He proved to be an able teacher, administrator and money raiser, and gave to the college a form and character which persisted in all essential features until the 19th century. In 1653 he scandalized the colony by adopting Baptist views and refusing to have his child baptized. His resignation was demanded by the general court: Gut the overseers refused to accept it in the hope that he might be persuaded to change his views or at least to keep silent. This he refused to do, and in 1654 he was ejected from the presidency, brought to trial, sentenced to be publicly admonished and put under bond to keep the peace. Although he had contributed generously out of his own limited means to the support of the college, there was delay in paying his back salary, and in the end he received only partial recompense. Removing to the more liberal atmosphere of Scituate, Mass., he continued to preach until his death on Feb. 27, 1659.

See S. E. Morison, *The Founding of Harvard College* (1935), *Harvard College in the Seventeenth Century (1936).* (W. S. H.)

DUNSTER, an old market town in Somerset, Eng., lies 1.5 mi. from Dunster Beach on the Bristol channel and 22 mi. N.W. of Taunton. Pop. of the civil parish (1951) 931.

Dunster lies in a striking setting on the edge of Exmoor National park. Dominated by its ancient castle, the long street of the tomn winds around the base of the castle hill. The yarn market. a 16th-century octagonal building with open sides and steeply sloping roof, stands in the middle of the wide main street. The Eutrell Arms hotel retains a late medieval porch and some 17th-century paneling. The castle, open to visitors during the summer, has a fine 18th-century staircase and plaster ceilings. A packhorse bridge spans the river Avill, and an 18th-century folly. Conegar tower, provides a well-known landmark. The church of St. George has some early ieatures, a good Perpendicular tower and a splendid screen, but all that remains of the Benedictine priory are a tithe barn and a circular dovecot.

The tourist trade provides the main occupation for Dunster's inhabitants. Agriculture and forestry and their associated industries, including two sawmills, occupy the remainder.

Remains of prehistoric Iron Age settlements lie in the deer park. The Domesday reference mentions Alvric, the Saxon lord of Dunster. but William de Mohun received the estate from the Conqueror. His castle became the *caput* of an honour including lands in Somerset. Dorset, Devon and Wiltshire that in the 14th century was purchased by the Luttrells. That family continued to live in the castle although the estate was sold in 1949 to the crown commissioners.

The town, created a borough in the 12th century, was represented in parliament in conjunction with Minehead until 1832. It provided a marketing centre for woolen yarn and for a local cloth called Dunsters. (T. J. HT.)

DUNWICH, a village in the Eye parliamentary division of East Suffolk, Eng., on the coast of the North sea, about 26 mi. N.E. of Ipswich by road. Pop. of civil parish (1951) 140. In ,Anglo-Saxon days it was the most important commercial centre of East Anglia and was probably a Romano-British site. Early in the 7th century, when Sigebert became king of East Anglia, Dunwich was chosen as his capital and became the nursery of Christianity in eastern Britain. A bishopric was founded (according to Bede in 630; the Anglo-Saxon Chronicle gives 635), the name of the first bishop being Felix. Sigebert's reign was notable for his foundation of a school modeled on those he had seen in

France; it was probably at Dunwich but formed a nucleus of what afterward became Cambridge university. At the Norman conquest the manor was granted to Robert Malet. In 1173 the sight of its strength caused Robert, earl of Leicester, to despair of besieging the place. Dunwich received a charter from King John. In the reign of Edward I it is recorded to have possessed 36 ships and barks trading to the North sea. Iceland and elsewhere, with 24 fishing boats, besides maintaining 11 ships of war. The Benedictines. Franciscans and Dominicans all had establishments there.

By the middle of the 11th century Dunwich had already suffered from an evil that later caused its total ruin— the inroads of the sea upon the coast. In 1347 more than 400 houses were washed away, and in 1570, after a terrible storm, appeal was made to Elizabeth I. However, the old wealthy port was gradually engulfed, and inroads of the sea still continue. Many relics have been discovered by excavation or recovered from the sea.

Until 1832 Dunwich returned two members to parliament. The corporation was abolished in 1886, and part of the civil parish was transferred to Southwold in 1934. In the same year a bishopric suffragan to St. Edmundsbury and Ipswich was constituted, receiving the name Dunwich.

DUPANLOUP, FÉLIX ANTOINE PHILIBERT (1802–1878), French Roman Catholic bishop of Orléans, clerical spokesman for the liberal wing of French Catholicism. was born illegitimately on Jan. 3, 1802, at St. Félix, Haute-Savoie. He was taken to Paris as a boy. Ordained priest in 1825, he inaugurated at the Madeleine his novel catechetical classes at which the duc de Bordeaux and the Orléanist princes received religious education. As director of the Parisian junior seminary of St. Nicolas-du-Chardonnet (1837–4j), he attracted by' his success many nonclerical students and contributed to a bourgeois return to religion. Prominent in the struggle for educational freedom under the July monarchy, he was an architect of the *loi Falloux* (1850), which gave legal status to independent secondary schools. Bishop of Orléans (1849) and member of the French Academy (1854), he helped reorganize the liberal Catholic journal *Le Correspondant*. He defended papal temporal sovereignty, when it was threatened by Louis Napoleon, in a series of public letters (1860), but supported Thiers' refusal to reopen the issue after 1870. His explanation of Pius IX's *Syllabus of Errors* under the terms "thesis and hypothesis" became famous. At the Vatican council (1869–70) he was one of the party that considered the definition of papal infallibility to be inopportune. Bishop Dupanloup died on Oct. 11, 1878.

Of his numerous writings, only *Christian Marriage* and *The Studious Women* have been translated into English. A good sampling is in *Oeuvres Choisies*, 4 vol. (1861). Three volumes on Higher Education have merit.

See the biography by F. Lagrange, Eng. trans., 2 vol. (1885).
(J. N. M.)

DUPARC, (MARIE EUGÈNE) HENRI (1848–1933), originally Fouques-Duparc, French composer known for his songs on poems of Baudelaire, Leconte de Lisle, Théophile Gautier and others. Born in Paris on Jan. 21, 1848, he studied with César Franck at the Jesuit college of Vaugirard. In 1869 he met Liszt and Wagner at Weimar and in 1870 published five songs (*Cinq Mélodies*, Opus 2) including "Soupir" and "Chanson triste," later incorporated in his collection of 15 songs, written between 1869 and 1884. In these, of which eight are with orchestral accompaniment, Duparc enlarged the French song into an operatic scena ("Au pays où se fait la guerre"), brought to it a poetic sense of musical prosody ("La Vie antérieure") and, in "Phydilé" and "L'Invitation au voyage;" a symphonic conception of form. In his youth Duparc wrote two orchestral works, *Aux Étoiles* and *Lénore*, and a motet. He was also keenly interested in Russian literature, planning an opera, *Roussalka*, based on Pushkin, and in the plays of Ibsen. Later he worked at painting, chiefly in water colours, sepias and pastels. About 1890 his creative faculties began to be undermined by doubts, and he thereafter produced little. In a spirit of severe self-criticism he destroyed nearly all his subsequent works and sketches, together with his earlier unpublished manuscripts and the correspondence addressed to him by Wagner and contemporary poets. During the latter part of his life he was associated with Francis Jammes and Paul Claudel and wrote a long religious prayer in prose (*Testament*, 1906–13). He died at Mont-de-hlarsan. Landes, Feb. 13, 1933.

DUPERRON, JACQUES DAVY (1 556-1618), French cardinal, memorable especially for his part in the conversion of Henry IV to Roman Catholicism, was born in the canton of Berne, Switz., on Nov. 25. 1556, the son of a Huguenot refugee from St. Lô in Normandy. who gave him an excellent humanist, education. Brought to France. however, he eventually became a Catholic, took holy orders and made a name for himself as a churchman attached to the crown's interests. Appointed reader to Henry III, to whom he was introduced in 1576. he kept this post until the king's death. He then for a time supported the claim of the cardinal de Bourbon ("Charles X") to the French crown, but soon transferred his loyalty to Henry IV. Bishop of Evreux from 1591. he instructed the king in the Catholic religion and in 1594 mas sent to Rome to obtain absolution for him from the pope. At the conference at Fontainebleau between Catholics and Huguenots in 1600 he eloquently defended the Catholic position against Philippe du Plessis-Mornay and Agrippa d'Aubigné.

In 1604 Uuperron was sent to Rome as charge' d'affaires and 'was created a cardinal. In 1606 he became archbishop of Sens. In the estates-general of 1614-15 he strongly opposed the attempt by the third estate to deny the pope's right to depose kings. Duperron died in Paris on Sept. 5, 1618, leaving a large number of writings dealing not only with religious and diplomatic affairs hut also with literary questions.

(Ro. M.)

DUPIN, LOUIS ELLIES (1657–1719), French ecclesiastical historian, born in Paris, June 17, 1657, was the author of *Nouvelle Bibliothèque des auteurs ecclésiastiques*, 58 vol. (1686–1704), breaking with scholastic tradition by treating biography, literary and doctrinal criticism and bibliography all in one work, and by writing in a modern language. Following violent opposition to its opinions, led by Jacques Bossuet, and on the advice of his friend and distant relative Racine, Dupin retracted; but the book was suppressed (1696) and only completed under a new title. It was placed on the Index in 1757. Although he was a Gallican apologist, in 1713, following his protest against the papal hull *Unigenitus*, Dupin was exiled to Châtellerault on a charge of Jansenism, regaining freedom only by another retraction. His later years were occupied by projects for reunion of the churches: he corresponded (1 718) with William Wake, archbishop of Canterbury, with ecclesiastical but not official approval; and in 1719, during his visit to France. Peter the Great commissioned Dupin to draw up a plan for Greek and Roman reunion. He died in Paris, June 6, 1719. His works include a *Bibliothèque universelle des historiens*, 2 vol. (1707), and *L'Histoire de l'église en abrégé*, 4 vol. (1712).

DUPLEIX, JOSEPH FRANÇOIS (1696–1763), French colonial administrator who, as governor general of the French establishment of India, was Robert Clive's great rival, was born at Landrecies. France, in Dec. 1696. His father, François Dupleix, who eventually became a farmer-general of taxes, sent him on a voyage to India and America in 1715 in a St. Malo ship. In 1721 his father's influence secured his appointment as a member of the superior council at Pondicherry. There, besides his official duties, he made large ventures on his own account and acquired a fortune. He was made superintendent in 1731 of the French factory in Chandernagore, which he administered with great success, and was appointed go ernor general of all French establishments in India in 1742. Within a year the news of the outbreak of the War of the Austrian Succession involved the English and French companies in conflict, but actual hostilities awaited the arrival of state forces on both sides. In 1746, with the help of a

French fleet under the comte, Mahé de la Bourdonnais, Dupleix took Madras, but the quarrels between the two prevented further progress. The French failed against Ft. St. David and the British could not take Pondicherry. The peace of Aix-la-Chapelle in 1748 restored the *status quo*.

Dupleix now embarked on a political career. Divining the military weakness of the Indian powers of the day. he entered into local alliances with the aim of ruining the British East India company. He supported Chanda Sahib's claim to the Carnatic nawabship, and when the nizam of Hyderabad intervened. placed his own candidate on the throne there (1751). The British supported a rival candidate in the Carnatic and a private war between the two companies, acting as auxiliaries to Indian princes, developed Largely as the result of Clive's exploits the French were defeated although those under the marquis de Bussy-Castelnau retained their hold in the Deccan. The French finances were ruined in the struggle. and Dupleix was replaced in 1754 by C. R de Godeheu, who had orders to arrest him if necessary. Dupleix embarked for France in Oct. 1754. He displayed great talents as an organizer and diplomatist, but lacked military acumen and the ability to work with others. He was the first European to exploit the weakness of Indian military science in order to gain political and territorial influence in India. Dupleix was discredited in his own country and died in obscurity in Paris on Nov. 10, 1763.

The diary of his Indian secretary. Ananda Ranga Pillai, gives a vivid picture of Dupleix's personality. In 1741 he married Jeanne Albert (d. 1756), widow of one of the councilors of the company, known to the Hindus as Joanna Begum, who proved of great help to her husband in his negotiations with the Indian princes. Dupleix defended his case against the company in his *Mémoire contre la compagnie des Indes avec les pièces justificatives* (1759), to which Godeheu replied in his *Lettre à* M. *Dupleix* (1760).

DUPONT, GABRIEL EDOUARD XAVIER (1878–1914), French composer of operas and light songs and piano pieces. Born March 1, 1878, at Caen, he was a pupil of Massenet at the Paris Conservatoire. In 1904 his opera *La Cabrera* was produced in Milan and in 1910 *La Glu,* based on the novel by Jean Richepin, was given at Nice. He later wrote *La Farce du cuvier* (Brussels, 1912) and *Antar,* posthumously produced in Paris in 1921. He also wrote songs and choral and orchestral works, notably a symphonic poem *Le Chant de la destinée.* His piano works include *Les Heures dolentes* and *La Maison dans les dunes.* A spontaneous lyrical gift accounted for his popular appeal. He died after a long illness at Le Vésinet, near Paris, Aug. 2, 1914.

See M. Dumesnil, "Gabriel Dupont: Musician of Normandy" in *The Musical Quarterly* (Oct 1944).

DU PONT, SAMUEL FRANCIS (1803–1865), **U.S.** naval officer, was born in Bergen Point, N.J., Sept. 27, 1803. Educated in Philadelphia, Pa., young Du Pont was attracted to the naval service as a result of the exploits of U.S. sea fighters during the War of 1812. He was appointed a midshipman and his training at sea began in 1817 under Capt. Charles Stewart in the ship of the line "Franklin." He served on various naval vessels in South American and European waters, being promoted a lieutenant in 1826 and a commander in 1842. In command of the sloop of war "Cyane," on the Pacific coast at the outbreak of the Mexican War, Du Pont distinguished himself in a series of daring amphibious operations that cleared the enemy out of the Gulf of California. He participated in the capture of Mazatlán and other cities, which drove the enemy from the Pacific coast of Mexico. For the next ten years Du Pont played an important part in the development of steam in the navy. In 1855 he was appointed a captain and, at the same time, brought congressional wrath upon himself as chairman of the naval efficiency board which found several hundred naval officers incompetent. As senior member of the commission of conference, Du Pont was instrumental in planning the naval strategy of the Civil War, and he carried out the first stages of that strategy when, in the command of the South Atlantic blockading squadron, he stormed and took the Confederate forts at Port Royal, S.C. (Nov. 7, 1861). Congressional thanks and a rear admiralcy followed the exploit, the capture of forts by ships previously having been regarded as impracticable. Eighteen months later, in a similar attempt upon the defenses of Charleston, S.C., and using a battle line of monitors and an ironclad, Du Pont met with a severe reverse. He was relieved in July 1863. A dispute with the secretary of the navy, Gideon Welles, as to the responsibility for this defeat continued until Du Pont's death in Philadelphia on June 23, 1865.

Du Pont circle and fountain in Washington, D.C., were named in his honour.

See H. A. Du Pont, *Rear Admiral Samuel Francis Du Pont* **(1926)**; *Official Records of the Union and Confederate Navies in the War* of *the Rebellion,* 30 vol. (1894–1922). (W. B. Cr.)

DUPONT DE L'EURE, JACQUES CHARLES (1767–1855), French lawyer and republican deputy whose distinctive surname indicates his lifelong connection with the *département* of Eure, was born at Neubourg on Feb. 27, 1767. He was admitted as advocate to the *parlement* of Rouen in 1789. From 1790, when the *département* of Eure was formed, he played an active part in its affairs, becoming mayor of Neubourg in 1792, public prosecutor for Eure in 1798, deputy for Eure in the Council of the Five Hundred from 1798 to 1799 and president in the state court at Rouen in 1812. Having been a member of the Corps Législatif in 1813 and vice-president of the chamber of representatives during the Hundred Days, he resisted the absolutism of the Restoration. Re-elected by Eure in 1817, he was dismissed without pension from his post at Rouen in 1818, but his constituents then bought him a property to qualify him for re-election as deputy.

On the establishment of the July monarchy in 1830, Dupont was made minister of justice and keeper of the seals, but he resigned in October in order to rejoin the republican opposition. He mas active in the "banquets campaign" for constitutional reform in 1847 and, at the revolution of Feb. 1848, became president of the council of ministers in the provisional government. After the April elections he sat for Eure in the constituent assembly, but his moderate republicanism was overshadowed by Ledru-Rollin's extremism, and he finally lost his seat in the elections of May 1819. He died at Rouge-Perriers, Eure, on March 2. 1855.

DU PONT DE NEMOURS, PIERRE SAMUEL (1739–1817), French economist whose numerous writings were mainly devoted to spreading the tenets of the Physiocratic school (*q.v.*) and whose unfailing adherence to these doctrines largely explains his conduct during his long political career, was born in Paris on Sept. 14, 1739. An early work on free trade. *De l' Exportation et de l'importation des grains* (1764), brought him the friendship of A. R. J. Turgot (*q.v.*), whose biography he wrote (1782) and whose papers he edited (9 vol. 1809–11). He assisted Turgot and, later. C. A. de Calonne (*q.v.*) at the *contrôle général* in planning reforms. He was largely responsible for the clause in the treaty of Versailles of 1783 which stipulated a trade treaty between France and Great Britain, and he greatly influenced the scope of the free-trade treaty which was signed in 1786. For these services he was ennobled. In 1787 he became secretary to the assembly of notables. After the fall of Calonne he joined the "patriots," who opposed privilege and the political claims of the *parlements;* and later he joined the Société des Trente, which favoured voting by head rather than by orders in the meeting of the estates-general convened for 1789. In the estates-general he represented the third estate of Nemours.

One of the chief promoters of the Tennis Court oath and, like his friend Talleyrand, an architect of the civil constitution of the clergy, he played an important part in the beginnings of the French Revolution. He was opposed to the issue of *assignats,* to war, to violence and to tyranny. He defended Louis XVI in hug. 1792. Though forced into hiding during the Terror and later imprisoned, he was eventually released through the help of influential friends. A member of the *anciens* at the time of the Directory, he was suspected of activities on behalf of the royalists and mas again

arrested, but was quickly released. He now planned to go to the United States, not as an *émigré* but hoping to combine official missions with private speculation and to convert the Americans to physiocratic principles. After much delay. he arrived in the United States with his sons, Eleuthère and Victor, in Jan. 1800. He drew up for Thomas Jefferson a scheme of national education and established companies to promote Franco-U.S. trade. These ventures were not successful, but Eleuthère, a pupil of Antoine Lavoisier, founded a powder manufacture which became world-famous. In 1802 Pierre Samuel returned to France to promote the sale of Louisiana to the United States. hoping thereby to improve Franco-U.S. relations. He became vice-president of the Paris chamber of commerce. His political theory enabled him to accept not only the consulate but also the first empire. Later, however, he became critical of Napoleon's economic and foreign policy. In 1814 he assisted Talleyrand to restore the Bourbons, became secretary general of the provisional government and was made councilor of state by Louis XVIII. During the Hundred Days he returned to the United States. He died at Eleutherian Mills, near Wilmington, Del , on Aug. 7, 1817.

Dupont's chief works were: *Physiocratie, ou Constitution naturelle du gouvernment le plus avantageux au genre humain* (1767); *Du commerce et de la compagnie des Indes* (1769); *Mémoires sur la vie et les ouvrages de M. Turgot,* 2 vol. (1782); *Philo-sophie de l'univers* (1796); an edition of the *Oeuvres de Turgot,* 9 vol. (1809–11); and *Examen du livre de M. Malthus* (1817).

See Pierre Jolly, *Du Pont de Nemours* (1956). (D. Dn.)

DUPPLIN, BATTLE OF. This battle, fought on Aug. 12, 1332, marked the renewal of the Scottish War of Independence, which apparently had been ended by the peace of Northampton (1328). But under Henry de Beaumont *(see* Beaumont), and with the secret connivance of the English king Edward III, those who had been disinherited by Robert I for their adherence to the English planned to recover their Scottish lands by force. Edward Balliol *(see* Balliol) came from France to head their expedition. Embarking at Ravenspur with about 1,500 men, the "disinherited" landed at Kinghorn in Fife and routed the local levies who opposed them. By way of Dunfermline the invaders reached the Earn river, on the opposite bank of which lay a Scottish force under Donald, earl of Mar, regent for the young David II. Fording the river on the night of Aug. 11–12, the "disinherited" overwhelmed a Scottish encampment. Despite this initial success dawn revealed the main Scottish force arrayed in two divisions and ready to attack. Greatly outnumbered, Balliol's men adopted tactics later copied by Edward III at the battles of Halidon Hill and Crécy; save for about 40 German mercenaries kept in reserve, all the men-at-arms dismounted, while archers were posted on either flank. When an impetuous charge by the first Scottish division failed to make headway its flanks were riddled by flights of English arrows and converged in disorder upon the centre. At this point the second division (under Mar), charged, collided with the rear-most ranks of the first division, but failed to communicate momentum to those in front. Losing their footing, the Scottish men-at-arms and spearmen trod one another underfoot; more died by suffocation than by the sword. Pursuing the fugitives, Balliol's men entered Perth and crowned their leader at Scone on Sept. 24, 1332. *See* also Scotland: *History.* (R. G. Ni.)

DUPRAT, ANTOINE (1463–1535), chancellor of France and cardinal, the chief judicial counselor of Francis I, was born at Issoire on Jan. 17, 1463. Duprat owed his success to his cousin Antoine Bohier, archbishop of Bourges, who had him well educated and helped his legal career. Duprat became *liezitenant de bailliage* at Montferrand (1490), attorney for the crown at Toulouse (1495), master of requests to Louis XII's household (1503), president in the Paris *parlement* (1507) and finally, because of the influence of Louise of Savoy, premier president of the Paris *parlement* (1508). Louise, moreover, had entrusted him with the education of her son, the future Francis I. On the latter's accession to the throne (1515), Duprat became chancellor of France. In this capacity he negotiated the concordat of Bologna (1516).

After the concordat was signed, Duprat took holy orders. He was given the bishoprics of Valence and Die (1522), Albi (1528) and Meaux (1534) and the archbishopric of Sens (1525) and was made a cardinal in 1527 and papal legate in France in 1530. He was a determined adversary of the Reformation.

Duprat meanwhile continued in his functions as a lawyer. He collaborated with the king in his centralizing policy and advised him on the prosecution of the constable duc de Bourbon. Having amassed great wealth and even entertained hopes of succeeding Clement VII as pope, he died at Nantouillet on July 9, 1535.

See Antoine, marquis Duprat, *Vie d'Antoine Duprat* (1854); *A.* Buisson, *Le Chancelier Antoine Duprat* (1935).

DUPRÈ, GIOVANNI (1817–1882), Italian sculptor, whose success was due to his lifelike and original interpretation of form when Italian sculpture was deteriorating into a mannered imitation of Canova, was born in Siena on March 1, 1817, the son of a carver in wood. By drawing and modeling in his spare time he succeeded in winning the prize competition of the academy in Florence in 1840 without having attended the academy schools. His first work of importance was "Abel" (1842, Pitti, Florence). He was befriended by L. Bartolini. The grand duchess Marie of Russia commissioned him to do a statue of "Cain" (1844. Pitti), and the grand duchess of Tuscany to do one of "Giotto" (1845, arcades of the Uffizi, Florence). The mourning "Sappho" (1857) was his most famous work of this period. A visit in 1856 to Naples and Rome, where he admired Canova's monument to Pius VI. influenced him toward neoclassicism. His monuments, *e.g.,* that of Cavour in Turin, suffer from the conflict between his temperamental naturalism and the necessities of allegory and ideal grandeur. Duprè also executed many portrait busts. He died in Florence on Jan. 10, 1882.

His autobiography, *Pensieri sull' arte e Ricordi autobiografici* (1882), was, translated into English by Peruzzi. (A. K. McC.)

DUPRE, JULES (1811–1889), French painter, one of the chief members of the Barbizon group of romantic landscape painters, was born at Nantes on April 5, 1811. Among the Barbizon painters, Corot tended toward the lyric, T. Rousseau toward the epic and Dupré toward the tragic and dramatic aspects of nature. He was the son of a porcelain manufacturer and started his career in his father's works, from which he went to his uncle's china factory at Sèvres. Dupré exhibited first at the Salon in 1831, and three years later was awarded a second-class medal. In the same year he came to England, where he was deeply impressed by the genius of Constable. From him he learned how to express movement in nature; and the district of Southampton and Plymouth, with its wide, unbroken expanses of water, sky and ground, gave him good opportunities for his special gifts. Late in life he changed his style and gained appreciably in largeness of handling, and he arrived at greater simplicity in his colour harmonies. He died at L'Isle Adam on Oct. 6, 1889. *See* also Barbizon School.

DUPUY, CHARLES ALEXANDRE (1851–1923), French statesman, three times prime minister, remembered chiefly for his role during the Dreyfus affair, was born at Le Puy, Haute-Loire, on Nov. 5, 1851. He was first elected deputy for Haute-Loire as an Opportunist Republican in 1885. He became minister of education under Alexandre Ribot in 1892. Dupuy formed a government in April 1893 but resigned at the end of November and on Dec. 5 was elected president of the chamber. During his first week of office the anarchist Auguste Vaillant threw a bomb at him, and Dupuy's calm words, "The debate continues, gentlemen," won him much credit. He became prime minister and minister of the interior in May 1894 and was by Pres. Sadi Carnot's side when the latter was assassinated at Lyons in June. His cabinet remained in office till Jan. 1895, and it was under it that Capt. Alfred Dreyfus (*q.v.*) was arrested and, two months later, condemned (Dec. 1804). In Nov. 1898, and after Henri Brisson had at last remitted the Dreyfus case to the judgment of the supreme court of appeal, Dupuy formed a government of Republican concentration. A special law was passed that transferred the decision from the criminal section to the court of appeal sitting as a whole (*toutes chambres réunies*). The latter decided that there must be a new court-martial, for the *bordereau,* the document that had led to Dreyfus' court-martial, was the work of Maj.

C. F. (Walsin-)Esterhazy. This infuriated the anti-Dreyfusards. who staged demonstrations and insulted Pres Émile Loubet at Auteuil Dupuy resigned on June 12. 1899. In June 1900 he was elected senator for Haute-Loire Dupuy died at Ille-sur-Têt, Pyrénées-Orientales, on July 23, 1923.

DUPUY, PIERRE (1582–1651), French scholar, born in Agen (Lot-et-Garonne), Nov. 27, 1582, was largely responsible for cataloguing the royal archives (*Trésor* des *chartes*) and, with his brother Jacques, the king's library. His manuscript inventory of the former is preserved in the Bibliothèque Nationale and transcriptions are in the national archives in Paris, the record office in London and elsewhere. He was also employed on the commission constituted to discover the legal titles of the king of France over the bishoprics of Metz. Toul and Verdun. His books on the conflict between Boniface VIII and Philip the Fair, the Templars and the great schism contain important documents.

Dupuy died in Paris, Dec. 14, 1651.

DUPUY DE LÔME, STANISLAS CHARLES HENRI LAURENT (1816–1885), French naval architect, who influenced the design of steamships and armoured vessels, was born at Ploemeur, near Lorient, on Oct. 15, 1816. He entered the École Polytechnique in 1835, and in 1842 was sent to England to study and report on iron shipbuilding. Acting on his report, published in 1844, the French government built its first iron vessels. He planned and built the steam line-of-battle ship "Napoléon" (1848–52) and devised a method of altering sailing ships of the line into steamers that was afterward practised in both France and England. His demonstration of the practicability of armouring the sides of a ship marked the beginning of a great change in ship construction. In 1877 he was elected a senator for life. He died in Paris on Feb. 1, 1885.

DUPUYTREN, GUILLAUME, BARON (1777–1835). French surgeon famous for his researches in surgical pathology. one of the best-known of which is his description of "Dupuytren's contracture" of the hand, a condition that occurs in persons whose work entails pressure on the palms. He was born at Pierrebuffière, near Limoqes. on Oct. 5, 1777. In 1802 he joined the staff of the great Paris hospital, the Hôtel Dieu. of which he became surgeon-in-chief and which he attended for over 30 years. In addition he carried on an immense private practice and was surgeon to Louis XVIII and Charles X. As an operator he was bold, self-controlled and undaunted by any emergency. He was the first to excise the lower jaw and to amputate the neck of the womb for cancer. Among his other great triumphs were the ligation of the subclavian artery. the introduction of a new classification of burns, the introduction of operations for the treatment of wryneck and for the creation of an artificial anus, the treatment of aneurysms by compression and the first clear pathological description of congenital dislocation of the hip. He died in Paris on Feb 8. 1835.

See H Mondor, *Dupuytren (1945).* (W. J BP.)

DUQUESNE, ABRAHAM, MARQUIS (1610–1688), French naval officer who served with distinction during two periods of great maritime activity in France, under Richelieu's administration and then under Colbert's, was born in Dieppe of a small Calvinist family who did some trade with Canada. He learned his seamanship on a small armed merchantman, the "Petit Saint André" on which he served as lieutenant to his father (1627) Richelieu, wanting to recruit captains for the royal navy, engaged Duquesne, who then served under two great commanders Henri d'Escoubleau de Sourdis and Armand de Maillé-Brézé. In 1638, in command of the "Saint-Jean," he took part in the destruction of a Spanish fleet in the battle of Guetaria. He fought off the coasts of Spain and was wounded at the Cabo de Gata (1643). After a short stay in Sweden as one of Queen Christina's admirals (1644–47), he returned to France. He served the crown loyally during the Fronde.

When Colbert began his great naval program, Duquesne commanded a squadron at Brest and supervised the development of the port. After war had broken out in 1672 (see DUTCH WARS). he was at Solebay when the Dutch admiral M. A. de Ruyter surprised the Anglo-French fleet. Accused by his superior, Jean, comte d'Estrées, of reluctance to obey orders, Duquesne was then deprived of his command No doubt he was, as Colbert said, "of an unaccommodating disposition." surly and always complaining and criticizing; but even so he was a conscientious and worthy officer uith a strong sense of duty. Neither prospects of promotion nor Bossuet's eloquent arguments could make him renounce his Protestantism. In the second period of the war, honever, when the English had left the French alliance and a skilful. hard and aggressive sailor was required to fight in the Mediterranean. Duquesne was chosen for the task. Sailing at the end of Jan. 1675 to help the Sicilian rebels against the Spaniards, he fought his way into Messina and then took Augusta before returning to France for reinforcements and supplies. The Dutch then sent the formidable De Ruyter to help the Spaniards. Duquesne, however, defeated him first off the Lipari islands (Jan. 1676). then in the great battle off Augusta (April 22), in which De Ruyter was mortally wounded. Colbert then wrote to Duquesne. "You have given such great proof of your valour, of your skill. of your consummate experience in naval matters that nothing could be added to the glory which you have acquired."

After peace had been signed with the Dutch, Duquesne fought against the Barbary pirates. Sailing into the Aegean, he bombarded Chios and threatened the Dardanelles (1681). He attacked Algiers in 1682 and in 1683. His last expedition was against Genoa (1684). The estate of Bouchet had been erected into a marquisate (du Quesne) for him in 1681, but his Protestantism prevented his ever being made admiral. After the revocation of the Edict of Nantes (1685) he was allowed to remain untroubled in retirement. He died in Paris in the night of Feb. 1–2, 1688.

See A. Jal, ***Abraham Duquesne et la marine de son temps (1873).*** (L. NI.)

DUQUESNE, a city of Allegheny county. Pa.. U.S.. on the south bank of the Monongahela river facing McKeesport and 10 mi. from downtown Pittsburgh. Both the advance and retreat routes taken by Gen. Edward Braddock's British army in its ill-fated march toward the forks of the Ohio in 1755 passed there. The city's only industry is steel. In 1885 the Duquesne Steel Co. selected the area as a mill site, and the town quickly attracted other steel companies. Duquesne was incorporated as a borough in 1891 and received its city charter in 1917. Its population reached a peak of 21,396 in 1930, slowly declining thereafter. For comparative population figures see table in PENNSYLVANIA: Population. (J. A. KE.)

DUQUESNOY, FRANÇOIS (1592/94–1643), called IL FIAMMINGO, Italo-Flemish sculptor, usually considered, along with Alessandro Algardi, as representing within the baroque movement a more conservative influence than G. L. Bernini, was born in Brussels but lived in Italy from about 1620. His two most famous monumental statues are those of St. Susanna (at Sta. Maria di Loreto, Rome) and of St. Andrew (in the crossing of St. Peter's), the latter being closer to Bernini than most of Duquesnoy's work. Portraits of Van Dyck (Brussels, Palais des Beaux-Arts) and Poussin (Earl Cowper at Panshanger) from his hand survive. He received much praise for his rendering of *putti* (Cupidlike nude child figures). which were perhaps more truly childlike than any by previous sculptors. Duquesnoy was also very skilled as a carver of small ivory figures. He died at Leghorn on July 12, 1643. (A. K. McC.)

DURALUMIN, an aluminum alloy discovered and patented by Alfred Wilm and originally made at Diiren in Germany. It possesses the important property of being strengthened and hardened by heat treatment and aging. In addition to 94% aluminum, 4% copper and 0.5% to 1.0% of manganese, duralumin-type alloys contain from 0.5% to 1.5% magnesium. The latter element is responsible for the natural age hardening of this alloy after heating and quenching. The original composition has been varied over a range with regard to copper, magnesium and manganese contents, and this class of alloys is described as the strong aluminum alloy type.

In the normal state these alloys are relatively soft, ductile and workable and may be rolled, forged, extruded or drawn into a variety of products. Cold working strain hardens duralumin al-

loys as it does all metals. The effects of this work-hardening can be removed by annealing at a temperature of 6j0° F. This type of alloy is heat-treated by heating to 920°–950° F.. depending on the alloy, and quenching rapidly in cold water. The heating dissolves and distributes the hardening components and quenching retains them in a supersaturated solid solution. Immediately after quenching, duralumin is relatively soft and workable. On aging at room temperature for about four days, the alloy becomes harder, stronger and less workable. Age-hardening results from precipitation of submicroscopic particles from the supersaturated solid solution. These particles key the slip planes and thereby harden and strengthen the matrix. The aging process can be accelerated in some of the alloys by reheating at temperatures from 200° to 350° F. *(See* also ALLOYS; ANNEALING.)

Heat-treated duralumin is comparatively resistant to corrosion. It is ductile (typical elongation 22% in 2 in.), will bear a load of about 40,000 p.s.i. without permanent deformation and breaks under a load of about 62,000 p.s.i.

These alloys are light (specific gravity 2.75 to 2.80). Thus. they have a high strength per unit of weight as compared with steel. This property makes them particularly suitable for aircraft construction, for which they have been used to a very great extent, and the development of the rigid airship would have been impossible without light, high-strength alloys of the duralumin type. As sheet for aircraft construction. these alloys are made in alclad form. a composite product which has thin surface layers of pure aluminum or some corrosion-resistant aluminum alloy covering the high-strength duralumin-type alloy core.

The duralumin alloys can be welded but they lose their high strength during welding. Duralumin lends itself to all ordinary fabricating processes such as spinning, pressing, riveting and machining. *See* also ALUMINUM. (F. KR.)

DURAN, a medieval Jewish family of rabbis and scholars.

PROFIAT DURAN, called also Efodi (full name. Isaac ben Moses Halevi) (c. 1350–*c.* 1415), was educated in Germany and lived in Catalonia. In 1391 he was compelled to profess Christianity, but remained devoted to Judaism. His chief works were grammatical and philosophical. In the former realm his most important contribution was the *Maaseh Efod* (completed in 1403); in the latter. his commentary to the *Guide* of *the Perplexed* by Maimonides.

SIMON BEN ZEMAH DURAN (1361–1444), called Rashbaz, rabbi of Algiers, was born at Palma, Majorca, but fled to Algiers during the persecutions of 1391. A doctor of medicine: he was one of the first medieval rabbis to be paid a regular salary by the community. Before the 14th century the rabbinical post had been almost invariably honorary. Duran wrote a systematic work on theology, *Magen Aboth,* but is chiefly famous for his numerous *responsa,* published in 1738–39, which give valuable information as to social and religious conditions of his day. He also wrote a critique of Catholic dogmas, pointing out the contrast between the religion of Jesus and the letters of St. Paul. (I. A.; X.)

SOLOMON BEN SIMON DURAN (*c.* 1400–1467), called Rashbash, son of Simon ben Zemah and his successor as rabbi of Algiers. was the author of a defense of Judaism, *Milhemeth Mizvah* (1437), and of a collection of *responsa.*

SIMON BEN SOLOMON DURAK (1339–after 1510), son of Solomon ben Simon, also was rabbi of Algiers.

DURAN, AGUSTÍN (1793–1862), Spanish Iiterary critic who emphasized the revival of traditional values which distinguished the Spanish romantic movement. He was horn in Madrid, Dec. 1, 1793, and became director of the national library there. He died in Madrid, Oct. 14, 1862. His edition of ballads. *Romancero general* (1828–32), the largest yet collected. and of the plays of Tirso de Molina. *Talia española* (1834; 1839–42), reinforced the claims advanced in his academy speech. *Sobre el influjo que ha tenido la crítica moderna en la decadencia del teatro antiguo español* (1828), that Spanish medieval and classical literature was more poetical and so unlike the classicism of Greece and France as to demand appreciation by different rules. (R. F. B.)

DURAN, CAROLUS (CHARLES AUGUSTE ÉMILE DURAND) (1837–1917), French painter. best known as a portrait painter and head of one of the principal ateliers in Paris, was born at Lille on July 4, 1837. He studied at the Lille academy. In 1859 he went to Paris and in 1862–70 to Italy and Spain, studying in particular Velázquez. "The Assassination" (1866) was one of his first successes. His "Lady With the Glove" (1869), a portrait of his wife, was bought for the Luxembourg museum. In 1905 he was appointed director of the French academy at Rome in succession to Eugène Guillaume. He died in Paris on Feb. 17. 1917.

DURANCE (ancient DRUENTIA), one of the principal rivers draining the French side of the Alps toward the Mediterranean. Its total length from its source in the High Alps of Dauphiné to its junction with the Rhône, a little below Avignon, is 189 mi. It takes its origin in some small lakes a little south of the Montgenèvre pass, but it has two other headstreams of much greater length and volume: the Clairée (flowing in from the north) and the Guisane (flowing in from the northwest and rising near the Col du Lautaret, 6,752 ft.). Between its junction with the Cerveyrette and the Gyronde, the Durance passes through spectacular gorges. It then runs through a stony plain where it frequently overflows and causes great damage, this being indeed the main characteristic of the Durance throughout its course. At the foot of the fortress of Mont-Dauphin and some distance above the town of Embrun, it receives (left) the Guil, which flows through the Queyras valley from near the foot of Monte Viso. It becomes the boundary between the *départements* of Hautes-Alpes and Basses-Alpes and receives (left) the considerable Ubaye river, flowing from near the foot of Monte Viso past Barcelonnette.

Flowing through Basses-Alpes, it is joined (right) above Sisteron by the wild torrent of the Buech from the desolate region of the Dévoluy and (left) by the Bléone (on which Digne, the capital of the *département,* is situated) and the Asse. The Verdon. flowing past the town of Castellane and famous for its scenic gorge. joins it from the lower summits of the Maritime Alps. After passing through some narrow gorges near Sisteron the bed of the river becomes wide and liable to flood, the frequent overflows being kept within bounds by numerous dikes and embankments. These features are especially marked when the river, after leaving Basses-Alpes, bends northwest and, always serving as the boundary between the *départements* of Vaucluse (north) and Bouches-du-RhBne (south), passes Cavaillon above its junction with the Rhône. The drainage area of the Durance is about 5.811 sq.mi. After World War II large dams were constructed on the Durance and its tributaries as part of hydroelectric-power and irrigation water-supply projects. (AR. E. S.)

DURAND, ASHER BROWN (1796–1886), U.S. painter and engraver. one of the founders of the Hudson river school of landscape painting, was born at South Orange, N.J., on Aug. 21, 1796. He worked with his father. a watchmaker; was apprenticed, in 1812, to an engraver named Peter Maverick; and his first work, the head of an old beggar after Samuel Waldo, attracted the attention of the artist John Trumbull. Duran established his reputation by his engraving of Trumbull's "Declaration of Independence." After 1835. however, he devoted himself chiefly to portrait painting. He painted several of the presidents of the United States and many other men of political and social prominence.

In 1840 he visited Europe to study the work of the old masters; after his return he devoted himself almost entirely to landscape. He was among the earliest Americans to work out-of-doors. His ability to romanticize landscapes can be seen in "Kindred Spirits" (1849), which shows his friends Cole and Bryant in a minutely detailed Catskill forest setting. He died at South Orange on Sept. 17, 1886. He was one of the founders of the National Academy of Design (1826) and was its president, 1845–61. He was a well-trained craftsman and his work is marked by sincerity.

CYRUS DURAND (1787–1868), a brother of Asher, formed a partnership with him for bank-note engraving. He invented machines for the mechanical drawing of lines which revolutionized the art.

See John Durand, *The Life and Times of Asher Brown Durand* (1894).

DURANDI, GULIELMUS (GUILLAUME DURAND, DURANTIS. DURANTI. DURANDUS) (c. 1230–1296), renowned canonist and liturgist, a churchman of vide judicial and administrative

experience, was born at Puymisson in Languedoc, and obtained the doctorate in canon law at Bologna. He taught briefly at Bologna and later at Modena. Some time after 1260 he was appointed *auditor causarum sacri palatii,* one of the judges commissioned to hear cases of appeal brought to the Holy See. At the second general council of Lyons (1274) he was one of the draftsmen of the statutes which Pope Gregory X promulgated in council; he later wrote a commentary on these *constitutiones.* In 1278, when the city of Bologna and the territory of the Romagna were incorporated into the Papal States, Durandi was one of the first group of commissioners sent there; subsequently he held various posts in the ecclesiastical and temporal administration of the new province and eventually (1283) became its governor general. In 1286 he was consecrated as bishop of Mende, in Languedoc, but took possession of his see only in 1291. At Mende he published a set of instructions and statutes for the clergy of his diocese and occupied himself with liturgical matters. In 1295 Pope Boniface VIII offered him the archbishopric of Ravenna, which Durandi declined, accepting however a new commission as *rector* in the Papal States. He died at Rome on Nov. 1, 1296.

The fame of Durandi as a writer rests chiefly on his *Speculum iudiciale* (first published between 1271 and 1276, revised and reissued *c.* 1289–92), an encyclopaedic treatise of canon law (and, to some extent. civil law) under the aspect of court procedure. The book remains valuable for the information it provides on the judicial practice of the medieval church courts, especially of the Roman curia. Of all his writings on canon law, this book was so universally known in the later middle ages that Durandi was often referred to simply as "the speculator" rather than by name. Of his liturgical works, the *Rationale divinorum officiorum* (*c.* 1286–91) is a general treatise on the liturgy and its symbolism, considered the most important medieval book on divine worship. The *Speculum* was printed at least 39 times between 1473 and 1678, and the *Rationale* even more often (over 40 editions from 1459 to 1500 alone). As bishop of Mende, Durandi undertook a revision of the *Pontificale Romanum,* the book of ceremonial directives and prayers to be used in the liturgical functions of bishops and prelates; this became the model for the official Roman text of the *Pontificale* published by Pope Innocent VIII in 1485.

See L. Falletti, "Guillaume Durand," in *Dictionnaire* de *Droit Canonique,* vol. v, cols. 1014–7j (1953), with full bibliography.

(S. G. K.)

DURANDUS OF ST. POURÇAIN (*c.* 1270–1334), French theologian and scholastic philosopher, was born at St. Pourçain, in the Auvergne. He entered the Dominican order and studied at Paris, where he received the doctorate in 1313. Shortly afterward Clement V summoned him to Avignon as "master of the sacred palace," in effect theological lecturer to the papal curia. He became successively bishop of Limoux (1317), of Le Puy (1318) and of Meaux (1326). He was known in the schools as *doctor resolutissimus,* and was especially famous for the hardihood with which he attacked the teachings of Thomas Aquinas at a time when Thomas was already accepted as the official doctor of the Dominican order. Durandus taught that a philosopher should prefer the conclusions of his own reason to any authority, except in articles of faith; the acceptance of truths of faith: on the other hand, did not depend on reason at all. He differed from Thomas on the problem of universals, preferring a solution closer to the nominalism of William Ockham; on the relation of divine causality to human free will; on the nature of the act of perception; and on sacramental theology (Durandus held that, while an infusion of grace accompanied the reception of a sacrament. the sacrament itself was not the direct cause of the grace received). Some of his teachings on the Beatific Vision were condemned by a pontifical commission in 1333. His major works are a commentary on the *Sentences* of Peter Lombard (1508) and the *De origine potestatum et iurisdictionum* (1506). Durandus died in 1334.

See J. Koch, *Durandus de S. Porciano O.P.* (1927); **E.** Gilson, *History of Christian Philosophy in the Middle Ages* (1955).

(B. TY.)

DURANGO, a state in north central Mexico, bounded north by Chihuahua, east by Coahuila and Zacatecas, south by Jalisco and Nayarit, west by Sinaloa, with an area of 47.691 sq.mi. Pop. (1960) 750.220. including fewer than 600 Indians. Rainfall in the eastern sections is sparse and agriculture depends exclusively on irrigation; stock raising and minor forest industries are carried on in the west. Coursing eastward from the Sierra Madre Occidental, the Nazas river, the largest in the state, flows for approximately 373 mi.; when swollen by spring rains it is the main source of water permitting commercial crops of cotton, wheat, maize, tobacco, sugar cane, vegetables and fruits. Durango shares with Coahuila the famous Laguna cotton district, a large co-operative enterprise.

The state is rich in minerals and mining has traditionally been a principal mainstay. Silver, gold, sulfur: tin, coal, cinnabar, antimony, copper and other valuable deposits exist, only partially exploited. A colossal helmet-shaped hill 700 ft. high of nearly pure iron, known as Cerro del Mercado, rises 2 mi. from the capital. Durango city. The hill is estimated to contain between 300,000 and 600,000 tons of hematite in various stages of oxidization, forced out by ancient volcanic action. It supports the iron and steel works near by. The Candelaria mine (argentite) is famous for its prodigious output and purity of ore. Other mining districts are Mapimí, a great arid depression 130 mi. N.N.E. of Durango city; Cuencamé; Nombre de Dios (first Spanish. settlement, c. 1555): Papasquiaro; and San Juan del Río. Inadequate transportation has hampered development of mineral resources. National Railways of Mexico lines traverse the state northeast to southwest, and another line crosses its eastern parts. The state is also crossed by two branches of the Pan-American highway and has air routes.

Originally explored by Francisco de Ibarra (1562–63), Durango shared the colonial history of Chihuahua as major parts of the realm of Nueva Vizcaya; the two became sovereign and separate states in 1823. At frontier zones, they were plagued by Indian uprisings until late in the 19th century. (HD. C.; J. A. CW.)

DURANGO (VICTORIA DE DURANGO), capital of the state of Durango, Mexico. Pop. (1960) 94,257. It lies 614 mi. N.W. of the federal capital on the main trunk highway to the U.S. border at Ciudad Juárez-El Paso, Tex., and on the Transoceanic highway from Matamoros to Mazatlán. At an altitude of 6,314 ft. it dominates the picturesque and fertile Guadiana valley formed by the eastern spurs of the Sierra Madre. Its climate is mild and healthful and a famous thermal iron water spring is found nearby. An outstanding feature is the Cerro del Mercado north of the city; it is a solid hill of iron that represents one of the world's largest deposits.

Durango is an important commercial and mining centre with diversified local industries that include reduction works, cotton and woolen mills. glass works, iron foundries, flour mills, sugar refineries and tobacco factories. The first Spanish settlement was established in 1jj6 by Fray Diego de la Cadena. Durango received its formal founding in 1563 under Captain Alonso Pacheco. It was the political and ecclesiastical capital of Nueva Vizcaya, which included Durango and Chihuahua until 1823. Long an important place in northern Mexico, Durango dwindled during the 19th century but revived thereafter. (HD. C.; R. B. MCCK.)

DURANT, WILL (WILLIAM JAMES DURANT) (1885–), U.S. author and lecturer well known for his popular expositions of history and philosophy. was born on Nov. 5, 1885, in North Adams, Mass. He was educated at St. Peter's college, Jersey City. N.J., and at Columbia university, from which he received a doctorate in philosophy in 1917. Durant's early life was marked by religious conflict and political and social disillusionment; *Transition* (1927), his only novel, is largely an autobiographical account of this part of his life. In addition to writing. Durant gave public lectures and had brief teaching assignments at Seton Hall college in New Jersey. at Columbia university and at the University of California at Los Anneles.

His succeisful career as a ariter of popular books on philosophy, history and sociological problems began with the publication of *Philosophy* and *the Social Problem* (1917). His second book, *The Story of Philosophy* (1926), established Durant as an outstanding stylist of popularized historical writing; more than 2,000,000 copies were sold in less than three decades, and it was

translated into several languages. The *Reformation* (1957) was the sixth volume of *The Story of Civilization,* begun by Durant in 1932. *The Story of Civilization* and *The Story of Philosophy,* although generally regarded as falling short of the exacting standards of historical scholarship, have depicted a pageant of history, both informative and vivid, to millions of readers who enjoy these "humanized" expositions. (J. M. BK.)

DURANT, WILLIAM CRAPO (1861–1947), U.S. automobile executive. who founded General Motors corporation, was born in Boston, Mass., Dec. 8, 1861. A carriage company he established in Michigan in 1886 soon became the largest buggy manufacturing firm in the world. In 1903 he took over a small firm and soon began manufacturing Buick motor cars. He brought together a large number of automotive manufacturers in the General Motors Co., which he organized in 1908. Financial difficulties cost him control of the company in 1910, but with Louis Chevrolet (1879–1941) he established the Chevrolet Motor Co. and made a remarkable comeback. In 1916 Chevrolet acquired control of General Motors and Durant became president of General Motors. From the General Motors Co. he created the General Motors Corp. and launched a large and successful expansion program. Difficulties encountered after World War I resulted in his being again forced out of General Motors in 1920. He then formed a new enterprise, Durant Motors, Inc. His later ventures, some of which were very large, were not generally successful. He died in New York city. March 18, 1947. (H. J. SG.)

DURANTE, FRANCESCO (1684–1755), Italian composer of religious and instrumental music, known chiefly as a teacher, was born at Frattamaggiore, in the kingdom of Naples, on March 31, 1684. The details of his early life and musical education are obscure, but he probably received his training at one of the Naples conservatories, and later may also have studied in Rome. All that is known for certain is that he taught at San Onofrio conservatory for a short time in 1710. From 1728 to 1739 he was *maestro di cappella* at the Conservatorio dei Poveri in Naples, from 1742 he taught at Santa Maria di Loreto conservatory. and in 1745 he succeeded Leonardo Leo as principal teacher at San Onofrio conservatory. There was much rivalry between his pupils and those of Leo, but Durante's pupils became the more renowned. They included Niccolo Jommelli, Giovanni Paisiello, G. B. Pergolesi, Nicola Piccinni and Leonardo Vinci. Durante died on Aug. 13, 1755, at Naples.

Many motets. several masses, at least three oratorios, a Pastoral Mass for four voices and the Lamentations of the prophet Jeremiah are among his more important settings. He also composed some harpsichord pieces and eight concertante quartets for strings. (CS. CH.)

DURÃO, JOSÉ DE SANTA RITA (*c.* 1737–1784), Brazilian poet, was born in the parish of Cata Preta, near the boundary of Minas Gerais, Braz., probably in 1737, though some authorities place his birth within the years 1; 18–22. He received his early education at the Jesuit college in Rio de Janeiro, and in 1756 obtained the degree of doctor of theology from the historic University of Coimbra. Port. Two years later he entered the Gratian convent of the Order of St. Augustine. Famous already as a preacher. he offended his superiors by his liberality of thought, and particularly by his openly expressed regard for the proscribed Jesuits. In consequence he was forced to leave the country. He was detained in Spain as a spy in 1762, but was released in the following year, and then went to Rome, where he became acquainted with Alfieri, Pindemonte, Casti and other literary men of the time. In 1778 he returned to Portugal to accept the chair of theology at the University of Coimbra. and at the opening of the university for the year delivered an address in Latin, *De sapientin,* which marked him as one of the foremost intellectuals of his day. He soon retired, however. to the Gratian convent, and became its prior. In 1781 he published in Lisbon his great epic *Caramúru: poema épico do descubrimento da Bahia,* a poetic treatment in ten cantos of the discovery of Bahia (southern Brazil) by Diego Alvarez. This is one of the masterpieces of Brazilian literature, and is remarkable especially for the beauty of its descriptions of South American scenery and Indian life. Failure of the poem to command instant recognition embittered its author, and he burned most of his other works. A French translation of *Caramúru* appeared in 1829. He died in Lisbon on Jan. 24, 1784. (W. B. P.)

DURATION AND TIME are abstract terms covering a wide range of facts of experience: the fact, for instance. that one thing, state or event lasts longer or shorter than another; or that it comes so much before or after another; or that it has existed, or will exist. or actually exists. Such facts (and a great many others like them) may be called temporal facts. and the notions and expressions that are used to deal with them may be called temporal notions and expressions. The interest of such notions and expressions is that, while they function quite smoothly in ordinary talk and thought, they readily give rise to profound puzzlements when looked at from the more detached standpoint of philosophy. But while older philosophers thought that such difficulties pointed to some radical inadequacy in our temporal notions (or even to some contradiction in the nature of things!, many 20th-century philosophers, in particular those influenced by Ludwig Wittgenstein, tend to hold that most of these difficulties have their origin in a misunderstanding and abuse of the normal working of temporal notions and expressions.

Problems in Regard to the "Absolute" or "Relational" Character of Time.—A large amount of our discourse concerning temporal facts is in terms of "times." which are spoken of as if they were entities independent of the things or events which "occupy" or "are present in" them. Thus one might say that a certain time was filled with stirring events. that it was the time of the young Wordsworth and of André Chénier, etc. It also seems proper to say that a time that we pick out by means of the demonstrative adverbs "now" and "then," might quite well have been filled with other contents than the ones that actually occupied it. Furthermore there are facts of experience that would readily be described in terms of empty or unoccupied time intervals, though we should probably hesitate, on reflection, to allow them to be wholly empty. Such modes of speaking readily develop into a metaphysic of "absolute" or substantival "times," which then become the subjects of our predications of duration. succession, futurity. etc., such predications only being made derivatively of other things, inasmuch as they occupy such absolute "times." Such a metaphysic must, however, lead to unhelpful complications, since whatever can be said in terms of it can be as well said without employing substantival phrases: one might say, for instance, that Wordsworth was alive when André Chénier was alive. or that the two men were contemporaries. It is plain, further, that we can attach no meaning to the passage of wholly empty "times." nor to a difference of "times" which is unrepresented in a difference of events and their relations. Talk in terms of "times" may therefore be regarded as a misleading substitute for talk which employs adjectives, adverbs and prepositions of time: events and things then become our only seriously acknowledged subjects of temporal predications. Historically the absolute view of time is associated with Newton and his disciple Samuel Clarke, whereas its criticism is associated with the name of Leibniz.

Problems in Regard to the Division of Time.—There is hardly any definiteness, in ordinary usage. as to what may be regarded as a single state, happening or time, a length that could be covered by one application of the demonstratives "now" and "then." A word. a sentence. a course of lectures, a century, a geological age can all be said to be running their course now, to be comprehended within a single time. If, however, we consider states, happenings and times of some length, we find that they can always be split up into shorter states, happenings and times; and we find also that, as we proceed to shorter sections, we can specify positions, speeds, qualities, etc.. more precisely. The notion therefore readily arises of a strictly momentary state or time, one so short as not to admit of further division and to involve the most perfect specification of position, quality, speed. etc. Such a notion has an approach to exemplification in the temporal minimum discernible, a time which could not further be reduced without sink-

ing below the threshold of discernibility But there remains always, even in such a minimum, a suspicion of variety or diversity thus the briefest of glimpses may reveal movement It is therefore necessary to place what is strictly momentary beyond the limits of possible experience and to say, further, that every happening of some length involves an infinite number of such momentary states, none of which comes next after any other But if we treat such strictly momentary states as events in the same sense as events which take time, we are at once involved in antinomies We may wonder, for example, how events and processes which have length can be made up of states which have no length (one of the chief norries of St. Augustine—see his Confessions, book xi); or how continuous processes can be composed out of elements which are wholly disjoined from one another; or how it is possible to pass from one such momentary state to another, if one has first to pass through an infinity of intermediate states (the basic difficulty involved in the paradoxes of Zeno). Such antinomies can be removed by jettisoning the notion of a strictly momentary state, or by giving it a variable and contextual interpretation, or by replacing it by some physical minimum of duration nhich is not strictly momentary. One may also remove it by interpreting moments in terms of the "abstractive sets" of A N. Whitehead; *i e*, infinite classes of events fitting into each other in Chinese-box fashion and not converging to any minimal event. although their properties converge to a limiting definiteness. One may also deal with it after the fashion of Henri Bergson (*q.v*), who distinguishes duration, or time as it is actually "lived through," from time abstractly conceived as a series of discrete instants or moments: with duration, "the past gnaws into the future and swells as it advances" (Creative Evolution, Eng trans 1912), whereas time abstractly conceived breaks itself up into a series of cinematographic "stills" The former is also the datum of an undistorting "intuition," whereas the latter represents an attempt, on the part of a measuring and merely practical intelligence, to assimilate time to space.

Problems in Regard to the Temporal **Modalities.**—Very severe difficulties have arisen in regard to the temporal modalities of futurity, presentness and pastness, as well as with the passing of events out of one of these categories into another. We have to use a future tense for speaking of events and times that follow the occasion of speech, a present tense for speaking of events and times that overlap it and a past tense for events and times that precede it. Noreover, our reference of events to these several categories constantly changes and may even change within the limits of a single experience (as when we watch a horse coming up to passing, and going on beyond the winning post) The fact. however, that what can at one time be spoken of in a present tense must at other times be spoken of in a past or in a future tense readily assumes the appearance of a contradiction. and this appearance has led to many philosophical rejections of change, culminating in the ingenious arguments of J. M E McTaggart These, in attempting to show that there is an irremovable contradiction in attributing futurity. presentness and pastness to the same event (because the times in which it shares in these modalities themselves change in temporal modality), really only bring out the impossibility of fitting changing temporal modalities into a scheme of speech which assumes that what is true at one time must also be true at every time. The many difficulties connected aith changing temporal modalities have led to views nhich regard them as "representing nothing in the facts" and as reflecting only the irrelevant standpoint of the speaker; they have also Icd to attempts to state the same facts in various unchanging tenseless forms of speech. It may be objected to all such schemes that the distinctions represented by the temporal modalities are so all-important for knonledge and practice—we cannot for instance give a satisfactory sense to the notion of controlling the past and perhaps not to that of completely foreseeing the future—that nonsense is likely to result if they are obscured in our language

For the questions about time raised by modern physical theory see SPACE-TIME

DURAZNO, a department bounded by the Negro and Yi rivers in central Uruguay. Pop. (1954 est.) 110.729; area 4.710 sq.mi. Mostly ranching country, in the early 1960s there were more than 500.000 cattle and 2,000,000 sheep in the department. Many of the ranches are huge, critics say excessively large. Agriculture is limited; some cereals and forage crops are grown. The departmental capital, Durazno (San Pedro de Durazno; population [1954 est.] 23,200), is a commercial and livestock-trading centre. (M. I. V.)

DURAZZO, the Italian, and conventional, form of the name of the principal seaport of Albania. DURRËS (*q.v.*). The Albanian name is now internationally recognized. It derives from the name Dyrrachium given by the Romans to the existing port of Epidamnus. founded by Greeks in the 7th century B.C.

D'URBAN, SIR BENJAMIN (1777–1849), British general and colonial administrator, chiefly remembered for his controversial frontier policy in South Africa. He entered the army in 1793 and saw varied service in the Napoleonic Wars. In the Peninsular War he distinguished himself as quartermaster general to Lord Beresford. In 1820, when he had attained the rank of major general, he was appointed governor of Antigua. There. and at Demerara and Berbice. where he was transferred as governor in 1824. Sir Benjamin seems to have assimilated the planters' views in the matter of slave amelioration and emancipation. In 1831 he became the first governor of the newly formed colony of British Guiana.

D'Urban arrived at the Cape of Good Hope (*q.v.*) as governor and commander in chief in Jan. 1833. Instructed by the colonial office. then under the influence of the humanitarians. to devise a new policy for the eastern frontier, the governor found the situation complicated by the beginnings of the Great Trek. the organized exodus of Dutch farmers away from the eastern districts of the colony. He also had to put into operation a new crown colony constitution for the Cape and supervise the local application of the Slave Emancipation act. In Dec. 1834 there began the most serious incursion of the colony by the Xhosa which had yet occurred in the course of the so-called Kaffir Wars. With the assistance of Col. (later Sir) Harry Smith. D'Urban expelled the invaders and in May 1835 annexed to the crown. as the province of Queen Adelaide, the region between the Keiskamma river (which was near the existing colonial boundary) and the Great Kei, threatening to expel the tribes "for ever" beyond the latter river. As this proved impossible of execution, Sir Benjamin produced four months later a revised settlement, allowing the natives, under certain conditions. to remain in the territory. D'Urban postponed communicating this revision to Lord Glenelg. the colonial secretary, who, having had to rely for information mainly on missionary sources, caused the abandonment of D'Urban's annexed province in 1836, to the disgust of white farmers in the vicinity. Recalled in May 1837, the governor finally vacated his office in Jan. 1838. He had been popular with the colonists. but the dilatoriness and lack of clarity of his dispatches to England vitiated his work.

In 1847, as lieutenant general. D'Urban assumed command of the imperial forces in Canada. He died at Montreal on May 25, 1849. Durban, the chief seaport of South Africa, is named after him. (L. M. Y.)

DURBAN, the chief seaport of the Republic of South Africa. is the largest city in the province of Natal and the third largest in southern Africa It is situated on the southeast coast overlooking the Indian ocean. 1.094 mi E.N E. of Cape Town by road and 7019 nautical miles from London by the west-coast route (7,785 nautical miles via Suez). City pop. (1961) 655,370 1194,276

Europeans). Warmed by the south ard Mozambique current and within 30° of the equator, Durban has a subtropical climate. The mean annual temperature is 69° F. with comparatively small daily and annual ranges. The mean temperatures for July and January are 61.9" and 74.7°, with a mean minimum of 43.7" for July and a mean maximum of 87.3" for January. In the winter season (especially May to August) the climate is brisk and sunny; the summer months are hot and humid. Of the average annual rainfall of nearly 40 in. only about 30% falls in the six months from April to September; the annual average of rainy days is 117.

Situated between the Gmgeni and Umlaas rivers, the city stands on alluvial ground which rises inland to 400–500 ft. at the Berea ridge. On the south a green-clad sandy ridge called the Bluff separates the sea from the harbour bay, a roughly circular expanse of former lagoon 6 sq.mi. in area. Northward the Bluff is separated by a 600-ft. entrance channel from the Point, a low sandspit which is chiefly a dock area. The main business area is laid out north and northwest of the harbour. Along the ocean frontage behind lawns and ornamental gardens stand modern hotels and blocks of flats, with open sandy bathing beaches stretching northward to the Umgeni. Durban is a favourite holiday resort of South Africans and Rhodesians.

The main thoroughfare is West street, named after the first governor of Natal and running inland from the Marine parade. Parallel to it is Smith street and between the two stands the handsome domed city hall with library, art gallery and museum. Nearby are the new government buildings and the general post office, which was formerly the town hall. There, in 1908–09, was held the national convention which led to the Union of South Africa. To the north of the city hall are the main railway station and the Old Fort (1842) and beyond them the Greyville racecourse on which is held South Africa's premier horse race, the July handicap.

On the Esplanade fronting the north shore of the harbour stand the law courts. In St. Andrew's street the Natal Settlers Old House museum is a replica of an early homestead that stood on the site. A short distance northward is the Gothic-style Roman Catholic cathedral, beyond which lie the colourful Indian and Bantu markets. The belt at the foot of the Berea is occupied largely by Asians and the buildings show oriental influences.

The central residential area for Europeans is the Berea, where pleasant houses with shaded *stoeps* stand along tree-lined roads. In 1961 large housing projects for the nonwhite population, including the 18,000,000-rand Kwa Mashu township for Bantus, were in course of construction. Durban is known to South Africans as "the garden city" and its flowering trees are a striking feature—red flamboyant, blue jacaranda, yellow cassia and rich scarlet Kaffir boom. Parks and open spaces include the Medwood gardens opposite the city hall and Albert park overlooking the harbour. The Snake park near the sea front contains many kinds of snakes in near natural conditions. The Ocean aquarium (1959) contains an outstanding collection of Indo-Pacific fishes and of sharks, rays and skates. On the Berea are Jameson and Mitchell parks, with aviaries and indigenous trees in which monkeys are often seen and the 50-ac. botanical gardens with a herbarium and a fine collection of trees, ferns and palms.

The University of Natal is established in Durban and Pietermaritzburg 156 mi. N.W.). Its faculty of medicine in Durban trains nonwhite students. Attached to the university are various research institutes. There are primary and secondary schools.

Communications, Trade and Industry.— Bus services connect the city with the suburbs and with Pietermaritzburg. Durban is linked with all parts of South Africa by railway and by national highways. The Louis Botha international airport is at Reunion, 8 mi. S.

Durban is the only port on the coast between East London and Lourenço Marques in Mozambique and is the nearest in the republic to the mining and industrial regions of the Rand and northern Orange Free State. The port has more than 30.000 it. of quays with fueling facilities and modern appliances, especially for bulk cargoes (grain. coal, fertilizers. fuels). and a separate fish wharf. A number of powerful tugs are equipped for salvage. There are ship-repair facilities and a 4,000-ton floating dock as well as a large dry dock. Cargo handled annually amounts to more than 8,000,000 tons. The main exports are ores and minerals, grain, sugar, coal: wattle bark, wool and hides; the main imports, petroleum fuels, general cargo, timber and grain.

Industrial development increased rapidly after World War I and by 1960 the gross manufacturing output exceeded 400,000,000 rands (£200,000,000) annually. Durban is the headquarters of the South African sugar industry and has important manufactures of textiles, soap, rubber, fertilizers, paint and food products. Oil refineries are situated on the Bluff, which also has a whaling station. The railway workshops employ more than 4,000 workers.

History.--What is now Durban bay was named Fort Natal by Vasco da Gama because he sighted it on Christmas day, 1497. Following a visit by the brig "Salisbury" seeking shelter from a gale in 1823, a landing was made in 1824 by Francis G. Farewell, John S. King and Harry Francis Fynn, accompanied by a band of pioneers who formed the nucleus of Natal colony. Farewell secured the cession of a strip of coast from the Zulu despot Chaka, who in 1828 made a further cession which included the present site of Durban. There followed a troubled period in which the tiny settlement was gradually consolidated as a British outpost. In 1835 it was visited by the missionary and former naval officer Allen Francis Gardiner, who intended to conduct a mission to the Zulus; its white population was then about 35. On June 23 Gardiner presided over a meeting of 15 settlers which decided to lay out the streets of a town to be named after Sir Benjamin D'Urban, governor of Cape Colony.

Durban grew and prospered despite troublks with the Zulu leader Dingaan and quarrels between the British and the Trek-Boers. The Boers proclaimed the area the "Republic of Natalia" and in 1842 besieged the British garrison of about 300 men under Capt. T. C. Smith in the Old Fort. Dick King, one of the settlers, escaped from the fort and with a Zulu outrider rode 600 mi. in ten days to fetch help from Grahamstown; he is commemorated by an equestrian statue on the Esplanade at the foot of Gardiner street. Natal was proclaimed British territory in 1843 and Durban was granted its seal of incorporation as a borough in 1854; in 1935 it was created a city. *See* also NATAL. (P. R. Su.)

DURBAR (Persian and Urdu, DARBAR), a term used in India for a court or levee. A durbar may be either a council for administering affairs of state or a purely ceremonial gathering. In the former sense the Mogul emperors of India received visitors and conducted business in durbar. In the latter sense the word came to be applied to great ceremonial gatherings like Lord Lytton's durbar for the proclamation of the queen empress in India in 1877 or the Delhi durbar of 1911, held to celebrate the accession of George V.

DÜREN, a town of Germany which after partition of the nation following World War II was included in the Land (state) of North Rhine-Westphalia of the Federal Republic of Germany. It lies on the Rur, on the northwestern slopes of the Eifel hills, 37 km. (21 mi.) W.S.W. of Cologne by road. Pop. (1950) 35.234; (1959 est.) 47,094. Destroyed in World War II, the town has been largely rebuilt. It produces paper, metal goods, cloth, carpets, felt, glass, sugar and chemicals, exported throughout the world.

Düren, a Frankish settlement first mentioned in 748, grew from Pepin's Villa Duria. Charlemagne held diets and church assemblies there and it was the base for several of his Saxon campaigns. Fortified about 1200, it became a free city. The emperor Frederick V gave it in pledge (never redeemed) to the dukes of Jülich. In 1543 it was destroyed in a war between Duke William V of Jülich and Emperor Charles V and later rebuilt.. (J. E. G.)

DÜRER, ALBRECHT (1471–1528), the greatest German Renaissance painter, engraver, woodcut and decorative designer as well as author of a number of theoretical works, was born in Nurnberg on May 21, 1471. He was the second son of the goldsmith Albrecht Durer, the elder (1427–1502), who had left Hungary to settle in Nürnberg in 1455.

Durer began his training in the goldsmith's workshop of his father, who in 1486 sent him for four years to the painter and

woodcut illustrator Michael Wolgemut. His years as a journeyman from 1490 to 1495 probably took the young artist first to the Netherlands and then in 1492 to Colmar in Alsace. There he found that Martin Schongauer, the leading German graphic artist of the time, was no longer alive; however, several of Durer's drawings from the time immediately preceding his travels bear signs that he had already seriously studied the work of Schongauer. In the same year, 1492, Durer went to Basel; during 1493 or 1494 he was for a short time in Strasbourg, returning again to Basel. At the end of May 1494 he returned to Nurnberg, where on July 7, 1494, he married Agnes Frey, the daughter of a merchant. There were no children of this marriage, and Agnes died on Dec. 28. 1539. In the autumn of 1494 Durer seems to have undertaken his first voyage to Italy, where he remained, mostly in Venice, until the spring of 1495.

Between 1494 and 1496 Durer produced a large number of drawings. mainly based on engravings from northern Italy, with which he may have been acquainted already before this journey to Italy. Some are based on Andrea Mantegna (Winkler 59, 60; 1494, Vienna); 20 follow the so-called Tarocchi di Mantegna (Venetian engravings from about 1460 based on Ferrarese drawings; W 122–141), which had already been used by Durer's teacher Wolgemut. The "Dying Orpheus" which originated from one of the Tarocchi engravers inspired Durer to a free re-creation (drawing of 1494 in Hamburg, etching Bartsch 73). Among the masters from central Italy, apart from Lorenzo di Credi (drawing, 1495, in the Louvre, Paris, W 84), it was Antonio Pollaiuolo who interested the young Durer most. He copied this artist's "Rape of Women" (1495, Bayonne, W 82) and freely adapted his Hercules from the "Rape of Deianira" (New Haven, Conn.) for his painting of "Hercules and the Birds of Stymphalis" of 1500 (Niirnberg). In the Job from the Jabach altarpiece one finds echoes of Giovanni Bellini! while the centre panel from the Dresden altarpiece (1498?) betrays Lombard influences (Bramantino).

Eleven years later, in the autumn of 1505, Dürer again went to Italy. where this time he remained until the spring of 1507. Once again he spent most of his time in Venice. Of all the Venetian artists, he most admired the old Giovanni Bellini (letter to W. Pirkheiiner of Nov. 7. 1506), and the pictures of men and women from this Venetian period reflect the portrait types specially favoured by Bellini, while the compressed half-length composition of the "Young Jesus With the Doctors" of 1506 (Rome) harks back to Mantegna's "Presentation in the Temple" (Berlin). which Bellini had freely recreated. Those works of Durer which clearly grew out of recollections of Italian models that particularly impressed him during this second visit to Italy mainly point in the direction of Mantegna and Bellini.

"The Assumption of the Virgin," the centre panel from the Heller altarpiece of 1509 recalls Mantegna (compare with the "Transfiguration of the Virgin Mary" from S. Agostino degli Eremitani in Padua, which, according to K. Gerstenberg. also inspired Diirer's woodcut B 88 from the "Life of the Virgin," depicting a man clasping a pillar). Echoes of Venetian triptychs (compare in particular the altarpieces by B. Vivarini and Giovanni Bellini of 1487 and 1488 in the church of the Frari at Venice) can be found in the side panels, each depicting two saints. from Durer's Jabach altarpiece (Munich, executed by H. L. Schaufelein?). in the grisailles from the Heller altarpiece (Frankfurt, executed by Hans Durer?) and in the so-called "Four Apostles" of 1526 (Munich). Toward the end of his second Italian journey Durer, according to F. Winkler, spent a further two or three weeks in Ferrara and Bologna, where the works of Cosimo Tura and Marco Zoppo impressed him most strongly.

By Feb. 1507, at the latest, Durer was back in Nurnberg. Between 1512 and 1519 he worked mainly for the emperor Maximilian I. and from 1515 he received a fixed yearly salary of 100 guilders from the court. In the same year Durer and Raphael exchanged works.

Between the summer of 1520 and that of 1521 Durer. with his wife, traveled along the Rhine and through the Netherlands, arriving in Antwerp on Aug. 2, after which he visited Brussels, Mechelen and Aachen, where, at the coronation of Charles V on Oct. 23, Durer met Matthias Grünewald and presented him with several etchings. Durer returned to Antwerp via Nijmegen and Cologne, remaining there until the summer of 1521. He maintained close relations with the leaders of the Netherlands school, Lucas van Leyden, Quentin Massys, Jan Provost and Bernaert van Orley, all of whom received him magnificently. In Dec. 1520 Durer visited Zeeland. and in April 1521 he traveled to Bruges and Ghent, where he saw the works of the brothers van Eyck, of Rogier van der Weyden and Hugo van der Goes, as well as the Michelangelo Madonna.

On July 12 the travelers were back in Nurnberg and, from this time onward, Durer's health began to decline. He devoted his remaining years to theoretical writings and on April 6, 1528. he died and was buried in the churchyard of St. John in Nurnberg.

Durer's earliest known work is his self-portrait at the age of 13, now in Vienna (silverpoint drawing. 1484). After this talented youthful drawing comes the composition of a "Madonna With Angels" of 1485 (pen drawing, Berlin) which is already a finished work of art in the late Gothic style. The drawing of Diirer's father, in Vienna. can be dated 1486, and in 1490 comes as his earliest painting the portrait of his father, now in Florence, which heralds the familiar characteristic style of the mature master. Against this, the first authenticated woodcut of "St. Jerome in the Wilderness," which appeared in Basel in 1492, seems somewhat ungainly and archaic. Among the Basel book illustrations which later research has ascribed to the young Durer (the "Comedies of Terence"—drawings on wood blocks; "The Knight of Thurn," 1493. and "The Ship of Fools," 1494—woodcuts) there can be found certain stylistic affinities with the authenticated, and in general more mature, drawings from the years 1493–95. **An** early masterpiece is the self-portrait with thistle painted on parchment in 1493 (Paris). Several small religious paintings (in Dessau and Karlsruhe) also belong to the period of Durer's travels. A number of bold water colours dealing with subjects from the Alps of the southern Tyrol are generally linked with Diirer's first journey to Italy in 1494–95, though one or two of the aquarelles may well refer to the second Italian journey of 1505–07.

Between 1495 and 1500. certain stylistic vacillations still remained to aggravate the task of assigning dates and authorship to Durer's works. A number of important paintings are known in copies only. such as the portrait of Durer's father (copies in Munich. Syon house, near London and Frankfurt); another is a "Girl in Prayer" (Augsburg. Frankfurt; variant in Budapest) and a "Portrait of a Young Girl" (Luzschena, Paris) which are all supposed to portray a member of the Nurnberg family of Furleger. On the model of the "Girl in Prayer," there is also an original tempera by Durer (Bibliothèque Nationale, Paris). Considerably more rigid and archaic than this last is the portrait of Federick the Wise in Berlin, which must have been painted about 1496. A year later. Durer painted another self-portrait (now in Madrid). The much more expressive Dresden altarpiece is generally also ascribed to about 1498 and it is difficult to reconcile this with the "Lamentation of Christ," painted for the Holzschuher family (Niirnberg): which by some scholars is also ascribed to the year 1498. On the other hand, stylistically equal with the Dresden altarpiece is the "Hercules and the Birds of Stymphalis," as well as a number of mostly early copperplate engravings (among them the "Prodigal Son," B 28; the "Penitence of St. Chrysostom," B 63; the "Eumenides." B 75, dated 1497; the "Dream," B 76; the "Sea Monster," B 71; "Hercules," B 73, and "St. Eustace," B 57). In 1498, beside some individual woodcuts, Durer completed his first great cycle of woodcuts, the "Apocalypse," to the 15 pages of which he added a title page in 1511. At the same time he began the cycle of the "Great Passion." completing the first five pictures in 1499 and the remainder in 1510.

Not until 1500 did Durer's restless striving find a definite direction. Firm ground is achieved in the penetrating half-length portraits of Oswolt Krell (Munich), in the three members of the Tucher family (Weimar and Kassel)—all dated 1499—and in the "Portrait of a Young Man" of 1500 (Munich). In the same year Durer painted a new self-portrait (Munich), which in its austere and completely symmetrical full-face position doubtless recalls

memories of Italy. The two engravings B 96 and B *9i* (1505) show Durer recalling Italian equestrian statues—a horse in exact profile and another seen from the rear—a favourite subject of the early Italian Renaissance. In the engraving "Adam and Eve" (1504) Durer expresses the essence of his classical experiences. The grisailles of the "Green Passion," notable for their large-scale composition (Vienna and Florence) and the opening pages of the "Life of the Virgin," the most supple of his graphic cycles, also belong to this period.

Among paintings which should be ranked with these classical endeavours are the Paumgartner altarpiece, the symmetrical, pyramidal construction of the "Glimm Lamentation" (both in Munich) as well as the "Altar of the Three Kings," executed with the help of pupils (Florence, Frankfurt, Cologne. Munich; reproduction in its entirety by H. Musper, 1952, p. 146).

In Italy, Durer painted among other things the formal and magnificent "Festival of the Rose-garlands" for the church of St. Bartholomew (1506, Prague), the "Virgin With the Siskin" in a similar vein (Berlin) and the more expressive Mantegna-like "Young Jesus With the Doctors," three charming portraits of women (Berlin and Vienna) and two heads of youths (Hampton court. London and Vienna) in the Venetian style.

Among the paintings belonging to the period after the return from Italy, the "Martyrdom of the Ten Thousand," painted for Frederick the Wise in 1508 (Vienna), and the "Adoration of the Trinity." apparently inspired by the peak of Italian Renaissance, 1511, Vienna are both crowd scenes whose failure is in varying ways due to the intractability of the design. The problem of crowd composition is solved more successfully in the "Assumption of the Virgin" (only known through a copy) from the Heller altarpiece in Frankfurt (1508–09), which again bears signs of Mantegna's influence. The drawings for this picture betray Durer's striving after classical perfection of form through sweeping lines of drapery of graphic simplicity and plastic firmness. Even greater simplicity and grandeur characterize the disputed "Madonna With the Iris" (traditionally dated 1508; examples in London and Prague), the diptych of "Adam and Eve" (1507, Madrid with a variant in Florence) and the "Holy Family," in half-length figures painted in 1509 and reminiscent of Mantegna (Vierhouten).

Between 1507 and 1513 Durer completed the "Passion" in copperplate engravings, and between 1509 and 1511 the "Little Passion" in woodcuts, both of which are characterized by their tendency toward spaciousness and serenity. During 1513 and 1514, Durer created the greatest of his copperplate engravings, the "Knight, Death and the Devil," "St. Jerome in his Study" and "Melancolia." To the same period belongs Durer's most expressive portrait drawing—that of his mother (Berlin).

The marginal drawings for the prayer book of the emperor Maximilian (Besançon) and a number of etchings in iron done between 1515 and 1518 proclaim Durer's complete mastery of the medium as well as his freedom of imagination. These improvisations form a pleasing contrast to the monumental woodcuts. overloaded with panegyrics, made for Maximilian: the "Triumphal March" of 1515 which, according to M. J. Friedlander, was completed by Hans Springinklee to Durer's specifications, and the "Triumphal Car," which appeared in 1522. Beside a number of formal show pieces ("Lucretia," 1518, in Munich, two portraits of the emperor, 1519, in Nürnberg and Vienna. also as woodcuts B 153, 154), there also belong to the second decade a number of more improvised paintings of considerably greater charm.

The sketchbooks of the Netherlands journey of 1520–21 contain immensely detailed and realistic drawings. Some paintings which were created either during the journey or about the same time seem spiritually akin to the Netherlands school, such as the portrait of Anna Selbdritt (New York), a half-length picture of St. Jerome (1521, Lisbon) and the small portrait of Bernaert van Orley (Dresden). These are followed by a succession of famous character portraits, such as the following paintings: Hans Imhoff (W. Pirkheimer. Madrid). an Unknown Man (1521, Boston) Hieronymus Holzschuher, Jacob Muffel (both dating from 1526, Berlin), and some important portrait engravings and woodcuts.

"PORTRAIT OF THE ARTIST'S MOTHER." A CHARCOAL DRAWING BY ALBRECHT DURER. IN THE MUSEUM DAHLEM. BERLIN

The so-called "Four Apostles" (St. John. St. Peter, St. Paul and St. Mark) of 1526 in Munich must be counted as the last of Diirer's important paintings.

Among Durer's various scientific drawings and engravings, the woodcuts such as B 151 and 152 are commissioned works. The two woodcuts B 137 I and II belong to the sketches which Diirer made for his own *Treatise on Fortification (M.* Thausing). Among Durer's theoretical writings, his *Treatise on Mensuration with the Compasses and Ruler in lines, planes and whole bodies* first appeared in Nürnberg in 1525. *The Treatise on Fortification* appeared in Nurnberg in 1527 under the title *Instruction on the Fortification of Cities, Castles and Towns* with a woodcut illustration. The *Treatise on Proportions* ("herein are comprised four books on Human Proportion") with woodcut illustrations B 146 and 147 (1525) appeared in Niirnberg posthumously in 1528.

D'URFEY, THOMAS (*c.* 1653–1723), English dramatist! satirist and writer of songs, some of which remained popular until the 19th century, was born in Devonshire, possibly at Exeter,

and is believed to have been related to Honoré d'Urfé, author of the famous pastoral romance *L'Astrée*. His first comedy, *Madam Fickle* (produced 1676), won the favour of Charles II, whom he also entertained as jester and singer, and 11 of his comedies were produced in London between 1677 and 1688. In 1689 he wrote an epilogue for Purcell's *Dido and Aeneas* and during 1690–91 edited a satirical weekly, *Momus Ridens*. In 1691 he produced *Love for Money*, a comedy anticipating the style of Colley Cibber. He had a light touch in dealing with topical subjects in satirical verse directed against the Whigs and was patronized by the nobility and, more cautiously, by James II. He changed his allegiance on the accession of William and Mary, by whom he was also favoured, and delighted Princess Anne with a poem maliciously satirizing the aged electress Sophia, her rival as heir to the throne. His last play to be produced was *The Modern Prophets* (1709), for which Pope wrote a prologue. He died in London, where he was buried on Feb. 23, 1723.

Tom D'Urfey was an attractive person despite his grotesquely exaggerated features and the stammer which he overcame only when singing or swearing, and was a friend of Addison, Steele and many other writers and musicians. Of his 32 plays, the best were the comedies. in which crowded. complicated plots are carried forward by lively dialogue, and which sometimes anticipate 18th-century sentimental comedy. He also wrote nearly 500 songs, several of which were incorporated in contemporary ballad operas. John Blow, John Eccles and Jeremiah Clarke were among the many composers who set his words to music. He wrote texts for works by Purcell, notably the ode, "The Yorkshire Feast Song," and Purcell wrote incidental music for eight of his plays.

BIBLIOGRAPHY.—D'Urfey's hrst collection of songs was *A New Cotlection of Songs and Poems* (1683) ; later songs were collected in the first 2 vol. of the 5-vol. *Songs Compleat, Pleasant and Divertive* which he edited in 1719. C. L. Day, *The Songs of Thomas D'Urfey* (1933) includes a biography. *See* also R. S. Forsythe, *A Study of the Plays of Thomas D'Urfey (1916)*; C. L. Day, *Dates* and *Performances of D'Urfey's Plays* (1950).

DURFORT, a French noble family that rose to great distinction in the 17th and 18th centuries. Bearers of the name are recorded from the 11th century, but it is uncertain whether the original seat was Durfort near Narbonne or Durfort in Quercy. Durfort in Quercy, however, was the seat of ARNAUD DE DURFORT (fl. 1305). This Arnaud married a niece of Pope Clement V, from whose brothers his descendants inherited much property, including the fief of Duras. GAILLARD IV DE DURFORT (d. 1487), of the fifth generation after Arnaud, went to England in 1453 and became a knight of the Garter but returned to France in 1476.

GUY ALDONCE I DE DURFORT (1605–65), marquis de Duras, of the fifth generation after Gaillard. married Élisabeth de La Tour d'Auvergne, the marshal de Turenne's sister. Of their eight sons. three became famous: JACQUES HENRI I (*c.* 1625–1704), marshal of France in 1675 and duc de Duras in 1689 (he is known as the marshal de Duras); GUY ALDONCE II (1630–1702). comte de Lorges, marshal of France from 1676 and duc de Quintin from 1691. who commanded the army in Germany from 1690 to 1695 (the marshal de Lorges); and LOUIS (d. 1709), who made his name in the English service. becoming earl of Feversham in 1677.

Jacques Henri's second son. JEAN BAPTISTE (1684–1770), duc de Duras. became marshal of France in 1741, as did his son and successor. EMMANUEL FÉLICITÉ (1715–89). in 1775. The latter's grandson AMÉDÉE BRETAGNE MALO (1771–1838), duc de Duras from 1800. married Claire de Kersaint (d. 1828), who was prominent in the literary world under the Restoration. As they had no sons. the Duras title passed to their son-in-law, Henri Louis de Chastellux.

GUY NICOLAS (1683–1758), son of the marshal de Lorges, changed his title from duc de Quintin to duc de Lorges in 1706. His elder son. GUY MICHEL (1704–73). was made duc de Randan in 1733 and marshal of France in 1768. After his death his niece's husband. JEAN LAURENT DE DURFORT-CIVRAC (1746–1826). a distant cousin descended from a grandson of Gaillard IV, succeeded to the Lorges title, which remained with his descendants in the 20th century.

DURG (DURGA, "Fort"),a town and district in the Chhattisgarh revenue division of Madhya Pradesh, India. The town, headquarters of the district, is on the South-Eastern railway about 150 mi. E. of Nagpur. Pop. (1961) 133,371 (including Bhilai). It is an important rice market. There are a college of arts and a college of science affiliated to Saugar university.

DURG DISTRICT has an area of 7.576 sq.mi. Pop. (1961) 1,885,-906. About a quarter of the district is under cultivation, and forests cover the hilly parts mainly in the northwest and southwest. In the middle of the district, 10 mi. E. of the town on the Durg-Raipur road, is Bhilai, a planned industrial township and the biggest urban centre in the district. At Bhilai is the third steel plant to be built in India under the second five-year plan (1957–61). The plant is a 1,000,000-ton project undertaken by the government of India with Soviet capital, equipment and technical assistance. Bhilai has nearly all the raw materials at hand: iron ore of excellent quality is obtained only 60 mi. to the south at Dalli Rajhara, which is approached by a railway line; water (30,000,000 to 60,000,000 gal. per day) is brought by the Tandula canal; fire clay, power and coal are supplied by the Korba coal field of Bilaspur district to the north; manganese is available in Balaghat and Bhandara districts on the west. By 1960 the third blast furnace was completed. (D. G. NA.)

DURGA, in Hindu mythology, one of the many cult titles of the wife of Shiva. Durga first appears in the epics as a name of Uma, and she may have been originally worshiped by the aborigines. Another of her manifestations is Kali (*q.v.*), and the hook-swinging rite of self-devotion is done in her honour. One of her principal festivals, as a war goddess, is the Durga-puja. Durga is pictured, in spite of her fierce nature, with a gentle face. *See* also HINDUISM.

DURHAM, JOHN GEORGE LAMBTON, 1ST EARL OF (1792–1840), English statesman who gave his name to the famous *Report on the Affairs of British North America* (1839), the "Durham report." which laid down the principles which thereafter guided British colonial policy. Born in London on April 12, 1792, he was the eldest son of William Henry Lambton of Lambton castle, Durham; his mother was Anne Barbara Villiers, daughter of the 4th earl of Jersey. Lambton succeeded to large estates when he was five years old. In 1805 he went to Eton, and in 1809 obtained a commission in the 10th dragoons (later hussars). In 1812, while still a minor, he made a runaway match with Henrietta, natural daughter of Lord Cholmondeley, whom he married at Gretna Green; she died in 1815. In 1813 he was elected to the house of commons as member for the county of Durham in the Whig interest.

In 1816 he married Louisa Elizabeth, eldest daughter of Lord Grey, and as early as 1818 he was taken into the political confidence of his father-in-law and other Whig leaders. However, Lambton belonged to the avowedly radical wing of the party with whose aims Grey had little sympathy, and when Lambton gave notice of a resolution in 1819 in favour of shortening the duration of parliaments and widely extending the franchise, he found himself discountenanced. He warmly espoused the cause of Queen Caroline. In April 1821 he made his first great speech in the house of commons on parliamentary reform, when he proposed a scheme for the extension of the suffrage to all holders of property, the division of the country into electoral districts and the disfranchisement of rotten boroughs. He was now one of the recognized leaders of the advanced liberals. forming a connecting link between the aristocratic Whig leaders and the liberals of the great towns. He supported the ministry of George Canning and. after Canning's death. that of Lord Goderich, on whose advice he was raised to the peerage in 1828 with the title of Baron Durham.

In Nov. 1830 Durham entered the Grey cabinet as lord privy seal. To ardent reformers in the country the presence in the cabinet of "Radical Jack" was a pledge that thoroughgoing reform would not be shirked by the Whigs, now in power for the first time in many years. Lord Grey gave him the task of preparing a scheme to serve as the basis of the proposed legislation. He was chairman of the famous committee of four. which met at his house in Cleveland row and drew up the scheme submitted by the government to parliament. It was Durham who selected Lord John

Russell, not then in the cabinet, to introduce the bill in the house of commons. When the deadlock between the two houses occurred over the third Reform bill (1832) he pressed on the prime minister the necessity for a creation of peers to overcome the resistance of the house of lords.

After the passing of the Reform act, Durham was sent on a difficult diplomatic mission to Russia (July–Sept. 1832). He resigned office in March 1833, ostensibly for reasons of health but in reality because of his disagreement with the government's Irish policy as conducted by Stanley (later Lord Derby; *q.v.*). In the same month he was created earl of Durham and Viscount Lambton. His advanced opinions gradually alienated the more moderate of his colleagues, and even Lord Grey often found his son-in-law intractable and self-assertive. The great banquet to Grey at Edinburgh in Sept. 1834, at which Lord Brougham (*q.v.*) made a venomous attack on Durham, touched off a dispute which raged for several weeks thereafter. The strength of Durham's position in the country was shown when a concourse of more than 100,000 persons assembled to hear him speak at Glasgow green in October. But radicalism and a difficult temper were not qualifications for Melbourne's cabinets, in which Durham found no place. He was ambassador at St. Petersburg (Leningrad) from Nov. 1835 to June 1837.

In Jan. 1838 Durham accepted the post of governor general and lord high commissioner in Canada, with the almost dictatorial powers conferred on him by an act passed in the following month by which the constitution of Lower Canada was suspended for more than two years. Having secured the services of Charles Buller as first secretary, and having appointed Thomas Turton and Edward Gibbon Wakefield (*q.v.*) to be his unofficial assistants, Durham landed at Quebec on May 29, 1838. Louis Joseph Papineau's rebellion had been quelled, but the French Canadians were sullen, the attitude of the United States equivocal and the general situation dangerous, especially in the lower province where government was practically in abeyance. Durham at once issued a conciliatory proclamation. He dismissed his predecessor's executive council and created a new and unprejudiced one. On June 28, the day of Queen Victoria's coronation, he issued a proclamation of amnesty, from which eight persons only were excepted; these were to be transferred from Montreal to Bermuda, where they were to be imprisoned without trial. Papineau and 15 other fugitives were forbidden on pain of death to return to Canada.

These proceedings were violently attacked in England by Brougham. With the exception of Lord John Russell, the ministers did not make a particularly effective defense of the public servant to whom they had promised the "most unflinching" support; the prime minister and the colonial secretary, who had signified their "entire approval," now disallowed the ordinance and allowed the passage of the Act of Indemnity, the terms of which were insulting to Durham. The latter immediately resigned, but before returning to England he put himself in the wrong by attempting a public justification of his actions. He laid his memorable *Report on the Affairs of British North Anzerica* before parliament at the end of Jan. 1839. This report, one of the greatest state papers in the English language, laid down the principles, then unrecognized, which afterward guided British colonial policy. With regard to the future government of British North America. Durham had at first inclined toward a federation of all the colonies on that continent, but as a more immediately practical policy he advised the legislative union of Upper and Lower Canada. He further urged the creation of an executive council responsible to the colonial legislature. He advised state-aided emigration on the broadest possible scale and the formation of an intercolonial railway for the development of the whole country. Meantime Durham, who almost alone among the statesmen of his time saw the importance of imperial expansion, became governor of Wakefield's New Zealand company and was thus concerned in the enterprise which forestalled France in asserting sovereignty over the islands of New Zealand. He died at Cowes on July 28, 1840.

Lord Durham's accession to supreme political power was for several years considered probable by many. His opinions were, however, too extreme to command the confidence of any considerable party in parliament. In the first Reform act, of which he was one of the chief authors, and in the famous *Report* on the principles of colonial policy he left an indelible mark on English history. His personal defects of character did much to mar the success of his career. He was impatient, hot tempered, hypersensitive to criticism, vain and prone to take offense at fancied slights, but he was also generous and unvindictive and, while he was personally ambitious, his care for the public interest was genuine and untiring.

By his first wife Durham had three daughters; by his second, two sons and three daughters. The eldest son, Charles William, the "Master Lambton" of Sir Thomas Lawrence's celebrated picture, died in 1831; the second, George Frederick d'Arcy (1828–79), succeeded as 2nd earl.

DURHAM, a county of England bounded north along the Tyne and Derwent by Northumberland, south along the Tees by Yorkshire, west by Westmorland and Cumberland, and east by the North sea. Area of the geographical county 1,015.1 sq.mi.; population (1961) 1,517,039.

Physical Features. — The northern Pennine hills in the west, reaching 2,452 ft. at Burnhope Seat, are carved from rocks of Lower Carboniferous age and Yordale facies (rhythmically alternating limestones, shales and sandstones) which dip eastward off the Teesdale dome. These rest on Lower Paleozoic slates which. however, outcrop only in upper Teesdale. The Carboniferous rocks are intruded into by basaltic sheets and dikes of the Whin Sill suite, well exposed around High Force and Stanhope. There are also numerous mineral veins which formed the basis of an ancient lead-mining industry.

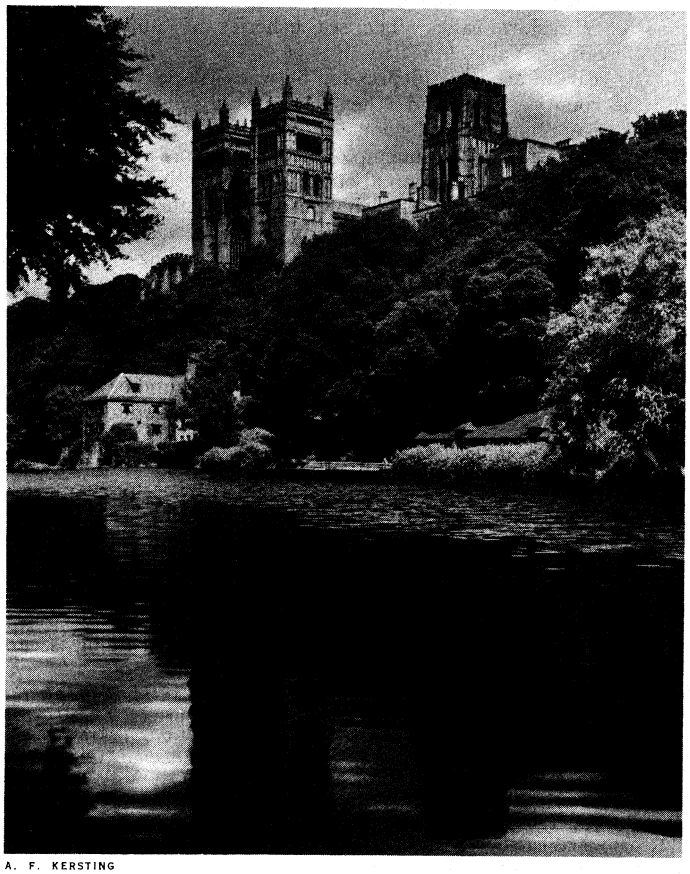
At Middleton and Wolsingham the Lower Carboniferous rocks disappear beneath Millstone Grit, replaced farther east by the overlying sandstones, mudstones and workable coals of the Coal Measures which form the central region of the county. The important east Durham coal field is partly exposed, partly concealed beneath yellow sands and Magnesian Limestone of the Permian, which make an escarpment running from South Shields to Ferryhill. The concealed basin of Coal Measures terminates southward along the Sedgefield-Hartlepool line. The low-lying southeastern part of the county is underlain by Upper Permian and Triassic rocks. A suite of Tertiary basaltic dikes associated with the Mull volcano can be seen near Egglestone and Cockfield.

Glacial deposits include boulder clay and extensive spreads of fluvioglacial sand and gravel. Evidence of Pleistocene and later changes of sea level is provided by concealed river courses like the Team Wash (the ancestral Wear), raised beaches, submerged forests and incised meanders such as the gorge nearly surrounding Durham cathedral.

The rainfall decreases sharply eastward. Temperatures are rather low; winters are cold and summers cool. In some western parts of the county frost may occur at any time of year. Spring is usually late and often extremely short.

In upper Teesdale there occur some rare flowering plants which are either confined to this area (*e.g., Viola rupestris,* the Teesdale violet; *Minuartia stricta,* the bog sandwort) or are to be found in very few other localities in the British Isles (*e.g., Potentilla fruticosa,* the shrubby cinquefoil; *Gentiana verna,* the spring gentian; *Draba incana,* the hoary whitlow grass; *Polygala amara,* the bitter milkwort).

Peat bogs and remains found in caves testify to the former occurrence of wild ox, elk, roe deer, red deer, boar and wolf. Some of these persisted until Tudor times, and the red deer re-



A. F. KERSTING

DURHAM CATHEDRAL. CHURCH OF CHRIST AND BLESSED MARY THE VIRGIN. ON THE WEAR RIVER. DURHAM. ENG.: BEGUN LATE 11TH CENTURY

mained until early in the 19th century. The black rat still maintains itself. In the 20th century the roe deer returned, with an intruder, the American gray squirrel. Similarly, after an absence. butterflies and moths such as the wall brown. the holly blue, the large skipper and the five-spot burnet re-established themselves.

History.—Evidence of early man is scarce. It would seem that the area was but sparsely populated, at least until Saxon times. Copt Hill, Houghton-le-Spring, has a barrow which shows a series of burials, the earliest of which may be Neolithic. Finds of the Bronze Age are more numerous, yet from their characteristic distribution along the river valleys, especially those of the Tyne and Wear, it may be taken that the Bronze Age invaders were more birds of passage than settlers. The Bronze Age hoard at Heathery Burn cave yielded important finds. A fine Late Iron Age sword at Barnston near Sadberge is the only evidence of Iron Age habitation.

In Roman and Romano-British times County Durham was an outpost, and the main concern of the Romans was for the safety of communications to the frontier and Hadrian's wall. Their Great North road entered the county at Piercebridge and passed through Binchester (Vinovia), Lanchester (Longovicium) and Ebchester (Vindomora) to Corbridge (Corstopitum), with a branch to Chester-le-Street (Concangium) and Gateshead (Pons Aelii) and a subsidiary branch to South Shields. There were Roman forts at Piercebridge and South Shields. The post-Roman centuries saw the county overrun by northern raiders until the Saxon settlement and the establishment of the kingdom of Northumbria. The church sites at Monkwearmouth (Sunderland), Jarrow and Escomb, near Bishop Auckland, and numerous sculptured crosses (as those at Aycliffe) are of the Anglo-Saxon period. In the 6th century Northumbria was divided into Bernicia and Deira, separated by the Tees, the latter including the district afterward known as Durham.

In the middle ages the great power exercised by the bishops of Durham as prince-bishops of a county palatine was a factor of cardinal importance in the history of the district. The origin of the palatinate goes back to an early date, certainly well before the Conquest. As early as King Alfred's time substantial grants of land had been made to the bishops, who inherited something of the prestige of St. Cuthbert (d. 687). The bishops of Durham became great feudal lords as well as ecclesiastical leaders and this, coupled with the remoteness of London and the nearness of the Scottish border, brought them political and military importance. They enjoyed great privileges—among other things the rights of holding courts of chancery, exchequer and admiralty, of appointing judges, justices of the peace, coroners and other legal officers within their diocese, of coining money in their own mint at Durham, of pardoning treasons and felonies, of holding councils similar to parliament, of granting charters to towns and of licensing fairs and markets. (All these powers would normally have been exercised by the king.) The bishops also had a great responsibility, the defense of England against invasion from Scotland. Some of them led their own armies into battle and many wielded great influence in national affairs. Between the time of the Conquest and the reign of Henry VIII about three-quarters of the bishops of Durham, including the greatest, were in fact appointed by the king, though in theory elected by the monks of Durham abbey. The palatine powers of the bishops were curtailed by the Tudors and abolished during the Commonwealth, but the palatinate was recreated at the Restoration. Many of the prerogatives were gradually lost, and the remaining powers were vested in the crown in 1836. Certain reflections of former glory still fall upon the bishop of Durham. He stands at the right hand of the sovereign at coronations (a privilege claimed and allowed on the grounds of "immemorial precedent") and takes precedence over all other bishops except those of London and Winchester.

Much of the history of Durham during, and even after, the middle ages is concerned with war. In the 13th century in particular there are repeated references to large-scale invasions of the county by the Scots, culminating in the battle of Neville's Cross, at which they were heavily defeated and their king, David Bruce, was captured. Two armed risings occurred in the 16th century. The Pilgrimage of Grace (1536) was inspired by opposition to changes being made by Henry VIII. The rising of 1569 was a struggle by adherents of the "Old Religion," always strong in the county, against the principles of the Reformation. In 1640, a breach having occurred between Charles I and the Scots. the latter, after the battle of Newburn (on the Tyne), took over the administration of the county and seized the revenues of the bishopric and the cathedral. In 1644 they were again in the county as part of the parliamentary forces.

During the 19th and 20th centuries the great change in the county was the increase in industrialization, based largely on the expansion of coal mining. Roads for the transport of coal had been introduced late in the 17th century and steam engines for draining mines early in the 18th. The first public steam passenger train in the world ran on the Stockton and Darlington railway, opened in 1825. Two well-known inventors of this period worked in the county: Sir Charles Parsons, an early inventor in the steam turbine field, and Sir Joseph Swan, who produced an electric light bulb.

Administration and Population.—The population of Durham (1951) was 1,463,868, including the county boroughs. The area of the administrative county (*i.e.*, excluding the county boroughs) is 969.5 sq.mi.; the population (1961) 953,410. The county boroughs are Darlington (pop., 1961, 84,162), Gateshead (103,232), South Shields (109,533), Sunderland (189.629) and West Hartlepool (77,073). Municipal boroughs are the city of Durham. the county town (20,484), Hartlepool (17,674). Jarrow (28,752) and Stockton-on-Tees (81,198). There are 21 urban districts and 10 rural districts. Durham is in the northeastern circuit, and assizes are held at Durham thrice yearly. There are 2 courts of quarter sessions, at Durham and Sunderland, and 18 petty sessional divisions. The county, which is in the diocese of Durham. has 274 ecclesiastical parishes and 190 civil parishes. Until 1654 the opposition of the prince-bishops prevented the return of members to parliament. The county returns one mem-

ber for each of 17 divisions. The five county boroughs and Stockton-on-Tees also return one member each, except Sunderland, which returns two.

Industries and Communications. — The agriculture of the county falls into three divisions: the western uplands. with thin soil and ill-drained peat supporting the hill sheep, the Swaledale breed predominating; the middle and lower reaches of the dales. where the traditional stock-rearing farms are found: and the lowlands in the east, lying below 500 ft.. supporting intensive milk production and cash-crop farming well suited to this urbanized area. More than half the county is under either grass (including rough grazing) or crops (oats, wheat, potatoes). The Shorthorn breed of cattle originated in Durham.

The economy of County Durham is based largely on heavy industry Of the county's working population, about one-fifth are engaged in mining and quarrving and one-eighth in engineering and shipbuilding Other important heavy industry groups include chemicals and allied trades and metal manufacture. These industries employ mostly men, but much new employment. for both men and women. was created after 1945, through the establishment of newer and lighter industries. Of these, the manufacture of electrical goods. clothing and textiles were numerically the most important.

The main concentrations of industry are on the south bank of the Tyne (South Shields, Jarrow, Hebburn and Gateshead), the north hank of the Tees (Stockton and Billingham). Sunderland on the Wear, the Hartlepools and Darlington. The coal-mining areas are scattered. and there are important industrial centres at Consett. Bishop Auckland, Chester-le-Street and Birtley. In northwest Durham the coal, mostly coking coal, is the best of its kind in the world, but most of the important seams have been extensively worked. Reserves are limited, and exist mainly in the upper seams, where the coal is gas and steam coal. In southwest Durham the position is more favourable. Measures to deal with flooding gave a new lease of life to a number of pits. In the east of the county deeper and thicker seams are found where considerable reserves still exist, particularly in undersea extensions. Other minerals which are extracted include fluorspar, barite and witherite. Frosterley marble has been quarried for many centuries. and excellent slate is found at several places.

Shipbuilding and ship repairing are the great industries of the Tyne. Wear and Tees rivers. It is claimed that Sunderland, with eight shipyards, builds more ships than any other town in the world. The yards on the "three rivers" (including the north bank of the Tyne and the south bank of the Tees) construct about two-fifths of the annual output of new tonnage in the United Kingdom and are responsible for an even greater proportion of the total repair work. Marine engineering is an important ancillary on the south bank of the Tyne, on Wearside and in the Hartlepools.

In the iron and steei industry enormous developments took place after World War II, particularly north of the Tees and at Consett. Mechanical engineering works exist at all the main centres of industry, notably the production of railway locomotives at Darlington and mining machinery at Gateshead. The expanding electrical engineering industry is centred on Tyneside.

The chemical industry. which has its main concentrations at Billingham. also greatly expanded. In south Durham there is an extensive salt field, the brine being refined to ordinary table salt at Greatham. At Billingham are the largest chemical works in the commonwealth. Petrol (gasoline) is produced in considerable quantities, by a catalytic process. Underlying the salt field is a bed of anhydrite which is used on a very considerable scale in the manufacture of ammonium sulfate and nitrochalk for agricultural fertilizers. It is also an essential raw material in the greatly increasing production of sulfuric acid.

Extensive port facilities exist on the Tyne. On the south bank the Tyne dock has been developed to handle iron ore for Consett, and deals with the export of coal. At Sunderland a wide variety of goods is handled, including an increasing tonnage of oil and petroleum products. At Hartlepool there is an extensive timber import. Seaham Harbour is essentially a coal port. Tees-side is a rapidly expanding area, but most of the port installations are on the Yorkshire bank. The sea fisheries of Sunderland and Hartlepool are valuable.

The pears of economic depression between World Wars I and II hit the county of Durham (then very heavily dependent on declining export and capital goods industries) extremely hard, and there was widespread unemployment and poverty. Misery reached a peak in 1933 when about one-third of the insured population was unemployed. The whole of County Durham was designated as a "special" area. Later, in 1945, it was scheduled as part of the North East Development area. Trading estates were established at Gateshead (Team Valley), Sunderland (Pallion) and St. Helen's Auckland to attract newer and lighter industries to the area, and some success had already been achieved when World War II broke out.

After 1945 there was a rapid increase in the number of estates and factories built. Simultaneously. there was a rapid expansion of newer industries on private sites, and many of the older industries turned to new types of production. Lighter industry includes clothing: hosiery and knitwear; light engineering; furniture and bedding; electrical equipment and radios; paint, chemicals and plastics; glass and china; cardboard and printing.

The main railway line to Edinburgh runs through Darlington, Durham and Gateshead and there are branches through the mining and industrial districts. Three main roads pass through the county from south to north. Some airfields exist and civil flying is carried out from Greatham airport near West Hartlepool.

DURHAM, a city, parliamentary borough and the county town of Durham, Eng.. 258 mi. N.N.W. of London and 16 mi. S. of Newcastle upon Tyne by road. Pop. (1961) 20.384. The nucleus of the medieval city is formed by a sharp bend of the river Wear round a rocky peninsula on which stand the castle and cathedral. Indications of an earlier settlement are to be found a short distance to the east on Maiden Castle. a plateau with steep sides bearing traces of pre-Roman fortifications, and at St. Oswald's church in the same direction, where Saxon work has been found. The only evidence of Roman occupation near the city came from the discovery of the remains of a Roman villa (later destroyed) at Old Durham. In 995 the body of St. Cuthhert. first buried at Lindisfarne in 687. was brought to Durham after two centuries of being taken from place to place in the northeast of England. The community of St. Cuthbert settled on the peninsula. a naturally strong position to which artificial fortifications were soon added. The layout of the old city has changed very little. later building being of necessity outside the fortified area.

The cathedral church of Christ and Blessed Mary the Virgin was begun in 1093 by Bishop William of St. Calais when he replaced the monks of the Saxon foundation by Benedictines. The nave. transepts and choir shorn typical Norman work, though the pillars bear decorations which are almost unique and the ribbed vaulting of the choir aisles is the earliest in England. The Galilee chapel, at the western end of the church, was begun by Bishop Hugh de Puiset in 1176, attempts to build a Lady chapel at the east end having failed; it is a fine example of the late Norman style and contains the tomb of the Venerable Bede. Early English work is to be seen in the eastern end of the choir which is there bounded by the Neville screen (1372–80). once bearing 107 statues. Bishop Thomas Hatfield (1345–81) built the bishop's throne, reputed to be the highest in Christendom. Farther east still is the Chapel of the Nine Altars. begun in 1242 in the style typical of that period. It contains the tomb of St. Cuthbert. long shorn of its magnificent medieval shrine which was despoiled in 1538, two years before the dissolution of the monastery. The greater part of the woodwork in the cathedral was introduced by Bishop John Cosin (1660–72) to replace that destroyed during the Civil War. Beside the adjacent cloisters is the chapter house, once a fine Norman building,

largely destroyed in 1796 and rebuilt in the original style in 1895. The former monastic dormitory (1400), with a fine timber roof. houses the chapter library. as does also the partly rebuilt refectory. It contains a collection of Saxon carved stones and grave covers, many illuminated manuscripts and relics of St. Cuthbert, including a stole (the only piece of Anglo-Saxon needlework extant) and his pectoral cross, which is believed to date from the 5th century. Substantial remains of other conventual buildings exist.

In the middle ages Durham was a fortified city and, with the exception of a section of about 50 yd.. the walls (sometimes modified) can still he seen. with their projecting turrets. The castle protects the northern side of the site, where there is no river to provide natural defense. The earliest part of the extant buildings is the Norman chapel (late 11th century). It is in the basement of Bishop Puiset's hall (12th century). the massive walls of which face Scotland. whence attack was most likely to come. The castle was until 1837 one of the palaces of the bishops of Durham. many of whom left their mark on the building—the great hall (Bishop Antony Bek, c. 1300), the Tunstall gallery and chapel (Bishop Cuthbert Tunstall, 1530–59), the black staircase (Bishop Cosin, 1660–i2). In 1928 the foundations of the building were found to be insecure. and collapse was averted only by prolonged repairs.

Three of Durham's parish churches, St. Giles's, St. Margaret's and St. Oswald's, show considerable 12th-century work. St. Mary-le-Bow is a 17th-century building on the site of a vanished 12th-century church; it has interesting contemporary woodwork. Of the three stone bridges, Elvet bridge is in large part 12th century and Framwellgate bridge was originally built in the same era. Each leads to one of the ancient suburbs of the city. Prebends' bridge, standing in the beautifully wooded ravine through which the river passes. was opened in 1778. Cosin's hall and almshouses and Cosin's library are all late 17th-century buildings. The Baileys, north and south. contain many 13th-century frontages. Durham school. an ancient foundation connected with the cathedral. has modern buildings.

The University of Durham was founded by act of parliament in 1832, after two abortive attempts, one immediately after the suppression of the monasteries in the 16th century and the other during the Commonwealth. A royal charter was granted in 1837, at the instance of the then bishop, William van Mildert. and the dean and chapter of Durham, who were responsible for financing it.

It consists of two divisions. in Durham and Newcastle. In the Durham division, formally styled "the Durham Colleges in the University of Durham," are University college (1833), housed in the castle. Hatfield college (1846), St. Mary's college (1920) for women and St. Aidan's college (1961). previously a noncollegiate society for women. Women were first admitted to the university in 1896. These four colleges are maintained by the council of the Durham colleges. St. Chad's college (1904) and St. John's college (1909) are constituent colleges of the university, but are independently governed. The College of the Venerable Bede was founded in 1841 as a Church of England training college for men teachers and became a constituent. college in 1947. St. Hild's college (1858). a Church of England training college for women teachers, and Neville's Cross college (1921j, for training women teachers, maintained by the Durham County council, are licensed halls of residence. and many of their students read for university degrees. These colleges are essentially residential; in addition there is a noncollegiate society, St. Cuthbert's, for men. The statutes of the university have undergone several revisions, latterly in 1937. King's college, Newcastle upon Tyne (*q.v.*), was constituted in that year by the fusion of the College of Medicine (1834) and Armstrong college (1871). The faculties of science. music. economic studies and education are represented in both divisions. that of theology only in Durham, those of medicine, applied science. law and agriculture only in Newcastle.

Codrington college. Barbados, became affiliated to the University of Durham in 1875. and Fourah Bay college, Freetown, Sierra Leone. in 1876. Students can read for Durham degrees at both. Sunderland Technical college, in the county of Durham, was similarly affiliated in 1930 in the faculty of engineering.

Durham city owes its origin partly to the fame of the 7th-century saint Cuthbert, which brought religious importance and pilgrim traffic. and partly to its strategic position on the invasion route between England and Scotland. These two factors combined to elevate the bishops of Durham and their office to a position of great ecclesiastical and political importance—a palatinate. (*See* also DURHAM [county].) In the middle ages the city was governed by the bishop through his bailiff. Charters granted by successive bishops gave to the city a limited amount of self-government which continued until the Municipal Corporations act of 1836. Before that year self-government rested in the hands of the freemen of the city, the members of the trade guilds, who controlled admission to their own ranks through charters granted to them by bishops of Durham.

Durham is not. and has never been, an industrial city, though it contains a number of small factories of which the best-known are those making organs (1873) and carpets (1814). In the 18th and 19th centuries it was noted for the manufacture of Durham mustard. The largest individual contributions to employment are made by the university, local government administration (the offices of the county council are in the city) and the distributive trades. A weekly market is held, and the city is a shopping centre for the inhabitants of the surrounding districts. (C. W. GY.)

DURHAM, a city of north-central North Carolina, U.S., seat of Durham county, is an industrial, educational and medical centre, located in the tobacco-growing eastern Piedmont area about 20 mi. N.W. of Raleigh, the state capital. Pop. (1960) 78.302; standard metropolitan statistical area (Durham county) 111,995. For comparative population figures see table in NORTH CAROLINA: Population.

Though the surrounding region was first settled about 1750 (largely by people of English and Scotch-Irish exlraction), Durham is one of North Carolina's youngest cities, dating from 1853 when a village called Prattsburg, after William Pratt, a large landowner. served the farmers of the vicinity with its wheat and corn mills. Construction of the North Carolina railroad (1852–56) encouraged growth. After Pratt had refused to give a right of way or land for a station, Bartlett Durham donated four acres about 2 mi. W. of Prnttsburg. The town which grew up there was known as Durhamville and Durham Station; the name was later abbreviated to Durham. The town was incorporated in 1866 and again in 1869. the first charter having been invalidated by action of the U.S. congress, since North Carolina was still out of the union. Durham became the county seat with the creation of Durham county in 1881. It adopted the city-manager form of local government in 1921.'

The tobacco industry transformed Durham from a small town of 256 people in 1870 into a flourishing manufacturing centre by 1900. The Duke family played the leading role in this development, though Washington Duke and his three sons Brodie. James Buchanan and Benjamin N. did not establish a factory in Durham until 1874. Robert F. Morris pioneered the tobacco industry in Durham in 1858, and John R. Green was manufacturing the famous Bull Durham smoking blend shortly after the close of the Civil War. To avoid competition with the blended tobacco, James Buchanan ("Buck") Duke decided to start making cigarettes. Within a quarter of a century Duke's tobacco business had 150 factories and controlled most of the tobacco trade of the United States.

Ranking high as a modern industrial city, Durham produces about one-fifth of the nation's cigarettes. It is also an important cotton textile and hosiery manufacturing centre. Other manufactures include lumber and wood products, machinery, electrical equipment. precision instruments, chemicals. flour and other food products, proprietary medicines. boxes. fertilizer and building materials. The status of the Negro is significant in Durham. Negroes. mainly in the Hayti section, control extensive business and industrial enterprises, including large insurance and bank interests, newspapers and real estate.

Durham became an important educational and medical centre largely through the philanthropy of the Duke family. Duke university. established there by "Buck" in 1924 as the principal beneficiary of the Duke endowment (*see* FOUNDATIONS, PHILANTHROPIC), was built around Trinity college. which was originally

known as Union institute, founded in 1839 and reorganized as Trinity in 1851. Undergraduate training is provided in Trinity college, the college of engineering and the woman's college and graduate work in the graduate school of arts and sciences, and in the schools of law, divinity, medicine, nursing and forestry. The university hospital serves the people of North Carolina and many other states and is a teaching institution for medical. nursing and auxiliary training. Other hospitals there include Lincoln hospital (for Negroes) and a Veterans administration hospital. The city also is the site of North Carolina College at Durham (formerly North Carolina College for Negroes), founded 1910.

Six miles west of Durham is the Bennett memorial, site of the signing on April 26. 1865, of the papers of surrender between Gen. William T. Sherman of the Union army and Gen. Joseph E. Johnston of the Confederate army. The spot is marked by a monument upon which is inscribed the word "Unity." (H. T. L.)

DURHAM'S REPORT (1839). Following the rebellions in Upper and Lower Canada (the present provinces of Ontario and Quebec) at the end of 1837, the British government appointed Lord Durham governor general of all the North American colonies and also high commissioner to make recommendations "respecting the form and future Government" of the colonies lately in rebellion. On Jan. 31, 1339. he submitted his *Report* on *the Affairs of British North America* (1839; *Lord Durham's Report*, 3 vol., ed. by Sir C. P. Lucas. 1912). generally regarded as the greatest state paper in British imperial history. Its breadth of view and plainness of speaking are probably unique in official reports of its kind.

Durham's two basic recommendations were that Upper and Lower Canada should be united and that these and other British colonies should be accorded the right of managing their local affairs through the device of responsible government.

Originally. Durham favoured a federation of the British North American provinces, thus anticipating the form of the later Canadian nation. Direct experience on the scene convinced him, however, that a legislative union of Upper and Lower Canada. and possibly including the maritime provinces of Nova Scotia. New Brunswick and Prince Edward Island, was preferable as the only means of anglicizing the French Canadians. He considered the latter to be a backward people whose feudal and unprogressive attitudes were delaying not only their own advance but that of the other colonies as well. He recommended that the French Canadians be submerged by a British majority until they gave up their language. laws and customs.

This proposal was the great blind spot in the report. He underestimated the tenacity of a people who had already been established in North America for two centuries, and he failed to see that French Canadians could be loyal subjects of the Queen without ceasing to he French.

It was in his recommendation for responsible government that Durham reached heights of greatness. By responsible government Durham meant simply that the executive council in each colony should be composed of men who had the support of a majority of the legislature, and who would resign when they lost that support. He was. in short, recommending that the British system of cabinet responsibility should be extended to the colonies, with the governor following the advice of the executive council in all matters of local concern. The result would be to "place the internal government of the colony in the hands of the colonists themselves," reserving only a few subjects for imperial authority.

In answer to those who argued that legislative union and local self-government would lead to independence and separation from the mother country. Durham asserted that they were the surest guarantees against absorption by the United States and the surest means of retaining the loyalty of the North American colonies. Thus he looked to the evolution of the empire into the modern Commonwealth of Nations.

The report and its appendixes also contained much informative material on land policy, emigration. education and other subjects. *See* also CANADA: *History;* DURHAM, JOHN *George* LAMBTON.

(G. M. C.)

DURIAN, the fruit of *Durio zibethinus,* a tree *of* the family Bombacaceae, which attains a height of 70 or 80 it., has oblong. tapering leaves, rounded at the base, and yellowish-green flowers, and bears a general resemblance to the elm. The durian is cultivated in Sumatra. Java, Celebes and the Moluccas and northward as far as Mindanao in the Philippines; it is also grown in the Malay peninsula and in southern Thailand. The fruit is spherical and 6 to 8 in. in diameter, approaching the size of a large coconut; it has a hard external husk or shell, and is completely armed with strong pyramidal tubercles, meeting one another at the base and terminating in sharp, thorny points. If the fruit is divided at the joints of the carpels. where the spines arch a little, it is found to contain five oval compartments. each filled with a cream-coloured, glutinous pulp, in which are embedded from one to five seeds about the size of chestnuts.

The pulp and the seeds, which latter are eaten roasted, are the edible parts of the fruit. Although the fruit has a sweet, somewhat balsamic flavour, it also has a rather offensive odour, which has been compared to that of rotten onions or of putrid animal matter. Because of its odour. the durian has had little popularity with people outside its natural range,

DURKHEIM, ÉMILE (1858–1917). pioneer French sociologist. achieved international recognition as a social scientist by successfully combining empirical research with sociological theory. He was born of a rabbinical family on April 15, 1858, in Alsace. A student of law, philosophy and social science. he was educated in France and Germany, where he also studied folk psychology and anthropology. A chair of sociology was established for him in 1887 at the University of Bordeaux where he taught ior five years before joining the faculty of the University of Paris and becoming a lecturer at the Sorbonne. He early became an exponent of the positive social philosophy of Auguste Comte (*q.v.*). Generally regarded as the founder of the French school of sociology. his n-ork and that of his disciples and their followers had broad influence on the methodology of all branches of social science. Such 20th-century anthropologists and ethnologists as A. R. Radcliffe-Brown and Robert Lowie, as well as Talcott Parsons, W. Lloyd Warner and other sociologists, acknowledged the value of the interest he aroused. (For a review of his influence in the field of sociology *see* SOCIOLOGY: *History of Sociology: Pioneer Sociologists.)*

Durkheim applied methods of objective science in the study of human relationships, but insisted that pure statistical correlations are not adequate unless logical connections are also established. He emphasized the importance of studying "social facts," such as social rules and customary beliefs, which are objective to the empirical observer and yet possess moral aspects, for they affect the welfare of individuals.

His best-known contribution to social theory is the concept of collective representations, which refers to group ideas or symbols that are widely accepted and socially forceful because they are collectively created and developed through the interaction of many minds. These symbols are the products of the *conscience collective,* usually translated "collective consciousness" (social psychology). although "collective conscience" (ethical) may be closer to the meaning intended by Durkheim. The *conscience collective* is viewed as the ethical authority of juridical decisions.

Division of labour is another important concept developed by Durkheim. In preliterate societies he found little division of labour but a great deal of "mechanical solidarity" (mutual dependence) or like-minded solidarity in which the individual is subordinated to the group. As a society develops, a division of functions and corresponding activities takes place. mechanical solidarity gives way to a considerable degree to an "organic solidarity" and individuals become aware of social values. Under organic solidarity, conflicts of interests occur and constraint. represented, for example, by juridical decisions. becomes necessary.

Durkheim is noted for his study of personality problems as found in his work entitled *Le Suicide* (1897). in which three types of suicide are described: (1) egoistic suicide. which may result when an individual shuts himself off from other human beings; (2) *anomique* suicide. which comes from the belief that one's social world has fallen apart around him; and (3) altruistic suicide. which springs from great loyalty to a cause.

Durkheim also attempted to demonstrate the social and ceremonial origins and basis of religion, especially totemism (*q.v.*). He held there are no religions "which are false." All are "essentially social" and a religion is "a universal system of beliefs and practices relative to sacred things" that are set apart and forbidden, that unite all those who adhere to them into "one single moral community called a church." (Émile Durkheim, *The Elementary Forms of Religious Life,* trans. by J. W. Swain, Free Press, Glencoe, Ill., 1947.)

He founded and served as editor of *L'Année sociologique* from 1897 to 1912. He died in Paris on Nov. 15, 1917.

His chief works are *De la division du travail social* (1893); *Les règles de la méthode sociologique* (1894); *Le suicide* (1897); and *Les formes élémentaires de la vie religieuse* (1912). The chief translations of his works are *The Division of Labor in Society,* trans. by George Simpson (1947); *The Elementary Forms of the Religious Life,* trans. by J. W. Swain (1947); *The Rules of Sociological Method,* trans. by G. E. G. Catlin (1950); *Suicide,* trans. by J. A. Spaulding and George Simpson (1951); *Sociology and Philosophy,* trans. by D. F. Pocock (1953); *Education and Sociology,* trans. by S. D. Fox (1956); and *Socialism and Saint-Simon,* ed. by A. W. Gouldner and trans. by Charlotte Sattler (1958).

DUROC, GÉRAUD CHRISTOPHE DE MICHEL, DUC DE FRIOUL (1772–1813), French general and diplomat, one of Napoleon's closest advisers, was born at Pont-à-Mousson, Oct. 25, 1772. The son of Claude de Michel, chevalier du Roc, who was a cavalry officer, he went to the Châlons artillery school, emigrated in 1792, but changed his mind, returned to France, entered the Metz school (1793) and was drafted to the artillery of the army of Italy. In 1796 Gen. A. de Lespinasse, the artillery commander, took him as aide-de-camp. Both were mentioned in dispatches after the battle of Roveredo (September) and a few weeks later Napoleon took Duroc as his aide. He was major in Egypt, colonel in Syria and, after the *coup d'état* of Brumaire (Nov. 1799), senior aide-de-camp of the first consul and his intimate friend. All contemporaries praised this reserved, unambitious man who so often checked Napoleon's angry impulses.

From 1804 he was grand marshal (lord high steward of the empire) and kept good order in the palaces. Furthermore he was often on diplomatic missions, and it was he who signed the treaties of Fontainebleau and Bayonne (1807–08) determining the intervention in Spain. He was also general of division (1803), led a division at Austerlitz and was in all the campaigns. He was usually consulted by Napoleon on questions of promotion and became the best channel by which Napoleon's lieutenants could approach him.

On his journey back from Russia in 1812 the emperor chose Armand de Caulaincourt as his immediate companion; Duroc and G. Mouton followed in another sledge. In 1813 Duroc, like Caulaincourt, was made a senator. He had heavy work in the organization of the new army and was with it at the battles of Lützen and Bautzen (1813). In the outposts in Silesia he came, by chance, under artillery fire and was mortally wounded. He died near Görlitz on May 22, 1813. Napoleon deeply regretted his death. (I. D. E.)

DURRA, a variety of sorghum, a grain-yielding grass. *See* KAFIR; SORGHUM.

DURRES (Ital. DURAZZO; Serb. DRAC), the first seaport of Albania and headquarters of the *rreth* (district) of the same name, is located on the Adriatic sea, 30.6 km. (19 mi.) W. of Tirane. Pop. (1955) 25,579. Until a few years before World War II the harbour was unprotected, subject to silting and suitable only for vessels of shallow draft. Sea walls and modern quays were then built. The quays and installations were destroyed by the retreating German forces in 1944 but they were later restored and improved and the harbour deepened. The railway runs to the dockside, and there are modern cranes and warehouses and an oil-discharging point on the east wall with oil storage tanks nearby. Wide streets, begun before 1939, were driven through the straggling town, and motor roads lead from the central square to the interior of the country. There are a railway station and repair yard, and two lines, built after World War II, link the port with the capital, Tirane, and with Elbasan. There are modern commercial buildings, flour mills, a rubber factory and a building yard for small vessels. The ruins of the Byzantine citadel overlook the town from a hill to the north, and the old towered walls, restored by the Venetians in the 14th century, run down to the harbour.

Epidamnus, the ancient name of Durres, was founded in the 7th century B.C. by Corcyraeans and Corinthians on the shore of Illyria. Disputes between these colonists led to its decline and in 312 B.C. it was seized by the Illyrian king Glaucias. It later passed to the Romans who renamed it Dyrrachium, and from it the military highway, the Via Egnatia, led past Elbasan and Lake Ohrid to Salonika and the east. The old harbour, known as Porto Romano, lay north of the hill at the entrance (later silted up) to a lagoon or marsh. Pompey made his last successful stand against Caesar just south of Durres in May 48 B.C., before his defeat at Pharsalus. Augustus made the place a free city, and it was most prosperous in the 4th century A.D. when it became the capital of Epirus Nova. A bishopric was created there about 58 and an archbishopric in 449. The town was besieged by the Ostrogoth Theodoric in 481 and attacked by the Bulgarian invaders in the 10th and 11th centuries. It was captured by the Norman Robert Guiscard in 1081, later passing to the Byzantines. It fell to King William of Sicily in 1185, passed to the Venetians early in the 13th century and to King Manfred of Sicily in 1258. In 1272 Charles of Anjou captured it with a Neapolitan army, but in 1273 it was devastated by an earthquake. Next it became an independent duchy under John of Anjou and later under Philip of Otranto. It was annexed by Achaea in 1333 but was conquered by the Serbs of Stephen Dushan in 1336. After Dushan's death in 1358 it passed into the control of the Albanian family of the Topias. It was ceded about 1394 to Venice, under whom it prospered. The Turks captured it in 1501 and held it until their defeat in the Balkan War of 1912. The Serbs then occupied it but were obliged by the great powers to withdraw. The Albanian Esad Pasha Toptani formed a government of his own there, but after the landing at Durres in 1914 of Prince William of Wied as king of Albania, Esad Pasha was arrested and deported. A revolt, however, led to the departure of Prince William. Austrian forces occupied the town during World War I and on their defeat Italian forces held it but withdrew from the country in 1920. On April 7, 1939, Durres was the main port of disembarkation for Fascist Italy's invasion of Albania, and during World War II it was bombed and shelled by British forces. Under the Communist regime Durres became the main lifeline of an Albania politically isolated from its landward neighbours. (D. R. O.-H.)

DURUKULI, the native name of a small South American monkey, the owl monkey or night monkey, *Aotes* (or *Aotus*) *trivirgatus.* Durukilis range from Colombia and the Guianas southward to Paraguay and northern Argentina. They are nocturnal in habit and are distinguished by their large eyes and by the pattern of the surrounding area, which includes three dark bands on the crown separated by lighter markings. The tail is bushy and not prehensile. The modified larynx ensures a powerful voice.

DURUY, VICTOR (1811–1894), French historian, author of a valuable *Histoire des Romains,* 7 vol. (1879–85) and, as minister of education, initiator of controversial reforms, was born in Paris, Sept. 11, 1811. From 1833 to 1861 he taught at the Collège Henri IV. His early publications were textbooks and works on historical geography and ancient history; his *Histoire des Romains et des peuples soumis à leur domination,* 2 vol. (1843–44), was later greatly enlarged. He assisted Napoleon III with his life of Caesar and was appointed minister of education by him in 1863. His policies enlisted liberal and anticlerical support and met with con-

siderable opposition. He organized higher education (*enseignement spécial*) and the training of teachers, initiated provincial extramural lectures (*conférences publiques*), began a course of secondary education for girls with lay teachers, and introduced the study of contemporary history and modern languages in *lycées* and colleges. His greatest interest was primary education, but his particularly controversial proposal to make it both free and compulsory failed to gain the emperor's support. In 1869 the government was reconstructed and Duruy made a senator; later he returned to academic work, becoming a member of the Académie Française in 1884. *Histoire des Grecs,* 3 vol. (1886–89), and an enlarged edition in 1891 of *Histoire de France de 1453 à 1815* (1856) renewed his reputation as a scholar, and many other works confirmed it as a writer of popular history. Duruy died in Paris, Nov. 25, 1894

See V. Duruy, *Notes et Souvenirs,* 2 vol. (1901); E. Layisse, *Un ministre, Victor Duruy* (1895); G. Monod, *Portraits et Souvenirs* (1897).

DUSE, ELEONORA (1859–1924), Italian actress, whose great powers were shown most fully in the plays of D'Annunzio and Ibsen, was born on Oct. 3, 1859, near Vigliano, in a railway coach. She came from a family of actors. Her grandfather, Luigi Duse (1792–1854), had specialized in Goldonian parts; her father, Alessandro Duse, was the leading man in a company of strolling players. and her uncles were members of the same troupe. Eleonora Duse acted for the first time at the age of four at Chioggia, when she played Cosette in a dramatization of Victor Hugo's *Les Misérables.* At the age of 14 she acted Juliet in Verona, where her talents were recognized by the critics. After she lost her family and was thrown on her own resources, she passed from one company to another, experiencing the hardships of a nomadic life and often enduring hunger, until she appeared in Naples in 1878. This marked the turning point in her career. Her Electra in Alfieri's *Oreste* received good notices, for her Ophelia she was acclaimed, and when she undertook the title role of Emile Zola's *Thérèse Raquin* (1879) audiences and critics had to admit that a woman's anguish had never before been portrayed with such truth. The actor Cesare Rossi hired her as the leading lady of his company, and with him she toured most of Italy. struggling to rouse lethargic audiences. bored by the stale pieces of the repertory.

In 1882 the Duse had the opportunity to watch Sarah Bernhardt perform. Bernhardt's success gave the Duse new courage and the idea of turning to the modern French dramatists for new plays. She studied the part of Lionette in the younger Dumas's La *Princesse de Bagdad,* a play from which Parisians had recoiled when Sophie Croizette played the lead. The new role was a triumph, however, for the Duse. who then selected another Dumas character for her next vehicle. Cesarine in *La Femme de Claude.* In 1884 she created the title role of Dumas's latest play, *Denise,* and in the same year Santuzza in Giovanni Verga's *Cavalleria Rusticana.* She toured in South America in 1885 as a member of the Cesare-Rossi company. After her return to Italy Rossi's star began to sink, and his company disbanded. The Duse then formed her own troupe, the Drammatica Compagnia della Città di Roma, and with it undertook tours to Austria, Germany, England, France, Russia. Egypt. Belgium and Portugal, making visits also to the United States in 1893, 1896 and 1902. She was idolized wherever she went, but she always regarded Vienna as the city where she was most appreciated as an artist.

In 1897 she met the rising young poet Gabriele d'Annunzio (*q.v.*) and fell in love with the man and the artist. The actress began to crusade for the playwright, who gave her three successful vehicles, *La città nzortu* (1898). *La Gioconda* (1898) and *Francesca da Rimini* (1902), and two failures. *Sogno d'un mattino di primavera* (1897) and *Gloria* (1899). Her faith in D'Annunzio was boundless, and his cult of beauty added another dimension to her acting; a radiant glow is said to have emanated from her when she played his characters. D'Annunzio wrote the story of their love in the novel *Il fuoco* (*The Fire;* 1900).

Aside from D'Annunzio's dramas, the Duse found those of Ibsen an inexhaustible source of self-expression. She never grew tired of Nora in *A Doll's House,* Rebecca West in *Rosmersholm,* Ella Rentheim in *John Gabriel Borkman* or, above all, of Ellida in *The Lady From the Sea.* To Hedda Gabler she brought something the author was troubled by when he saw her perform the part: a demonic quality, a touch of the fantastic; she went beyond the narrow frontiers of realism. One of her Viennese critics wrote at the time of her first appearance in Vienna (1892) that the Duse played what was between the lines, she played the transitions. Hugo von Hofmannsthal. one of her Austrian admirers, stated that the actress supplied psychological motivation wherever it was lacking in a play. To watch her was to read a psychological novel. She even was able to introduce Ibsen psychology into the marionettes that were pulled by the strings of Sardou and Dumas, lending her soul to these stiff figures and completing what the dramatists had left uncompleted. In every role she was different, in contrast to the great technician Sarah Bernhardt, who never pretended to hide her personality. The Duse had a thousand faces. Bernard Shaw was one of the critics who studied her metamorphoses with fascination. He was struck by her ability to produce the illusion "of being infinite in variety of beautiful pose and motion." A tremor of her lips revealed what went on in her mind; her hands spoke a distinct language; she had a different way of walking for each part; she even mastered the colour of her face (unspoiled by make-up); and Shaw's professional curiosity was aroused when he pondered the question whether the Duse's blush always came spontaneously. And yet, this was not naturalistic acting, for the Duse acted not only the reality but also commented on the characters: as Hofmannsthal said, she knew more about Nora than Ibsen's heroine could possibly know about herself. Shaw confessed that "in an apparent million of changes and inflexions" he had never seen her at an "awkward angle" in defiance of the "natural gravitation to the finest grace." (George Bernard Shaw, *Dramatic Opinions und Essays,* Brentano's, New York, 1907. By permission of The Public Trustee and The Society of Authors.)

In 1909 Eleonora Duse decided to quit the stage, primarily for reasons of health. During World War I, however, she incurred financial losses that forced her to emerge from her solitude in 1921. Her acting powers were undiminished, but her health was failing and interfered with her late career. In 1923 she appeared in London in six matinee performances. Three nights in Vienna followed before she embarked upon her last tour of the United States, which began with an appearance on the yawning stage of the Metropolitan Opera house and ended in Pittsburgh, Pa.. where the actress died on April 21, 1924. In compliance with her request, she was buried in the small cemetery of Asolo.

DUSHANBE (STALINABAD from 1929 to 1961), the capital of the Tadzhik Soviet Socialist Republic of the U.S.S.R.. is situated on the Dushambinka river, a branch of the Kafirnigan, at the junction of the Karshi-Ordzhonikidzeabad and Dushanbe-Nizhni Pyandzh railway lines and of the Dushanbe-Kurgan-Tyube-Kirovabad-Kulyab and Dushanbe-Khorog metaled roads. Pop. (1959) 223,242. The town, which occupies the site of an old Tadzhik village (formerly spelled Dyushambe or Diushambe), has developed greatly since 1926, when the population was only 6,000. It has been completely rebuilt on modern lines with large public buildings. squares and gardens. There is a thriving light industry including one of the largest cotton textile works in the U.S.S.R. and there are many other factories and spinning works. An Academy of Sciences was founded there in 1951. There are more than 30 schools and a number of technical and educational training establishments including the T. G. Shevchenko Pedagogical institute. Public health has been greatly developed: in addition to a piped water supply there are hospitals, maternity clinics and dispensaries. In 1939 a state medical institute was established and named after Abu-Ali ibn Sina (Avicenna). After the renewed denunciation of Stalin at the 22nd congress of the Communist party of the U.S.S.R. in Nov. 1961 the town reverted to its former name. (G. E. WR.)

DUSSAUD, ÉLIE PIERRE RENÉ (1868–1958), French

orientalist who encouraged the excavations at Ras Shamra, Mari and Byblos, was born at Neuilly-sur-Seine, near Paris, on Dec. 24, 1868. Five journeys in Syria between 1895 and 1901 resulted in his first publications, which included *Notes de mythologie syrienne* (1903) and *Les Arabes en Syrie avant l'Islam* (1907). a subject to which he returned in his last book, *La Pénétration des Arabes en Syrie avant l'Islam* (1955). A visit to Crete led to *Les Civilisations préhelléniques* (1910; 2nd ed. 1914). After a brief university career he joined the staff of the Louvre in 1910, being head of the department of oriental antiquities from 1928 till his retirement in 1935. In 1927 he published his most important work, *Topographie historique de la Syrie antique et médiévale*. From 1929 onward he became passionately interested in the discoveries at Ras Shamra. which were the subject of *L'Art phénicien du IIe millénaire* (1949) and *Les Découvertes de Ras Shamra (Ugarit) et l'Ancien Testament* (2nd. ed. 1941) and necessitated the revision of *Les Origines cananéenes du sacrifice israklite* (1921; 2nd ed. 1941). He touched on the problems of Anatolian history in *La Lydie et ses voisins aux hautes époques* (1930) and *Prklydiens, Hittites et Achéens* (1953). From 1908 he was co-editor of the *Revue de l'histoire des religions* and from 1920 of the periodical *Syria* which he helped to found. He died in Paris on March 17, 1955. By his personal activities even more than by his publications he exercised a profound influence on French oriental studies.

(R. DE V.)

DUSSEK (DUSIK), **JAN LADISLAV** (1760–1812), Bohemian pianist and composer known for his piano music, was born at Caslav. Bohemia, on Feb. 12, 1760, the son of the cathedral organist. He studied with his father. sang in the choir at Iglau and later studied theology at Prague. He found a patron in Count Manner, whom he accompanied to the Netherlands. He attained a great reputation as a pianist and wrote a large number of "accompanied sonatas" for pianoforte and strings before going to Hamburg about 1783 to study under C. P. E. Bach. Later he went to Berlin and St. Petersburg and found another patron in the Polish prince Sapieha. on whose estate he remained for a year. In 1786 he went to Paris, where he was patronized by Queen Marie Antoinette. After a stay in Italy he returned to Paris in 1788. but later left the unsettled French capital for London, where he made a successful debut in 1790. In 1792 he married Sophia, the daughter of the music publisher Domenico Corri. with whom he entered into business partnership. The business failed, and about 1800 Dussek fled from England to escape his creditors; he never saw his wife and daughter again. He went to Hamburg and Berlin. and again was fortunate in securing wealthy patrons. Prince Louis Ferdinand of Prussia and later Talleyrand. He lived in Talleyrand's household from about 1809 until his death at St. Germain-en-Laye, March 20, 1812.

Dussek's works include a large number of pianoforte sonatas and concertos and numerous chamber works for piano and strings. His piano sonatas represent him at his best, and though his works were later forgotten he had a considerable influence on the growth of piano technique, both as pianist and composer.

See L. Schiffer, J. L. Dussek (1914); S. V. Klima "Dussek in England," *Music* and Letters (April 1960).

(CS. CH.)

DÜSSELDORF, a city of Germany which after partition of the nation following World War II became capital of the *Land* (state) of North Rhine-Westphalia. Federal Republic of Germany. The centre of the industrial Rhine-Ruhr area, it lies mainly on the right bank of the Rhine, 25 mi. N.N.W. of Cologne. Pop. (1950) 500,516; (1959 est.) 691,740.

Although industrial, it is a finely laid-out town which attracts an elegant and often international society. especially at the Carnival season, the shooting festival (July). the traditional St. Martin's procession (Nov. 10) and when exhibitions and congresses are being held. The main street is the Konigsallee, with its town moat and beautiful chestnut trees, under which are terrace cafés. Among old buildings is the town hall (1567; later extended), in front of which is the equestrian statue of the elector palatine Johann Wilhelm II (Jan Wellem) by the Flemish sculptor Gabriel Grupello. The crooked tower of the 13th–14th century St. Lambertus-Kirche has become the town's symbol. Only the tower of the electoral prince's castle, otherwise burned down in 1872, remains. Schloss Jagerhof, which houses the town historical collection. mas built in 1752–63; Schloss Benrath, with its great park, was built by Nicolas de Pigage in 1755–69. To the north in the district of Kaiserswerth lies the palace of the emperor Frederick I Barbarossa. Notable 20th-century buildings include the Wilhelm-Marx-Haus and the Ehrenhof buildings by W. Kreis (1924–26). Dusseldorf was badly damaged in World War II and consequently contains much modern architecture.

Among Diisseldorf's institutions of learning are a medical academy and an academy of arts (founded 1767). The Hetjensmuseum has a notable collection of ceramics covering 6,000 years. The unusual *Land* museum, "People and Industry," illustrates the society and industry of the world. There is a Goethe museum and the city library contains a unique collection of Heinrich Heine's work and his library.

Dusseldorf lies on the *Autobahn* and is a big railway junction. It has one of the most important German civil airfields. at Lohausen, 4 mi. from the town. Three Rhine harbours connect it with ports in Great Britain. northern Europe and the Mediterranean.

The city is a banking and wholesale centre, the home of many industrial associations and of the international wool secretariat. Its chief industry is iron and steel but its manufactures also include chemicals (washing powders, etc.), cars, concave glass, electrical engineering and precision tools, paper, textiles and clothing (it is the centre of the women's clothing industry in Germany).

Dusseldorf's importance began when it was raised to the rank of city by Count Adolf von Berg in 1288. It suffered considerably in the Thirty Years' War and the War of the Spanish Succession but regained its consequence under Johann Wilhelm II, who was born and died there. In 1795 the town surrendered to the French after a violent bombardment, and after the peace of Lunéville the fortifications mere dismantled; in their stead arose the royal garden and the Konigsallee. In 1805 the city became the capital of the Napoleonic grand duchy of Berg and in 1815 was transferred with it to Prussia. Its industrial development dates from 1870.

(O. J.-A. H.)

DUST is finely subdivided solid matter that can be carried in suspension by air. It is normally lifted by the wind from its place of origin, is carried along by the turbulent atmospheric currents and finally settles either by gravity under conditions of calm or is brought to the surface by precipitation. Wind can carry tremendous quantities of dust from one region of the earth to another. Geologists have generally accepted the theory of German geologist and geographer Ferdinand von Richthofen (1833–1905) that loess deposits are wind-borne sediments. In China these deposits reach thicknesses of 700 ft.

Dust plays an important part in cloud formation and precipitation processes in the atmosphere. In 1875 M. Coulier first recognized that condensation of water vapour in air occurs only when nuclei are present around which water droplets form. Not all of these atmospheric condensation nuclei are solid particles. Some of them are hygroscopic liquids such as nitric and sulfuric acid, others are ionized gas molecules. Christian Junge showed in 1933 that all particles of sizes between 10^{-7} and 10^{-5} cm., even oils, will act as nuclei for condensation. Hygroscopic nuclei only act sooner than the others. For the formation of clouds, 300 to 500 nuclei per cubic centimetre are needed. In some cases coagulation of cloud droplets to raindrops will take place only if ice crystals form initially. The small water droplets usually subcool below the freezing point and require other particles, so-called freezing nuclei, before ice crystals are formed.

Sources. — The main sources of dust in the free atmosphere are soil blowing, oceanic spray, volcanic activity, forest fires, domestic and industrial combustion processes, vehicle exhaust and meteoric matter penetrating from the universe into the earth's atmosphere. Organic dusts such as parts of plants, pollen and bacteria are minor constituents of atmospheric dust. Air currents and turbulence are responsible for the horizontal and vertical distribution of dust, sometimes to points at considerable distances from its origin.

Oceanic spray has been estimated to bring annually about 2,000,000,000 tons of salt dust into the air. The main chemical constitu-

ents of the salt left in the air after the spray water has evaporated are sodium chloride, calcium chloride. potassium bromide and magnesium chloride. The individual salt nucleus weighs between 10^{-10} and 10^{-18} g. and has radii up to 10^{-4} cm.

In settled areas combustion processes are next in importance as sources of dust. The estimated annual world dust production of all major cities is 0.2 cu.mi. Another man-made dust source is the atomic explosion. Debris from thermonuclear blasts has been carried in the air around the earth. Occasionally, volcanic eruptions bring tremendous amounts of dust into the atmosphere. The spectacular eruption of Krakatau (*q.v.*) in the Sunda strait, between Sumatra and Java, on Aug. *26–27. 1883.* threw about *4* cu.mi. of earth into the air, where some of it stayed for three years.

Dust storms originating in deserts and during droughts in areas where natural vegetation has been removed bring thousands of tons of dust into the air and carry vast amounts at times as far as *2.000* mi. from the point of origin. For example, the great dust storm of Nov. 12–13, 1933, starting in the plains states of the U.S., caused discoloration of snow in New England where 25 tons of dust per square mile were deposited. Sahara dust has been noted as far east as Syria. It is rather regularly observed in the Alps; when air masses originating in North Africa are carried by storms into that region. and gives rise to red- and yellowish-coloured snows and rains (blood rains). These also have been occasionally reported from the British Isles and most areas of central Europe.

Some meteoric dust penetrates from space into the atmosphere. Magnetic dust definitely traced to a meteorite was first observed on Jan. 13, 183j, at Löbau, Saxony. In *1883* John Murray and Alphonse F. Renard reported the find of magnetic dust traces in deep-sea sediments dredged by the expedition of H.M.S. "Challenger." Brown or black in colour the dust had diameters of 0.2 to 0.5 mm. From its suspected origin it got the name cosmic spherules. A systematic survey was made in 1910 during the passage of the earth through the tail of Halley's comet. Inadequate methods led to negative results. In 1940 H. H. Nininger reported on nickel-containing dust found in the western United States, allegedly of cosmic origin. Particles had diameters of 90μ (*1* micron= $1\mu = 10^{-3}$ mm.). Rather positively identified as micrometeorites were dust particles collected after the Giacobini-Zinner meteorite shower of Oct. *9, 1946.* These had sizes from 5 to 30μ. *A* systematic analysis of dust precipitated with rain by John Davis Buddhue yielded magnetic particles with a most frequent size range of 5 to 25μ. A check on dust layers found on an arctic ice island (T-3) showed magnetic spherules of sizes 0.01 to *0.4* mm. The age of the dust deposits ranged from several hundred to several thousand years. This and the remote locality ruled out the possibility of industrial contamination. The various size ranges were found to agree fairly well with theoretical calculations by Ernest Opik. placing micrometeorites of the aerolite type in the bracket of *0.03* to *0.23* mm. The amount of meteoric dust accretion by the earth is widely in dispute. While the ice island data yield an accretion of only 125 tons per year for the earth, W. D. Crozier has estimated as much as 200 to 800 tons per day or up to *292,000* tons per year. Buddhue's data point to 35,000 to 70,000 tons per year. Paul W. Hodge in *1956* published data leading to the then highest estimate of 1,000,000 tons accretion per year.

Concentration. — Dust exists in the atmosphere in prodigious quantities. It has been estimated that over the United States about 43,000,000 tons settle per year. Of this, 31,000,000 tons is from natural sources, including 1,000,000 tons of pollen. The remainder of 12,000,000 tons is caused by human activities. Near cities the pollution is a particularly serious problem. Measurements of the dust fall per square mile per month have indicated the following general variations: Detroit, Mich., about *72* tons; New York city. *68* tons; Chicago, Ill., *61* tons; Pittsburgh, Pa., 46 tons: Cincinnati. 0.. *34* tons; and Los Angeles, Calif.. *33* tons. In sections with heaviest industrialization amounts of *200* tons per square mile per month have been observed. Industrial pollution in valleys or troughs combined with suitable weather conditions can lead to a serious health hazard. A combination of low wind speed with stable air stratification, *i.e.*, cold near the ground and warmer aloft, and dry weather for any length of time can lead to dangerous accumulations of contaminants. Catastrophic incidents of this nature occurred in the Meuse valley. Belg. (1930), and in Donora, Pa. (1948), where deaths and many cases of respiratory diseases were attributed to aggravated combinations of these circumstances. At Donora, for example, zinc plants were found to discharge *67.000* lb. of particulate matter per day. One of the worst "smog" disasters on record occurred between Dec. 4–9. 1952, in London. where about *1.000* persons died as a result of exposure to contaminant concentrations of up to 4 mg. per cubic metre. This is about ten times the amount usually found in heavily polluted localities. The concentrations usually decrease by one-half for every three-mile interval from the polluting source. Industrial combustion and smelting operations, mining, construction and road-building activities, traffic and incinerators are the worst sources of dust. Coal. *e.g.*, contains 4% to 11% ash, much of which escapes through chimneys and smokestacks. Of thr typical incinerator charge, 1% results in fine dust with particle sizes less than 6μ. Table I shows the usual size ranges of some of the commoner air contaminants.

TABLE I.—Size Ranges of Contaminants

Type	Usual radii in μ
Carbon smoke	0.01— 0.2
Metal oxide fumes	0.03— 0.3
Hazardous silica dust	0.5 — 10
Bacteria	1 — 15
Cement	10 — 150
Pollens	20 — 60
Fertilizer	30 — 800
Sand	200 —2,000

Many cities instituted vigorous campaigns to prevent air pollution, and industries installed devices to remove the offending substances from their exhausts. For example, Pittsburgh reduced fly ash and other contaminants by 69% between 1946 and 1953. Weather observations showed that periods of poor visibility caused by pollution were reduced from 1,000 to *300* hr. per year. A major factor was the replacement of steam locomotives by diesel engines on the railroads. (See also SMOKE AND SMOKE PREVENTION.)

The environmental variations of condensation nuclei are good indicators of relative pollution. *See* below, *Methods for Measuring Dust* for a description of condensation nuclei counting. On the basis of about *20.000* measurements in all parts of the world these variations are summarized in Table II.

TABLE II.—*The Environmental Variation of Condensation Nuclei*

Type of environment	Average number of nuclei per cubic centimetre
Cities	147,000
Towns	34,300
Countryside	9,500
Oceans	940
Mountains, 300-1,000 m. elevation	6,000
Mountains, 1,000–2,000 m. elevation	2,100
Mountains, higher than 2,000 m.	950

Of the values measured over the ocean two-thirds indicated less than 400 nuclei per cubic centimetre. In the free atmosphere A. Wigand found on balloon flights the average concentrations shown in Table III.

TABLE III.—The Average Concentrutions in Free Atmosphere

Elevation in metro above surface	Average number of nuclei per cubic centimetre
1,000–2,000	,500
2,000–3,000	780
3,000–4,000	340
4,000–5,000	170
more than 5,000	80

Indoors the concentration of dust is normally higher than in the free atmosphere. although the variations follow the outdoor changes, depending somewhat on ventilation conditions. Ordinarily, room air contains between 50,000 and 100,000 condensation nuclei per cubic centimetre. From a hygienic point of view it is

important to note that the number of bacteria indoors varies in the same sense as the number of dust particles. Similar environmental conditions. such as humidity and ventilation: keep both in suspension.

Plant pollens suspended in the atmosphere are often responsible for attacks of hay fever in allergic persons. During the summer and autumn these are usually counted, in a somewhat unsatisfactory manner. by observing the number of pollens settling on a coated slide of 1.8 $cm.^2$ in 24 hours. In the case of pollen from ragweed, which is the pollen most commonly associated with hay fever, attacks in sensitive persons start with counts of 10 to 25. Maximum counts in midseason may reach up to 1,000 pollens per 24 hours.

Since the mid-1950s the problem of fallout of radioactive dust from nuclear explosions has become a matter of considerable attention. Natural radioactive substances always have been minor constituents in the atmosphere. Minute quantities of radon and its decomposition products, carbon-14 and potassium-40, are usually among the atmospheric admixtures and suspensions, Most of the fission products in nuclear blasts are quite short-lived and are quickly eliminated from the atmosphere by fallout and washout. The principal exception is strontium-90 which has a half-life of about 28 years. The force of the explosions brings nuclear debris into the stratosphere. Air currents at the high levels carry the dust from the point of origin to practically all parts of the earth. Settlement may take from weeks to years. One year after the first hydrogen bomb tests in the Marshall Islands, strontium-90 dust from these explosions caused an average soil contamination in the United States of 2 to 3 millicuries per square mile. This is about $\frac{1}{240}$ of the activity caused by natural radioactive sources. Because of the long half-life each explosion with significant fallout adds to the total amount of radioactive dust in transit or in the upper soil layers.

The Dust Problem in Industry. — In many industrial establishment, dust is of paramount concern to management and labour. Abrasive dusts cause considerable wear on machinery. hut even more important is the menace dust constitutes in many cases to the safety and health of employees. One of the most dangerous hazards is created by explosive suspensions of dust in mills and mines. The explosibility of dust is governed by its fineness and its contents of volatile combustible matter. The danger of dust explosions is reduced by higher moisture and ash contents of industrial dust. By admixing either inert. noncombustible dusts or water to combustible dusts the hazards are kept under control, especially in coal mines. The concentration of various types of dust which causes maximum explosibility is given in Table IV. The size of these dusts is such that all will pass through a zoo-mesh sieve (200 holes per lineal inch).

TABLE IV.—*Dust Concentrations of Maximum Explosibility*

Type of dust	Ounces per 1,000 cu.ft.
Coal	200- 600
Sugar	200-1,000
Corn, wheat, starch	2 0 0 000
Aluminum	500
Sulfur	1,000

The most disastrous dust explosions have occurred in coal mines, often as a sequel to methane explosions. The ignition of air-dust mixtures is often due to sparks of accumulated static electricity, which, if created by moving parts such as transmission belts, may convey uniform charges to the particles. This will cause them to remain dispersed and suspended for a longer period of time and counteract coagulation and settling.

The health of workers in dusty trades is continuously menaced by large concentrations of particles. These may be (1) toxic dusts which cause direct poisoning: (2) nuisance dusts which generally increase the incidence oi diseases of the upper respiratory tract; and (3) fibrosis-producing dusts which lead to chronic lung ailments. Among the toxic dusts are those of lend, arsenic and manganese and their compounds. The fibrosis-producing dusts lead to the so-called pneumonoconioses or pneumoconioses (dust-lung diseases). The most prevalent among these are known by names incorporating the causative agent (*e.g.*, silicosis, anthracosis and asbestosis). The best-explored hazard is that caused by the breathing of free silica! SiO_2, in the mining, quarrying, ceramic and abrasive industries. However, pneumoconiosis is also caused by other silicates such as pyrophyllite (a hydrous aluminum silicate) and talc (a magnesium silicate).

'Most dangerous from a health point of view are particles below 5μ in diameter. The hazard to the individual is predicated not only on the amounts present in the air breathed by the worker but on the period of time for which he is exposed to the polluted air. The acute danger limit is reached if 5,000,000 free silica particles per cubic foot of air with sizes below 5μ are present. Of these as much as 25% is retained in the respiratory tract. In typical industrial dusts 70% of the particles are between 1 and 3μ and 20% below 1μ in diameter. The median was found around 1.3μ. In outdoor dusts the median of gross particles is around 0.5μ, in sandblasting and granite cutting 1.4μ, in aluminum plant dusts 2.2μ, in anthracite coal mining 0.8 to 1.0μ.

Table V shows some typical dust exposures according to surveys of the U.S. public health service and the U.S. bureau of mines.

For industrial dust control, the use of hoods over dust-producing machinery is recommended. Ventilation systems of the exhaust type, vacuum cleaners or blower fans in mines help dilute the dust concentrations. Some high-voltage electrical precipitators have been installed. especially where valuable materials can be recovered from the dusts. Wet drilling and water sprays through the air also materially reduce the suspensions. Individual protection of workers exposed to dust hazards is afforded by wearing of pressure masks or respirators. Industrially, maximum allowable concentrations of contaminants, in milligrams per liter, are: iron or zinc oxide 0.015, arsenic. 0.0005, lead 0.00015, uranium 0.00005. (See also COAL AND COAL MINING; PNEUMONOCONIOSIS.)

TABLE V.—*The Concentration of Typical Dust Exposures*

Type of work or location	Concentration in millions of particles per cubic foot
Talc mining; jack hammer drillers	2,160
Granite quarrying; iack hammer drillers	112
Anthracite coal mining; miners and helpers	231
Bituminous coal mining; coal cutters and loaders	112
Bituminous coal mining. 3 to 5 min after blasting	3,300
Bituminous coal mining: before work	0.5
Municipal dust: street cleaners, congested district	4.1
Municipal dust; street cleaners, residential district	1.8

Relation to Atmospheric Phenomena. — Dust that is able to remain suspended in the atmosphere for any length of time cannot be discerned by the human eye. Most individual particles remain below 0.5μ diameter. In accumulation they can be noted as haze or by the Tyndall phenomenon (see below) in bright light. The rate of fall of particles in calm air under the influence of gravity is given by Stokes's formula:

$$v = \frac{2}{9} g \frac{(D_p - D_a) r^2}{\eta}$$

where v is the velocity of fall in centimetres per second, g the acceleration of gravity, η the viscosity of air, r the radius of the particles, D_p the density of the particles and D_a the density of the surrounding air.

For particles with diameters less than 10^{-4} cm., Stokes's formula is inadequate. At sea level pressure particles of 10^{-5} cm. diameter will fall about tmice as fast, particles of 10^{-6} cm. diameter about 12 times as fast as indicated by Stokes's formula. A few velocities of fall for rock particles of density 2.3 at sea level pressure are as follows:

Size of particle in microns:	0.25	0.5	1	2	5
Time *needed* to fall 1 ft.:	10 hr.	3 hr.	1 hr.	15 min.	3 min.

In the free atmosphere only the largest dust particles will settle by gravity. Thermal and dynamic turbulence keeps most of the smaller ones in suspension long beyond the period indicated by Stokes's formula. The particles hurled by the Krakatau eruption to heights of 20 mi. needed about one year to fall to 10 mi. In

lower layers condensation in the form of cloud droplets and precipitation are by far the most effective eliminators of dust from the atmosphere.

Although supersaturations of atmospheric water vapour of 400% to 800% would be necessary for spontaneous condensation, there are nearly always enough condensation nuclei present to cause condensation at 100% relative humidity. Spontaneous freezing of water droplets will take place only at about −40° C. Since ice crystals initiate many precipitation processes, nuclei inducing freezing at higher temperatures have to be present. Vincent J. Schaefer found that loam and loess particles begin to act as freezing nuclei at −12° C. and are fully active at −25° C. Usually there are sufficient particles of this type in the atmosphere. At Mount Washington, N.H., the iollowing irequency distribution of ice crystal nuclei was found:

Number per cubic metre	Per cent of cases
$1 \times 10^0 - 1 \times 10^2$	23.5
$1 \times 10^2 - 1 \times 10^4$	31.3
$1 \times 10^4 - 1 \times 10^5$	38.7
$1 \times 10^5 - 1 \times 10^7$	6.j

Bernard Vonnegut reported in 1947 that silver iodide particles are highly effective as freezing nuclei, acting at temperatures between −4° and −8° C. This material has been widely used for modification of clouds. Lead iodide and cupric sulfide are also effective ireezing nuclei. Temperature inversions in the free atmosphere form sharp boundaries with the air below the inversion having normally about 20 times as many nuclei as the air just above the inversion.

W. D. Crozier and Ben K. Seely collected air-borne particles in the 0.5 to 30μ size class on a transcontinental flight from California to the Appalachians at 3,000-m. height. They found a minimum of 15,000 per cubic metre over Santa Catalina Island, Calif., and a maximum oi 207,000 per cubic metre near Dunning, Neb. The high inland values presumably resulted from blowing soil in the Great Plains. Chlorides, presumably NaCl, dropped from a high value of 4,800 per cubic metre in eastern California to o in Nebraska.

The diurnal variation of nuclei in areas undisturbed by local pollution sources shows a maximum in daytime, a minimum at night. The same variation is noted for mountains where upward directed convection carries nuclei aloft during the day and where at night subsidence brings cleaner air to lower levels. The annual variation always shows more nuclei in winter than in summer. This is caused partly by greater pollution through domestic heat sources in winter and partly by the greater stability of the air which tends to keep the nuclei during that season close to the surface.

The variation of nuclei and gross particles in relation to the meteorological elements is not uniform. Both types tend to decrease in number with increasing wind speeds. However, in case of the relative humidity the gross particles tend to decrease with lower humidity values, while the nuclei. especially in areas iar from pollution, increase in number. It is probable that with high humidities many of the hygroscopic nuclei grow into relatively big droplets and either escape counting in the conventional Aitken counter or settle because of their size. For the gross particles it was found that their number also shows a maximum directly under clouds and decreases rapidly inside a cloud.

Similarly, the relation of the number of nuclei to visibility is very complicated, although in first approximation the visibility increases with a decrease in nuclei. In air with a uniform type of nuclei, such as salt particles, at visibilities below 1 mi., only about one-half to one-fourth the number of nuclei is found than with visibilities above 20 mi. For the gross dust the inverse proportionality oi numbers to visibility is much closer.

Industrial areas receive more rainiall because of the increased pollution with hygroscopic nuclei. In the Ruhr region of Germany the difference is about 1.2 in. to 1.6 in. per year compared with undisturbed surrounding areas. The increase is mostly noted in the number of rainialls with less than 0.04 in. in 24 hours. It results in an average increase of 20 rainy days per year for the polluted region. For Tulsa, Okla., a 7% increase in rainfall compared to the environment has been calculated. Similar differences were found in Moscow, Munich and the English midlands. In addition to the pollution factor, it is likely that the increased turbulence over the cities and the water vapour added to the atmosphere by industrial processes are also responsible ior the increase.

The reduction of visibility and absorption of solar radiation is another important influence of atmospheric dust. It depletes particularly the short wave lengths of the solar radiation.

Harry Wexler iound in central North America that the turbidity of clean continental polar air originating in Canada is only one-half of that observed in continental tropical air from the southwestern interior of the continent, carrying considerable quantities of dust.

Other measurements of turbidity showed that in the Alps radiation at the surface was only 69% of the normal at times when Sahara dust storms were observed there. After the Katmai eruption in Alaska in 1912 only 80% of the normal radiation was observed in the subsequent summer and autumn. Following the Krakatau eruption. measurements at Montpellier, Fr., indicated that radiation had decreased by 25%; it remained below normal for three years. A smoke pall from forest fires in Alberta, drifting across eastern North America and the Atlantic ocean into Europe and the near east in Sept. 1950 cut the radiation at Washington, D.C., to 52% of normal and lowered maximum daily temperatures by an estimated 6° F., according to Wexler.

These effects are cited because pollution of the atmosphere by volcanic dust has been adduced as a cause of major climatic changes on the earth. William J. Humphreys advocated the hypothesis that more frequent volcanic eruptions in earlier geological periods led to climatic changes causing ice ages. It has been claimed that both the Krakatau and Katmai eruptions were followed by abnormally low temperatures throughout the world.

The everyday influences of dust on the optical properties of the atmosphere find, for the casual observer, expression as haze of varying intensity. Yet sometimes more striking phenomena are noticeable. One is the familiar Tyndall phenomenon of a bright streak of glittering minute particles scattering light from an intense source. In the open atmosphere this can be noted as sunbeams on cloudy days when a few rays penetrate through small holes in the clouds and cause the dust to scintillate in the illuminated column. During twilight hours similar beams originating from broken clouds below the horizon cause the so-called crepuscular rays, which give evidence oi the presence of dust particles in high layers oi the atmosphere as light from the setting sun strikes them.

During the periods of highest concentration of volcanic dust in the upper atmosphere after the Krakatau and Katmai eruptions, a corona of brownish colour known as Bishop's ring, caused by diffraction, was seen around the sun. In the case of the Krakatau dust the width of this ring was about 10 angular degrees, and the distance from the sun to its outer edge was 22 angular degrees. Joseph M. Pernter found from diffraction equations that the size of the particles causing the ring was about 1.85μ. Optical phenomena reierred to as blue sun or blue moon are not infrequently noted as a result of high smoke or dust layers.

In the free atmosphere sharp horizontal boundaries separating a dusty layer from the clean upper layer can frequently be noted. These dust horizons are invariably associated with inversions of temperature which prevent convection and keep the polluted air confined to the lower layer. Over industrial regions, especially in winter and during the night and early morning hours, dust horizons are observed almost daily. Increasing daytime convection raises the ceiling of the dust horizon and the boundary becomes diffuse.

Methods for Measuring Dust.—In order to determine the concentration and properties of atmospheric dust, the amount of dust in the air, the size of the particles and the chemical and mineralogical composition are measured. For the first two objectives, methods developed by mid-20th century were adequate; for the last only qualitative tests existed. The determination of amounts of dust in the air is based on six fundamental principles: (1) deposition; (2) absorption; (3) impingement; (4) condensation;

(5) electrical precipitation; and (6) thermal precipitation.

The deposition methods are all simple but give only crude results. Paper strips, glass or metal plates, bowls coated with adhesive material or grids of very fine wires are exposed for specified intervals, and the dust particles spontaneously deposited on them are counted through a microscope, or. in case of heavy deposits, the weight increase of the sampler is determined. An instrument employing the deposition principle is called a konimeter. The British advisory committee on atmospheric pollution made use of the Cohen gauge as a standard. It is a funnel collector similar to the familiar rain gauge. Filtration of dust precipitated with rain has been resorted to. and similarly the dust deposited on a snow cover has been recovered by melting and filtration. This leaves, of course, only the water insoluble constituents.

Some of the absorption methods aspirate air through a filter, which in some designs is in the form of a porous paper thimble. The weight increase of the filter is measured after a specified amount of air has passed through it. In some recorders air is passed through a slowly moving band of filter paper. It leaves gray to black spots which are evaluated colorimetrically. For insoluble dusts a layer of moist, clean sugar has been successfully used as a filter. The air is passed through this filter and after sampling. the sugar is dissolved in water and the dust in a drop is counted microscopically. In another procedure the dust is centrifuged from the sugar solution and later weighed. Still another process is to bubble dusty air through clean liquids and count the number of particles in a sample of the liquid. This method is often combined with an impingement method in which the dusty air is expelled at high speed through an orifice against a surface and the deposited dust washed away by a liquid. such as grain alcohol. A sample of liquid is drawn into a pipette and a specified amount transferred to a counting cell similar to those used in bacteriological work. The counting is done microscopically, or, more conveniently, by microprojection of the cell onto a ruled screen. This general principle is used in the Greenburg-Smith impinger apparatus which became the widely used standard in the U.S. for investigation of dust in industrial establishments.

The irnpinger principle is also used in the various konimeters. The first construction of that type was developed by R. S. Kotze in 1916. A sample of dusty air is drawn by a pump through a nozzle 0.0225 in. in diameter and impinged on a glass plate, covered with a sticky substance. 0.0197 in. away from the nozzle. The dust particles are deposited on this plate by the high impact velocity. Modifications of the original construction have a round disk as impinger surface. This disk can be rotated so that a number of samples can be taken in rapid succession, each forming a dust spot on a numbered sector of the disk.

For recording purposes W. G. Hazard and Philip Drinker had the dust impinge on a slowly moving gelatinized film and recorded the density of the deposit photoelectrically.

A further modification combining the impinger feature with the condensation principle is used in J. S. Owens' jet dust counter. A measured amount of air is passed by a pump through a small chamber with wet blotting paper on its walls. The air is moistened to saturation and expelled through a narrow jet against a microscope slide. 1 mm. away. The sudden expansion of the air after exit from the jet causes condensation by adiabatic cooling, and droplets surrounding the dust particles are deposited on the slide. The water evaporates and the dust is left on the slide where it can be counted microscopically. Owens' counter is one of the most widely used pieces of equipment for the determination of dust in the open air.

The very small, submicroscopical condensation nuclei require a different technique to make them accessible to counting, as in the ingenious nuclei counter invented by John Aitken. An air sample is drawn by a graduated pump into a receiver which is kept near saturation by wetted filter paper. Afterward the air in the closed receiver is rapidly expanded by pumping with adiabatic cooling taking place. Water droplets form around the condensation nuclei and a shower of these droplets falls on a graduated disk where they can be counted through a lens system in dark-field illumination. It is assumed that each droplet represents one nucleus.

For continuous records a compressor-activated adiabatic expansion chamber with a photoelectric cell measuring the density of the cloud formed was described by Vonnegut in 1950.

The electrical precipitation method for dust sampling, using an alternating current of 15,000 v. on a wire and thus attracting and collecting dust, had not found widespread application by mid-20th century. The same could be said of the thermal dust precipitator. In that apparatus a heated wire is exposed between microscope slides. Around the wire a dust-free space develops while the dust in the aspirated air is deposited on the slides by convection currents.

To determine composition, microanalytical spot tests have been used. Counts of salt particles have been attempted by counting the number of yellow flashes (sodium D-linej in a flame. Radioactive particles have been counted by Geiger or scintillation counters.

Size Determinations. — For obtaining the size distribution of large samples as they settle on the floors of factories and mines the sedimentation balance has been used. A balance pan is suspended in a cylinder filled with liquid into which the dust sample is introduced at the top. The particles are weighed at fixed time intervals as they settle on the pan. The size distribution can be calculated from Stokes's formula from the observed settling rates.

The turbidity of the liquid in a sedimentation cell in which a sample of dust is settling can be measured photoelectrically at specified intervals. The absorption of light at a fixed level in the cell is a function of the size of the particles.

Air separation methods are also used for size determinations of large samples. A slow air current of known speed is passed through the sample. The smallest particles are raised, carried along and deposited in a filter thimble. The filter is removed and weighed. Then the air speed is increased and the procedure repeated. In this fashion the whole sample can be fractioned'into size groups, the diameters being determined by Stokes's formula.

In the case of industrial dusts the X-ray diffraction method *(see* X-RAYS: *Modern Industrial Applications: Powder Diffraction Analysis)* and petrographic immersion methods, have been used. the last ones particularly for the determination of free silica in the suspensions. (H. E. LG.)

DUST STORMS

The term dust storms covers a class of phenomena resulting from palpable amounts of dust or sand being raised from the ground into the air. Included are sandstorms, rising sand, blowing sand, sand drift, blowing dust, duster, dust haze and harmattan haze. They are common to most semiarid and desert regions of the continents. Excluded from this article are dust devils (*q.v.*).

Although dust connotes finer particles than sand, it is not customary to make a distinction between a dust storm and a sandstorm. Dust storm is the more popular term in the U.S., and sandstorm in north Africa and Asia Minor.

Meteorologists have long studied the occurrence of dust storms with respect to appearance, severity, distribution by region, season and hour, and to associated meteorological conditions. Maj. R. A. Bagnold has made the best field observations (Sahara) on the physics of blowing sand and checked them with aerodynamic theory and laboratory experiments. He found that when the wind at the ground exceeds a certain critical speed, its stress on the exposed sand grains moves the lighter grains to bump into other larger ones, rolling and jumping them along the ground in a general sand drift. This drifting reaches greater heights as the wind speed increases, but under thermally stable air conditions (temperature lapse rate less than the dry adiabatic equilibrium of 1° C. per 100 metres) it is unable to exceed several hundred feet. However. with unstable air, finer sand (*i.e.*, dust) is rapidly carried farther upward, as high as the rising currents go, an altitude which may sometimes surpass 15,000 ft. If referred to some standard height close to the ground, the critical wind speed for starting a sand drift depends on the size distribution of the exposed grains and their stability as an aggregate. Long exposure to a

given regime of winds may sort the grains into an arrangement which tends to resist erosion. Livestock and vehicular traffic can disturb this balance, and initiate wind erosion. M. G. El-Fandy computed that the rising dust particles heated by the sun's rays may warm the air as much as 3° C. per day (summer). increasing the thermal instability and thus accentuating the lifting of the dust.

It is now generally agreed that there are two essential requirements for the initiation of the dust storm: (1) Wind speed at the ground must exceed a certain critical speed. This generally ranges between 1 j and 30 m.p.h., depending on the shape, size, specific gravity, dampness and temperature of the ground particles. In addition, the turbulence and instability of the lower atmosphere tend to enhance the raising of the dust (*i.e.*, lower the critical speed). (2) The ground must provide loose particles of the size that can be lifted by the air, and this loose material must not be so damp from dew or rain as to prevent the wind from raising it.

Most dust storms fall into one or the other of two broad types, though cases of an intermediate or mixed character do occur. The khamsin of Egypt (or gibleh of Libya) is the classical example of the first type. In this the blowing dust occurs over a rather extensive area associated with one or more sectors of air masses of a traveling barometric depression. The other type is local, associated with a thunderstorm or cumulo-nimbus cloud. The haboob of the Sudan is the classical example of the latter.

Haboob Type.—M. H. Freeman, writing of the Khartoum region, describes the well-developed haboob as

> . . . an impressive sight. It begins to form on the edge of a cumulonimbus cloud from which rain has begun to fall. The rain evaporates before reaching the ground and is visible as virga (precipitation trails). At first dust is blown upwards from the ground and resembles smoke from a line of fires on a windy day, with dense columns swirling upwards. As the haboob develops the columns merge to form a billowing wall of dust. The leading edge bulges forward to form a nose and the upper surface slopes back as in well-developed cold fronts. The dust soon rises to the level of the cloud base, about 5000–6000 feet and later extends still higher. Haboobs near Khartoum are usually reddish in colour, but they may be yellow or black according to the type of sand in the locality. When viewed from a distance a haboob appears as a whitish haze below the cloud. This is due to dust reflecting the sunlight, the wind is light aqd variable ahead of the haboob. Its arrival coincides with a sudden increase of wind and the initial squall is often severe. Almost instantaneously the visibility falls from good to some hundred of yards. Thereafter the gusty wind gradually decreases and the visibility improves. Most storms are over in less than an hour and a half, but occasionally one may last several hours. Many of the shorter ones are terminated by the onset of rain which soon washes the dust out of the air and damps the ground, thereby preventing further dust rising. Once formed haboobs sometimes move away from their parent cumulonimbus, and the deterioration is then likely to last longer. Three quarters of the haboobs started between noon and an hour after dusk. Many of those which began during the night were formed elsewhere earlier and arrived at Khartoum after dark. (M. H. Freeman, "Duststorms of the Anglo-Egyptian Sudan," *Meteorological Reports No. 11,* pp. 6–7, Meteorological Office, H.M.S.O. 1952.)

The haboob type belongs to the warmer season, especially the late spring and early summer. It occurs in dusty regions other than Khartoum, particularly those of India, Asia Minor, Australia and west Africa.

Khamsin Type.—The khamsin type is primarily a phenomenon of the colder season, in many regions tending to occur in the late winter and spring. It is the characteristic weather situation causing dust over coastal north Africa. From time to time, between October and June, a low-pressure area, passing eastward along the Mediterranean coast, causes, on its forward side, a strong flow of warm, desert air from the south (the khamsin proper); it is followed by a burst of cold air from the north on the rear side. The southerly current, as a result of its desert origin and its force, is always more or less dusty or hazy, and in spring and fall is likely to bring severe sandstorms as well. After the cold front leading the northerly current has passed a station, the sand may rise there again in the cold air rendered unstable by its transit over the warm Mediterranean and desert, especially in winter; it soon subsides, except well inland. There is likely to be a greater frequency, thickness and extent of the dusty air during the daytime, as a result of convection. The sandstorm, on the other hand, may begin and end at any hour, and it often continues severely all night, indeed for several days consecutively. Extensive dust storms analogous to the khamsin occur in Asia Minor, Iran, the U.S.S.R., India, China, Australia and the United States. The many severe dust storms over the Great Plains of the United States are mostly formed in the sectors of cyclonic storms occupied by dried-out polar maritime air of Pacific origin, as this is usually the most unstable air. The khamsin dust which follows a cold front may approach as a wall like the haboob, but the dust in the warm-air current generally sets in gradually as the wind slowly increases. The extent of the dust is variable, from scattered areas of a few hundred yards each to solid belts of over 100 mi.

Special Considerations.—Outside of khamsin and haboob situations of the classical type, sandstorms or shallow blowing sand and dust may occur locally over loose sand areas whenever in unstable air (afternoon hours) the wind speed rises to more than 1 j or 20 m.p.h., whether summer or winter.

Dust once raised into the atmosphere takes on a variety of appearances as it is carried upward and away with the winds aloft. The typical dust wall, as with the haboob, forms when a sudden and marked increase of wind speed raises the dust along a broad and more or less continuous advancing front (squall line or cold front). Another aspect of some khamsin-type dust storms is the dust ceiling or dust overcast. This results when a warm dust-laden air mass overruns a shallow cooler air mass, and a heavy dustfall follows. Dustfalls around the Canary and Cape Verde islands are sometimes so thick that navigation is dangerous and birds roost it out on ships' riggings. Dusty air drawn into a distant cyclonic wind system and forced to rise over a colder air mass may precipitate muddy rain or snow down through the clean underlying air—the mud rains (*q.v.*) or red rains well known in Europe, and recorded occasionally in the U.S., Australia and China.

As the wind and instability associated with a dust storm subside, the larger (sand) particles soon fall out. However, the fine particles, of the order of .01 mm. diameter, have a terminal falling speed of about 1 cm. per second. Thus the upper air currents, usually moving more rapidly than the surface air layers, can carry dust composed of finer particles for several thousand miles before a sufficient amount has settled out or the dust has become so diffused by vertical and lateral mixing that the visibility and colour of the sky are no longer noticeably affected. This explains the widespread dust haze observed in regions far removed from the area of dust storms. Dust from the frequent haboob-type squalls (simooms, tornadoes) in the Sudan is spread by the prevailing easterly winds so that for much of the year the whole of west and central Africa from lat. 5° to 30° N. experiences a persistent dust haze (harmattan haze, dry haze, French: *brûme sèche*) which changes in density from day to day and season to season, becoming at times troublesome to aviation. This type of haze in more transitory form is also a feature of the Saudi Arabia-Iraq-Iran-Pakistan region.

The dust storm has serious practical consequences in obstructing vision, damaging machines and matériel, causing electrostatic discharges and radio static, soil erosion and dust deposition, impairing human health, etc.

For predicting dust storms the weather forecaster requires experience with the local vulnerability to blowing dust, a knowledge of the usual behaviour of the storms and an ability to forecast the winds, the thunderstorms or low-pressure systems with which the dust is associated.

DUST DEVIL. Also called sand devil, diablo, is a dusty whirlwind normally a few feet in diameter and about 100 ft. tall. At times it may he several hundred feet wide and several thousand feet high. Low pressure at the centre and strong vortex winds cause dust and small debris to be carried upward making the whirl appear as a vertical tube or funnel. Duration of the whirls range from a few minutes to more than an hour; wind speeds range from less than 10 to over 50 m.p.h. Strong ones may cause property damage. In appearance. a dust devil resembles a small tornado (see TORNADO); however, it usually forms over dusty, sandy, barren soil strongly heated by the sun on days of fair weather, such as are common in desert regions in the summer. Rotation of the whirls may be either clockwise or counterclockwise. They generally move with the wind but follow a curved path which depends on the direction of rotation and topography.

DUST STORM: see DUST.

DUTCH EAST INDIA COMPANY, a body founded by a charter from the Netherlands states-general on March 20, 1602. It had a double purpose: to regulate and protect the already considerable trade carried on by the Dutch in the Indian ocean; and to help in prosecuting the long war of independence against Spain. Before the union between Portugal and Spain in 1580–81, the Dutch had been the chief carriers of eastern produce from Lisbon to northern Europe. When they were shut out from the Portuguese trade by the Spanish king they were driven to sail themselves to the east in order to make good their loss. Unsuccessful attempts were made to find a route to the east by the north of Europe and Asia, which would have been free from interference from the Spaniards and Portuguese. It was only when these failed that the Dutch decided to intrude on the already well-known route by the Cape of Good Hope and to fight their way to the Spice Islands of the Malay archipelago. A first expedition, commanded by Cornelius Houtman, a merchant long resident at Lisbon, sailed on April 2, 1595. It was provided with an itinerary or book of sailing instructions drawn up by Jan Huyghen van Linschoten (*c.* 1563–1611). a Dutchman who had visited Goa with the Portuguese before taking part in the Dutch arctic voyages of 1594–95 (his *Navigatio ac itinerarium* was published in 1595–96; Eng. trans., 1598). The voyage was marked by many disasters and losses, but the survivors, who reached the Texel on their return in Aug. 1597, brought back some valuable cargo and a treaty made with the sultan of Bantam in Java.

These results prompted a great outburst of commercial adventure. Companies described as "Van Ferne"—that is, of the distant seas—were formed, and by 1602 from 60 to 70 Dutch vessels had sailed to Hindustan and the Indian archipelago. On the distant seas the traders could neither be controlled nor protected by their home government. They fought among themselves as well as with the local peoples and the Portuguese, and their competition sent up prices in the eastern markets and brought them down at home. Largely at the suggestion of Johan van Oldenbarneveldt, and in full accordance with the economic principles of the time, the states-general decided to combine the existing separate companies into one united Dutch East India company, which could discharge the functions of a government in those remote seas, prosecute the war with the Spaniards and Portuguese and regulate the trade. A capital, estimated variously at a little above and a little under 6,500,000 florins, was raised by national subscription in shares of about 3,000 florins. The independence of the states which constituted the United Netherlands was recognized by the creation of local boards at Amsterdam, in Zeeland, at Delft and Rotterdam, Hoorn and Enkhuizen. The boards directed the trade of their own districts and were responsible to one another, but not for one another as toward the public. A general directorate of 60 members was chosen by the local boards. Amsterdam was represented by 20 directors, Zeeland by 12, Delft and Rotterdam by 14, and Hoorn and Enkhuizen also by 14. The real governing authority was the "Collegium," or board of control of 17 members, of whom 16 were chosen from the general directorate in proportion to the share which each local branch had contributed to the capital or joint stock. Amsterdam, which subscribed a half, had eight representatives; Zeeland, which found a quarter, had four; Delft and Rotterdam, Hoorn and Enkhuizen had two respectively, since each of the pairs had subscribed an eighth. The 17th member was nominated in succession by the other members of the United Netherlands.

A committee of ten was established at The Hague to transact the company's business with the states-general. The "collegium" of 17 nominated the governors-general who were appointed from 1609. The charter, which was granted for 21 years, conferred great powers on the company. It was endowed with a monopoly of the trade with the East Indies, was allowed to import free from all custom dues, though required to pay 3% on exports and charged with a rent to the states. It was authorized to maintain armed forces by sea and land. to erect forts and plant colonies, to make war or peace, to arrange treaties in the name of the stadtholder and to coin money. It had full administrative, judicial and legislative authority over the whole of the sphere of operations, which extended from the west of the Strait of Magellan westward to the Cape of Good Hope. Its headquarters were early fixed at Batavia in Java. Only the main dates of its progress can be mentioned here. By 1619 it had founded its capital in Batavia on the ruins of the native town of Jakarta. It expelled the Portuguese from Ceylon between 1638 and 1658, and from Malacca in 1641. Its establishment at the Cape of Good Hope, its only colony in the strict sense, began in 1652. A treaty with the local princes established its power in Sumatra in 1667.

The flourishing age of the company dates from 1605 and lasted till the closing years of the century. When at the summit of its prosperity in 1669 it possessed 150 trading ships, 40 ships of war and 10,000 soldiers and paid a dividend of 40%. In the last years of the 17th century its fortunes began to decline, for a variety of causes. The rigid monopoly that it enforced wherever it had the power provoked the anger of rivals. When Pieter Both, the first governor general, was sent out in 1609, his instructions from the board of control were to see that the Dutch had the entire monopoly of the trade with the East Indies, and that no other nation had any share whatever. The pursuit of this policy led the company into violent hostility with the English, who were also opening a trade with the east. Between 1613 and 1632 the Dutch drove the English from the Spice islands and the Malay archipelago almost entirely. The English were reduced to a precarious footing at Bantam in Java. One incident of this conflict, the torture and judicial murder of the English factors at Amboina in 1623, caused bitter hostility in England. The success of the company in the Malay archipelago was counterbalanced by losses elsewhere. It had in all eight governments: Amboina, Banda, Ternate, Macassar, Malacca, Ceylon, Cape of Good Hope and Java. Commissioners were placed in charge of its factories or trading posts in Bengal, on the Coromandel coast, at Surat and at Gambroon (or Bandar Abbas) in the Persian gulf, and in Thailand. Its trade was divided into the "grand trade" between Europe and the east, which was conducted in convoys sailing from and returning to Amsterdam; and the "Indies to Indies" or coasting trade between its possessions and native ports.

The company always placed its trading interests first, often preferring in the East Indies to rule indirectly through local princes who could relieve them of the work of government and supply contributions in kind. Nevertheless its political and military burdens slowly destroyed its profits. and, like the British East India company, it suffered from servants who put their own private trading interests before those of the company in an attempt to "get rich quick." In addition, the company's dividend policy

proved to be disastrous. The level of dividends was allowed to remain unduly high when the financial position would no longer justify it, money being borrowed for the purpose at the cost of creating a heavy burden of debt for the future. The final blow to its credit came when in 1780 the Dutch were involved in war with the British during the American Revolution. Thereafter it remained in existence only with help from the state, until the United Provinces were overrun by the French revolutionary armies in 1795. With the connection between the Dutch and their overseas empire broken, the company was administered by a government committee from 1796 and the government officially took over its possessions in 1798. See also references under "Dutch East India Company" in the Index volume.

DUTCH EAST INDIES (NETHERLANDS EAST INDIES), located between 6° N. and 11° S. and between 95° and 141° E., was until Dec. 1949 one of the overseas territories of the Kingdom of the Netherlands. It comprised Sumatra and adjacent islands, Java with Madura, Borneo except for the British-controlled north and northwest parts, Celebes with Sangihe and Talaud Islands, the Moluccas and the so-called Lesser Sunda Islands east of Java with the exception of the Portuguese (eastern) part of Timor. These former Dutch territories form the Republic of Indonesia. New Guinea west of the meridian of 141" E., with its offshore islands of Waigeo, Salawati and Misoöl, was retained as Dutch territory in spite of Indonesian claims on this area which they call Irian Barat or West Irian. Before 1922 the Netherlands Indies were among the "colonies and oversea possessions" of the Kingdom of the Netherlands, but in that year an amended constitution recognized in principle the equality of the parts of the kingdom by using the term "territories" for describing the Netherlands as well as the overseas units. In World War II the entire area was occupied by Japan. The years 1945 to 1949 formed a transition period in which the Netherlands tried to regain control of the islands, but failed because of stubborn nationalist resistance and pressure from the United Nations. For geography see MALAY ARCHIPELAGO and articles on the separate islands, and for history, MALAY ARCHIPELAGO and INDONESIA. (J. O. M. B.)

DUTCH ELM DISEASE: see ELM.

DUTCH GUIANA: see GUIANA: Surinam.

DUTCH LANGUAGE is the name popularly applied to the Netherlandic (Netherlandish) language as spoken in Holland (kingdom of the Netherlands), whereas the same language in northern Belgium is popularly called Flemish. During the middle ages the name of the language was Dietsc or *Duutsc,* historically equivalent to German Deutsch and meaning simply "language of the people," as opposed to Latin, the language of religion and learning. The form Duutsc was borrowed into English and gives modern "Dutch." The present official name of the language is Nederlands, "Netherlandic." In Holland it is also popularly called Hollands, "Hollandish," reflecting the fact that the standard language is based largely on the dialect of the old province of Holland (now North and South Holland). See NETHERLANDIC LANGUAGE. (W. G. MN.)

DUTCH LITERATURE. Of the earliest inhabitants of the Netherlands only the Frisians have survived and although the modern province of Friesland is but a small part of the territory once held by them, they have maintained their own separate language and literature from the time of Bernlêf, who lived in the 8th century, to the 20th century. The remainder of the Netherlands was overrun and colonized by the Saxons and Franks between the 3rd and 9th centuries, resulting in a predominantly Frankish culture in the south and Saxon or an amalgam of Saxon and Frankish language and culture elsewhere.

Under the less nomadic Franks the south prospered more than the north and it was there that a literary language first developed, but only very gradually because of the marked differences between the dialects of the east (Limburg, with Middle German traits), the centre (Brabant) and the west (Flanders, with many Inguaeonic features which link the coastal dialects with Old English; see BELGIAN LITERATURE: *Flemish*).

In the early middle ages when Latin and, later, French were the languages of the educated, the vernacular was largely confined to unrecorded oral legend and folk songs. The earliest text which can claim to contain Old Dutch is the "Wachtendonk Psalm Fragments" (early 10th-century), though since the preponderant dialect is Middle Franconian, it probably originated on the German side of the border; and of course even the specifically Low Franconian parts are representative only of the eastern form of Old Dutch.

Medieval Poetry.—The writings of the earliest known Dutch poet. Henric van Veldeke (see HEINRICH VON VELDEKE and BELGIAN LITERATURE: Flemish), are typical of an age of religious zeal emanating from the centres of learning in France. His life of Servatius (c. 1170), patron saint of Maastricht, is a rendering of a Latin original into the Limburg dialect and his Eneide (*c.* 1185) is a diffuse Limburg version of the 12th-century French transposition of Virgil's epic into a Christian and feudal setting. The Eneide and his love songs (see MINNESINGER) had a significant influence on poetry in Germany, where Rudolf von Ems (1200–54?) referred to him as the originator of rhymed verse. That neither Henric himself nor any of his countrymen made this claim suggests that there were earlier Dutch poets in rhyme who were unknown in Germany.

Apart from one other early Limburg text, a fragment of the Carolingian epic Aiol (c. 1200), 13th- and 14th-century texts were generally written in Flanders and Brabant, provinces where expanding trade produced centres of culture in which the prevailing influence was French. A large number of fragments of indifferent Dutch versions of Frankish precourtly epics (Renout van Montalbaen, Het *Roelantslied*, De Lorreinen, etc.) is redeemed by a complete and probably entirely original romance, Karel ende Elegast (c. 1300). a Flemish masterpiece of feudal reverence quickened by dry humour (see CHARLEMAGNE LEGENDS).

The crusades brought the courtly romances into vogue: some were derived from classical history, such as Segher Dengotgaf's delightful Het Prieel van Troyen and Parlement van Troyen (both from the French of Benoît de Sainte Maure (*q.v.*), also the source for van Maerlant's history of Troy); others, like the sentimental idyl *Floris* ende Blanccfloer by Diederic van Assenede (d. c. 1292), were oriental tales; and most popular of all were the Celtic sagas, including the Arthurian cycle which came to the Netherlands through France, and De *reis* van *Sinte* Brandaen (12th-century), a lively tale based on an Irish odyssey in Latin. But by the 1260s, when Jacob van Maerlant (*q.v.*) wrote his Alexander, Die Historie van den Grale, *Merlijns* Boeck and Historie van Troyen, chivalry was on the decline and the titles of van Maerlant's later works reveal something of the utilitarian reaction to romanticism and mysticism at the end of the 13th century: Der Naturen Bloeme, *Rijmbijbel* and *Spieghel* historiael (1290). The compendia of knowledge which van Maerlant had popularized were multiplied in worthless imitations in the 14th century, though two clercken ("scholars") are worthy of note, Jan van Boendale (1280–1365) for his Der Leken *spieghel* (written 1325–30) and Melis Stoke for his Rymkronek van Holland (1305). Indeed popular didactics have remained, as will be seen, a favoured genre throughout Dutch literature.

Equally typical of the change in fashion and of far greater literary importance is Van den vos Reinaerde (c. 1250), one of the most important versions of the cycle of stories associated with Reynard the Fox (*q.v.*). A parody of the Germanic epic and manners at court, it is a composite work by two Flemish poets (Aernout and Willem). The best part is also the earliest, a late 12th-century rendering of the French poem Le Plaid. This ageless classic of subtle caricature and sly good humour is an outstanding contribution to the whole world of literature.

Far removed from the clamour of the rising third estate for factual knowledge, the nun Hadewych was writing (c. 1250) mystical songs that winged their way over the level of popular taste. Her poetry is a radiant example of the love lyric, which must have been passed on from van Veldeke in works now lost. The burning

sincerity of the ecstatic minnesangen and *Visioenen* and her hortatory letters inspired later mystics, the greatest of whom was Jan van Ruysbroeck (*q.v.*). This disciple of the great 14th-century German mystic Meister Eckhart (*q.v.*) was undoubtedly the Netherlands' greatest medieval prose writer. He was also typical of Dutch didacticism at its best, for (like the 19th-century Flemish poet Guido Gezelle, *q.v.*) he had the true artist's gift of expressing great truths in simple terms. His most famous work, a guide to the soul in search of God, is De Chierheit der gheestliker *Brulocht* (1350, "The Glory of the Spiritual Marriage"). The rapid spread of Ruysbroeck's prose writings in Latin translations and the powerful influence of German mysticism in the 14th century were due to a reawakening in the religious foundations which called for and produced a quantity of instructional literature for the laity. Ruysbroeck's influence is appreciable well into the 15th century, when Thomas a Kempis' *Imitatio* Christi sets the tone of the devotio *moderna.* Other popular means of instructing the laity in the middle ages were the exempelen, short stories illustrating tracts, sermons, Bible stories and so on, and of course the legends. Beatrijs, the best of the European Mary legends. was written in a dialect similar to Hademych's East Flemish and the courtly reverence in it suggests that it is a 13th-century work. Legends about the miraculous powers of the Virgin were widely current at this time. One other, *Theophilus,* has been preserved and many others were later collected in abridged prose versions; but there is a rare beauty in the simplicity of Beatrijs.

Medieval Drama and the **Rederijkers.**—It is unfortunate that no early religious drama has been preserved, particularly since there must have been a dramatic tradition up to the abele spelen. These were entirely secular plays, possibly the first in Europe, exotic romances of chivalry and love, such as might well have been the natural development of simple mime added to the minstrel's popular ballads and lays. It is impossible to discover the date of the songs since they had been in circulation for centuries before scribes and printers started recording and collecting them in the 15th and 16th centuries. But many of them have Germanic line structures and sing of ancient legends and sagas. The earliest abele spelen and farces (sotternieen or kluchten) that often followed them as a light (and frequently bawdy) diversion date from the 14th century. Further romantic plays were certainly written in the 15th and 16th centuries, but only one of these has survived, Colijn van Rijssele's Spiegel der Minnen. Van Rijssele was a "Rederijker," and it was in the "Rederijkers Kamers," or chambers of rhetoric, that the farce thrived in the 15th century.

These chambers, which spread rapidly from the French border in the 15th century, were organized like guilds with functions similar to those of the medieval French dramatic societies (*puys*); French influence is evident both in their organization and in their name (from *rhétoriquer*). Towns which protected them commissioned them to provide the ceremonial at local religious and secular festivals and they were of great influence in popularizing art and morals.

Drama by this time had largely passed from the hands of the clergy to the hands of the laity (see DRAMA: *Medieval* Drama); and the introduction of secular themes had necessitated the use of stages or carts outside religious buildings. The Rederijkers *Kamers* depended on literary performance for their very existence and lacked neither the enterprise nor the wealth to display their prowess on a grand scale. To this end national festivals (*Landjuwelen*) were lavishly organized and competitions held at which prizes were offered for poetry and drama. One of the finest plays of this period, Elckerlyc, a morality of c. 1470 (by Pieter Doorlant?) won a prize at a Landjuweel and became famous in England (as *Everyman*). *Mariken* z'an Nieumeghen, a miracle play (*c.* 1500), is remarkably modern both in its psychological insight and its technique. The "miracle" of the renegade's conversion is achieved by the simple and realistic device of confronting her with a topical "pageant" street play, a theme within a theme.

The Rederijkers also developed a new poetic form, the *referein,* seen at its best in the militant anti-Lutheran poetry of Anna Bijns (1494–1575). But as the number of Kamers multiplied they degenerated into mutual admiration societies for poetasters and only the Egelantier ("Wild Briar") and the Wit Lavendel ("White Lavender") remained famous into the 17th century because of the leading Renaissance poets associated with them in Amsterdam.

Renaissance and Reformation.— The 16th century is characterized by the diversity of its literary forms which reflect an age in decline confronted by the first articulation of the new art coming to the Netherlands from Italy through France. The new printing presses not only served the demand for popular literature, both from medieval sources and from the pens of the reformers; they were also the means of spreading the esoteric poetry and learning of the humanists. Chapbooks, containing prose versions of medieval romances and new translations from the French, folk songs and Rederijkers verse; the new psalm translations by Pieter Datheen (Dathenus, c. 1531–90), Philips van Marnix van Sint Aldegonde (*q.v.*) and others, Reformation propaganda in the form of pamphlets such as Marnix's Biencorf der H. Roomsche Kercke (1569) and the marching songs, the Geuzenliederen, of the Calvinist revolt against Spain (one of which, the "Wilhelmus," became the national anthem); the first sonnets, the first dissertations in the vernacular and the first grammars of the Dutch language—the very abundance of the flow as well as its diversity displays the restlessness of an age of change, in social and political patterns, religion, art and learning.

The new iambic metres and the first echoes of classical antiquity came to the Netherlands in the odes, sonnets and translations of Jan van der Noot and of the first northern poet of the Renaissance, Jan van Hout (1542–1609). Carel van Mander (1548–1606), painter and poet, introduced scholarly prose writing in his well-known Schilderboeck (1604), though. of course, the noble Latin prose of Erasmus (*q.v.*) had been famous throughout Europe for nearly a century.

Van der Noot's Het Bosken (1570 or 1571), a collection of Petrarchan sonnets in the manner of Pierre de Ronsard, was published in London, where he was then an exile on account of his participation in an insurrection in 1567. Indeed, in the wresting of the tiny Dutch republic from a European empire many Dutchmen suffered, none more so than the moderates who could appeal to neither side for protection. Dirck Volkertszoon Coornhert (1522–90) was one of a number of Erasmian moderates whose outspoken views cost him his freedom. Humanist poet, doctrinal pamphleteer, translator and moral philosopher, he is justly remembered for his stoical Christian ethic Zedekunst dat is *Wellevens*kunst (1586). Montaigne and the Bible are his mentors, but the supple and lucid, even entertaining, style is his alone and in a work. moreover, of which the subject required a vocabulary that had to be created for the purpose. Indeed, it was Coornhert and his successors, in particular the translators of the Dutch authorized version of the Bible (1637), who laid the foundations of the standard language of today. The importance of the non-Flemish dialects in the compounding of this literary norm was strikingly demonstrated in more recent times, when the 19th-century revival of literary Flemish in Belgium necessitated further efforts toward standardization between north and south.

The Spanish hold on the Catholic south during and after the Eighty Years' War (1568–1648) caused a decline in Brabant and Flanders; by contrast there was a spectacular expansion in Holland. to which artists, intellectuals and financiers had fled from the Spanish armies. The sudden rise of Amsterdam and The Hague as the emergent capitals of an empire and the birth of civic pride in the writers of the Golden Age symbolize the final passing of a medieval age belonging to Ghent, Bruges, Liège and Antwerp.

The Poets of the Golden Age.—Henric Laurenszoon Spiegel, Coornhert's friend and kindred spirit, is the greatest of a generation straddling the old and the new. He was a member of the medieval Egelantier Kamer in Amsterdam and he wrote both for the burgher and for the scholar. His Nieu Jaar *Liedekens* (incomplete first ed.. 1609) and *Lieden op 't* Vader Ons (first printed 1723; modern ed.. 1957) continued a medieval tradition recast in Renaissance style and re-echoing Erasmian moderation; at the same time his learned Twespraack van de *Nederduytsche Letter*kunst (1584) with its preface by Coornhert was intended to popularize the proper use of a national language. On the other hand,

his unfinished Hertspiegel (published 1614) is particularly abstruse because it is a first attempt at philosophizing in the vernacular and in poetry. Only seven of the nine proposed cantos were completed, forming a very personal pendant to Coornhert's Wellevenskunst. The dichotomy inherent in the Renaissance—between popular religious revival and humanism (of interest only to the few)—was particularly marked in Holland because of the incompatibility of rigorous Calvinistic principles with the ideals of pagan antiquity. This caused a tense ambivalence in many writers of the 17th century who took both their religion and art seriously, such as Heinsius, Bredero and Vondel. Others, like Jakob Cats and Jacobus Revius, were less concerned about the new learning than they were about the Protestant faith, whereas Hooft was more a humanist than a Christian.

Daniel Heinsius (*q.v.*), a celebrated humanist at Leiden university (though of Flemish extraction) wrote Latin plays which, like those of Hugo Grotius (*q.v.*), were models for Hooft and Vondel. But he also added his considerable aufhority to the claims of the vernacular by writing a shamelessly Dionysian *Hymnus* oft Lofsanck van *Bacchus* (1614) and an equally devout Lofsanck van *Jesus Christus* (1615). It was a sign of the times that his fellow Calvinists, such as Revius, saw no incompatibility in the work of the first poet to "launch an arrow of true religion across the country."

In his work (which has great charm and forthrightness) Gerbrand Adriaenszoon Bredero (*q.v.*) gives the impression of having lived, loved and suffered to the full during his short life in the bustle of cosmopolitan Amsterdam. His material is the life of the commoner, his medium the folk song, farce or comedy. His secular songs in medieval style and devotional songs in Renaissance verse tell of a passionate devotion to women and a yearning for religious moderation as taught by Coornhert and Spiegel. His three tragicomedies based on the Amadis novels were not successful, but he wrote three farces which mark the zenith of this medieval genre: Klucht van de Koe (1612), Klucht van den Molenaar (1613), *Klucht* van Symen sonder Soetigheyd (1612 or 1613). Day-to-day existence in the up-and-coming metropolis of Arnsterdam provides material for two comedies, Het Moortje (1615, inspired by Terence's Eunuchus) and his masterpiece, De *Spaan*schen Brabander (1617).

Amsterdam, the raucous, bustling city of the Spanish Brabantine, was also the home of Joost van den Vondel (*q.v.*). Indeed, as one of many Brabantines entering the capital, he joined the Rederijkers Kamer founded there for southerners, the Wit Lavendel. Like Bredero he was a self-educated man of humble stock and he resolved the conflict between artistic and religious leanings only when he entered the Roman church at the age of 54. This, a courageous act of faith at a time when Catholics were an unpopular minority, is typical of his integrity. His pursuit of truth and perfection lasted right up to the culmination of his work at the age of 80 and led him from a Baptist upbringing to Remonstrant liberalism and onward, from self-taught French to Latin (Seneca) and thence to Greek (Sophocles), deferring as he learned to his "masters," Guillaume Du Bartas, Grotius, Caspar van Baerle (1584–1648) and Geraert Vos (1577–1649). It is a measure of Vondel's indomitable personality that his attitude toward contemporary people and events, of which he was a fearless chronicler, prevails to this day, even where history records a different view. Yet because he does not allow his personality to impose on the scriptural authenticity of his plays, these are too austere and remote to be popular today. Nevertheless in his baroque masterpieces Joseph in *Dothan* (1640). Lucifer (1654), Jephta (1659) and Adam in *Ballingschap* (1664) he is as great an artist of the Counter Reformation as his contemporary, Rubens.

If Bredero was the noble commoner and Vondel the noble citizen, Pieter Corneliszoon Hooft (*q.v.*) was certainly the noble aristocrat. He was one of the fortunate few in Holland to bring the refinements of the new art from Italy direct. He lavished an Italianate flourish alike on his Petrarchan sonnets, his pastoral *Granida* (1605), his Senecan and Plautian plays. on the studied prose of his letters and his monumental (and unfinished) history of the war against Spain and his art of living. His castle at Muyden became a neo-Florentine centre for the entertainment of artists and scholars attracted by mutual interest in poetry, music and learning and the charm of such gifted young women as the Roemer Visscher daughters.

Anna Visscher (1583–1651), like her father Roemer (1547–1620; Spiegel's contemporary in the Egelantier), versified popular ethics in the manner that was to bring Jakob Cats (*q.v.*) such unmerited fame. Cats' prolix moralizing, pedestrian doggerel and patronizing tone force their way into the literature of his country if only because of the disastrous influence they had on the taste of the middle classes; until, half way through the 19th century, Multatuli (Eduard Douwes Dekker) let fresh air into the smug atmosphere of the Dutch front parlour.

As learned as Hooft but less of a poet, as humorous as Bredero but a more harmonious individual, Constantijn Huygens (*q.v.*) had all the qualities to which the Dutchman of his day might aspire. Of strict Calvinist principles, he was an able if not brilliant diplomat who wrote trenchant, shrewd and witty poetry in his leisure hours (as he called his first volume of moral emblems—Otia of Ledighe *Uren,* 1625) as well as making excellent translations of some of John Donne's poetry.

There were many who attempted to emulate the work of these masters and few who had talent enough to be remembered. Jan Janszoon Starter (1594–1626) rarely attains Bredero's subtlety or feeling in his amorous and jocular poetry contained in Friesche Lusthof (1621). Of those who cultivated Vondel's poetic diction the best was Jeremias de Decker (1609–66), who in his Rym-*Oeffeningen* (1656) does sometimes convey deep and moving feeling. Hooft's prose writing provided a model for Geeraert Brandt (1626–85) who wrote a very readable, straightforward account of the Reformation and biographies of M. **A.** de Ruyter, Hooft and Vondei.

But there were also four poets, three of whom were clerics, who contributed religious verse of considerable merit in its own right. The Roman Catholic Joannes Stalpart van der Wiele's Geestelijke Lofsangen (1634) contains songs of medieval simplicity and devotion. Jacobus Revius (1586–1658), stern poet of Calvinist orthodoxy, was such a master of the Renaissance forms and the sonnet in particular that he could use them with great effect to express the vigour and sincerity of his dogmatism. By a strange fate Revius, teaching the faith of so many in a language they could understand, was almost unread, whereas Dirk Rafaelszoon Camphuysen (1586–1627), who was removed from his parish because of his unorthodoxy, satisfied a widespread demand for personal, devotional poetry in his Stichtelyke *Rymen* (1625).

Equally popular were the introspective collections of mystical poetry (*e.g., Jesus* en de Ziel, 1678) by the ascetic Jan Luyken (1649–1712). He was a layman who had started by writing hedonistic songs in Duytse Lier (1671) containing love lyrics as fine as any in this country.

Writers of the Late 17th and 18th Centuries.—If the transformation of the amalgamated Amsterdam Kamers into a theatre and thence into the embryo of a university had been symbolic of the advance in art and learning, the appearance in 1669 of the first literary society (dichtgenootschap) must be regarded as an omen of a decline at this time which was to last right through the 18th century. Material well-being sapped the vitality of a nation, which slipped into an ignoble era of emasculate flirtation with its heroes of the past and fashionable French contemporaries. This was the heyday of what later generations dubbed "pen-lickers and tipplers in powdered wigs." Even where real talent was evident in the one poet, Hubert Poot (1689–1733), this was prostituted by the delusion of his day that rococo flourish and prescribed form were the criteria of true poetry. And prose, which had worthy antecedents in the august style of Hooft and Vondel, the less ornate writing of Coornhert and Huygens and the homespun ship's journals of William Bontekoe (Journael . . . van de Oost-Indische Reyse, 1646), consisted in the 18th century almost exclusively of translations and bombastic disquisitions. It is significant that Justus van Effen (1684–1735) wrote in French before he made his name as the founder of De Hollandse Spectator

(1731–35). The simple style in his pedagogic, moralizing essays makes a welcome contrast to the work of his contemporaries, and his descriptive realism links his name with other popular writers of the Dutch domestic scene. Cats, Elisabeth Wolff-Bekker and Agatha Deken and Nicolaas Beets.

Elisabeth Wolff-Bekker (1738–1804) was more than a realist, however. She was a highly intelligent woman with a nice sense of humour, in her unorthodoxy the child of rationalism, in her romanticism the precursor of the 19th century. She had made a name as an essayist and poet before her association with Agatha Deken (1741–1804), a close friend with some talent, though less spirit. The work for which they are most famous is the epistolary novel Sara Burgerhart (1782), dedicated to "Dutch young ladies" and proudly announcing "Not translated" on the title page. This is the first Dutch novel and in its remarkable realism and intricate composition it improves on Richardson, on whose writings it was modeled. The eight-volume *Willem Leevend* (1784–85) has a similar purpose of educating the young in moral virtue and here, too, the original didactic intention recedes behind the authors' creative genius.

By the end of the 18th century there were a number of poets, Hieronymus van Alphen (1746–1803), Rhijnvis Feith (1753–1824), Jacobus Bellamy (1757–86) and Antony Staring (1767–1840), who were reacting against flaccid neoclassicism, but only Staring achieved more than a naïve or melancholy echo of German sentimentalism. He had a keen awareness of beauty in nature and was sufficiently original to avoid the banalities then in circulation. Staring is an undemonstrative poet with the descriptive talent of Cats and something of Huygen's subtlety. He was, in fact, too pure an artist for his contemporaries, who preferred the self-appointed leadership of Willem Bilderdijk (*q.v.*). Bilderdijk's turgid excesses almost smother a real spark of genius, yet where his feeling is true his poetry carries conviction despite its rhetoric. In fact his Protestant zeal had repercussions in the "Reveil," a spiritual movement which gave the impetus to the literary revival of the 1830s.

The Reveil and De Gids.—Jacob Geel's essays in Onderzoek en Phantasie (1838) set a new standard in philological and philosophical criticism. Yet he, like Staring, was almost swept aside by the growing wave of romanticism. At the same time, the reactionary freethinking of the new Enlightenment roused the dormant militancy of the Calvinist church, which realized the danger to its entrenched position. Bilderdijk and his disciple Isaac da Costa (1798–1860) had vociferously reminded the nation of its divine mission and the historical novel abroad (particularly the work of Chateaubriand and Scott) provided an ideal form for a specifically Christian national romanticism. When in 1826 David van Lennep (1774–1853) published a paper calling for Dutch novels modeled on Walter Scott, his son Jacob van Lennep (*q.v.*) promptly responded with a medieval story, De Pleegzoon (1833). He was a prolific writer of poetry, novels, drama, libretti, translations (of Byron, Scott, Shakespeare), history and literary criticism, though the only work of his that is now read is a romantic rather than historical novel, Ferdinand Huyck (1840). Far more important, however, was Hermingard van de *Eikenterpen* (1832) by Aarnout Drost (b. 1810), published two years before his death at 24. In this sensitive and moving story of missionary evangelism in 4th-century Holland, the modern novel suddenly made its appearance, despite an archaic use of language and romantic lapses into naïve characterization. During his short life Drost also started a new literary journal which was, like his novel, true to the spirit of the "Reveil." Though De Muzen (1834) only ran for less than a year, it attracted to its staff the historian R. C. Bakhuizen van den Brink (1810–65) and the future leader of the literary revival, E. J. Potgieter (*q.v.*). These two men continued the campaign to improve critical standards in De Gids (1837 et seq.), soon to be known as the "Blue Butcher" because of its merciless treatment of complacency. It was Potgieter who stated the requirements of the historical novel and Anna Bosboom-Toussaint (1812–86), who put them into effect by transposing the universal Christian idealism of Drost's book to the national Protestant faith of the Golden Age. She even reproduced Drost's archaic language but improved greatly on his technique and characterization in her diffuse novels which include a ten-volume cycle set in the Holland of the Leicester administration. Her best-known book, Majoor Frans (1874), is not a historical novel since it belongs to a less romantic era, one of liberal politics and female emancipationists. One other historical novel had an effect out of all proportion to its literary value. Hendrik Conscience's De Leeuw van Vlaanderen (1838) brought southern literature out of an obscurity that had lasted for nearly 300 years, for it aroused a national consciousness in Flanders which matured in the Flemish revival. (See BELGIAN LITERATURE: Flemish.)

Nicolaas Beets (*q.v.*) was and still is undoubtedly the most popular writer of his period. His valueless collections of poems (e g., Korenbloemen, 1853) were very popular during his lifetime and he was fêted as the national Protestant poet of his day. His valid claim to fame rests solely on the sketches in his Camera *Obscura,* published under the pseudonym "Hildebrand" in 1839, which reveal a power of observation almost as shrewd as that of Dickens, whom he admired. But Dickensian humanity is all too often lacking in the bright young theologian who, having "stripped the language of its Sunday suit," somewhat incongruously maintains a supercilious attitude toward the middle classes. His patronizing tone irritated Potgieter, whose subtler humour never had the appeal of the work of Beets or of Johannes Kneppelhout (1814–85), a fellow-student at Leiden who wrote Studententypen (1839–41) and Studentenleven (1841–44). But Potgieter's quest for originality in his prose and poetry tends to deprive his style of simplicity and clarity. His great talent is never in doubt; his genius frequently is. Such was the duration of Potgieter's dominant influence that whereas Geel was discredited when Potgieter planned De Gids and the romantic movement, Geel's successor Busken Huet became Potgieter's fellow critic toward the end of his life when skepticism was undermining romanticism.

Conrad Busken Huet was a progressive who. like several of his generation, left the church rather than uphold conformity. An admirer of French sophistication and the critical tenets of Sainte-Beuve and Taine, he adopted sober, personal and frequently merciless standards which at last placed Dutch writing in a truer perspective with western European writing. His essays were collected in the 25 volumes of *Litterarische* Fantasien en Kritieken (1868–88) and his later work, which gains in composure what it loses in brilliance, is best represented by *Het* Land van *Rembrandt* (1882–84).

Meanwhile, a furor had been caused by an entirely unknown writer, "Multatuli," whose first book "fell like a thunderbolt from Insulinde [*i.e.,* the East Indies], and set the country ablaze." This was the description of the editor of De Nederlandsche Spectator, the classical scholar Carel Vosmaer (1826–88). who by his immediate recognition of the genius of Multatuli was the lone forerunner of the critical theories of the review De Nieuwe Gids ("The New Guide"). Multatuli was the pseudonym of Eduard Douwes Dekker (*q.v.*), whose Max Havelaar (1860), a masterly satire of Dutch exploitation of the Dutch East Indies, suddenly revealed the full poignancy of a language which had too long been insipid or artificially flavoured. As quixotic as his Woutertje *Pieterse* (1865–77), as disharmonious as his *Minnebrieven* (1861), Douwes Dekker's writing vibrates between extremes of sentimentality and anarchy, ambitious arrogance and self-sacrifice, iconoclasm and utopianism. It is not surprising that although poetry as a convention was anathema to him he was greatly admired by the coming generation of reactionaries and Jacques Perk (1859–81) wrote sketches in the humorous style of Multatuli before writing the sonnet cycle Mathilde (published posthumously in 1882), which opened a new epoch in Dutch literature.

Renaissance of the 1880s.—Publication of the first number of De *Nieuwe* Gids in 1885 marked the beginning of an important renaissance of literature in the northern Netherlands. De *Nieuwe* Gids differed from De Gids in that it pursued an exclusively aesthetic ideal. The leaders of the movement were the poets Willem Kloos and Albert Verwey and the prose writer Lodewijk van Deyssel (*qq.v.*). Kloos sang the beauty that pleases the senses. Verwey passed from impressionistic to symbolical

verse. He also did good work in literary history. Van Deyssel was the violent and lyrical critic of the movement. Frederik van Eeden (*q.v.*), dramatist, poet and prose writer, occupied a special place. His best work in prose is De *Kleine Johannes* (1885), the story of the soul of a child. His Van de Koele *Meren* des Doods (1900) is an important novel about mental disturbance. The poet Hélène Lapidoth-Swarth (1859–1941) stood very near to the movement with her lyrical works written in particularly delicate language full of resonance. Herman Gorter (*q.v.*) acquired the foremost position in Dutch poetry when he published his poem Mei (1899). Jan Hendrik Leopold, poet of a tragic individualism, produced work of great sensitivity. Pieter Cornelis Boutens (*q.v.*) gradually acquired a mastery of his poetic form and expressed himself in strongly rhythmic verse, sometimes of an unearthly beauty.

Among the men of the 1880s (De Tachtigers) must also be placed Jacobus van Looy (1855–1930), a writer of beautiful prose (*Proza*, Gekken, *Feesten, Jaapje, Jaap*, the last two of which are autobiographical). The great novelist Louis Couperus (*q.v.*) described the life of The Hague society (*Eline* Vere, De Boeken der *Kleine Zielen*) and made splendid imaginative reconstructions of antiquity (De Berg van Licht, *Antiek* Toerisme, Herakles, De Komedianten, Iskander). The movement of the 1880s was mainly individualistic. Immediately afterward came a group of authors whose feelings were more social. The dramatist and writer of sketches, Herman Heijermans (*q.v.*), wrote social dramas which are among the greater triumphs of the Dutch stage. The novelist Israel Querido (1872–1932) was a typical Dutch naturalist. In addition may be mentioned the novelists Carel and Margo Scharten-Antink and some women novelists: Augusta de Wit, Ina Boudier Bakker, Top Naeff and Carry van Bruggen.

20th-Century Writers.—After the intoxication of the soul and the senses in the revival of the 1880s most of the writers of the early 20th century turned from this pronounced individualism to a socialistic or ethical vein. The language became sober once more. In prose, reasonableness and wisdom were stressed more than beauty and colour. This sentiment found expression in Albert Verwey's magazine De *Beweging* ("The Movement," 1905–19). Another important reaction to the 1880s was that of the idealistic prewar socialists such as Herman Gorter and the powerful lyrical poet Henriette Roland Holst van der Schalk.

Some of the most significant poets of the early 20th century were Adriaan Roland Holst (1888–), who, like W. B. Peats, constructed his own mythological world; J. C. Bloem (1887–), who wrote poetry of longing and disillusion; P. N. van Eyck (1887–1954), poet and essayist; Martinus Nijhoff (*q.v.*), whose work seems to catch the crystal clear morning light of a Dutch interior by Vermeer; and Victor Emmanuel van Vriesland (1892–), an erudite essayist and poet steeped in the French symbolist tradition.

The principal prose writer of the period of neoromanticism was Arthur van Schendel, who in his most mature writing created the same scenic and especially moral world found in Rembrandt's paintings. Aart van der Leeuw (1876–1931) was a subtle poet and prose writer of an idyllic romanticism. Anthonie Donker (1902–) wrote reflective verse of a melancholic nature.

World War I produced three great poets, Jan Slauerhoff (1898–1936), Hendrik de Vries (1896–) and especially Hendrik Marsman (*q.v.*) who, under the influence of German expressionism, attempted to break with all tradition. Jan Greshoff (1888–), poet and essayist, has his proper place among the younger generation grouped around the literary magazine *Forum*, established in 1932 by Menno ter Braak (*q.v.*), a brilliant cultural philosopher and independent thinker, and Edgar du Perron, eminent polemical essayist and novelist of great force; leaders of a movement of writers who wanted in literature less surface, fewer beautiful words and greater sincerity.

Between World Wars I and II, a period of anxiety and mental stress, the influence of Sigmund Freud became strongly marked in irrational poets such as Gerrit Achterberg (1905–1962) and Eduard Hoornik (1910–) but was most clearly noticeable in the prose, poetry and essays of the extremely subtle, astonishingly gifted Simon Vestdijk (1898–), the most important and prolific Dutch writer of the mid-20th century. The work of the novelist Frans Bordewijk (1884–) moves between the two opposites of chaotic fear and severe discipline. Among other popular novelists mention should be made of A. M. de Jong (1888–1943). Antoon Coolen (1897–1961), A. den Doolaard (1901–), Johann Fabricius (1899–), Albert Helman (1903–), Clare Lennart (1904–), Aar van de Werfhorst (1907–) and Theun de Vries (1907–).

World War II and the resulting occupation of the Netherlands released a new creative force in Dutch poetry especially. Poets such as Leo Vroman (1915–), J. B. Charles (1910–), Hans Lodeizen (1924–50). Guillaume van der Graft (1920–), Lucebert (1924–), Paul Rodenko (1920–), Remco Campert (1929–), Hans Andreus (1926–), Simon Vinkenoog (1928–) and Ellen Warmond (1930–) made use of the innovations which had been developed especially in France and the United States. Important as well were more traditional poets such as Bertus Aafjes (1914–) and M. Vasalis (1909–). The background of the literary work of most of the young novelists, often working in an existentialist vein. such as Gerard Kornelis van het Reve (1923–) and Willem Frederik Hermans (1921–). is ferociously pessimistic. Anna Blaman (1906–60), Adriaan van der Veen (1916–). Pierre H. Dubois (1917–), Hella S. Haasse (1918–), Bert Schierbeek (1918–), Alfred Kossmann (1922–) and Harry Mulisch (1927–) are also representative of this postwar generation. Reminiscences of earlier times in the former Dutch East Indies appeared in the novels and stories of Marie Dermout (1888–) and H. J. Friedericy (1900–). Humour was represented by Annie M. G. Schmidt (1911–), S. Carmiggelt (1913–) and A. Koolhaas (1912–).

DUTCHMAN'S-BREECHES (Dicentra *cucullaria*), a North American plant of the fumitory family (Fumariaceae), known also by various local names as butterfly-banners, boys-and-girls, eardrops and soldier's-cap. native to woods from Nova Scotia to South Dakota and southward to North Carolina and Kansas. It is a smooth, delicate plant. rising from a granulated bulb. with the slender-stalked, finely dissected leaves appearing to spring from the surface of the ground. In shape the irregular flowers. about $\frac{3}{4}$ in. broad, resemble a pair of baggy trousers, whence the popular name. The flowers are white or pinkish, tipped with yellow. and hang tremulously from a slender stalk, 5 in. to 10 in. long. This plant, closely related to the bleeding heart (*q.v.*), hlosaoms abundantly in early spring. and is one of the most dainty of North American wild flowers.

ROCHE

DUTCHMAN'S-BREECHES (DICENTRA CUCULLARIA)

DUTCH METAL. A variety of brass. in which the proportion of zinc: is high, giving the alloy a yellow colour, simulating

gold. The proportions of copper and zinc in dutch metal range from 88:12 to 85:15, the colour becoming paler with the higher zinc content. Dutch metal is used in bronzing, and in the preparation of imitation gold leaf, its great ductility lending itself to the purpose. Gilding with dutch metal costs less than one-third the price of real gilding, but the work rapidly tarnishes unless coated with a lacquer. See BRASS.

DUTCH WARS, a general title which includes the three naval wars fought between England and the United Provinces of the Netherlands (1652–54; 1665–67; and 1672–74) and the first of the three great wars of Louis XIV, namely the Franco-Dutch War (1672–78), of which the third Anglo-Dutch War was a part.

THE FIRST DUTCH WAR, 1652–54

The Thirty Years' War (*q.v.*) was a confusion of many issues, religious, political and dynastic, both between states and within them. During it the United Provinces were engaged from 1621 in warfare against Spain, still ruler of the southern Netherlands, and they acted generally in support of the Protestant and French cause against the Roman Catholic and Habsburg, securing final recognition of their independence at the peace of Westphalia in 1648. English participation in the European wars, however, was both inconsistent and unsuccessful and ceased altogether after 1630. Then, for two decades, internal political crises and civil wars cut England off from the main stream of continental history. During this period the English developed new attitudes governing the conduct of their foreign policy, and these proved to be of profound significance in European history.

Most important among the new attitudes were (1) the replacement of the traditional national hostility toward Spain by a new dislike of the Dutch, born of envy for their commercial prosperity; and (2) the assertion, first by Charles I, but later much more widespread, of English sovereignty over the Narrow seas round the south and east coasts of England. Behind these national and royal prejudices lay a real commercial rivalry, existing especially in the East Indies and over the herring fishery in the North sea. It brought about the Navigation act passed by the Long parliament in 1651, requiring goods imported into England to be carried only in English ships or, if coming from Europe, in those of the country of origin. The immediate cause of the First Dutch War, however, was rather the accumulation of a series of irritations betneen the two countries. Some were purely diplomatic and went back to the actions of the English and Dutch governments in the Thirty Years' War and the English Civil Wars respectively. Others, more recent, were the result of the conflict which arose between the English claim to exercise sovereignty in the Narrows and the Dutch insistence on the freedom of the high seas. during the unofficial war which had started between England and France in 1650.

A victory for the Dutch might have been expected in the two crowded years of naval engagements which made up the war in view of the great superiority of their merchant marine. In fact, however, the contribution of armed merchantmen to warfare at sea was diminishing in face of the development of specially built and professionally manned warships, and the superior numbers of the Dutch merchant marine proved something of a handicap, since they required the services of considerable numbers of warships for their protection. The Commonwealth government in England had doubled the size of the'navy bet een 1649 and 1651, and the new warships were larger than those of the Dutch and carried heavier armament. The English had a further advantage in their geographical position which lay across the Dutch trading routes.

Operations. — In the spring of 1652, the Dutch admiral Maarten Tromp took a strong fleet into the channel to protect the returning trade. Neither country was anxious to appear as the aggressor, but a collision occurred with the English squadron under Robert Blake on May 29 (new style; 19, old style) off Dover. Nehemiah Bourne came up later with a squadron from the Downs to assist Blake, whereupon Tromp withdrew to the French coast.

Blake was now ordered north to destroy the Dutch herring fisheries, which he succeeded in doing, and also, if possible, to intercept the Dutch East Indiamen, said to be returning by the north of Scotland, as well as to harry their Baltic trade. Tromp was ordered to follow, and, after a delay through contrary winds, he sighted Blake's fleet off the Shetlands on Aug. 4 (N.S.; July 25, O.S.). There both fleets were scattered by a storm and returned to harbour — Tromp, however, in company with the fleet from the East Indies which had rounded the north of Scotland in the middle of the storm.

Meanwhile M. A. de Ruyter successfully convoyed the outward-bound Dutch Mediterranean fleet through the channel. forcing the English squadron under Sir George Ayscue into Plymouth. Blake, after refitting, appeared at the mouth of the channel, but De Ruyter succeeded in passing him and joining the main Dutch fleet off Bruges, bringing with him several homeward-bound merchantmen. Cornelis de Witt, who had replaced Tromp after the loss of the herring fleet, was now ready to go over to the offensive, but in a two-day battle fought in the Kentish Knock on Oct. 8–9 (N.S.; Sept. 28–29, O.S.) was defeated by Blake with heavy loss, many of his captains refusing action toward the close, being jealous of De Witt on personal and political grounds.

The Dutch now decided that a successful attack on the English fleet was to be their first aim; Tromp was recalled and given command of a much strengthened fleet for this purpose, with the secondary task of escorting the outward-bound East Indiamen through the channel. Blake was at the same time much weakened by having a squadron detached from his ships for the Mediterranean, where superior Dutch strength had completely eclipsed English trade. When Tromp appeared off Dungeness, therefore, he was superior to Blake by at least two to one, and in a general engagement on Dec. 10 (N.S.; Nov. 30, O.S.) Blake was defeated and withdrew to the Thames. Tromp was then able to escort his convoy unmolested and to exercise undisputed mastery in the channel.

A considerable reorganization and re-equipment was now carried through in England, and in Feb. 1653 Blake took a strong fleet down the channel in order to intercept Tromp, who was known to be about to conduct a homebound convoy of merchantmen through the channel. A stubborn engagement was begun on Feb. 28 (N.S.; 18, O.S.), and Tromp was only just able to prevent his retreat from becoming a rout, passing Cap Gris-Nez three days later only after suffering heavy losses.

The Dutch were now faced with the problem of protecting their trade without command of the channel, and Tromp, when refitted, decided to escort the outbound ships through the North sea, planning also to meet a homebound convoy off the north of Scotland. In all this he succeeded, and so was able to put to sea next time unencumbered by merchantmen. He sought out and engaged the English fleet, now commanded by George Monck and Richard Deane in the absence of Blake (who had been wounded in the previous engagement), off the Gabbard shoal on June 11 (N.S.; 1, O.S.). A furious battle raged for three days, ending near the Dutch coast. For the first time, the English fleet showed a definite superiority, recent fighting instructions having strictly enjoined them to maintain a line-ahead formation and so to develop their broadside fire to the utmost. Deane was killed, but Blake joined in with reinforcements on the second day, and the Dutch fleet was decisively defeated. Blake and Monck at once established a blockade of the Dutch coast which completely disorganized Dutch trade. Tromp at last succeeded in breaking out from his anchorage in the Wielings on Aug. 4 (N.S., July 25, O.S.) and effecting a junction with De Witt's squadron blockaded in the Texel, but in the battle which followed on Aug. 10 (N.S.; July 31, O.S.), the fiercest engagement of the war, he was again defeated and lost his life. However, with the approach of winter, the English lifted the blockade in order to prepare for the coming spring.

The Treaty of **Westminster (1654).**—As it happened, no further operations of any importance took place, for the war was ended by the treaty of Westminster in April 1654. The Dutch conceded the honouring of the English flag in British seas and agreed to pay an indemnity for English merchant losses in the far east and for the massacre at Amboina. Other provisions, designed

to discourage Dutch support for the exiled Stuarts and to exclude the house of Orange from public office in the United Provinces, proved unimportant or ineffectual. The real significance of the war lay in the emergence of English naval power as something separate from English mercantile interests. This was to make England a great power for the next three centuries.

THE SECOND DUTCH WAR, 1665–67

In 1660 Charles II was restored in England, but popular sentiment was as strong as ever against the Dutch and the new regime pursued just as aggressive a commercial policy as had that of Cromwell. Though the king himself, his minister Edward Hyde, earl of Clarendon, and even some important trading interests such as the East India company had doubts about the advantages likely to be secured from a second Dutch war, popular enthusiasm and the support of those politicians who sought to take advantage of it brought about a renewal of the conflict, and war was declared on March 4 (N.S.; Feb. 22, O.S.), 1665.

Already, early in 1664, Capt. Robert Holmes had seized Goree and other trading centres on the African Guinea coast, while an expedition under Capt. Richard Nichols captured New Amsterdam (renamed New York) in August. The Dutch replied by sending De Ruyter from the Mediterranean to recapture Goree and reduce the English West African forts (Oct. 1664). Later, he crossed the Atlantic and attacked Barbados.

After war was declared, it was the English fleet which first put to sea—under the duke of York (afterward James 11), assisted by Prince Rupert and Edward Montague. earl of Sandwich. It cruised for a period off Texel in May 1665. but it had returned temporarily to reprovision when news came that the Dutch had set sail under Jacob Opdam and were prepared to seek out the English fleet even in the Thames. The duke of York set sail at once and, on June 13 (N.S.; 3, O.S.), won a decisive victory off Lowestoft. Opdam being blown up in his flagship. A misunderstanding, however, allowed the remains of the Dutch fleet to escape under Cornelis Tromp to Texel.

The English failed to follow up this early success. An enterprise in August against the Dutch ships in the neutral port of Bergen, planned mith the connivance of the king of Denmark, was frustrated, and soon afterward De Ruyter was able to reach port nith the Indies and Smyrna convoys. Sandwich, who had been placed in command after the duke of York's return from the battle of Lowestoft, did succeed in capturing a convoy of nine East Indiamen, but his action in distributing part of his prize amongst his flag officers and himself led to his being superseded by Monck, now duke of Albemarle.

At home in England, not only was the money granted by parliament for the war running out, largely because of mismanagement, but most of the life of the country was paralyzed by the last outbreak of the plague, which reached its peak in Sept. 1665. Both factors reduced the momentum acquired by the victory at Lowestoft, and in addition England's diplomatic position was deteriorating. The Dutch states-general had concluded a somewhat dubious alliance with France in 1662, by which each party had agreed to come to the aid of the other in any war in which it was not the aggressor. At first, the French contented themselves with suggesting terms of peace, but English attempts to enforce non-intervention through a Spanish alliance proved barren. England's one ally was the bishop of Miinster, Bernhard von Galen, who, in return for a small subsidy, invaded Holland from the east, but French forces, sent after France's formal declaration of war in Jan. 1666. compelled his withdrawal. No other allies were anxious to incur France's displeasure, and England began the operations of 1666 entirely isolated.

Though the French fleet under François de Vendôme, duc de Beaufort, did not proceed beyond Lisbon, intelligence reached London warning of its advance toward the channel, and accordingly Prince Rupert was detached with a third of the main fleet to meet it. Consequently, Albemarle was faced by a much superior Dutch fleet put to sea under De Ruyter. Nevertheless, after some debate, he began what is known as the Four Day's battle on June 11 (N.S.; 1, O.S.), 1666, sending word for Rupert to rejoin him with all speed. He concentrated his attack on the Dutch rear under Tromp, but was unable to achieve anything decisive before the remainder of the Dutch ships belonging to the van and centre came up and inflicted heavy losses on his own rear. Next day, therefore, he began a well-executed retreat, now outnumbered two to one. On the third day he mas at last rejoined by Rupert and so was able to join battle again on the fourth day on a more equal basis, though still inferior to the Dutch by the amount of his loss on the first day. A fierce and somewhat confused engagement then took place mith losses on both sides, and at the conclusion both were content to withdraw to their own harbours. Repairs were soon effected, and the two fleets faced one another again on almost equal terms off the mouth of the Thames on Aug. 3 (N.S.; July 24, O.S.). The St. James's fight (St. James's day, July 25, O.S.) was entirely an English victory! secured with very little loss. The English fleet now proceeded to blockade the Dutch coast, and a special squadron under Sir Robert Holmes burned about 150 merchantmen anchored in the Vlie channel on Aug. 18 (N.S.; 8, O.S.). The Dutch now called for more active French assistance: and Beaufort received orders to meet De Ruyter in the channel. The latter, however, was engaged and compelled to retreat into Brest. After this, further English operations were disorganized by the Great Fire of London (September).

In the West Indies, the French played a more prominent role, capturing the English settlement on St. Kitts (April 1666), Antigua (Nov. 1666) and Montserrat (Feb. 1667). A strong force was then sent out under Sir John Harman, which defeated the Franco-Dutch fleet off the island of Nevis on May 30 (N.S.; 20, O.S.), 1667. and played havoc with the French trade. In England, meanwhile, the cost of the war, added to the economic burden imposed by the Plague and the Great Fire of London, induced a readiness for peace, and negotiations were begun, first with France, then with the United Provinces. Accordingly, a risk was taken, and no preparations were made for fitting out a fleet for the coming year. The Dutch were equally keen for peace but saw an opportunity to deliver a substantial final blow against their enemy first. On June 22 (N.S.; 12, O.S.), 1667, taking advantage of the laying-up of the English fleet. De Ruyter sent a squadron under Adm. W. J. van Gent up the Medway while he himself stood guard off the Thames. The state of the defenses was deplorable, and several warships were destroyed in Chatham dock, others being captured, among them the flagship "Royal Charles." This episode was considered in England to be a national disgrace and did much to undermine confidence in the government and its foreign policy.

The Peace of Breda.—Peace was made at Breda on July 31 (N.S.; 21, O.S.), 1667. England recovered the West Indies possessions taken by France, promising in return not to engage in any anti-French alliance for a year. The English moreover kept New York, but the United Provinces retained their other colonies and secured a relaxation of the Navigation laws in their favour, being allowed henceforth to carry any goods from the Spanish Netherlands or Germany into England. The commercial rivalry between England and Holland was therefore still unresolved, and a third war seemed inevitable. Before it took place, however, an altogether different diplomatic situation had evolved in Europe out of Louis XIV's search for prestige. Commercial considerations thenceforward diminished in the sight of both parties, though they never disappeared altogether.

THE FRANCO-SPANISH WAR OF DEVOLUTION, 1667–68

For a period after the treaty of Westphalia, France had been preoccupied with the difficulties of a royal minority, the distractions of civil war and the continuing war against Spain. Eventually, with the attainment by Louis XIV of his official majority, the suppression of the Fronde and the treaty of the Pyrenees with Spain (1659), France was once more ready to become involved in Europe.

For a period, no particular issue invited France's close attention, but the death of Philip IV of Spain in 1665 left the Spanish dominions in the hands of the sickly epileptic Charles II, who seemed unlikely at that time to live long or produce heirs. Louis

XIV therefore took the initiative by advancing the altogether spurious claims of his wife, Philip IV's daughter, to inherit. immediately certain territories in the Spanish Netherlands (see DEVOLUTION, WAR OF), winding up his commitments in the Second Dutch War to that end. The French army under Marshal de Turenne advanced into Flanders in May 1667 and easily secured its objectives. Louis then turned to diplomacy in order to secure a speedy peace with concrete gains. In Jan. 1668 he and the Holy Roman emperor Leopold I concluded a treaty in nhich they agreed to partition the Spanish dominions between themselves on the Spanish king's death and in which it was also stipulated how much territory in the meantime France was to annex in the Netherlands. The French had also tried to win English support for their claims, but a new ministry in England turned instead to the Dutch. Despite their mutual distrust, an alliance was concluded between the two maritime powers on Jan. 23 (N.S.; 13, O.S.), 1668, to which Sweden adhered later, thus forming the Triple alliance.

The Peace of **Aix-la-Chapelle.**—The allies sought to contain the French advance by persuading Spain to agree to moderate terms and by supporting Spain in war if this proved of no avail. The settlement envisaged was much the same as that on which Louis XIV and the emperor had agreed (though the maritime powers were not to know this), and so peace was soon concluded at Aix-la-Chapelle in April 1668, though not before the prince de Condé had overrun Franche-Comté with a French army The latter province was returned to Spain, but France retained Bergues, Furnes. Armentières, Oudenaarde, Courtrai, Lille, Douai, Tournai, Binche, Ath and Charleroi.

THE **WAR** OF 1672–78

The towns gained by Louis XIV at Aix-la-Chapelle were intended as a foundation for further gains in Flanders, so that he would be in a strong position to insist on a partition of the Spanish dominions advantageous to France at some time in the future. He was to engage in fact in a further war within four years, but this time against the United Provinces. Its cause lay partly in the colonial and commercial rivalry of the Dutch, which was as great with France as with England, partly in the French king's preoccupation with his personal prestige. He resented more than anything being opposed by a country that was republican, Protestant and bourgeois and also had reason to be alarmed at the steadily growing hostility of the Dutch, which had been aroused by both the tariff and the foreign policy of France.

France and England Against the Dutch.—Diplomatic action was made the forerunner of military attack. France concluded treaties with Brandenburg in 1669, with Bavaria in 1670 and with Sweden in 1672, while the emperor, for the time being, remained bemused by the secret partition treaty of 1668. More important mas the detachment of England through the secret treaty of Dover (*q.v.*) in June 1670. There were still strong commercial motives for England's engaging in a commercial war with the United Provinces. and these were urged in England by Anthony Ashley Cooper, earl of Shaftesbury; also the English government was genuinely anxious lest the strength and success of the Dutch should persuade France to partition the Spanish Netherlands with them. However, it was Charles II's personal political and religious ambitions which were used by Louis XIV to secure English support for a war in 1672, and in consequence English foreign policy was to a great extent governed by considerations of the subsidies paid by Louis XIV and by Charles II's apprehension lest his diplomatic folly and religious treason of 1670 be revealed. So it was that, though the naval strength forged in two Dutch wars already entitled England to the rank of a great power in Europe, this rank was not attained until after the Glorious Revolution of 1688–89.

The imminence of war led the Dutch in Feb. 1672 to appoint as captain-general for a year William III, prince af Orange. whose family had been excluded from office in the United Provinces since his father's death in 1630. The administration of the grand pensionary, John De Witt, was totally unprepared for war and almost powerless to resist the double attack which developed by land and sea. The English and French fleets arranged to combine under the duke of York, and an attempt by De Ruyter in April to forestall their junction failed. The allies, however, were suffering from hasty preparation and went to Solebay (Southwold bay) on the Suffolk coast to complete their complements and stores. Early in the morning of June 7 (N.S.; May 28, O.S.), 1672, they were surprised by De Ruyter. Sandwich with the Blue squadron routed the opposing Dutch squadron, though he himself was drowned and his flagship burned; but when the French in the van turned south and were unable to play an effective part in the action, the duke of York in the centre was very hard pressed, and only the arrival later of the ships of the Blue squadron prevented complete disaster, after which De Ruyter drew off. The losses were fairly considerable on both sides, and the result could be counted as a draw, except for the fact that the English and the French, who with their superior numbers had expected a decisive success that would have made possible an invasion of the Dutch coast, were completely disappointed. The Dutch could be satisfied with what they had achieved.

On land, however, the French had it all their own way. The army under Louis XIV himself, assisted by Turenne, Condé and Vauban, moved down the Meuse from Charleroi unopposed and thence, masking the powerful Dutch fortress of Maastricht, crossed the Rhine at Dusseldorf and marched down it through the friendly territory of the archbishop of Cologne to the Dutch frontier, which was crossed at Tolhuis on June 12, 1672. Meanwhile, in the north, the marshal duc de Luxembourg (François Henri de Montmorency-Boutteville), in co-operation with the forces of Cologne and Munster, marched against Groningen. William of Orange could offer no substantial resistance; Utrecht surrendered on June 26 and the fall of Amsterdam seemed imminent. The states-general therefore asked for terms. but those offered were so severe and humiliating that it was every here agreed that the mar must be continued at all costs. The dikes were cut and the sluices opened, and the countryside around Amsterdam was extensively flooded. Johan de Witt and the republican party were swept from power; and, by what was little short of a revolution, De Witt and his brother Cornelis (*q.v.*) being assassinated by the mob, William of Orange was made stadholder.

In autumn 1672, the war spread to the middle Rhine. The German princes began to show hostility toward the French. Frederick William of Brandenburg, "the Great Elector," had concluded an alliance with the Dutch in April and a defensive alliance with the emperor in June, the latter considering himself freed from his commitments to Louis XIV in view of the French action in Holland. Condé was therefore despatched to Alsace, and Turenne to Westphalia, where by energetic operations continuing into the winter he was able to maintain Munster and Cologne in the war against all the emperor's efforts and to drive Frederick William's army across the Weser. Profiting meanwhile from this diversion of the French effort. William of Orange attempted a bold stroke against Charleroi (Sept.–Dec. 1672). but without success. Then, with the arrival of winter, Luxembourg made a bold attempt to capture Leiden and The Hague by marching a corps from Ctrecht across the frozen inundations, but a sudden thaw imperiled his force and he had to make a painful retreat along the dikes to Utrecht. Condé meanwhile failed to make any headway against the defenses of Amsterdam.

At sea, the duke of York uas unable either to bring De Ruyter out to give battle or to intercept the Dutch Indies convoy. Without full command of the sea, he could do nothing to assist operations on land. Therefore, in Sept. 1672. the English abandoned all further action for the year. The winter in England witnessed a parliamentary crisis. Though a supply of money was voted, an act was also passed excluding all Roman Catholics from public office. The duke of York was accordingly removed from his command and replaced by Prince Rupert in 1673.

In April 1673, an English fleet was assembled to assist the landing of an expeditionary force in Zeeland, but, with De Ruyter as active as ever, the plan had to be set aside until the French ships under Jean. comte d'Estrées, should arrive and De Ruyter be brought to battle. The combined fleet then arrived off Ostend on June 2 (N.S.; May 23, O.S.) and five days later prepared to

move in to attack De Ruyter with fireships in the Schooneveldt channel. Before this plan could be fully implemented, the Dutch admiral came out unexpectedly and engaged Rupert at a disadvantage, inflicting serious damage on him and then returning to his anchorage at night. Rupert retired again to the Oyster bank off Ostend and was renewing his supplies when, a week later on June 14 (N.S.; 4. O.S.). De Ruyter again emerged unexpectedly from the Schooneveldt and inflicted considerable losses on Rupert, who had to withdraw to the Nore.

The European Coalition.—Brandenburg having signed a separate peace with France at Vossem in June 1673. delegates now assembled at Cologne to make a second attempt at a settlement, but the French and English demands remained as stiff and unacceptable as ever. Very soon, however, the whole situation changed, and the Dutch war became a general European conflict. In Xug. 1673 the emperor, the king of Spain and the states-general allied themselves together, the two former agreeing to send troops to help the latter. These three powers, with the addition of Lorraine, constituted the grand alliance of The Hague, directed against Louis XIV, which was signed in Jan. 1674.

On land, Louis XIV had begun the campaigns of 1673 with the siege and capture of Maastricht on June 30 (N.S.; 20, O.S.). Turenne then advanced to the Main at Aschaffenburg to await the imperial army from Bohemia. but was outmaneuvred by Raimund Montecuccoli and forced to undertake a difficult and costly retreat down the Rhine in September. Montecuccoli crossed the Rhine at Mainz and advanced on Trier. whither Turenne was forced to withdraw. Then Montecuccoli turned north to meet William of Orange, who had evaded Condé's weak army in Holland and marched rapidly on Coblenz. Together they besieged and captured Bonn on Nov. 12 (N.S.; 2, O.S.), thus isolating Louis from his German allies, Cologne and Münster, who were compelled to make peace.

At sea, a combined Anglo-French fleet was again fitted out in the second half of 1673, with orders to appear off the Schooneveldt and then proceed north to the Texel. in the hope of luring De Ruyter into the more spacious waters there for a decisive engagement that would at last open the way for a landing on the coast. The plan nearly worked, but a change of wind enabled De Ruyter to return to the Schooneveldt. However! in August he was ordered to put to sea to protect the homecoming Indies fleet. and Rupert came upon him off Kijkduin on Aug. 21 (N.S.; 11, O.S.). The French van again became separated from the English centre and rear, so that De Ruyter once more enjoyed a superiority. but the exchanges were still even, and the failure of the comte d'Estrées to support Rupert turned a probable victory into another indecisive encounter that the Dutch could regard with satisfaction. Supply shortages prevented the Anglo-French fleet from being got ready for sea again until it was too late for any substantial operations to be begun on land, and so in Septemher the French fleet was ordered to Brest and the English ships to be laid up for the winter.

The Treaty of Westminster (1674).—Charles II soon saw that he could continue no longer with the Dutch War and the French alliance in face of the growing hostility of the house of commons, which had been recently reinforced by the inadequacy —or even, it was thought, treachery—of the French fleet as an ally at sea. The treaty of Westminster, signed on Feb. 19 (N.S.; 9, O.S.), 1674, conceded that Dutch ships would salute the English flag, as a mark of respect only, in the waters between Norway and Cape Finisterre and ordered an indemnity to be paid by the Dutch of 500.000 crowns, but brought few other advantages except those which accrued from the neutrality now followed by England for the next four years while the rest of Europe remained at war.

The French War Continued, 1674–78.—After 1673, the war had a new character. The French armies had to abandon the United Provinces (where they had been able to enjoy free quarter). hut still Louis XIV determined to keep to the offensive, striking wherever possible against Spanish territory. Condé, with inferior forces. successfully held a combined Dutch and Spanish army under William of Orange along the frontier of the Spanish Netherlands and inflicted the first of many defeats suffered by that prince at Seneff on Aug. 11, 1674. The losses suffered by both sides. however, were considerable and the engagement was strategically indecisive, the Dutch being able to capture Grave in October. Another army under Louis XIV's personal direction invaded Franche-Comté, which it overran in six weeks, Besanqon being reduced with Vauban's assistance in nine days.

Turenne. opposed on the Rhine by Alexandre-Hippolyte, prince de Bournonville, Montecuccoli's successor in command of the imperial forces, and threatened also by another army under Charles IV of Lorraine and Aeneas Sylvius Caprara advancing toward the Neckar valley. resolved to attack before they could effect a junction. He therefore crossed the Rhine at Philippsburg early in June and defeated Caprara at Sinsheim on June 16, 1674, and Charles of Lorraine at Ladenburg on July 7. After that, having systematically devastated the Palatinate so that it could not support an army operating through it that year, he withdrew into Lorraine. Bournonville, however. moved south and crossed the Rhine at Strasbourg to invade Alsace. He met Turenne in an indecisive battle at Enzheim on Oct. 3 and then, after being reinforced by the troops of Frederick William of Brandenburg. who had allied himself with the emperor again in July, overran the whole of Alsace. Turenne retired before him, and the allies withdrew into winter quarters in November.

Turenne. however, had determined upon a winter campaign. Collecting his forces in Lorraine, he marched south behind the Vosges to enter Alsace near Belfort. Taken by surprise. the allies were defeated at Mulhouse, at Colmar and at Turkheim (Dec. 1674—Jan. 1675). The last engagement was decisive and the imperial forces were compelled to evacuate Alsace entirely, at which Turenne at last retired into winter quarters.

Montecuccoli again commanded on the Rhine in 1675, the Brandenburg army having been withdrawn to meet an attack by Sweden from Pomerania. Turenne obtained an advantage over him after a prolonged period of maneuvre, designed by both commanders to obtain control of enemy territory for the support of their army, but he was killed by a cannonball at the battle of Sasbach on July 27. Subsequently, the French retreated over the Rhine. while a second French army under Franqois de Créquy was defeated on the Moselle and lost Trier to Charles of Lorraine. Condé was thereupon withdrawn from Flanders. where earlier he had taken Liège and Limburg. He succeeded in forcing Montecuccoli back across the Rhine. This was his last campaign, for he retired at its conclusion. France thus lost the services of both Turenne and Condé in one year.

A revolt had broken out against Spanish rule in Sicily in 1674, and a French expeditionary force sent to support it had captured Messina. The Spanish government thereupon appealed to the Dutch for naval assistance! and De Ruyter was sent out with a squadron in the latter half of 1675. He engaged the French admiral. Abraham Duquesne, who was bringing reinforcements, on Jan. 8, 1676, but without success. Later, De Ruyter joined in an attempt to recapture Messina, but this failed, and he was himself mortally wounded off Augusta on April 22. Dutch attempts to employ their fleet in the channel and on the Atlantic coasts after the withdrawal of England from the war were similarly unsuccessful.

In 1676, William of Orange failed in an attempt to capture Maastricht, but the imperial army captured Philippsburg on Sept. 17. Thereupon the French devastated the country between the Meuse and the Moselle in the same way and for the same reason as Turenne had devastated the Palatinate in 1674. This tactic was a classic of 17th-century military operations and was particularly effective in depriving enemy cavalry of their supplies of forage.

Louis XIV began 1677 with the capture of Valenciennes on March 17. William of Orange was defeated in trying to relieve St. Omer (April 11) and was equally unsuccessful in the summer. Créquy outmaneuvred Charles V of Lorraine. Charles IV's son and heir. on the Rhiné throughout the summer and finally defeated him at Kochersberg on Oct. 7, capturing Preiburg on Nov. 13.

The End of the War.—Military success, however, was becoming less and less relevant to the outcome of the war. Louis XIV's original aim of humiliating the Dutch had failed when the French armies had had to be withdrawn from the United Provinces and could now never be realized because the rest of Europe would not allow it. Instead he now faced nearly all the rest of Europe in a hostile alliance. The war moreover put a heavy burden on France's economy, and there were revolts against war taxation in Normandy and Brittany. The United Provinces were equally ready for peace, and the threat of England's re-entry into the war, this time on the Dutch side, encouraged both belligerents to come to terms lest England should become the arbiter of their affairs. Fighting continued in Flanders while peace was being negotiated during most of 1678. The French captured Ghent and Ypres in March, and Luxembourg defeated William of Orange near Mons on Aug. 14. On the Rhine, war went on into 1679, for the emperor was unwilling to make peace while he still saw a chance of winning gains in Alsace. Créquy, however, twice defeated his forces in 1678, at Rheinfelden on July 6 and at Gengenbach on July 23. The series of treaties constituting the peace of Nijmegen (*q.v.*) was completed in 1679.

CONCLUSIONS

If the significant result of the three Anglo-Dutch naval wars was the establishment of English naval power, with all that that was to mean in European and in world history, the lesson to be drawn from the first of Louis XIV's three great wars concerned the immense superiority of French military resources: even against a general European coalition. The emergence of England as a great power in Europe, however, was eventually to turn the balance against France in the War of the Grand Alliance and in the War of the Spanish Succession (*qq.v.*).

BIBLIOGRAPHY.—Apart from the general histories of Europe and of the belligerent states covering the second half of the 17th century, and the lives of the sovereigns, statesmen and commanders mentioned in the text above (*see* the several biographies in this Encyclopædia), naval histories are especially valuable for the Dutch Wars. *See* for instance S. R. Gardiner and C. T. Atkinson (eds.), *Letters and Papers Relating to the First Dutch War,* Navy Records society, 6 vol. (1899–1930); H. T. Colenbrander (ed.), *Bescheiden uit vreemdre archieven omtrent de groote Nederlandsche zeeoorlogen* (1919); C. de La Roncière, *Histoire de la marine française,* vol. v (1920); R. C. Anderson (ed.), *Journals and Narratives of the Third Dutch War,* Navy Records society (1946); Sir H. Richmond, *The Navy as an Instrument of Policy, 1558–1727* (1953). For diplomatic history *see* particularly F. A. M. Mignet, *Négociations relatives à la succession d'Espagne,* 4 vol. (1835–42); and F. A. Westergaard (ed.), *The First Triple Alliance . . . 1668–72* (1947). (*I. F. B.*)

DUTCH WEST INDIA COMPANY, a company founded by letters patent from the Netherlands states-general dated June 3, 1621. The purpose for which the company was formed was to regulate and protect the contraband trade already being carried on by the Dutch in the American and African possessions of Spain and Portugal, and to establish colonies on both continents and their islands. By the terms of the charter the company was to be composed of five boards or branches, established in Amsterdam, Zeeland, the Meuse (Rotterdam), the North Department (west Friesland and Hoorn), and Groningen. Each was to be represented on the general governing board according to the importance of the capital contributed by it. Thus Amsterdam; which contributed four-ninths of the capital, had eight directors on the board; Zeeland, which subscribed two-ninths, had four; the other three departments, which each contributed one-ninth, had two each.

The company was granted the monopoly of the trade with America and Africa and. between them, from the Arctic regions to the Straits of Magellan, and from the Tropic of Cancer to the Cape of Good Hope. The company proposed to use its monopoly on the coast of Africa in order to secure the cheap and regular supply of Negro slaves for the possessions which it hoped to acquire in America. The trade was thrown open by the voluntary action of the company in 1638. The general board was endowed with ample power to negotiate treaties and make war and peace with native princes; to appoint its officials, generals and governors; and to legislate in its possessions subject to the laws of the Netherlands. The states-general undertook to secure the trading rights of the company, and to support it by a subvention of 1,000,000 florins (about £100,000). In case of war the states-general undertook to contribute 16 vessels of 300 tons and upward for the defense of the company, which, however, was to bear the expense of maintaining them. In return for these aids the states-general claimed a share in the profits; stipulated that the company must maintain 16 large vessels (300 tons and upward) and 4 "yachts" (small craft of 50 to 100 tons or so); and required that all the company's officials should take an oath of allegiance to the Netherlands as well as to the board of directors and that all dispatches should be sent in duplicate to the government and to the board.

The history of the Dutch West India company is one of less prosperity than that of the Dutch East India company. In early days the trade was not sufficient to meet the expense of the armaments raised against Spain and Portugal. The company was never able to secure the control of the supply of slaves from Africa.

For the already existing colony of New Netherland, formally constituted as a province of the company in 1623, see NEW YORK: History; NEW YORK (CITY): History.

In the West Indies the company gained a valuable footing among the islands. It occupied St. Eustatius in 1634, Curaçao with Bonaire and Aruba in 1634 and 1635, Saba in 1640 and St. Martin in 1648. Apart from their own products these islands could also serve as a means of smuggling slaves into the Spanish colonies. The greatest achievement of the company's fleets was the famous capture of the Spanish silver fleet by Piet Hein off the coast of Cuba in 1628; the sale of the booty yielded some 12,000.000 florins and enabled a 75% dividend to be declared. But the greatest effort was made in Brazil. After a first unsuccessful occupation in 1624 of Bahia, which was immediately retaken by a combined Spanish and Portuguese armament, the company obtained a firm footing in Pernambuco in 1630. The conquest of much of Brazil which followed lasted until the last footing at Recife was recaptured by the Portuguese in 1654. The most prosperous period of the Dutch rule in Brazil was during the tolerant and liberal administration of Count John Maurice of Nassau-Siegen, from 1636 to 1644; but the expense proved to be beyond the company's financial resources. and the states-general did not give adequate support, while the Portuguese planters were never reconciled to their new rulers.

The company resigned all claim on Brazil in 1661, and by the treaty of Breda in 1667 gave up New Netherland to England: but this last treaty gave to the company some compensation in Surinam (Dutch Guiana). The resources of this colony were not, however, developed by the original company, which became so embarrassed that it was dissolved in 1674 and reconstructed in 1675. The newly formed company continued to exploit the Dutch possessions in the Caribbean until 1791, when it was taken over by the state, only to be swept away altogether in 1794 with the conquest of the United Provinces by the French Revolutionary armies.

DU TOIT, JAKOB DANIEL (pseudonym, TOTIUS) (1877–1953). Afrikaans poet, pastor, biblical scholar and compiler of an Afrikaans Psalter, was born at Paarl. Cape Province. Feb. 21, 1877, son of the Rev. S. J. du Toit, who has been called father of the movement for Afrikaans. He was educated in Pretoria. Rustenburg and Daljosafat, studied at the theological seminary at Burgesdorp and passed his final examination for the ministry in 1899.

On the outbreak of the South African War he joined the Boer forces as chaplain. In 1900 he went to the Free university. Amsterdam, Neth.. where he received his doctor's degree in theology in 1903, and then entered the ministry. From 1911 he was professor of theology at the University of Potchefstroom, Transvaal; on retirement in 1949 he was elected chancellor. He died in Pretoria, July 1, 1953.

Du Toit was responsible for the greater part of the transla-

tion of the Bible into Afrikaans. completed in 1932. His Afrikaans Psalter (1936) is regarded as one of the finest poetic achievements of its kind in Dutch. Flemish or Afrikaans. The Calvinism and patriotism confirmed in him by the circumstances of his childhood and training are revealed at a high artistic level in his finest volumes of poetry, the patriotic poems *Trekkerswee* (1915) and the personal lyrics in *Passieblomme* (1934) and *Skenzering* (1948). These and other volumes! including *By die Monument* (1908), *Verse van Potgieter's Trek* (1909), *Wilgerboombogies* (1912), *Rachel* (1913) and *Uit donker Afrika* (1936), also show the poetic influence of the Flemish poet andpriest Guido Gezelle.

See C. M. van den Heever, *Die digter Totius* (1932), and an anthology with introduction, *Keur uit die gedrigte van Totius* (1949).

DUTRA, EURICO GASPAR (1885–), Brazilian soldier, president of Brazil, 1945–51. Dutra was born on May 18, 1885, in Cuiabá, Mato Grosso state. He was commissioned a second lieutenant in the cavalry in 1910 and had routine assignments and promotions for the following 22 years. Uninterested in politics during this period, Dutra consistently supported the established government. Thus he opposed the successful revolution led by Getulio Dornelles Vargas in 1930 but defended the Vargas regime during the 1932 São Paulo rebellion. From that date Dutra rose rapidly. As commanding general of army troops in Rio de Janeiro, he suppressed the brief communist revolt in 1935. From 1936 to 1945 Dutra was minister of war. in which position he was instrumental in establishing the Vargas dictatorship in 1937. Dutra influenced the decision to support the Allies in World War II and was principally responsible for organizing the Brazilian Expeditionary force that fought in Italy, 1944–45. Selected as the administration's presidential candidate. he led the *coup d'état* in Oct. 1945 that overthrew the dictatorship when Vargas attempted to forestall elections. Dutra was elected president of Brazii on Dec. 2, 1945 and served until Jan. 31. 1951. His administration witnessed the full restoration of democratic, constitutional processes in Brazil. *See* BRAZIL: *History.* (R. E. P.)

DUTT, MICHAEL MADHU SUDAN (MICHAEL MADHUSUDAN DATTA (1824–1873), Indian poet and dramatist, the first great poet of modern Bengali literature (*q.v.*), was a dynamic. erratic person, and an original genius of a high order. Born at Sagardari. Bengal. on Jan. 25, 1824, he was educated at the Hindu college: Calcutta, the cultural home of the western-educated Bengali middle class. In 1543 he became a Christian. From 1848 until 1856 he lived in Madras. then returned to Calcutta. where he lived busily and happily for six years. The period 1862–67 he spent in England and France. returning to India to die in Calcutta six years later, on June 29, 1873. in utter poverty.

His early compositions were in English, but they were unsuccessful and he turned reluctantly at first to Bengali. His principal works, written mostly between 1858 and 1862, include prose drama. long narrative poems and lyrics. His first play. *Sarmishtha* (1858). based on a *Mahabharat* episode. was well received. In 1860, he wrote *Ekei ki Bale Sabhyata* and *Buro Saliker Ghare Ro*, two popular but not outstanding social satires; and in 1861. *Padmabati,* a version of the *Judgment of Paris* in Indian guise, and *Krishnakumari,* a Rajput story. His poetical works are *Tilottamasambhab* (1860), a narrative poem on the story of Sunda and Upasunda; *Meghnadbatlh* (1861), his most important composition, an epic on the *Ramayan* theme; *Brajangana* (1861), a cycle of lyrics on the *Radha-Krishna* theme; and *Birangana* (1862), a set of 21 epistolary poems on the model of Ovid's *Heroides.* In Europe he worked at *Caturdaspadi Kabitabali,* a collection of 102 sonnets; and later in Calcutta wrote a prose narrative bnsed on the *Iliad, Hektarbadh* (1871); and an unfinished play, *Maya-Kanan.*

Madhu Sudan experimented ceaselessly with diction and verse forms and it was he who introduced *amitraksar* (a form of blank verse with run-on lines and varied caesuras), the Bengali sonnet—both Petrarchan and Shakespearean—and many original lyric stanzas. His diction ranged from the lyric smoothness of the *padavali* to the sonorousness of Milton, who was his model for *Meghnadbadh.* He loved the "grand mythology" of ancient India. For him it was "full of poetry," and from it came most of his subjects.

(T. W. CL.)

DUTTON, CLARENCE EDWARD (1841–1912), U.S. geologist and pioneer seismologist who developed and named the principle of isostasy (*q.v.*), was born at Wallingford, Conn., on May 15, 1841. He graduated from Yale university at the age of 19 and in 1862 entered the U.S. army as first lieutenant. After many periods of inactive service he became a major in 1890 and retired in 1901.

In 1865 Dutton began to study geology under James Hall (*q.v.*) and his assistant, R. P. Whitfield. In 1875 he joined the U.S. geographical and geological survey of the Rocky mountain region (the Powell survey) and spent ten years in the plateaus of Utah. Arizona and New Mexico. There he investigated the causes of volcanic action, of uplift and sinking, and of movements which twist, fold and hreak rocks of the earth's crust. Dutton believed that lavas were melted by radioactive heat and that weight of overlying rocks forced them to the surface. The latter idea was an outgrowth of his studies of basaltic eruptions in southern Utah.

As a member of the U.S. Geological survey, Dutton studied the Charleston, S.C., earthquake of 1886. In 1889 he discussed it in a report of 323 pages. It advanced a new method of determining the depth of earthquake focuses and measured with unprecedented accuracy the rate at which earthquake waves traveled. In 1904 he published a semipopular treatise, *Earthquakes in the Light of the New Seismology.* He died in Englewood, N.J., on Jan. 4, 1912. (M. A. F.; C. L. FE.)

DUTY, a term loosely applied to any action or course of action which is regarded as morally incumbent, apart from personal likes and dislikes or any external compulsion. Such action must be viewed in relation to a principle. which may be abstract in the highest sense (*e.g.,* obedience to the dictates of conscience) or based on local and personal relations. That a father and his children have mutual duties implies that there are moral laws regulating their relationship; that it is the duty of a servant to obey his master within certain limits is part of a definite contract, whereby he becomes a servant engaging to do certain things for a specified wage. Thus it is held that it is not the duty of a servant to infringe a moral law even though his master should command it. For the nature of duty in the abstract, and the various criteria on which it has been based, *see* ETHICS.

From the root idea of obligation to serve or give something in return, involved in the conception of duty, have sprung various derivati e uses of the word: thus it is used of the services performed by a minister of a church. by a soldier, or by any employee or servant. A special application is to a tax. a payment due to the revenue of a state, levied by force of law. Properly a "duty" differs from a "tax" in being levied on specific commodities, transactions, estates. etc.. and not on individuals; thus it is right to talk of import duties. excise duties. death or succession duties, etc., but of income tax as being levied on a person in proportion to his income. *See* also TARIFFS.

DUUMVIRI (DUOVIRI) in ancient Rome, an official term for a college of two magistrates.

The following colleges are attested in Rome: *Duumviri perduellionis* were the judges appointed by the chief magistrate in the early criminal procedure for trying offenses against the state. *Duumviri sacris faciundis* were the two priests who originally had charge of the books of Sibylline oracles and the matters involving worship in the Greek manner arising from them: they were increased in number to 10 (*decemviri*) in 367 B.C. and by Sulla to 15 (*qziirzdecimviri*). *Duumviri navales* were officers appointed to have charge of equipping a fleet and were elected by the people from 311 B.C. onward. None is named after 178 B.C. *Duumviri aedi locandae* and *duumviri aedi dedicandae* were two colleges. sometimes composed of the same men for the same temple. the one to let the contract for construction and the other to perform the dedication. *Duumviri viis extm urbem purgandis* formed a minor magistracy for cleaning the streets outside the city and were replaced under Augustus by the *curatores viarum.*

In the colonies and *municipia* (*see* MUNICIPIUM) *duumviri iure dicundo* was frequently the title of the two chief magistrates.

Their duties included especially the administration of justice. Those who took the census and revised the roll of decurions every five years were known as *duumviri iure dicundo quinquennales.*

DUUN, OLAV (1876–1939), Norwegian novelist, who, after Knut Hamsun and Sigrid Undset, is the outstanding name in 20th-century Norwegian literature. He was born in Namdalen, in the north of Norway, Nov. 21, 1876, and worked as a folk-school teacher until 1926. when he retired to Holmestrand. on the Oslo fiord. He died at Tonsberg. Sept. 13, 1939. His many novels. written for the most part in a language strongly influenced by his regional dialect, analyze the psychological and spiritual characteristics of peasant life. His masterpiece is a series of novels. *Juvikfolke* (1918–23), describing the development of a peasant family through four generations. It has been translated as follows: *The Trough of the Waves* (1930), *The Blind Man* (1931), *The Big Wedding* (1932), *Odin in Fairyland* (1932), *Odin Grows Up* (1934) and *Storm* (1935).

See R. Thcsen, *Mennesket og Maktene* (1945); *D.* Haakonsen, *O. Duun* (1958). (D. A. H.)

DU VAIR, GUILLAUME (1556–1621), French lawyer and writer, the master of a prose style of exceptional purity and felicity, whose blend of Christianity and Stoicism had great political, philosophical and literary influence, was born in Paris, March 7, 1556. He became clerk-counselor of the *parlement* of Paris in 1584, at a time of great political disturbance, and his conciliatory influence was soon highly valued. As deputy for Paris to the estates of the League, he was informed of the Spanish marriage intrigues, and his most famous political discourse, *Suasion de l'arrest pour la manutention de la loi Salique,* delivered in the *parlement* in 1593, was designed to counteract them. This, and his many other services in the cause of peace, earned the gratitude of Henry IV. In 1596 he was sent to England to negotiate a league against Spain and on his return was sent to restore order as governor of Provence. He became in 1599 first president of the *parlement* of Aix. and in 1616, for a short time, keeper of seals. He died at Tonneins (Lot-et-Garonne), Aug. 31, 1621. From 1617 he was bishop of Lisieux; it is not known when he took orders.

Du Vair devoted his leisure to learning. As a moralist and Christian philosopher, his outstanding works were *Manuel d'Epictète,* which was probably read by Descartes, Corneille and Pascal; *La Sainte Philosophie;* and *La Philosophie morale des Stoïques,* translated into English by Charles Cotton (1664). The philosopher Pierre Charron drew freely on these works. The most beautiful of Du Vair's philosophical writings is *De la constance et consolation ès calamités publiques,* written during the siege of Paris (1593) and translated into English as *A Buckler Against Adversitie* (1622). As a literary critic, he was the author of a treatise *De l'éloquence française et des causes pourquoy elle est demeurée si basse.* Malherbe, who often visited him in Provence, and other men of letters. for instance, Peiresc, greatly admired his writings and learned much from his conversation.

BIBLIOGRAPHY.—R. Radouant (ed.), *De L'éloquence . . .* (1908) and *Actions et traictez oratoires* (1911); F. Funk-Brentano (ed.), De *la constance (1925);* G. Michaut (ed.), *De la Sninte Philosophie* (1946). *See* also P. Nicéron, *Memoires,* vol. xliii (1745); and monographs by A. Sapey (1847 and 1858) and R. Radouant (1909). (J. CN.)

DUVAL, CLAUDE (1643–1670), a famous highwayman, was born in France at Domfront, Normandy. in 1643. He entered domestic service in Paris when he was 14, went to England in attendance on the duke of Richmond at the time of the Restoration, and soon became a highwayman notorious for the daring of his robberies and for his gallantry to ladies. After some time he was obliged to retire to France, but he soon returned to England and was eventually captured in London while drunk.

He was hanged at Tyburn on Jan. 21, 1670. His body was buried in Covent Garden church under a stone with the following epitaph:

> Here lies Du Vall: Reader, if male thou art,
> Look to thy purse; if female, to thy heart:
> Much havock has he made of both; for all
> Men he made stand, and women he made fall.

See the anonymous *Memoirs of Monsieur Du Vall* (1670), ascribed *to* William Pope, reprinted in *Harleian Miscellany,* vol. iii, pp. 308–316 (1809).

DUVEEN, JOSEPH DUVEEN, 1ST BARON, OF MILLBANK (1869–1939). international art dealer, was born in Hull, Yorkshire, on Oct. 14, 1869. He was the son of Sir Joseph Joel Duveen (1843–1908), of Dutch-Jewish descent, who established the family art business in London in 1877. With an inherited flair. great boldness that several times resulted in litigation, a keen sense of art values and an insight into the psychology of rich clients, Joseph Duveen, as a young man, began to buy and sell on an unprecedented scale.

Before 1914 he had established a monopoly of old masters on both sides of the Atlantic. His principal headquarters were in New York, and he will long be remembered as the dealer who largely built up the collections of U.S. millionaires such as Benjamin Altman, Henry Huntington, Joseph E. Widener. Henry C. Frick. John D. Rockefeller and Andrew W. Mellon. It can fairly be claimed that he changed American taste in directing buyers to the greatest Italian, Dutch, French and English masters, most of which are now represented in U S. museums.

For his services to British art, for the Duveen wing at the Tate gallery in London and for adding a gallery to the British museum to house the Elgin marbles, he was knighted in 1919, made a baronet in 1926 and raised to the peerage in 1933. He died in London on May 25, 1939. His *Thirty Years of British Art* was published in 1930.

See S N Behrman, *Duveen* (1952), an amusing but unfair biographical sketch. (ST. PN.)

DUVENECK, FRANK (1848–1919), U.S. painter, sculptor and art teacher, who helped awaken American interest in European naturalism, was born at Covington, Ky., Oct. 9, 1848. A pupil of Wilhelm Dietz at Munich, he was a great admirer of Frans Hals, Rembrandt and Rubens. An exhibition in Boston in 1875 first attracted attention to his work.

Many young American artists, including John Twachtman, John W. Alexander and William Merritt Chase, studied under him at Munich and Florence between 1878 and 1888, and at Cincinnati, O., where he was dean of the art academy for many years after 1888. The Cincinnati museum owns the largest collection of his works. His best work in sculpture, a memorial to his wife, is in the English cemetery in Florence. He died in Cincinnati, Jan. 3, 1919. (D. H. W.)

DUVERGIER DE HAURANNE, JEAN (1581–1643), abbot of St. Cyran, one of the fathers of the Jansenist movement in France, was born of wealthy parents at Bayonne and studied theology at Louvain. After taking holy orders he settled in Paris, where he became known as a man of extraordinary erudition. His friendship with Cornelius Jansen, a young champion of Augustinianism, led him to oppose the Louvain Jesuits who stood for scholasticism. The two retired to Duvergier's home at Bayonne, where he became a canon of the cathedral and Jansen a tutor in the bishop's seminary. There they remained from 1611 to 1616, intently studying the fathers. Eventually Jansen went back to Louvain, while Duvergier became confidential secretary to the bishop of Poitiers, where he met Richelieu. In 1620 he was made sinecure abbot of St. Cyran, and was thereafter generally called M. de St Cyran.

Western Touraine being the headquarters of French Protestantism, St. Cyran's learning was turned against the Huguenots. He began to dream of reforming Catholicism on Augustinian lines, and thus defeating the Protestants by their own weapons. They appealed to primitive antiquity; he answered that his church understood antiquity better than theirs did. They appealed to the spirit of St. Paul; he answered that Augustine had saved that spirit from etherealizing away, by coupling it with a high sacramental theory of the church. They flung practical abuses in the teeth of Rome; he entered on a bold campaign to bring those abuses to an end.

Before long. his reforming zeal necessitated his removal to Paris, where his attempt to gain the support of influential people led to his friendship with the Arnauld family and, from **1635** onward, to his taking control of the convent of Port Royal.

Jansen was now attacking the principles of scholastic method (as exemplified in his day especially by the Jesuits, who he thought had corrupted theology) by writing a book on Augustine, the great master of an older theological method. St. Cyran attacked the Jesuits' hand-to-mouth utilitarianism, which had played havoc with traditional church institutions, and their defiance of episcopal authority, in his publication under the pseudonym of Petrus Aurelius **(1633).** This work so annoyed Richelieu, now the powerful and extremely Erastian prime minister, that St. Cyran was imprisoned until Richelieu's death in **1642.** St. Cyran himself died in Paris on Oct. 11, **1643.**

St Cyran's character has been always something of a puzzle. Many excellent contemporary judges were profoundly impressed by him; others, as one of them said, went away bewildered by this strange *abbe'*, who leaped from one point to another in incoherent phrases. Grace of expression he had none; perhaps no man of equal spiritual insight ever found it so hard to make his meaning clear. On the other hand. Jansenism, considered as a practical religious revival, is altogether his work. Without him there would have been no Pascal—no *Provinciales* and no *Pensées.*

See C. A. Sainte-Beuve, *Port-Royal,* 5th ed, *6* vol. (1888); J. Orcibal, *St-Cyran et son temps, 1581–1638,* 2 vol. (1947–48).

(X.; N. J. A.)

DUVEYRIER, HENRI (1840–1892), French explorer of the Sahara. was born in Paris on Feb. **28, 1840.** At the age of **19,** having already learned Arabic, he began a journey in the northern parts of the Sahara which lasted nearly three years. In **1864** he published *Exploration du Sahara: les Touareg du nord.* After **1870** he made several other journeys in the Sahara. He also examined the Algerian and Tunisian *shats* (shallow saline lakes) and explored the interior of western Tripoli. Duveyrier devoted special attention to the customs and speech of the Tuareg, and to the organization of the Senussi.

In **1881** he published *La Tunisie,* and in **1884** *La Confrérie musselmane de Sidi Mohammed Ben Alî-Es-Senôusi et son domaine géographique.*

See C. Maunoir and H. Schirmer, *Sahara, Algérien et Tunisien,* with *a* biography of Duveyrier by C. Maunoir (1905).

DU VIGNEAUD, VINCENT (1901–), U.S. biochemist and winner in 1955 of the Nobel prize in chemistry, was born in Chicago, Ill., on May **18,** 1901. He was educated at the University of Illinois, Urbana (B.S. 1923, M.S. 1924), and at the University of Rochester (N.Y.) school of medicine (Ph.D. 1927). Awarded a National Research council fellowship, he then studied at Johns Hopkins university school of medicine, Baltimore, Md., the Kaiser Wilhelm institute in Dresden and the University of Edinburgh medical school. He served on the staff of the biochemistry department of the University of Illinois (1929–32) and was head of the department of biochemistry at George Washington university, Washington, D.C. (1932–38), before becoming head of the department of biochemistry at Cornell university (Ithaca, N.Y.) medical college. Du Vigneaud's researches were centred mainly around studies of insulin, elucidation of the structure of biotin, transmethylation, neogenesis of methyl groups, transulfuration, metabolism of amino acids, synthesis of penicillin and determination of the structures and synthesis of the posterior pituitary hormones, oxytocin and vasopressin. It was for his work on these two hormones that he was awarded the Nobel prize, their synthesis being, as the Royal Swedish Academy of Science acknowledged, "a historic feat in biochemistry." He also received many other honours, including the Nichols, Chandler and Willard Gibbs medals and the Passano, Lasker and Osborne-Mendel awards, and was elected a member or honorary member of the leading scientific societies in the United States and of many abroad.

(R. As.)

DVINA, NORTHERN (SEVERNAYA DVINA), a river of the north European part of the U.S.S.R., is formed by the confluence of the rivers Sukhona and Yug at Veliki Ustyug. The river then flows north for about **37** mi. as the Lesser Northern Dvina (Malaya Severnaya Dvina) to its confluence with the Vychegda at Kotlas. Thereafter, as the Northern Dvina proper, it flows northwest into the Dvina gulf of the White sea, where it forms a delta with five main distributaries. The Northern Dvina is **466** mi. long, but its basin covers **139,768** sq.mi. Many of its headstreams and tributaries are rivers of great size, the largest being the Sukhona, **348** mi., and the Vaga, **340** mi., on the left bank, and the Yug, **305** mi., Vychegda. **689** mi. and Pinega, **484** mi., on the right. The volume of flow of the Northern Dvina is large, the annual average discharge being **124,661** cu.ft. per second. Almost half the water supply comes from snow-melt, bringing a marked maximum flow in spring. At the Pinega confluence a maximum of more than **1,000,000** cu.ft. per second has been recorded. Widespread floods accompany the snow-melt. Freeze-up begins in October, although a firm ice cover is not established until early November. The breakup of the ice begins in early April on the upper reaches and early May at the mouth. The Northern Dvina flows across a low plain, broken by lines of morainic hills. The basin is covered by dense coniferous forest and widespread sphagnum bogs. Only along the flood plains are there open meadows.

The river is navigable for **342** mi.; considerable lengths of its tributaries are navigable, although there are many sandbanks on the Lesser Northern Dvina. Since early times this river system has been the main way of communication throughout northern Russia, for fur hunters and, later. colonists. Monasteries and towns were established at confluences and at portages with other river basins. Notable among these mas Archangel (*q.v.*), which was founded in 1583 and supplanted the older port of Kholmogory. The river, which is connected to the Mariinsk waterway via the Sukhona, retains its importance and there are regular passenger and cargo services. The major freight is timber, cut on a large scale throughout the basin and rafted to the sawmilling centres along the Dvina. The most important of these are Veliki Ustyug, Kotlas and, above all, Archangel, the largest sawmilling centre of the Soviet Union, where the sawmills line the river bank for many miles. Archangel is a major timber exporting port and one of the western terminal ports of the Northern Sea route. At the western side of the delta is the port of Severodvinsk, formerly Molotovsk.

(R. A. F.)

DVINA, WESTERN (ZAPADNAYA DVINA), a river of the Union of Soviet Socialist Republics, rises in the Valdai hills. issuing from the small Lake Dvinets. It flows south and southwest into the Belorussian Soviet Socialist Republic and below the town of Vitebsk swings northwestward into the Latvian S.S.R. (where it is known as the Daugava), to enter the Gulf of Riga. The largest river of the Soviet Union draining to the Baltic, it is **634** mi. long and the area of its basin is **32,857** sq.mi. Most of its tributaries are small, the larger ones being the Mezha. Kasplya, Luchesa. Ulla and Disna on the left bank and the Drissa and Aiviekste on the right. Apart from the morainic hills along the upper reaches of the Dvina. where the valley is deep and the banks are steep, the river flows through broad lowlands, often with wide swampy areas and many lakes. Boulders of glacial origin cause rapids in the upper course. but the river is navigable from a point between the town of Zapadnaya Dvina and the Mezha confluence, although further rapids below the Disna confluence are a hindrance. Ice begins to form in late November and the freeze-up is complete by early December in the upper reaches and mid-December in the lower. Ice-melt begins in early April and lasts **5-10** days. At this time widespread flooding occurs. because of the melting of the snow. which provides about 46% of the river's water. Midsummer is a period of low water. The average annual discharge is **24,014** cu.ft. per second.

From earliest times the Western Dvina has been an important routeway and towns along its banks are among the oldest in Russia. Polotsk (*q.v.*), founded in the 9th century, is one of the first for which there is documentary evidence. The Western Dvina. connected in its upper reaches by easy portages to the basins of the Dnieper. Volga and Volkhov, formed part of the great trade route (the "Water Road from the Varangians to the Greeks") of Kievan Russia *(see* KIEV). Between **1797** and **1804** the Dvina, by way

of its tributary the Ulla, was linked by a system of canals to the Berezina and so to the Dnieper. This system. always small and suitable only for rafting timber, has now fallen into disuse. The Dvina is still used for navigation, with passenger services from Riga to Daugavpils (Dvinsk). Much timber is floated to the sawmilling and timberworking centres of Vitebsk, Polotsk and Daugavpils. The largest city on the river is Riga (*q.v.*), on the right bank, a few miles above the mouth; it is the capital of the Latvian S.S.R., and has long been a major port, famous in the past for its export of ship timbers and naval stores. The Kegums hydroelectric plant. southeast of Ogre, supplies power for industry.

(R. A F.)

DVORAK, ANTONIN (1841–1904), the first Czech composer to achieve world-wide recognition, was born at Nelahozeves, a small village on the Vltava north of Prague, on Sept 8, 1841. Bedrich Smetana, his senior by 17 years, had already laid the foundations of the Czech nationalist movement in music, but it was left to Dvorak to develop and extend it in an impressive series of works which quickly came to rank in popularity with those of his great German contemporaries.

His father was a humble innkeeper and butcher, and Dvorak was undoubtedly influenced by the amateur music-making which he heard and contributed to at the inn. He soon became an accomplished violinist, and in 1857 a perceptive local teacher, A. Liehmann. recognizing his unusual talent. persuaded his father to send him to the Organ school in Prague. After a two-year course Dvorak worked as an orchestral viola player. organist and teacher in order to keep himself while engaged on his first serious compositions. The numerous and varied works of this period show that his earlier leanings toward Beethoven and Schubert mere becoming increasingly tinged with the influence of Wagner and Liszt. In Nov 1873 at a time when a few successful concerts of his works had begun to make his name well known in Prague. he married Anna Cermakova, and thus began an unusually happy family life. In 1875 he was awarded a state grant by the Austrian government. and this brought him into contact with Brahms, with whom he formed a close and fruitful friendship. Brahms not only gave him valuable technical advice but also found him an influential publisher in Fritz Simrock, and it was with his firm's publication of the Moravian duets (1875) for soprano and contralto and the Slavonic dances (1878) for piano duet that Dvorak first attracted world-wide attention to himself and to his country's music. The admiration of the leading critics, instrumentalists and conductors of the day continued to spread his fame abroad, which naturally led to even greater triumphs in his own country. In 1884 he made the first of ten visits to England, where the success of his works, especially his choral works, was a source of constant pride to him. In 1890 he enjoyed a great personal triumph in Moscow with two concerts arranged for him by his friend Tchaikovsky. The following year he was made an honorary doctor of music of Cambridge university. In 1892 he accepted the post of director of the National Conservatory of Music in New York, but, much as he found to interest and stimulate him there he soon came to miss his own country and he finally returned to Bohemia in April 1895. The final years of his life saw the composition of two string quartets, five symphonic poems and his last three operas. He died in Prague on May 1. 1904, from a stroke of apoplexy.

Few composers have achieved such widespread and, as far as can be judged, lasting popularity so quickly as Dvorak. The reasons for this lie in a gift of melody only surpassed by Schubert's and in the delightfully fresh Czech character of his music which offered a welcome contrast to the heavier fare of some of his contemporaries. He was also fortunate in flourishing at a time when Smetana and the Russian nationalists had made nationalism in music an important new trend. Again his technical fluency and abundant melodic inspiration helped him to create a large and varied output. All his mature symphonies (known as No. 1 to 5, though there are four earlier ones) are of a high quality although only the sombre No. 2 in D minor (1885) is thought to be as satisfactory in symphonic design as it is musically. No. 5 ("From the New World," 1893) still retains its immense popularity, largely due to the mistaken though understandable belief that what in reality are characteristically Czech themes are Negro spirituals, but in fact it is inferior to No. 1 (1880) and 4 (1889) and less characteristic of its composer Of the four concertos, only that in B minor for cello, op. 104 (1895), can safely be called a classic; indeed its success began a revival of interest in this instrument as a concerto solo.

In spite of the fact that the medium is sometimes overstrained, Dvorak's chamber music is also of a high quality. The Piano Quintet in A. op. 81 (1887), is one of the glories of chamber music, and the String Quartets. op. 51 (1879), 105 (1895) and 106 (1895), the Sextet, op. 48 (1878), and the "Dumky" Trio, op. 90 (1891), also rank high. The choral works, so popular when they first appeared, have suffered the fate of most late-19th-century choral music, yet the *Stabat* Mater (1877) and Te Deum (1892) deserve to be placed among the better examples of their kind. Opera was the one medium that proved recalcitrant to Dvorak's genius—a fact which he felt keenly and contended nith all his life. Only in his last years did he write two that achieved more than local success—*Cert* a Kacn ("The Devil and Kate," 1898–99) and *Rusalka* (1900); *Rusalka* has even achieved a certain popularity, though this is more on account of its lyrical than dramatic qualities. Many of Dvorak's most attractive works, however, are to be found in the miscellaneous less ambitious works—the Slavonic Dances and other piano duets, the Scherzo *Capriccioso,* Symphonic Variations and Carnival Overture for orchestra, the "Gypsy Songs" and the Bagatelles (for string trio and harmonium. op 47)

Dvorak's chief faults and limitations are his overdiscursive and repetitive manner, occasional lapses of taste, and the weakness of design in his larger works He has also been charged with false exploitation of the simple and naïve charm of his work. Such shortcomings, however. amount to little in the light of the astonishing fertility of his melody and the simplicity and directness with which he achieves his ends. As might be gathered from his music, Dvorak had an attractive personality; he was a humble and deeply religious family man of simple tastes and a great lover of nature.

BIBLIOGRAPHY.—*Antonín Dvořák: His Achievement,* ed by V. Fischel (1943); A. Robertson, *Dvoldk* (1945); O Sourek, *Antonín Dvořák: His Life and Works* (1952). (D. M. L.-J.)

DVUR KRALOVE NAD LABEM (KÖNIGINHOF), a town of northeast Bohemia, Czech., 24 km. (15 mi.) N. of Hradec Kralove on the left bank of the Elbe. near its emergence into the plain country of Polabi. Pop. (1957 est.) 15.196. The name means "the court of the queen on the Elbe," and recalls the founding of the city by King Wenceslas II at the end of the 13th century and the gift of the settlement to his queen. Elisabeth. It was the scene of a major Austrian defeat by the Prussians in 1866. The town received some publicity in the 19th century when a Bohemian librarian. V. Hanka. claimed to have discovered a Czech manuscript (rukopis Kralovedvorsky) in a church steeple there; it later proved to be a forgery. The town is a centre of the cotton, linen and jute industries.

DWARF, a word generally used to describe an extraordinarily small individual of a race of normal stature (see also DWARFISM AND GIGANTISM; PYGMY).

In Scandinavian and Teutonic Folklore.— The term dwarf denoted a species of fairy (*q.v.*) inhabiting the interiors of mountains and the lower levels of mines. Dwarfs were of various types, all of small stature, some being no more than 18 in. high and others about the height of a two-year-old child. In appearance they were sometimes beautiful, but more usually they resembled grave old men with long beards and, in some cases, humped backs.

The mountain dwarfs were organized in kingdoms or tribes, with their own kings, chieftains and armies. They lived in subterranean halls, believed to be full of gold and precious stones. They were principally famous for their skill in all kinds of metalwork and the forging of magical swords and rings, but they were also credited with profound wisdom and secret knowledge, having power to foresee the future. assume other forms and make themselves invisible. In the Eddaic lays Thor's hammer and Odin's spear are their handiwork and in the *Volsunga* Saga and the *Nibelungenlied* (*q.v.*) dwarfs guard hoards of gold. (See also EDDA; SAGA.)

Many legends show them as kindly beings, generous to those who

pleased them, but revengeful when offended. The Swiss dwarfs or "earth-men" sometimes helped in agricultural work, found straying animals and put out firewood or fruit for poor children to find. In Scandinavia and Germany also they were friendly to men, but occasionally they stole corn, teased cattle and abducted children and young girls. Services rendered to them were often repaid by gifts of gold from their hoards; but those who stole their treasures either met with great misfortune thereafter or found the gold turned to dead leaves when they reached home.

Mine-dwelling dwarfs were usually more capricious and spiteful than their mountain brothers. They could be heard moving about the lower levels and were sometimes seen by miners. who took care to placate them by gifts of food. If these were withheld or if their movements were too curiously observed, they retaliated by igniting fire-damp. breaking tools or pulling down the roof. When pleased, they often helped in the work or gave warning of impending danger by tapping. In England the mine-dwarf tradition survives in legends of the "Knockers" who inhabit mines in Cornwall and Staffordshire and behave in much the same way as their continental cousins. (See also BROWNIE; ELF.) (C. S. HE.)

In History.— Household dwarfs were kept by the early Pharaohs and still abounded at the courts of the Ptolemies. They played no part in Homeric and classical Greece but flourished in imperial Rome where slave children were sometimes stunted to increase their price. They functioned in medieval Europe and during the Renaissance their vogue increased and individual dwarfs became famous. Although they might be served in mock pies at banquets, they were treated kindly and sometimes had their own servants. Isabella d'Este designed part of her palace for them and remembered two in her will. Velasquez has familiarized us with the appearance of the dwarfs of Philip IV of Spain.

In the 18th and 19th centuries, the tsars and noblemen of Russia kept innumerable dwarfs. Elaborate dwarf weddings were celebrated at court and in 1710 a dwarf couple spent their wedding night in the tsar's bedchamber. In 1715 the funeral procession of a favourite dwarf was headed by ecclesiastics followed by 24 pairs of male and female dwarfs arranged in sizes, the tsar and his ministers bringing up the rear.

Dwarfs occasionally held responsible positions, but were primarily entertainers and often served as household fools (see FOOL). In western Europe household dwarfs were still heard of in the 18th century; but the institution declined and dwarfs such as Charles Stratton ("Gen. Tom Thumb") who won money and reputation in the 19th century belong to a different category.

Abnormality can excite awe as well as ridicule. The pygmy Dangas, who entertained some of the early Pharaohs, came from Puanit near "the land of ghosts" and could "dance the god"; medieval Irish dwarfs were sometimes credited with poetic and supernatural powers; a 19th-century traveler noted that African dwarfs were regarded as wizards; a traveler in 20th-century Spain saw a dwarf's hump touched for luck. *See* also references under "Dwarf" in the Index volume. (E. E. H. W.)

BIBLIOGRAPHY.—Thomas Keightley, *The Fairy Mythology* (1850); The Brothers Grimm, *Kinder und Hausmärchen* (1812, Eng. trans. *German Popular Stories*, 1824–26); C. S. Burne, *Shropshire Folk-Lore* (1883); M. A. Courtney, *Cornish Feasts and Folk-Lore* (1890); E. J. Wood, *Giants and Dwarfs* (1868); E. Welsford, *The Fool* (1935). (C. S. HE.; E. E. H. W.)

DWARFISM AND GIGANTISM are terms which designate conditions of size outside (below or above) the range of the normal variation of living organisms. Such abnormal variants are found among plants as well as among animals, including man. The terms usually refer to comparisons within one species but, especially in evolutionary studies, may apply also to the relative sizes of related species and genera. In speaking of dwarfs and giants the allusion ordinarily is to size of the organism as a whole, but parts and organs may be affected selectively or preferentially. Entirely proportionate dwarfism or gigantism is, in fact, an exception rather than the rule. As in all development of living beings, interactions between the environment and the hereditary endowment are of prime importance; yet, in different circumstances the contributions of these two sources of variation differ greatly in extent.

Gigantism and dwarfism, titans and midgets have fascinated men since the dawn of recorded history and probably long before. "What he often sees," said Cicero of man, "does not excite his wonder, even though he knows not the cause of it. But if a thing happens that he has not already seen, he regards it as a prodigy." The belief was common that "there were giants in the earth in those days" (Gen. vi, 4). Many peoples traced their origin to giants. There are legends of the Titans who made war against the Olympian gods. Polyphemus and Goliath, Gargantua and Rubezahl, Gog and Magog are among the more famous representatives of the many legends that had giants for heroes. J. G. Frazer in *The Golden Bough* gave an account of the Norse legend about the giant who had no heart in his body as an example of the widespread primitive belief in the external soul. The manifold roles of dwarfs in myths and legends are too well known to call for comment. In poetry, romance and satire, giants and dwarfs, Brobdingnagians and Lilliputians, continue to serve as a measure of human stature and human frailty. Sculptors and painters also have often fashioned dwarfs—in ancient Egypt, at Pompeii and Herculaneum, in engravings by Tiepolo and portraits by Velázquez, among many others—and many of these works of art are of considerable cultural as well as medical-historical interest. (See also DWARF; GIANT.)

Dwarfism.— In man and other higher animals four principal kinds of dwarfism may be distinguished: (1) Racial dwarfism, represented by groups of diminutive individuals whose physiological bodily functions are quite normal. (2) Dwarfism due to genetic changes (mutations) arising in the progenies of normal parents; the primary effect of such mutant changes may be on an endocrine gland (*e.g.*, the pituitary) or more directly on cellular functions related to growth. (3) Dwarfism produced by metabolic disturbances due to organic disease. (4) Dwarfism determined by forces of the environment with which the hereditary constitution of a particular organism is unable to cope.

All these categories of dwarfism are encountered in man. For anthropological purposes the lower limit of "normal" height of adult men has, and of necessity in a somewhat arbitrary manner, been set at 4 ft. 11.1 in. (150 cm.); any group with a lesser mean height for males is considered as composed of dwarfs. By this criterion dwarf populations exist in central Africa, the Andaman Islands, the Philippines and New Guinea. The pygmies of central Africa are frequently used as the prototype of such racial dwarfism. Height among these pygmies varies down to 4 ft. 3 in. for men and to 4 ft. for women. The Bushmen of the south African Kalahari desert: though somewhat taller than pygmies, are also dwarfs. The natives of the Andaman Islands in the Indian ocean and the Negritos of the Philippines and New Guinea are other dwarf populations. No demonstrable relations have been found among these dwarf groups of Africa, Asia and Oceania. Their peculiarities presumably arose by mutation and may have been fixed by isolation. (*See* also PYGMY; BUSHMAN; NEGRITOS.)

Among several types of hereditary dwarfism occurring in populations of normal stature, the commonest is known as achondroplasia or chondrodystrophy. Achondroplasia is a form of disproportionate dwarfism in which the extremities are greatly reduced in length, shortness of the legs being the principal or sole cause of wanting stature. This disproportion is congenital. Adult body height approximates that of normal children aged nine years. In many achondroplastic persons the root of the nose is depressed and the antero-posterior diameter of the pelvis is reduced; other skeletal peculiarities are often associated. There is much variation in the severity of achondroplasia. In the presence of the most extreme symptoms death occurs before, during or shortly after birth, but the life expectancy of other affected individuals is normal. The pathological processes that produce achondroplasia remain unknown. All physiological functions appear to be normal, except that (with rare exceptions) achondroplastic women, because of the shallow pelvis, can give birth only by Caesarean section. Intelligence is normal. Most court jesters were men afflicted with achondroplasia; so are many circus clowns. Achondroplasia occurs whenever one of the two germ cells that give rise to an individual contains the relevant hereditary factor; it is a dominant genetic

trait. It has been found that about one birth in every 10,000 represents an achondroplastic individual. The majority of achondroplastic children are born to normal parents, evidently as a consequence of a mutation in the gonads of one of them. Several additional hereditary disturbances of skeletal growth produce disproportionate dwarfing; *e.g.*, dyschondroplasia (Ollier's disease).

In other forms of hereditary dwarfism the bodily proportions remain relatively if not altogether normal. In this group are found the smallest individuals on record; these are the midgets or ateliotic dwarfs, the lowest authentic stature on record being 30.7 in. for an adult male. Some of these dwarfs are already below normal size at birth (primordial dwarfism), but in others the retardation of growth becomes effective in the course of the first two years of life. Midgets remain sexually immature. The nature of the inborn errors of growth in this kind of dwarfism is obscure, but abnormalities of pituitary function probably play a role in at least part of the cases.

Dwarfing may occur as a consequence of varied metabolic or functional disturbances, such as chronic nephritis (renal dwarfism), fibrosis of the pancreas (intestinal dwarfism), brain pathology (dyscerebral dwarfism) and subnormal thyroid activity (endemic cretinism, myxedema [*qq.v.*]). Some mental defects are also associated with dwarfism (*e.g.*, mongolism). Finally, dwarfing (such conditions as rickets; *q.v.*) may be a consequence of nutritional inadequacies and deficiencies.

Among other mammals and among birds the varieties of dwarfism show a spectrum very similar to that found in man. Among many domestic animals are found dwarf races or breeds: ponies, African dwarf goats, toy dogs, Bantam fowl. In the Dexter breed of cattle the genetic factors for reduced body size are responsible for the occurrence of monsters, known as bulldog calves. In several breeds of beef cattle a mutation for dwarfism, associated with other defects, is responsible for serious losses to breeders. Several mutations to dwarfism have been reported in mice. In one of these, size is normal at birth, but begins to lag at about two weeks of age, producing an adult size one-quarter to one-third of normal; both sexes are sterile and the life expectancy is poor. This form of dwarfism is inherited as a recessive trait; *i.e.*, both parents must transmit the mutated gene before it can come to expression in the progeny. The primary effect of the mutation is an abnormality of pituitary activity, all consequences of which (dwarfism, sterility, etc.) can be overcome by proper hormone medication. In poultry hereditary dwarfism has been encountered in association with defective activity of the thyroid. Deficiencies and metabolic disturbances are often responsible for underdevelopment, and breeders refer to such animals as runts.

The situation in plants is similar to that in animals. On the one hand dwarfism occurs as a consequence of changes in the hereditary endowment; on the other hand stunting of growth is produced by forces of the environment which impose their effects upon the genetic constitution. Mutant forms, such as dwarf roses, often have considerable horticultural value. Hereditary dwarfism (*e.g.*, in maize) frequently is brought about by interference with the synthesis or with an abnormal rate of destruction of essential hormonelike growth substances (auxins. gibberellins), compounds which in some instances can be provided extraneously and then support normal growth. The emergence of a dwarf form of pigweed was ascribed to the selective effect of the regular mowing of meadows. Climatic and nutritional conditions are more often instrumental in the selection of dwarf varieties (mountains, sea shore), but dwarfing also may occur as a direct adaptation to an unfavourable environment. The production of dwarf plants for ornamental purposes, known as bonsai (*q.v.*), which originated in China, was brought to a high degree of perfection by Japanese horticulturists.

Gigantism. — Gigantism is much rarer among recent organisms than dwarfism. In man the conventional definition of a giant is a height exceeding 6 ft. 6.7 in. (200 cm.) in men and 6 ft. 1.6 in. (187 cm.) in women. The giantess Marianne Wehde had a height of 8 ft. 4.4 in. (255 cm.), and hers appears to be the maximum recorded stature on which reliance can be placed, though claims for other giants go as high as 9 ft. 3 in. The commonest form of gigantism in man is brought about by hyperactivity of the pituitary gland, frequently as a result of benign tumours of the pituitary. As a consequence of such glandular disturbances in adolescents longitudinal bone growth may continue long beyond its normal time of cessation. In older persons pituitary gigantism is often limited to a special enlargement of the hands, feet and jaws (acromegaly; *q.v.*). Another form of gigantism is produced in men by early castration.

The history of evolution offers many interesting aspects of dwarfism and gigantism. One of the most peculiar among these is the nearly universal occurrence of a trend toward gradually increasing body size, a fact known as Cope's rule. This trend culminated in the real giants of evolutionary history, including the mighty dinosaurs and equally impressive mammals. Human evolution did not escape this trend. Suggestively large skeletal fragments (*Meganthropus*) have been found in Java, and molars of tremendous dimensions were located in China and ascribed by some investigators to a human stock (Gigantopithecus), probably of Pleistocene times. According to F. Weidenreich, "it may not be too far from the truth if me suggest the Java giant was much bigger than any living gorilla and that the Chinese giant was correspondingly bigger than the Java giant — that is, one and one-half times as large as the Java giant, and twice as large as a male gorilla." (Apes, Giants and Man, The University of Chicago Press, 1946. Copyright 1946 by The University of Chicago.) A fully grown male gorilla weighs upward of 400 lb. It is clear that evolution, with the extreme specialization that produced dinosaurs and similar forms of gigantism, had led into a one-way street from which there was no escape, but it is not certain that the Javanese and Chinese giants became extinct for similar reasons.

DWARKA (Sanskrit DVARAKA, also DVARAVATI, "city of many gates." also known as Jagat or Jigat), a municipality of Jamnagar (formerly Halar) district in Gujarat, India, lies on the west coast of the Okhamandal peninsula in the northwest of the Kathiawar peninsula, 115 mi. W. of Rajkot. Pop. (1951) 9,765. According to legend Dwarka was the capital of Krishna (*q.v.*), who founded it after his flight from Mathura (Muttra). Its consequent sanctity makes it one of the seven great places of pilgrimage for Hindus and most of its revenue is derived from the pilgrim traffic. The original temples were destroyed in 1372 by Mahmud Shah Begada of Gujarat. (J. B.-P.)

DWELLING: see HOUSE DESIGN; RESIDENTIAL ARCHITECTURE.

DWELLINGS, PRIMITIVE. Human shelter, like clothing, is a nonbiological adaptation to external conditions. Man is physically ill-adapted to withstand the rigours of climate, but his intelligence and dexterity provide compensation by enabling him to manipulate the external world to fit his needs. All land animals except the hoofed mammals regularly make use of shelter if only for the period of rearing their young. Their shelters are fixed by instinct; in contrast, human dwellings are diverse products of invention and cultural tradition. Housing provides shelter from the elements, protection from human enemies and predatory animals, security for infants and a place for social intercourse.

It is presumed that beginnings of construction among protohumans resembled the crude nests of apes — those of chimpanzees in trees. the heavier gorilla more often on the ground. The earliest fully evolved humans of Paleolithic times had their abodes in the mouths of caverns and under rock overhangs They probably also built elsewhere in the open. but little is known of such perishable structures. By the time of the Neolithic period, dwellings were constructed much Iike those of modern primitive peoples. (See ARCHAEOLOGY: Prehistory; LAKE DWELLINGS.)

Adjustment to climatic conditions was sometimes incomplete. The half-open lodges of Indians'in northwest Canada and the brush huts of Fuegians at the southern tip of South America afforded poor protection against frigid weather. The wandering life of these peoples permitted no more substantial construction and they

were inured to hardship. Adaptations also involve availability of materials and their utility. The Eskimo snow house and the Congo palm-thatched hut are obvious examples. In spite of abundance, limitations may exist: mud, though often used as building material, is impractical where rainfall is heavy. Adaptations are not made anew by each individual; rather, the selection of materials and the form of house are dictated primarily by traditional building practice.

In addition to dwellings, primitive peoples often had public buildings and auxiliary storehouses whose construction was sometimes quite elaborate and according to different principles.

Furnishings of dwellings were simple: possessions were few and mostly necessities. Bed places, hearth, cooking utensils, mortar and storage receptacles comprised the lot among most peoples. Facilities for sanitation were rare. Offal scattered about was scavenged by animals, domestic or wild. Latrines were established at cliff edges at Maori (New Zealand) hilltop villages, and on many Oceanic atolls it was obligatory to use the beach between low and high water.

Africa.— Primitive habitations in each continent were primarily of a few widespread forms. In Africa, houses in the Sahara oases followed Mediterranean style (rectangular, mud or stone walls, flat roofs), while those of the seminomads (Tuareg and Tebu) showed adaptations to more southern forms, with the nomadic Arabs using their characteristic cloth tent.

South of the Sahara two forms predominated: one circular-walled and conical-roofed, the other rectangular-framed and gabled. From the western Sudan eastward and southward toward the Cape of Good Hope was a round house with the roof conical or drawn in beehive fashion. In this semiarid region clay or mud was often utilized for walls, thatch of grass or palm leaves for roofs. Hausa dwellings (western Sudan), clustering in towns, had grass-thatched conical roofs on low walls. The roof framework was sometimes put together on the ground and bodily lifted into place, whence it could be readily transferred to other walls when the first ones rotted. Alternatively there were small rectangular houses, mud-walled, with roofs gabled, flat or conical. Ambitious houses bore modeled decoration or 'incised designs. Upper Nilotic villages were straggling clusters of conical-roofed houses raised on platforms to avoid dampness and wild beasts. An east African village was typically a ring of houses occupied by the wives and relatives of a chief with a surrounding wall of stone or thorns within which cattle were driven at night. The large conical-roofed structure of the Ila (Northern Rhodesia) had atop its centre pole a wooden disk from which rafters descended to the walls of closely planted posts, with the interior clay coated and the exterior thatched with grass like the roof. A sleeping compartment was set off by a row of clay grain bins. The beehive-shaped house prevailed in the northeastern and southeastern coastal districts.

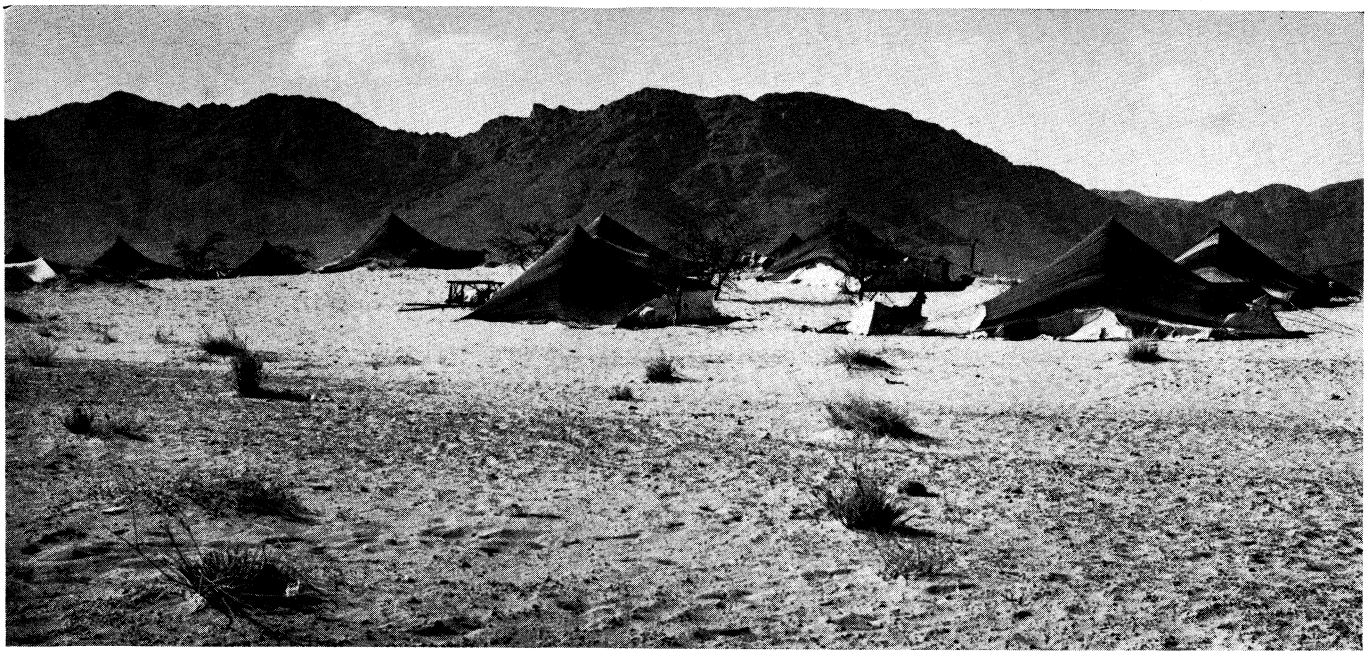
The second general African type, the rectangular gable-roofed house, was built throughout the forested Congo and Guinea coast, with those of the Congo generally smaller. House walls among the Kuba (Bushongo) of the lower Congo had decorative patterns formed by the lashings holding the palm thatch in place. Southward and eastward, rectangular houses formed a hybrid with the conical roofs of east Africa. Pile dwellings were constructed along water courses of the Congo and Zambesi. In desertic southwest Africa the cattle-raising Hottentot, obliged to move from one water hole to another, made an easily transported low-domed hut of sewn reed mats over a frame of pliable poles. The shelters of the roving Bushmen in the Kalahari desert were mere semicircular windbreaks or rock overhangs.

Asia.——Habitations of natives in northern and central Asia had an east-west zonal distribution corresponding to the northern tundra with its reindeer herding and to the central forest and steppe with its mixed-herding economy. A conical tent was in use in the tundra from the Yukaghir (northeast Siberia) westward to the Lapps (northern Scandinavia) and in the forests from the Tungus (Amur river) to the Kalmy (north Caspian sea). This Eurasiatic occurrence may have been historically linked with the conical tent of North America. The more northerly peoples made tent covering of unsewn reindeer skins, carrying their poles and cover as they followed roaming herds in the treeless land; those of the southern Siberian forests could afford to abandon their bark-covered tents to rebuild at new pastures. Both types were often banked with snow or earth; the Bashkir (Ural district) plastered their houses with dung and straw. In the Altai-Lake Baikal region the Buryat alternated skin and bark covering in winter and summer, and their southern neighbours, the Northern Mongols, substituted the felt-mat covering of the steppe-desert zone. A cylindrical tent (yurt) with a conical or domed roof prevailed throughout central Asia from Mongolia to the Black sea, the conical-roofed in the east among Mongolic tribes, the domed among Turkic tribes to the west. Where Altai-Tatars of the forest made a cylindrical wall of posts, the commonest wall frame was a joined lattice with pliable poles bent for the roof, covered with overlapping felt mats, the whole easily collapsible for transportation. But yurts were also carried bodily on wagons by tribes of the Black sea area, as they were by the Scythians of the 5th century B.C.

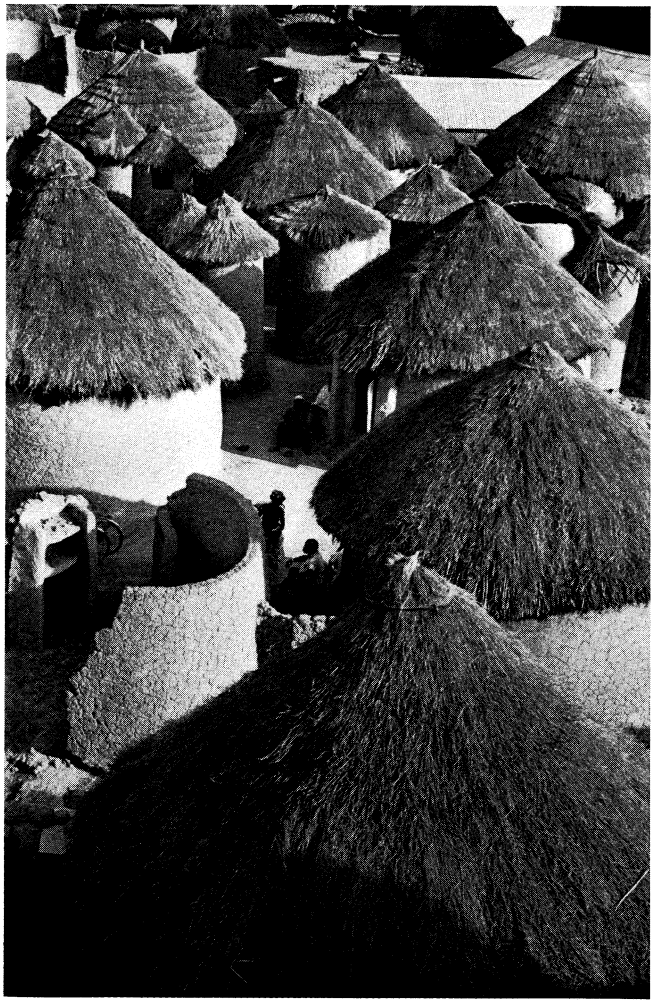
In northeastern Siberia the maritime Chukchi and Koryak built semisubterranean timbered, earth-covered houses, those of the Koryak being distinguished by a funnellike contrivance over the roof entrance to deflect drifting snow. Herdsmen inland made a skin replica of these large houses, ill-adapted for sled transport. In Tibet there was contrast between the yak-cloth tents of the nomadic Drupa and the clustering stone-walled, flat-roofed houses of the settled population. The former were rectangular. with a low gable having a smoke outlet along the ridge. The shapeless-appearing Arab tent had a standard form: roughly rectangular, its haircloth cover was supported by poles on the median line, paired with others at the open front, and guyed by taut ropes. The short rear wall was a hanging valance; the higher front might be closed with a curtain in cold weather. A cloth partition sometimes set off the women's compartment. Southeast Asia was in general an area of rectangular, timber- or bamboo-framed houses, with thatched or lattice sides. The Lolo (Yi) of southwest China interwove bamboos in patterns for their walls. The similar habitations of the Lamet (northern Vietnam), raised on piles, had a veranda at each gable end. Berths were ranged along one side, each with a hearth to furnish a smudge against mosquitoes. Houses throughout Malaysia were of much the same type, with local variations, and frequently set on piles. Most were small, but in inland Borneo a building might house an entire village; in central Sumatra such houses had elaborately carved and painted gable ends. Exceptional were the beehive-shaped huts found in outlying sections, as in the Lesser Sunda Islands.

Oceania.— In Oceania, houses were most commonly rectangular aith thatched gable roofs. These were the products of guilds of house builders in Polynesia and Micronesia. In both areas timbers were accurately fitted, and lashings of coconut fibre (sennit) were commonly interlaced in ornamental patterns. While in some islands indoor hearths provided light and warmth, cooking was in a small detached hut. Polynesian dwellings were almost always raised on stone-faced or paved platforms. Hawaii, Marquesas and New Zealand houses were square; in Easter Island they were elongated nith pointed ends. Variation appeared in central Polynesia (Samoa, Tonga, Society Islands), where round additions at opposite ends produced an elliptical ground plan which in Samoa often approached a circle. Mat curtains, hung between wall posts, provided protection. Fiji showed by far the greatest variations in house form. Micronesian structures were frequently divided by partitions. which were lacking in Polynesia except for temporary bark-cloth (tapa) curtains. Melanesian houses were less well made: timber frames were cruder and often the frame, even of large houses, consisted of poles set along opposite long sides and brought together in a pointed arch. Wooden floors were raised on posts separate from the house frame; on these, earth-filled boxes functioned as hearths. Circular houses in the mountains and large communal dwellings on the southeastern coast marked New Guinea variants. In contrast, the hunting, roving peoples of Australia and Tasmania pitched camp near water holes, making a lean-to of boughs or bark that rested against a pole set on two forked sticks. backed against the prevailing winds.

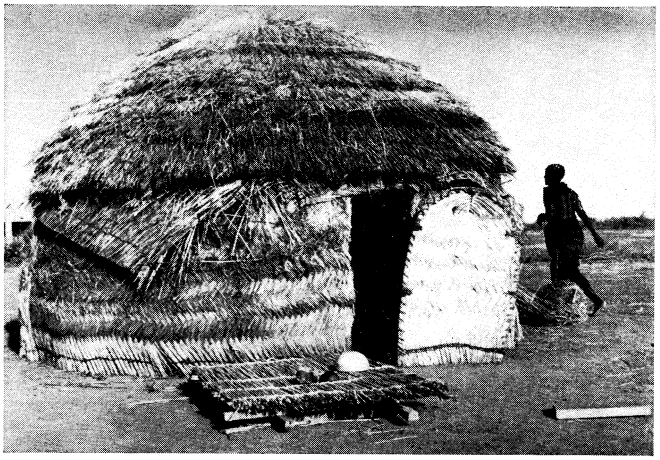
North America.--Regional distinctiveness also characterized



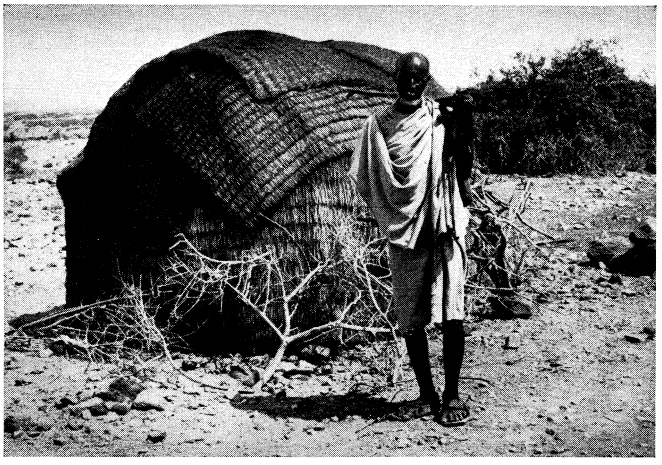
Camp of nomadic Arabs of the Saharan region of north Africa. The tents are usually made of strips of cloth woven from goat's or camel's hair, and vegetable fibres



Houses of the Senufo tribe, Ivory Coast. The cylindrical walls are made of mud, the conical roofs of thatched grass



Circular-walled hut made of woven reed with a thatched conical roof; Jerma dwelling near Niamey, Republic of Niger



Shelter of the nomadic Isa tribe of Somalia, a portable, low-domed tent of reed mats supported by a hemispherical framework of curved poles

the dwellings of North American Indians. Different winter and summer forms were built by natives from the Atlantic to the Mississippi. In the north the winter dome-shaped house (wigwam) was small, framed of flexible poles and thickly covered with overlapping mats or bark. In the south, as among the Chickasaw and Choctaw, walls and roof were distinct; the timbers were shaped and notched; at the centre, four tall posts supported a hexagonal cribmork from which rafters reached to the wall plates; the houses were thatched. clay-plastered inside and out and partitioned into two rooms. The summer lodge of the east was rectangular with a gable roof; the covering of mats or bark was held down by poles which duplicated the inner framework. Along the middle Atlantic coast, the roof was a half-cylinder (barrel vault). Platform beds lined the walls in both domed and gabled houses. An open pavilion served as a summer house near the Gulf. Both winter and summer houses were usually small. The Iroquois long house was rectangular, lengthened as needed for additional families: partitions marked off family spaces, while down the centre was a line of family hearths. Transitional forms appeared among the Natchez and other tribes on the lower Mississippi, where domed roofs were supported on rectangular bases, the walls heavily clay-coated. Farther west the larger circular Wichita houses, framed of supple poles, resembled giant beehives neatly thatched with grass.

Conical tents were typical of the plains and interior Canada. The Plains Indian tent (tepee or tipi, the Dakota name) had a tripod or four-pole foundation supporting other poles; on this was tightly stretched a decorated, semicircular, fitted hide cover. Wings at the apex prevented a downdraft at the smoke hole. After the introduction of the horse (17th–18th centuries) had facilitated transportation, larger tepees were made by the central tribes. During the summer hunt, tepees were pitched in a great circle, each family in its allotted place. Sedentary tribes of the eastern plains (Hidatsa, Pawnee) built large earth-covered lodges with a circle of wall posts, four higher centre posts, rafters extending from centre posts to wall and a tunnellike entrance. Inside were family compartments and a pen for horses. On the summer hunt, Hidatsa used tepees pitched in camp-circle fashion. Northward in Canada was a small bark- or mat-covered tepeelike structure, its covering often extending for but two-thirds of its height and hence not much more than a windbreak. Only mats mere carried to new locations since poles were available everywhere. The earth-covered lodge used by tribes of southern British Columbia resembled that of the eastern plains but with different timbering and often a roof entrance. Along the middle Columbia, the winter house was a large gable set on the ground. usually with rounded ends. In summer, tribes there used the conical forms. The Athapaskans of northwestern Canada had merely double lean-tos, like two halves of a gable face to face, with a fireplace between—again a bare shelter from the weather.

The Eskimo snow house (igloo or iglu), built at sealing grounds, was characteristic only of the Arctic coast between the Mackenzie river and Baffin Island. Carved blocks of snow were laid in an upward spiral to form a domed house with a low tunnel entrance, a platform of snow inside forming a sleeping and lounging place. For inland travel in summer a rudimentary skin tent was carried. Eastward in Greenland and Labrador, houses were roughly of this domed shape but with walls of stone and sod, arched above by whale ribs or large stone slabs. Westward, the Alaskan Eskimo made a squarish house of logs with a pyramidal roof.

Gable-roofed rectangular houses on the coast from Alaska southward were often very large, accommodating several families. These were framed of heavy timbers between which riven planks were set vertically or horizontally with others for roofing. The circular doorway at a gable end could be closed by a sliding panel. Totem poles and painted heraldic devices decorated such house fronts. A wide platform ran along the walls, either built up or produced by a square excavation at the centre. Plank houses with a single pitch, shedlike, were also built in southern British Columbia and western Washington. At the southern end of the plank-house range in northwest California, the Yurok and Hupa built without the timber frame, placing crude planks vertically in the ground and resting roof planks on a ridgepole and the walls.

In the central valley of California, northern tribes (such as the Maidu) had a semisubterranean house, its conical roof, with brush and earth covering, extending to the edges of a shallow pit. These of the San Joaquin drainage (Yokuts) had elongated elliptical houses, mat-covered, with numerous posts holding up the ridge, and partitioned into family quarters. In the coastal areas and Sierra foothills were varieties of small conical, bark- or brush-clad huts. These aligned with the crude conical or subconical dwellings (wickiup)—with a base of four crooked branches covered with brush—of the semidesert country from Idaho to Arizona and New Mexico. Local variations appeared: on the eastern border some Shoshone used skin covering in imitation of the plains tepee; in northern Arizona, Navaho heaped dirt over their subconical house to render it raintight. A semicircular windbreak was the sole shelter of tribes in central Nevada. Yuman tribes of the lower Colorado built a rectangular low structure with a double-pitched (gambrel) roof, the whole covered with sand. In the Gila drainage, Maricopa and Pima dwelt in dirt-clad flattened domed houses; four or six centre posts supported stringers to which encircling poles were tied.

The architecture of Pueblo tribes of northern New Mexico and Arizona differed markedly from that to the north. Their houses were blocks of square masonry-walled rooms ranged in a single line, or stepped up to two to four stories—each level set back from the lower—or rising in pyramid fashion. Western pueblo walls were of sandstone blocks, the eastern more commonly of sun-dried bricks or lumps of adobe. Entrance to the lowest story was by way of a roof hatchway, reached by a ladder which could be drawn up for security. The strongly built flat roofs of lower stories provided access for residents above. (See also CLIFF DWELLINGS; ADOBE.) To the south. in the northern Mexican highlands. houses were often of stone or mud wattle, square and, less frequently, round, with occasional buildings of more than one story. Flat-roofed houses were more common to the west, but arched or domed thatched roofs occurred. Mat-covered houses, mostly rectangular and gable-roofed. were in use in coastal Sinaloa. Through most of central Mexico and southward to Yucatan, the habitations of common folk—whether Aztec, Maya or lowly Chinantec—were rectangular, often with rounded ends, with wattle walls daubed with mud or built of undressed stone, and with a four-sided (hip) roof with a short ridge, heavily thatched. The more pretentious establishment of a chief was a group of such houses around a patio, with walls plastered a rich red and with red cement floors.

South America.—Subsistence. climate and availability of materials influenced dwellings in South America as elsewhere. Sedentary Andean cultivators built permanent structures of stone or adobe, whereas Amazonians, whose fields were exhausted in a few years, constructed dwellings whose life was brief. In the Andean zone and the adjacent coast, villages comprised several walled compounds, placed irregularly, within which were small stone- or adobe-walled houses surmounted by gabled thatched roofs. Within were low clay stoves, shelves or wall niches for storage and sometimes a raised bed. The dwellings of nobles were larger and more elaborately furnished. But the Chibcha (Colombia) built the gable-roofed house of Amazonian type. Throughout the forests of the Amazon and Orinoco and in the West Indies, thatched frame construction was employed: a rectangular gabled structure, or a large gable resting on the ground or a round house with conical roof. Villages comprised numerous single-family dwellings or a few large communal houses; within the latter each family had its assigned, but not partitioned, space where its hammocks were slung. Through the pampas and Patagonia the shifting population employed windbreaks and lean-tos, covered with brush, grass or skins. Among the Fuegians there was a beehive-shaped or conical structure, with bark, turf or skins covering it. After the introduction of the horse (17th century), the skin tent (toldo) tended to supplant brush construction, some tents being very large but still of open-sided pattern.

DWIGHT, the family name of a group of U.S. educators, clergymen, lawyers and authors.

Timothy Dwight (1752–1817), U.S. educator, minister and writer, was one of the most influential intellectual leaders during the first decades of the new American republic. He was born at Northampton, Mass., May 14, 1752. His father, Timothy Dwight, a merchant, was a graduate of Yale; his mother, Mary, was the third daughter of Jonathan Edwards. After the son's graduation from Yale in 1769 he taught in a grammar school at New Haven; he was a tutor in Yale college from 1771 to 1777 and a chaplain for a year in a revolutionary regiment. From 1778 until 1783 he lived at Korthampton, teaching, farming, preaching and becoming active in politics. From 1783 until 1795 he was pastor of the Congregational church at Greenfield, Conn.. where he opened a coeducational academy which at once acquired a high reputation.

From 1795 until his death on Jan. 11, 1817, he was president of Yale college. By his judicious management, remarkable ability as a teacher and force of character he won great influence and did much to raise the standard of the institution and set the pattern for the "New England type college" in other parts of the country. He became such a powerful leader of conservative Federalism after the French Revolution that he was sometimes referred to as "Pope" Dwight. Dwight was also well known as an author and as a young man had been associated with the Hartford, or Connecticut. wits, a group of writers that endeavoured to establish an American literary tradition; the group included Joel Barlow and John Trumbull (*qq* v.). In verse Dwight wrote an ambitious epic in 11 books, the *Conquest of Canaan,* virtually finished in 1775 but not published until 1785, and interpreted by analogy as a patriotic work, with Washington corresponding to Joshua; a satire. *The Triumph of Infidelity* (1788), directed against Hume Voltaire and others; *Greenfield Hill* (1794); and a number of minor poems and hymns. Many of his sermons were published posthumously in *Theology Explained and Defended* (5 vol.. 1818–19), to which a memoir of the author by his two sons. W. T. and Sereno E. Dwight, is prefixed, and in *Sermons by Timothy Dwight* (2 vol , 1828), which had a large circulation. Probably his most important work however, is his *Travels in New England and New York* (4 vol., 1821–22), which contains much material of value concerning social and economic New England and New York during the period 1796–1817.

Theodore Dwight (1764–1846), lawyer, editor and author, a brother of President Dwight, was born at Northampton on Dec. 15, 1764. Reared on a farm by his mother after his father's death in 1777. he turned to the study of law after an injury prevented him from doing farm work. He read law with his uncle Pierpont Edwards of New Haven, Conn , and was admitted to the bar in 1787. and practised first at Haddam and then at Hartford. from 1791 to 1815. He also edited the *Hartford Courant* and the *Connecticut Mirror.* He shared his brother's political views. wrote and spoke much on Federalism and wrote a good deal of verse. mainly occasional. He served in the U.S. house of representatives 1806–07 and as member of the council from 1809–15. In 1814 he was secretary of the Hartford convention, which was critical of the administration's conduct of the War of 1812. In 1815 Dwight moved to Albany, N Y., where he founded the *Daily Advertiser,* and in 1817 to New York city, where he founded the *New York Daily Advertiser,* in whose management he was active until he retired to Hartford in 1836. He died in New York city, June 12, 1846.

Sereno Edwards Dwight (1786–1850), the fifth son of President Dwight, was born in Greenfield, Conn., graduated at Yale in 1803. and was a tutor there, a lawyer, a preacher and president of Hamilton college (Clinton. N.Y.). His publications include *Life and Works of Jonathan Edwards* (10 vol., 1830); *The Hebrew Wife* (1836) ; and *Select Discourses* (1851), to which was prefixed a biographical sketch by his brother. William Dwight (1795–1865), who was also a lawyer and a Congregational preacher.

Theodore William Dwight (1822–1892), a grandson of President Dwight, was a jurist and educator, a prominent figure in political and social (notably prison) reforms. He was born July 18. 1822. in Catskill. K.Y . a cousin of Theodore Dwight Woolsey and of Timothy Dwight (1828–1916). He graduated at Hamilton college in 1840 and studied law for one year at Yale. After teaching law history, civil polity and political economy at Hamilton, he accepted in 1858 an invitation from Columbia university to teach law, upon his own condition that he found a law school. For many years he himself was the school; he did not retire from it until about a year before his death, in Clinton, N.Y., June 28, 1892.

A man of broad culture, Dwight used the Socratic method of teaching. For several years he was a nonresident professor of law at Cornell and at Amherst. An able jurist, he frequently acted as referee in difficult questions and engaged in other legal and judicial work He published in 1867 a *Report on the Prisons and Reformatories of the United States and Canada* (with E. C. Wines); favoured indeterminate sentences; drew up the bill for the establishment of the Elmira reformatory; and organized the State Charities Aid association. He edited Sir Henry Maine's *Ancient Law* (1864); was associate editor of the *American Law Register* and legal editor of *Johnson's Cyclopaedia,* and published *Charitable Uses: Argument in the Rose Will Case* (1863).

Timothy Dwight (1828–1916), also a grandson of President Dnight. was a preacher and educationalist. born at Norwich, Conn . Nov. 16. 1828. Educated at Yale, Bonn and Berlin, he was professor in the Yale Divinity school from 1858 to 1886, was licensed to preach in 1861, and from 1886 to 1899 was president of Yale, which during his administration prospered greatly. He was also a member from 1872 to 1885 of the American committee for the revision of the English Bible, was an editor from 1866 to 1874 of the *New Englander,* which was much like the later *Yale Review;* and in addition to his translating and editorial work he published numerous magazine articles and a collection of sermons *Thoughts of and for the Inner Life* (1899). He died on May 26, 1916.

Cunningham, *Timothy Dwight* (1924) and Leon Howard. *The Connecticut Wits* (1943) For the younger Timothy Dwight, see *Timothy Dwight: Memorial Addresses,* issued by Yale university; also, for a full record of his scholastic life, *see* his *Memories of Yale Life and Men, 1845–1899* (1903) (Ln. H.; X)

DWIGHT, JOHN (d. 1703), the first distinguished English potter, was born about 1637. He took the degree of bachelor of civil law at Christ Church, Oxford, in 1661 and was appointed in that year registrar and scribe to the diocese of Chester. In 1665 he moved to Wigan and at some time between 1671 and 1674 to Fulham. London, where he worked until his death in 1703.

In 1671 Dwight took out his first patent for making "transparent earthenware, commonly knowne by the names of porcelaine or china" and "stoneware, vulgarly called Cologne ware." Between 1693 and 1696 he was involved in lawsuits with 19 other potters, over infringements of his stoneware patent.

Dwight's most important wares are a series of finely modeled stoneware busts and statues, including busts of Prince Rupert of the Rhine and Charles II, a recumbent half figure of his daughter, Lydia, and various classical figures. The modeler of these works is unknown. Useful wares attributed to Dwight's pottery include rough stoneware bottles similar to contemporary Rhenish *bellarmines,* thinly potted stoneware mugs, gray stoneware bottles decorated with marbled bands and applied reliefs and red stoneware mugs with similar applied decoration. Dwight did not make porcelain and the partly translucent nature of some of his stoneware must have led him to mistake it for that material. The Fulham pottery remained in the hands of Dwight's descendants until 1862.

DYCE, ALEXANDER (1798–1869), Scottish editor of Shakespeare and other Elizabethan dramatists, was born in Edinburgh on June 30, 1798. As an Oxford undergraduate he edited S. Jarvis' *Dictionary of the language of Shakespeare* and. after serving as a curate in Cornwall and Suffolk. settled in London and devoted himself to literature. In addition to completing William

Gifford's *James Shirley* (1833) and revising his *John Ford* (1869), he edited the works of George Peele. John Webster, Robert Greene, Thomas Middleton. Beaumont and Fletcher and Marlowe. These editions consolidated interest in Shakespeare's contemporaries aroused by Charles Lamb's *Specimens of English Dramatic Poets* (1808). Dyce's edition of Shakespeare (pub. 1857; rev 1864–67) was supplemented by *Remarks on Mr. J. P. Collier's and Mr. Charles Knight's Editions of Shakespeare* (1844), *A few notes on Shakespeare* (1853) and *Strictures on Mr. Collier's New Edition of Shakespeare* (1859), each work characterized by scrupulous care and integrity.

An industrious editor of the poets, Dyce published many 17th- and 18th-century works, "specimens" of *Poetesses* and *Sonnets* and, most important, an edition of John Skelton (1843) which revived interest in this 16th-century poet. A founder of the Percy society (1840), he also published works for the Camden and Shakespeare societies. He died in London on May 15, 1869. (G. A O)

DYCE, WILLIAM (1806–1864), Scottish painter and pioneer of state art education, mas born at Aberdeen on Sept. 19, 1806. At 16 he graduated M.A. of Marischal college, Aberdeen, but later studied at the Royal Scottish academy, Edinburgh. and the Royal Academy schools, London. One of the first British students of early Italian painting, he visited Italy in 1825 and 182 7–28, meeting in Rome the German Nazarene (Pre-Raphaelite) painters. He exhibited regularly at the Royal Academy, being elected associate of the Royal Academy in 1844 and academician in 1848. In 1830–37 in Edinburgh he practised portraiture for a livelihood, using a direct technique traceable to that of Sir Henry Raeburn. But his Italian studies led him, anticipating the English pre-Raphaelites, to a primitivist simplicity and repose in his painting. Impressed also with the importance of a basic relationship between painting and architecture and design. he became deeply interested in art education. In 1840 he was appointed secretary and director of the new government school of design at Somerset house London. Although he largely failed to influence manufacturers' patterns, his training of teachers of design was important.

Successful in the houses of parliament fresco competition (1844), he painted the "Baptism of Ethelbert" in the house of lords (1846) and the "King Arthur" series (1848 ff.; unfinished) in the queen's robing room. For the prince consort he undertook frescoes at Osborne (the "Neptune") and in the Buckingham palace summerhouse; he decorated the church of All Saints. Margaret street, London, to the specification of the Anglo-Catholic Cambridge Camden society, in a more consciously primitivist style (1858–59). Typical of his early portraits is the child study "Contentment" (Maconochie Welwood collection; R.A. 1832); later easel pictures include "Pegwell Bay" (National gallery, London; R.A. 1860) and "George Herbert" (Guildhall, London; R.A 1861) Dyce died at Streatham, Surrey, Feb. 14, 1864.

DYCK, SIR ANTHONY VAN: *see* VAN DYCK, SIR ANTHONY.

DYER, SIR EDWARD (1543–1607), English courtier and poet whose reputation rests on a small number of certainly ascribed lyrics of great dexterity and sweetness, was born at Weston, Somerset. in Oct. 1543. Educated at Oxford, he went to court under the patronage of the earl of Leicester, was a friend of Sir Philip Sidney on whose death he wrote an elegy showing personal grief and a typical morbid melancholy, was employed on missions to the Netherlands (1584) and Denmark (1596) and was knighted in 1596. He died in London in May 1607. His contemporary reputation as a poet was high, but little of his work, published anonymously or under initials in collections, is certainly identifiable. His handling of metre and language, his tendency to antithesis and his power to convey a personal mood in memorable words are exemplified in his best-known poem "My mind to me a kingdom is."

See R. M. Sargent, *At the Court of Queen Elizabeth: the Life and Lyrics of Sir Edward Dyer (1935)* which corrects numerous errors in earlier accounts of his life and includes his poems, with notes on their ascription.

DYER, SIR JAMES (1512–1582), English judge who began the modern system of case reporting, was born at Roundhill in Somersetshire. He studied at Oxford, according to tradition at Broadgates hall (where Pembroke college now stands), but took no degree He was called to the bar by the Middle Temple at some time before the year 1537, when his name first appears on his own reports. He was elected to parliament for Cambridgeshire in 1547 and became a sergeant-at-law and was knighted in 1552. In 1553 he was chosen speaker of the house of commons. He took part, as one of the counsel for the prosecution, in the trial of Sir Nicholas Throckmorton in 1554 on charges of complicity in the Wyatt rebellion; and two years later was made a judge in the court of the common pleas. From 1559 until his death in 1582 he presided over that court as chief justice. He died at Great Staughton, Huntingdonshire, on March 24. 1582.

Dyer acquired a great reputation as a judge for both integrity and learning. His case reports begin at 4 Henry VIII and end in the year of his death. They were written in law French and were first translated into English by John Vaillant of the Inner Temple (1794). (R. G. M. B.)

DYER, JOHN (1699–1757), British poet, born in 1699 and baptized on Aug. 13 at Aberglasney. Camarthenshire, is chiefly remembered for "Grongar Hill," a short descriptive and meditative poem in the tradition of Sir John Denham's *Coopers Hill* and Alexander Pope's *Windsor-Forest.* The poet describes the view from a hill overlooking the vale of Towy and uses this as a starting point for meditation on the human lot:

> A little rule, a little sway,
> A sunbeam in a winter's day,
> Is all the proud and mighty have
> Between the cradle and the grave.

The description owes much to Dyer's studies as a painter, and to a considerable extent portrays the countryside in terms of classical landscape. *The Ruins of Rome* (1740) again combines both description and meditation. Dyer's longest work is *The Fleece* (1757), a blank verse poem in four books on the tending of sheep. It is one of the many 18th-century attempts to imitate Vergil's *Georgics* in English verse. The interest of the poem lies partly in perceiving the skillfulness of the imitation and partly in seeing how Dyer elevates an essentially unpoetic subject by his choice of language and turn of euphemism. Dyer died in Coningsby. Lincolnshire, in 1757, and was buried on Dec. 1j. (JN. C.)

DYER, REGINALD EDWARD HARRY (1864–1927), British general, remembered for his severe handling of the riots at Amritsar, India, in 1919. was born at Murree, in the Punjab, on Oct. 9, 1864, the son of a brewer, and educated at Middleton college, County Cork. He joined the army in 1885. and served in the Burma campaign in 1886–87, in the Waziristan blockade in 1901–02 and against the raiding Sarhad tribesmen during World War I. He was brigade commander at Jullundur when, in April 1919. serious rioting broke out in parts of the Punjab. *(See* INDIA: *History.)* Martial law was proclaimed and Dyer hurried to Amritsar. where mobs had killed Europeans and beaten and left for dead Miss M. Sherwood, a missionary. All meetings were prohibited. When a large meeting was held in the Jallianwalla Bagh. an enclosed space, Dyer went there with a small force and opened fire without warning. He used 1,650 rounds, killing 379 people and mounding probably three times as many more. He also took other severe measures, including the '(crawling order" that Indians passing along the lane in which Miss Sherwood had been beaten must go on hands and knees. A committee was appointed in 1919, under Lord Hunter. to investigate these matters, and criticized Dyer for opening fire without first ordering the crowd to disperse and for continuing to fire even when the crowd tried to disperse. Dyer's claim that he had intended to produce a "moral effect" throughout the Punjab was condemned by the committee as also was the "crawling order."

Sir Michael O'Dwyer, the lieutenant governor, thought that Dyer's severity had averted a general revolt in the Punjab. How-

ever, it alienated many Indians who had been otherwise well disposed to British rule, and was seized upon as a weapon by the Congress party. Dyer was removed from his command and returned to England. There was some feeling that he had been victimized, some expressions of sympathy were voiced in parliament and subscriptions were raised for a fund on his behalf. This further alienated opinion in India. He died on July 23, 1927, at Long Ashton, Bristol. It was later suggested that Dyer, not realizing the crowd had no exit, had feared that they were about to rush him, and that his subsequent evidence that his severity had been deliberate was mere bravado.

DYES. Dyes are colour-producing substances, either natural or synthetic, that can be permanently attached to or incorporated into fibres, fabrics or similar materials. Such substances differ from stains by being fast to light, water and cleaning agents. The affinity between fibre and colouring matter depends upon the physical and chemical properties of both. Fibres behave very differently toward a solution of any given colouring matter, and the method of dyeing employed varies with each fibre. As a general rule wool has the greatest attraction for dyes, silk is more difficult to dye, cotton has still less attraction and man-made fibres are the hardest of all to dye.

Dyes can be classified in at least four groups, according to (1) the material on which they are used; (2) the method of application; (3) chemical structure; or (4) whether they are natural or synthetic. This article uses the fourth basis for classification.

NATURAL DYES

Natural dyes, *i.e.,* those of plant or animal origin, have been known and used for thousands of years although in the last 100 years they have been replaced almost completely by the cheaper and superior synthetic dyes.

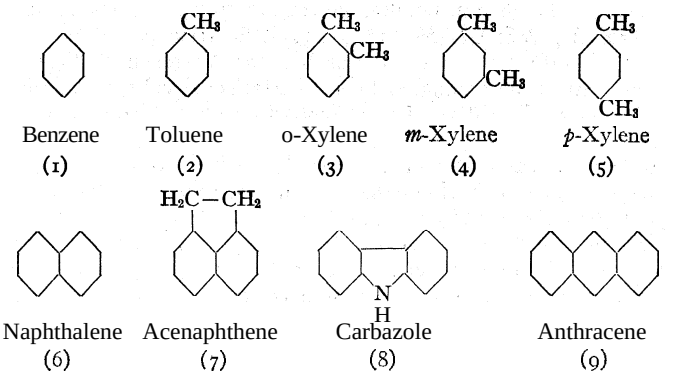
The utilization of plant products for dyeing is of ancient origin and probably at first consisted in the staining of material with the coloured juices of fruits, flowers and the like. Certain of these effects resisted the washing process since a true fixation of colour occurred; but few substantive dyestuffs exist in nature, the variety of shade they yield is limited and their effects in the main are not permanent in sunlight. It was early observed that the juice of the indigo plant leaf develops a blue colour and that the sea snail *Murex,* when crushed and exposed to light, acquires a purple tint.

The antiquity of the use of indigo (*q.v.*) is evident from the discovery at Thebes of an indigo-dyed garment dating from about 3000 B.C., while the words "blue" and "purple" occurring in Ex. xxv, 4 and xxxv, 25 can hardly refer to colours other than indigo and Murex purple. The latter, also known as "Tyrian" or "royal" purple, was of much importance, and the city of Tyre, where, according to legend, it was discovered, became famous for its production. The scriptural quotation "clothed in purple and fine linen" refers not only to this dyestuff but also to its expensive character. (*See* PURPLE.) It was only as the result of the discovery of the art of mordanting, however, which occurred (probably in India) not later than 2000 B.C., that the practice of dyeing really advanced, for as a result many natural colouring matters otherwise useless could be applied to fabrics. Thus, the biblical scarlet without doubt refers to the colour given by kermes on alum-mordanted material, whereas both madder and the lac dye of India give red only to fabrics that have been similarly treated. Early references to mordant yellow dyestuffs are meagre, although saffron was known to both Egyptians and Greeks, and there is evidence that the Egyptians used the yellow colouring matter of safflower as a dye or stain for mummy cloths. Alizarin (*q.v.*), which occurs in the root of the madder plant, was known to the ancient Egyptians and Persians. Other natural dyes include fustic, logwood (*q.v.*) and cochineal (*q.v.*). (X.)

SYNTHETIC DYES

Synthetic, or coal-tar, dyestuffs, known also as aniline dyes, are like the dyestuffs of natural origin in that they are complex compounds of carbon, hydrogen and oxygen. By far the greater number also contain nitrogen and sulfur; the metallic elements chromium, copper and zinc are present in a few. Invariably, too, they are derived from compounds belonging to the aromatic class of organic chemical compounds; *e.g.,* benzene, toluene, the three xylenes, naphthalene, acenaphthene, anthracene and carbazole.

Coal-tar dyestuffs do not exist as such in coal tar but are made from these nine primary substances, which do occur as such in coal tar or are formed along with the tar in the coking of coal. The first five—benzene, toluene and the xylenes—are water-white liquids at ordinary temperatures; the last four are white solids. All are characterized chemically by the presence of the benzene ring, and the last six may be regarded as simple or complex derivatives of benzene in which hydrogen atoms have been replaced by radicals consisting primarily of carbon and hydrogen.



Raw Materials.— In the destructive distillation of coal for the production of coke or gas, many organic chemical reactions occur and form a wide variety of organic chemical compounds. The products distilling from the coke or gas retorts are fractionally condensed; that is, the more complex compounds with the higher boiling points are liquefied first from the gas stream, then the middle cuts (compounds with intermediate boiling pointsj are condensed and finally the lighter oils with the lowest boiling points are obtained.

The first fraction condensed is coal tar. It contains little or no benzene, toluene or xylene; these materials comprise the bulk of the lighter oils. But it does contain the anthracene, carbazole and acenaphthene and a part of the naphthalene formed in the coking process. To separate its valuable constituents, coal tar is fractionally distilled in great retorts holding 20–30 tons. Among the products taken off from the lower fractions are naphthalene and acenaphthene; anthracene and carbazole are obtained from the highest fractions. The residue left in the retorts is pitch, which is used either for the manufacture of roofing materials or in road construction.

In the United States, coal-tar distillers as a rule do not carry the distillation as far as it is taken in Europe. The anthracene and carhazole fractions are left in the pitch. The latter then is softer and more pliable and therefore more useful in road construction. The anthracene derivatives required for dyestuff manufacture are made synthetically from phthalic anhydride, which in turn is made from naphthalene.

Naphthalene and acenaphthene are present also in the middle cuts from the coke retorts. These cuts are likewise fractionally distilled for the separation of their valuable constituents. Finally, the lighter oils are fractionated for the separation of benzene, toluene and a mixture of the xylenes.

The nine raw materials obtained in a crude state by the processes outlined are refined for usage in the organic chemical industry (1) by fractional distillation; (2) by hot pressing; (3) by washing or crystallization; and (4) by sublimation. Hot pressing consists of applying pressure to a mixture of solids and oils at an elevated temperature, the lower-boiling oils being thus squeezed out. This process is applied particularly to naphthalene. Washing consists of thoroughly mixing the material to be purified with a solvent, whereby undesired compounds are dissolved. The mixture is

then filtered either at ordinary or at elevated temperatures. This process is applied primarily in the purification of anthracene.

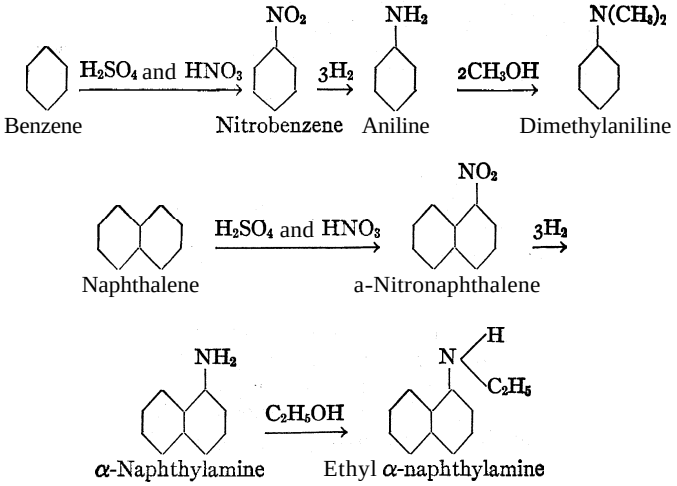
Intermediates. — From the nine basic raw materials. properly refined, literally thousands of products, termed intermediates in the dyestuff industry, can be manufactured. In their production. many products of the heavy chemical industry, such as sulfuric, nitric and hydrochloric acids, caustic soda and caustic potash, sodium carbonate, ammonia and chlorine. must also be used.

For the manufacture of by far the greater number of these intermediates, a few relatively simple chemical reactions, termed "basic intermediate processes" by the dyestuff chemist, are used. Any process of this type consists in the application of a chemical reaction of a particular type to any one of a number of different materials. For example, benzene, toluene, xylene and naphthalene are nitrated; *i.e.*, subjected to the action of nitric acid. Nitration then is a "basic intermediate process" and, in the case of the dyestuff industry, the most common one.

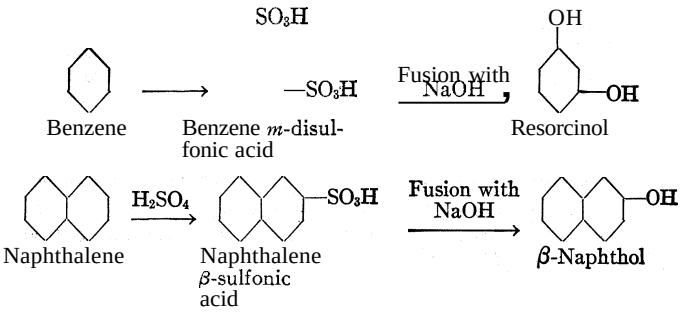
Other widely used processes include reduction, sulfonation, chlorination, oxidation, hydrolysis by fusion with caustic soda (sodium hydroxide) or potash (potassium hydroxide), alkylation and amidation.

A few examples (I–VII) will illustrate the enormous diversity of intermediates that can be made from the nine basic raw materials.

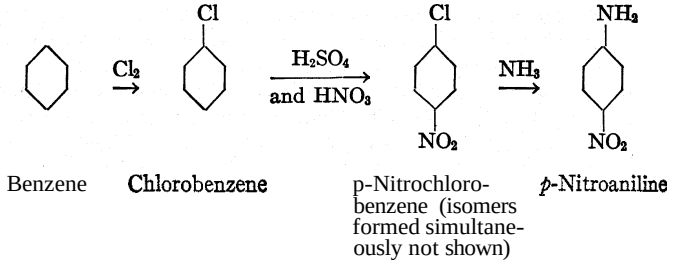
(I) Nitration, reduction and alkylation



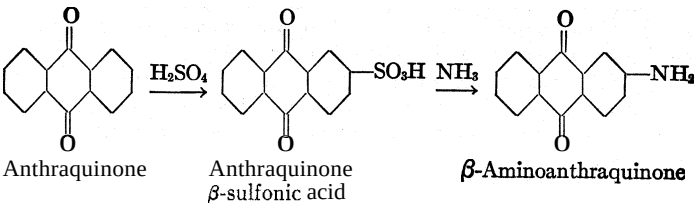
(II) Sulfonation and fusion



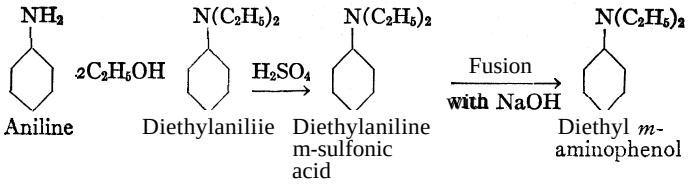
(III) Chlorination, nitration and amidation



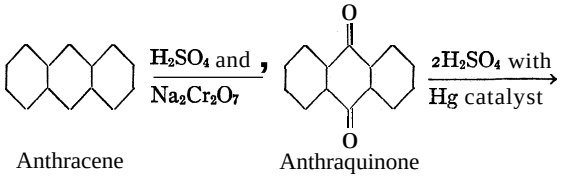
(IV) Sulfonation and amidation

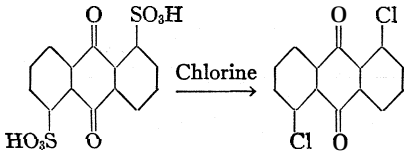


(V) Alkylation, sulfonation and fusion

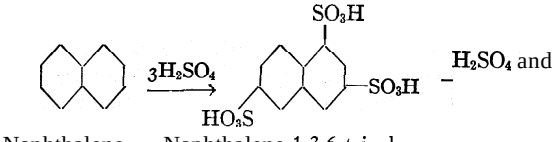


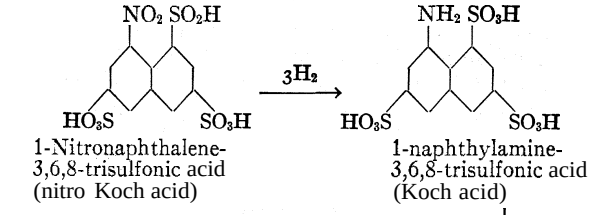
(VI) Oxidation, sulfonation and chlorination

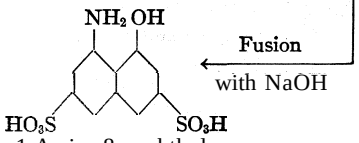




(VII) Sulfonation, nitration, reduction and fusion



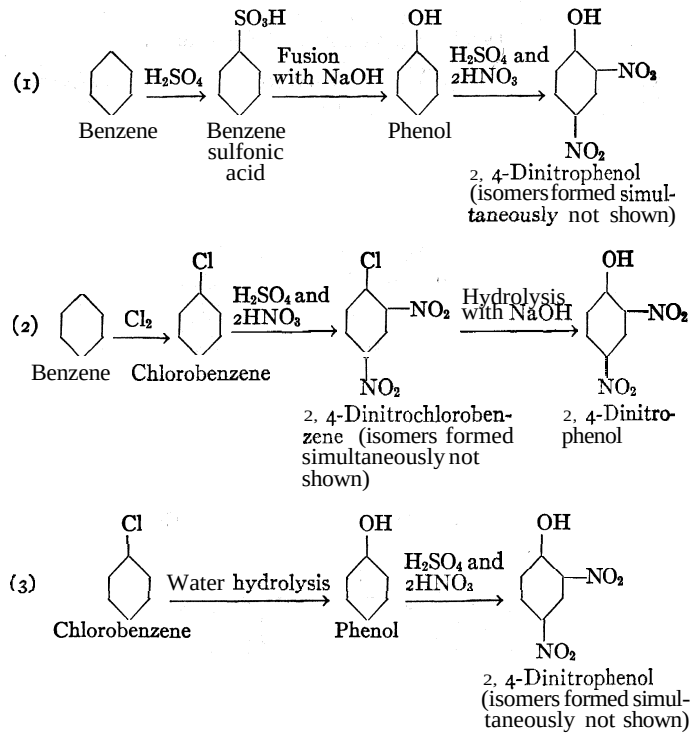




In commercial practice, the intermediates shown in the examples (I–VII) are not necessarily made in the designated manner; it is possible in many cases to make a given product over two, or even three and four routes. Here chemical economics comes into play. Frequently, because of the phenomenon of isomerism (*q.v.*), valuable by-products are formed, and what is an economical process for one manufacturer may be an uneconomical process for

another. Indeed, in the dyestuff industry a by-product sometimes becomes the main product when new and important uses are found for it. Sometimes, too, a new and improved route may be discovered by one manufacturer and patented.

A single example having to do with the manufacture of a very important dyestuff. sulfur black, will illustrate this choice of routes. The most important intermediate in general use for the manufacture of this dye is 2.4-dinitrophenol. It can be made from benzene in three ways:



Isomerism plays an extremely important role in the manufacture of dyestuffs and often determines the route over which an intermediate is made. The very important compound 1,5-diaminoanthraquinone, for example. can be made either by dinitrating anthraquinone, separating the 1,5- and the 1.8-isomers and then reducing the 1,5-*dinitro* compound to the corresponding diamine; or by disulfonating anthraquinone. separating the 1,5- and the 1.8-isomers and then subjecting the 1,5-disulfonic acid to the action of aqueous ammonia at high temperatures and pressures. In the first case, the by-product 1,8-dinitroanthraquinone possesses little utility. whereas in the second, the 1,8-disulfonic acid can be used much more advantageously.

Sometimes the purity of an intermediate when made over two routes determines the process used for the manufacture of the product. It is very difficult, for example, to obtain a-naphthol of high quality by sulfonating naphthalene and then fusing the sulfonic acid with caustic. On the other hand, a relatively pure material can readily be made by the hydrolysis of a-naphthylamine with acid. All this follows from the fact that it is much easier to obtain pure a-nitronaphthalene than it is to obtain pure naphthalene a-sulfonic acid.

Basic intermediate processes can be applied not only to the nine raw materials of the dyestuffs industry but also to many products derived from these raw materials. For example, the nitrotoluenes may be chlorinated; or the naphthylamines sulfonated. Here, too, isomeric products are formed and separated. Great difficulty is occasionally encountered in the separation of these highly substituted isomeric products because of the similarity of their chemical and physical properties.

From a consideration of the use of nine basic raw materials, of the application of at least ten important basic intermediate processes and of the phenomenon of isomerism, it can be seen why the number of intermediates that can be made runs into the thousands. On the other hand, it is estimated that 90% of the tonnage of synthetic dyestuffs made in the world is derived from less than 200 intermediates.

A so-called "specialty dyestuff," sold in limited quantities for one particular usage. may require one or more intermediates of use for no other organic chemical product.

Nomenclature. — Almost every manufacturer of dyestuffs produces, as at least part of its line. exactly the same substances that are made by competitive firms. There is no difference chemically between the dyestuff called eosin when made in Italy. England. Germany or the United States. The same may be said for a wide variety of dyes. each of which has become, following its discovery and introduction. a standard article of commerce. Both process and product patents expire after a given number of years, and any manufacturer is then free to produce a dyestuff on which another firm previously held a monopoly.

The nomenclature employed in the dyestuffs industry follows from these facts. When the chemical compound benzene-meta-diazo-his-metaphenylenediamine dihydrochloride was discovered in 1863 and manufactured as a dyestuff, it was sold under the simple name of Bismarck brown. Its success was instantaneous. In time it was manufactured by no less than 21 firms and in almost all cases under the name Bismarck brown. When the chemical compound tetraethyldiamino-orthocarboxy-phenyl-xanthenyl chloride was first manufactured in 1887, it was sold under the name rhodamine B. In time, 12 other manufacturers made the product and 11 of them sold it under the name of rhodamine B. When a closely related chemical compound, diethyldiamino-orthocarbethoxy-phenyl-xanthenyl chloride, was first made in 1892 and found to dye textile fabrics in much yellower shades of red than rhodamine B, it was marketed under the name of rhodamine 6G. In time 11 manufacturers made the product, and 7 of them sold it under the name of rhodamine 6G.

In general, it may be said that synthetic dyestuffs are so complicated structurally that it would be impossible to market them under their chemical names. It is for this reason that names such as eosin, Bismarck brown and rhodamine are invented Sometimes such names are trade-marked by the original manufacturers; and, since trade-marks as a rule run much longer than patents, it is necessary on occasions for other producers to invent new names for a particular dyestuff or line of dyestuffs.

Usually, the trade names given to dyestuffs designate all characteristics of the products that can be gathered into a single catchy word. Thus. the name Indanthrene is derived by combining "ind" of indigo, designating a vat colouring matter, and "anthrene" from anthracene — the whole name thus implying a vat dyestuff from anthracene. But occasionally names that have little or nothing to do with dyestuff characteristics are chosen. In these cases, however, the names are suggestive: sirius yellow G, orion blue 2B, nigrosine B, pluto black BL, malachite green, etc.

Early in their development of the industry, the Germans invented a system of nomenclature whereby the approximate shade of a dyestuff could be designated, letters being added to its name to indicate variations in shade. Most common of these letters were G for *grün* (green), B for blau (blue) and R for rot (red). If the product gave a green shade of blue on dyeing, it was designated as blue G, and, as it gave progressively greener dyeings, as blue 2G, blue 4G or even blue 6G, the latter being a very greenish blue. If, on the other hand, the shade of the blue dyeings tended to purple, the letter R was suffixed, as in blue R, blue 2R and blue 3R, etc. The system proved to be helpful to the industry and has been generally adopted.

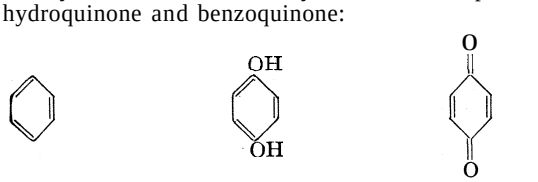
Theoretical. — Intermediates used in the manufacture of dyestuffs derived from benzene, toluene, the xylenes, naphthalene. acenaphthene and carbazole are in general white or colourless substances. Intermediates from anthracene are coloured, and here in a few cases a product may be both an intermediate and a dyestuff. The compound 1,4-diaminoanthraquinone, for example, is an excellent product for colouring gasoline in violet shades, a usable material for dyeing cellulose acetate in bluish-red shades and at the same time an intermediate for several extremely important anthraquinone vat dyestuffs. Thus, with the introduction of man-made fibres and with the wide employment of colour-

ing matters in the modern world, the line of demarcation between an intermediate and a dyestuff cannot be so sharply drawn as it was prior to World War I.

Early in the development of the industry it was found that many synthetic dyestuffsknown at the time lost their colour when treated with a reducing agent (*e.g.*, with hydrogen). The resulting colourless bodies. known as leuco dyes or leuco bases, contained a larger percentage of hydrogen than the dyestuffs and could be converted into the latter by reversal of the process; *i.e.*, by oxidation. In the years from 1865 to 1910 much work was done by dyestuff chemists. particularly in Germany and Switzerland, to clear up the problem of why one compound is coloured, whereas a very near relative is colourless, 0. N. Witt, A. Hantzsch and R. Nietzki being the leaders in this work.

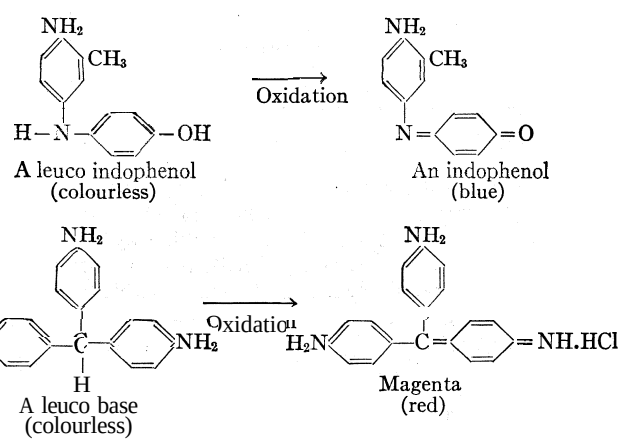
As early as 1876 Witt propounded a theory of colour that has been strengthened with the discovery in subsequent years of many new classes of compounds useful for dyeing. Witt assumed that colour is dependent upon the presence of groups of atoms, held together by valence bonds in certain specified ways, in the organic chemical molecule He termed the colour-giving group the chromophore, and the compound containing it was chromogen. The chromogens of themselves are not dyestuffs, Witt argued: dyes are formed only by the introduction into the molecule of one or more additional groups of atoms, either acidic or basic, that are capable of salt-forming properties. In time, certain of these groups came to be known as auxochromes, the most common ones being NH_2, $N(CH_3)_2$ and OH. Auxochromes intensify colour and fix the dye to the material being dyed.

Witt's theory can be illustrated by the relationship between benzene, hydroquinone and benzoquinone:

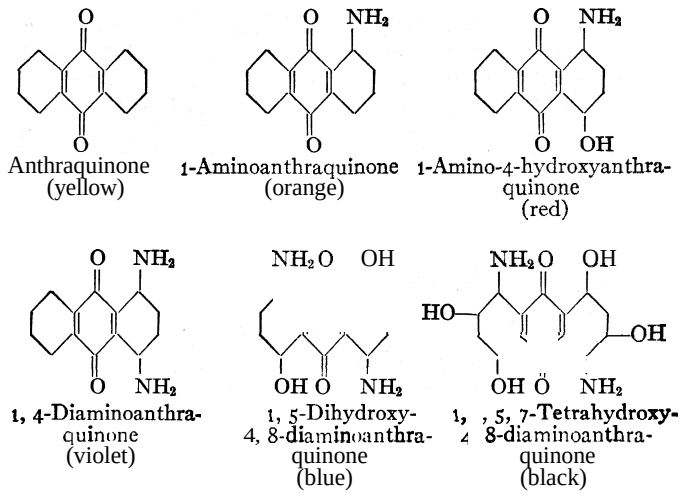


Benzene (water-white liquid) — Hydroquinone (white solid) — Benzoquinone (yellow solid)

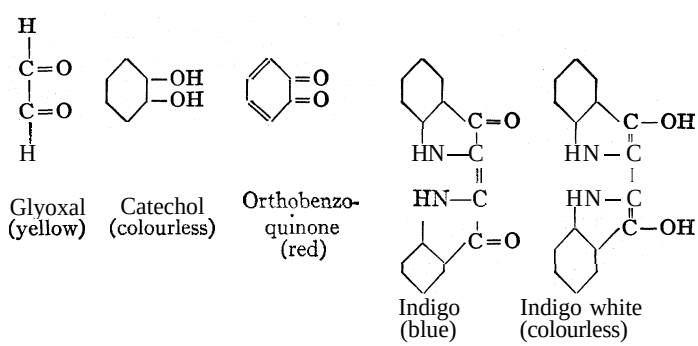
The first two of these substances are assigned structures with alternating double and single bonds in the ring, whereas benzoquinone is assigned the paraquinoid structure in order that the valencies of the carbon atoms to which the oxygen atoms are attached may be satisfied. Thus, by the shifting of bonds, colour is produced. The paraquinoid structure is therefore the chromophore, and all compounds containing this grouping should be coloured, according to Witt's assumption. Such is generally the case, although a few exceptions have been noted. Some further similar examples are given below:



In the given examples, the indophenol that is blue in colour is not a dyestuff, whereas magenta, red in colour, is a dyestuff. This seeming contradiction follows from the fact that many coloured compounds are not useful as dyestuffs, since they may not have affinity for fibres of various sorts, or since they may have poor fastness properties when dissolved in an organic solvent to colour it. The indophenol cited has little or no affinity for natural or man-made fibres. On the other hand, it could be used to colour gasoline but the colour would be entirely too fugitive for commercial usage. The effect of auxochromes in modifying the colour of a compound with the paraquinoid chromophore can be illustrated by the example of anthraquinone and such of its derivatives as are listed below:

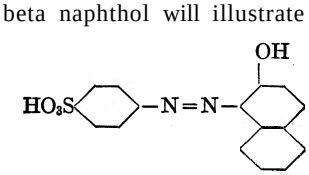


Although the paraquinoid chromophore is the most common one in the dyestuff industry, several other important types are also recognized. One of these is the indigoid, which occurs in indigo and in a large number of further dyes of closely related structure. The orthoquinoid chromophore characteristic of o-benzoquinone is similar to the indigoid but is much less important since it occurs in only a few dyestuffs of commercial importance. Moreover, some compounds of the aliphatic series containing the grouping O=C—C= characteristic of both the indigoids and orthoquinoids are also coloured, the relationship being shown in the following examples:



It will be noted that when the O=C—C= grouping is changed into HO—C=C, the product is no longer coloured.

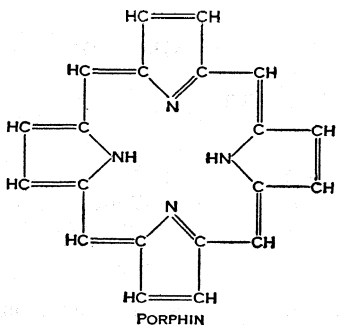
Only one other grouping is of extreme importance in the dyestuff industry. It is responsible for colour in a large series of compounds made by the diazo reaction, and it can be expressed as R—N=N—R, where R stands for substituted hydrocarbon radicals of the benzene, toluene, xylene and naphthalene series, the most common substituent groups being NH_2, OH, SO_3H and COOH. An example of a simple azo dyestuff made from sulfanilic acid and beta naphthol will illustrate the chromophore:



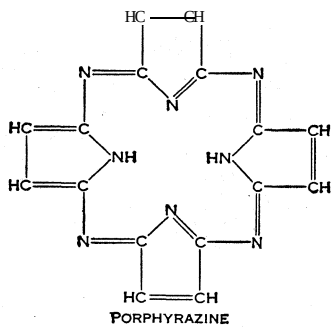
Orange II

In the given example, the function of auxochromic groups is

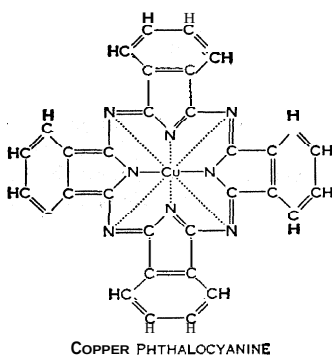
illustrated in two directions. First, diazo compounds will not react with hydrocarbons of the benzene series themselves to yield dyestuffs; substituent groups such as $-NH_2$ and $-OH$ must be present if dyestuffs are to be produced. Second, the group SO_3H is not necessarily an auxochromic group. In orange II it merely imparts water-solubility to the product. If aniline is substituted for sulfanilic acid, an oil-soluble dyestuff, made and sold as such, results. It was not until the fourth decade of the 20th century that coal-tar derivatives based on the chromophore present in the natural colouring matters of the chlorophyll and hemin classes were manufactured and sold commercially as dyestuffs and pigments. All of them belong to the phthalocyanine class and contain the porphyrazine chromophore, porphin being the parent structure present in the above-mentioned natural products. The most important dyestuff of the group is copper phthalocyanine. The relationship is shown in the following structures:



PORPHIN



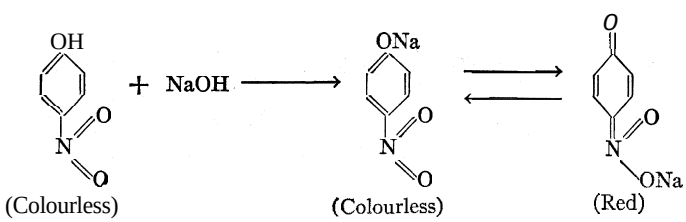
PORPHYRAZINE



COPPER PHTHALOCYANINE

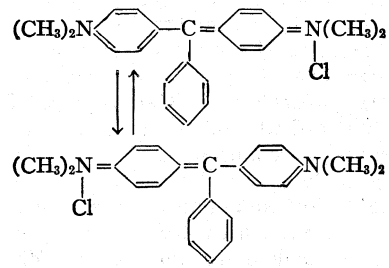
Witt's theory of colour has been more fully explained in the 20th century by applying to it other and newer theories of organic chemistry, particularly those having to do with ionization and with the role of the electron in valency. Although a complete description of these newer theories would lie outside the scope of this article, a brief discussion of the manner in which they regard the paraquinoid chromophore may be given here.

As may be seen from a consideration of the examples mentioned above, paraquinoid compounds result in general from the oxidation of substances with structures of a certain type. As has been noted, these latter substances are termed leuco compounds or leuco bases in the dyestuff industry, and up until the decade 1900–10 they and their oxidation products (the dyestuffs) were considered to be made up of molecules to which unique structures could be assigned. But in the first decade of the 20th century Hantzsch introduced the concept of tautomerism into the theory; thus, he explained the change of colour that takes place upon the conversion of paranitrophenol into its sodium salt by assuming that two forms of the phenol exist in equilibrium with each other, the one nonquinoid, colourless and a very weak acid, the other one quinoid, red in colour and a very strong acid. Upon the addition of alkali, Hantzsch argued, salts of the strong acid are formed almost exclusively; such quinoid salts he assumed to be red. On reversal of the process by the addition of acids, the equilibrium again shifts back and the colourless nonquinoid form of the free nitrophenol predominates.



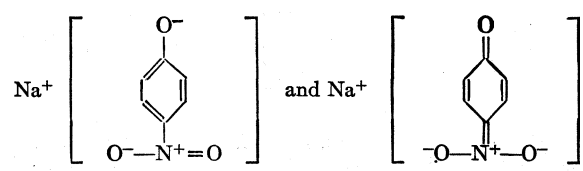
(Colourless) (Colourless) (Red)

A rather different theory, which, however, likewise admitted the possibility of variable structure. was advanced in 1907 by A, von Baeyer, who suggested that the colour of a dyestuff such as malachite green is caused by the oscillation of an anion from one end of the molecule to the other. The type of oscillation thus proposed for malachite green is illustrated by the equation

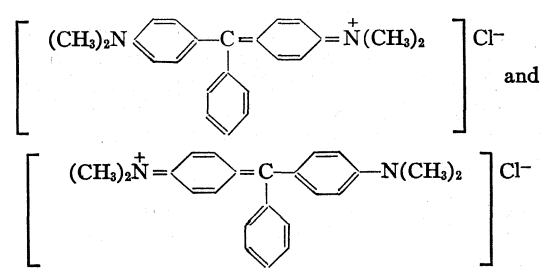


It will be noted that each of these two structures contains one quinoid ring.

The theories of Hantzsch and of Baeyer suffered from the fact that, at the time at which they were proposed, the distinction between covalent and electrovalent bonds was not fully realized. Somewhat later, however, in 1914, E. Q. Adams and L. Rosenstein advanced the theory that, since the observed colours of substances of the present type might be properties of their ions and not of any postulated unionized molecules, the transitions among the structures in question involve only redistributions of valence bonds and of electric charges. and do not require the movement of any atoms or ions. Thus, with the sodium salt of paranitrophenol, the two structures proposed by Hantzsch might be replaced by the two corresponding ones



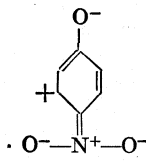
If the theory of Adams and Rosenstein is correct, there is no necessity to postulate, with Hantzsch, the existence of an un-ionized red quinoid form. Similarly, with malachite green, the two structures proposed by Baeyer might be replaced by



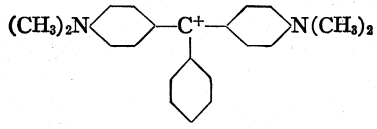
In these two cases, the sodium and chloride ions are considered to have nothing directly to do with the production of colour. Adams and Rosenstein, moreover, suggested that the colours of ions like the ones under discussion are caused by rapid oscillations of the ionic charges back and forth between the extreme positions characteristic of the various structures. In this way, they were able to avoid the necessity of assuming, with Baeyer, that a relatively heavy, and hence relatively immobile, anion is able to vibrate with the extremely high frequency necessary to account for the absorption of visible light.

Further contributions to the theory of colour were made by J. Stieglitz (1924), who employed more or less the same approach as Adams and Rosenstein. The modern period may be said, however, to have started in the 1930s with the development of the theory of resonance. According to this theory, the actual distribution of electric charge in any molecule or ion is always intermediate among the distributions characteristic of any given structure that may be written and of all the further structures that can be derived from the first by merely a redistribution of

valence bonds and electric charges. Thus, the actual distribution of charge in the anion of p-nitrophenol is considered to be some sort of average of the distributions not only in the two above structures but also in several further structures, such as

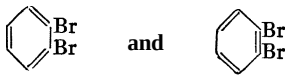


Similarly, the distribution of charge in the cation of malachite green is considered to be some sort of average of the distributions illustrated not only in the two above structures but also in several further structures, such as



It is a corollary of the theory that the so-called "resonance" among these various structures leads to increases in the wave lengths at which the absorption of light occurs. If these increases are sufficiently great, the absorption of light may come into the region of the visible spectrum, so that the substances are coloured.

There can be no doubt that some such phenomenon occurs in organic compounds. F. A. Kekulé, who postulated the ring structure for benzene, was forced to accept the concept of a shifting of valences, even in this substance, although he did not comprehend the nature of the shifting. He saw that if no such shifting occurred, two orthodibromobenzenes should exist.



However, only one form exists; at any rate, no second form has ever been isolated.

In this connection it is pertinent to note that 1,1-diphenylethylene, an unsubstituted hydrocarbon of the benzene series, and 2,4,6,8,10,12-tetradecene, a straight-chain compound of carbon and hydrogen, are coloured. The important thing in colour formation, therefore, seems to be the presence of a "conjugated" carbon chain; *i.e.*, a chain of alternating single and double bonds between the carbon atoms that constitute the skeleton of a compound. Such a skeleton, present in each of the compounds of carbon and hydrogen mentioned above, permits the phenomenon called resonance to such an extent that both substances absorb light in the visible ranges of the spectrum. Yet they are nonionic. Moreover, in some instances a coloured neutral molecule gives rise to a less deeply coloured, or even colourless, ion. For example, the intense yellow colour of a solution of p-nitrodimethylaniline in aqueous alcohol is largely discharged by the addition of hydrochloric acid; thus, the *p*-nitrodimethylanilinium ion must be

p-Nitrodimethylaniline (yellow) — *p*-Nitrodimethylanilinium ion (colourless)

colourless, or nearly so. It cannot therefore be concluded that resonance, and hence colour, are properties of only ions, since actually resonance is considered always to occur both in ions and in the corresponding neutral molecules. Most commonly, however (and, in particular, in all the foregoing examples), the data are in at least qualitative agreement with the supposition that the depth of the colour of a substance is increased by any structural change that permits a more effective resonance.

Although the presence of the chromophore and auxochrome groups in organic compounds used as dyestuffs increases the possibility of resonance and thus brings about selective absorption of light in the visible ranges of the spectrum, all colourless organic compounds, too, show this same selective absorption, but in the invisible ranges of the spectrum. In some cases such selective action is exceedingly strong and plainly apparent. Highly refined anthracene and chrysene, for example, pure white in colour. exhibit marked bluish fluorescence, which results from the selective absorption of ultraviolet light.

It has been noted that coloured compounds are not necessarily dyestuffs, and that a product may dye one material satisfactorily but not another. The problem of why various fibres absorb and hold certain coloured compounds designated as dyestuffs has never been completely solved. Both silk and wool contain basic and acidic groupings in their molecular structures, and the presence of such groups doubtless accounts for the fact that these materials are more readily dyed than cellulose fibres which contain only weakly acidic groupings. The vast majority of dyestuffs, too, contain basic or acidic groups in their molecular structures; many contain both.

Numerous theories have been advanced to account for the mechanism of dyeing, and it is clear that the process must be (1) purely physical adsorption; (2) actual chemical union; or **(3)** a combination of both. Theories advanced in the decade between 1935 and 1945 stressed hydrogen bonding and were based on relationships existing in the linear distances between reactive groups in fibre and dyestuff molecules. When these distances are approximately equal. the theory assumes, hydrogen bonding can occur; when grossly unequal. combination is impossible. This "molecular-space" conception of the dyeing mechanism agrees in many cases with observable facts and explains why a given organic compound may be utterly useless as a dyestuff for cotton or wool and yet be a very valuable colouring'matter for acetate or some other man-made fibre. But much work remains to be done before the theory can be generally accepted.

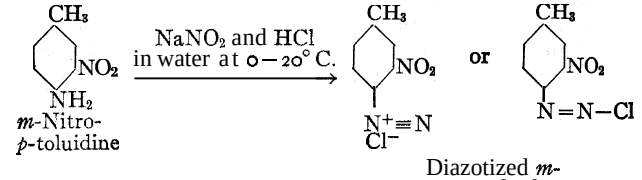
The fastness of a dyestuff on any fibre is, in general, directly proportional to the chemical stability of its molecule against destructive agents such as oxygen, light. heat and certain salt solutions, or combinations of these. Chemically, the azo compounds, for example, are relatively unstable as compared with the indigoids and anthraquinones. The latter are therefore, in general, the faster dyestuffs on textile fibres. Copper phthalocyanine is an extremely stable substance, withstanding heat up to 900° F. and resisting the action of oxidizing agents that would destroy other organic compounds. It is, therefore, an extremely fast colouring matter.

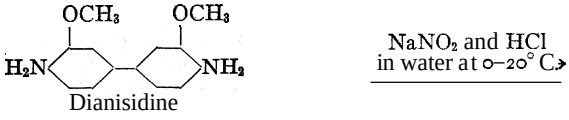
Processes for **Making** Dyestuffs. — Only a relatively few simple organic chemical processes are used to convert intermediates into dyestuffs. These processes, which may be termed "basic dyestuff processes," are applicable to a wide variety of intermediates. For example, each product in the large series of closely related compounds termed indophenols can be subjected to the action of sodium sulfide and sulfur, and a correspondingly large series of products, known as sulfur dyestuffs, can be thereby obtained. The process is commonly known as thionation. Other processes generally in use are diazotization, condensation, oxidation, esterification and halogenation.

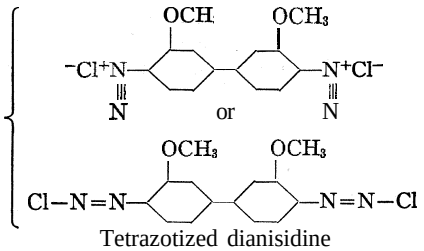
Of all these basic dyestuff processes, thionation is the only one that is not clearly understood by the dyestuff chemist; *i.e.*, the only one in which he does not know the exact nature of the products resulting from the application of the process. In this process, compounds composed of giant molecules, and incapable of being crystallized and thoroughly purified, are formed; in many cases mixed products are obtained. The process, which can be carried out with or without the use of a solvent, is applicable not only to indophenols but also to a wide variety of intermediates, and to another series of compounds termed azines.

Dzazotization consists in the treatment of an amine with nitrous acid, the latter generally being obtained, and the process being carried out, by the treatment of sodium nitrite with hydrochloric or sulfuric acid in the presence of the amine, which has been dissolved or dispersed in cold water. The resulting diazonium salts are relatively unstable (hence, the use of cold water) and extremely reactive. Some are relatively insoluble at temperatures at which the process is carried out, whereas others are very soluble. In some cases, one amino group per molecule is so transformed;

in other cases, two; in the latter event, the process is called tetrazotization. The following examples will illustrate the reaction. Two possible structures of the diazo and tetrazo compounds are shown, the latter one in each instance being analogous to the structure assigned to the dyestuffs that result from the subsequent condensation reaction *(see* below).







The dyestuff chemist generally writes the structures of the diazonium compounds as R—N≡N—Cl, for the structures of the azo dyestuffs made from these intermediates are doubtless R—N=N—R′, where R and R′ are residues of the benzene, toluene, xylene or naphthalene series containing one or more auxochrome groups. The alternative structure R—N≡N⁺—Cl⁻ is, however, generally considered to be the more nearly correct, and it is the one universally employed in the scientific, as distinguished from the technical, literature.

Condensation is the most widely diversified of the dyemaking processes, for many types of compounds will condense with other compounds or even nith themselves.

In some cases condensation occurs readily when two intermediates are stirred together in cold water; in others condensation requires drastic conditions of reaction, particularly of temperature. Frequently, condensing agents such as dehydrating materials and "acid acceptors" *(i.e.,* weak bases like sodium acetate) are required to facilitate the process; and, on occasion, catalysts must be used to bring about condensation. The following examples will not only illustrate these reactions but will also explain actual processes by which many dyestuffs are made from intermediate products:

The condensation process illustrated by (1) in the foregoing examples, and designated as coupling, is generally carried out at temperatures between 0° C. and 20° C., and under weakly acid or alkaline conditions. The time for the completion of the reaction may vary from one hour to five days, depending upon the reactivity of the diazo or tetrazo compounds and of the intermediates with which they are being coupled. The products are azo dyestuffs.

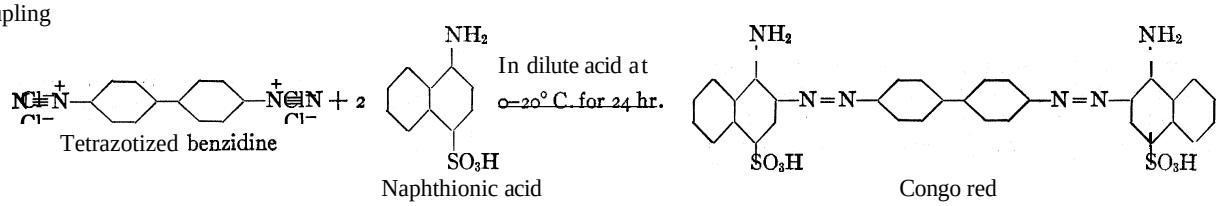
The fusion of benzanthrone to violanthrone, as illustrated by (2), is generally carried out under anhydrous conditions, and with the addition of a material to lower the melting point of the caustic potash. Anhydrous alcohol or aniline is used for this purpose.

In order that complete reaction may be obtained between resorcinol and phthalic anhydride as illustrated by (3), anhydrous zinc chloride must be used. The product obtained, fluorescein, is tinctorially among the most powerful of the coal-tar dyes, inasmuch as extremely low concentrations of its sodium salt exhibit intense yellow colour with a greenish fluorescence.

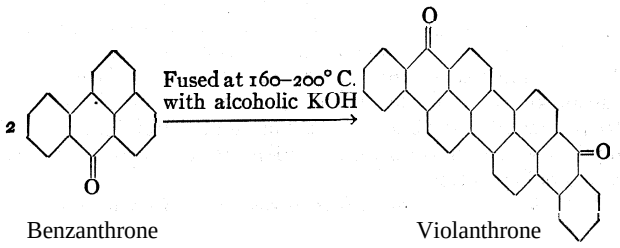
The process by which a chloroanthraquinone condenses with an aminoanthraquinone as illustrated by (4) was not discovered until 1903. The reaction. named for F. Ullmann, who discovered it. is best brought about by heating the intermediates together in a high-boiling solvent, such as dichlorobenzene or nitrobenzene, and in the presence of an acid acceptor and of a trace of copper or of one of its salts as a catalyst.

Oxidatzon is employed as part of the manufacture of a large group of dyestuffs whose parent compound is triphenylmethane H—C≡$(C_6H_5)_3$. By the condensation. for example, of one mole of benzaldehyde with two moles of dimethylaniline, the colourless compound tetramethyldiaminotriphenylmethane is formed. When this product is oxidized in acid solution to the corresponding carbinol, water is lost and the intensely green dyestuff malachite green is obtained The oxidation of the triphenylmethane compounds, generally termed leuco bases, is normally brought about by means of freshly prepared lead dioxide, PbO_2, but other oxidizing agents can be employed; in some cases atmospheric oxygen is sufficient.

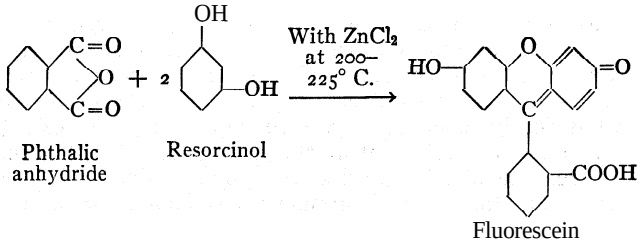
(1) Coupling



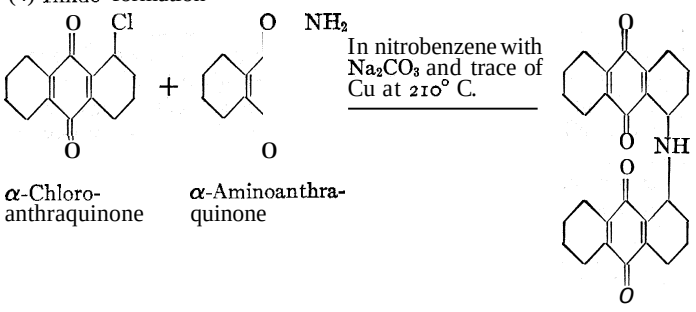
(2) **Fusion**



(3) Fusion with zinc chloride

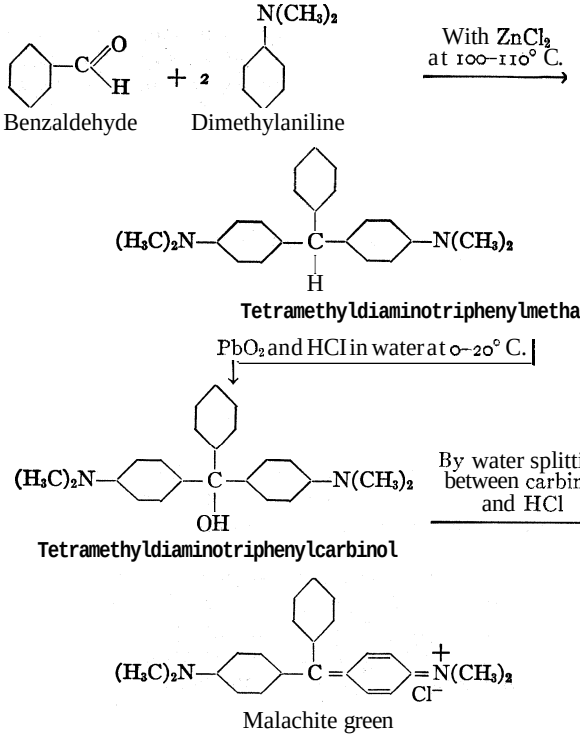


(4) Imide[1] formation



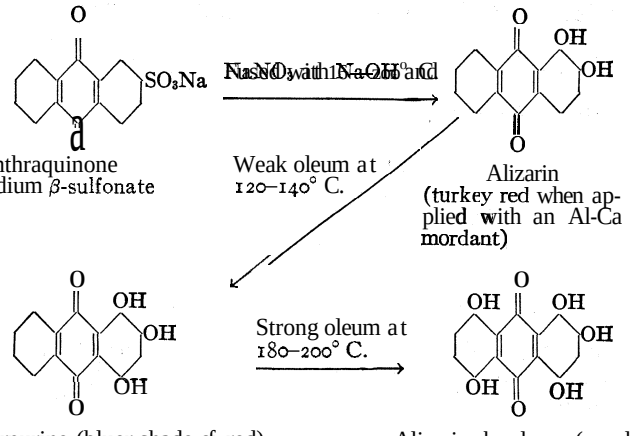
[1]Strictly speaking, the products are anthraquinonyl amines, but the dyestuff literature invariably refers to them as imides

Malachite green is made in the following manner:



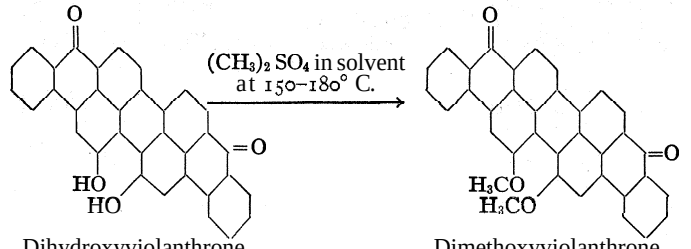
Frequently, oxidation is employed to bring about condensation; *i.e.*, to tie together molecules of two or more intermediates by the removal of hydrogen.

In dyestuffs derived from anthraquinone, the hydroxyl group (—OH) plays an extremely important role in colour formation. In some cases this group is introduced by fusion of the sulfonic acids with NaOH or $Ca(OH)_2$, although in others it is obtained by direct oxidation. When anthraquinone β-sodium sulfonate is fused in an oxidizing mixture of sodium hydroxide and sodium nitrate, 1,2-dihydroxyanthraquinone, the dyestuff known for centuries as alizarin, results. If this compound is further oxidized by means of oleum (fuming sulfuric acid), a reaction discovered by René Bohn in 1890, there is obtained a range of dyestuffs whose shades depend on the number of hydroxyl groups introduced.

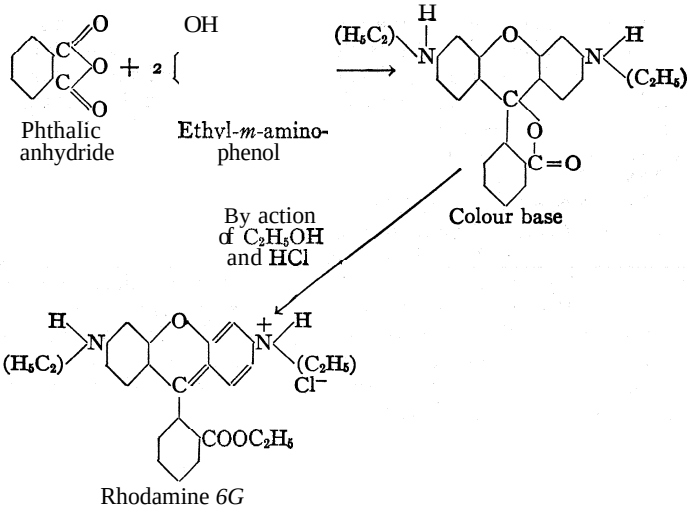


Esterification.—In a number of cases in dyestuff manufacture, hydroxy (OH) and carboxy (COOH) groups have to be "protected," that is, rendered nonionic, in order to obtain desired properties of dyeing or fastness. The reaction by which this is accomplished is generally termed esterification, although etherification would be a more exact term when the reaction is applied to hydroxy compounds.

Dihydroxyviolanthrone is a poor dyestuff, being fugitive to light and bleaching agents. However, if the hydroxy groups are etherified by means of dimethyl sulfate, the dimethyl ether, an exceedingly fast green dyestuff, sold under the name of jade green, is obtained.

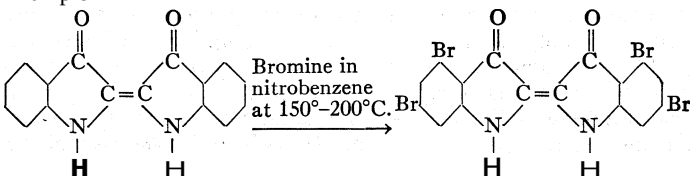


Esterification can also be illustrated by the process by which rhodamine 6G is made. Here two moles of ethyl-m-aminophenol are condensed with one mole of phthalic anhydride and the base thus obtained is esterified with ethyl alcohol, sulfuric or hydrochloric acid being used as the esterification catalyst. With the latter acid the reactions are as follows:

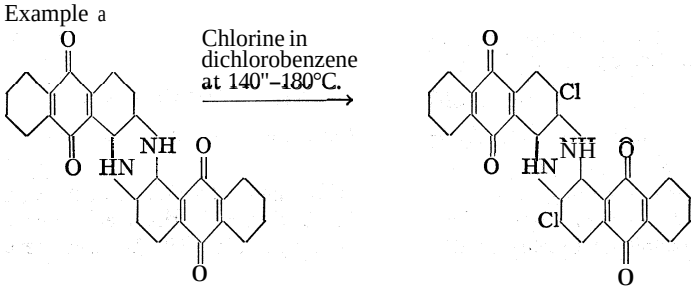


Halogenation means the introduction of chlorine or bromine into a dyestuff molecule. Usually in the carrying out of the process, the dyestuff is dissolved or suspended in a solvent such as acetic acid, dichlorobenzene or nitrobenzene, and the chlorine or bromine is added directly at ordinary or elevated temperature.

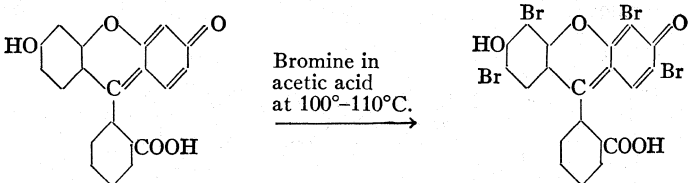
Example 1



Example 2



Example 3



Fluorescein (yellow) — Eosin (scarlet)

The process invariably brings about a marked change in the shade of a dyestuff, and thus the halogen atoms can be considered as auxochromes. Halogenation is most widely applied in the manufacture of indigoid and anthraquinone dyestuffs although it was applied as early as 1874 in the preparation of eosin by the bromination of fluorescein to its tetrabrom derivative.

In the case of the anthraquinone vat colouring matters, it is usually impossible to represent with certainty the position of the halogen atoms entering the molecule. But in the particular example given for anthraquinone derivatives an accurate representation can be made, since dichloroindanthrone can be made by another method whereby the positions of the chlorine atoms are definitely established. The product is the fastest, bright-blue dyestuff known for dyeing cellulose fibres; cotton dyed with it can be subjected to the action of dilute hypochlorite solutions without materially changing the shade of the dyeings. See also references under "Dyes" in the Index volume. (J. H. Ss.)

DYKE: *see* DIKE.

DYNAMICS (in music): *see* EXPRESSION. MUSICAL.

DYNAMICS is the branch of science which is concerned with the motions of bodies and the ways in which these motions are influenced by applied forces. Its underlying principles are described in the article MECHANICS, the parent subject of which it forms a part. Dynamics is commonly divided into kinematics, which deals with the purely geometric considerations of motion, and kinetics, which concerns the ways in which motions are produced and modified by forces.

Certain general results of dynamics are arrived at by reasoning from Newton's laws. These relate to any body be it solid or fluid, although the methods of applying them depend largely upon the type of body. It would be difficult in a short article to indicate clearly the general nature and scope of this branch of science since it is a vast subject which has received a great deal of attention from mathematicians, physicists and engineers. In the present article, therefore, an attempt will be made to describe the dynamics of rigid bodies for the sake of definiteness. The motion of fluids is covered in MECHANICS, FLUID.

Particle dynamics is discussed in the article MECHANICS and it sometimes suffices for the discussion of the motions of real bodies, notably in astronomy. But the majority of technical problems of dynamics cannot be solved directly by the methods described. This is because it is comparatively seldom that the size of a body can be neglected in comparison with all the relevant distances involved in its motion. If, as is often the case, distortion is negligible (or. rather, does not matter), then it is necessary to turn to rigid dynamics; if it is not (as in vibration problems) then rigid dynamics must be discarded in favour of the mechanics of deformable solids. The problems which arise are of many types. Some are essentially two-dimensional, like that of a conventional clock escapement, while others (such as problems involving gyroscopes [*q.v.*]) are three-dimensional.

TWO-DIMENSIONAL RIGID DYNAMICS

The relative simplicity and wide application of the two-dimensional (or plane) dynamics of rigid bodies has caused this branch of mechanics to become highly developed. In fact almost every elementary textbook on dynamics begins with the treatment of problems of this sort. Plane rigid dynamics will be used here, however, to provide a simple, and mainly descriptive, introduction to the more complicated three-dimensional theory which covers plane dynamics as a special case. The elements of three-dimensional theory are presented later in more detail.

The tipping mechanism of a truck shown in fig. 1 will be used as the basis of this preliminary discussion. The dynamical problems set by a mechanism of this sort are typical of those met in engineering practice. It is necessary to calculate the forces transmitted by the various parts, and to find suitable sizes, materials and shapes of those parts.

Kinematics of Plane Motion.—A rigid body is said to execute a plane motion when every point within it remains at constant distance from some fixed reference plane. Evidently the members **A,** B, C, D and E in fig. 1 all perform such motion when the truck is stationary.

Suppose that the truck is standing still and that for some given tipping position the piston attached to D has some prescribed speed of sliding within the hydraulic cylinder. The angle made by a line fixed in the body C and the horizontal will clearly be varying and its rate of change is called the angular velocity of C. The deduction of this angular velocity from the given piston speed is a typical problem in plane kinematics and it can, in fact, be solved in a number of ways; of these, a graphical method involving geometrical constructions is probably the best.

There is no reason why a uniform piston speed should produce a uniform angular velocity of the body. The rate of change of angular velocity is called the angular acceleration, and the value of this quantity can again be found by the methods of plane kinematics. This latter type of calculation is important by reason of its significance in plane kinetics as will be shown.

Kinetics of Plane Motion.—If plane motion of a system occurs parallel to a reference plane OXY, then as *a* consequence of Newton's laws *(see* MECHANICS)

$$F_x = M\frac{d^2\bar{x}}{dt^2} \qquad F_y = M\frac{d^2\bar{y}}{dt^2}$$

In words, the total applied force F_x which acts in the direction OX is equal to the product of the total mass M and the acceleration of the centre of mass of the system in the direction OX. Similar reasoning holds good for the force-component F_y. The co-ordinates $\bar{x}$, $\bar{y}$ determine the position of the centre of mass and this point will not, in general, be fixed in the system.

A third equation of motion may be found, again from Newton's laws. This states that the total moment. M_z say, of the applied forces about the axis which is perpendicular to the plane OXY and which passes through the centre of mass of the system is equal to the rate of change of the total moment of momentum H_z about that axis. This can be expressed symbolically as

$$M_z = \frac{dH_z}{dt}$$

although this result will be used in another form.

The three equations which have been quoted govern the plane motion of any system and, if the system is a rigid body, then their interpretation is much simplified by the fact that the centre of mass is a point fixed in the body. The first two equations may therefore be written as

$$F_x = M\frac{d^2x_g}{dt^2} \qquad F_y = M\frac{d^2y_g}{dt^2}$$

where x_g and y_g denote the co-ordinates of the centre of mass G with respect to fixed axes OXY.

Consider now the rotation equation which governs H_z. The moment of momentum is reckoned about the axis through the centre of mass G and perpendicular to the plane OXY. This quantity is not affected by the motion of the centre of mass so that this point of a rigid body can conveniently be imagined fixed; only rotation then will be possible about G as the centre. Fig. 2 shows a body whose centre of mass has been fixed in this way.

The angle made by a line GJ fixed in the body with a line GK which is fixed relative to the reference axes OXY is denoted by θ. Thus the angular velocity of the body is $d\theta/dt$.

The displacement of J during a short interval of time δt is $r\delta\theta$ where r is the distance GJ and $\delta\theta$ is the appropriate small angle of rotation. The velocity of J and hence the momentum of an

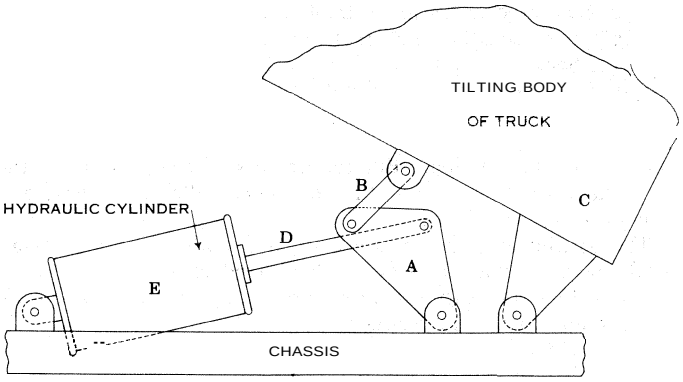


FIG. I.— — HYDRAULICTIPPING MECHANISM FOR MOTOR TRUCK BODY

element of mass δm at J are therefore

$$r\frac{d\theta}{dt} \text{ and } \delta m.r\frac{d\theta}{dt}$$

respectively. These are directed as shown by the arrow (perpendicular to GJ). Therefore, the moment of momentum of the small mass is

$$\delta m.r^2\frac{d\theta}{dt}$$

Now the derivative $d\theta/dt$ relates to the whole body whereas the quantity $r^2\delta m$ is identified with the particular point J. The total momentum is thus

$$H_z = \frac{d\theta}{dt}\int r^2 dm$$

where the integral is evaluated over the whole body. This integral is a constant which may be identified with the body and it is known as the moment of inertia with respect to the chosen axis through G; let it be represented by $\mathbf{I}_z$. Returning now to the equation of rotational motion it is evident that it may be written as

$$M_z = I_z\frac{d^2\theta}{dt^2} \qquad (2)$$

All the members A, B, C. D and E in fig. 1 move in conformity with equations (1) and (2).

The reason for the relative simplicity of plane rigid kinetics (as opposed to the kinetics of rigid bodies in three dimensions) can now be seen. For equations (1) and (2) are mathematically identical and, moreover, they are obviously mathematically identical with the equations of motion of a particle, *i.e.*, a body of negligible size. This greatly simplifies matters.

D'Alembert's Principle.—Direct application of these equations to a moving mechanism, like that shown in fig. 1, would necessitate separate treatment of each of the individual members A, B. C. D and E and the determination of the forces at the various junctions between them. Unless these are required this procedure is unnecessarily tedious and the analysis may be much simplified by invoking the principle of virtual displacements. This is a theorem of statics which is particularly useful in solving problems of equilibrium so that, for the purpose of analysis. it is necessary to imagine the dynamical problem as if it were a statical one.

Consider a single link, say C in fig. 1, whose motion is determined by equations (1) and (2). It may be thought of as being composed of a light skeleton, or matrix, in which a large number of small massive particles are embedded. The mass of C is then embodied entirely in the particles. The matrix is acted upon by sets of forces which may he conveniently placed in three categories. First there are the applied forces; these act at the pins and are transmitted from the abutting members (B and the chassis). Secondly, there are the reactions equal to the weights of the attached particles. These two sets of forces account for the left-hand terms in equations (1) and (2). Finally the matrix feels the reactions that are equal and opposite to the forces which impart accelerations to the attached particles. This effect will now be examined separately.

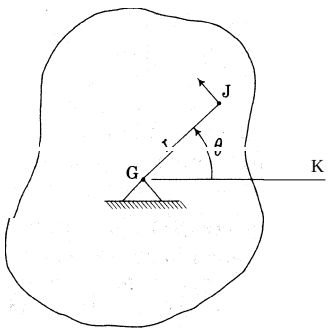

FIG. 2. (SEE TEXT FOR EXPLANATION)

The resultant of the forces acting on the various particles can evidently be thought of as possessing components whose values are given by the terms on the right-hand sides of equations (1) and (2). These components are applied to the particles by the massless matrix and therefore, by Newton's third law of motion, they react on the matrix with equal magnitudes but in opposite directions. The components of reaction on the matrix are called inertia forces.

The matrix is a system to which the forces applied must be in equilibrium if its accelerations are finite, since it possesses no mass. Analytically. this is expressed by the fact that, if equations (1) and (2) were to be applied to the matrix alone their right-hand sides always would be zero since $M = 0$ and $\mathbf{I}_z = 0$. It follows that, for the matrix of member C, the three sorts of forces together constitute a system in static equilibrium.

The analytical statement of this is

$$F_x - M\frac{d^2x_g}{dt^2} = 0 \qquad F_y - M\frac{d^2y_g}{dt^2} = 0 \qquad M_z - I_g\frac{d^2\theta}{dt^2} = 0 \qquad (3)$$

and although this appears to be a rather trivial rearrangement of the previous equations, it has a clear physical significance.

The purpose of this rearrangement now can be seen. Suppose that the applied forces (including those of gravity) and the inertia forces are imagined as acting on the massless matrices of all the members of the mechanism shown in fig. 1. The whole may then be regarded as a single system which can be analyzed using any of the techniques of statics and, in particular, that of virtual displacements. Analysis will be greatly simplified by the fact that all the forces at the connections between the various members occur in pairs which cancel out. This type of approach is associated with the name of D'Alembert.

KINEMATICS OF A RIGID BODY

A more detailed discussion of dynamics and the general theory relating to three-dimensional systems will now be given. The reader may well find that a preliminary reading of MECHANICS is desirable.

If a single point of a rigid body is fixed in space, the body is left free to turn about any axis through that point The freedom is reduced if a second point is fixed so that only rotation is possible about the axis joining the two fixed points. Provided that it does not lie on this axis, the fixing of a third point suffices to fix the body in space. Nine co-ordinates determine the positions of the three points, but there are three relations governing the distances separating them within the body, so that six independent variables serve to specify the position of an unconstrained body in space. It will he seen that the increase in the number of these variables, or degrees of freedom, from three (for a particle) to six may introduce considerable complications.

Quite simple considerations as to the freedom of rigid bodies are of practical importance in the design of structures and of scientific instruments. For instance, consider an instrument which stands on three rounded feet. Let two of these rest in contact with the sides of a V-shaped groove which is machined in a horizontal plane surface uhile the third foot rests on the plane. The instrument can slide parallel to the groove but no other horizontal motion is permitted. A modified form of this arrangement is used in the construction of a lathe in which the tailstock must be capable of movement along the bed without loss of alignment.

Displacement of a Rigid Body.—A rigid body is capable of two basic types of motion. that is, of translation and rotation When it undergoes translation, all points within it describe equal

and parallel straight lines. Rotation, on the other hand, occurs about an axis and is such that all points describe circles whose centres lie on this line. The reader can demonstrate for himself by simple reasoning that any displacement of a rigid body can be brought about by a suitable succession of translations and rotations. Now any displacement by which three points of a body take up fresh positions can, in fact, be effected by a translation with a single rotation about a fixed axis. Rather than pursue the problem of general displacements, however, certain particular cases which are of special importance will be considered here.

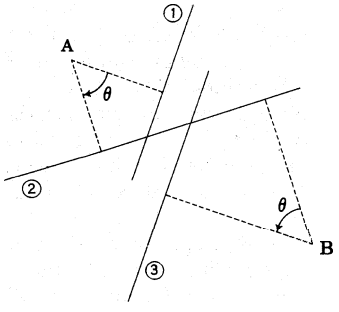

FIG. 3.

Consider the displacement of a body that suffers successively equal and opposite rotations about parallel axes. As there is no motion parallel to these axes, the kinematical problem can be examined by reference to a plane which is perpendicular to the axes. Let the line 1 in fig. 3 be drawn in such a plane. If the body is rotated through an angle θ about the axis which intersects the plane at A, the line is brought to position 2. An equal and opposite rotation θ about the axis B brings the line to position 3. Now the line 3 is parallel to 1 so that the two rotations restore the line's original direction but not its position. The resultant displacement is such that all lines in the plane are unaltered in direction so that the total effect is to translate the body in a direction perpendicular to the axes of rotation.

This result can be expressed symbolically as follows:

[rotation $(+\theta)$ about A]
+ [rotation $(-\theta)$ about B]
= (translation perpendicular to the axes through A and B).

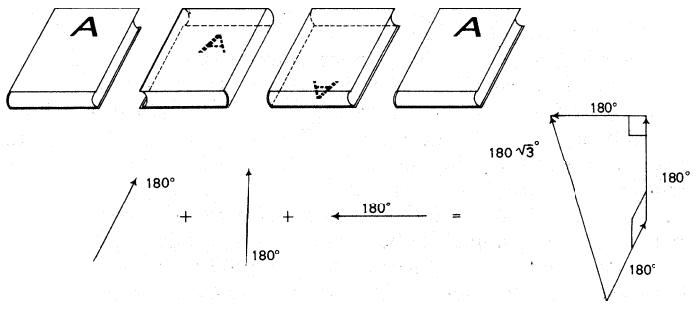
Alternatively,

[rotation $(+\theta)$ about A]
= [rotation $(+\theta)$ about B]
+ (translation perpendicular to the axes through A and B) **(4)**

The conclusion is therefore that a rotation about any axis produces the same displacement as an equal rotation about a parallel axis together with a translation. The converse is also true.

The significance of equation (4) will become apparent later. Its effect is to simplify greatly the theory of the kinematics and kinetics of rigid bodies since it is only necessary now to discuss the rotations of a body about intersecting axes.

If a body rotates through a finite angle about a fixed axis, this displacement may be represented by a line whose length represents the angle and whose direction and sense are related to the rotation in the same way as the advance to the rotation of a right-handed corkscrew. But if the body rotates about an axis which is fixed relative to a frame of reference and that frame is itself rotated about an intersecting axis fixed with respect to stationary axes, the lines representing these displacements cannot be added to give the correct resultant rotation by the parallelogram rule. Equally, if several such component rotations take place about axes meeting in a point, they cannot be compounded by the polygon law. In other words. a finite rotation is not a vector quantity.



This is illustrated in fig. 4. A book is given three rotations each of 180° about perpendicular axes, the resultant rotation being nil since the book ends up in its initial position. Vector addition here would indicate not a zero resultant, but one of $180\sqrt{3}°$.

Rotations through finite angles about intersecting axes are, in fact, equivalent to a single rotation about a third axis passing through the intersection. But the process of composition of the component rotations is not that of the parallelogram law, and is more complicated.

The position is different, however, if a body performs a very small rotation about an axis which is fixed in a frame of reference and that frame itself rotates through a small angle about an intersecting axis. In contrast with finite rotations, these can be compounded by the vector law to give a resultant rotation about an appropriate axis. Let the body rotate through a small angle $\delta\theta$ about the axis AD (see fig. 5 in which A B, C, D, P lie in a plane). AD is fixed relative to some frame of reference. If PE is perpendicular to AD, then the displacement of P, a point within the body, is PE X $\delta\theta$.

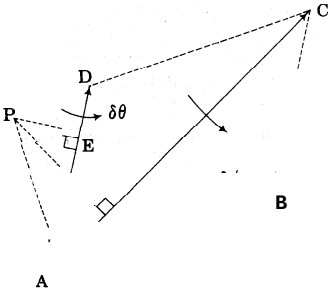


FIG. 5.

If the magnitude $\delta\theta$ of the rotation is represented to some scale by AD. then the displacement of P is AD × PE; this can be regarded as the "moment of AD about an axis through P which is perpendicular to the plane of the figure" by analogy with the notion of a force which is represented by a vector. Again, if a small rotation $\delta\phi$ of the frame now takes place about the fixed axis AB, the displacement of P is represented by the moment of AB about the same axis through P.

If the parallelogram ABCD is now completed, the sum of the moments of AB and AD about P is equal to the moment of AC about the axis through P, again by analogy with the like result for forces. This is true for all points P in the plane so that all points in the plane move as though a single angular displacement about a fixed axis had taken place uhich is represented to the chosen scale by AC. Since the body is rigid, only this resultant small rotation could have produced these displacements in the plane and the displacements of all other points must conform with it.

Very small rotations can also be compounded like forces when they occur about parallel axes. Suppose for instance that these rotations are $\delta\theta$ about the axis through A and $\delta\phi$ about that through B, both axes being perpendicular to the plane of the paper (fig. 6). By an extension of the previous argument, it is found that the motion of any point P is the same as if the body undergoes the small rotation $\delta\theta + \delta\phi$ about an axis through C. This axis is parallel to those through A and B and divides the distance AB inversely as the magnitudes of the component rotations about these axes.

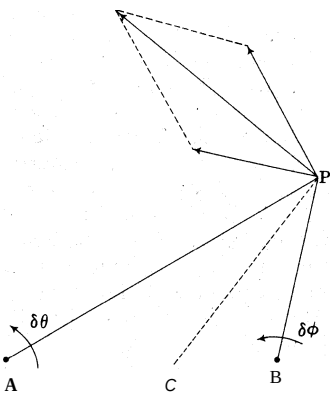

FIG. 6.

These conclusions as to the vectorial nature of small rotations are only valid if the rotations are infinitesimal. Their significance becomes apparent on taking into account the time intervals during which they occur. This leads to the concept of angular velocity.

Angular Velocity and Angular Acceleration.— A body which moves in such a way that some point O within it remains fixed does not in general turn about a fixed axis, so that an instantaneous axis of rotation may be defined. This axis is determined if the directions of motion of any two points A and B in the body are known. During an infinitesimal time, let A move to A′

and B to B′ so that AA′ and BB′ are very small distances. Then AA′ must he perpendicular to OA. and BB' must be perpendicular to OB. The instantaneous axis of rotation lies in a plane containing OA which is perpendicular to ***Ah'*** and also in a plane which contains OB and is perpendicular to BB′. The instantaneous axis of rotation is the line of intersection of these two planes and. although it always passes through O, its position may vary both with respect to the body and in space.

It has been shown that very small angles of rotation of a rigid body about various axes which intersect at a point can be compounded by the vector law into a resultant rotation about a certain axis. The theory can now be extended to introduce the notion of angular velocity. The angular velocity of a body about an axis is defined as the rate at which the angle increases between two planes which intersect on the axis, the one plane being fixed in the body and the other in space.

Suppose that a body performs a small rotation 68 during the short interval of time δt about an axis fixed relative to a frame of reference. Let this frame simultaneously rotate through the small angle 64 about an axis which intersects the first. The resultant small rotation may be found by the parallelogram law. If the lengths $\delta\theta$, 64 of the sides of the parallelogram are divided by δt, and the limit is approached as δt is taken indefinitely small, the parallelogram becomes a representation of angular velocities. Component angular velocities (of a rigid body about an axis fixed in a frame of reference, of rotation of the frame about an intersecting axis fixed relative to another frame, and so on) may be added as vectors to give the resultant angular velocity about the instantaneous axis of rotation.

It follows, by a similar argument, from the result indicated in equation (4) that an angular velocity about an axis involves the same motion of a rigid body as would an equal angular velocity about a parallel axis together with a velocity of translation perpendicular to the axes. Again the converse is also true. From this it can be deduced that the motion of a rigid body can be specified by the velocity of one point together with the angular velocity about an axis through that point. Further, the magnitude of the resultant angular velocity and the direction of its axis do not depend upon the particular reference point.

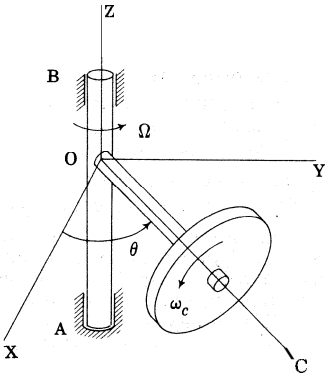

FIG. 7.

Angular acceleration is defined as the rate of change of angular velocity. It, too, is a vector quantity. For consider a body which has an angular acceleration a, about an axis OA, fixed in a frame of reference which, simultaneously, suffers an angular acceleration a, about an intersecting fixed axis OB. In the small interval of time δt, a, produces an angular velocity $\alpha_a\delta t$ about OA and a, produces an angular velocity $\alpha_b\delta t$ about OB. Since these angular velocities are vector quantities, they can be compounded by the parallelogram rule. But the result of doing this is the same as that obtained by compounding a, and a, directly using the parallelogram rule.

The resultant angular velocity ω of a body, nhich rotates about an axis passing through a fixed point **O,** can be resolved into components w_x, w_y, ω_z in the directions of fixed orthogonal axes OX. OY. OZ. The corresponding components of the angular acceleration are then

$$\alpha_x = \frac{d\omega_x}{dt} \qquad \alpha_y = \frac{d\omega_y}{dt} \qquad \alpha_z = \frac{d\omega_z}{dt} \tag{5}$$

As an illustration, consider the disk shown in fig. 7, which has an angular velocity ω_c relative to an axis fixed in the frame ABC, which frame rotates about the fixed axis AB. Let OC rotate with angular velocity Ω about the spindle AB, with OC perpendicular to AB. If a set of fixed axes OXYZ is used as shown in the figure and θ denotes the angle between the fixed line OX and the moving axis OC. then $\omega_x = \omega_c \cos\theta$; $\omega_y = \omega_c \sin\theta$; $\omega_z = \Omega$. The components of angular acceleration are thus. from equations (5),

$$\left.\begin{aligned} \alpha_x &= \frac{d\omega_x}{dt} = \frac{d\omega_c}{dt}\cos\theta - \omega_c \sin\theta\frac{d\theta}{dt} = \frac{d\omega_c}{dt}\cos\theta - \Omega\omega_c \sin\theta \\ \alpha_y &\equiv \frac{d\omega_y}{dt} = \frac{d\omega_c}{dt}\sin\theta + \omega_c\cos\theta\frac{d\theta}{dt} = \frac{d\omega_c}{dt}\sin\theta + \Omega\omega_c\cos\theta \end{aligned}\right\}$$

$$\alpha_z = \frac{d\omega_z}{dt} = \frac{d\Omega}{dt}$$

Further development of the kinematics of rigid bodies is often difficult when fixed axes of reference are employed. It becomes simpler to refer motion to moving axes. A treatment of this aspect will be found in A. S. Ramsey, Dynamics, part ii.

THE KINETICS OF A RIGID BODY

An explanation has been given of the kinematical result that any motion of a rigid body at any instant can be described completely by the velocity of some point of it combined with an angular velocity about some axis through that point. It has also been shown (in the article MECHANICS) that the forces which act on a rigid body produce a motion of the centre of mass together with an independent motion relative to the centre of mass; this is a rotation about an axis through that point.

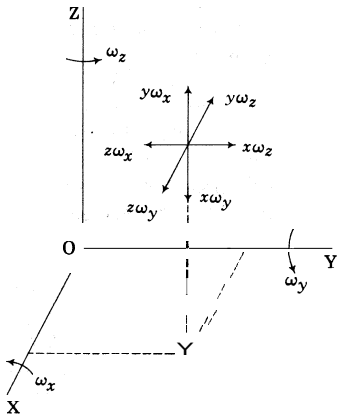

FIG. 8.

When considering the motion of a rigid body, the motion of the centre of mass may first be dealt with as if the body were a single particle with its entire mass concentrated at that point. The rotation about the centre of mass may be treated separately as if this point were fixed in space. The motions of translation and of rotation are independent and the latter may be analyzed by assuming the centre of mass to remain at the origin of fixed axes.

The motion of translation is covered by the discussion of the kinetics of a particle. The problem of rotational motion about an axis through a fixed centre of mass must now be dealt with.

Angular **Momentum of** a Rigid Body.—Suppose that a rigid body rotates about an axis which passes through its centre of mass and that this point is fixed at the origin of fixed co-ordinate axes OXYZ. Let the angular velocity be ω at some instant with component angular velocities ω_x, w_y, ω_z in the directions of the axes OX. OY. OZ respectively (fig. 8). The components of velocity of the point (x, y, z) within the body will be

$$v_x = z\omega_y - y\omega_z \text{ in the direction OX}$$
$$v_y = x\omega_z - z\omega_x \text{ in the direction OY}$$
$$v_z = y\omega_x - x\omega_y \text{ in the direction OZ}$$

Consider the moment of momentum of a small element of the body. mass δm, about the three axes. If this element lies at the point (x, y, z) its moment of momentum about the axis OX is

$$\delta m(yv_z - ev_y) = \delta m[y(y\omega_x - x\omega_y) - z(x\omega_z - z\omega_x)] = \delta H_x$$

If this is rearranged, and the analogous expressions are written for the remaining axes, it is found that the contributions made by δm to the total moments of momentum about the axes are

$$\delta H_x = (y^2 + z^2)\omega_x\delta m - xy\omega_y\delta m - xz\omega_z\delta m$$
$$\delta H_y = (z^2 + x^2)\omega_y\delta m - yz\omega_z\delta m - yx\omega_x\delta m$$
$$\delta H_z = (x^2 + y^2)\omega_z\delta m - zx\omega_x\delta m - zy\omega_y\delta m$$

The total moments of momentum about the three axes can now be found by integration over all the elements of the body. This yields the expressions

$$\left.\begin{aligned} H_x &= I_{xx}\omega_x - I_{xy}\omega_y - I_{zx}\omega_z \\ H_y &= I_{yy}\omega_y - I_{yz}\omega_z - I_{xy}\omega_x \\ H_z &= I_{zz}\omega_z - I_{zx}\omega_x - I_{yz}\omega_y \end{aligned}\right\} \tag{6}$$

where the following abbreviations are used:

$$\left.\begin{array}{llll} I_{xx} = \int(y^2+z^2)dm & I_{yy} = \int(z^2+x^2)dm & I_{zz} = \int(x^2+y^2)dm \\ I_{xy} = \int xydm & I_{yz} = \int yzdm & I_{zx} = \int zxdm \end{array}\right\} (7)$$

It will become apparent that these quantities I are of fundamental importance since they determine the dynamical behaviour of the body. The quantities I_{xx} I_{yy} I_{zz} are called the moments of inertia of the body about the axes OX, OY, OZ while I_{xy} I_{yz} I_{zx} are termed the products of inertia, although they are not usually defined in quite this way. If the axes, by reference to which the integrals (7) are defined, were fixed in the body, the appropriate quantities would be constants whose values characterize the body's dynamical behaviour. It is these constants which are usually referred to as the moments and products of inertia (see *Two-Dimensional Rigid Dynamics* above). They have some interesting and important characteristics, a knowledge of which is essential for complete understanding of the motions of rigid bodies. These quantities will continue to be regarded as being time dependent.

The components H_x H_y H_z refer to the axes OXYZ which, for the present purpose, are only *assumed* to be fixed; for the dynamical properties are unaffected by motion of the origin O which is at the centre of mass. It follows that the components are not normally equal to the moments of momentum about parallel axes which really are fixed and which do not have their origin at the centre of mass. A nonrotating body has zero components H_x H_y, H_z but will not necessarily have zero moments of momentum about the fixed axes. For this reason it is desirable to distinguish between the two sets of components and to this end, H_x, H_y H_z are referred to as the components of angular momentum in the directions OX, OY, OZ, respectively.

There is a general theorem that can now be restated in a more useful form. It relates to the components of moment of momentum about fixed axes of a system of particles and it is now seen that, for a rigid body, these are equal to the sums of two other convenient sets of components. The first are the components of moment of momentum of a particle placed at the centre of mass and the second are the components of angular momentum.

The angular momentum about an axis is shown in equations (6) to depend not only on the angular velocity about the axis concerned but also on the angular velocities about axes perpendicular to that axis. Again, in general, angular velocity about one axis implies angular momentum about all three axes. Now the quantities H_x, H_y H_z can be regarded as the components of a vector—that of angular momentum. This may be proved by an extension of the previous argument relating to angular velocity. It follows from equations (6), then, that the vectors of resultant angular velocity and of resultant angular momentum have not, in general, the same direction.

The Equations of Rotation. — Another of the general results (also deduced in MECHANICS: *Systems Containing More Than One Particle)* for any system can now be restated for a rigid body. This is to the effect that the rate of change of angular momentum of a body about a fixed axis passing through the centre of mass, is equal to the total moment of the external forces about the axis.

Insymbols, $$M_x = \frac{dH_x}{dt} \qquad M_y = \frac{dH_y}{dt} \qquad M_z = \frac{dH_z}{dt} \qquad (8)$$

These are the equations of rotation.

If these derivatives are formed, by introducing the expressions (6) for the quantities H_x H_y H_z, it is found that the resulting equations are somewhat complex. The complication arises from the fact that the quantities I, defined in equations (7), are not constants but have diiferent values at different instants. Rather than deal with the general problem, therefore, a special case will be examined whose technical importance scarcely needs emphasis.

Suppose that a rigid body rotates about a fixed axis and let this be identified with the axis OX. Under these conditions, I_{xx} = constant and $\omega_y = \omega_z = 0$, so that

$$\left.\begin{array}{l} H_x = I_{xx}\omega_x \\ H_y = -I_{xy}\omega_x \\ H_z = -I_{zx}\omega_x \end{array}\right\}$$

That is to say

$$\left.\begin{array}{l} M_x = I_{xx}\dfrac{d\omega_x}{dt} \\ M_y = -I_{xy}\dfrac{d\omega_x}{dt} - \omega_x\dfrac{dI_{xy}}{dt} \\ M_z = -I_{zx}\dfrac{d\omega_x}{dt} - \omega_x\dfrac{dI_{zx}}{dt} \end{array}\right\}$$

Reference to the definition of I_{xy} in equations (7) reveals that the derivative of I_{xy} with respect to t is given by

$$\frac{dI_{xy}}{dt} = \int\left(x\frac{dy}{dt} + y\frac{dx}{dt}\right)dm = \int(xv_y + yv_x)dm$$

If the values for v_x and v_y are now substituted into this result, it yields simply

$$\frac{dI_{xy}}{dt} = -I_{xx}\omega_x$$

Similarly,

$$\frac{dI_{zx}}{dt} = I_{xy}\omega_x$$

For the rigid body which rotates about the fixed axis OX, therefore,

$$\left.\begin{array}{l} M_x = I_{xx}\dfrac{d\omega_x}{dt} \\ M_y = -I_{xy}\dfrac{d\omega_x}{dt} + I_{zx}\omega_x^2 \\ M_z = -I_{zx}\dfrac{d\omega_x}{dt} - I_{xy}\omega_x^2 \end{array}\right\}$$

This result shows that the body has an angular acceleration about the fixed axis OX only if the external forces have a net moment about the axis. The angular acceleration is also associated with moments (about OY and OZ) of forces which must be applied at the bearings in order to keep the axis of the body fixed. Moreover, bearing forces must act even if the body runs with constant speed. If the body does not have its centre of mass on the fixed axis of rotation, then the bearing forces will be further augmented on that account.

It is often preferable, in three-dimensional problems of rigid dynamics, to use moving axes rather than fixed ones. Thus it may be possible by this means to ensure that the quantities I_{xx} I_{yy} . . . will not vary with time. One way of achieving this would be to fix the axes relative to the rigid body.

DYNAMOELECTRIC MACHINES: *see* GENERATOR, ELECTRIC; MOTOR, ELECTRIC.

DYNAMOMETER, a device which permits the measurement of a force exerted by or the power associated with a machine. In general usage, dynamometers are regarded as a means for measuring power. In actuality, dynamometers permit the measurement

of a force, and this measurement in combination with a velocity measurement makes it possible to calculate the power.

Theory. — Power is by definition the time rate of doing work, *i.e.*, work per unit time. Work is the equivalent of the product of a force and the distance traveled in the force direction. In other words, power is the product of force and distance divided by time; and the quotient of distance and time is a velocity. For linear movements, power P equals force F times linear velocity V, or $P = FV$. For rotating machines, power P equals force F times lever arm r times angular velocity w, the product Fr being the torque t. In summary, (1) P = FV for linear motion; and for rotary motion the following equations apply: (2) P = Frw; (3) P = tw; (4) P = $Fr2\pi N$; and (5) P = $t2\pi N$.

Basically power measurement is a combination of the measurements of time, distance and force. Therefore, the force- or torque-indicating element of a dynamometer is used in conjunction with a revolution counter and timer (or speed indicator) for speed measurement and some means for measuring the lever arm length. Thus, for any given device (in which the distance r is fixed), it can be said that $P = FN/K$, where K is the dynamometer constant for the machine and is equal to $33{,}000/2\pi r$, when r is in feet. F in pounds, N in revolutions per minute and P in horsepower. From this equation, it can be seen that for successive power measurements with a given dynamometer it is sufficient to measure F and N at each new condition.

It is convenient to classify dynamometers into two types, absorption and transmission. Absorption dynamometers convert the energy involved into heat and this energy usually serves no useful purpose. Absorption units are used for loading devices whose output is to be measured. Transmission dynamometers transmit the energy and power involved from the dynamometer in a form and to a location where it can be usefully employed. Transmission units may be used for driving machines in order to measure the power output.

Absorption Dynamometers. — The original dynamometer of Gaspard de Prony (1755–1839) has been modified in many ways. The modern form (fig. 1) consists of a brake band to which are attached wooden cleats. The adjusting screw permits tightening

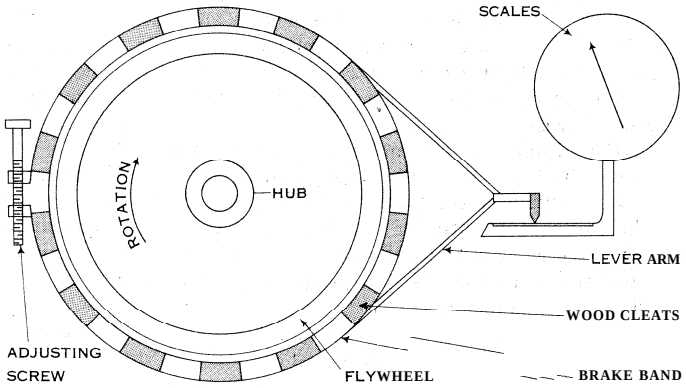

FIG. 1.—PRONY BRAKE

or loosening the band, thus varying the frictional effect between the cleats and the smooth surface of the flywheel. The frictional force is transmitted to the scales through the lever arm which restricts the movement of the brake band. The force indicated on the scales is that exerted by the driving member plus any tare load, or additional force resulting from unbalance caused by the band, the lever arm or the adjusting screw mechanism. For smooth operation, the rubbing surface may have to be slightly lubricated. In addition. the heat evolved may have to be dissipated by circulating cooling water over the inner side of the flywheel. The power absorbed is equal to the force on the scales minus the tare load; this remainder is multiplied by the lever arm length (the perpendicular distance from the line of action of the force on the scales to the axis of rotation) and 2π times the speed, and the result is divided by a suitable constant (equation 4, above). Many modifications of this basic brake have been made using ropes or belts, and ingenious refinements have been used to compensate

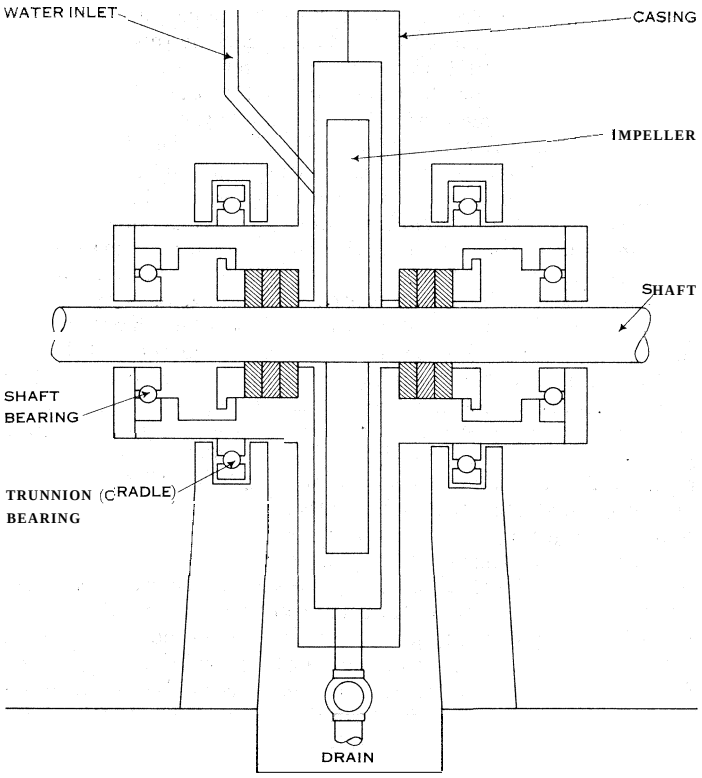

FIG. 2. — CRADLE-MOUNTED. HYDRAULIC DYNAMOMETER (WATER BRAKE)

for load variations. In general, this type of device is applicable to machines of low speed and low, steady power output.

One type of hydraulic dynamometer is a simple solid disk contained in a closely fitted casing (fig. 2). Water enters the casing and is thrown outward by the rotating disk impeller. The quantity of water admitted and retained within the casing affects the absorption capacity of the brake. Drains allow the water to leave the bottom of the casing and thereby some circulation is possible to dissipate the absorbed energy. By mounting the casing on trunnion bearings, the casing becomes "cradled" and free to rotate within limits. A lever arm extending from the casing to a platform scale permits determination of the torque. The power-absorbing capacity of this type of brake varies almost as the cube of the speed, a desirable feature for nongoverned engines. Sizes as large as 3,000 h.p. have been made. For certain types of work, small diameter, multidisk impeller rotors have been made that will rotate at 25,000 r.p.m.

An electromagnetic brake is another type of absorption dynamometer. There is a small air gap between the toothed rotor of this machine and the direct current energized coils of its stator. Lines of magnetic force producec! in the stator pass principally through the teeth of the rotor so that as it turns this magnetic field sweeps through the iron of the stator, thus causing the stator to tend to turn in the direction of the rotor. The stator is restrained and eddy currents are produced which heat the dynamometer; a cooling water jacket in the stator carries the energy away to prevent overheating. The torque produced by this device is transmitted through the cradled casing. Sizes of the order of 2,000 h.p. are not uncommon for this unit and its ease and refinement of control are decided advantages.

An electric generator is yet another type of absorption dynamometer. In this application a separately excited D.C. generator can be connected to the driving machine. The output of the driver is determined by either the po er generated by, or the reaction torque on, the generator. In the first case, the generator must be tested so its losses can be accurately determined (*i.e.*, so that its efficiency can be evaluated). From these data the input-output curve can be drawn for the machine. As an absorption device. it would be necessary to note the electrical output of the generator, refer to the input-output curve (giving credence to the

proper operating conditions), and thus determine the shaft input to the generator; for a direct-connected machine this latter quantity is the shaft output of the driving engine. Determination of the reaction torque on the generator involves the use of a cradle mounting for the generator stator (similar to the cradle mounting for the hydraulic dynamometer in fig. 2). In this situation, the reaction force, the appropriate lever arm length and the rotational speed are the necessary observations for determining the power input to the generator. Advantages of this dynamometer are the refinement of control of both speed and load which is possible and the ease with which changes in these quantities may be effected.

Transmission Dynamometers.—These machines are a class which can be used to (1) drive the machine whose input is to be measured; (2) indicate the force or torque required to deflect an elastic member such as a spring, or the angle of twist of a shaft; (3) indicate the force or torque necessary to produce a change in electrical resistance of (or voltage on) an electric resistance strain gauge; or (4) indicate the load or force required to produce a pressure in a hydraulic or pneumatic load cell. All such devices do not dissipate the energy but rather they transmit this energy to serve, in general, some useful purpose.

A calibrated electric motor makes an excellent transmission dynamometer. The calibration procedure is performed in order to relate the motor input (measured in volts and amperes, or in watts) to the motor output. The ratio of the output power to the input power is the motor efficiency for that condition of operation (understanding that efficiency may be affected by things other than power alone). The significant losses in a D.C. electric motor are the brush loss, the armature resistance loss and the rotation loss. For A.C. motors, the losses are usually reported in terms of motor efficiency. The calibrated-motor dynamometer has distinct advantages in measuring power in ranges that would be beyond the capacity of conventional dynamometers.

A cradle-mounted electric motor is one of the most easily regulated dynamometers. This device is mounted with the stator supported by ball or roller bearings so that it can rotate within limits. The reaction torque between the stator and the mounting is effectively the driving torque of the motor. Cradle mounting is accomplished in a fashion similar to that used for the hydraulic dynamometer in fig. 2. The torque, or the force and lever arm, and speed must be measured in order to calculate power. One of the most versatile dynamometers is the cradle-mounted D.C. motor-generator type dynamometer. A direct-current motor can operate effectively as a generator. Therefore. the controls of this dynamometer are made so that the unit can be operated as a motor to drive a machine whose input is to be measured, or the controls can be reset so the unit operates as a generator and loads a machine whose output is to be measured. Because of its versatility as well as its ease and refinement of control within the operating limits of the machine, this type of dynamometer is widely used.

Indicating Devices.—A number of contrivances are used for indicating the force exerted by a dynamometer. The spring scale is a common device, but it requires frequent calibration because the physical characteristics of the spring change with service, time and the ambient conditions. The movement of the spring is usually amplified by a suitable mechanism.

A beam balance is perhaps the most widely used force meter because of its stability and ruggedness and the fact that it requires infrequent calibration (although occasional checking is good practice). Platform scales are a form of beam balance. Both of these devices have the advantage that only small displacements are required for sizable forces; therefore, the dynamometer torque arm can remain at essentially the same level throughout its range of operation. A movement of the torque arm of as much as an inch requires a reorientation of the scale in order to measure the total force along its line of action rather than along some other line which would represent a fraction of the total force.

In the proving-ring force gauge the change in inner diameter of a ring because of a force acting on opposite points on the outer diameter is correlated in terms of the force required to produce the change. The proving ring and the spring previously described must not be distorted beyond the point at which their elastic properties will return them to their original dimensions when the force is removed.

Hydraulic and pneumatic force meters are commonly called load cells. These devices are used for transmission dynamometers which measure drawbar pull on a tractor or locomotive. The load cell consists of a chamber completely filled with either a liquid or a gas and enclosed on one side by a flexible diaphragm. A force on the diaphragm increases the fluid pressure, and the increase can be indicated by some type of pressure gauge (either a Bourdon-tube gauge or a manometer, depending upon the range required). One type of pneumatic load cell uses a regulated air supply with a diaphragm-operated pilot valve; an increase in force causes a deflection of the diaphragm, which in turn causes the pilot valve to connect the enclosed space to the air supply (at a higher pressure). Air is bled into the space until the diaphragm is returned to its neutral position. Displacement of the diaphragm in the opposite direction operates the pilot valve to bleed the air out of the cell. The air pressure required to keep the diaphragm in a neutral position is proportional to the load on the cell. Another type of load cell uses an electric resistance strain gauge as the primary element. This gauge is a small pad of fine resistance wire insulated electrically from its surroundings. As a load is increased or decreased on the assembly to which it is attached, deformation of both the assembly and the strain gauge occurs. This change in dimension alters the electrical resistance characteristics of the strain gauge and the change in resistance can be correlated in terms of the force required to produce the change.

Torsion Meters.—Torsion dynamometers are transmission dynamometers of a type; viz., torque meters indicate a force at some lever arm, and torsion meters indicate the force required to change the angle of twist of a member such as a shaft. Many of the devices previously mentioned can be arranged to perform as torque meters. For the torsion meter several techniques have been worked out to translate the angle of twist into the force required to produce the twist. In the Thring-Hopkinson torsion meter, the twist between points on a short length of shaft is observed. A cylindrical sleeve is gripped to the shaft at one end and is free at the other end so that there is relative motion of twist between the free end of the sleeve and the shaft. The relative motion is used to give angular displacement to a mirror which reflects light from a fixed source to a fixed scale. The reflected light impinges on the scale at different points for different angles of twist.

In the Moulin torsion meter the relative twist of a defined length of shaft is made to alter the self-induction of a coil mounted on and rotating with the shaft. An alternating current is supplied to the coil through brushes and slip rings, and the variation in current can be related to the twist of the shaft. An ammeter can be used to indicate the torque directly once the proper calibration has been made.

In the resistance-wire strain gauge torsion meter the unit is mounted between flanges in series with the shaft. Other variations can be made so that a network of strain gauges can be mounted directly upon the shaft whose power is to be measured. In both of these adaptations, the twisting of the shaft causes a deformation of the gauge which in turn changes the resistance of the gauge and the voltage drop across it. These electrical effects can be calibrated in terms of force required to produce the twist.

(R. A. O.)

DYNAMOTOR, an electrical machine usually having a single field coil and two windings on its armature such that when one winding is supplied with electrical energy from an external source, the other winding delivers electrical energy at a different voltage. It is thus a combination of motor and generator, or a rotary trans-

former. See GENERATOR, ELECTRIC; MOTOR, ELECTRIC.

(R. M. SN.)

DYNASTY, a family or line of rulers, a succession of sovereigns of a country belonging to a single family or tracing their descent to a common ancestor (Gr. dynadeia, "sovereignty"). The term is particularly used in the history of ancient Egypt as a convenient means of arranging the chronology.

DYNE, the unit of force in the centimetre-gram-second system. It is the force which, acting on one gram of mass, produces an acceleration of one centimetre per second per second. See GRAM [GRAMME]; PHYSICAL UNITS.

DYNEL: see SYNTHETIC FIBRES: True Synthetic Fibres.

DYOTT, THOMAS W. (1771–1861), U.S. glass manufacturer uho introduced a number of designs which were later copied extensively and still later became collectors' items, was born in England. Kothing is known of his early life until his arrival in the United States toward the end of the 18th century. He soon established himself in Philadelphia. where he set himself up in nhat became an immensely successful shoeshining enterprise, the first of its kind in the city. It is not known exactly when he entered the patent medicine business but in that field, too. the enterprising Dyott was soon successful. His medicines, with which he claimed to be able to cure all human ailments, were used throughout the entire United States. About 1812 he took, with no authority but his own, the title of doctor of medicine. Dyott soon began to advertise the sale of bottles, as well as medicines, and about 1818 he became the agent for a number of glass manufacturers. There is some dispute about the year in uhich he first began to manufacture glass himself, the date sometimes being put as early as 1822. but in any case he probably did not purchase the Philadelphia and Kensington Glass Works until 1833. He enlarged and improved the plant and was soon manufacturing bottles of every description. Dyott's downfall was caused by the failure of the bank he had established as a part of his model community. Dyottville, or. as it was sometimes called, Temperanceville. because Dyott mould not hire any worker until he had taken a temperance pledge. When the bank failed in the late 1830s, Dyott' was proclaimed a "fraudulent bankrupt" and the Kensington works fell into other hands while Dyott served a prison sentence. He died Jan. 17, 1861.

DYSART: see KIRKCALDY.

DYSENTERY. The term dysentery, the "bloody flux" of former times, denotes a symptom complex, the passage of blood and mucus in the stools, together with abdominal pain and straining. This combination of symptoms is common to a number of conditions with ulceration and inflammation of the large intestine and is determined by a variety of different microbial agents.

Types of Dysentery.— Dysentery may be classified as follows:

Bacillary or *Epidemic* Dysenteries.—The following organisms are responsible: (1) Shiga's bacillus (Shigella skigae) causes the most acute and fatal form in most tropical countries. (2) Schmitz's bacillus (Shigella ambigua) closely rosembles the former in its biochemical reactions and in many other respects. It produces usually a less serious clinical manifestation and accounted for 12% of cases during World War II. (3) Flexner's bacillus (Shigella *flexneri*) is a species divisible into several subtypes. It is common in temperate countries, as well as in the tropics, and produces a clinical disease of average severity. (4) Sonne's bacillus (Shigella sonnei) is common all over the world, especially in temperate countries, and spreads with great rapidity, causing epidemics in infants and children; it may produce severe dysentery also in adults. It differs from all other dysentery bacilli in fermenting lactose, but produces its own specific antigens and agglutinins in the body.

Protozoal or Endemic Dysenteries— (1) Amoebiasis, or infection nith the dysentery amoeba (Endamoeba [*Entamoeba*] *histolytica*, F. R. Schaudinn, 1903), includes (a) primary intestinal amoebiasis or amoebic dysentery and (b) secondary amoebiasis—hepatic amoebiasis—or amoebic abscess of the liver, lung, brain or spleen, sometimes also amoebic extraintestinal ulcers (of buttocks or perineum) and amoebic invasion of the skin. (2) Balantidiasis, or infection of the intestinal canal with an infusorian, *Balantidium* coli. The course and pathology of this disease resembles amoebic dysentery. This infection is rare in man, but common in animals, especially pigs and larger apes. (3) Coccidiosis (*q.v.*), an infection with *Isospora hominis,* a rare disease of the intestinal tract of man. (4) Giardiasis (or lambliasis). an infection of the small intestine with Giardia intestinalis, a protozoan flagellate, common in children and producing a mucoid diarrhea. (5) Malarial dysentery, the passage of blood and mucus in the course of infection with the malaria parasite (Plasmodium *falciparum*), which congregates in the capillaries of the intestinal walls (see MALARIA). (6) Leishmania1 dysentery. an infection of the intestinal canal with the parasite of kala-azar (Leishmania donovani), when these organisms are found in the pathological exudate in the feces (see LEISHMANIASIS).

Helminthic Dysenteries.—A dysenteric syndrome is evoked by ulceration and inflammation, and subsequently by the formation of adenopapillomata in the intestinal tract by deposition of the eggs of certain trematode worms (or flukes) of the Bilharzia genus, which are those known as the bilharzial dysenteries (see SCHISTOSOMIASIS). Of these the most important is Bilharzia (or *Schistosoma*) mansoni in Africa and South America. Two other species, B. haematobia and B. japonica, may occasionally give rise to similar phenomena. Some other trematodes may evoke dysenteriform symptoms of a minor degree, such as the small fluke Heterophyes heterophyes (in Egypt), and those which inhabit the intestinal tract, and a much larger species, *Fasciolopsis* buski (in China). Of the nematodes the most striking example is *Oesophagostomum apiostomum,* commonly found in monkeys, but rarely in man, in southern Nigeria and central Africa and on the Amazon river. These worms encyst in the mucous membrane of the large intestine, thereby giving rise to dysenteriform symptoms. A small nematode, *Strongyloides* stercoralis, which is found in most tropical countries, has been accredited, on rather slender grounds, with similar properties, although it does not appear to burrow into the mucous membrane.

This formidable list does not exhaust the known causes of dysentery. There are the various forms of colitis, which are found in civilized peoples all over the world, the exact etiology of which remains obscure. These include mucous colitis, a secretory neurosis of the large bowel, which gives rise to diarrhea with the passage of much ropy mucus and, occasionally, of blood. Membranous colitis is an exaggerated form of this disorder in which casts of the mucous membrane appear in the stools, accompanied by blood and mucus. Idiopathic ulcerative colitis (colitis gravis) is a very severe. and sometimes fatal, disease of the colon with the passage of blood-stained mucous discharges, eventually producing severe anemia, toxemia and death. It is mainly a disease of early adult life and is liable to remissions and sudden exacerbations. By reasons of its course and manifestations it is liable to be confused with the other forms of bacillary dysentery of which the cause is accurately known. Mercurial colitis is one of the clinical manifestations of mercurial poisoning and closely resembles the above, and a somewhat similar condition is sometimes observed in the uremic state. Other familiar disorders, such as carcinoma of the large intestine, cecum, colon or rectum, occasionally produce dysenteric symptoms long before their serious nature can be recognized. Polyposis, or multiple adenomata of the large intestine, may do the same, and simple polyps in the lower bowel may produce spasmodic contraction and passage of blood-stained mucus. Diverticulitis, a common affection of advancing age, lymphogranuloma of the rectum and Crohn's disease, or chronic cicatrizing enteritis, have also to be reckoned with. Intussusception of the small or large intestine may be associated with amoebic or bacillary dysentery, or, in small children, arise from irritation by a polyp. Submucous lipoma and Meckel's diverticulum may produce a tumour and blood and mucus in the feces. Finally, tubercular ulceration of the large intestine and septic ulceration of the rectum due to internal hemorrhoids must be included.

Bacillary Dysentery.—The bacillary dysenteries are characterized by inflammation of the mucous membrane of the large intestine and occasionally of the terminal portions of the ileum

which may lead to superficial necrosis. The symptoms are provoked by efforts of the body to rid itself of the products of this destruction. together with absorption of the exotoxins elaborated by the various dysentery bacilli. Death takes place from dehydration and intoxication. The infection is spread in most tropical countries by contaminated water, food and most probably by the housefly *(Musca domestica)* in those hot countries where this insect abounds. Carriers of dysentery bacilli must also be taken into account. The healthy carrier (that is, one who excretes dysentery bacilli without having suffered from the disease) is rare, but the convalescent carrier is comparatively common. The incubation period varies from three to seven days.

The clinical course of bacillary dysentery is extremely varied and ranges from comparatively mild types to acute fulminating cases with intense toxemia, in which death takes place within two to three days. The latter type has become increasingly uncommon. In most tropical countries an explosive diarrhea attacks most newcomers and is labeled in various places by appropriate synonyms. In Egypt it is familiar as "gippy tummy" and is usually due to *Shigella sonnei*. It is a fleeting but disagreeable disorder not attended by any serious aftereffects. In the acute type of bacillary dysentery the onset is abrupt and within a few hours there is fever with a temperature of 101°–105° F. The patient suffers from severe toxemia, and dehydration soon becomes obvious. Sometimes there is vomiting. Within three or four hours violent diarrhea sets in with severe colic and straining. Blood and mucous discharges are continuous and there is usually incontinence. Abdominal pain and tenderness are severe The colon is contracted. painful and spastic. In children the onset may be heralded by convulsions Chronic bacillary dysentery is an extremely exhausting, debilitating disease caused by chronic ulceration of the large intestine and was a common sequel in World War I, but later became rare.

The complications of bacillary dysentery are dysenteric arthritis (which resembles rheumatoid arthritis but is of a more fleeting character), conjunctivitis, iritis, neuritis and sometimes glomerulonephritis. Occasionally there is peritonitis and massive intraperitoneal serous effusions. The disease is diagnosed by the character and appearance of the stools. the serous and blood-stained mucus, by the isolation on culture of the specific organisms in which special selective media are employed (Liefson's desoxycholate-citrate agar). As seen by microscopy the characteristic cellular exudate of the discharges, such as pus cells and large histiocytes derived from the mucosa are important. In doubtful cases sigmoidoscopy may be employed when the typical granular appearance of the mucosa is distinctive.

Treatment.—The treatment of this group was revolutionized by the introduction of special sulionamide drugs—sulfaguanidine, sulfasuxidine and sulfadiazine. The former practice of drenching the intestinal tract by saline purgatives has been abandoned For any severe case rest in bed is imperative; in *S. shigae* infections the heart muscle may be damaged by the potent toxins of this organism. All food should be withheld for the first 48 hours, but plentiful amounts of nater should be permitted. The usual treatment involves prescribed dosages of sulfaguanidine; if a patient does not respond it is usually advisable to change over to some other sulfonamide, such as sulfasuxidine. It nas formerly thought that sulfaguanidine was bacteriostatic because of poor absorption, but it is now known that absorption takes place, though slowly, so that in overdosage toxic symptoms may result. Among these are obstruction of the renal tubules by crystals, leading to suppression; various toxic rashes; and sometimes acute psychoses. If sufficient fluid cannot be absorbed by mouth, parenteral salines should be given intravenously by drip transfusion. This prevents renal blockage which is especially dangerous in hot countries. Total and differential white blood counts should be made at suitable intervals to give warning of granulocytopenia, which may complicate sulfonamide therapy. Of the antibiotics. streptomycin has been found to be the best, especially in the more chronic stages of this infection. Other antibiotics have been used in the treatment of bacillary dysentery; for example, chloromycetin (chloramphenicol) has been used successfully in Hong Kong in association with sulfaguanidine. Aureomycin and terramycin also have been found equally effective.

The patient's pain and sleeplessness should be relieved Lavage of the lower bowel aith hot saline is comforting and suppositories containing local anesthetics relieve straining In *S shigae* infections antidysenteric antitoxin administered intravenously, if given nithin the first 24 hours, is still employed with good results. It is important that patients with subacute or chronic bacillary dysentery not be kept on semistarvation diet or they will develop evidence of hypoproteinemia. It is therefore necessary after the fifth day to provide a well-balanced, nutritious diet of high vitamin content and with a sufficiency of animal protein.

Amoebic Dysentery.— The *Endamoeba histolytica* is a protozoan which is essentially a tissue parasite and obtains its nourishment from the cells of the intestinal wall. It occurs in the human body in several stages. In the intestine, the trophozoite, or tissue-invading stage, is 20 μ to 30 μ in diameter, though *minuta* stages, 10 μ to 12 p are often present. There is a characteristic nucleus and a labile protoplasm composed of an inner granular and an outer hyaline zone. By means of pseudopodia the parasite progresses and ingests food, mostly consisting of red blood corpuscles and tissue cells. E *hzstolytica* has to be distinguished from *E coli*, and three other species of nonpathogenic amoebae which inhabit the intestinal tract of man

Cyst formation takes place for the purpose of transmission from one host to another Before this occurs all food contained in the amoeba is thrown out, a thin cyst wall is formed. and there is one large nucleus, constituting the precystic form. The cysts vary in size from 5 μ to 20 p in diameter. They contain at first a single nucleus, which soon divides into four, the daughter nuclei separating and taking up separate positions at opposite poles. There are also in the cytoplasm chromatoid bodies and sometimes glycogen vacuoles which show up with iodine. The cysts are formed within the amoebic ulcers and are then passed out in the feces. They remain viable for some days in water and apparently in this medium are passed on to another individual. Neither precystic forms nor cysts are produced in the metastatic lesions of amoebiasis.

Amoebic dysentery is usually much more chronic and insidious than is the bacillary disease. It also occurs as an endemic or sporadic infection. The incubation period is variable: it may be 60 days or longer, but in the Chicago outbreak of 1933 it was about a week, in some instances. Apart from individuals who manifest the symptoms of dysentery, there are many others in whom the cysts appear in the feces and these are known as "carriers." In England there are a number of healthy people who harbour the cysts, though indigenous amoebic dysentery is rare. Therefore, some believe that there are two strains of E. *histolytica:* one, the large strain, being high pathogenic; the other, with low invasive powers, not being so.

The pathology of amoebic dysentery consists of ulceration of the large intestine as a result of invasion of the submucosa by E. *hzstolytica.* Amoebic granulomata are irregular erosions of the mucosa and formations of granulation tissue. The ulcers may be of a large size and solitary, with normal intervening mucosa, or may become confluent. Multiple small ulcers covering the whole surface are known as "sea anemone" ulcers. The ulcerations are apt to congregate at the flexures.

The clinical picture in amoebic dysentery is extremely variable. It may constitute a trivial affection or be very severe; it may be transient, or last for many years. Two chief types may be distinguished. one with insidious onset commencing with diarrhea without much general disturbance; the other more acute with abdominal pain, colic and the passage of blood-stained mucous stools. Very acute fulminating attacks are rare. As a rule three or four stools are passed in the day. Incontinence and tenesmus are uncommon. The chronic type is much commoner, and this manifests itself by frequent remissions and exacerbations with vague abdominal disturbances. There is usually tenderness and induration over the caecum in the right and over the sigmoid in the left iliac fossae. The stools are much more offensive than those passed in the bacillary dysenteries, and contain much altered

blood intermingled with the fecal contents, but in the later stages are dark and fluid; solid feces with congealed blood and mucus may be passed when the process is quiescent. As a rule there is no fever, but nausea is often present. Vomiting is uncommon. The disease tends to recovery as a rule and is the outcome of the activities of the parasite and the recuperative powers of the intestine. Rare forms are those with fever and toxemia, which are probably due to secondary bacterial infection of the ulcerations. Death takes place either from perforation of the large intestine and consequent peritonitis, from intestinal hemorrhage or from gangrene of the bowel, especially at the site of the flexures. In the chronic stage, amoebic hepatitis frequently supervenes, there is a gradual loss of weight, the skin becomes dry and sallow and introspective neurasthenic manifestations make their appearance.

In amoebic dysentery there are often long periods of latency which may last a year. or even longer, and it is in these cases that liver abscess may intervene. In others the disease appears to be confined to the caecum (amoebic typhlitis) and may closely simulate appendicitis. Attention has been increasingly drawn to the "amoeboma." This is a tumour composed of hyperplastic granulation tissue occurring at different sites, in the ileocaecal region, the transverse colon, sigmoid flexure or rectum, which closely simulates a malignant growth, and is apt to appear in chronic amoebic dysentery. It may also give rise to a local intussusception which complicates the clinical picture still further. Pericolic amoebic abscesses may also form, but are rare. Complications are amoebic hepatitis (fever, leucocytosis and hepatic pain) and amoebic abscess of the liver and of the lung, rarely of brain or spleen. Amoebic abscess of the epididymis has been reported, while fistulas of the buttocks, perianal amoebic ulcers and abscesses, and similar lesions of the cervix uteri in the female have been described. Amoebic invasion of the skin, producing gangrene, is apt to occur from a pararectal abscess or from a liver-abscess sinus. or to follow on abdominal operation in a subject who is infected with *E. histolytica.* Sometimes these accidents happen in those who have never suffered from clinical amoebic dysentery but nho harbour *E. histolytica* cysts in the feces.

Apart from the information to be obtained from the history of the patient and character of the stools, absolute diagnosis is founded upon the detection of *E. histolytica* in the feces. In the acute stage this is comparatively easy when the large active tissue-invading trophozoites can be recognized with ingested red blood corpuscles. They are not always evenly distributed and those portions of the stools containing blood and mucus should be selected. The examination should be conducted while the excreta are warm, since these organisms soon deteriorate and die. It is often more practicable to make scrape preparations by a special instrument (Volkmann's spoon) directly from the rectal mucosa through a proctoscope or sigmoidoscope. In the chronic stages the cysts are found in the diarrheic feces and are often present in enormous numbers, but they tend to vary from day to day and there may often be long periods during which they are absent altogether.

Sigmoidoscopy and proctoscopy are most important. By means of these instruments the characteristic ulcers may be demonstrated. These are often of a small size and superficial character. There may be small submucous hemorrhages and, in the chronic stage, minute pittings with crateriform edges giving rise to what is known as the "pigskin appearance." As a rule, amoebic lesions are visible in the lower rectum in the vicinity of Houston's valves and therefore can easily be seen through a simple proctoscope.

Treatment.—There is one drug, emetine, which is specific for amoebic dysentery. This is the alkaloid of ipecacuanha, which destroys the parasite in very dilute solutions (1:1,000,000). In the acute stages, emetine hydrochloride is injected deeply subcutaneously. Although this method controls the acute manifestations, it does not eradicate the infection and has no effect upon *E. histolytica* cysts. For this purpose emetine bismuthous iodide is given. This compound is decomposed in the intestinal tract into bismuth sulfide and emetine is liberated on the surface of the ulcers. It is best given in enteric or gelatine-coated capsules. A dispersible form has been prepared which is very efficacious. The dose is spread over a period of 10 to 12 days. The patient should be confined to bed on a light diet and the drug should be administered at 10 P.M. No food should be taken after 6 P.M. and a sedative should be taken one-half hour before the specific drug. Another amoebicidal drug is quinoxyl (yatren) given in the form of retention enemata. The bowel should be cleansed with a 2% sodium-bicarbonate solution beforehand. Other drugs are carbarsone, stovarsol and diodoquin. The latter, another quinoxyl compound, is useful in clearing up the carrier state. Other specific drugs in the treatment of the dysenteries are atabrine (mepacrine) and chloroquine in giardiasis, paludrine in malarial dysentery. neostibosan in leishmaniasis and sodium antimony tartrate in bilharziasis. *See* also BACTERIAL AND INFECTIOUS DISEASES; PARASITIC DISEASES; *see* also references under "Dysentery" in the Index volume.

DYSMENORRHEA, or pain on menstruation. *See* GYNECOLOGY.

DYSON, SIR FRANK WATSON (1868–1939), British astronomer and ninth astronomer royal, was in 1921 awarded the royal medal for his important investigations of the distribution and movements of stars and the bearing of these upon the structure of the stellar universe. He was born near Ashby-de-la-Zouch, Leicestershire, on Jan. 8. 1868. and was educated at Trinity college, Cambridge. In 1894 he became chief assistant at the Royal observatory, Greenwich, and in 1905 was appointed astronomer royal for Scotland. He returned to Greenwich as astronomer royal in 1910 and held that post until his retirement in 1933. He was elected fellow of the Royal society in 1901 and was knighted in 1915. His extensive observations of the spectrum of the corona and chromosphere of the sun during an eclipse were published in *Determination of Wave Length From Spectra Obtained at the Total Solar Eclipses of 1900, 1901 and 1905* (1906). His *Eclipses of the Sun and Moon* (1937), written with R. v. d. R. Woolley, who later became the 11th astronomer royal. was a standard textbook in the late 1950s. Dyson died at sea, during a voyage from Australia. on May 25, 1939. (O. J. E.)

DYSPEPSIA: *see* INDIGESTION; GASTROINTESTINAL TRACT, DISEASES OF.

DYSPROSIUM, a chemical element of the rare-earth group, is a hard and very reactive metal. It is oxidized by air and by water; below −123° C. the metal is ferromagnetic and at very low temperatures it is a super-conductor. Because of the presence of unpaired electrons the trivalent ion is strongly paramagnetic; dysprosium oxide and holmium oxide are the most powerful paramagnetic substances known.

Lecoq de Boisbaudran proved the existence of this element in 1886; it was not until 1906, however, that G. Urbain obtained a reasonably pure fraction. The name dysprosium comes from the Greek *dysprositos,* meaning "hard to get at." The element occurs in a number of minerals; those commercially important are monazite, gadolinite, euxenite, xenotime and samarskite. It also occurs in the products of atomic fission. Before the mid-1940s the element was separated by fractional crystallization; since that time commercial processes have used ion-exchange methods.

The symbol for dysprosium is Dy, the atomic number is 66 and the atomic weight is 162.50; the naturally occurring stable isotopes of mass numbers 156, 158, 160, 161, 162, 163 and 164 are known. Dysprosium behaves as a typical trivalent rare earth and forms a series of pale yellow-green compounds. The ionic radius

is 0.908 A. Solutions of Dy^{3+} are also a pale yellow-green and show sharp, discrete absorption bands in the ultraviolet and visible regions of the spectrum that may be used for quantitative analysis.

The metal has been prepared by thermoreduction of the anhydrous halides with alkali or alkaline earth metals. The melting point is in the range 1475" to 1500° C.; its density is 8.565 g. per c.c. for the hexagonal close-packed form.

Because of its high melting point and relatively high neutron cross section (about 1000 barns), dysprosium metal in the early 1960s was being considered as a material for constructing control rods for nuclear reactors. Its compounds have been used as catalysts in the oil refining industry, as components in some electronic equipment and as phosphor activators. See RARE EARTHS.

(LD. B. A.)

DZERZHINSK, a town of Gorki *oblast* in the Russian Soviet Federated Socialist Republic of the U.S.S.R., stands on the left bank of the Oka, 18 mi. above its confluence with the Volga at Gorki, and on the Moscow-Gorki railway. Pop. (1959) 163,000. Part of the Gorki conurbation, Dzerzhinsk and its satellite townships stretch for 15 mi. along the river, amid pine woods and lakes. It is an important centre of the chemical industry, producing phosphate and nitrate fertilizers, material for artificial textiles and caustic soda. The production of building materials, engineering and flour milling are also carried on. A power station near the town operates on local peat. (R. A. F.)

DZERZHINSKI (Pol. DZIERZYNSKI), **FELIKS EDMUNDOVICH** (1877–1926), Bolshevik revolutionary, a Pole who rose to be head of the political police of the U.S.S.R., was born in Vilna on Sept. 11, 1877, the son of a country squire. He joined the Social Democratic party of Poland and Lithuania in 1895 and two years later was arrested at Kaunas and exiled to Siberia for political agitation. Escaping in 1899. he was rearrested in Warsaw in 1900, but escaped again in 1902 and went to Berlin. After he had taken part in the revolution of 1905–06 in Poland, there followed further years of exile until 1912 when he returned to Warsaw. was arrested again and sentenced to nine years' hard labour. After the Russian Revolution of March 1917 he was released and. as a member of the central committee of the Communist party and of the military revolutionary committee of the Petrograd soviet, played an important part in organizing the Bolshevik Revolution in November. In Dec. 1917 he organized the *Cheka*, the security and terror arm of the Communist party, and became its chairman, winning a reputation for fanaticism in the cause of Communist power. In July 1920, when the Red army was marching on Warsaw, he was a member of a Polish Revolutionary committee in Bialystok, intended to be the government of Poland. After 1921. at his own wish, he devoted himself mainly to economic matters, though retaining general supervision over the security and terror apparatus—renamed O.G.P.U. in 1922—in his capacity of people's commissar for internal affairs, which he had been from 1919. In 1924 he was placed at the head of the supreme economic council. He died suddenly, in Moscow, on July 20, 1926. (L. B. Sc.)

DZHAMBUL (formerly AULIE-ATA), an *oblast* and town lying in the south of the Kazakh Soviet Socialist Republic of the U.S.S.R. The *oblast* (formed 1939) consists of a narrow strip of fertile irrigated land along the foothills of the Karatau and Kirgiz mountains, and a wide strip of desert including the sandy Muyun-Kum south of the Chu river, and the clay desert of Bet-Pak-Dala to the north. The climate is continental with hot, dry summers and cold winters. Sugar beet, cotton, wheat, rice and tobacco are grown along the Chu, Talass and Assa rivers. In the drier areas cattle, sheep, horses and camels are raised. Apart from the large phosphate works built in 1945 at Chulak-Tau in the Karatau mountains, industry consists mainly of processing agricultural products.

The population, 561,546 in 1959 (359,876 rural), consists mainly of Kazakhs and Russians, with some Uzbeks, Ukrainians and Koreans. In the early 1960s there were more than 460 schools and 270 libraries in the *oblast*.

The Turksib railway traverses the *oblast* with a branch line from Dzhambul to Chulak-Tau. Lugovoi is the junction with the Frunze-Rybachye line. A new line joining the Turksib railway at Chu with the Balkhash-Karaganda line at Mointy was built during the fourth Five-Year plan (1946–50).

DZHAMBUL, the capital of the *oblast*, is one of the oldest cities of Kazakhstan. Pop. (1959) 67,000. It stands on the site of Taraz. a 5th-century city, later called Yany (or Yangi) and then Aulie-Ata. In 1933 the city was renamed Mirzoyan, and again in 1937 after the Kazakh poet D. Dzhambul (1846–1945). It has sugar-refining, fruit-canning and wool-washing plants.

(G. E. WR.)

DZIERZONIOW (Ger. REICHENBACH) is a town in the Wroclaw (Breslau) *wojewodztwo* (province) of Poland. Pop. (1960) 27.000. It lies on the Pilawa (Peile) river, below the northeastern slope of the Sudetens and 48.3 km. (30 mi.) S.S.W. of Wroclaw, on the main road to Prague. It is the chief town of a district of the same name and a supply centre for an old established textile (flax and cotton) region in Lower Silesia. Heavy industry and the electrotechnical industry have also been developed there.

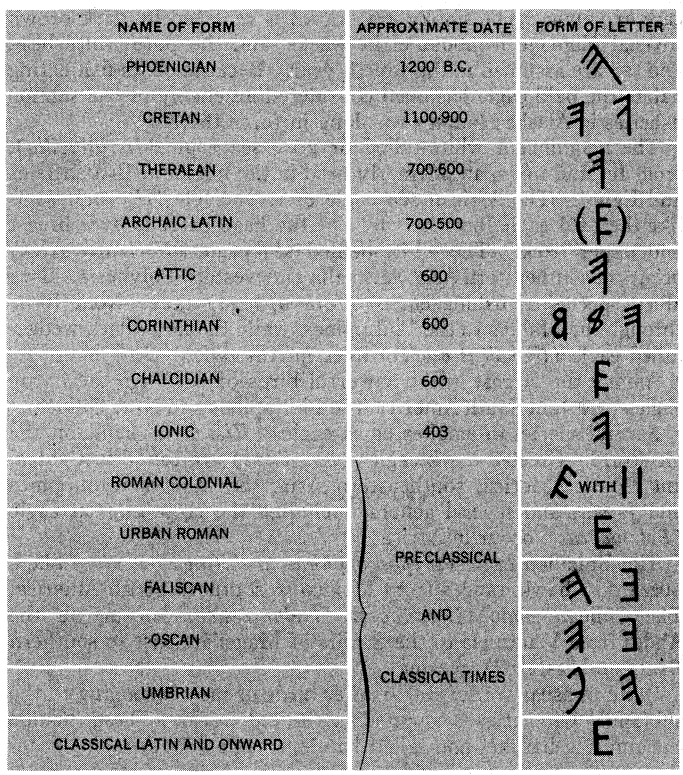
Tradition places Reichenbach's origin in the mid-12th century and it received town rights in the 13th century. On the division of Wroclaw principality, the town passed to the duke of Ziebice (Münsterberg), who in 1335 became a vassal of the Bohemian king. After the period of Habsburg domination it passed in 1712, with most of Silesia. to the Prussians. In 1945, with Silesia, it returned to Poland and was renamed Dzierzoniow after the Polish patriot-priest Jan Dzierzon (1811–1906). (K. M. WI.)

DZUNGARIA, DSONGARIA or JUNGARIA, a former Mongolian kingdom of central Asia, raised to its highest peak by Kaldan or Bushtu Khan in the latter half of the 17th century. but completely destroyed by Chinese invasion about 1757–59. It derived its name from the Dsongars, or Songars, who were so called because they formed the left wing (*dson*, left; *gar*, hand) of the Mongolian army. Its widest limit included Kashgar, Yarkand, Khotan (*qq.v.*), the whole region of the Tien Shan (*q.v.*) and the greater proportion of that part of central Asia which extends from 35" to 50° N. and from 72° to 97° E.

Dzungaria now forms the northern part of the Sinkiang Uigur Autonomous Region (*see* SINKIANG). It is a sparsely settled semiarid area occupied mainly by non-Chinese people, most importantly the Kazakhs. Mongols. and various Muslim groups. It consists largely of a basin north of the Tien Shan, between those mountains and the Altai range, bounded by the Soviet Union on the west and by the Mongolian People's Republic on the north and east. Urumchi (Ti-hua), the chief city, is the capital of Sinkiang, and lies on the route of the railway under construction between Lan-chou and Alma-Ata. (R. M.; X.)

E THE fifth letter of the alphabet, is derived from Semitic 𐤄 (a consonant representing a sound similar to the English "h"), Greek 𐌄, 𐌴 or 𐌴, and Latin **E**. The Semitic character may have derived from an earlier pictograph representing a lattice window or a fence. Forms in use at Corinth were 𐌲 or **B**. The uncial form was from the 4th century A.D. rounded, 𐌴, and the cursive form was also round, 𐌴. From these developed the Carolingian **e** from which the modern minuscule *e* is derived.

The sound represented by the letter was a mid front vowel corresponding, though inexactly, to the sound of English a in *take*. The latter is a diphthong, whereas *e* represented an unmixed vowel sound, such as that heard in French *tête* or *été*. In Greek ε stood



THE DEVELOPMENT OF THE LETTER "E" FROM THE PHOENICIAN THROUGH CLASSICAL LATIN TO THE PRESENT FORM

for a short, close vowel as opposed to η whose sound was long and open. although in all local alphabets, especially in early times, this distinction was not exactly observed. In Attic Greek the long. close sound was expressed by EI. In the Latin alphabet the letter **E** did duty for all shades of the sound, long or short, close or open. (*See* ALPHABET.)

In English an extensive change took place in the sound of the long vonel during and after the later Middle English period (probably between the 11th and 17th centuries). Just as the sound represented by *a* moved forward till it now covers the ground of that formerly represented by e, so the latter moved upward, encroaching upon and occupying the territory of the sound of *i*, which became a diphthong. (For a fuller discussion of these sound changes, see the subsections on phonology in ENGLISH LANGUAGE: *Middle English* and *Modern English.*) The sound of English long *e* is now a close high front vowel, as when written double (*e.g.*, in *feed?* or when followed by a single consonant plus silent final e (*e.g.*, in *precede*), that of short *e* a more open and less high front vowel, as in *bed*, that has not to any great extent shifted from what may be called its original position (cf. the sounds of French *été* and English *bed*). When followed by *r* the sound is modified and is less high, as in *here*. In the word *there* the vowel has the same sound as that of a in *hare*. In many English words a mute final *e* is employed as a device to mark the fact that the preceding vowel is long. e.g , *take, wine, stone*. This occurs only when the final *e* is separated from the long vowel by a single consonant. Again, in words such as *added, rotten*, the letter represents little more than a voice glide.

In music. E is the fifth note of the musical alphabet and the third degree of the natural scale of C. Its syllabic name, employed in France and Italy, is *mi*. (J. W. P.)

EA (ENKI), the third member of the primary triad of the Sumerian pantheon, Anu and Bel (*qq.v.*) being the first and second members. His chief city was Eridu, in southern Babylonia. The name Enki means "Lord of the Earth"; *i.e.*, of the earth downward, and so of the deep. The god is mentioned on Sumerian texts of Lagash, *c.* 2400 B.C., as king of the *ab-zu* or *apsu* (fresh-water deeps) and as an oracle god. King Shulgi of Ur built a temple for Enki, and his son Amar-Sin added the *ab-zu* fresh-water basin *c.* 2000 B.C. Hammurabi, in his code, attributes his gift of understanding to Enki, whom he describes as the wisest of the gods, the all-knowing, with power to deprive men of understanding.

On Sumerian literary tablets of the 2nd millennium B.C. (but based on earlier sources) the building of the *ab-zu* temple is attributed to and was initiated by the divine Enmerkar, ruler of Erech (Uruk; modern Warka). The tablets tell how the goddess Inanna (Ishtar) goes to Eridu to ask the wise Enki how to capture one who has wronged her; and how she obtains more than 100 heavenly laws from the near-drunken god, who repents of his generosity, attempts to recover the laws but is outwitted by her messenger. These Sumerian tales present the god, as Enki, in a less pacific character than do the Semitic stories where he is Ea. The organizer of the earth is not always wise: he is on occasion foolish.

As Ea, a name written by means of two signs signifying "house" and "water," this deity was the god of the fresh water below the earth. His temple at Eridu was *é ab-zu*, house of *apsu*, the fresh-water deeps below the earth, from which it is separated by clay. Ea's membership of the divine triad derives from his rank as *shar apsi*, king of the *apsu*. Appropriately he is figured as a man covered with the body of a fish.

His works are works of beneficence to mankind. In the story of the goddess Ishtar's descent into the underworld he is described as creator god. In the deluge story he saves Utnapishtim, the Babylonian Noah. Ea's characteristic is wisdom. but this includes cunning deceit. as shown in his behaviour to Adapa in the myth of mankind's loss of immortality. He is patron of exorcists, the "sons of Eridu." His holy waters are used to purify places, priests and utensils at ceremonies of exorcism, besides houses, temples, cities and persons inhabited by evil spirits. Because sickness was thought to be devils' work, he is the god of physicians, of men who "know water," *i.e.*, the water of Ea. With his wisdom kings and craftsmen are endowed: the arts of civilization are by his grace.

The name Ea first appears in general use in theophoric names after the dynasty of Akkad (late 3rd millennium B.C.) but without the divine determinative. See also BABYLONIA AND ASSYRIA. *Religion;* OANNES; and references under "Ea" in the Index volume. (T. FH.)

EADS, JAMES BUCHANAN (1820–1887), U.S. engineer whose reputation rests principally on his work in deepening and fixing the channel at the mouth of the Mississippi river, was born

at Lawrenceburg, Ind., on May 23, 1820. His first engineering work involved the salvage of sunken steamers in the Mississippi, using a diving bell he invented and patented. After a brief, unsuccessful venture in a glassworks at St. Louis, Mo., he returned to salvage work. Upon the outbreak of the American Civil War, he submitted to the U.S. government a bold proposal to construct, within 65 days, seven 600-ton gunboats, steam-powered and armour-plated; the first of these actually was completed in 45 days and the rest soon thereafter. During the war Eads built or converted a total of 25 vessels that saw service on the Mississippi and its tributaries and in the Gulf of Mexico. His next important engineering achievement was the construction of the great steel arch bridge across the Mississippi at St. Louis (1867–74); the specifications—for a 520-ft. clear span and 50-ft. clearance—were pronounced impractical by many of the leading civil engineers of the time.

Among engineers, Eads is best known for opening and maintaining a ship channel at the mouth of the Mississippi. By means of an ingenious system of jetties that redirected and accelerated the current, the river was made to scour its own channel and deposit its load of silt at sea. Shortly before his death, Eads proposed a scheme for a ship railway across the isthmus of Tehuantepec, opposing the proponents of the Panama canal. He died at Nassau, in the Bahamas, on March 8, 1887.

EAGLE, any of several large day-flying birds of prey which along with hawks, harriers and old-world vultures comprise the family Accipitridae. Eagles belong to the subfamily Buteoninae, typified by the European buzzards and large American hawks (*Buteo*); they are distinguished from others of the subfamily by their large, strongly hooked beak, great talons and keen vision. They range throughout the world, and are famous for their powerful, stately flight.

Since ancient times eagles have been used as symbols of empire, of courage. of military prowess. Their likeness is found on Greek and Roman ruins: coins and medals. The bald eagle *(see* below) was adopted as the emblem of the United States, probably because of the ancient usage of the symbol and also because of the b'rd's magnificent majesty in flight—an almost effortless mastery of the air.

GEORGE M. BRADT FROM NATIONAL AUDUBON SOCIETY

GOLDEN EAGLE (AQUILA CHRYSAËTOS), IN JUVENAL PLUMAGE

The typical eagles (*Aquila*) include species with "booted" legs, feathered to the toes. The best known is the golden eagle *(A. chrysaëtos)*, inhabiting mountainous or rocky regions of North America, Europe and Asia. They build a large nest of sticks on cliffs or tall trees, returning year after year to lay one to four large white eggs mottled with brown. The young, clad in white down, assume the dark brown juvenal plumage after ten weeks, and molt annually until the adult golden brown is acquired at four years. Rirghiz Tatars used the golden eagle to capture antelopes; but in Europe, during the height of falconry, it was flown only by kings. *(See* FALCONRY.)

Of eight geographic races, the typical form is found in Europe, another (A. *c. fulva*) breeds in Scotland and the Hebrides. while a third (A. *c. canadensis*) is familiar in North America from Alaska and northeastern Canada south in the Appalachians to North Carolina, Tennessee and central Mexico, especially in the western mountains. Other races are found in Spain, northwest Africa and Asia. Related species include the spotted eagle (*A. clanga*) and the imperial eagle *(A. heliaca),* southern Europe to China: the tawny eagle *(A. rapax)*, Africa and India; and several smaller species in Asia, Africa and eastern Europe.

The sea eagles (*Haliaeetus*) range across all continents except South America, and may be distinguished from typical eagles by the naked lower leg. They generally eat fish, and are largely robbers and scavengers. Of the eight species. the noble-looking bald eagle *(H. leucocephalus)*, is confined to North America. The bald eagle is not in fact bald; the name derives from the conspicuous appearance of its white feathered head. The typical race breeds in the southern United States and northern Mexico, while a larger form *(H. l. alascanus)* occurs from Connecticut, the Great Lakes and Washington to northern Canada and Alaska. The nest is a large tangle of sticks atop a large tree or pinnacle of rock. within easy flight of sea, lake or stream; one to three eggs hatch in 35 days, both parents sharing incubation and care of young. The smoky gray down is replaced by dark brown juvenal plumage in about eight weeks, and the pure white head and tail are assumed in the fourth year. Because of its fish-eating habits the bald eagle has been considered an enemy of the salmon fisheries in Alaska; bounty was long in force there.

CY LA TOUR

BALD EAGLE (HALIAEETUS LEUCOCEPHALUS)

The magnificent white-tailed or gray sea eagle (H. *albicilla*), from Iceland to Japan, formerly bred in the northern British Isles and Egypt. The African sea eagle or river eagle (*H. vocifer*) is like the bald eagle, but the white of the head extends over breast and upper back. The white-bellied sea eagle *(H. leucogaster)* occurs in southeastern Asia, Australia and western Polynesia. Two allied species of fishing eagles *(Icthyophaga)* range from India through the Malays to the Philippines, while the large dark wedge-tailed eagle (*Uroaëtus audax*) lives in Australia.

Among the largest, most powerful birds of prey are the harpy eagles (*q.v.*), in South America, the Philippines and New Guinea.

Several species of smaller hawk eagles *(Hieraaetus)* inhabit the old world. Crested hawk eagles (*Spizaëtus*) are found in Central and South America, southeastern Asia, the Malays, Philippines and Japan; and several genera, including the large martial eagle *(Polemaetus)*, occur in Africa.

The Brazilian eagle *(Hypomorphnus urubitinga)*, a large black buzzard or hawk. ranges from Mexico to southern South America. The Chilean eagle (*Geranoaetus melanoleucus*) occurs in the Andes from Venezuela to the Straits of Magellan, east to southern Brazil and eastern Argentina.

Quite unusual are several smaller birds of prey belonging to the subfamily Circaetinae, confined to the old world. These include the amazing batlike, bob-tailed bateleur eagle (*Terathopius ecaudatus*) of Africa; the harrier eagles (*Circaëtus*) of Africa, Asia and southern Europe; and the serpent eagles of southeastern Asia and the Malays and Philippines (*Spilornis*), central Africa *(Dryotriorchis)* and Madagascar (*Eutriorchis*).

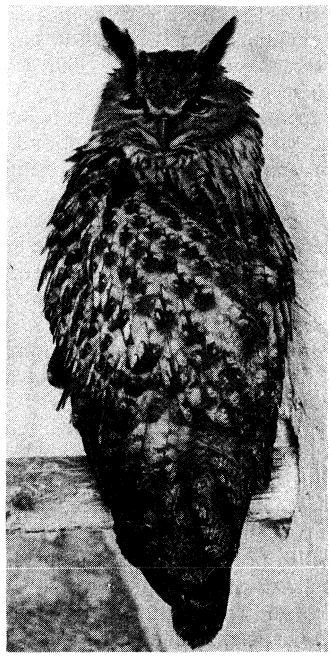
One old world species of vulturelike bird has been called eagle. its feathered head being quite different from the naked heads of vultures. This is the vulturine fish eagle (*Gypohierax angolensis),* a striking white and black bird of central west Africa. Intermediate between eagles and vultures is the so-called bearded vulture or lammergeier (*q.v.*), now considered to be a giant kite. Any large bird of prey is likely to be called an eagle in a loose way; for example, one large owl of the old world is often called "eagle owl" (*q.v.*). (G. F. Ss.; Ht. Fn.)

EAGLE OWL *(Bubo bubo)*, an owl inhabiting Europe and Asia, though only a straggler in most of Great Britain, and characterized by its large size (often 26–28 in. long), two tufts of feathers on the head and large orange eyes. The over-all coloration is tawny, mottled with brown, lighter below. The eagle owl roosts and breeds within rocky niches and hollow trees. From the vantage of a nearby branch this twilight hunter perches while he surveys his territory in search of prey, mainly

rodents, hares, rabbits and large game birds. It is allied to the great horned owl (*q.v.*; B. *virginianus*) of North America, but is larger.

EAKER, IRA CLARENCE (1896–), U.S. army officer, strategic air commander in Europe during World War II, was born in Llano county, Tex., on April 13, 1896. He entered the air service during World War I and during the next two decades became one of the U.S. army's outstanding pilots. Eaker led 12 B-17 Flying Fortresses in the first U.S. bombing attack against western Europe on Aug. 17, 1942. As commander of the 8th air force in England, he went to the Casablanca conference in Jan. 1943 and persuaded Winston Churchill and Franklin D. Roosevelt to give daylight bombardment a thorough trial rather than abandon it as had been recommended. Round-the-clock bombing of Germany was developed in concert with the Royal Air Force, which bombed by night. In Jan. 1944 Eaker moved to Italy and took command of the Mediterranean Allied air forces, including the U.S. 15th air force, which waged the strategic air offensive against Germany and the Balkans from bases in Italy. Eaker was promoted lieutenant general in 1943 and retired in Aug. 1937.

(A. GG.)



JOHN MARINUS FROM NATIONAL AUDUBON SOCIETY

EAGLE OWL (BUBO BUBO), ONE OF THE LARGEST OWLS

EAKINS, THOMAS (1844–1916), U.S. painter, considered one of the supreme masters of American art, was born at Philadelphia, Pa., on July 25, 1844. At the École des Beaux-Arts in Paris he studied with Léon Bonnat and Augustin Dumont and was the favourite pupil of Jean Gérôme. Later he studied in Spain. Returning to Philadelphia in 1870, he opened his own studio and studied anatomy at the Jefferson Medical college. In 1373 he began to teach at the Pennsylvania Academy of Fine Arts, where he eventually succeeded in transforming the entire course of study, particularly emphasizing the scientific study of anatomy and perspective. He performed many experiments in the photography of motion. In 1886 he was dismissed after he undraped a male model before a mixed class, the culminating incident of a series in which his teaching fervour offended prudish tastes.

A large canvas, "The Gross Clinic," completed in 1875, has sometimes been called Eakins' masterpiece. It contains life-sized figures and portrays the demonstration of a surgical operation to a group of medical students. He did another medical group, "The Agnew Clinic," in 1889.

Eakins executed several pieces of sculpture. With his pupil Samuel Murray (1870–1941) he modeled the heroic "Prophets" for the Witherspoon building, Philadelphia. There is a sculptural quality in his painting and it was not unusual for him to make studies in clay for them. He experimented in many directions. Among his sporting subjects are "Max Schmitt in a Single Scull" (1871) and "Between Rounds" (1899). "The Fairman Rogers Four-in-Hand" (1879) demonstrates the meticulous study that he devoted to a composition. His genius for penetrating, uncompromising character analysis that sometimes offended his sitters can be seen in his many figure studies and portraits.

Eakins died in Philadelphia on June 25, 1916. In his last years he began to receive some recognition, but it was not until after his death that his real stature was appreciated.

See L. Goodrich, *Thomas* **Eakins,** *His Life and Work* (1933).

EALING, a municipal (1901) and parliamentary borough of Middlesex, Eng., returning two members (for Ealing South and Ealing North—Hanwell being included in Southall for parliamentary purposes). It is a suburb of London, 8½ mi. W. of Hyde Parkcornerby road. Pop. (1961) 183,151.

Roman remains have been found, and the Saxon Gillingas who were in the area by the 8th century gave Ealing its name. Hanwell and Greenford (including Perivale) urban districts were added in 1926 and Kortholt in 1928. The area, though largely residential, has many industries, producing scientific instruments, foodstuffs, pharmaceutical products, plastics, glass, silk thread, wallpaper, vacuum cleaners, engineering appliances, etc. The borough has a technical college and an art school. The open spaces include the ancient common (47 ac.); Walpole park (30 ac.), where Pitshanger manor house contains the central library; and Gunnersbury park (186 ac.), the former estate of the Rothschild family purchased in 1925 and shared by Ealing, Acton, and Brentford and Chiswick councils. Gunnersbury house in the park is a local history museum. Famous names associated with Ealing include John Henry Cardinal Newman and Bishop G. A. Selwyn who were educated at Great Ealing school; William Makepeace Thackeray who went to a private school there; Louis Phillipe, later king of France, who taught at Great Ealing school; and Spencer Perceval, the prime minister. At Hanwell is a railway viaduct built by I. K. Brunel, at Perivale a tiny timber-spired church dating to the 12th century, at Greenford a church with a 12th-century structure on the tower and at Northolt an ancient village green and church.

EAR, ANATOMY OF. The ear of vertebrates is the organ in which are centred the senses of hearing and equilibrium. This article is concerned mainly with the structure and functions of the vertebrate organ, especially the human ear; for a discussion of invertebrate "ears" and the physiology and evolution of hearing see HEARING. The human ear is divided into three parts—external, middle and internal.

External Ear.—The external ear consists of the fleshy, cartilaginous outer flap (auricle or pinna) and the opening and its inwardly directed tube (external auditory meatus) (fig. 1). The auricle is formed by a yellow fibrocartilage covered by skin. Round the margin in its upper three-quarters is a rim called the helix, in which is often seen a little prominence known as Darwin's tubercle, representing the folded-over apex of the ear of a prick-eared ancestor. Concentric with the helix and nearer to the meatus is the antihelix, which, above, divides into two ridges. Surrounded by the antihelix is a deep pit known as the concha, from whose anterior part the external meatus passes inward into the skull. Overlapping the meatus in front is a flap called the tragus, and below and behind the meatus another small flap, the antitragus. The lower part of the auricle is the lobule, which contains no cartilage. The auricle can be moved slightly (or considerably in some persons) by the anterior, superior and posterior auricular muscles.

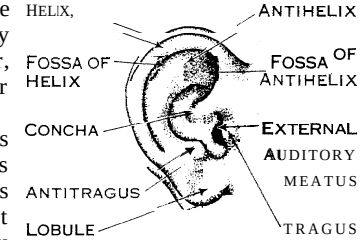


FIG. 1.—STRUCTURE OF THE OUTER EAR

The external auditory meatus is a tube about an inch long, its outer third being cartilaginous and its inner two-thirds bony. It is lined in its whole length by skin, the sweat glands of which are modified to secrete a waxlike substance, cerumen. Internally the meatus is closed by the tympanic membrane or drumskin, the eardrum.

Middle Ear.—The middle ear; or tympanum (fig. 2), is a small cavity in the temporal bone. From it the Eustachian tube runs forward, inward and downward to open into the nasopharynx, thus admitting air into the cavity. From the upper part of the posterior wall of the middle ear an opening leads backward into the air cells of the mastoid process. Lower down is a little pyramid that contains the stapedial muscle, and at the base of this is a small opening that allows passage of the chorda tympani branch of the facial nerve.

The roof of the tympanum is formed by a very thin plate of bone which separates the cavity from the middle depression (fossa) of the skull. Below the roof the upper part of the tym-

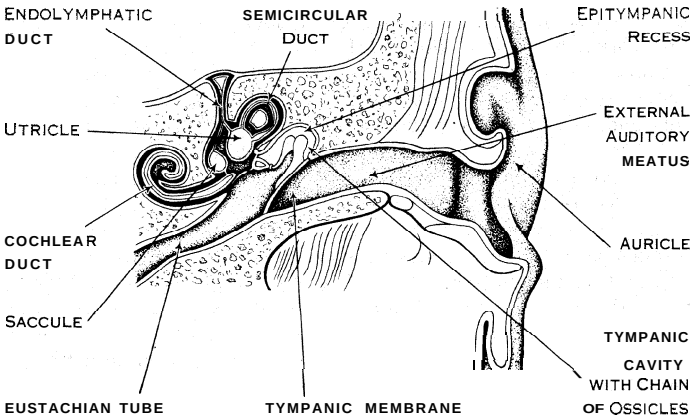

FIG. 2.— DIAGRAMMATIC VIEW OF THE ORGAN OF HEARING. SHOWING THE RELATIONS OF THE EXTERNAL, THE MIDDLE AND THE INTERNAL EAR

panum is somewhat constricted off from the rest, and to this part the term "attic" is often applied. The floor is a mere groove forined by the meeting of the external and internal walls. The outer wall is largely occupied by the tympanic membrane (fig. 2), which entirely separates the middle ear from the external auditory meatus; this membrane is circular and so placed that it slopes downward and inward from above, and forward and inward from behind. Externally the tympanic membrane is lined by skin, internally by mucous membrane: between these two layers is a firm fibrous tissue, convex inward about its centre to form the umbo. or navel.

The inner wall of the middle ear cavity shows a promontory caused by the spiral-shaped cochlea and grooved by the tympanic plexus of nerves. Above and behind the inner wall is the oval window; below and behind is the round window, closed by a membrane. Curving round above and behind the promontory and windows is a ridge caused by the Fallopian aqueduct or canal, which carries the facial nerve.

The whole tympanum is about half an inch long from front to back and half an inch high; it is spanned from side to side by three small bones (ossicles), of which the hammer is external. The hammer is attached by its handle to the navel of the tympanic membrane, whereas its head lies in the attic and articulates posteriorly with the upper part of the next small bone, the anvil. The long projection of the anvil runs downward and ends in a lens-shaped nodule that is jointed to the stapes, or stirrup bone. The two branches of the stirrup are anterior and posterior, nhereas its footplate fits into the oval window to which it is bound by the annular ligament. The stirrup thus lies nearly at right angles to the long process of the anvil. Bony processes of the hammer and anvil articulating respectively with the anterior and posterior walls of the tympanum form a fulcrum by which the lever action of the hammer and anvil is brought about. When the handle of the hammer is pushed in by the tympanic membrane, the head moves out; the top of the anvil, attached to it, also moves out; and the lens-shaped nodule moves in, pressing the stirrup into the oval window. Two minute muscles — stapedial and tensor tympani — modify the movements of the ossicles.

The mucous membrane lining the middle ear is continuous through the Eustachian tube with that of the nasopharynx and is reflected onto the ossicles, muscles and chorda tympani nerve. It is covered with minute, hairlike cilia except where it covers the tympanic membrane, ossicles and promontory; here it is stritified.

Internal Ear. — The internal ear, or labyrinth, consists of a bony and a membranous part, the latter contained in the former.

Bony Labyrinth. — The bony labyrinth is composed of the vestibule, the semicircular canals and the cochlea. The vestibule lies just internal to the rear part of the tympanum, and there would be a communication between the two, through the oval window, except that the footplate of the stirrup blocks the way. The inner wall of the vestibule is separated from the bottom of the internal auditory meatus by a plate of bone pierced by many minute passages for branches of the auditory nerve. At the lower part of this wall is the opening of the vestibular aqueduct, by means of which a communication is established with the rear cranial fossa. At the rear the three semicircular canals open into the vestibule; of these canals the external has two independent openings, but the superior and posterior join together at one end and open separately at their other ends. One end of each canal is dilated to form an ampulla. The superior semicircular canal is vertical, and the tno pillars of its arch are nearly external and internal. The external canal is horizontal, its two pillars being anterior and posterior. The convexity of the arch of the posterior canal is backward, and its two pillars are superior and inferior. Anteriorly the vestibule leads into the cochlea (fig. 2, 3), which is twisted $2\frac{1}{2}$ times round a central pillar called the modiolus — the whole cochlea forming a rounded cone something like the shell of a snail, though it is only about five millimetres from base to apex. Projecting from the modiolus is a horizontal bony plate, the shelflike osseous, or bony spiral lamina, which runs round the modiolus from base to apex; it stretches nearly halfway across the canal of the cochlea and carries branches of the auditory nerve.

Membranous Labyrinth. — The membranous labyrinth lies in the bony labyrinth but does not fill it; between the two is the fluid called perilymph, whereas inside the membranous labyrinth is the endolymph. In the bony vestibule lie two membranous vesicles, one of which, the saccule (fig 3), is in front, and the other, the utricle, behind; each has a special patch of sensory epithelium called macula to which twigs of the auditory nerve are supplied, terminating around specialized sensory hair cells.

Attached to the maculae are crystals of carbonate of lime called otoconia. The membranous semicircular canals are very much smaller in section than the bony; in the ampulla of each is a ridge, called crista acustica. made up of modified epithelium containing sensory hair cells resembling those in the maculae. All the canals open into the utricle.

From the lower part of the saccule runs a small canal called the endolymphatic duct. Anteriorly the saccule communicates with the membranous cochlea, or scala media, by a short connecting duct.

A section cut through each turn of the cochlea shows the bony spiral lamina which is continued right across the canal by the basilar membrane, thereby cutting the canal into an upper and lower half, and connected with the outer wall by the strong spiral ligament. Near the free end of the spiral lamina the membrane of Reissner is attached and runs outward and upward to the outer wall, taking a triangular slice out of the upper half.

Three canals may be seen in section: the upper is the scala vestibuli: the middle, or scala media, is the cochlear duct or true membranous cochlea; and the lower, the scala tympani. The scala vestibuli and scala tympani communicate at the apex of the cochlea, so that the perilymph can pass from one canal to the other. At the base of the cochlea the perilymph in the scala vestibuli is continuous with that in the vestibule, but that in the scala tympani bathes the inner surface of the membrane stretched across the round window and also communicates with the subarachnoid space (the space between the inner and middle layers of the meninges, covering the brain) through the cochlear aqueduct, which opens into the posterior cranial fossa. The scala media. containing endolymph, communicates with the saccule through the connecting canal of Hensen, while, at the apex of the cochlea, it ends blindly.

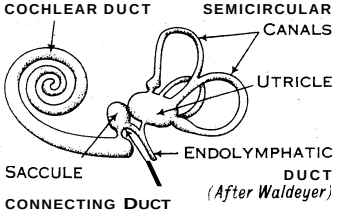

FIG. 3.— DIAGRAM OF THE DIFFERENT PARTS OF THE MEMBRANOUS LABYRINTH

The scala media contains the essential organ of hearing. the organ of Corti, which lies upon the vestibular side of the basilar membrane; it consists of a tunnel bounded on each side by the inner and outer rods of Corti; on each side of these are the inner and outer hair cells, between the latter of which are found the supporting cells of Deiters. Most externally are the large cells of Hensen. A delicate membrane called the reticular lamina covers

the top of all these and is pierced by the hairs of the hair cells, while above this is the loose tectorial membrane attached to the periosteum of the spiral lamina, near its tip. internally, and possibly to some of Deiters' cells externally. The fibres of the cochlear, or auditory. nerve enter the spiral lamina from the spiral ganglion and are distributed to the inner and outer hair cells.

Function of the Ear.—Equilibrium.—Originally the function of the ear was to preserve the proper position of the body in space, or balance. (See EQUILIBRIUM, ANIMAL.) This is still the principal and, in most species of the low vertebrates such as fishes, the only function. The maintenance of the body balance through the appropriate reflex reactions of the bodily muscles and those of the eyes is, then, the function of the vestibular apparatus, in particular of the utricle and the semicircular ducts.

Part of the labyrinth, the saccule, apparently responds to the sound vibrations, as in certain fishes. In the terrestrial vertebrates the auditory function becomes firmly established and increases in importance, culminating in the birds and mammals. The vestibule. in its own right, undergoes a further parallel development and perfection necessitated by the varied and more specialized use of the limbs in land animals.

Hearing.—The function of the auditory system in the proper sense is to react to the sound vibrations. Ordinarily the bulk of the sound vibrations is caught by the external mobile flaps called auricles, or pinnae, and less so by applying directly to the skull and the body. From the auricle the vibrations enter the external auditory meatus, passing over to the tympanic, or eardrum, membrane and finally to the chain of auditory ossicles. These latter act as an elastic bridge along which the sound is transmitted to the stirrup's footplate elastically fitted into the oval window. The other opening, the round window, is in turn closed off by an elastic secondary tympanic membrane. The perilymphatic fluid filling the rigid bony labyrinth, because of its incompressibility, has only one exit (the round window) by which it may give way whenever the footplate of the stirrup is pushed in, or is sucked in when the footplate is pulled out. The oscillatory movements thus caused pass through the two scalae of the bony cochlea, taking a short cut through one or the other segment of the basilar membrane, closer to the base in the sounds of high pitch and nearer the apex of the cochlea in low-pitched sounds. The remaining sound vibrations pass through the intermediate segments.

Comparative Anatomy.—Fishes.—The ectodermal invagination of the internal ear has probably a common origin with the organs of the lateral line of fishes. In the lower fishes the endolymphatic duct retains its communication with the exterior on the dorsum of the head, and in some elasmobranchs the opening is wide enough to allow the passage of particles of sand into the saccule. In certain bony fishes (Teleostei) the swim bladder forms a secondary communication with the internal ear by means of special ossicles. Among the lampreys and hagfishes (Cyclostomata) the external semicircular canals are wanting; *Petromyzon* has the superior and posterior only, whereas in *Myxine* these two appear to be fused.

In higher fishes the three canals are constant. Concretions of carbonate of lime are present in the internal ears of almost all vertebrates; when these are very small they are called otoconia, but when, as in most of the teleostean fishes, they form huge concretions, they are spoken of as otoliths. One shark, *Squatina,* has sand instead of otoconia. The utricle, saccule, semicircular canals, endulymphatic duct and a short lagena are the only parts of the ear present in fishes.

Amphibians.—The Amphibia have an important sensory area at the base of the lagena; it is probably the first rudiment of a true cochlea. The endolymphatic duct has lost its communication with the skin, but it is frequently prolonged into the skull and along the spinal canal, from which it protrudes—through the intevertebral foramina—bulging into the coelom. This is the case in the common frog. In this class the tympanum and Eustachian tube are first developed; the tympanic membrane lies flush with the skin of the side of the head, and the sound waves are transmitted from it to the internal ear by a single bony rod—the columella.

Reptiles.—In the Reptilia the internal ear passes through a great range of development. In the turtles and snakes the cochlea is as rudimentary as in the Amphibia, but in the higher forms (Crocodilia) there is a lengthened and slightly twisted cochlea, at the end of which the lagena forms a minute terminal appendage. At the same time indications of the scala tympani and vestibuli appear. As in the Amphibia the endolymphatic duct sometimes extends into the cranial cavity and on into other parts of the body. Snakes have no tympanic membrane.

Birds.—In the birds the cochlea resembles that of the crocodiles, but the posterior semicircular canal is above the superior where they join. In certain lizards and birds (owls) a small fold of skin represents an external ear.

Mammals.—In monotremes the internal ear is reptilian, but above them the mammals always have a spirally twisted cochlea, the number of turns varying from one and a half in the whales to nearly five in the rodent *Coelogenys.* The lagena is reduced to a mere vestige. The organ of Corti is peculiar to mammals? and the single columella of the middle ear is replaced by the three ossicles already described. In some mammals, especially Carnivora, the middle ear is enlarged to form the tympanic bulla, but the mastoid cells are peculiar to man.

Embryology.—The auricle is formed from six tubercles that appear around the first pharyngeal groove, or gill cleft. Those for the tragus and anterior part of the helix belong to the first, or mandibular, arch, while those for the antitragus, antihelix and lobule come from the second, or hyoid, arch. The tubercle for the helix is dorsal to the end of the cleft where the two arches join. The external auditory meatus, tympanum and Eustachian tube are remains of the hyomandibular cleft, the tympanic membrane being a remnant of the cleft membrane and therefore lined by ectoderm outside and entoderm inside. The auditory ossicles are modified bones of the visceral skeleton of lower vertebrates (*e.g.*, fishes, etc.). The internal ear first appears as a pit from the cephalic ectoderm, the mouth of which in mammals closes up to leave a pear-shaped cavity. The lower part of the vesicle grows forward and becomes the cochlea, while from the upper part three hollow circular plates grow out, the central parts of which disappear, leaving the margin as the semicircular canals. Subsequently, constrictions appear in the vesicle marking off the saccule and utricle. From the surrounding mesoderm the petrous bone is formed by a process of chondrification and ossification.

EAR, DISEASES OF. The ear is a complex organ of hearing and balance. Any disease that affects the ear may disturb these two vital functions. For a discussion of the structure of the ear, see EAR, ANATOMY OF. For a discussion of the hearing process, see HEARING.

Diseases of the External **Ear.**—*Injury* (Trauma).—Injury to the auricle or external ear may cause a blood blister or an infection. Scar tissue may then develop and produce a permanent deformity; a common example of this is the cauliflower ear seen in professional boxers and wrestlers.

Itching Ears (Otitis *Externa).*—This affliction is very annoying and is usually present in allergic persons who possess a sensitive skin (lining) of the ear canal. The skin may be dry'and scaly or it may be moist and weepy in these cases. Scratching the ear and applying soap and water to it should be avoided if relief is to be obtained.

Boils (*Furunculosis*).—Infection develops occasionally in the skin of the ear canal, resulting in localized swelling and severe pain. These cases respond readily to medical care. Lancing of the localized abscess is sometimes necessary to obtain relief.

Wax (*Ceruminosis*).—Wax is secreted by cerumen glands in the skin of the external canal. An excessive amount of wax may obstruct the ear canal, causing a sensation of fullness and a hearing impairment. These symptoms are relieved by having a physician remove the wax.

Diseases of the Middle Ear.—Eardrum Injury.—The delicate eardrum membrane is easily perforated by direct trauma or by concussion such as may be created by a gentle slap of the hand over the ear canal. Sharp pain followed by a sensation of fullness and a hearing impairment characterize this injury. Perforations due to injury usually heal spontaneously with relief of all symptoms unless infection develops. Immediately following injuries of this type, blowing of the nose and introduction of water into the ear should be avoided until healing has occurred.

Middle Ear Infection (Otitis Media).—Acute otitis media usually follows a cold. The infection spreads from the nose to the middle ear through the Eustachian tube. Constant and severe pain in the affected ear, a sensation of fullness, fever and a hearing impairment characterize this condition.

Chronic otitis media develops following acute otitis media and occurs when the bone of the middle ear becomes involved in the infection. This disease is characterized by persistent discharge from the ear through an eardrum perforation and is associated with a hearing impairment. The discharge may be intermittent or constant and often has a foul odour. Chronic ear disease may respond to local and general treatment. Surgical removal of the infected bone, however, is often necessary to eradicate the infection.

Rather serious complications occasionally develop from otitis media. Such complications include mastoid disease, extension of the infection into the inner ear with further loss of hearing, and impaired balance. At times even the brain area can be involved.

The danger signs of middle ear disease include persistent pain in the ear region and/or balance difficulties. If either or both of these symptoms develop, a physician should be consulted.

Fluid in the Middle Ear (Serous Otitis Media).—This condition usually develops when the Eustachian tube is blocked because of allergic swelling. Fluid accumulates in the middle ear without evidence of infection. This disease is characterized by a feeling of fullness in the ear and a mild hearing impairment. Treatment consists of lancing the eardrum and releasing the fluid. The underlying cause of the allergy must be corrected if relief is to be permanent.

Factal *Nerve* Paralysis (Bell's Palsy).—The seventh cranial (facial) nerve enervates the muscles of facial expression. Any interference with the function of this nerve produces a facial paralysis. The nerve may be injured by trauma but the most common cause of facial paralysis is Bell's palsy, The palsy develops because of swelling of the facial nerve as it passes through its bony canal in the ear. Usually the swelling is temporary, but occasionally it may be permanent. If the function of the face does not return spontaneously within three or four weeks, surgical decompression of the nerve to relieve the swelling may be necessary to prevent permanent paralysis.

Otosclerosis (Hardening of *the* Ear Bones).—Otosclerosis is a hereditary type of hardening of the bone in the stapes (stirrup) area. It is the most common type of conduction hearing impairment in the young adult, is usually bilateral, slowly progressive and occurs more frequently in women than in men. As the bone continues to harden, the condition may involve the hearing portion of the inner ear and result in a nerve type of hearing impairment. No medical treatment will benefit this condition, but surgery will often restore serviceable hearing.

Diseases of the Inner Ear.—Dizziness (Vertigo).—Although many physiological conditions may produce dizziness, the most common cause is disturbances in the inner ear mechanism.

Ménière's disease (*q.v.*) is due to disturbances in the fluid pressure in the inner ear mechanism. It is characterized by acute attacks of dizziness. often associated with nausea and vomiting, together with hearing impairment and head noise (tinnitus). Treatment is aimed at controlling the fluid pressure changes in the inner ear mechanism.

Labyrinthitis (inflammation of the inner ear) is usually caused by the extension of an infection from the middle ear area. It is characterized by sudden and total loss of hearing, severe balance disturbances associated with nausea and vomiting, and frequently by severe head noise. Treatment is directed toward controlling the infection in the middle ear as well as the inner ear. Such a condition often necessitates surgical drainage of the involved region.

Hemorrhage (*Vascular* Disturbances).—The blood vessels that supply the inner ear mechanism are very tiny and delicate. Any spasm or rupture of these blood vessels interferes with nutrition to the inner ear. As a result, hearing may be lost suddenly, with associated severe head noise and often by loss of balance. Early intensive medical treatment may restore total inner ear function but often there is some permanent loss of hearing in these cases.

Growths (*Tumours*).—Growths may develop in the middle and inner ear regions. The development of such tumours is characterized by gradual loss of hearing, head noise, dizziness, facial weakness and later head pain. Treatment of this condition usually requires surgical removal of the growth.

Head Injuries With or Without Skull Fracture may cause inner ear damage, which in such cases is characterized by loss of hearing, head noise and balance disturbances. Occasionally the facial nerve may also be injured, resulting in facial weakness.

Head Noise (Tinnitus).—Ringing or buzzing in the ear is common and may be due to irritation of the hearing nerve (eighth cranial nerve) as well as to other inner ear trouble as described above. This irritation may be due to infection (neuritis), pressure on the nerve or inadequate circulation.

EAR, NOSE AND THROAT, DISEASES OF. The human ear, nose and throat have such an intimate relationship by virtue of their location and function that they are usually considered together for purposes of medical training and practice. The ear is connected with the nasopharynx by the Eustachian tube (see EAR, ANATOMY OF). Consequently, certain diseases of the nose and throat may spread to and affect the ear. The nose and throat are parts of the respiratory and digestive systems. Because of this, the diagnosis and treatment of all types of diseases, including tumours, and the handling of foreign bodies in the lower digestive and respiratory tracts are included in dealing with diseases of the ear, nose and throat. A physician trained in diseases of the ear, nose and throat was once known as an otorhinolaryngologist but the term was later shortened to otolaryngologist.

The ears, nose and throat are of particular interest because they include some of the special senses such as hearing, equilibrium, taste and smell.

See EAR, DISEASES OF; NOSE, DISEASES OF; THROAT, DISEASES OF; EQUILIBRIUM, ANIMAL. (D. M. L.)

EARHART, AMELIA (1898–1937), U.S. aviation pioneer, was born in Atchison, Kan., on July 24, 1898. Her career ended in an unknown spot in the Pacific ocean early in July 1937. Amelia Earhart, after a tour of duty as a military nurse in Canada during World War I and several years of social work in Denison house, Boston, Mass., learned to fly, against the wishes of her family. She achieved fame as the first woman to cross the Atlantic by air when, on June 17–18, 1928, she crossed as a passenger from Newfoundland to Wales in a trimotored Fokker monoplane, with W. Stutz and L. E. Gordon. Four years later (May 20–21, 1932) she made a solo Atlantic crossing and subsequently made a number of solo long-distance flights across the United States both by airplane and by Autogiro. In the early 1930s she took great interest in the development of commercial aviation in the United States. For a time she served as an officer of the Luddington line, which operated one of the first regular passenger services between New York city and Washington, D.C. In Jan. 1935 she made a solo Pacific crossing from Hawaii to California. In 1937, accompanied by Lieut. Comdr. Fred Noonan, she attempted a round-the-world trip in a twin-engined Lockheed. After negotiating over two-thirds of the distance safely, the plane vanished in the vicinity of Howland Island in the South Pacific on July 2. Miss Earhart married the

publisher George Palmer Putnam in 1931, but continued her aviation career under her maiden name. Her biography, Soaring Wings, was written by her husband in 1939.

(S. P. J.)

EARL (corresponding to Lat. comes; Fr. comte), a title and rank of nobility in the British peerage which, while it confers no official power or authority, is inalienable, indivisible and descends in regular succession to all the heirs under the limitation in the grant until, on their failure, it becomes extinct. Earl is the oldest title and rank of English nobles, and was also the highest until 1337 when Edward the Black Prince was created duke of Cornwall by Edward III. It now stands third in precedence, between marquess (1385) and viscount (1440).

The title is of Scandinavian origin and first appeared in England under Canute (1016–35) as jarl, of which the Anglo-Saxon version was eorl. The eorl, as a great royal officer, superseded the ealdorman and was sometimes set over several counties, in the courts of each of which he presided with the bishop of the diocese. After the Norman Conquest his sphere was restricted to a single county and his official duties soon came to be performed by the sheriff, a position he himself might often hold. But the earl was in general still entitled to the "third penny," a third of the profits of justice in the shire court. In the two great palatinate earldoms of Chester and Durham the earl and bishop respectively possessed regalia, special royal privileges; they had their own courts and exercised their own jurisdiction. The earl's hereditary position was strengthened by the system of feudal tenure, under which he was also a tenant in chief, holding estates of the crown. His fief would descend to the heirs of his body. and the earliest charters creating earldoms, such as that (the first known) by which Stephen bestowed on Geoffrey de Mandeville the earldom of Essex (c. 1140), were granted with the same limitations. The dignity might thus descend to a woman, and in that case, like the territorial fief, it would be held by her husband in right of a wife. The earldom of Warwick passed in this way through several families till it was finally obtained (1449) by Richard Neville, earl of Salisbury. who had married the heiress of the former earls. If there were co-heiresses (more daughters than one), the king determined which, if any, should inherit the dignity.

In the later middle ages letters patent which restricted the succession to the male heirs of the grantee's body gradually superseded other methods of creating earls. From the time of the creation of the earldom of March (1328) their titles no longer always reflected the old county territorial associations and thus the way was paved for the 18th-century practice, which has become even more popular in the 20th. of simply adding the surname to the title —*e.g.*, Earl Poulett, Earl Temple, Earl Lloyd George, Earl Attlee. In Scotland medieval practices lasted longer and it was not till 1600 that letters patent were used to create an earldom (Winton). This helps to explain why so few ancient Scottish earldoms with their almost unlimited right of succession ever became extinct.

The girding with the sword was the only ceremony observed at an earl's investiture until the first years of Edward VI (1547–53), when the imposition of the cap of dignity and a circlet of gold was added. Under James I the patent of creation was declared to be sufficient without any ceremony (1615). An earl's robe of estate has three bars of ermine on the cape.

The earldom of Chester has been held by the princes of Wales since 1301, and the Scottish earldom of Carrick was granted to the eldest son of the sovereign by act of parliament (1469).

The premier earldom is that of Arundel (1139), but it is at present merged with the dukedom of Norfolk. The oldest earldom not merged in a higher title is that of Shrewsbury (1442), the next in seniority being Derby (1485) and Huntingdon (1529). The premier earldom of Scotland, as recognized by the Union Roll (1707), is that of Crawford, held by the Lindsays since its creation (1398), but it is not one of the ancient seven Scottish earldoms and the claim is disputed by the earls of Mar. In the Decreet of Ranking 11606) the earldom of Sutherland, one of the original seven, is regarded as the most ancient in virtue of a charter of 1347, but a house of lords decision (1771) accepted its descent from at least 1275 and it may date back to 1228. It is at present united with the dukedom of Sutherland. The original seven earldoms represented seven provinces, each of which was under a mormaor or steward. This Celtic title was rendered jarl by the Norsemen and under Alexander I (d. 1124) began to be replaced by earl (comes) as a result of Anglo-Norman influence. In Ireland the duke of Leinster is, as earl of Kildare, premier earl as well as premier duke.

An earl is "Right Honourable" and is styled "My Lord." His eldest son bears his father's second title, which is in most cases a viscountcy; where, as with Devon and Huntingdon, there is no second title, one using the family name may be assumed for convenience. The eldest son of an earl, whatever his title, always takes precedence immediately after the viscounts. The younger sons of earls are styled "Honourable"; all the daughters are styled "Lady." In formal documents and instruments the sovereign, when addressing or mentioning any earl, usually designates him "trusty and well-beloved cousin," a form first adopted by Henry IV. The wife of an earl is a countess; she is "Right Honourable" and is styled "My Lady."

(S. B.-R. P.)

EARLE, JOHN (c. 1600–1665), English clergyman, author of one of the best of the 17th-century "character-books," was born at York about 1600. He matriculated at Christ Church, Oxford, and in 1619 obtained a fellowship at Merton college. A man of great charm and universally beloved, he was a member of Lord Falkland's circle at Great Tew, and chaplain to Philip, earl of Pembroke, who probably introduced him at court. In 1643 he was summoned to the Assembly of Divines at Westminster, but declined to sit. During the Civil War he was deprived of his rectory of Bishopstone (Wiltshire) and of the chancellorship of Salisbury cathedral, and in 1646, as one of his chaplains and tutors, he accompanied Charles, prince of Wales, to France. He remained abroad with the exiled court during the interregnum, earning the high regard of the king, who made him clerk of the closet in 1651. At the Restoration he became dean of Westminster, and played an important part in the re-establishment of the Church of England. He was consecrated bishop of Worcester in Nov. 1662, and translated ten months later to Salisbury. Earle's wide tolerance, which won him praise from both Roman Catholics and Nonconformists, led him to deplore harsh treatment of the dissenters. He died in Oxford on Nov. 17, 1665.

Earle's Micro-cosmographic: or, a Peece of the *World* Discovered, in Essayes and Characters (1628), ran through several editions in his lifetime, though not under his name. He made the Latin translation of Eikon *Basilike*, published in 1649.

See editions of the *Micro-cosrnographie* by Philip Bliss (1811) and by S. T. Irwin (1897); B. Boyce, *The Theophrastan Character in England to 1642* (1947).

(E. A. O. W.)

EARL MARSHAL, in England, ranks as the eighth of the great officers of state, is the head of the college of arms and appoints the kings of arms, heralds and pursuivants. He attends the sovereign in opening and closing the session of parliament, walking at his or her right hand. He arranges state processions and ceremonials, especially coronations, royal marriages and funerals, and with the lord great chamberlain he assists in introducing newly created peers in the house of lords.

He exercised joint and co-ordinate jurisdiction with the constable in the court of chivalry, and afterward became the sole judge of that tribunal till its obsolescence in 1737. The marshalship of England was formerly believed to have been inherited from the Clares by the Marshal family, who had only been marshals of the household. It was held. however, by the latter family as early as the days of Henry I and passed to the Bigods. In 1306 it fell by inheritance to Edward I and in 1316 was granted by Edward II to his own younger brother, Thomas "of Brotherton," earl of Norfolk. As yet the style of the office was only "marshal." The office, having reverted to the crown, was granted out anew by Richard II in 1385 to Thomas Mowbray, earl of Nottingham, the representative of Thomas "of Brotherton." In 1386 the style of "earl marshal" was formally granted to him in addition. After several attainders and partial restorations in the reigns of the Tudors and the Stuarts, the earl marshalship was granted anew to the Howards by Charles II in 1672 and entailed on their male line,

under which settlement it has regularly descended to the present duke of Norfolk. Its holders, however. as Roman Catholics, could not execute the office until a special act of parliament was passed in 1824.

His grace appends the letters "E.M." to his signature. and bears behind his shield two batons crossed in saltire, the marshal's rod (*virga*) having been the badge of the office from Norman times. There appear to have been hereditary marshals of Ireland, but their history is not uell ascertained. The Keith were great marischals of Scotland from at least the days of Robert Bruce, and were created earls marischal in or about 1458, but lost both earldom and office by the attainder of George, the 10th earl, in 1716. *See* also MARSHAL; PEERAGE.

See "The Marshalship of England" in J. H. Round, *Commune of London and Other Studies* (1899); *G. E.* C(okayne), *Complete Peerage.* (J. *H.* R.)

EARLOM, RICHARD (1743–1822), English mezzotint engraver. was born and died (Oct. 9, 1822) in London and was a pupil of G. B. Cipriani. He is remembered principally for the 200 plates which he executed, in a technique combining etching and mezzotint, from the drawings in Claude Lorrain's *Liber Veritatis* in the duke of Devonshire's collection. These were published by John Boydell in 1777. Earlom also did several of the plates for Boydell's Houghton gallery; a collection of prints of pictures from the collection of Horace Walpole, which were acquired by Catherine the Great of Russia in 1779; besides plates from William Hogarth and from Dutch and Flemish still-life painters. (R. E. W. J.)

EARLSTON (formerly ERCILDOUNE, of which it is a corruption), a civil parish in Berwickshire, Scot. Pop. (1951) 1.761. The village is on Leader water in Lauderdale, 34 mi. S.E. of Edinburgh by road, and on the Roxburghshire border. Originally it was called Arcioldun or "prospect fort," an ancient earthwork on Black hill. In the 12th and 13th centuries the Lindsays and the earls of March and Dunbar were the chief baronial families. The ivy-clad ruin of the ancient tower, the "Rhymer's castle," was the traditional residence of Thomas Learmont, commonly called Thomas of Erceldoune or Thomas the Rhymer, poet and prophet, who was born there about 1225. The Edinburgh Border Counties association acquired this relic and surrounding lands in 1895. The leading manufacture is tweeds, and the town is also an agricultural centre. About 4 mi. S.S.E. is Bemersyde, which has been in the possession of the Haigs since probably the 12th century, and which was presented to Field Marshal Earl Haig by the nation in 1921.

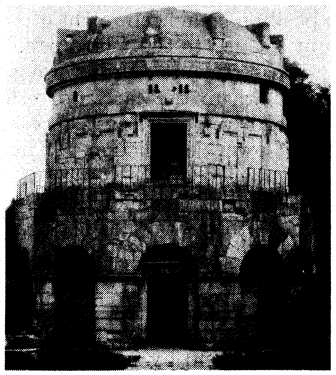
EARLY, JUBAL ANDERSON (1816–1894), U.S. lawyer and Confederate army officer in the American Civil War, was born in Franklin county, Va., on Nov. 3, 1816, and graduated at West Point in 1837. He served in the Seminole War of 1837–38 and then resigned to practise law in Franklin county and take part in Virginia state politics. During the Mexican War he served as a major of Virginia volunteers. He was strongly opposed to secession, but when Virginia withdrew from the Union in 1861 he thought it his duty to conform to the action of his state. As a colonel in the Confederate army, he rendered conspicuous service at the first battle of Bull Run. Promoted brigadier general, later major general, Early served throughout the Virginia campaigns of 1862–63. In the campaign of 1864 Early, who had now reached the rank of lieutenant general, commanded the Confederate forces in the Shenandoah valley. After several successful actions in the Shenandoah and Potomac valleys and a threatened attack on Washington, D.C., he was defeated by Gen. Philip H. Sheridan at Winchester, Fisher's Hill and Cedar Creek. Waynesboro (March 1865) was his last fight, after which he was relieved of his command.

At the end of the war he went to Mexico and then to Canada but in 1867 returned to resume the practice of law. For a time he managed the Louisiana lottery in conjunction with Gen. P. G. T. de Beauregard. He died at Lynchburg, Va., on March 2, 1894. General Early was for a time president of the Southern Historical society, and wrote, besides various essays and historical papers, *A Memoir of the Last Year of the War, etc.* (1866).

See *Lieutenant General Jubal Anderson Early; an Autobiographical Sketch and Narrative of the War Between the States (1912);* D. S. Freeman, *Lee's Lieutenants* (1944).

EARLY CHRISTIAN ARCHITECTURE, in this article, refers to the religious architecture that developed in Europe during the 4th. 5th and 6th centuries of the Christian era. (For the architecture of the Eastern Church during this period *see* BYZANTINE ARCHITECTURE; for European architecture of the preceding era *see* ROMAN ARCHITECTURE; and for that of a later era *see* ROMANESQUE ARCHITECTURE.)

The meeting places of Christians, in the years before the Edict of Milan (313) brought official acceptance of the new religion, were necessarily inconspicuous and tentative. Initial emphasis on the cult of the dead resulted in the need for funerary space, which was provided in rude catacombs, crypts, martyria and chapels. These were fitted with altars and sarcophagi decorated with symbolic paintings of miracles or the agape feast, as in the catacomb of St. Calixtus, or the Virgin Mary. as at St. Priscilla, both at Rome, possibly of the late 2nd century; whether from the Old or New Testament. the scenes strongly emphasized salvation. The ecclesia, or congregations, met in the catacombs or in houses. The Jonah sarcophagus at the Lateran museum suggests that Christians could commission sumptuous art, and the restrained character of their early architecture may reflect furtiveness and indecision, more than poverty or austerity.



ALINARI

TOMB OF THEODORIC (*c.* A.D. 520), RAVENNA, ITALY, AN EXAMPLE OF A CENTRAL-DOMED BUILDING OF THE EARLY CHRISTIAN PERIOD

After 313 the west developed elaborate churches of the basilica (*q.v.*) type in which rows of columns divided a rectangular hall into three or five aisles. The basilica (from a Greek word meaning "kingly") had been a major form in Classic times; suggestions of it appeared in Hellenistic Piraeus and it was brought to noble scale by the Romans in imperial law courts such as the Basilica Ulpia in Trajan's forum at Rome. The royal and juridical implications of the Roman basilica were appropriated by the Christians whose mosaics often depicted Christ as judge, as in the apse over the altar at Sta. Pudenziana, Rome (398), where the enthroned emperor had formerly tried criminals. The imperial symbol, a baldachin or ciborium, rose above the altar, and a domical apse terminated the long vista down the central aisle. Thus Christian architecture retained classical pagan features. much as Christian art did. The Junius Bassus sarcophagus (359), though it depicted Christ's passion, was strongly classical in both the style of its figures and its colonnaded format. The principal elements of the typical Christian basilica strongly affected later architecture. First. one encountered a propylea, or gateway. which gave entrance to an atrium or paradisus. which was a colonnaded court, often with a fountain at its centre, where the faithful gathered before the religious service began. A narthex, or entrance vestibule, located between the atrium and the basilica, provided a space for novices and penitents who were not permitted to enter the basilica itself to hear the service. Inside, the basilica had a broad nave and either two or four side aisles. which mere separated by colonnades with arcades or flat entablatures that carried the nave wall to the band of clerestory windows below the gabled roof. In the west men stood in the nave and women in the side aisles, but eastern practice reserved the east end for men, while women stood either at the west or in galleries above the aisles. The end of the sanctuary was enclosed by the apse. usually a vault and half-dome, which had celestial, mortuary and imperial connotations. To mark the sanctified area uhere only clergy were permitted, a bema or platform, sometimes with a chancel rail, otiered a raised base for the cathedra (seat of a bishop), the ciborium (in early times of

wood covered with a veil) and the altar (usually a table). Thus the basilica's strong axis thrust attention at the focus for the liturgy, and, in some instances, a transept, which offered more space for clergy near the altar, increased the terminal emphasis and enhanced the sculptural furniture such as the choir for singers and the ambos or pulpits where the Epistles (right side) and Gospels (left side) were read. No fixed orientation aligned the axis until the 5th century when the liturgical practice of having the priest face the altar, with his back to the congregation. was canonized, and thereafter the apse stood at the east end of the basilica, the atrium at the west.

A time-defying reverence has preserved many of Christianity's early edifices. This is the more remarkable in view of their inferior architectural quality. Structurally, their thin brick walls and wooden roofs were unsubstantial and subject to rotting or fires; their alabaster windows, distended plans and primitive provisions for sound and heating offered little convenience; and their plain, even crude, exteriors were ill-composed aesthetically. These shortcomings were nullified as ceremonies were developed that capitalized upon the deficiencies, so that long spaces, resplendent mosaics and sculptured capitals augmented the incense, the mysteriously dim light and the muffled chants. In Rome there is an extant three-aisled basilica, S. Clemente, erected in the 5th century on land that once supported a Roman wall, then a house (about A.D. 100) and later a mithraeum where the Persian cult of Mithras worshiped. Repaired in the 8th century, the basilica was rebuilt in the 11th, revealing the continuity of the tradition. Constantine built three great metropolitan churches at Rome: St. John Lateran (324, but remodeled beyond recall), St. Peter's in the Vatican (with a western apse, dedicated in 326; destroyed in the 15th century) and St. Paul's Outside the Walls (erected in 324, and rebuilt in 1823 after a fire).

In the near east after 330, Constantine erected basilicas at Bethlehem (Church of the Nativity), Jerusalem (Church of Golgotha) and Constantinople (Church of the Holy Apostles). all generally of the Latin type seen at Rome. A new liturgy, however. the Antiochian or Jacobite, from Syria, demanded a tripartite apse, the pastophoria, consisting of the prothesis, where the bread and wine were prepared, the diaconicon, where vestments and utensils were kept, and the apse proper, where the chalice and paten were brought to an altar that was regarded as the tomb of Christ. Christian Syria reveals such basilicas at Ruweha (South church. 4th century), Kalat Siman (St. Simeon Stylites, after 459; with a central octagon and four basilica1 arms), Kalb Lauzeh (6th century) and Kuweha (6th century). The influence of the eastern basilica, by nay of Greece (St. Demetrius, Salonika) and Dalmatia (Cathedral. Parenzo), reached the west, as may be seen at Sta. Maria in Cosmedin at Rome and S. Apollinare in Classe (534–539) at Ravenna. With further modifications the basilica form persisted in the churches of the Carolingian period; it strongly affected the Romanesque and Gothic churches of Germany, France and Spain; and it retained almost classical features in S. Miniato at Florence and the cathedral at Pisa (1063–1118).

'Central: domed buildings of the Early Christian period were developed for use as tombs, martyria and baptisteries. The dome (*q.v.*) was often used in primitive architecture, since pliable reeds and branches were easily made to assume hemispherical and conoidal forms. Acquiring. symbolic status through use as the ancestral house or tomb. the form was retained in less compatible materials, such as brick. stone and wood. The dome became the symbol of ruling power, whether political or religious. In spite of the obvious difficulties in erecting, maintaining and expanding them. domical structures were valued for their religious symbolism and were erected even in countries where earthquakes frequently demolished them. The tomb chapel of Sta. Costanza at Rome (323 and later), probably built for Constantine's daughter: was of circular plan. as was the tomb of Theodoric at Ravenna (*c.* 520). Baptisteries. which imply the idea of rebirth, shared the symbolism; they followed the centralized plans of classic baths, as did the orthodox baptistery at Ravenna. called S. Giovanni in Fonte (449–452). Some imperial churches were of the central type, notably Justinian's Church of S. Vitale at Ravenna (526–547), which is thought to have suggested to Charlemagne the form for his palace church at Aachen.

The churches in the west of the central type frequently reflected eastern buildings, such as the rotunda built over the Holy Sepulchre at Jerusalem by Constantine. The east placed liturgical emphasis on the cult of the dead; the ritual emphasized an altar that was regarded as a tomb from which Christ rose at Easter, and the architectural canopy over the tomb had mortuary and celestial symbolism. Central-type churches were built at Antioch. Kalat Siman, Ruweha (where there was a fine cut-stone dome, though the usual practice was probably to make domes of wood), Bozrah and Zorah. The central type grew in importance during the 5th and 6th centuries and prepared the way for the great buildings of the Byzantine period, such as Hagia Sophia. Admired also by non-Christians, the domical sanctuaries eventually provided a basis for Islamic religious architecture.

While the exteriors of Early Christian buildings were plain. their interiors were decorated with fine mosaics. and the splendid panels remaining in Byzantine Ravenna in S. Xpollinare Nuovo and S. Vitale. as well as in jth century Sta. Maria Maggiore at Rome, suggest the rich effect the early churches made (see MOSAIC). Naturalism in figure style was replaced by abstraction. so that the friezes of saints and martyrs at S. Apollinare Nuovo gain their power through rhythmical statement and varied pattern, rather than three-dimensionality. The way in which this planar art perfectly reinforces the architecture deserves close study.

Early Christian architecture reveals an exciting insight into the development of the Christian religious institutions; it suggests how old architectural forms and their symbolism were transformed for new uses; it reveals how firmly ideas and rituals require programmatic expression in the plans of buildings; it cautions against an undue emphasis upon physical efficiency and its functional corollaries lest intellectual and aesthetic performance be curtailed; and it shares with other great architectures the insistence that all the visual arts, including ceremonial ones, support the spaces where sight. hearing and touch are intended to affect reason and emotions.

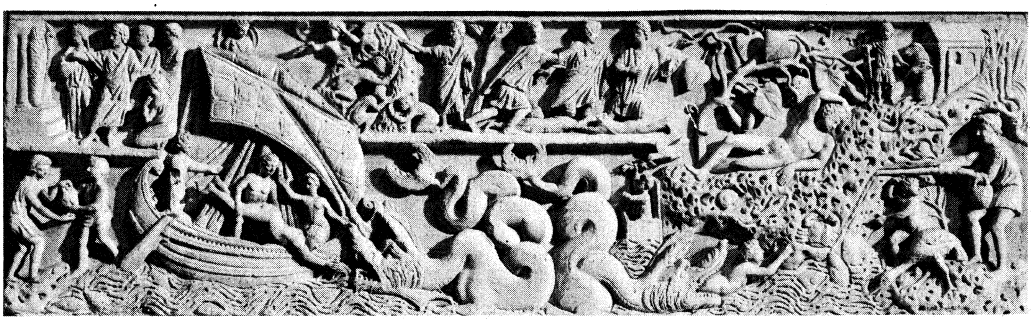
EARLY CHRISTIAN ART, the basis and point of departure of medieval western and Byzantine art, sprang from Greco-Roman art, of which, during the first 150 years of its existence, it merely formed a branch. It was not until Christianity became a permitted religion under Constantine I that it began to develop its own characteristics. From the second half of the 4th century onward the great artistic creations are Christian. The transition from early Christian to Byzantine art (*q.v.*) is taken in this article to date from the first half of the 5th century. The geographical area it covers is that of the Roman empire.

The most important monuments of early Christian art are to be found in Italy. The catacomb paintings. chiefly dating from the period when Christianity was still merely tolerated, or was even persecuted, and the sarcophagi provide the earliest examples. From the mid-4th century wall mosaics become the form of art most representative of the triumphant church.

By far the most important catacombs are those in Rome, though there are others elsewhere in the Mediterranean region. Frescoes cover their walls and ceilings, the earliest dating from the end of the 2nd century. They do not differ in style from contemporary paintings in pagan cemeteries (*e.g.*, at Ostia), but there is some difference in subject. Together with the traditional secular decorative motifs—birds, flowers. emblems of the seasons, rustic scenes—appear subjects from the Old and, more rarely, from the New Testament. By the 3rd century a Christian iconography had been established which depicted the miraculous intervention of God in favour of his chosen people: the sacrifice of Isaac. Susanna and the elders. Daniel in the lions' den, the miracles of Christ, etc. It has therefore with reason been called an iconography of salvation. Similar subjects are depicted in the frescoes of the Christian



ALINARI

baptistery at Doura-Europus on the Euphrates (c. 230).

The majority of early Christian sculptured sarcophagi have been found equally in Italy, but an important group derives from the south of France (Arles, Marseilles, Toulouse. Aix-en-Provence, Narbonne), others from Spain and north Africa and some from the Rhineland. A separate group, dating from the 3rd to the 5th century. belongs to Asia Minor. As in the catacombs. the subjects are at first chiefly secular! for instance a portrait of the deceased, a philosopher reading or pastoral scenes. But these are increasingly supplanted by cycles of biblical and Gospel scenes such as the passion of Christ, the martyrdom of the apostles Peter and Paul or the Israelites' crossing of the Red sea. Other important works of early Christian sculpture are the wooden reliefs on church doors (Sta. Sabina, in Rome: S. Ambrogio in Milan; first half of the 5th century).

Some of the earliest-known Christian wall mosaics, dating from the mid-4th century, adorn the vaults of Sta. Costanza in Rome. The subjects in these mosaics, except for those in two of the side recesses. are also part religious, part secular. The style is that of contemporary pagan art, which tended toward decorative effects at the expense of elegance of form. The apse mosaic in Sta. Pudenziana in Rome, dating from the close of the 4th century. and those in the two recesses in Sta. Costanza, probably a little earlier, represent new themes inspired by imperial iconography: Christ enthroned in majesty and Christ giving the law and the keys to St. Peter. In the baptistery at Naples (first half of the 5th century) the iconography of the mosaics is dictated by the baptismal liturgy. The mosaics on the walls of the nave in Sta. Maria Maggiore in Rome, executed under Pope Sixtus III (432–440), are the earliest cycle of biblical pictures extant (the stories of Abraham. Jacob. Moses and Joshuaj; on the triumphal arch appear scenes from the life of Christ. In Milan a few 5th-century works still exist in S. Aquilino and S. Ambrogio; in Ravenna the baptistery of the orthodox and the mausoleum of Galla Placidia already herald the Byzantine style. Early Christian floor mosaics, found chiefly in northern Italy, on the Dalmatian coast (Salonae), in Greece, Syria, Palestine, Jordan and north Africa, represent either secular subjects or geometric and botanical designs. Religious subjects are found only rarely (Aquileia).

Coptic art, a popular transformation of the Greco-Roman art of Egypt, produced a good deal of sculpture in stone (Ahnas), and some frescoes (Bagawat, Bawit, Saqqarah), whose nai've style, which achieves a powerful decorative effect, survived into the period of Arab occupation.

Early Christian art also produced numerous objects of daily usage. which. being portable, it is not always possible to attach with certainty to any locality. Oil lamps and gilded glass have been found in great numbers in Italy and north Africa: a school of ivory sculptors may have existed at Rome and in northern Italy during the second half of the 4th and the first half of the 5th centuries. Numerous pieces of cloth, both silk and woolen, have been discovered in Egypt (El Faiyûm, Antinoë) but not all are native to that country. The only surviving illuminated manuscript of this period is a few leaves in Berlin of the Itala of Quedlinhurg, a fragmentary text of the Old Testament.

The early Christian style can be characterized by a tendency toward spiritualization and by a progressive abandonment of the imitation of nature. Plastic beauty of form is sacrificed to intensity of expression, which is sometimes allied to a certain physical ugliness. Light and shade play over stylized and summarily treated forms; the paintings are in bright, contrasted colours. See also CATACOMBS; MOSAIC.

EARLY CHRISTIAN CHURCH. This article is intended as a sketch of the development of the church up to the time of Constantine I, the first Christian emperor.

Origin and Growth.—The Christian Church is the Body of Christ, the society of those who accept him as Messiah, Lord, Saviour and Son of God and are incorporated into him through baptism. It is continuous with the Old Testament people of God who looked for a Messiah and his Kingdom, and it inherits the promises made to them. But it took new shape and new life through the teaching and ministry of Jesus, through his training of the apostles and above all through his redeeming death, resurrection and ascension and through the coming of the Holy Spirit at Pentecost.

This new start was at first believed to be nearer the end than the beginning. In daily expectation of the return of Christ as judge, the faithful must prepare themselves for his kingdom and. by urgently preaching his gospel. bring others into the redeemed community. In the event. longer perspectives of a "time of the church" opened up. Christians faced the problems of living among a pagan majority, the missionary challenge proved to be far greater than could have been foreseen, and with it came the task of building a Christian social life. It became necessary to determine a new canon of authoritative scriptures (the writings of the apostles and their circle); on this basis to draw out the theological implications of the gospel; and to adopt such institutional forms as would preserve and propagate the inner life in Christ.

The church spread with astonishing rapidity. Already in the Acts of the Apostles its movement from one headquarters to another can be traced: Jerusalem, Damascus, Antioch; the Pauline missions to Asia Minor (Tarsus, Iconium, Ephesus and Cyprus); the crossing to Macedonia (Philippi, Thessalonica) and Achaea (Athens, Corinth); the beginnings in Rome. Other early evidence tells of more churches in Asia Minor and of Christians in Alexandria. Though Christianity found a springboard in Jewish synagogues, it owed even more to the crucial decision to open the church to gentiles without either circumcision or complete adherence to the Law; and though Roman roads and comparative security facilitated missionary work, much more was due, humanly speaking. to the widespread longing for personal religion and the assurance of salvation.

By the end of the 2nd century there were well-established churches in Gaul (Lyons. Vienne, perhaps Marseilles) and Latin Africa (Carthagej, with perhaps a start in Britain, Spain and Roman Germany, though little is known of these areas for another century. To the east, Edessa soon became the centre of Syriac Christianity. which spread to Mesopotamia, the borders of Persia and possibly India. Armenia adopted Christianity at the beginning of the 4th century, by which time there may have been a Christian majority, or near it, in some cities of Asia Minor and Africa *proconsularis,* while progress had been substantial in Gaul and Egypt. The faith had demonstrated its appeal to men of different cultures and environments; the church could be catholic, universal.

This was not done without opposition. First, their stern moral standard (though attractive to some) and their fear of contamination by the idolatry woven into the texture of social life around them compelled Christians to stand aloof from their neighbours and earned them the reputation of being enemies of humanity, or at best useless to society. Second, the Roman state doubted their loyalty and became increasingly convinced that the growth of the church was incompatible with the unity, safety and prosperity of the empire. Serious action against the church corporately was not taken until Septimius Severus forbade conversion under pain of death (202); but long before him a tradition of administrative action against individual Christians and a presumption that they were wicked and dangerous people had been established, ever since Nero had made them scapegoats for the fire of Rome. Although Trajan forbade magistrates to take the initiative against them, Christians denounced by others could be punished simply for persistence in their faith, the proof of which lay often in refusal to participate in the cult of the emperor. Persecution at Lyons in 177, when Marcus Aurelius abandoned Trajan's principle "that they are not to be sought out," pointed to what might come, for apologists (*e.g.*, Justin, Tertullian, Origen) protested in vain that Christians were moral, useful and loyal citizens. In 250, eager to revitalize the empire on conservative lines, Decius ordered all citizens to worship the gods; persecution was extensive and many apostatized, but the church was not destroyed. Valerian tried new methods against the clergy and other leaders (257–258), but the church held firm, and his successor Gallienus granted toleration in practice and perhaps legal recognition. A period of comparative security was ended by the series of persecutions launched in 303 by Diocletian and Galerius. Harsh though they were, they entirely missed their objective. Public opinion, now better aware of the nature of Christianity, was revolted by the bloodshed; first Diocletian and later Galerius (311) acknowledged the failure of this policy, and in 313 Constantine and Licinius agreed upon a policy of toleration (the "edict of Milan") which Constantine soon turned into active patronage. Through nearly three centuries the martyrs had been the seed of the church, and now the accession of a Christian emperor changed the whole situation.

Organization. — By this time the church had considerably developed its organization, partly against these external pressures and partly in order to express its own nature as a historically continuous society with a corporate unity, a ministry and sacraments "given" in Christ. Not later than the first decades of the 2nd century there is evidence in Antioch and several Asian cities of congregations being governed by a single bishop assisted by a group of presbyters and a number of deacons. The bishop was the centre of unity, the chief minister in worship, teaching and pastoral care as well as the supervisor of all administration. The presbyters were collectively his council; individually the bishop might call upon them for help in any of his ministerial duties. The deacons came to be specially associated with the bishop in his liturgical office and in the administration of property, including assistance to the needy.

How far back this threefold ministry can be traced has long been a matter of controversy (see MINISTRY, THE CHRISTIAN). It is certain that the normal Christian group, at least in cities, possessed a recognized ministry from its very beginning, and it is almost as certain that the pattern of ministry was not derived from Greek models. The presbyters (elders) were clearly taken over from the Jewish synagogue; the bishop (where this title is not simply an alternative for presbyter) may be related to the supervisor of the communities known from the Dead sea scrolls. How and when the bishop came to be regarded as having authority over his presbyters and how such a "monarchical" bishop was related to the original apostles — whether by direct succession of appointment, by localization of missionary-founders, by elevation from the presbyterate — remains uncertain. While apostles and other first-generation leaders were alive, there was understandably some fluidity in organization, with apostles, prophets and teachers at work side by side with bishops, presbyters and deacons; moreover, some New Testament terms may indicate at one time an office, at another a function.

Though the first local unit of organization must have been the congregation, the church was soon making use of the administrative divisions of the Roman empire. Normally each bishop became responsible for the church in a recognized civitas; *i.e.*, an urban centre with its surrounding territorium. This was his diocese, the fundamental unit of ecclesiastical geography; the subdivision of a diocese into parishes was a much later development. By the late 2nd century, when heresy and other problems compelled the bishops to meet together in councils, they tended to group themselves according to the civil provinces, and by the next century there is clear evidence of the ecclesiastical province, usually coinciding in area with the civil province and accepting the bishop of the civil capital (metropolis) as its primate (metropolitan), a system which received canonical status and further precision at the Council of Nicaea (325). Besides such metropolitans, the bishops of a few outstanding sees acquired a special authority through a combination of the secular importance of the city and its place in missionary history as a mother church. In Egypt, for example, the bishop of Alexandria ruled six provinces, and in Latin Africa the bishop of Carthage was the accepted leader, though without juridical or canonical rights, of the whole area. The Council of Nicaea, while defining the canonical status of the provincial synods and metropolitans, reaffirmed the ancient customary privileges of Rome, Alexandria, Antioch and certain other unnamed sees. Out of this the patriarchates of later times were developed.

Until the destruction of Jerusalem in A.D. 70 the mother church there may have held a certain primacy; but with the shift in emphasis to gentile Christianity Rome quickly became the preeminent see, the church of Peter and Paul, the only apostolic see in the Latin west, the capital of the empire. No one in the west doubted that the bishop of Rome possessed a primacy of some sort; but in the early centuries this was undefined, and attempts to interpret it (whether or not on the basis of Matt. xvi, 18: "And I tell you, you are Peter, and on this rock I will build my church . . .") as containing anything like jurisdictional sovereignty were resisted even in the west (for instance by Cyprian of Carthage) as well as in the east, where the see of Ephesus maintained its own apostolic tradition against Victor of Rome in the Quartodeciman controversy (c. 190); and Firmilian of Cappadocian Caesarea supported Cyprian in his dispute with Pope Stephen (c. 256; see CYPRIAN, SAINT). Here again the accession of Constantine was a turning point, for, with the expansion of the church and its recognition by the state, questions of jurisdiction became more acute (they were exacerbated by the Donatist and Arian controversies; see ARIANISM; DONATISTS), while the foundation of Constantinople as the eastern capital, with no ecclesiastical but strong secular claim to pre-eminence, caused Rome to develop and assert the exclusively religious grounds of its own primacy against a possible rival.

Doctrine.--Organization is but means to an end. The church exists to promote the worship of God. the inner life of the spirit, the evangelization of the world and the molding of society according to the will of God. All these things, if they are to be properly Christian, demand constant witness to the saving acts of God in Christ as they were made known to the primitive apostolic community and recorded and reflected upon in the Bible. Hence early Christian doctrine, however much helped to articulation by Greek thought, had to maintain its biblical character, historical, concrete, personal, against other elements, speculative, abstract, rationalist, in its Hellenistic environment. One wing of the church clung so tenaciously to its Jewish heritage that it failed to grasp what was new in Christ; it had no future, especially after the fall of Jerusalem. The mainstream of Christianity worked out a standard of orthodoxy in the course of its struggle with various forms of Gnosticism (*q.v.*), which, though itself soteriological in intention, threatened to spiritualize away the historic acts of divine redemption and to deny a true incarnation of God in Christ, partly on the ground that matter is evil. While apologists of the 2nd century like Justin, Theophilus and Athenagoras went as far as they could to conciliate Greek thought (see APOLOGISTS, EARLY CHRISTIAN), the genius of Irenaeus (see IRENAEUS, SAINT), who in his book

Against Heresies comes to grips with the Gnostic challenge, not only emphasized the "threefold cord" of apostolic scripture, apostolic rule of faith and apostolic ministry by which the continuity of the church is preserved, but also grasped the Pauline gospel of redemption (the true understanding of which the half-Gnostic Marcion had arrogated to himself) and stated it afresh with a just appreciation of the coherence of particular doctrines in the Person of Christ. The almost contemporary conflict with Montanism (*q.v.*) and the pungent development of certain aspects of Irenaeus in the early writings of Tertullian (*q.v.*) confirmed the church's awareness of its nature as a continuous society originating in and tied to a divine revelation, identical with the church of the apostles, a true perception which, however, brought with it some danger of traditionalism and institutionalism.

Apart from Origen's De *principiis* (c. 225) Christian theology in this period was not systematic, and doctrines were examined rather as circumstances demanded. Gnostic dualism compelled consideration of the creation, the fall and free will, as well as the authority and exegesis of the Old Testament. On the other hand, some matters, precisely because they were not then subjects of serious controversy, were not searchingly studied; thus an aspect of baptism (whether it could be administered outside the church) could receive more attention in the dispute between Cyprian and Stephen than the essential character of the sacrament itself, and eucharistic theology was not yet elaborated. Even the doctrine of redemption was less fully pondered than might have been expected, though the concepts of ransom and deification were brought forward for future development.

But a Christian society was bound to reflect upon the Person of Christ. The material reality of his human body had soon to be affirmed against those who thought it derogatory to a divine Saviour. It took longer to perceive that his complete humanity must be as firmly proclaimed. And although Tertullian taught expressly that Christ combined perfect divinity and perfect humanity in one Person, the theoretical problems of this dogma awaited exploration and clarification in the 4th and 5th centuries. In the intellectual formulation of their belief in the deity of Christ simultaneously with the unity of God, many were helped by the concept of the Logos ("word" and "reason") of God, which had roots both in the Bible and in Greek philosophy and so had at once an apologetic and a constructive value. It proved almost as dangerous as it was fruitful, since it was difficult to understand what kind of subordination is involved in the fact that the Logos is generated by the Father. Some points in Origen's thinking led toward the Nicene orthodoxy of the future. others toward Arianism. Some theologians held that Jesus was a man raised to divine honours through his moral and spiritual perfection (adoptionism; *q.v.*); others allowed no permanent reality to Son and Spirit, treating them as aspects of the one God, modes of his dealings with mankind (modalism, Sabellianism; see SABELLIUS). Such problems were argued principally in terms of the relation between Father and Son, with comparatively little attention to the Person of the Holy Spirit.

Again, the doctrine of the Trinity was firmly stated, almost in the later terminology, by Tertullian, followed by Novatian—three co-equal and co-eternal personae in one substantia—but new problems emerged and deeper thought was required in the following century (see also JESUS CHRIST: The Dogma of Christ in the Ancient Councils; TRINITY).

During this gradual clarification of the essentials of Christian orthodoxy there was also scope for free discussion and speculation within the limits of the rule of faith and the baptismal creeds, a freedom of which the adventurous mind of Origen took full advantage. Heresy meant denial of the basic tenets of faith rather than departure from a complete and formally accepted scheme of doctrine. Whether these tenets suffered from the slackening of eschatological expectation and the introduction of Greek forms of thought is open to debate. But it was not only, or even primarily, the theologian who was responsible for the preservation of authentic Christianity; it was maintained in the worship and discipline and common life of the churches. Once more, the conversion of Constantine exposed this continuity of tradition to fresh dangers while opening up fresh opportunities for the intellectual conquest of the empire.

The **Life** of the Church.—Candidates for admission to the church were instructed during a lengthy catechumenate, after which they were baptized, generally at Easter, by their bishop. As the sacrament of baptism included what was later separated off in the west as confirmation, the newly baptized faithful (*fideles*) were at once admitted to the full privileges and obligations of the Christian life. Though adult baptism was perhaps the norm, especially for baptismal theology, infant baptism was also practised from an early date (see BAPTISM, CHRISTIAN: *Early* Church). The Holy Communion (Eucharist) was the principal Sunday service, the regular gathering (synaxis) of the faithful for worship, the preaching of the Word, instruction, discipline and fellowship. While it was never shapeless and always included certain actions taken over from the Last Supper, it was only gradually, and perhaps not within this period, that the liturgies of the leading churches took a fixed verbal form (see EUCHARIST). Easter, Pentecost and, in the east, Epiphany were annually commemorated, before long anniversaries of martyrs were being observed, a system of feasts, fasts and vigils was worked out, and so a Christian year was established (see CHURCH YEAR). At first worship must have taken place in private houses. Sometimes houses were handed over to the community and transformed into churches (*e.g.*, Doura-Europus on the Euphrates, c. 232, and several at Rome), but numerous churches were constructed as such in the peaceful intervals of the 3rd century, and they were plentiful by the time of Constantine, who added some notable ones (*e.g.*, the Anastasis or Holy Sepulchre at Jerusalem. St. Peter's at Rome). Where catacombs (*q.v.*) existed, as at Rome and Naples, they were burial places, not, by intention, places of refuge or ordinary worship; but they and the open-air cemeteries (areae) contained chapels commemorating martyrs which frequently grew into great churches or monasteries.

Christians thought of themselves as a redeemed community, promised eternal life in Christ and meanwhile charged to live a holy life in expectation of the end of this world, which might come at any moment with the advent of Christ as judge; yet charged also to preach the gospel to the world. This created a tension not easy to resolve. On the one hand it seemed necessary to separate themselves from a society that was not only, by Christian standards, immoral but also riddled with pagan practices; this conviction is fully displayed in Tertullian's De idololatria, in a rigorist sect like Montanism and eventually in monasticism. Public life and much social intercourse were precluded. On the other hand, Jesus had mixed with publicans and sinners, and evangelization was a plain duty. Before Constantine, however, this meant bringing individuals out of the world into the church rather than making society Christian; a high moral standard, refusal to compromise, steadfastness before persecution, proved to be powerful missionary weapons. Evidence of direct missionary campaigns such as Gregory the Illuminator's in Armenia (3rd century) is scanty (see MISSIONS: Early History).

Since Christians were not automatically made perfect by baptism, and periods of peace removed the selective test of persecution, the moral life of the church was protected by a disciplinary system. Grave offenders publicly acknowledged their sin before the bishop and the congregation, were excommunicated for a greater or lesser period, during which they performed works of satisfaction, and finally (in parts of the church penitents passed first through several grades) were publicly restored to communion by the bishop. Private penance was a later development. Public penance for grave sin was only available once, and, although practice was not everywhere uniform, it was widely held that apostasy, adultery and murder involved final excommunication. Relaxation of this early severity caused much unrest among the rigorists and sometimes led to schism. Montanism, Novatianism and Donatism were all, in part, movements of protest against what was felt to be an abandonment of the standard of individual holiness required if the church was itself to remain holy. This disciplinary system carried with it a threat to the central doctrine of justification by faith, since the conditions of forgiveness tended to be assessed

quantitatively; and works similar to those performed by penitents (*e.g.*, almsgiving) were believed to merit heavenly rewards. Ascetic practices were also encouraged. partly as a means toward the purification of the soul for the contemplation of God. but in part as works to be rewarded. Thus a double standard of morality was countenanced, one level of life sufficient to ensure salvation, another aspiring after perfection and proportionately higher rewards; a distinction was made between the precepts (commandments) of the Lord and the counsels.

Nevertheless, the penitential system and the ascetic movement, together with the eremitical monasticism which was firmly established in Egypt under the leadership of Anthony in the opening years of the 4th century, played an important part in maintaining the high, sacrificial demands of the Christian faith, keying the church up to face the final persecution under Diocletian and his colleagues, from which it emerged victorious to meet the new difficulties and new opportunities afforded by the conversion of Constantine.

EARLY ENGLISH PERIOD, in architecture, the first of the three divisions into which the English Gothic style is usually divided. Although originally the term was applied to English Gothic up to the beginning of the 14th century (as by Rickman and R. P. Spiers), it is more customarily limited to the first half of the 13th century. In the last quarter of the 12th century, partly through the influence of the Cistercian order and partly through that of the French design of the early Gothic parts of Canterbury cathedral (choir, *c.* 1175–78), pointed arches and other Gothic ideas became more and more common, so that by the end of the century the transitional period was over and the architecture of England completely Gothic. It is this earliest developed Gothic which is known as Early English. The chief characteristics of the style are: frequent use of high, slim openings, capped with steeply pointed arches, known as lancets, often grouped in threes. fives (the "five sisters" in the transept of York cathedral) or even in sevens: simple four-part church vaulting (see ARCH AND VAULT), often with a ridge rib in addition to groin, cross and wall ribs: arch moldings. consisting of complex combinations of convex projections with deep, rounded hollows; nave and chapter-house piers of a central core of stone surrounded by a number of black Purbeck marble shafts, tied together by occasional molded bands: capitals. almost always consisting of a circular abacus with rich moldings below. or sometimes with conventionalized foliage with many rounded lobes:. frequent use of ball-flower and dogtooth ornament. Toward the end of the period the use of tracery became general, lavishness of ornament increased, as in the diaper patterns in the arch spandrils of Westminster abbey, and naturalism in the carving grew. Outstanding examples of the style are Salisbury cathedral. begun 1220; the nave and transept of Wells cathedral. end of the 12th century to 1242: parts of York cathedral transepts. 1230–60. See GOTHIC ARCHITECTURE; DECORATED PERIOD. (T. F. H.)

EARN, a loch and river of Perthshire, Scot. The loch is 6½ mi, long from east to west and ½ mi. in maximum breadth. It discharges by the Earn river. On its shores are Lochearnhead (at the west end of the lake and at the southern extremity of Glen Ogle): which has a station on the railway from Perth to Stirling, and where are the ruins of St. Blane's chapel; Edinample castle, an old turreted mansion situated in well-wooded grounds near the falls of the Ample; Ardvorlich house, the original of Darlinvarach in Sir Walter Scott's Legend of *Montrose;* and the village of St. Fillans at the foot of the loch. The river! a notable fishing stream, flows out of Loch Earn eastward for 46 mi. with a gentle inclination toward the south, and reaches the Firth of Tay, 6½ mi. below Perth. The principal places of interest on the banks of the Earn are Dunira house; the village of Comrie; the town of Crieff; Forgandenny; Bridge of Earn: a pleasant health resort: and several mansions and ruined castles. Strathearn, as the valley of the Earn is called, extending from the loch to the Firth of Tay, is a scenic and, on the whole, fertile tract, though liable at times to heavy floods in low-lying areas.

EAR SHELL: *see* ABALONE.

EARTH. In this article the earth will be considered as a whole, ignoring the details of its surface features. the oceans and the atmosphere. The subject will be treated under the following headings: (1) the earth as a planet; (2) structure of the interior; (3) origin, composition and age; (4) magnetism and temperature; and (5) origin of the surface features.

THE EARTH AS A PLANET

Figure of the Earth, Gravity.— The view that the earth is a sphere goes back to classical antiquity. It was held by Pythagoras as early as the 6th century B.C. Aristotle, in the 4th century B.C., supported it by such arguments from observation as the circular form of the earth's shadow seen on the moon during an eclipse. Similarly, he noted the changes in the position of the sun and stars observed by one who travels north–south. Eratosthenes (about 250 B.C.) used the latter argument for the first quantitative determination of the size of the earth. He found that when, at Syene in southern Egypt, the sun was vertically overhead at noon during the summer solstice, it deviated from the zenith by about 7° at Alexandria in northern Egypt. Eratosthenes' result for the size of the earth agrees remarkably well with modern data. The spherical form, however, did not become generally accepted until! in the 16th century, explorers actually sailed around the earth. The distance a traveler has to proceed northward in order to make the height of the pole star increase by 1° is "the length of one degree of latitude" (fig. 1). The first reliable modern determinations date from the 17th century.

Actually, the length of a degree of latitude depends in turn slightly on the latitude itself at which it is measured. This indicates that there is a deviation of the earth from spherical shape. Newton was the first to demonstrate that the centrifugal force of the earth's rotation would tend to make the earth bulge out at the equator, giving it the shape of an oblate spheroid (the surface swept out by an ellipse when it is rotated about its short axis). Such a surface is flatter near the pole than near the equator and 1" of latitude is therefore longer in high latitudes than it is in low ones. Whereas the length of a degree is determined by geodetic (surveying) methods, flattening is most accurately found from certain astronomical observations. If a is the major (equatorial) half-axis of the earth and b the minor (polar) half-axis, the flattening is defined as $\alpha = (a - b)/a$. Determinations of this quantity yield: $\alpha = 0.003367$.

Geodetic determinations of the size of the earth achieve a high degree of accuracy. Values for the axes are: a = 6,378,388 metres and b = 6,356,912 metres. The distance from pole to equator

FIG. 1.—THE LATITUDE OF A PLACE ON EARTH EQUALS THE ALTITUDE OF THE NORTH CELESTIAL POLE AT THAT PLACE

measured along the earth's surface, it may be noted, is nearly 10,000 km. or 10,000,000 m., this being the original definition of the metre at the introduction of the metric system. For practical purposes it is necessary to have a standard of length independent of the geodetic determinations of the size of the earth, but the above relationship holds true to a high degree of approximation (the error being about 2 parts in 10,000). It follows that the mean length of a degree is about (10,000/90) km. = 111 km., or 69 mi.

Since the earth is not a perfect sphere, the strength of gravity depends on latitude. In 1671 a French astronomical expedition to Cayenne, in Guiana, found that its pendulum clock ran more slowly there than at Paris. The following is an abbreviated form of the accurate formula for gravity: $g = 978.05\ (1 + 0.00529 \times \sin^2 \varphi)$, where g is the acceleration of gravity in cm./sec.^{2} and φ the latitude.

Clearly, if extreme precision is sought, the irregularities of the earth's surface constitute deviations from the spheroidal shape. Gravity measurements offer a convenient means of defining an idealized, smoothed earth's surface. which deviates somewhat from the spheroidal shape. This surface, serving as reference to the geodesist, is known as the "geoid."

The total mass of the earth is found from absolute gravity measurements in conjunction with measurements of its size. This also determines the mean density (the density is, however, not constant throughout the earth, as will be shown). The precise measurements of Charles Boys (1895) and of Karl Braun (1896) gave 5.527 whereas Paul Heyl found 5.517 (in 1930) and 5.514 (in 1942). It seems certain that the mean density is very near 5.52. This corresponds to a total mass of the earth of 6×10^{27} grams.

Earth Dimensions

Circumference, equatorial	24,902.45 mi.*
Diameter	
Polar	7,899.98875 mi. (12,713,824 m.)*
Equatorial	7,926.6779 mi. (12,756,776 m.)*
Flattening	0.003367*
Volume	1.083×10^{27} cu.cm. (1,083,319,780,000 cu.km.)
Mass (weight)	5.98×10^{24} g. (6,586,242,500,000,000,000,000 tons, est.)
Mean density	5.52 g. per cu.cm.
Ratio of mass	
Sun to earth	333,432:1
Earth to moon	81.43:1
Revolution	365.25 days
Rotation	23 hr. 56 min. 4.09 sec.
Orbital velocity	18.5 mi. per sec.
Distance from sun	
Aphelion (max.)	1.520×10^{13} cm. (94,448,000 mi.)
Perihelion (min.)	1.470×10^{13} cm. (91,341,000 mi.)
Mean	1.495×10^{13} cm. (92,894,000 mi.)
Area	
Total	510.1×10^{6} sq.km. (196,949,971 sq.mi.)
Land	58,552,330 sq.mi. (52,559,999 sq.mi. excluding Antarctica)
Altitudes	
Highest	29,028 ft. (Mt. Everest)
Lowest	−35,800 ft. (Challenger deep, Mariana trench)
Lowest on land	−1,286 ft. (Dead sea)

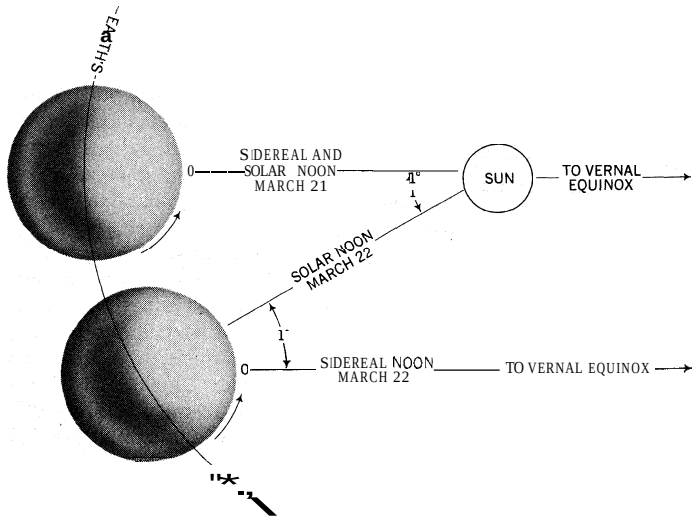
Rotation and Precession.—The time in which the earth revolves once around its axis is known as the sidereal day. Since the earth at the same time revolves around the sun in 365 days, the sidereal day is shorter than the conventional mean solar day by about 1 part in 365 (fig. 2). The exact length of the sidereal day is 23 hr. 56 min. 4.09 sec. of mean solar time. Astronomical observations show that the earth is not an ideal timekeeper. The length of the day is subject to certain minute changes. These might be classed under three headings: (1) a gradual slowing down of the earth's rotation—*i.e.*, lengthening of the day; (2) small annual or seasonal variations; (3) small irregular variations in the length of the day. The magnitude of the gradual slowing down is found from ancient astronomical observations; especially from ancient eclipses and from the more accurate astronomical data available since about 1600. This effect amounts to a change in average time of about 30 sec. per century. However, if this phenomenon is assumed to have existed throughout the earth's lifetime, the earth must once have rotated much more rapidly than it does now. The cause of the slowing down has not been established with complete certainty, but most probably it is due to the effect of tidal friction in the oceans. The loss of angular momentum by the earth is compensated by the moon, whose orbit moves farther away from the earth in this process. The theory has been developed in detail by Sir Harold Jeffreys. The seasonal fluctuations in the length of the day are minute, of the order of some thousandths of a second per year; they can be explained by changes in the size of the polar icecaps, changes in atmospheric circulation, etc. The irregular changes are equally minute and can apparently be traced to motions in the earth's core (see below).



FROM R. H. BAKER, "ASTRONOMY," D. VAN NOSTRAND COMPANY, INC., 1959

FIG. 2.—THE SIDEREAL DAY IS SHORTER THAN THE SOLAR DAY BECAUSE THE EARTH, ALSO REVOLVING AROUND THE SUN, MUST ROTATE FARTHER AFTER COMPLETING THE SIDEREAL DAY BEFORE THE SOLAR DAY IS ENDED. (ANGLES ARE EXAGGERATED)

In the absence of any external influences upon the earth, the direction of its axis of rotation in space would remain the same for all time. There are, however, other members of the solar system, in particular the moon (and also the sun), whose gravitational forces influence the earth. Since the earth is flattened, the moon's gravity tends to tilt the earth's axis so that it becomes perpendicular to the moon's orbit (and to a lesser extent the same is true for the sun). A spinning body (gyroscope) subject to such a force will not, however, yield to it, but the axis of rotation will precess—*i.e.*, sweep out a cone in space. This motion of the earth's axis is known as the precession of the equinoxes. It was discovered by the astronomer Hipparchus (120 B.C.) and first theoretically explained by Sir Isaac Newton. Precession implies that the pole of the heavens is not always in the same place among the constellations but moves about: for instance, 12,000 years hence it will coincide with the star Vega. The length of one period of the precession is 25,800 years. The precession makes the sun's orbit in the heavens (the ecliptic) and its intersection with the celestial equator (the equinoxial points) move in such a direction as always to meet the sun, at a rate of 50″.26 per year. This amounts to about 29° since Hipparchus' time; hence the ancient Greeks' description of the sun's yearly path across the constellations no longer fits. (See also PRECESSION OF THE EQUINOXES.)

The force tending to alter the tilt of the axis is not constant; when the sun or moon is crossing the equator, for instance, it has no effect. The path of the pole is therefore not exactly a circle but contains a superimposed smaller oscillation, the nutation, with a period of 18.6 years and an amplitude of 9″.2. The "Chandler wobble" is another gyroscopic effect of extremely minute amplitude and a period of 440 days; it is accompanied by a slight deformation of the earth's body. The solid body of the earth undergoes a slight daily tidal deformation due to the gravitational action of the moon and sun. The amplitude is small, about 25 cm. at most: it must be taken into account, however, in extremely accurate gravity measurements.

STRUCTURE OF THE INTERIOR

Seismic Exploration.—Two phenomena provide information about the deeper layers of the earth's interior. They are seismic waves and. to a lesser degree. the earth's magnetic field (discussed later). These are completely out of human control. Some hydrogen bomb explosions have produced earth tremors that could be observed at great distances from the source, so that the shocks generated by them penetrated deeply on their way across the earth. But apart from this relatively novel and rather expensive method. investigators have had to wait for major earthquakes to occur now and then. Larger quakes are recorded at seismological stations all over the world. If the station is far enough away from the focus (source) of the quake, disturbances reaching it must have traveled through the earth's deep interior. The disturbances have the form of shocks or pulses. but by the time they reach the observer they are usually spread out in time and are referred to as seismic waves.

The first effective seismographs were developed toward the end of the 19th century. By 1903 the International Seismological association was founded and from about that time a world-wide quantitative survey of earthquakes has been conducted. The information hearing on the earth's interior has been carefully analyzed by Jeffreys. Beno Gutenberg and K. E. Bullen. There are two main types of seismic waves, the P waves (primary, because they travel fastest) and the S waves (secondary. because they travel more slowly and hence arrive later at the station than the P waves). The P waves are compressional (longitudinal) in nature, whereas the S waves are shear (transverse) waves. For purposes of this article. this fact is not of major importance; it should be noted, however, that the existence of two types of waves greatly increases the amount of information to be had about the earth's interior. If the material of the earth's interior were uniform, all seismic disturbances would propagate along straight lines. But the mechanical properties of the material change with depth, and this leads to a phenomenon akin to refraction: the paths of the seismic disturbances are curved. They are convex toward the inside of the earth. Frequently, a seismic wave, on emerging to the surface of the earth, is reflected there and then progresses through the interior along another curved path. This may be repeated several times. The paths are determined by means of a step-by-step mathematical process, starting with short paths and then going to longer ones that reach progressively greater depth. The primary data are the travel times, the times elapsed from the moment of the earthquake to the arrival at the observing station. They depend in a rather complicated way on the distance between focus and observer. The derived data are the elastic properties of the interior as functions of the depth. (See also EARTHQUAKE.)

The most conspicuous feature of the earth's interior is the existence of a sharp boundary at which reflection and refraction occurs and which encloses the part known as the core; it represents an extremely well-defined discontinuity. The mean radius of the core (ignoring flattening) is 3,470 km. or nearly 55% of the earth's radius. The most outstanding feature of the core is that it never transmits S waves. Because this is a distinctive characteristic of liquids, it is generally accepted that the material of the core is in a liquid state. probably consisting in the main of molten iron. The existence of the core was first quantitatively established by Gutenberg in 1913. Later studies have shown that there exists a further boundary, somewhat diffuse, which encloses the so-called inner core. Its radius, not precisely known, is about 1,300 km. There is some evidence that the inner core is solid again, and a number of investigators believe it consists of solid iron (solidified again under the extreme pressures prevailing), but the question is not definitely settled.

The folloning terminology for the main layers of the earth is generally accepted (*see* fig. 3). Outermost is the crust: it is about 30 km. deep belon the continents but extremely thin, if not completely absent, below the oceans; its lower boundary is called the Mohorovičić discontinuity, after its discoverer. This is not everywhere a sharp discontinuity. The region below this and above the core is designated as the mantle, extending to the boundary of the core at a depth of about 2,900 kin. The mantle has some internal structure, but this structure is not too pronounced considering the mantle's enormous depth. The lower part of the mantle. below a depth of about 900 km., seems to be completely homogenous. The core (outer core) is fluid and appears quite homogenous; little is known about the inner core.

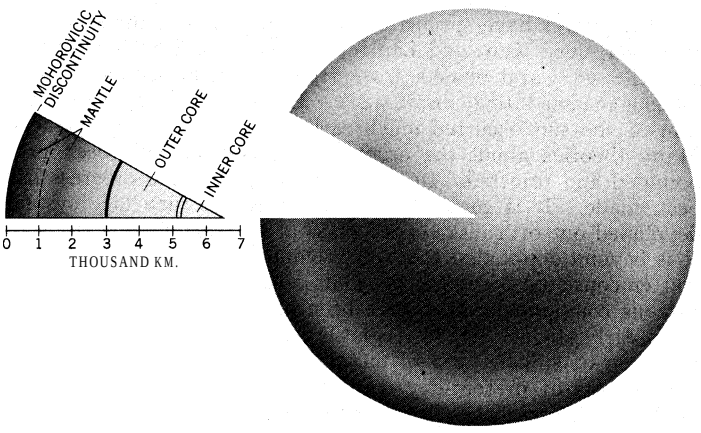


FIG. 3.— MAINLAYERS OF THE EARTH

Seismic Velocities, Density, Pressure.— From the primary data of seismology, namely. the travel times as function of distance, the variation of seismic velocities with depth can be computed. In the mantle as well as in the core there is a progressive stiffening of the material with increasing pressure; this makes the waves run faster at greater depths. The density distribution in the earth's interior cannot be uniquely determined from such data, but certain rather restrictive conditions are imposed on it thereby. A further condition results from a knowledge of the "moment of inertia" of the earth about its axis. This latter quantity is known with great accuracy from a combination of astronomical and geodetic observations. For a homogeneous sphere the moment of inertia about an axis through the centre is 0.4 ma^2 where m is the total mass: a the radius of the earth. The observations show that the moment of inertia of the earth is 0.333 ma^2, which can only be interpreted as indicating a rather pronounced increase of density toward the central parts of the earth. Combining the last figure with the seismic data and arguments regarding homogeneity of certain layers, Bullen determined a number of possible density distributions of which a plausible one is shown in fig. 4. The graph does not include the inner core. since little can be said about its density.

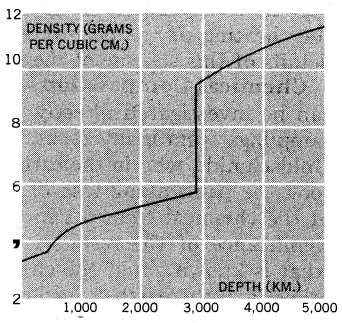

FIG. 4.—PROBABLE DENSITY DISTRIBUTION IN THE EARTH DOWN TO THE LIMIT OF THE INNER CORE

The pressure inside the earth rises rather regularly with increasing depth. In the mantle the rise is at a rate of about 370 atm./km. (1 atmosphere of pressure = 14.7 lb. per square inch). The pressure at the boundary of the core is 1.370.000 atm.. at the centre of the earth it is 3,700.000 atm. The strength of gravity is also a function of the depth; it clearly must vanish at the centre of the earth. Calculations based on the density distribution of fig. 4 show. however, that gravity is remarkably constant throughout the mantle, to within 1% or 2%; but beginning at about the boundary of the core it decreases steadily to zero.

ORIGIN, COMPOSITION AND AGE

Formation of the Earth.— The physics and chemistry of the earth are extraordinarily complex and have many interrelated facets. This makes it difficult to present the subject in a straightforward logical order. Some physical properties, such as density and gravity, which can be deduced, in part at least, from direct seismic observations, have been referred to. Other physical properties, such as the temperature, are best deferred until after the chemical composition of the earth has been discussed.

Astronomers have speculated about the origin of the solar system ever since Kant and Laplace suggested in the 18th century that the stars and planets arose from the condensation of vast gaseous masses filling cosmic space. It is possible that the formation of the sun occurred much earlier than that of the planets. Many theories about the origin of the planets have been propounded and rejected. In more recent times some progress has been made. It is generally accepted that the planetary system developed out of a disk-shaped mass of gas surrounding the sun. It is beyond doubt that the overwhelming part of original cosmic matter consisted of hydrogen (and some helium) and that these gaseous components must have been lost to space from the disk at an early stage. The less volatile matter condensed, mainly in the form of silicates and of metallic iron, these being the prime constituents of present-day meteorites as well as of the interior of the earth (see below). At the time the gas escaped, the solid matter probably consisted of bodies much smaller than the present planets, since the latter would hold on to a gaseous envelope by gravitation, at least to some of the gases heavier than hydrogen. The smaller lumps of silicates and iron eventually collected by gravity and, colliding with each other, formed the present planets.

While this picture is crude and speculative in its details, it brings out one crucial point common to all modern theories as distinct from the views held in the 19th century. The original matter from which the planets condensed must have been relatively cold. It could have been warmed only by the slight absorption of sunlight possible in the planetary disk. The corresponding temperatures were probably lower than those prevailing now at the surface of the earth. This is a fact of importance for an understanding of the history and even of the constitution of the earth. It follows that the original earth was not a molten mass. It might have come near to melting at a later stage as a result of the heat developed by radioactive substances, which heat remains largely trapped inside the earth. But this is a secondary process, and the picture is different from that of an original ball of molten lava cherished by earlier speculations. At some time the earth must have been soft enough to permit separation into the present layers, and at this time the radioactive substances, which tend to associate chemically with the relatively lightweight compounds, would have become concentrated in the outermost layers, thus preventing further heating of the deep interior. H. C. Urey worked out many details of this scheme of the formation of the earth.

Chemical Composition. — The composition of the earth's crust can be investigated directly by quantitative chemical analysis of samplings from many rocks. The pioneer in this field was V. M. Goldschmidt, who in the early decades of the 20th century undertook the painstaking task of determining the average proportions of the chemical elements in the earth's crust. To appreciate the significance of the results it is necessary to compare them with what is known about the chemical composition of cosmic objects other than the earth. Such objects are, in the first place, meteorites, messengers from outer space falling upon the earth. It is generally conceded that meteorites are fragments of a larger body pertaining to the solar system which was shattered by a collision with some other planetary object. A great number of chemical analyses of meteorites have been made. Next, quantitative determinations of the relative proportions of the chemical elements can be made for the sun by spectroscopic methods. Finally, the same can be done for other stars, although there the accuracy is limited.

One conclusion that long has been drawn from the vast mass of observations is that the gross chemical composition of matter in the universe is relatively uniform. There might be small variations from one star to the next, but on the whole the impression of over-all uniformity is strong. Scientists are thus led to think of a definite gross composition of primordial matter from which the earth and the other planets were formed. The figures given below for the relative proportions (known as "cosmic abundances") of the most important elements are from a compilation by H. Suess and Urey (1956). Since the abundances are only relative, they are expressed as the numbers of atoms existing per one atom of a reference substance. The latter is taken to be the element silicon, since rocks consist largely of compounds of silicon. These abundances are as follows:

Hydrogen ... 40,000.0	Sodium 0.04	Sulfur 0.37
Helium 3,100.0	Magnesium 0.91	Argon 0.15
Carbon 3.5	Aluminum 0.09	Calcium 0.05
Nitrogen 6.6	Silicon 1.0	Iron 0.6
Oxygen 21.5	Phosphorus 0.01	Nickel 0.03
Neon 8.6		

Remarkably enough, only six of the remaining elements have abundances that lie between 0.001 and 0.0001; all other elements are so rare that they exist only in minutest traces on the cosmic scale.

At the formation of the earth most of the volatile gases must have escaped to space. Some of them remain on the planet Jupiter, which has a density much lower than that of the earth. These volatiles must have included most of the carbon, nitrogen and oxygen, except for a fraction that may have been able to form nonvolatile compounds. The most important nonvolatile elements in the above table are magnesium, silicon, sulfur and iron; on the earth they are to be found mostly in the form of compounds rather than of the elements themselves. Some fraction of the oxygen is retained by forming compounds with the nonvolatile elements, especially silicon; a relatively small amount of hydrogen is retained in the form of water, although even all the water of the oceans and such water as is contained in rocks constitutes only a minute fraction of the total mass of the earth.

On the whole, the lighter compounds are more concentrated in the crust; they include oxides and more complex compounds of sodium, magnesium, aluminum and calcium that form many important constituents of common rocks. Geologists are able to discriminate between rocks pertaining to the surface layers and others that have been pushed up from lower layers and should therefore resemble more closely the chemical composition of the earth's mantle. On the basis of such data it is commonly believed that the earth's mantle consists primarily of certain compounds (silicates) containing oxygen combined with silicon, magnesium and iron. This takes care of three of the commonest nonvolatile elements. leaving sulfur to be accounted for. So far as sulfur exists in the interior of the earth, it is most probably in the form of iron sulfide. Geochemical evidence, however, indicates that the element is far less abundant on earth than the over-all cosmic abundance figure given above; much of it must have escaped and the remainder is not likely to be a major constituent of the earth.

Many students of the problem of the earth's constitution have proposed that the main constituent of the mantle is a mineral called olivine, since the oldest known rocks are largely composed of this substance. Olivine is a composite of magnesium orthosilicate, Mg_2SiO_4, and iron orthosilicate, Fe_2SiO_4. The two can crystallize together with any proportion of magnesium to iron. The common variety of olivine contains about one part of iron to nine parts of magnesium, but it is quite possible that farther down in the mantle the relative proportion of iron increases. Another group of minerals that might be important in the constitution of the mantle are the metasilicates of magnesium, $MgSiO_3$, and of iron, $FeSiO_3$, known as pyroxene. Olivine and pyroxene make up most of the silicate component of meteorites. Since there is good evidence that meteorites are fragments of a planetary body that has been shattered, their chemical composition is likely to be representative of the interior of a planet. Furthermore, seismic data as shown in fig. 1 agree well with the assumption that the earth's mantle consists mainly of minerals of the olivine type. There is some evidence indicating that at greater depth minerals of this kind might change their crystal structure to a more compact form.

The core is most probably composed of molten iron. This view has been held for many years and is generally accepted, although a few isolated dissenters look for a more complicated constitution. There is undoubtedly also a small amount of nickel, and some other impurities might be dissolved in the fluid mass. The view that the core consists of iron fits all the known physical and chemical facts. It is in agreement with the seismic data and, since the melting point of iron at high pressures is much lower than

that of the compact silicates, it explains the appearance of a sharp discontinuity at the core's boundary. Iron is by far the heaviest of the common nonvolatile elements, hence it will try to find its way toward the more central parts of the earth. Meteorites are composed mostly of the silicates mentioned above and of metallic iron (or an iron–nickel alloy). Some meteorites consist almost entirely of silicates, others entirely of iron and some contain lumps of metallic iron embedded in the silicates. This is commonly interpreted by saying that meteorites are fragments of a cosmic body smaller than the earth in which the temperature, pressure and force of gravity were smaller, so that the rather complete separation of metallic iron and silicates by gravity which exists in the earth did not take place.

The composition of the inner core is doubtful. The cosmic abundance tables show, however, that the sum total of all the elements heavier than iron (relative to the main constituents of the earth) is not remotely enough to fill a volume the size of the inner core; hence it is usually assumed that the inner core consists of iron, solidified under the extreme pressures prevailing near the centre of the earth.

Radioactive Age Determinations. — For many years geologists have estimated the length of periods in the earth's history on the basis of the rate of deposition of sediments. the thickness of observed layers and so on. They early arrived at minimum figures of well over 100,000,000 years for the main part of geological history The discovery of radioactive decay around 1900 provided an entirely new and much more reliable method for dating events in the earth's history. Radioactivity consists in the transformation of one species of atomic nucleus into another. In the case of naturally radioactive substances this transformation occurs spontaneously, and no chemical or physical condition of the environment has any effect on the rate of radioactive decay. In any given interval of time a fixed fraction of the atoms of the mother substance decay into atoms of the daughter substance. Radioactive decay, therefore, furnishes a natural and trustworthy type of clock wherewith to probe the distant past. Only the most long-lived of radioactive substances can be used for the dating of earlier periods in the history of the earth.

Sometimes several radioactive transformations occur in succession. The first radioactive substances that were discovered form a "family" of this type. Its parent substance is uranium, which through a series of decay processes goes over into radium and thence through a series of further decay processes into lead. The decay of uranium is by far the slowest process, so that by measuring the rate at which lead is formed in a substance containing uranium, the rate at which uranium decays is measured directly, inasmuch as the subsequent processes require only a short time compared with the decay of uranium itself. Each chemical element consists of a mixture of several types of nuclei (isotopes), and only one isotope of each element participates in a given radioactive transformation. Thus if a substance contains both uranium and lead it is possible to separate the particular isotope of lead produced by radioactivity, and by comparing this with the amount of uranium present, the time during which the radioactive decay has been going on can be ascertained.

The radioactive processes given below are used in the dating of rocks. The first two are complex families terminating in two different isotopes of lead, the other two are one-stage transformations. The numbers indicated are half lives—*i.e.,* they give the time in which exactly half the nuclei of the mother substance present to begin with have been transformed into nuclei of the daughter substance.

Uranium-lead	4,500,000,000 pears
Thorium-lead	14,000,000,000 years
Potassium-argon	1,500,000,000 years
Rubidium-strontium (est.)	50,000,000,000 years

The techniques of finding minute quantities of certain chemical elements and in particular their isotopes are extremely delicate, and it has taken many years to develop them. They are now sufficiently advanced so that if the age of certain rocks is determined by means of two or three of the radioactive schemes, the results agree closely.

In making these determinations it is assumed that at the time of the formation of the rock (for instance, by solidification from a volcanic magma) the isotopic constitution of the daughter substance is that normally found in the absence of radioactivity. As time goes on the isotope newly formed becomes enriched, and it is this enrichment that is measured. The oldest rocks thus dated are nearly 3,000,000,000 years old. None older than these have been found near the surface of the earth, but a series of dates extends from there with almost no gaps down to the present. It is interesting to see how these dates are tied in with the series of events determined by geologists. As is well known, the order of geological strata is fixed entirely by means of fossils; thus the geological method presumes the existence in these periods of living beings of gradually increasing complexity. By means of radioactive dating methods it is possible to ascertain definite lengths for the periods of geological history, especially more recent ones. The earliest period distinguished by geologists is the Cambrian, which occurred about 400,000,000–500,000,000 years ago. All older rocks are somewhat loosely lumped together as Pre-Cambrian. This is not to say that life did not exist in the Pre-Cambrian but merely that fossils have not been distinguished in these old rocks, and hence their position in a geological sequence cannot be ascertained as simply as that of more recent rocks.

Attempts have been made to estimate the total age of the earth. This is done under certain plausible assumptions, using data on the relative proportions of lead isotopes in very old rocks and in meteorites. In this way an age of the earth is arrived at of about 4,500,000,000 years. The figure is not too accurate, and it might be better to say that the earth is probably between 4,000,000,000 and 5,000,000,000 years old. The term "age of the earth" is not well defined here, since it is not quite clear through what processes the solid substances passed before forming a body approximately the present size of the earth.

MAGNETISM AND TEMPERATURE

Earth's Magnetic Field.——Seismic waves that have traversed the deeper layers, it has been noted, give us information about the earth's structure. An entirely different type of messenger from the interior is provided by the earth's magnetic field. The magnetic compass has been used by mariners for navigation from about the end of the middle ages. The earliest compasses consisted of lodestone (a magnetic mineral) fastened to a piece of wood which floated on water. Later, this mas replaced by a magnetized steel needle resting on a sharp point and free to swing about it. The magnetic needle points approximately to the north, but usually its direction differs from true geographical north by several degrees of angle, depending on position on the earth. This deviation is known as magnetic declination. If the magnetic needle is made to move freely in a vertical plane rather than a horizontal one and if this plane is oriented in the direction of magnetic north, the needle will come to rest in a position that makes an angle with the horizontal, the north pole of the needle pointing downward in the northern hemisphere and upward in the southern hemisphere. The angle with the horizontal is known as magnetic inclination. By combining the measurements of declination and inclination a direction in space is obtained along which a needle would point if suspended so that it could rotate freely in any direction. It is possible to measure the strength of this pull, the "intensity" of the magnetic force. If the spatial direction and the intensity of the magnetic force are measured at all places of the earth's surface, the results constitute what is knonn as the earth's magnetic field. Knowledge of this field has been gradually accumulated by magnetic surveys extending all over the earth.

In 1600 William Gilbert enunciated the proposition that "the whole earth is a big magnet," based upon the knowledge of that time and borne out by all later observations. All magnetic fields have sources, either in the form of magnetic substances such as magnetized steel, or in the form of electrical currents which are surrounded invariably by fields of magnetic force. The question arose whether the sources of the earth's magnetic field are inside or outside the earth. About 1830 the mathematician C. F. Gauss proved that if the magnetic field is known at all points of the

earth's surface, the field can be separated into two parts: one whose sources are entirely inside and another whose sources are entirely outside the earth's surface. Subsequently it was shown that only a small fraction of the earth's magnetic field comes from outside sources; the overwhelming part originates inside the earth. For a long time physicists thought that the magnetic field was due to magnetic materials embedded inside the earth, but as knowledge of the interior grew this possibility was gradually eliminated, since at the high temperatures prevailing in the earth all substances lose their magnetization. Thus it became necessary to look for another source.

The earth's magnetic field has two outstanding characteristics. The first is its irregularity, as seen for instance in the variation of the magnetic declination from place to place, the over-all pattern of which is quite complicated. The second is its gradual change in time. This is a phenomenon well known to all navigators: since the declination of the needle changes continuously, magnetic maps that indicate the declination are seriously in error after a few years and must be redrawn periodically from new observations. This change is known as the "secular variation" of the earth's magnetic field. If a variation of 10' per year continues over, say, 60 years, it corresponds to the considerable change of 10" in declination. The pattern of change is, however, itself variable.

These rapid changes make it clear that the field does not originate in the solid mantle of the earth. W. Elsasser demonstrated that the magnetic field is caused by electric currents that flow in the fluid, metallic core. The secular variation indicates that the fluid of the core is in motion. This motion carries the electric currents about and thus produces the variation of the field observed at the surface. The details of this variation, rather irregular, may be interpreted as representing so many large-scale eddies in the fluid. From the secular magnetic variation may be obtained a value for the average speed of the fluid iron; this is 0.03 cm./sec. or about 10 km. (6 mi.) per year. Further development of these ideas leads to the conclusion that the fluid motion not only modifies the electric currents but also can produce and maintain them. This process resembles closely the one that takes place in a rotating generator of electric current as found in power stations, where current is produced by the motion of metallic wires past each other. In the core, streams of molten metal are the equivalent of the moving wires. This explanation of the earth's magnetic field, known as the dynamo theory (Elsasser, 1947), has become accepted generally. The question as to what keeps the core in motion is taken up below.

Rock Magnetism. — When a lava melt is solidified in a magnetic field and the field is removed later, it is found that the solid rock formed retains a slight amount of so-called remanent magnetization along the direction in which the original magnetic force pointed. The remanent magnetism is due to small grains of magnetic material (iron oxide) embedded in the rock. On the basis of this it becomes possible to infer the direction of the earth's magnetic field at the time an ancient lava flow occurred. Similarly, sandstones have been shown to retain a small remanent magnetization along the direction of the field in which the material was deposited. The study of rock magnetism has been developed to the level of a systematic approach, giving information about the character of the magnetic field at earlier times in the earth's history. There seems to be little doubt that during the last 500,000,000 years or so that are accessible to detailed geological study the earth has had a magnetic field similar to its present one.

Work on rock magnetism has shown, surprisingly, that apparently the magnetic field has reversed its polarity many times, perhaps hundreds of times during the past history of the earth — that is, the magnetic south pole became the north pole, and conversely. A detailed explanation of this remarkable phenomenon is lacking; it can be said merely that its occurrence is conceivable in terms of the dynamo theory, since a self-excited generator can produce electric current in one direction as well as in the other, depending on its starting conditions.

One school of geologists maintains, largely on the basis of evidence provided by ancient climates, that the earth's geographic poles have shifted their position relative to the crust. According to this view the north pole was somewhere in the Pacific in early geological ages. Rock magnetic studies may permit verification of this hypothesis. No final conclusion had been reached by the 1960s, but there is much evidence that such pole migration indeed occurred in the past.

Temperature and Heat Transport. — There is no direct way of determining the temperature distribution inside the earth, but an instructed guess may be ventured. Something can be said about the surface layers, and it is a well-known fact that the temperature rises in the lower levels of deep mines. The rate at which heat is delivered to the surface is given by the rate at which the temperature rises (the thermal gradient), multiplied into the thermal conductivity which is a characteristic constant of the material. Thus by measuring the two last-named quantities the heat flowing out of the earth can be determined. The results of heat-flow measurements on the ocean bottom indicate that even where the oceans are very deep the heat flowing out of the earth is comparable to that flowing out on the continents. The average thermal gradient in the outermost layers of the earth is about 12°–15° C. per kilometre of depth. The average heat flow near the surface of the earth is about 1.2×10^{-6} cal. per square centimetre per second.

Assuming that. say, a thermal gradient of 14°/km. continued to greater depth, the temperature at a depth of 300 km. would be about 4,200° C. This is certainly far above the melting point of any silicate, even at the pressures prevailing at such depth. Hence the temperature must level off; that is, the thermal gradient must radically diminish even at moderate depths inside the earth. It long has been concluded that most of the heat flowing out of the earth is produced by radioactivity (the most important contributions coming from the decay of the uranium and thorium families) and that the radioactive material must be strongly concentrated in the top layers of the earth. If the material were distributed at greater depth, the earth would have been completely melted long ago. On the assumption that the earth was formed in a cold condition and that radioactivity was evenly distributed in the beginning, then the earth would gradually heat up by radioactivity during its early history. This follows from the fact that heat conductivity of rocks is poor: in a crude way of speaking, heat cannot penetrate a layer of silicates more than 200 km. thick even in the course of several billion years. Eventually, then, the iron will melt and thereafter the melting point of silicates will be approached. After the silicates have become soft enough (they perhaps need not melt completely) a separation of the material into layers will take place. It may be shown that radioactive substances form compounds that are relatively light and tend to float toward the surface.

For a long time it was believed that most of the radioactive material is in the crust, and since the crust is thick under the continents but thin or almost absent under the oceans, this would mean that most of the heat flow would occur in continental areas. Heat-flow measurements on the ocean bottom have shown that this view is wrong; the radioactive material is there, though under the oceans it is apparently in the mantle (below the Mohorovičić discontinuity) and not in the crust.

Next consider the temperature distribution in the deeper layers of the earth. In this it is necessary to rely largely on guesswork, but any assumed distribution is subject to certain conditions. It must remain below the melting point of the simple silicates throughout the mantle, it must be above the melting point of iron in the outer core, and if the inner core consists again of iron the temperature must rise to the melting point of iron at the boundary of the inner core and exceed it inside the latter. The best way to obtain the temperature inside the earth is therefore to estimate the increase of melting point with increasing pressure. This can be done only roughly since the pressure at the boundary of the core is about ten times that of pressures obtainable in the laboratory.

Estimates of the temperature in the earth's interior tend toward relatively low values, perhaps in the neighbourhood of 3,000" C. at the boundary of the core and near 4,000" at the centre

of the earth. These estimates, however, may be in error by many hundreds of degrees.

Silicates, as has been said, conduct heat only very slowly, and on this basis any heat contained in the deeper layers of the mantle would, as it were, remain nearly sealed in during the lifetime of the earth. In 1956, however, E. Clark and Francis Birch brought to light another mechanism of heat transport in the mantle, namely, by radiation. All substances radiate when raised to sufficiently high temperatures. At moderate temperatures this radiation consists of infrared rays: the heat radiated by a hot stove can be felt but not seen. As the temperature increases. more and more of the radiation becomes visible, first as red, then as yellow and finally as white glow. Stefan's law says that the total amount of energy radiated is proportional to the fourth power of the absolute temperature, hence it rises extremely steeply with increasing temperature. There is no doubt that such radiation is present inside the earth; the main question is whether it can travel fast enough from place to place to transport an appreciable amount of heat. The rate of heat transport by means of radiation depends essentially on the transparency of the materials involved; the more transparent they are, the more rapidly heat can flow by radiation. Such minerals as olivine are rather transparent even to the naked eye, as may be seen by holding a thin plate against the light. At an early stage of the investigation of this effect, it appears that at temperatures somewhat above 1,500° C. radiative heat transport begins to approach the magnitude of ordinary heat conduction. and at somewhat higher temperatures radiative transport becomes much more efficient than ordinary conduction. The result of all this is that in the deep interior of the earth the temperature can be equalized much more readily than had been assumed; hence only a moderate thermal gradient should be present in the lower parts of the mantle.

In regard to the core, there is one piece of fairly direct evidence, namely, the relatively rapid fluid motions that are mirrored, as it were, in the variation of the earth's magnetic field. By far the most plausible explanation of these motions is that they represent a form of thermal convection, entirely akin to the upwelling that is observed when a pot of water is heated from below, making the warm water from the bottom rise to the surface. This view is held by most students of the problem. For a long time it was difficult to understand how such convection can occur in a notoriously good conductor of heat such as a metal which is surrounded and thus shielded by a poor conductor such as the rocky mantle. The obstacle disappears when radiative heat transport is taken into account. Radiative transport is quite small in the core since metals have a very low transparency; on the other hand, the radiative transport in the lower mantle appears to be more effective than the transport by conduction in the core, and this difference keeps the convective process in the core going. Whether the core cools down gradually as a result of the heat carried away through the mantle, or to what degree this loss is compensated by heat produced by radioactive materials in the core or in the inner core, had not been decided in the early 1960s.

ORIGIN OF THE SURFACE FEATURES

The surface of the earth shows a remarkable degree of irregular structure. In spite of the assiduous work of generations of geologists very few generalizations have emerged. One of them is that the levels of the earth's surface cluster around two preferred heights: (1) sea level—most of the areas of the continents and of the offshore continental shelves do not differ much from sea level—and (2) ocean bottoms, with an average depth of about 5 km. (3.1 mi.). Levels between these are rare. Another remarkable regularity has to do with the asymmetrical distribution of land and water masses. If a diameter is drawn arbitrarily across the earth's centre in more than 90% of all cases one end of the diameter is on land, the other on the sea. The fact that conclusive explanations, going beyond mere speculation, of such simple regularities cannot be given is indicative of lack of understanding of most of the basic physical and chemical processes that have shaped the surface of the earth in its present form.

Isostasy.—There is, however, a hypothesis, founded on physical law and accepted on observational evidence, according to which the surface features of the earth are subject to the principle of isostasy. first developed by J. H. Pratt and G. B. Airy around 1850. Clearly, if the continents were fluid they would flow out laterally and eventually disappear in the ocean deeps, covering the earth uniformly. The fact that this is not observed indicates that the material of the continents has a finite strength. On the other hand, rocks can be deformed, and this type of deformation is known as plastic flow. The deformation of the earth's crust may be visualized by means of the flow of pitch (although pitch, technically speaking, is not plastic but viscous). If a load is put on the pitch—for instance, a piece of rock—the load will gradually sink down. The crust considered as a load on the mantle differs from this example in an important respect: the load is less dense, it is specifically lighter than the substratum. Such a load will sink only to a depth where it is floating freely with respect to vertical displacements; it resembles an iceberg floating in the water with the larger part submerged beneath the surface. According to the principle of isostasy there is a tendency toward vertical equilibrium of the crust, which is much easier to achieve than horizontal spreading. Quantitatively speaking, the total mass encountered on going from the surface down toward the earth's centre tends to be the same for any point of the surface. Where there is a mountain there seems to be more mass, but isostasy indicates that there must be a deficiency of mass farther down: the mountain has a root consisting of matter less dense than the material farther down and than the material under the oceans. The root is bigger than the mountain itself; the lighter material extends down to about six times the mean elevation of the mountain.

This idea of isostatic (vertical) compensation was first developed on the basis of gravity observations. If ideal isostatic balance prevailed. gravity would be the same over the oceans and continents (apart from variation with geographical latitude). Actually most mountainous elevations and most oceanic deeps are fairly well compensated isostatically. Deviations, known as gravity anomalies, occur in the regions where active mountain building goes on. The Pacific island areas (*e.g.*, the Japanese islands) are an example. Volcanic activity is concentrated in these same regions, as are earthquakes. Many earthquakes originate fairly near the earth's surface, but in these active regions earthquakes are observed to originate at depths down to 700 km.; these are known as deep-focus earthquakes. Thus the upper mantle seems to participate to at least this depth in the mountain-building processes. Whether the lower mantle also plays a role, more or less indirect, in influencing the geological activity near the surface is unknown. (See also ISOSTASY; GEODESY: Isostasy.)

Theories of Mountain Building.—The problem of the formation of the continents and mountains is one of the few great unsolved questions of physical science. A series of four agencies has been held responsible for mountain building, either individually or jointly, though it is probable that several (especially the last three) have been acting together. The actual mechanisms as related to geological observation cannot be discussed here; the principles will merely be enumerated.

1. Contraction.—The meaning is best represented by the popular simile that the earth resembles a shrunken apple, the mountains and valleys being the wrinkles of its skin. This is the oldest hypothesis, but ever since the discovery of radioactive heating of the rarth it has been difficult to believe that the earth has shrunk appreciably in geological times.

2. Convection.—If the mantle were a viscous fluid heated from below, convective upwelling would occur at a slow rate. Speeds have been estimated as of the order of one millimetre per year. If the thermal conditions are right there must certainly be a tendency toward convection, though the mantle is a plastic solid and not a viscous fluid, and this might make actual patterns look quite different from those of a fluid. With the leveling off of the temperature curve down in the mantle, moreover, it is doubtful whether convective motions can extend deeper than the upper mantle. It has been impossible to identify any specific geological phenomenon as caused by convection, but the general idea is strongly in the mind of geologists and geophysicists.

3. Phase Change.—By this is meant a change in crystalline structure of minerals, which may occur as a result of either temperature or pressure changes. In particular, there is much evidence that at high pressures certain more compact forms of minerals are stable that do not exist at the surface of the earth. It has been claimed that the Mohorovičić discontinuity at the bottom of the crust represents such a phase change. Temperature might rise by radioactive heating and this could shift the discontinuity downward. Temperature falls again and the discontinuity rises if the heat is carried off by volcanism and other agencies. The tendency toward isostatic equilibrium might then produce fairly large vertical displacements. Such ideas are comparatively new, and while they may not be enough to explain mountain building alone. the process can play an important subsidiary role in a complete theory.

4. Accretion.--Since, on going down into the earth, the temperature first rises very rapidly and then more slowly, the silicates of the mantle might be closer to melting at a few hundred kilometres depth than elsewhere. If melting occurs locally, the material will separate into its lighter components on top, the heavier below. Lighter material might gradually make its way through the overlying layers to the top, and in this manner the amount of crustal material can grow. Volcanism appears to be a process of this kind. It is thus possible that the continental blocks of the crust have only gradually accumulated through geological ages. There is also strong evidence to the effect that the ocean and the atmosphere are secondary products of accretion — that is. have been slowly formed in the course of the earth's history from material coming out of the rocks. The accretion theory has become popular, and there is little doubt that some of the insights it provides are highly significant. A definitive theory of mountain building. which remains to be propounded, is likely to be very complex and to contain a combination of several of the aforementioned mechanisms.

Encyclopedia *Britannica* contains a vast number of articles relating to the earth. For the main article on the science of the earth, see GEOLOGY; for composition and chemistry of the earth, see GEOCHEMISTRY; for earth physics. see GEOPHYSICS and the numerous related articles on various branches of geophysics cited there; geodesy, the science of earth measurements and internal structure, is discussed at length in GEODESY. See also references under "Earth" in the Index volume.

EARTHENWARE, opaque ceramic bodies that are permeable under the glaze. They are composed of varying mixtures of three basic ingredients: (1) plastic clays, to give workability; (2) flint. to prevent deforming during firing; and (33 feldspar. to act as a flux and give hardness to the fired body. Small amounts of other ceramic ingredients are also added, depending on production needs. Earthenwares are bisque fired from about 650° to 1.000" C. and then are covered with a glaze coating to make them nonabsorbent; the glaze coating is fired at temperatures ranging from 1,000" to 1,100° C. Decorating processes are similar to those for chinaware. (See CHINAWARE: *Decorating* the *Ware.*)

Principal earthenware types include faïence, majolica, delftware, terra cotta and queen's ware. See POTTERY AND PORCELAIN: *European* Pottery; see also references under "Earthenware" in the Index volume. (P. V. G.)

EARTH INDUCTOR COMPASS: see COMPASS.

EARTHNUT, a European plant. *Conopodium majus* (Umbelliferae. or parsley family), so-called because of its edible tubers. It grows in woods and fields in the British Isles, and from Norway, France, Spain and Portugal to Italy and Corsica. It is a slender, smooth perennial two to three feet high, with much-divided leaves and small white flowers in compound umbels. The basal leaves wither at flowering time, and the stem leaves wither as the fruits mature. The tubers. reaching one inch in diameter, are more commonly used as food on the continent than in Britain. The plant is also called pignut or hognut. The peanut (*q.v.*) or groundnut (*Arachis* hypogaea) is sometimes called earthnut. (J. W. TT.)

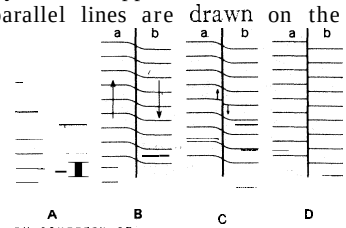
EARTH PILLAR, a column of soft rock. or earth, which has not a homogeneous structure throughout but contains large blocks embedded in much finer material. By exposure to conditions of denudation, especially rain action, the large blocks protect the material beneath and so, by differential action, the earth pillars are produced. Glacial drift and morainic deposits are ideal substances in which earth pillars can be formed and these structures are therefore found in regions of recent glaciation. Earth pillars are most likely to be found where the climate is semiarid with precipitation concentrated. The "bad lands" of western North America furnish excellent examples, and there are specimens in Tirol and other parts of the Alps, in Scotland and in the Dead sea region.

EARTHQUAKE. Whenever the state of elastic strain or distortion of a limited portion of the earth is suddenly changed, either increased or decreased. elastic waves are set up which travel outward in all directions. The shaking of the ground produced by the waves is known as an earthquake. The limited region in which the strain increment occurs is called the earthquake source. Earthquakes are classified according to the nature of their sources. Those originating in a strain increase are termed explosion earthquakes. They are produced by man-made dynamite or nuclear-energy blasts and by volcanic-steam explosions and sudden movements of molten lava within the earth in association with the activity of volcanoes. The latter, called volcanic earthquakes, are generally small in size in comparison with other natural earthquakes, although a few are large enough to be severely destructive over small areas.

All great earthquakes and the great majority of small ones are generated by the sudden decrease or release, in a volume of rock. of elastic strain previously accumulated over an interval of time varying from a minimum of about a year in regions of great activity to many centuries in others. Earthquakes of this type are designated tectonic earthquakes. The volume of rock involved is related to the energy of the earthquake and is roughly 2,000.000 cu.mi. for the largest shocks. The strain accumulation is produced by differential movements of portions of the earth's outer layers. In the majority of shocks the movements are horizontal. The processes of orogeny — the growth and wearing down of mountains — result in vertical differential movements and these are also responsible for a substantial number of earthquakes.

MECHANISM OF GENERATION

In the case of explosion shocks. the sudden expansion of the charge produces an outward movement of the surrounding rock and this movement is propagated to great distances in the form of to-and-fro wave motion owing to the elastic nature of the rock (see GEOPHYSICAL PROSPECTIKG). In tectonic earthquakes, the sources are associated with great fractures in the crust of the earth known as faults. The behaviour of a fault (*q.v.*) in the generation of an earthquake is illustrated in fig. 1. In drawing (A), on the left, the fault is represented by the heavy line. Suppose that after the occurrence of an earthquake. parallel lines are drawn on the ground perpendicular to the fault as shown at (A). It will be found that the blocks (a) and (b) have moved relative to each other as shown at (B). The high pressure existing within the earth produced by the weight of the overlying material presses the blocks together with great force and the resulting friction between the two surfaces of the fault



BY COURTESY OF HUGO BENIOFF

FIG. 1.—DIAGRAMS ILLUSTRATING MECHANISM OF EARTHQUAKE GENERATION ON A FAULT (see TEXT)

prevents them from slipping past each other. Consequently, the adjacent regions are distorted (strained) and the original parallel lines become curved in the vicinity of the fault as indicated. The strain involves a storage of elastic energy in the same way that a bent bow contains stored elastic energy available for driving an arrow. As the strain gradually increases there comes a time when at some point along the fault the elastic stress becomes sufficiently large to break the restraining frictional bond and at that point. called the focus or hypocentre, the fault surfaces suddenly slip as represented in (Ci. The slip at this point increases the stress at neighbouring points caused by crowding and these then slip also. In this way slip is propagated rapidly along the fault for a greater or less distance depending upon the size of the original strained volume and the strength of the frictional bond,, After the slip has occurred the configuration appears as in (D) with the fault surface of block (a) permanently displaced relative to block (b). The release of frictional restraint and the sudden consequent fling of the two fault surfaces converts the stored elastic strain energy into kinetic energy in the form of elastic waves in the rock that travel in all directions from the region of strain relief.

In any single earthquake the amount of slip—that is, the relative displacement of the two fault surfaces—may be a few inches in a very small earthquake or up to 50 ft. or more in a large earthquake. 'The largest measured slip was in the Uakutat, Alaska: earthquakes of 1899 where a vertical slip of 47 ft. was measured.

After the earthquake has taken place the fault surfaces again become locked by friction and cementation. The blocks then continue their relative movement as before and in time another earthquake is produced. The rate of the steady relative block motion has been measured on only one fault. the San Xndreas of California. where it was found to be approximately two inches per year. During the 1906 San Francisco earthquake, the slip occurred on a northern 270-mi. segment of the fault from San Juan to Upper Mattole. The slip was horizontal with a maximum displacement of 21 It. In 1357 a similar slip occurred on the southern segment from San Bernardino northward. The total accumulated slip on this fault since movement began has been estimated by California geologist Mason Hill to be not less than 350 mi. It may be very much greater.

The extent of faulting. defined as the length of the fault segment over which slip takes place, varies from a few hundred yards in a small shock to a maximum of several hundred miles in the greatest earthquake. The great Kamchatka earthquake of Nov. 4, 1952, and the Aleutian earthquake of March 9, 1957. each exhibited active segments of approximately 600 mi. as indicated by the distribution of aftershocks (see fig. 6).

The direction of slip may be horizontal, vertical or a combination of the two depending on the nature of the fault. The volume of strained rock which constitutes the source of earthquake energy is roughly a rectangular prism with approximate dimensions that may extend up to 600 mi. in length. as at Kamchatka. by 150 mi. in width and 20 mi. in depth. When a seismologist announces the position of an earthquake he usually refers to the position of its epicentre. the point on the surface vertically above the hypocentre. rather than the centre of the source.

The three principal kinds of faults are illustrated in fig. 2. Fault (A) is known as a normal fault. The plane of the fault is inclined to the vertical and the overlying block slips downward relative to the underlying block. This type of fracture is generated by tensional forces directed horizontally at right angles to the fault acting together with the downward force of gravity. In (B) the character of the fault is the same as the one in (A) except that the direction of motion is reversed. This type is termed a reverse fault and originates from compressive forces acting horizontally at right angles to the fracture. In (C) the slip is strictly horizontal and the fault is known as a strike-slip or lateral fault. Faults are fairly common in which the slip direction is a combination of that of (C) with either (A) or (B). The San Andreas fault is a good example of a fault with horizontal slip only, as in (C) in the figure. It is branched in the southern portion and fig. 3 shows an air photograph of a segment of one of the branches, looking northward. The town of Indio is below to the left just off the .picture. Because of the desert climate of this region, weathering is slow and the fault stands out as a clean cut. Although the two truncated mountain areas at the lower left and at the centre of the photograph appear to be the two parts of a single mass displaced by the fault, they are in fact entirely unrelated structures. The relative block motion as shown by the arrows is such that the one on the left has moved up from the south relative' to the other, and the total motion has been so great that the mating portions of both blocks are not identifiable because of differences in the geologic processes to which they have been subjected.

OCCURRENCE

Depth Distribution.— Earthquakes are conveniently classified in three depth ranges—shallow, intermediate and deep. The shallow shocks have hypocentres extending from the surface to a depth of 30 mi. This classification includes most of the great earthquakes and those of greatest destructiveness. The intermediate group has hypocentres ranging from 30 to 185 mi. below the surface of the earth. These are fewer in number than the shallow type and, except for those occurring near the upper boundary, are smaller and less destructive. 'The deep earthquakes have hypocentres extending in depth from 185 to 450 mi., approximately one-tenth of the earth's radius. No shocks have occurred at greater depths since seismographs have been available for observing them. It is assumed that they do not occur deeper, since at the high temperatures which prevail there the rock flows or creeps under stress and consequently is unable to accumulate sufficient strain to generate earthquakes. Honever, it is possible that under the conditions existing within the earth, processes may occur at rare

intervals involving sudden changes of state with consequent sudden changes in volume of a mass of rock and so produce earthquakes deeper than those observed in the short time since the seismograph (*q.v.*) was invented.

Geographic Distribution. — Although probably no area of the earth is entirely free of earthquakes if a sufficiently long time interval is considered, in recent times the great majority have occurred in well-defined regions. The epicentres of large shallow earthquakes, magnitude 7.9 and greater (see *Magnitude*, below), that occurred in the 20th century are plotted in fig. 4 together with a few dating back to 1896. From this map it can be seen that there are two principal active regions, a rather narrow belt extending around the margins of the Pacific ocean and a wedge-shaped area lying across southern Asia. Asia Minor and the Mediterranean region, with its broad base in China and the point off the coast of Portugal. The circumpacific belt thus includes the western coasts of North and South America, the Aleutians, Kamchatka, the Kuriles. Japan. the Philippines and a strip through the East Indies to New Zealand. The wedge-shaped area includes, among others, portions of Mongolia, southern and western China, Tibet. Baluchistan, northern India, Assam, Turkistan. Iran, Turkey. Bulgaria. Greece, Italy, Algeria and Portugal. Fairly large earthquakes occur in the antarctic region to complete the Pacific circle, although no great shocks have been recorded from that region since instrumental data have been available. Other regions of minor activity with smaller earthquakes include a narron band along the mid-Atlantic ridge from Spitsbergen and Iceland south to about latitude 60" S. This joins another narrow belt from the southern tip of South America running east to a point south of Malagasy (Madagascar) nhere it bends to the north and extends into the Indian ocean to the coast off Arabia and then turns west to join another narrou belt running north to south donn the eastern part of Africa through the Great Rift valley of that continent.

The geographic distribution of intermediate-depth earthquakes (fig 4) is very similar to that of the great shallow earthquakes except that their epicentres generally lie farther inland along the Pacific margins and they are entirely absent along the Pacific coast of North America from Lower California to Alaska. Moreover. they are almost entirely absent from the regions of minor shallow activity.

FIG. 5.—MAP OF THE KAMCHATKA-KURILE REGION WITH PROFILES AND A SECTION SHOWING DISTRIBUTION IN DEPTH OF EARTHQUAKE HYPOCENTRES (M = MAGNITUDE: 1 KM. = 0.621 MI.)

The deep earthquakes are still more restricted in their distribution (fig. 4). They follow the western rim of the Pacific from Kamchatka to the Tonga-Kermadec islands and the eastern arc from Chile to Peru only. Moreover, their epicentres generally lie still farther inland as compared with the intermediate-depth shocks. In the Asiatic-Mediterranean wedge they are represented by only two shocks. One appeared under southern Spain on March 29, 1954, at a depth of 400 mi., and the other under Sicily on Feb. 19, 1955, at a depth of 290 mi.

Along the circumpacific margins the spatial distribution of the three depth classes of earthquakes follows a unique pattern illustrated on the map and vertical section of the Kamchatka-Kurile region (fig. 5). The geographic distribution of epicentres of larger earthquakes from 1904 to 1945 is shown on the map, the open circles referring to shallow shocks and the filled circles and triangles to intermediate and deep shocks respectively. The

FIG. 4.— WORLDDISTRIBUTION OF EPICENTRES OF EARTHQUAKES

locations of volcanoes are also included together with a rough outline of the great oceanic trench which lies off the coast. Vertical sections indicated (A') (B') are taken along the dashed lines on the map and show the relative position of the trench. the neighbouring uplift and the line of volcanoes. (C'D') is a vertical section on which the earthquake hypocentres are plotted showing their horizontal distances from the line of volcanoes and their depths. Thus the shallow shocks are distributed farthest away from the continent. The intermediate shocks and deep shocks appear to lie in two fairly thin plane regions which dip under the continental margin at angles of about 35° and 60" respectively. This distribution is typical of all of the circumpacific margins where deep earthquakes occur. In the Aleutians and the Mexico-Central America segments of the arc, the deep shocks are missing but other features are the same. On the segment of the Pacific coast of North America from Lower California to Alaska, the intermediate and deep shocks and the trench are all missing.

Foreshocks.—Although many large earthquakes occur without any forerunners, a few are preceded by one or more small shocks known as foreshocks. In some instances, the foreshocks appear in rather large numbers for several days or hours before the main shock. Thus in the Pleasant Valley, Nevada, earthquake of 1915, people living near the fault felt almost continuous shaking accompanied by rumbling noises beginning at 5:49 P.M. and continuing until 10:53 P.M. when the principal shock occurred. In about 1 case in 20 a large earthquake is followed by another of equal or greater energy.

Aftershocks. — Every large earthquake is followed by a number of smaller earthquakes known as aftershocks. They appear immediately after the principal shock and may continue to occur for a period extending from a day or two, in exceptionally short sequences, to a maximum of about 15 years. The majority of sequences continue for about two years. Following the Kern county, Calif., earthquake of 1952, a seismograph of high sensitivity located at Palomar observatory, 172 mi. from the epicentre, exhibited continuous ground vibration for more than 24 hours due to the large number of aftershocks. The aftershock epicentres are usually distributed over a roughly rectangular area having a long dimension corresponding with the active fault segment of the principal shock and a transverse dimension extending up to 150 mi., depending upon the region and the size of the earthquake. When the principal earthquake is small the aftershocks tend to be concentrated near the ends of the active fault segment. With large principal earthquakes they are more nearly uniformly distributed along the length of the segments as illustrated on the map (fig. 6), which shows the location of the epicentre of the Aleutian earthquake of March 9, 1957, and the distribution of the epicentres of some of the iarger aftershocks.

The manner in which the frequency of occurrence and size of aftershocks are related in time has indicated that about half of them are due to elastic afterworking of the fault rock. If a thin flat strip of steel is bent and then released, it returns immediately to its original flat shape. Some other materials, however, behave differently. Thus a strip of leather or plastic will recover only part of its strain immediately after release; the final portion of recovery takes place at a slow rate that may require days or months for completion. This effect is known as elastic afterworking. It has been observed in rocks subiect to stress in the laboratory, and the law of recovery so found coincides with that observed in a large class of aftershocks.

Another class of aftershocks appears to be produced by final release of strain redistributed during the original fling of the blocks and retarded by viscous flow of subcrustal material. In general, aftershocks are less destructive than their principal shocks but occasionally a relatively small aftershock can produce more damage as a result of being closer to a populated area. A case in point is the Kern county earthquake mentioned above. The city of Bakersfield, situated about 15 mi. from the active segment of the principal shock. suffered relatively little damage in the principal shock. A small aftershock with about one-hundredth the energy of the principal shock, but occurring near the city. produced a greater amount of destruction than the principal shock.

FIG. 6.—EPICENTRES OF THE ALEUTIAN EARTHQUAKE OF MARCH 9, 1957, AND A NUMBER OF ITS LARGER AFTERSHOCKS

Tsunami. — Large earthquakes with sources near coasts either inland or offshore, and particularly those occurring in the vicinity of great oceanic trenches, occasionally produce great ocean waves known as tsunamis (sometimes erroneously called tidal waves). Some are believed to be caused by vertical fault movements and others by submarine landslides initiated by earthquakes. In the open ocean the wave amplitudes are small, two or three feet at the most, but their wave lengths — distance from crest to crest — may be more than 100 mi. The wave periods — the time from crest to crest — usually range from 15 to 30 min. The waves travel at speeds ranging from about 150 m.p.h. in water 1,600 ft. deep to about 670 m.p.h. in water 30.000 ft. in depth. Although the amplitudes are small in the open ocean. they increase greatly upon approaching shore. especially in V-shaped bays where they may rise to 90 ft. or more and thus produce very great destruction and loss of life. The initial wave usually, but not always, begins with a recession which appears as an abnormally low tide occurring in a matter of minutes and exposing the ocean floor far beyond the limits of normal low tides. Residents of coastal regions subject to these waves recognize these abnormal recessions as the first movements of a tsunami and flee immediately to high ground. Tsunamis travel great distances across the ocean with relatively little loss of energy. A tsunami originating in the Aleutian earthquake of April 1, 1946, produced waves up to 55 ft. high in the Hawaiian Islands, where more than 150 lives were lost and 488 homes demolished. The waves were 12 ft. high on the California coast at Santa Cruz, where one man was drowned.

Seismic **Seiches.**—Seismic seiches are oscillations generated by earthquake surface waves in closed or partially closed bodies of water such as lakes, harbours, fjords and rivers (see SEICHE). In great earthquakes, seiches may be produced at large distances from the source. The great Lisbon, Port., earthquake of 1755 set up seiches all over western Europe including the Scandinavian countries and Finland. In Scotland, Loch Lomond oscillated for an hour with-an amplitude of about two feet.

GREAT EARTHQUAKES

About 50.000 earthquakes of sufficient size to be felt or noticed nithout the aid of instruments occur annually over the nhole earth. Of these about 100 are large enough to produce substantial destruction if their centres are near areas of habitation. The very great earthquakes occur at an average rate of about one per year. Among the great earthquakes of historic times have been those of Lisbon, Port.. in 1755; New Madrid, Mo . in Dec. 1811 and Jan and Feb. 1812; California (San Francisco) in 1906; and 'Tokyo, Jap , in 1923.

Lisbon **(1755).**—On Nov. 1, 1755, Lisbon Port., was destroyed by a great earthquake uhich occurred at 9.40 in the morning. The source was probably situated some distance off the coast. The principal shock nas felt strongly for about six minutes. The violent shaking demolished all large public buildings and about

12,000 dwellings. Nov. 1 being All Saints' day, a large portion of the population was in the churches, most of which were destroyed with great loss of life. The total number of persons killed in Lisbon alone was estimated to be at least 60,000, including those who perished by drowning and in the fire that burned for six days following the shock. Damage was severe in Fès, Mor., and some damage was reported in Algiers, 700 mi. to the east. The earthquake generated a tsunami which produced waves 60 ft. high at Cadiz, Spain. and 40 ft. high at Lisbon. They traveled on to Martinique. a distance of 3,710 mi., in ten hours and there rose to a height of 12 ft.

New Madrid (1811–12).—One of the greatest earthquakes occurred near New Madrid in southern Missouri. Actually. there were three large shocks. on Dec. 16, 1811. Jan. 23, 1812, and Feb. 7, 1812. Very likely one was the principal shock and the others were foreshocks or aftershocks, but the available information is inadequate to settle this point. There were numerous other aftershocks of which 1,873 were large enough. to be felt in Louisville. Ky., 200 mi. distant. The principal shock produced waves of sufficient amplitude to shake down chimneys in Cincinnati, O..400 mi. away. They were felt as far away as Canada in the north and the Gulf coast in the south. The area of greatest shaking was about 30.000 sq.mi., considerably greater than that which accompanied the California earthquake of 1906, and largely on this basis it has been assumed by many seismologists that this earthquake was the largest United States earthquake since white men arrived. However, continental channel waves travel great distances with little loss of energy. Consequently, in continental earthquakes such as the Missouri shock, the area of strong shaking can be abnormally large as compared with coastal shocks. In coastal regions the channel is distorted or absent and hence the waves are attenuated faster with distance as compared with the mid-continental areas. If judged on the basis of the size of the shaken area, an earthquake of a given energy situated well inland will thus appear to be greater than one of the same size occurring in the more active Pacific coast areas. There is no question, however, that the New Madrid shock was a great one. In one region 15'0 mi. long by 40 mi. wide, the ground sank from 3 to 9 ft. and was covered by river water which rushed in. In places, forests were overthrown or ruined by loss of soil shaken from the roots of the trees.

California (1906).—On April 18. 1906, at about 5:12 A.M., the San Andreas fault slipped over a segment about 270 mi. in length extending from San Juan in Benito county to Upper Mattole in Humbolt county, and from there out under the sea an unknown distance. The slip was felt from Los Angeles in the south to Coos Bay, Ore., in the north. Damage was severe in San Francisco and in other towns situated near the fault such as San Jose, Salinas and Santa Rosa (20 mi. from the fault). Approximately 700 people were killed. The earthquake started a fire which did about $400,000,000 damage. Several European companies in which the burned property was insured went bankrupt in their attempts to cover the losses; others defaulted.

Tokyo (1923).—An earthquake struck Tokyo, Jap., near noon' on Sept. 1, 1923. The death toll from this shock was estimated at 74,000. Fifty-four per cent of the brick buildings and 10% of the reinforced-concrete structures collapsed. One per cent of the dwellings were shaken down and 700,000 houses burned. The shock started a tsunami which reached a height of 36 ft. at Atami on Sagami bay, where it destroyed 155 houses and killed 60 persons.

ENGINEERING ASPECTS

In the early engineering applications of seismology, it was assumed that the destructiveness was directly related to the maximum horizontal ground acceleration taking place during passage of the seismic waves. A structure was thus considered immune to earthquake damage if it was designed to withstand a constant horizontal acceleration of some standard force usually taken as one-tenth to one-quarter of gravity. Although this approach results in a substantial reduction in earthquake damage as compared with designs that do not take horizontal forces into consideration, it fails in many cases to offer effective protection, first because earthquake accelerations are not constant but oscillate to and fro, and second because acceleration is not the characteristic of motion responsible for destruction. During an earthquake a structure or member of a structure is bent or distorted back and forth and when the bending exceeds a certain critical value the structure fails. The maximum flexure or amplitude is determined by the value of the earthquake spectrum at the frequency of vibration of the structure and by the damping or friction of the structure. In other words, although the earthquake is made up of vibrations of many frequencies occurring together, a structure responds only to those frequencies which lie in a narrow range near its own free vibration frequency, and the response is reduced by friction. In designing an earthquake-resistant structure, the engineer requires knowledge as to the maximum values of the earthquake spectrum likely to occur at a given site, and the vibration characteristics of the structure he designs. He then makes certain that walls, joints, ties and other members are designed so as to permit the structure to undergo those maximum strains or flexures without failure. Steel reinforcing is introduced into brick and masonry structures, since nithout it a small amount of flexure usually produces failure. The engineer rnay also introduce frictional members to reduce the anticipated response generally. Moreover, stone and other ornamentation on the exteriors of buildings is either entirely eliminated or greatly reduced, and that which is retained is anchored firmly to the building to prevent its being shaken loose to fall to the streets below

An example of some of the unexpected effects that may arise from failure to take into account the spectrum aspects of seismic destruction may be cited. In the Kern county earthquake of 1952, the destructiveness nas quite low in Los Angeles because of the moderate intensity of the shock there. However, one of the newly constructed office buildings, which went through the earthquake nithout even a crack in its principal components, suffered extensive damage to its lighting system. The lights in the offices were of the fluorescent type and mere mounted in long. flat rectangular metal boxes. The boxes were suspended from the ceiling by aluminum tubes 30 in in length, rigidly fastened to the ceiling and to the boxes. The fixtures thus formed pendulums with low damping and with periods that happened to resonate with a frequency range in the earthquake spectrum that was strong. The fixtures were set into violent oscillations and in a matter of seconds the supporting tubes sheared off at the junctions mith the boxes and $60,000 worth of light fixtures were draped over the desks below. Had the designers introduced a small amount of friction in the mountings such as wrapping the tubes with plastic ribbon, or if the joints had been stronger, the fixtures nould have withstood the shaking without damage.

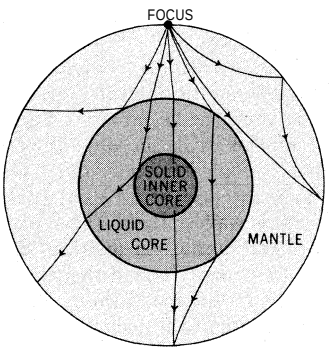
THEORY AND RESEARCH

Origin of Earthquakes. — Earlier it was stated that the source of seismic energy is elastic strain set up by differential movements in the earth's outer layers (see Mechanism of Generation, above). Attempts to explain the origin of these movements—the ultimate causes of earthquakes — are very nearly in the realm of pure speculation. In the early days of seismology it was confidently believed that these differential movements were produced by buckling of the surface layers of the earth as a result of cooling of the interior from a warmer state. Later, geophysicists learned that the radioactive constituents of rocks are such that, instead of cooling, the earth is more likely warming up from a colder state. Hence, the hypothesis of the cooling origin has been abandoned by most research men.

Another hypothesis assumes that as a result of the interior of the earth being warmer than the outer portion, convection of the viscous molten material takes place between the two. It has been shown by geophysicist Chaim Perkeris that convection currents, if they exist, should occur in large convection cells of particular dimensions and form so that under large parts of the crust the moving material rises and at other parts it descends. Between the two there is a horizontal flow and it is argued that friction between this flow and the under side of the solid crust above results in the forces responsible for the fault strain accumulation.

One of the difficulties with this hypothesis is that the predicted shapes of the convection cells do not correspond with the shapes of the corresponding earthquake belts. Another objection is associated with questions of symmetry. In the regions of convection rise and descent. material should flow in or out equally from opposite directions forming symmetrical stresses above, whereas in the Pacific arc, such as shown in the Kurile-Kamchatka region and in the Asiatic-Mediterranean wedge, the sections are highly unsymmetrical.

Another hypothesis which attempts to explain the origin of the vertical differential movements assumes that in the vicinity of the circumpacific marginal belts the continents are growing by accretion of material acquired from below by chemical or physical differentiation and that growth is greatest at the margins. Being of lower density than the surrounding medium, the continents float in it and thus, as material is added to their undersides. they rise and spread proportionately. Being in contact with the lower oceanic block of higher density, the upper continental material flows out over the oceanic block which pushes under the lighter continent to form a slanting fault plane on which the earthquakes occur. as shown in fig. 6. Bulging and overriding of the continental margin produces the mountain chain, and the downward movement of the adjacent oceanic block forms the trench. A difficulty with this hypothesis is that during formation of this marginal structure the earthquakes should exhibit fault slips upward on the continental side and downward on the ocean side. In many earthquakes occurring in or near these marginal contacts with vertical fault slip components. the directions are reversed, indicating that the continent is descending at the margin rather than growing.



BY COURTESY OF HUGO BENIOFF

FIG. 7.— SECTION OF THE EARTH SHOWING A FEW OF THE PATHS TRAVERSED BY LONGITUDINAL WAVES FROM AN EARTHQUAKE FOCUS OR HYPOCENTRE

The origin of block movements responsible for horizontal slip earthquakes is even more obscure. In studying the directions of horizontal slip around the Pacific arc, it is found that in nearly all of the great faults lying parallel to the rim, such as the San Andreas fault, the sense of slip is right hand when viewed from above. It appears. therefore, that around the n-hole Pacific arc the continents are rotating clockwise relative to the bottom of the ocean. The earthquakes are thus generated at the contact between these two great structures moving relatively to each other. (One cannot say as yet which is rotating and which is stationary or whether they are both rotating.) What agent is responsible for this rotation? Wandering of the pole of rotation of the earth has been suggested, here again as pure speculation. There is evidence that long ago the north pole of the earth lay in what is now the Pacific ocean. In moving from that point to its present position, rotational forces of the right direction would tend to make the oceanic area rotate relative to the continent. The fact that motion continues now as a result of stresses acting in the past is explained on the basis of viscous effects delaying the strain release. This speculation also is not without serious difficulties.

Earthquake Waves.—Earthquakes generate four principal types of waves. Two of them are propagated within the earth and are known as body waves. The other two are propagated along the surface and are called surface waves. The body wave with the higher speed is known as a longitudinal, compressional or primary or P wave. In this wave the motion of the rock particles is to and fro in a straight line, parallel to the direction of propagation. Thus. as the wave passes a given point, the rock is alternately compressed and stretched. The speed of this wave varies from about 3.7 mi. per second in surface rock to 6.45 mi. per second in the earth's mantle near the boundary of the earth's core, which is 1.800 mi. below the surface. The increase of speed with depth is a result of the increase of hydrostatic pressure with depth. The speed drops to five miles per second when it enters the core and increases again to seven miles per second at the center of the earth. It takes slightly more than 20 min. for a P wave to travel from a shallow hypocentre through the centre of the earth to the antipodal point. In general, the increase in speed with depth makes the longitudinal waves travel in curved paths. concave upward. A few of the many paths which these waves take are shown in fig. 7. It will be noticed that some are direct from focus to observing site. Others involve one or more reflections at the surface, or reflections from the discontinuity at the surface of the earth's liquid core. Many other paths occur so that the whole pattern of them is very complex.

S *Waves.*—The other body wave is called a transverse, shear or secondary or S wave. The particle motion in this wave is in a plane at right angles to the direction of propagation. During passage of this wave, a small volume of rock is distorted in shape, first in one direction and then in the reverse. In P waves. the volume changes while the shape remains fixed; in S waves, the volume remains constant but the shape varies. The speed of the shear wave increases from about 2.1 mi. per second at the surface to 4.5 mi. per second near the boundary of the core. Shear waves cannot be propagated in a liquid, and the observed absence of such waves passing through the core is one of the compelling arguments for the hypothesis of the liquid nature of the outer portion of the earth's core. However. the seismic evidence indicates the existence of a small solid inner core. The paths of S waves within the earth are very nearly identical with those of P waves except for the absence of paths passing through the core. Transverse waves vibrate at a slower rate than longitudinal waves from the same source, or in more precise terms it is said their periods are longer. The vibratory excursions of the ground which they produce—their amplitudes—are also larger.

Surface Waves.—Of the two surface waves, the Love wave, named after A. E. Love who first predicted its existence, travels faster. It is a transverse wave in which the particle motion is horizontal only. Love maves exhibit dispersion; *i.e.*, up to a certain limit those of longer period (or slower vibration rates) travel faster than the shorter period waves owing to the deeper penetration of the former into the higher velocity regions of the earth. One Love wave that travels at high speed is known as a G wave after Beno Gutenberg who first observed it. This wave travels at a speed of 2.7 mi. per second. It requires 152.2 min. to make a complete circuit around the earth.

The other surface wave is called a Rayleigh wave after Lord Rayleigh who first theoretically predicted its existence. In these waves, the ground particles vibrate in vertical ellipses in such a direction that when at the top of the ellipse they are moving opposite to the direction of travel of the wave. Like the Love waves, Rayleigh waves are dispersed, the longer periods traveling faster and for the same reason. Their maximum speed has been figured at about 2.55 mi. per second, although higher speeds have been recorded, and their circuit of the earth at about 163 min. As they move away from the source, body waves spread out in the two dimensions perpendicular to the direction of travel; thus their vibration amplitude decreases rapidly with distance. Surface waves are confined to a thin surface layer and thus spread in one dimension only. Consequently, their amplitudes decrease more slowly with distance. Hence, in seismograms (recordings made with seismographs) of distant earthquakes, the surface waves generally appear with larger amplitudes than the body waves. In very large earthquakes, surface waves have been recorded after six complete passages around the earth requiring about 12 hours.

Another wave, discovered by Maurice Ewing and Frank Press and called Lg by them. is related to the surface waves. It is a form of guided wave which travels in the continental crust only. As a result of this characteristic, the wave has served effectively to outline continental boundaries in regions where they lie under shallow ocean areas.

Fig. 8 is a recording of the great Chilean earthquake of May 21–22, 1960, made at Isabella, Calif.. with the fused quartz strain seismograph of the California Institute of Technology. The large scale sinuous displacement of the trace is the response to the tidal

FIG. 8.—SEISMOGRAM OF THE GREAT CHILEAN EARTHQUAKE OF MAY 21–22, 1960, RECORDING CIRCUITS OF G WAVES AND RAYLEIGH WAVES AROUND THE EARTH (*see* TEXT)

strain of the solid earth produced by the gravitational attraction of the sun and moon. The different seismic waves are identified as follows: P, the direct compressional body wave; S. the direct shear body wave; G_1, the direct surface shear or G wave; G_2, the surface shear wave which left the source in a direction opposite Isabella and traveled around the earth along a major arc; G_3 is G_1 after making an additional circuit around the earth; G_5, G_6 and G_8 are G_2 after one. two and three additional circuits around the earth respectively: R_1, the direct Rayleigh wave: R_2, the Rayleigh wave around the major arc; R_4 and R_6 are R_2 after one and two additional circuits around the earth respectively. (The time scale of the seismogram is expressed in Greenwich civil time [GCT].)

Seismic Intensity.— Seismic intensity is a term intended to refer to the level of violence of shaking at any given place and, as such, it can have a precise scientific meaning. Unfortunately, when the term first began to be used, instrumental techniques capable of accurate measurement were not yet developed. The early seismologists, consequently, established a substitute in the form of a scale based on a set of arbitrarily chosen effects resulting from the shaking. The first such attempt was known as the Rossi-Forel scale after its authors. M. D. DeRossi and F. A. Forel. This was later modified by G. Mercalli and finally by H. O. Wood and Frank Neumann, and in this form is known as the Modified Mercalli scale. It has 12 grades or steps, given below in abridged form.

Modified Mercalli Scale of *Felt Intensity (1931; Abridged)*

1. Not felt. Marginal and long-period effects of large earthquakes.
2. Felt by persons at rest, on upper floors or otherwise favourably placed to sense tremors.
3. Felt indoors. Hanging objects swing. Vibration like passing of light trucks. Duration can be estimated.
4. Vibration like passing of heavy trucks (or sensation of a jolt like a heavy ball striking the walls). Standing motorcars rock. Windows, dishes, doors rattle. Glasses clink. Crockery clashes. In the upper range of 4, wooden walls and frames creak.
5. Felt outdoors; direction may be estimated. Sleepers wakened. Liquids disturbed, some spilled. Small objects displaced or upset. Doors swing, open, close. Pendulum clocks stop, start, change rate.
6. Felt by all; many frightened and run outdoors. Persons walk unsteadily. Pictures fall off walls. Furniture moved or overturned. Weak plaster and masonry cracked. Small bells ring (church, school). Trees, bushes shaken.
7. Difficult to stand. Noticed by drivers of motorcars. Hanging objects quiver. Furniture broken. Damage to weak masonry. Weak chimneys broken at roof line. Fall of plaster, loose bricks, stones, tiles, cornices. Waves on ponds; water turbid with mud. Small slides and caving along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged.
8. Steering of motorcars affected. Damage to masonry; partial collapse. Some damage to reiniorced masonry; none to reiniorced masonry designed to resist lateral forces. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on ioundations if not bolted don-n; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.
9. General panic. Weak masonry destroyed; ordinary masonry heavily damaged, sometimes with complete collapse; reinforced masonry seriously damaged. Serious damage to reservoirs. Underground pipes broken. Conspicuous cracks in ground. In alluviated areas, sand and mud ejected, earthquake fountains, sand craters.
10. Most masonry and frame structures destroyed with their ioundations. Some well-built wooden structures anti bridges destroyed. Serious damage to dams, dikes, embankments. Large landslides. Water thrown on banks of canals, rivers, lakes, etc. Sand and mud shiited horizontally on beaches and flat land. Railway rails bent slightly.
11. Rails bent greatly. Underground pipelines completely out of service.
12. Damage nearly total. Large rock masses displaced. Lines of sight 1 level distorted. Objects thrown into air.

It is clear that the Mercalli scale lacks scientific precision and is, in effect, only a rough, arbitrary classification of earthquake effects depending upon such observations as whether or not the shaking is felt by persons at rest or in motion, the stopping of clocks, damage to buildings and so on. Since all of these effects depend upon sensitivity of particular individuals, vulnerability of types of architecture. construction practice and such. the value of the scale is clearly in its descriptive qualities only. Moreover, it must be emphasized that intensity as indicated by any method and particularly by the Modified Mercalli scale, does not refer to the size of the earthquake. Thus, the intensity at a point close to a small earthquake may be the same as that distant from a large earthquake.

Destructiveness.—A more nearly precise approach to the specification of the intensity or damaging effects of an earthquake at any point has been made on an instrumental basis and, to eliminate confusion with the old intensity scales, the term destructiveness is substituted for intensity. Destructiveness at any pnint depends upon the size of an earthquake, that is, the energy liberated in seismic waves; the distance of the point from the source; the number and amplitude distribution of vibration periods at the earthquake source (called the spectrum of the source); the modifying effects on the spectrum by the intervening paths of the waves; and the nature of the ground at the observing site. To measure the destructiveness. a large number (theoretically an infinite number) of free-swinging pendulums might be set up, each with a different period covering a range from about $\frac{1}{20}$ sec. to about 10 min. After the occurrence of an earthquake. a curve could be drawn, plotting the maximum excursion of each pendulum against its frequency. This curve is the spectrum of the earthquake vibratory motion at the given site, and destructiveness is defined as the ares under this curve. If the effects of the earthquake on a particular structure situated at the site where the spectrum was measured are now considered, it will be found that the maximum vibratory excursion to which any particular structure such as a flagpole, a building or the water in a reservoir will he subject is the amplitude of the spectrum for the frequency of vibration of the structure, provided that the damping (a factor which indicates how quickly its vibratory motion dies down when the excitation is removed) of the structure is small. When the excursion reaches a certain value for any structure, the structure is permanently damaged or destroyed. The reason; then, that destructiveness is defined as the area under the curve is that it involves not only the height of the curve at any point but also the number of periods at a given height. Thus, a narrow, higher spectrum would produce much damage in a few structures while a broad lower spectrum having the same area would produce a little damage in many different structures. The total destruction would then be the same in the two cases. Although a multipendular array as described above can be used to record the seismic spectrum. in practice it is obtained from records of a single pendulum by means of a rather complex mathematical operation.

The destructiveness at a given site is determined by the size and character of the earthquake at the source, by the distance from the source and by the character of the ground at the site. In soft ground such as alluvium. the amplitude of ground motion for higher frequencies is much greater than it is in hard rock—as much as eight times greater in extreme cases. For this reason. in estimating earthquake risk or probable destructiveness in a region such as California where fault- are fairly uniformly distributed. the principal criterion is the density and rigidity of the ground or in phys-

ical terms the ground impedance. Each type of ground can thus be specified crudely by a ground factor which expresses the increase of vibratory motion compared with the motion in firm rock. Maps showing roughly the distribution of probable maximum destructiveness of a region can thus be drawn by assigning ground factors to the various geologic formations included within the area, and combining these with information of past earthquake activity. Such maps were constructed by C. F. Richter in detail for California and in less detail for. the whole United States. Since the ground factor is not a constant but in fact varies from an average maximum of about three at high frequencies to unity at frequencies less than about $\frac{1}{6}$ cycle per second, it must be used with caution in estimating probable damage to structures that have long periods, such as reservoirs. dams; large bridges and towers.

Magnitude. — The only precise way in which the size of an earthquake can be accurately specified is by the energy released as seismic waves. Before the days when electronic computers became available, the calculation of the energy of an earthquake from the data given by seismographs was very laborious and, consequently, was carried out for only a few earthquakes. In order to provide a quick and easy means of classifying nearby earthquakes as to relative size, Richter devised a magnitude scale based on the maximum trace amplitude of a seismogram written by a horizontal pendulum seismograph of 0.8 sec. period and magnification of 2,800. He chose as a standard earthquake one providing a maximum trace amplitude of one micron (one-thousandth of a millimetre) on this instrument at a distance of 100 km. (62 mi.). He then defined magnitude as the logarithm to the base ten of the ratio of the amplitude of any earthquake at the standard distance to that of the standard earthquake. Since earthquakes occur at varying distances, it was necessary also to devise an empirical rule showing how the amplitude varies with distance. In this form the scale was useful only for earthquakes of small size at distances less than about 600 km. (370 mi.). The scale was later extended by Gutenberg and Richter to apply to distant shallow earthquakes recorded on other types of instruments and still later, by Gutenberg, to deep earthquakes. In applying the scale to nearly all earthquakes for which instrumental data were available over the interval from 1900 to 1950: Gutenberg and Richter found that the largest magnitude on the list was 8.6 and the smallest recorded earthquake on high sensitivity instruments had a magnitude of about 0. Thus, the theoretical ratio of trace amplitudes on the standard instrument of the largest magnitude earthquake to smallest is about 400,000,000 to 1. Since the magnitude represented only a measure of the ratio of trace recordings made with a given instrument, it was clear that its value would be greatly enhanced if a way could be found for relating magnitudes to energy. This proved to be a difficult task. A formula was devised by Gutenberg and Richter in the form: $\log E = A + B \log M$, where E is the energy in ergs, M is the magnitude and A and B are constants. For a number of years they used values of 12 and 1.8 for A and B, respectively. and it was found later that these constants gave values for the energy of earthquakes from 100 to 1,000 times too large. The formula was later modified to provide values of the energy more nearly in line with calculations based on direct methods. From a precise scientific point of view, the magnitude scale has very serious limitations as a means for determining the energy of earthquakes. Crude as it is, however, it represents a great advance over preceding methods of rating the size of earthquakes.

Energy. — The range of energy released as seismic waves in earthquakes of various sizes is enormous. The smallest earthquakes recorded at short distances by the most sensitive instruments have energies of only a few millionths of a kilowatt hour (10^5 ergs). The largest earthquakes have energies of about 280,000,000,000 kw.hr. (10^{25} ergs). The ratio, thus, is 10^{20} to 1. During the time the earthquake is being generated, the maximum power produced in the greatest earthquakes amounts to about 3,000,000,000,000 kw. The average energy released per year in earthquakes is approximately 300,000,000,000 kw.hr. and is derived principally from a small number of the largest shocks.

EARTHSHINE. The earth is a luminary to the moon as the moon is to the earth; consequently the portion of the moon's disk which is not illuminated by the sun is illuminated by earthshine analogous to moonlight. It is a familiar observation that when the moon is a crescent the earthshine is powerful enough to make the whole disk easily visible. The phases of the earth and moon are complementary, so that the earth is near "full" when the moon is near "new" and the earthshine is then strongest.

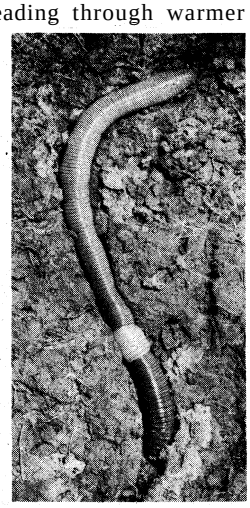
JOHN MARKHAM

EARTHSTAR (GEASTER LIMBATUS)

EARTHSTAR (*Geaster*), a fungus, a kind of puffball (*q.v.*) with a distinct outer coat that, on separating from the inner, splits into several divisions that become reflexed and spread like a star. The inner coat enveloping the spores is supported, like a ball, with or without a stalk on the upper face of the star. The spores generally escape by an opening that appears in the top of the ball. Earthstars are generally distributed in temperate zone woodlands, on the ground or on decaying leaves. See FUNGI.

EARTHWORM, a popular name sometimes erroneously thought to be restricted to the night crawler, *Lumbricus terrestris*, but now usually applied to all segmented worms that. with the night crawler, belong to certain families of the class Oligochaeta of the phylum Annelida (*q.v.*). Other common names loosely given to various earthworms are rainworm, angleworm, garden worm, manure worm. etc.

Distribution and Abundance. — In many areas native species were exterminated during the ice ages, and more recently have been disappearing in agricultural lands of Australia: New Zealand, Republic of South Africa and southern South America. Hardy species that survived the glaciation were carried everywhere that men settled. European forms able to survive agricultural practices, successfully colonized both temperate zones. some arctic areas and tropical mountains. Oriental *Pheretima* species. common in greenhouses for more than a century. are spreading through warmer parts of temperate zones. In the tropics transported African and American species have colonized widely.



JOHN H. GERARD

EARTHWORM OR NIGHT CRAWLER (LUMBRICUS TERRESTRIS) IN BURROW

Most of the hundreds of already described species of earthworms live in soil. but any area with adequate food, moisture and oxygen may be occupied if it is not too sour or alkaline (pH between 4.5–8.4). Among sites often colonized are compost and manure heaps; sewage beds; undersides of bark and holes in trees; axils of banana leaves: staghorn ferns 40–60 ft. above ground in tropical rain forests; caves and mines; and underground waters. They are found in mud 180 ft. below the surfaces of lakes, in moss on rocks above the tree line in the Himalayas and at a height of 15,870 ft. in the Andes. Earthworms are even found in gutters at eaves of buildings. Salt is harmful to most earthworms but species of *Pontodrilus* are restricted to the shores of warm oceans. A few small spe-

cies live only on trees in the rain forests of New Guinea, Burma and southwestern China (Szechwan).

Populations of earthworms vary in density from 13.000 to 500,000 per acre in cultivated fields. 2,000,000 per acre in pastures and 3,000.000 in Oxford meadows, to possibly 5.000,000–7,000.000 in areas in Switzerland, the Netherlands and New Zealand. The combined weight of the population of worms may equal or exceed the weight of sheep that a pasture supports. Fifteen gallons of the Chinese green earthworm Pheretima *hupeiensis* were removed at one time from an American golf green without causing noticeable population decrease.

Earthworms of forest litter and similar sites feed selectively, and little or no soil is found in their guts. Others eat their way through soil but only digest organic matter. Undigestible residues, after being milled in gizzards and acted on by digestive juices, are ejected underground or cast onto the surface as piles of short pellets or long cords, as hollow towers 1 to 4 in. tall or as irregular mounds up to 18 in, high. Estimates of the yearly deposition above ground of soil by earthworms in tons per acre are: 7–16 in England, 16 near Rangoon, Burma. 20 in Nigeria, 30–40 in Germany and Switzerland, 1–41 in cultivated fields of Nebraska, according to method of tillage and amount of mulching. Tunnels of burrowing forms branch frequently and are mostly horizontal, but vertical passages may go down 20 ft. Night crawlers plug the mouths of their burrows, especially in the fall, with pebbles, feathers, string, leaves and tnigs. Clearly, earthworms have considerable influence on their surroundings, but Darwin's overpublicized conclusions about their activities have been challenged or denied and the importance of earthworms to soil structure and soil fertility remains debatable. Certainly P. *hupeiensis* has been an expensive nuisance in golf greens, and other species are considered agricultural pests in parts of the world.

General Description. — Size and Growth. — Earthworms are long, relative to the thickness of the body, and are marked off by fine circular furrows into 50–600 segments. All the segments may be delimited before hatching or additional segments may be formed at the hind end. Growth involves increase in the size of segments. During extended fasts the segments may. however, become much smaller than normal. The size of the body varies within a species according to heredity, age, physical condition and amount or kind of available food; some well-fed individuals become much larger than those in ordinary environments. A naturally relaxed worm may be nearly twice as long as when it is uniformly contracted, and if stretched or anesthetized becomes much longer still. Published measurements in absence of information as to age and condition accordingly have little significance. In pygmy species contracted specimens at maturity average about one inch long and $\frac{1}{32}$ to $\frac{1}{16}$ in. thick. Fully contracted adults of giant species, *e.g.*, the Gippsland worm (Megascolides australis) of Australia, may be three to four feet long and nearly two inches thick: extended specimens have been said to attain 10–12 ft. Large species are found on each continent and are especially abundant in Ceylon, Hainan Island and New Zealand. South America has several giant species, and there is one in Texas.

Sound Production. — The slurping sound produced by rapid contraction of an Australian giant in its burrow is easily audible above ground. A large Indonesian earthworm. *Pheretima musica,* makes birdlike notes; hence, its specific name. Other worm sounds include clicking. sucking and rasping noises.

Odour *and* Taste. — The South African giant earthworm has a creosotic smell so unpleasant that hogs. which generally are indiscriminate eaters. will not eat it The odour of the small manure worm or brandling worm, *Eisenia* foetida, smells foul to some persons but only pungent to others. The Chinese earthworm smells like raw carrots, and an Oregonian species delightfully like a fragrant trillium. The taste of edible worms was praised by medieval epicures in France. Choice kinds of earthaorms could be eaten, among the Maori in New Zealand, only by chiefs or by a dying commoner in his last meal.

Colour.—Green colouring is rare among earthworms but in many species red or brown pigment is deposited under the skin, either uniformly or in bands. stripes and splotches arranged in characteristic patterns. Forms with a glistening metallic coloration have been mistaken, even by zoologists. for snakes. A Philippine *Pheretima* that is bright yellow mottled with light blue has a Latin name meaning snakelike. Unpigmented worms may seem dark coloured when the gut is filled with black earth; rosy if the peripheral vessels are distended with the red blood; or milky white when the body wall is opaque. Refraction of light by the transparent cuticle covering the body produces an iridescence in some species, even unpigmented ones. A golden colour at the tail end of common European earthworms results from the aggregation of yellow corpuscles. During the breeding season of some worms a bright yellow, fiery red or orange colour appears in the clitellum—a saddle- or ring-shaped band of skin that becomes swollen at maturity. At the end of the breeding season the swelling gradually disappears and then the site of the clitellum is indicated only by a yellow-brown skin coloration. Green and pinkish varieties of the temperate zone species Allolobophora *chlorotica* exist.

Reproduction and Life Cycle.—*Reproduction.*—Reproduction usually is sexual and involves simultaneous transfer of sperm from each hermaphroditic member of a copulating pair into the paired sperm receptacles (spermathecae) of its partner. Among the various organs functioning in the exchange are suckers, claspers, adhesive glands, temporary or permanent seminal grooves, special muscles. bristles with hooks or microscopic teeth, prostates of several types and protrusible penes sometimes provided with ejaculatory bulbs (*Eudrilus* eugeniae). Some or all of the male organs of the earthworm, including the testes and spermathecae, have disappeared in those races producing eggs that do not need to be fertilized.

Life Cycle. — The life history varies within certain limits for each species according to environmental conditions such as temperature and moisture. Development always takes place in a tough capsule or cocoon secreted by the clitellum. As the worm backs out of the cocoon, eggs, sperm and a nutrient fluid are passed into the cocoon. E. foetida may deposit a cocoon 48 hours after copulation and thereafter once every three to five days for four and one-half months without another copulation. The young, averaging two per cocoon, hatch after 16–28 days, maturity being reached 70–120 days later. In the laboratory their life span has reached four and one-half years. L. terrestris deposits its cocoons about eight days apart, one worm issuing from each capsule after 61–80 days incubation at 70° F.; maturity is reached five and one-half to six months after hatching. Its life span in the laboratory has attained six years. Allolobophora *longa* is even more long-lived, reaching ten years in the laboratory. The European *Criodrilus lacuum* becomes mature in the third or fourth year. E. foetida may breed throughout the year if conditions permit, but in many species most individuals rest during summer heat and drought as well as winter cold. Restoration of favourable conditions brings the worms to activity. Other species periodically rest regardless of conditions and cannot be brought into activity by a change in external environment. Breeding in the temperate zone usually is in the spring and fall. The rest period in the tropics occurs during the dry season, the worms emerging early in the rainy weather and breeding as rainfall decreases at the end of the season.

Although water comprises 80%–85% of the weight of an earthworm. a considerable amount can be lost without fatality Drowning seems unlikely among earthworms as submerged individuals have lived more than three months. Emergence of hordes of worms after cold and heavy rain in spring and fall has been explained in various ways but the cause remains unknown. However. birds do not eat these emergent worms, which usually die.

Regeneratiom — Regenerative capacity among earthworms varies considerably. Night crawlers can replace the first two or three segments but do not regenerate lost tail portions. A manure worm can replace the first eight segments, and a head piece of 30 or more segments can grow a new tail. but an amputated tail eventually dies. In *Criodrilus lacuum* and several oriental earthnorms some fragments can form new heads and tails simultaneously to become normal worms with functional sex organs. However, a small fragment cut from the hinder part produces a new tail at each end and eventually dies of starvation, whereas pieces

cut from the front part form a head at each cut surface and eventually die of constipation.

Importance. — Earthworms have served as fish bait for more than a thousand years. Sales in North America, including specimens preserved for dissection in schools and colleges, run to millions. Two native European species provide most of the merchandise: Lumbricus terrestris, collected at night while the worms feed and copulate on the surface; and Eisenia foetida, sold by nearly all who raise worms. Two red forms, L. *rubellus* from Europe and E. eugeniae from Africa, have been grown by several dealers. Fishermen have contributed significantly to the dispersal of exotic species through uninhabited areas.

Earthworms, when especially abundant, may be considered pests. Among the methods of control is the addition of actual chlordane dust, alone or with fertilizer, to the soil at the rate of 1 lb. per 1,000 square feet of soil surface; the surface should be thoroughly wetted before and after application.

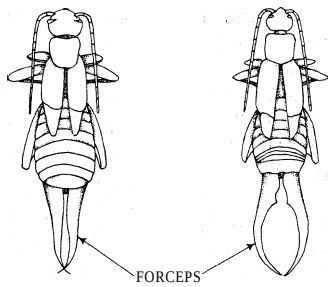
(ti h ti)

EARWIG, an insect of the order Dermaptera, characterized by peculiar wings and a pair of horny forceps terminating the abdomen. Most species are less than one inch in length; the largest, Titanolabis colossea of Australia being about two inches The large, membranous, radially veined hind wings fold both radially and transversely so as to lie hidden under the short leathery forewings (tegmina). Winged species rarely fly, and many are wingless They are chiefly nocturnal and are frequently attracted to lights. The male forceps, larger and differently shaped from those of females, are in some species bizarre. The male forceps also usually fall into two sharply marked size classes, with few of intermediate length; *Forficula* affords a classic example of such bimodality, nhich, however, is more complex than was supposed (Chopard 1938); the cause may be a variable relation between time of last molt and beginning of rapid forceps growth The name earaig comes from the Anglo-Saxon meaning "ear creature," and most European languages have an equivalent popular name because of an ancient, widespread but unfounded superstition that eanvigs crawl into the ears of sleeping persons.

Several families and about 1,000 species are known, mostly from the tropics; Europe has about 30 species, North America 15 and Great Britain 7. A fossil eanvig (Protodiplatys) from Jurassic beds in Kazakhstan seems to link Dermaptera with ancestral cockroaches (Protoblattoidea). The peculiar insects of the genus *Hemimerus* (family Hemimeridae), parasitic on giant African rats (Cricetomys), are sometimes ranked as a suborder of Dermaptera, sometimes as an order (Hemimerina). The Dermaptera were formerly placed with grasshoppers, crickets, etc., in the order Orthoptera.

The common European earwig (*Forficula auricularia*) is a well-knonn pest of gardens and houses Commerce-borne from its native Europe, it has become established in North and South America, New Zealand and Tasmania, and seems destined to become cosmopolitan It is omnivorous, feeding mainly on green plants; but it prefers anything more nourishing than it can find in nature, therefore sometimes swarms in kitchens Labidura *riparia* and other earwigs use the forceps to catch insects and hold them for eating When alarmed or aggressive, earwigs carry the forceps over the head in scorpion fashion; the males often use them to fight battles for the possession of a female. F. auricularia overwinters in small cavities in soil; 40 to 60 eggs are laid therein in fall or early spring, and the mother guards and cares for the eggs and young. Nymphs hatch in middle and late spring and remain in the nest, fed by the mother, until after the first molt. When the female opens the nest, the young wander off. Four to six molts occur; after each molt the nymph is inflated with swallowed air and appears white, but soon darkens. After the young depart the female feeds for a time and then rears a second brood.



COMMON EUROPEAN EARWIG (FORFICULA AURICULARIA) (A) FEMALE; (B) MALE

The best control is by scattering bran bait poisoned with sodium fluoride over the ground and in places where earwigs congregate; it is best done in the evening. If the bait is applied when most of the first brood of young earwigs have begun to feed at night, this brood and the adults can be poisoned before the second lot of eggs is laid. See also INSECT: Dermaptera (earwigs).

EASEMENT (SERVITUDE), in law, signifies a property interest giving a limited right to use or to prevent the use of the land of another. An easement map give the right to engage in a limited activity on the land of another, such as the privilege to maintain and use a driveway, a pipeline, or a railroad track (called affirmative easements), or it may involve a legal power to prevent the general owner and possessor of the burdened land from doing some act on his own land, such as a power to insist that light, air and view be unobstructed by structures (called a negative easement), or it may involve the privilege to go upon the land of another and sever some physical substance such as gravel (called more usually in England a profit a prendre). If this privilege to use the land of another is so tenuous that it is personal to the creators of the instrument, nonassignable and revocable at will or by death, it is usually called a licence, and rights and duties are governed by contract and not by property law (*e.g.,* rights of a theatre ticket-holder).

Also to be distinguished from an easement. which is basically a consensual relationship. are the natural servitudes such as the right as against one's neighbours to have a stream flow down to one's land without change. 4 further differentiation is made from an easement in situations where the general owner is subject to some active duty to do something on his land, such as to maintain a boundary fence in repair, which arise when an owner makes a promise with respect to the use of his land. This type of restriction on use and also many types of negative restriction for the benefit of neighbouring land are dealt with as covenants running with the land. (See COVENANT.)

An easement (rights in the land of another) is a burden to one parcel of land (the servient estate) and is a benefit to other land (the dominant estate) or to a person other than the owner of the burdened land. The easement is conceived of as appurtenant to (that is, as an attribute of) the dominant land itself, rather than as property of a person. Thus, transfer of the dominant land transfers the benefit of an easement without express reference to it. So strong is this idea of appurtenance that the benefit could not be transferred apart from the land; moreover. English law concluded that there could not be an easement in gross, that is. an easement without a dominant estate. In the United States, such an easement is recognized. Thus the owner of a pipe-line right of way running from Texas to Boston may be said to be the owner of an easement in gross and not appurtenant to some parcel at its terminus.

Another major difference between England snd the United States concerns ancient lights (*q.v.*). In England an owner may have an implied or prescriptive right of light to the windows of his house across the land of another. In the United States this was thought to be inimical to land development and is not upheld. An easement of light in the United States must be based upon agreement.

Easements or servitudes may be acquired by express conveyance meeting the formalities required for transfer of other interests in land; by implication from the circumstances of a conveyance of a

portion of a larger parcel (*e.g.,* transfer of a parcel drained by a sewer running through land retained by the seller); by eminent-domain (*q.v.*) proceedings; and by prescription (*q.v.*), *i.e.,* by proof of uninterrupted enjoyment of the right (called user) for a prescribed period of time adverse to the interest of the general landowner.

The so-called easement of necessity is really an implied easement since it is not based on necessity alone. An easement of necessity for one parcel of land cannot arise across land of a stranger but only across land that was once in common ownership. When an owner of land conveys to another an inner portion of a larger parcel surrounded by land including other land of the conveyor, a right of access across land retained by the conveyor is implied if there is no other reasonable means of access. Such an easement may also be implied over the transferred land in favour of the retained land.

Historically, prescription created an easement through the legal fiction of a lost grant. A grant of an easement was presumed from the fact of long-continued user of the right. In early English law the enjoyment had to be "from time immemorial"; *i.e.,* from the commencement of the reign of Richard I (1189). Modern prescription statutes in England and the United States fix the period of continuous user required, usually at 15 or 20 years. To become an easement by prescription the user must be open and not hidden from reasonable inspection by the owner of the burdened land and it must also be adverse to that owner, *i.e.,* without his consent and wrongful, so that he could have brought legal proceedings to stop it.

Prescriptive user must also be uninterrupted. Owners of private streets or of rectangular parcels of urban land with buildings not built to the boundary line sometimes put up barriers on one or two days of a year in order to interrupt claims of user. Thus the path through the cemetery in Trinity churchyard in the Wall street area of New York city is barricaded from time to time to prevent the public acquiring a right of passage by prescription.

An easement may be extinguished by release, abandonment (*q.v.*), prescription, by unity of ownership of the servient and dominant estates, by conveyance of the servient estate to a third person not charged with notice of its existence, and sometimes by excessive use.

The kinds of easement which may exist, despite some language about closed categories in a few 19th-century cases, are almost as unlimited as the uses to which land may be put. Rights of pasture and footpaths of an agrarian society have given way in importance to easements of navigation (the right to unobstructed flight by an airplane at a certain height over land) and of trajectory and other easements of the age of the airplane and the missile.

In Roman and civil law the term servitude is used to describe substantially the same subject matter as easement describes in Anglo-American law. The term also includes, however, some matters which the common law classifies as covenants or equitable servitudes. (A. Dm.)

EAST, EDWARD MURRAY (1879–1938), U.S. geneticist, who helped develop hybrid corn (maize), was born in Du Quoin, Ill., Oct. 4, 1879, and was educated at the University of Illinois. After four years at the Connecticut agricultural experiment station, where he investigated the heredity and breeding of maize, tobacco and the potato, East moved permanently in 1909 to Harvard university where he became a professor in 1914. East is well known for his contributions to the development of hybrid corn, widely used in important maize-growing regions, for his investigations on the inheritance of quantitative characters and for studies on self-sterility in tobacco. His graduate students included many who became outstanding plant geneticists.

East wrote on many subjects. *Inbreeding and Outbreeding* (1919), a book written with D. F. Jones, had an important influence in genetics. His books *Mankind at the Crossroads* (1923), *Heredity and Human Affairs* (1927), plus numerous essays, express his views on the urgency of controlling the growth of human populations. (G. W. Be.)

EAST, THOMAS (*c.* 1540–1609), English music printer, who had the distinction of publishing many of the English madrigalists, became a freeman of the Stationers' company as early as 1565. William Byrd's *Psalmes, Sonets and Songs of Sadnes and Pietie* (1588) was his first venture into the field of music printing; he undertook it as the "assigne" of Byrd, who had been granted a monopoly by Queen Elizabeth I. Later, when this monopoly had been transferred to Thomas Morley, the latter also entrusted work to East, who clearly enjoyed the confidence of the best musicians of his day. Among the other composers he published were William Mundy, Thomas Weelkes, John Dowland, Robert Jones, Thomas Bateson and Francis Pilkington. In 1592 he edited *The Whole Booke of Psalmes, With Their Wonted Tunes,* in four parts, employing ten well-known musicians to supply the harmonizations, which were printed in score and not in the customary partbooks.

Michael East (*c.* 1580–1648), though probably the son of the above, did not succeed him as a printer. Understandably he appears to have been trained as a musician, and his father's connections may explain how, as a young man, he was invited to contribute to *The Triumphes of Oriana* in 1601. He became a prolific if not a very individual composer, publishing no fewer than seven sets of books containing madrigals, anthems and instrumental fantasies between 1604 and 1638. In about 1618 he was appointed organist of Lichfield cathedral and held this post until his death. His secular vocal music was reprinted by E. H. Fellowes in *The English Madrigal School,* vol. xxix–xxxi (1913–24). (J. J. N.)

EAST AFRICA, a term widely used for that part of Africa covered by the territories listed below, most of which are administered by the United Kingdom. The more general term "eastern Africa" covers the area extending from Sudan and Ethiopia in the north to the Zambezi river in the south. Until 1920 Kenya was generally known as the East Africa Protectorate. Mozambique (*q.v.*), or Portuguese East Africa (297,846 sq.mi.; pop. 6,575,257; density per square mile 22) is sometimes included in East Africa, although in the 1960s its economic links were much closer with the Federation of Rhodesia and Nyasaland and the Republic of South Africa.

Country	Political status (1961)	Area	Population (1957–1960)	Density of population (per sq.mi.)
Kenya	British colony and protectorate	224,960	6,450,000	29
Uganda	British protectorate	93,981	6,538,031	70
Tanganyika	Parliamentary state	361,800	8,788,466	24
Zanzibar	British protected sultanate	1,044	299,111	287
Ruanda-Urundi	United Nations trust territory (Belgian)	20,916	4,941,000	236

Following World War I, German East Africa was divided into Tanganyika and Ruanda-Urundi; the small Kionga (Quionga) triangle was allocated to Mozambique. Ruanda-Urundi's links with its British neighbours were reinforced by extensive migration of labour from its densely populated countryside to Uganda and by special arrangements for the transit of Belgian goods through the port of Dar es Salaam, Tanganyika.

The Tanganyika mandate gave Britain a continuous territory stretching from the upper Nile to the Zambezi. There were various proposals for closer political association, but the East Africa commission (1925), whose survey covered Northern Rhodesia and Nyasaland as well as East Africa proper, emphasized the communication and other difficulties dividing East Africa from the Zambezi basin. Subsequent nonpolitical arrangements for closer association included regular governors' conferences. World War II necessitated much closer collaboration and led to the establishment in 1948 of the East Africa High commission (*see* British East Africa).

Much of East Africa is a plateau 3,000 ft. or more above sea level, crowned by some of the highest peaks in the continent such as Kilimanjaro (19,340 ft.) and crossed by the Great Rift valley containing large lakes such as Rudolf, Nyasa and Tanganyika. Similarities of climate, vegetation and soils are reflected in common agricultural and economic problems over wide areas. Attempts to study such problems for large parts of East Africa have included the East African Royal commission (1953–55), whose

report dealt with Kenya. Tanganyika and Uganda. Though there are wide cultural and other differences between the peoples of East Africa, nearly all of them have come under a greater or less degree of Hamitic influence. Swahili is widely spoken and is regarded as a common language.

EAST ANGLIA, one of the kingdoms of Anglo-Saxon England was an area of early settlement, consisting of the north people (Norfolk), the south people (Suffolk) and parts of Cambridgeshire. Bede called the royal family Wuffingas, from Wuffa, grandfather of Raedwald (d between 616 and 628), the first king of nhom anything is knoun. One royal seat was Rendlesham, near which is the ship barrow of Sutton Hoo, the contents of which show the wealth of East Anglian royalty in the mid-7th century. Raedwald, who nas partially converted to Christianity at the court of his overlord. Aethelberht of Kent. had begun before the latter's death in 616 to wrest from him the overlordship of the peoples south of the Humber. He supported Edwin, heir to the throne of Deira, and helped him to kill Aethelfrith and gain the throne of Northumbria at the Idle in 616. losing his son Raegenhere in the battle. Edwin soon superseded Raedwald as overlord Raedwald's son Eorpwald nas converted by Edwin (627 or 628), but killed soon after by a heathen Ricberht; three years later his half brother Sigeberht. who had become a Christian in Gaul, introduced a Burgundian bishop. Felix, giving him a see at Dunuich. and gave Burgh Castle to an Irish pilgrim, Fursa, for a monastery. Sigeberht retired into a monastery, but was unwillingly brought from it when Penda of Mercia attacked East Anglia. and both he and his successor. Ecgric, were killed. Penda also killed (c. 653) their successor. Anna. son of Raedwald's brother Eni, a devout Christian who converted Coennalh of Wessex and who was remembered as the father of several saintly daughters. His brother Aethelhere. who succeeded probably oned his throne to Penda, for whom he fought in 654 at the battle of the river Winwaed, where he was killed. He may be the king commemorated at the Sutton Hoo barrow. for which a date of about 650–660 has been suggested on coin evidence. His brother and successor, Aethelwald, stood sponsor to Swithelm of Essex. He was succeeded in 662 or 663 by Aldwulf, son of his brother Aethelric. whom Bede (d. 735) mentions as living until his own time. Aldnulf's son Aelfwald corresponded with St. Boniface, and Felix dedicated his *Life of St. Guthlac* to him. After his death in 749, events in East Anglia become obscure. Symeon of Durham says that Hunbeanna and Alberht divided the kingdom; Florence of Worcester follows Aelfwald's name with Beorna, Aethelred, Aethelberht and Edmund. The third of these is the king beheaded by Offa's orders in 794, but between him and Edmund, killed in 869. coin evidence supplies the names of Aethelstan and Aethelweard. East Anglia was subject to the Mercian kings Aethelbald, Offa and Coenwulf, but in 825 the East Angles killed King Beornwulf of Mercia, and in 827 inflicted a severe defeat on his successor, Ludeca. East Anglia was raided by the Danes in 841. and in 865 the great army wintered there. It returned in the autumn of 869, defeated King Edmund, and killed him in circumstances that led to his being regarded as a martyr. In 875 Guthrum and two other Danish kings wintered in Cambridge. and late in 879 he and his forces settled in East Anglia and began to share out the land.

The Danish settlers supported the Vikings against Alfred, and fought for Aethelwold, a rival to Edward the Elder, in 902. when their king. Eohric, was slain. A later king was killed in 917 and toward the end of the year East Anglia accepted Edward's rule. King Aethelstan appointed as ealdorman Aethelstan "half-king," whose sons Aethelwold and Aethelwine (d. 992) succeeded him. Under Ulfcetel, the East Angles fought heroically against the Danes in 1004 and 1010. Among the 11th-century ealdormen nere Harold Godninson and Aelfgar, son of Leofric of Mercia.

East Anglia was divided into the dioceses of Dunwich and Elmham about 673, but both sees perished at the Danish conquest. Christianity was rapidly re-established, but in the first half of the 10th century the province was administered by Theodred, bishop of London. Elmham was established as the East Anglian see in 956. The monasteries of Ely, Thorney and Crowland were refounded about 970, and the secular priests of Bury St. Edmunds were replaced by Benedictine monks in 1020.

The dialect, personal names and place names, and institutions of East Anglia were much influenced by the Danish settlers, and it belonged to the area governed by the laws of the Danelaw (*q.v.*).

EAST BARNET, an urban district comprising East Barnet, New Barnet, Monken Hadley, Osidge and Brunswick Park in the Barnet pprliamentary division of Hertfordshire, Eng., 9 mi. N. of London on the Great North road. Pop. (1961) 40,599. It lies in a valley between Barnet and Enfield and is a residential area with light industries. East Barnet parish church (1100) is a Norman building; the beaconed tower of Monken Hadley parish church (rebuilt 1494) is a landmark. Hadley Green, site of the battle of Barnet, is within the urban district, and near to the green at Hadley Highstone stands the obelisk which marks the traditional spot where the earl of Warwick fell. The battle was fought on Easter day, April 14, 1471. Its result was momentous. In routing his Lancastrian opponents and in killing their leader: the earl of Warwick, Edward IV struck the Lancastrian cause a mortal blow. He completed its destruction a month later at the battle of Tewkesbury (*q.v.*).

EAST BENGAL: *see* BENGAL.

EASTBOURNE, a seaside town, municipal and county borough in the Eastbourne parliamentary division of East Sussex, Eng., 63 mi. S.S.E. of London by road. Pop. (1961) 60,897. Eastbourne lies partly on the coastal plain and partly on the eastern slopes of the South Downs below Beachy head (532 ft.). Because of its position and easy access from London it became a health and holiday resort and also a popular conference centre as well as a residential town with a number of boarding schools, including Eastbourne college for boys (founded 1867), and convalescent homes. The accommodation and entertainment of visitors provide the chief employment; fishing, toymaking, brewing and printing are also carried on.

The earliest settlement, East Bourne, was a mile from the sea in what is now called the Old Town; there is the parish church of St. Mary, a fine Transitional-Norman building; there too can be seen the bourne or stream to which the name alludes. Subsequently two small fishing settlements grew up, South Bourne lying back from the shore and Seahouses facing the beach, but the modern development of Eastbourne dates from the early 19th century. It owes its charm as a town to the 7th duke of Devonshire; the family is one of the principal landowners, and a family seat, Compton place, lies between the old and new towns. Eastbourne was one of the first English experiments in town planning, with wide, tree-lined streets and ample open spaces. The Saffrons sports ground faces the town hall; the Manor house (18th century) houses the Towner art gallery. The sea frontage extends for more than 3 mi. and is partly built in terraced promenades; the Wish tower (a Martello tower) and the Great Redoubt date from the early 19th century. The borough includes a considerable area of the neighbouring downs, about 4,000 ac. of which are preserved.

Eastbourne was incorporated in 1883 and was constituted a county borough in 1911; the present parliamentary division mas constituted in 1948.

EAST CHICAGO, an industrial city and port in Lake county, Ind., U.S., adjoining Gary, Hammond and Whiting (*qq.v.*) about 20 mi. S.E. of downtown Chicago, Ill. Expansion of the steel industry from Chicago eastward along the shore of Lake Michigan was largely responsible for its creation. A part of the Chicago-

Calumet industrialized metropolitan complex, it is included in the Gary–Hammond–East Chicago standard metropolitan statistical area. (See GARY.) East Chicago was laid out in 1887 and incorporated in 1889. Construction of Indiana harbour, connected with the Grand Calumet river by a 3-mi. ship canal, stimulated the city's industrial development which includes an extensive system of docks. Among its densely concentrated industries are steel mills, foundries, oil refineries, a refractory, railway equipment shops and producers of chemicals, industrial tanks and valves.

East Chicago is the site of the Calumet Extension centre of Indiana university. Population increased from 3.411 in 1900 to 19,098 (55% foreign-born) in 1910. Pop. (1960) 57.669. For comparative population figures see table in INDIANA: *Population.*

(P. ME.)

EAST CHINA SEA: see CHINA SEA.

EAST CLEVELAND, a suburb on the east of Cleveland (*q.v.*) in Cuyahoga county, O., U.S., and a part of the Cleveland metropolitan area, is situated on Lake Erie's plain and the rolling upland of the Appalachian plateau. Settlement began in 1901 as a farming community, serving the city of Cleveland 6 mi. W., with which it was connected by rail. Suburban development was aided by the streetcar and automobile. Although it is primarily a residential suburb, there are some 50 industries. East Cleveland became a city in 1911 and adopted a commission-manager form of government in 1918. In 1938 it received 180 ac. of John D. Rockefeller's scenic summer estate "Forest Hills," now a municipal park. For comparative population figures see table in OHIO: Populnfion.

(M. M. WA.)

EAST DETROIT, a city of Macomb county, Mich., U.S., is adjacent to northeastern Detroit. A post office, designated as Halfway, was established there in 1897, in a small settlement at Nine Mile road and Gratiot avenue midway between downtown Detroit and Mount Clemens. In 1925 the community was incorporated as the village of Halfway with a population of approximately 1.000, and four years later was reincorporated as the city of East Detroit. When first incorporated as Halfway the town had no industries, but by the early 1960s a number of small plants were located there. About 70% of the manufacturing is in the fields of nonelectrical machinery and fabricated metals.

East Detroit is a rapidly growing commuters' suburb of Detroit. For comparative population figures see table in MICHIGAN: Population.

(J. L. N.)

EASTER, the principal festival of the church year (*q.v.*), celebrates the resurrection of Jesus Christ on the third day after his crucifixion; its origins go back to the beginnings of Christianity and it is probably the oldest Christian observance of the kind after Sunday, which was regarded as the weekly celebration of the resurrection. The English name Easter is of uncertain origin; Bede in the 8th century derived it from that of the Anglo-Saxon spring goddess Eostre.

Date of Easter.— Easter day in the west is the first Sunday after the full moon which happens upon or next after the vernal equinox; if the full moon occurs on a Sunday, Easter day is the Sunday after. Easter therefore can fall between March 22 and April 25 inclusive. This rule was fixed after much controversy and uncertainty, lasting in various parts of the church down to the 8th century. The difficulty was caused primarily by the fact that the Jews observed a calendar based on the lunar months (see CALENDAR). The Jewish Passover (Hebrew Pesach, Gr. Pascha), to which Easter, the Christian Passover, succeeded, was celebrated on the 14th of the Jewish month Nisan and was not therefore tied to any one day of the meek (see also JEWISH HOLIDAYS). The first dispute was whether Christians should celebrate the festival on a weekday or on the following Sunday. Eusebius (4th century) in a famous passage in his ecclesiastical history describes this discussion:

> The Christian communities of all Asia [*i.e.*, the Roman province so-called] thought, according to a very old tradition, that the feast of the Saviour's pascha ought to be kept on the 14th day of the moon, on mhich the Jews mere ordered to sacrifice the lamb, and that therefore, on whatever day of the week this might fall, it was essential to end the time of fasting then. But the churches of all the rest of the world were not accustomed to observe this practice: in virtue of an apostolic tradition they followed the custom now in force and considered that on no other day was it right to end the fast but on that of our Saviour's resurrection. Synods and councils of bishops met at this time, and all unanimously, by their letters, issued a decree of the church for those in all parts. They decided that the mystery of the Lord's resurrection from the dead should not be celebrated on any day but Sunday and that only on this day should we observe the end of the paschal fasts.

Those who kept Easter on the 14th Nisan were called Quartodecimans. As one of them, Polycrates, a 2nd-century bishop of Ephesus, explained, they appealed to local tradition including the practice of St. John to support their custom. In the late 2nd century Pope Victor excommunicated Asia, but Quartodeciman practices continued there for several centuries. The suggestion that the churches of Asia celebrated Christ's death and the others his resurrection is unfounded. Christians in the 2nd century celebrated the death and resurrection together as two sides of the same mystery of redemption. By the end of the 4th century the separate celebrations of Maundy Thursday, Good Friday and Easter had clearly emerged, and evidence of their observance in Jerusalem at this time is to be found in Etheria's account of her pilgrimage (see CHURCH YEAR: Jerusalem).

The date of Easter was again raised at the Council of Nicaea (325), when, acceptance of the Sunday celebration of the festival being almost everywhere agreed, the question of which Sunday this should be came up for decision. It was still a matter of achieving uniformity among all churches. The difficulty had occurred because some churches followed the imperfect Jewish calendar and celebrated Easter on the first Sunday that actually followed the Jewish Passover; by this reckoning, as the Jewish calendar was based on the lunar calendar (which was 11 days short), Easter sometimes occurred before the equinox (14th Nisan being the full moon in the first Jewish month after the spring equinox). Other churches settled the biblical date (full moon after the spring equinox) by their own scientific methods. At Rome (since Caesar) the equinox was fixed on March 25; at Alexandria, for astronomical reasons, on March 21. Nicaea adopted the Alexandrian reckoning, fixing the equinox on March 21, its true date in the Julian calendar.

In the 4th and 5th centuries divergencies between the Roman and Alexandrian methods of computation again caused difficulties but were usually settled by compromise. Nevertheless, until the time of Charlemagne, considerable uncertainty existed in Gaul owing to the adoption of the paschal tables drawn up in Rome in 457, with a cycle of 432 years. But these tables were not used in Rome and thus differences between Rome and Gaul occurred.

The Celtic churches followed their own method of computation, though it is difficult to determine what it was. They were not, as has sometimes been asserted. Quartodecimans. On the arrival in southern England of the missionaries from Rome under Augustine (597), disputes on the date of Easter arose between the two parties. The matter was settled by the adoption of the Roman reckoning for Northumbria by the Synod of Whitby (664 or 663) and this reckoning was ordered to be observed by the whole of England by Theodore, archbishop of Canterbury, in 669.

Easter is nowadays kept by all western Christians on the same day, in accordance with the rule stated above. In the Orthodox Eastern Church a slightly different calculation is followed, with the result that the Orthodox Easter, although sometimes coinciding with that of the west, can fall one, four or five weeks later.

In the 20th century there has been some discussion in the west of the possibility of a fixed Easter (the first Sunday in April has been suggested in all those schemes of calendar reform which fix the first day of each quarter year on a Sunday). The suggestion has found support among some churchmen and of course there is no theological objection to it; its adoption would depend on agreement being reached among the various churches.

Religious Observances.— The festival of Easter occurs on a particular Sunday, but its importance is emphasized in the worship of the church by the long preparation of Lent. by Holy Week with its solemn services and by the following seven weeks until Whitsun (or Pentecost) observed as Eastertide (or Paschaltide). a period of rejoicing. Easter is central to the whole Christian year; not only does the whole ecclesiastical calendar of movable feasts depend upon its date but the whole year of worship is ar-

ranged around it. In the liturgical texts the emphasis is laid on its being the Christian Passover. From the earliest times Christians have kept Sunday as the weekly commemoration of the resurrection of Christ. "We keep the eighth day with joy on which also Jesus rose from the dead." says the epistle ascribed to Barnabas (1st century), and Justin Martyr (2nd century) remarks in his first apology. "We all gather on Sunday because on this first day... Jesus Christ our Saviour rose from the dead." Sunday was a "little Easter."

By the time the liturgy had begun to take shape (2nd century) the Sunday Eucharist was preceded by a vigil service of Scripture readings and psalms. In this must be seen the origin of the Easter vigil service, one of the striking celebrations of Easter in both east and west; from being a weekly observance the vigil has turned into an annual one at Easter only. As it is now constituted in the Roman missal this vigil consists of the blessing of the new fire (a practice introduced during the early middle ages); the lighting of the Paschal candle; a service of lessons, called the prophecies; followed by the blessing of the font and baptisms and then the Mass of Easter. This pattern is quite primitive and in its principal elements can be traced back to the 3rd–4th centuries. In course of time the vigil in the west (but never in the east) came to be anticipated first to the Saturday evening then to the Saturday afternoon and finally, by the end of the middle ages, to the Saturday morning. In 1951 (optionally) and 1955 (obligatorily) throughout the Roman Catholic Church the Easter vigil was restored to its proper time, starting about 10 P.M. so that the first Mass of Easter begins at midnight.

The connection of baptism with Easter is of early date. During the first centuries the whole of Lent was not only a time of penance but also the period during which the catechumens were prepared for baptism, which was given only once a year at Easter. For the six weeks preceding Easter the catechumens were instructed in the Christian faith, and the texts of the Lenten liturgy in the Roman missal still preserve very clear indications of this practice. The catechumenate came to an end with the solemn baptisms of Easter night. This is the explanation of the present practice of the long ceremony of blessing the font on Easter night and of the great emphasis on baptism and its meaning and the many allusions to it still present in the Easter services.

In the modern rite after the blessing of the fire the Paschal candle is lighted and carried into the church, which until this moment is in darkness; when the candle is set up in the sanctuary the deacon sings the *Exultet,* which recounts the origins of the Jewish Passover and God's mercies to the Jews in bringing them safely to the promised land. This theme is continued in the lessons which are then read (especially Ex. xiv, 24–31). All this leads up to the blessing of the font and the baptisms, which after the litany may take place at this point. The congregation then renews its baptismal promises. The theme of the Passover, referring to Christ's passage through death to life, is applied also to baptism whereby the neophytes pass through the waters of baptism to Christian life and the resurrection is evoked at the same time— the resurrection of Christ and that of the neophytes rising from the waters of baptism to new life. This forms the theme of the whole Easter liturgy not only on the day itself but also throughout the following week. Low Sunday, the octave day of Easter. is called in the missal *Dominica in albis,* a relic of the earlier practice whereby on this day the newly baptized put off their white baptismal robes which they had worn since Easter day (*in albis* is an abbreviation of *in albis deponendis,* "laying aside white garments").

During the whole of Eastertide the *Alleluia,* which has not been said since Septuagesima, is added to many parts of the breviary and missal services. At the Mass of Easter day after the epistle and gradual a sequence, *Victimae paschali laudes,* is sung. In the middle ages the anticipation of the Easter vigil left a gap in the series of offices for the end of Holy Week and Easter day. In some countries therefore, especially France, Germany and England, a new ceremony was evolved. On Good Friday the cross was laid in a sepulchre where it remained until before the matins of Easter. At midnight the clergy entered the dark church, removed the cross from the sepulchre to the high altar, and when the candles had been lit a solemn procession was held. At a later date the host, consecrated on Maundy Thursday, was used instead of the cross.

Another ceremony of the same kind, known as the visitation of the sepulchre, mas held in some places after matins. Two of the clergy, representing the women at Christ's tomb, went to the empty sepulchre where another priest, taking the part of the angel, announced the resurrection. The two thereupon returned to the choir and two other priests, taking the part of Peter and John, ran to the sepulchre and finding it empty held up to the people the linen representing that in which Christ's body was wrapped. The choir sang the *Te deum* and the *Victimae paschali laudes.* The dramatic quality of this hymn lent itself admirably to the purpose.

The continual elaboration of ceremonies of this nature, which date from the use of the dramatic sequence *Quem quaeritis in sepulchro* in the 10th century, led to the eventual development of the Easter mystery plays *(see* DRAMA: *Medieval Drama).* As time went on a considerable amount of vernacular dialogue was introduced, not without some burlesque and buffoonery, and bishops on occasion protested at the unsuitability of some of the plays for use in church.

Among the Greek and Russian Orthodox perhaps even greater emphasis is laid on the central position of Easter not only as an annual observance of the church year but in the whole worship and spiritual life of the church. The vigil service is preceded by a procession outside the church representing a fruitless search for the body of Christ. Then comes the joyful announcement, "Christ is risen," followed by the Easter Eucharist. When the procession first leaves the church there are no lights anywhere, but on its return hundreds of candles and coloured lamps are lighted to show the splendour of Christ's resurrection.

In the Church of England the Book of Common Prayer provides special anthems to take the place of the *Venite* (Ps. xcv) at matins. Lutheran hymn books, which contain orders of service, use special sentences at Easter. The Book of Common Order of the Church of Scotland includes prayers for Easter, and the *Divine Worship* of the Methodists has an order of worship for Easter morning, but the use of these is not compulsory. (L. C. S.)

In the Protestant churches, Easter Sunday observances are the culminating point of a series of services held during Holy Week, beginning with Palm Sunday. It is customary for the sacrament of Holy Communion to be administered during Holy Week, but the time of its observance varies. Many denominations have established the custom of celebrating Holy Communion on Maundy Thursday, others administer the sacrament on Easter morning some time before the regularly established hour of worship. Many Protestant churches hold joint interdenominational Good Friday services, prepared under the auspices of the local ministerial association. These services in many communities centre around the traditional seven last words of Christ and are conducted from 12:00 noon to 3:00 P.M. with choirs and clergy of the participating denominations. This interdenominational pattern culminates in the Easter dawn service, which is of such interest in the United States that it commands wide television and radio coverage. The origin of the sunrise service is not known, but it would appear to be rooted in the Gospel narratives describing the resurrection of Christ; *e.g.,* John xx, *1* ff., "Now on the first day of the week, Mary Magdalene came to the tomb early, while it was still dark . . . ." The congregations that gather for the sunrise service are in effect attempting to re-enact the drama described in the Gospels. Mingled with this biblical warrant is an association with the spring of the year and the idea of the new birth symbolized in nature's renewal of itself out of the death of winter. Thus the service is held out-of-doors in some scenic spot, a hilltop, a park or lake shore. The service begins at sunrise, symbolizing the end of night (death) and the revival of hope in the hearts of the congregation. The sunrise service, like the Good Friday service, is organized and conducted by the local council of churches or ministerial associations; in smaller communities it is frequently conducted by young people under the auspices of the Y.M.C.A. or Protestant youth councils. (R. W. D.)

Popular Customs. — Around the Christian observance of Easter

as the climax of the liturgical drama of Holy Week and Good Friday folk customs have collected, many of which have been handed down from the ancient ceremonial and symbolism of the pagan spring festival brought into relation with the resurrection theme. When the medieval miracle plays of northern and central Europe came to an end in the 16th century under the pressure of the Reformation, the way was open for the gradual revival of the calendar customs and folk drama, in spite of Puritan opposition to revels, acting and dancing. Thus, the liturgical portrayal of the death and resurrection of Christ enacted in the ecclesiastical Easter plays gradually found its secular counterpart in the popular survivals of the ancient seasonal ritual connected with the spring equinox.

These took a variety of forms in which Easter eggs, formerly forbidden to be eaten during Lent, have been very prominent as symbols of new life and resurrection. In Lancashire on Easter eve boys and men have been in the habit of touring the towns and villages as "Pace-eggers" begging for eggs before performing the "Pace-Egging" or *Pasch* (*i.e.*, Easter) play. This was the Easter version of the St. George mummers' play. This death and resurrection theme recurs in the sword dances which were also of frequent occurrence among the traditional ritual dances at this season. The widespread belief that the sun danced for joy on Easter morning at dawn led to the custom of going to the hills at sunrise to see and take part in this event, a practice that was still prevalent in the British Isles in the 19th century. Rolling coloured eggs down slopes on Easter Monday remains a popular observance especially in the north of England. Formerly Easter eggs sometimes were consecrated for ceremonial use in churches, and at Chester cathedral the bishop and the dean are said to have engaged in an egg-throwing match with the choir boys when the antiphon *Quem quaeritis* was sung on Easter day.

In Greece each person in a group bangs his red Easter egg against the eggs of all the others present in turn, saying "Christ is risen," and receives the reply "He is risen indeed." In the U.S. egg-rolling on the lawn of the White House has become traditional.

The hare, the symbol of fertility in ancient Egypt, a symbolism which it kept in Europe, is not found in North America and its place is taken by the Easter rabbit, the symbol of fertility and periodicity both human and lunar, accredited with laying eggs in nests prepared for it at Easter, or with hiding them away for children to find. But it was not until the latter part of the 19th century, especially during the Civil War, that Easter customs were observed in the U.S., except in a few states, such as Louisiana and Virginia, not dominated by the Puritan element. Then those who had died in the war were commemorated in the churches which were decorated with flowers on Easter day. This brought the festival into prominence and gradually some of the folk customs were revived, notably under Irish influence.

In the north of England on Easter Monday and Tuesday parties of women surrounded any man they met in the street and "heaved" him three times over their heads. Then they sprinkled him with water and each of them kissed him. In return he made an offering of money to them. The next day the men lifted the women in the same manner. Originally it would seem to have been a spring rite to promote the growth of the crops, like the leaping of the Salii in the March festivals in ancient Rome. At Hocktide on the Monday after Low Sunday the women demanded a forfeit from the men whom they succeeded in binding with ropes, the men retaliating the following day. At Hungerford in Berkshire on Low Tuesday men paraded the town carrying "tutti" poles adorned with ribbons and flowers, collecting coins from men and kisses from women, before assembling for a banquet and the initiation of newcomers to the town. The enforced payment of dues and forfeits, and the devices adopted for extracting money from wayfarers at these observances, may be relics of methods of redemption.

(L. C. S.; E. O. J.)

EASTER ISLAND (ISLA DE PASCUA), also known as RAPA NUI, a dependency of Chile administered from Valparaíso province and situated in the South Pacific ocean in 27° 05′ S. latitude, and 109° 20′ W. longitude, about 2,000 mi. W. of Caldera, Chile, and 1,100 mi. E. of Pitcairn, the nearest inhabited island. Easter Island is volcanic and reaches a height of 1,765 ft. It is about 11 mi. long and 15 mi. wide (46 sq.mi. in area). The population was 809 at the 1952 census. Though leprosy has been endemic since 1889, the health of the islanders is good and the Chilean government has taken steps to improve conditions.

The island was discovered by the Dutch admiral Jacob Roggeveen on Easter Sunday of 1722, whence its name. Although the population of the island prior to its discovery is not known, it is unlikely that it exceeded 4,000. Death from introduced diseases, capture by slave traders, internecine warfare and voluntary emigration reduced the population to 175 in 1872, largely destroying the aboriginal culture of this agricultural people, whose ancestors carved remarkable stone monuments and incised mysterious signs on wooden tablets. Between 1863 and 1864 the islanders were converted to Catholicism by Brother Eugène Eyraud of the Congregation of the Sacred Hearts of Picpus. Easter Island was annexed by Chile in 1888, and under Chilean authority the native inhabitants were confined to the village of Hanga-roa on the west coast, where they had approximately 5,000 ac. of land for subsistence purposes. The remainder of the grass-covered island (30,000 ac.) was leased by the Compañía Explotadora de la Isla de Pascua and was devoted to the grazing of sheep and cattle.

Archaeology.—Easter Island is destitute of metal objects and pottery, although clay suitable for potting occurs in the craters. The stone remains include houses, platforms, semipyramidal cairns, circular towers, cisterns, statues, rock carvings, adzes or chisels, obsidian spearheads and fishhooks. A few small objects in shell and bone have been found. The skulls collected from graves show no traces of high antiquity.

The most striking monuments are the burial platforms, called *ahu,* and the statues surmounting them. About 260 platforms have been counted in varying degrees of preservation, fringing the coast in almost unbroken succession, while a few are also found inland. Only about 100 of these were intended to support images.

A typical image *ahu* consists of a wall parallel with the sea, measuring up to 300 ft. in length and 15 ft. in height and buttressed to landward with a slope of masonry. The images stood in a single row facing inland on the central portion of the wall, which projected toward the sea, and a single *ahu* might contain from 1 to 15 statues. The maximum extension of the landward slope was about 250 ft., and beyond this was a paved area. The masonry, of huge polygonal or rectangular blocks, is sometimes beautifully finished and fitted together but is more often of rough material. These *ahu,* which were still used within living memory, served for the exposure of dead bodies and contained vaults for the subsequent burial of the bones.

All the statues belonging to the *ahu* have been thrown down and many broken. But by the accounts of the early voyagers the greater number of them were standing in the 18th century and Roggeveen referred to religious ceremonies that appeared to him to indicate worship of the statues. The *ahu* were sacred places corresponding to the Polynesian *marae* and some if not all of the statues were erected in honour of ancestors.

The statues were cut from compressed volcanic ash, a soft and easily worked stone. All conform to a single distinctive type, representing only the upper half of the body with an upturned face and long ears. The usual height of the images on the *ahu* was from 12 to 20 ft., and they were surmounted by tall cylindrical hats or crowns (as much as 6 ft. high and 8 ft. in diameter). These consisted of a red volcanic tuff and were quarried in a different crater from the statues.

The quarry for the statues was both inside and outside the large crater of the volcano called Rano-raraku at the northeastern end of the island; there they are found in large numbers and in all stages of completion, as though the work had suddenly been interrupted and never resumed. The sculptors worked in niches surrounding the statues, and the carving mas completed before the back was detached by undercutting. The stone chisels used were found in *situ.*

The means of transporting the larger images, the heaviest of which must have weighed about 50 tons, has never been satisfactorily explained. But a native account states that they were dragged into position (presumably with ropes. the native hemp and hibiscus fibre furnishing adequate materials) and that round pebbles were placed underneath to serve as rollers. Seaweed may also have been used to minimize friction with the ground. The statues probably were erected on the *ahu* by being hauled up an incline of earth or stones and then gradually up-ended into position by withdrawing the supporting material from under their bases.

Dwellings, though generally constructed of perishable materials, were sometimes provided with wrought foundation stones, resembling curbstones. sunk into the ground and provided with holes in their upper surface for inserting the wooden rods that provided the framework of the houses. Their ground plan was long, narrow and boat-shaped, and they were large enough to accommodate from 10 to 30 persons. There also are remains of stone chicken houses and round-chambered towers on the coast used as fishing lookouts. Natural caves were widely used as dwellings, some supplemented by frontal walls.

Apart from these houses, there is one sacred village at the southwestern corner of the island. called Orongo. It contains 48 houses built entirely of stone. This village was connected with a bird cult (still remembered) that once played an important part in native life. A leading feature was an annual competition to secure the first egg laid on an outlying islet by the migratory sooty tern. Orongo was occupied by the competitors. and the numerous rock carvings in the vicinity depicting a bird-headed man. sometimes holding an egg in his hand, presumably commemorate the victors.

There can be little doubt that the stone structures of Easter Island are the work of the ancestors of the present native inhabitants. The statues and platforms were actually in use at the time of discovery, and some of the sculptors' names are still remembered. But apart from traditional evidence, the occurrence of certain peculiar designs carved on the backs of some of the stone statues. as well as on small wooden figures of recent date, furnishes an unquestionable link between past and present culture.

Date of Settlement. — The date of the earliest settlers' arrival is still uncertain. as is their point of departure and whether there was more than one migration. Tradition holds that the ancestors arrived from the west in two canoes under a chief named Hotu-matua, but supplies no clear evidence of previous inhabitants or of subsequent immigrations. The story of the war between the "short- and the long-ears" has been construed as the legendary account of a struggle between early settlers and late invaders. Excavations made during the Thor Heyerdahl expedition on the island (1956–57) have shown that the earth-oven in which the long-ears are said to have perished was actually a defense ditch containing ashes. According to radiocarbon dating. the fire was lighted in the 17th century A.D., a short time before the discovery of the island. On the basis of the shortest recorded genealogy of 22 chiefs descended from Hotu-matua the migration of the Polynesians to the island can hardly be assigned to a period later than the 14th century A.D. The archaeologists of the Heyerdahl expedition found evidence of architectural stratigraphy. but final conclusions as to the scope of this discovery require more detailed information.

GIGANTIC STONE FIGURES WHICH HAVE STOOD FOR CENTURIES ON THE SLOPES OF RANO-RARAKU, AN EXTINCT VOLCANO ON EASTER ISLAND

Physical and Cultural Affinities. — Racially and linguistically Easter islanders are Polynesian. though their heads are longer than those of any other peoples in Polynesia. This feature has been attributed to a considerable Melanesian admixture. Negroid features, however, are rarer in Easter Island than in other Polynesian islands. Moreover, the blood group frequencies on the island are typically Polynesian. The mixture with Melanesians might well date from a period prior to the arrival of the Easter islanders' ancestors in their new country. The present very heterogeneous population is rapidly increasing and spreading over formerly deserted territory. The main handicraft of the natives consists in the carving of wooden and stone images modeled on traditional patterns.

Script. — The writing engraved on wooden tablets, unique in Polynesia and first noted in 1564. is undoubtedly ancient. It takes the iorm oi symbols. strongly stylized. representing human beings. birds, fish. crustaceans. plants, ceremonial articles and designs of a purely geometrical character. The symbols. all of the same height. are incised on both sides of the tablets in regular longitudinal channels or flutes. separated by low ridges. Each row of signs runs in the opposite direction to the one above and below it (the boustrophedon system) so that the tablet has to be turned around at the end of each line in order to have the signs in their correct sequence. Some of the chants and stories which the tablets record have been obtained from living natives, who were unable nonetheless to give a coherent interpretation of the system used by the *tangata rongorongo* (chanters and scribes). The tablets seem to have been aids to memory like the knotted bundles of the Marquesans and the notched staves of the Maori, but according to T. S. Barthel the tablets show a real script consisting of 120 elements combined in various ways to form more than 1,000 compound signs. It is mainly ideographic with rudiments of phoneticism. Russian scholars — B. Kudriavtzev, N. A. Butinov and Y V Knorozov — nho tried to unravel the secret of the tablets. also arrived at the conclusion that the Easter script reached the stage of an elementary hieroglyphic script. Only the actual deciphering of the tablets can confirm the validity of such theories. *See* also POLYNESIA; POLYNESIAN LANGUAGE.

EASTERN HIGHLANDS, a series of plateaus and mountain ranges running parallel nith the east coast of Australia. They were for long known as the Great Dividing range. but the term is falling out of use. The various locally named ranges that rise above the general level do not form anything like a continuous chain. Nor does the watershed betueen streams flowing to the Pacific and those flowing westward coincide very often with any definite range. In places, indeed, the divide is indeterminate, *e.g.,* Duck Flat, New South Wales, and in places bifurcated by small interior drainage basins; *e.g.,* Lake George. (O. H. K. S.)

EASTERN NIGERIA occupies the eastern part of the Niger delta fronting the Gulf of Guinea and the country east of the river up to about150 mi. inland. Pop. (1960 est.) 8,224,000. Area 29 484 sq.mi. Rainfall is heavy, ranging from more than 100 in.

annually in the Niger delta, the Cross river (q v.) valley and along the coast to 73 in. at Enugu, the regional capital. The rural population densities are among the highest in tropical Africa, reaching 1,500 per square mile in parts of Owerri and Calabar provinces. To support the dense population the rain forest has been cleared in many places for the cultivation of food staples (cassava. yams. coco yams). Severe population pressure on the land has caused spectacular soil erosion in parts of the western provinces of Onitsha and Owerri. Of the total population. 14% were urban dnellers in 1953. Ibo (*q.v.*) peoples, located particularly in Onitsha, Ouerri and Ogoja provinces, form about 60% of the total; the next most important group, the Ibibio in the southeast, number about 750,000. Nearly half the people profess Christianity and the influence of Islam is negligible.

The chief towns are Onitsha (pop. [1960 est.] 88,358), Port Harcourt (42,553), Enugu (82,594) and Aba (66,379). Calabar (until 1904 called Old Calabar) on the Cross river delta was in the late 19th century the chief port and centre of British influence in the Oil Rivers (later Niger Coast) protectorate. In the early 19th century the port of Brass, 60 mi. W.S.W. of Port Harcourt, was the focus of European trade with the hinterland.

The fragmentary organization of the local peoples caused difficulties of administration under British rule. Eastern Nigeria (until 1951 known as the Eastern provinces) in 1957 obtained self-government within the Federation of Nigeria, with a single-chamber government elected by adult suffrage Christian missions fostered education and literacy is higher than elsewhere in Nigeria A uni ersity was founded in 1960 at Nsukka. 40 mi. N. of Enugu, incorporating a branch of the former Nigerian College of Arts, Science and Technology.

The oil palm grows well on the leached and acid sandy soils covering much of the region but is not deliberately cultivated; its products are the mainstay of the region's economy. Coal of poor quality is mined around Enugu but falling demands caused by a change to oil fuel reduced the output to about 700.000 tons in 1959. Oil was struck in the Brass district at Oloibiri and Afam in 1956, being carried by pipeline to Port Harcourt and to a terminal at Bonny, 22 mi S. In the early 1960s rubber plantations near Calabar were being extended to 20,000 ac. There is a large cement factory at Nkalagu. 33 mi. E. of Enugu, and secondary industries have been developed at Aba and Port Harcourt.

Port Harcourt, which after Lagos is the second port of the federation, is the terminus of the eastern branch of the Nigerian railway, which runs north through Enugu to cross the Benue at Makurdi. Over much of the region the road network is good and in 1960 a road bridge was begun across the Niger at Onitsha as a link with Western Nigeria. Nigeria Airways provides links between Enugu, Port Harcourt and Calabar and other centres in the federation.

See K. O. **Dike,** *Trade and Politics in the Niger Delta, 1830–1885* (1956). (R. M. P.)

EASTERN PROVINCE, CEYLON, stretches in a band (seldom more than 25 mi. wide) down the east coast of the island. Pop. (1953) 354,410. Area 3,840 sq.mi. At Trincomalee quartzite ridges come out to sea and, a little to the south, the Mahaweli Ganga enters the Bay of Bengal through a delta. Elsewhere the coast of the province is made up of sand bars backed by shallow, muddy lagoons, in process of being filled in by alluvium, and fringed in places by mangrove swamps. Behind the lagoons the land is solid crystalline rock, mainly gneiss. Relief is generally low but broken by isolated hill masses. Some of these are high and spectacular (Friar's Hood, so called from its shape, 2.159 ft.) and give a special quality to the western sky line seen against a sunset.

Climatically, the Eastern province is wholly inside the lowland dry zone of Ceylon (see CEYLON: Physical Geography) with its marked alternation of heavy rains during the northeast monsoon and severe drought during the southaest. The drought is intensified in the south by a hot, searing nind (kachchan) which descends foehnlike from the highlands to the west Much of the province is covered by forest but fairly large areas are under poor grassland (damana), which is perhaps the result of repeated burning. The alluvial infill. together with certain other areas, is under cultivation. Game, including the elephant, is abundant and the area round the Gal Oya reservoir is a sanctuary.

It appears that what is now the Eastern province was not densely settled or highly developed during the days of the ancient Sinhalese civilization, but there is a scattering of archaeological finds, many cave inscriptions in the interior, and a number of irrigation works (Kantalai tank behind Trincomalee) which are of ancient origin. Later, Tamils inhabited the coastal sand bars and the interior has been the home of surviving aboriginal Veddas and of poor Sinhalese. The chief towns are Trincomalee (*q.v.;* pop. [1953] 26,356), capital of a district, and Batticaloa (*q.v.;* pop. [1953] 17,439), capital of the province and of a district.

The coast and the Mahaweli Ganga delta produce rice and the sand bars, coconuts. The great Gal Oya development scheme was planned to open up over 100,000 ac. of country south of Batticaloa; to produce rice, sugar, tobacco and other crops; to generate hydroelectric power; and to develop tilemaking and other industries. The road network of the province is rather rudimentary and the only railways are branches terminating at Trincomalee and Batticaloa. (B. H. F.)

EASTERN PROVINCE (PROVINCE ORIENTALE), **REPUBLIC OF THE CONGO** (former Belgian Congo), lies for the most part north of the equator and borders on the Central African Republic, Sudan and Uganda. Pop. (1958 est.) 2,491,500, of whom 16,867 were not indigenous. Area 194,300 sq.mi. The climate is equatorial, except in the north where there is a short dry season. The southern half is covered by rain forest and the northern by savanna mixed with forest. The province includes a part of the central Congo basin, surrounded by plateaus of about 2,000 ft. elevation. Geologically it consists of Secondary, Tertiary or Quaternary deposits (sand, clays, sandstones) south and west of Stanleyville; Pre-Cambrian formations (notably the sandstones and limestones of the Lindi river) around Stanleyville; and vast stretches of metamorphic, crystalline and granitic rocks in the northeast and east, among which are some of the oldest known formations in the republic. On the Sudan frontier the Garamba National park (1,900 sq.mi.) contains some of the largest surviving land animals (elephant, hippopotamus, white rhinoceros, giraffe); okapi live in the Ituri forests.

Eastern province is occupied by very diverse tribes, including Sudanese-speaking Azande and Mangbetu (*qq.v.*) in the north, Bantu peoples (Turumbu, Bali) in the west and south and some Nilotic peoples in the northeast (Kakwa) and along the shores of Lake Albert (Alur and Bahema who are shepherds). Pygmies dnell in the Ituri forests. The most populous regions are betneen Paulis and Niangara, and the mountainous district bordering Lake Albert. The capital is Stanleyville (*q.v.*) at the foot of Stanley falls; it is the terminus of Congo navigation. Other towns, mostly between 8,000 and 15.000 population, are Aketi, Bunia, Watsa, Paulis, Buta and Yangambi. Administrative districts with their headquarters are: Upper Congo (Stanleyville), Lower Uele (Buta), Upper Uele (Paulis) and Ituri (Bunia).

Activity is mainly agricultural. Bananas, rice, cassava and vegetables are the chief subsistence crops. Cotton is grown in the northern savannas and is transported toward the Congo by the Vicicongo railway of 60-cm. gauge (Aketi-Mungbere). In the south and east coffee is grown, together aith oil palms, peanuts and rubber. There is also a timber industry. Under Belgian rule the chief centre of the Congo agronomic institute was at Yangambi, about 50 mi. W. of Stanleyville. The chief mineral is gold, of which about three-quarters of the output of the republic is mined in the province, mainly in the Watsa and Kilo districts in the east. The chief river ports are Stanleyville and Aketi. A metre-gauge railway links Stanleyville with Ponthierville, 78 mi. S. (HE. NI.)

EASTERN PROVINCE, TANGANYIKA, borders the Indian ocean from the Mligasi river to the Rufiji delta. extending inland about 200 mi. from the coastal plain to the escarpment fringing the plateau Pop. (1957) 1,084,570, including 44.7'79 non-Africans of nhom 6,184 nere Europeans. Area 41,450 sq.mi. The chief highlands are the Nguru mountains in the north, reaching

6,923 ft., and the Uluguru mountains (7,940 ft.) south of Morogoro. From Morogoro the province extends for about 250 mi. S.W. between the upper Rufiji and the eastern escarpment of the southern highlands. Geologically, the metamorphosed rocks of the Archean plateau are flanked by younger sedimentary rocks, ranging from fossiliferous Karroo sediments to recent estuarine clays. For climate see TANGANYIKA.

The major river systems are those of the Wami with its tributary the Mukondokwa; the Ruvu; and the Rufiji with its western tributaries the Great Ruaha and Kilombero. The Rufiji is navigable up to about 50 mi. inland but upstream is blocked by rapids, notably the Pangani rapids and Shuguri falls. Soils vary widely. Near the coast they are sandy on limestone, and river alluvium. Inland the use of valley soils, ranging from silty clays to fertile sands, depends on the control of floodwater. The fertile soils in the Morogoro district derive from material eroded from the Uluguru mountains.

Along the coast grow moist forest and coconut palms, with extensive mangrove swamps in the Rufiji delta. Inland, the *miombo* or open woodland gives place to montane forest on the hills and relatively moist savanna in the Kilombero valley. In Ulanga district west of the Rufiji is the Selous game sanctuary (11,512 sq.mi.), an important refuge for elephant, hippopotamus, rhinoceros. buffalo and antelope. Much of the province is infested with tsetse fly. (J. M. KE.)

Population and Administration.— The largest tribe, the Luguru, live in the mountains in the Morogoro district and number about 200,000. The Zaramo (176,800) live mostly in the coastal districts, especially in and around Dar es Salaam. The Rufiji (77,300) are mostly to be found in the district of that name. The Pogoro (70,700) and Kaguru (52,100) occupy the Kilosa district. Other tribes in the province are the Ndengereko (43.100). Kwere (39,000), Ngindo (33,900), Zigula (30.700) and Nguru (27,200), but there are numerous smaller tribes, some indigenous to the province and others which have entered it to settle.

The province is divided into eight districts: Bagamoyo, Dar es Salaam. Kilosa, Kisarawe. Mafia. Morogoro. Rufiji and Ulanga. Provincial headquarters are at Morogoro (pop., 1957, 14,507) on the Central railway line, at the junction of the link road to Korogwe (on the Tanga line) and the main road to the southern highlands. The capital of Tanganyika is Dar es Salaam (*q.v.*), nhich uas founded in the 1860s by Majid bin Said. sultan of Zanzibar, as a "haven of peace" for his relaxation. It was laid out and developed as a port by the Germans after 1884. Its population was 128.742 at the 1957 census and it forms an extra-provincial district. Morogoro is the only other sizable town.

Economy.—Morogoro and Kilosa are important sisal-growing centres and the province is noted for its cotton. Other crops are cashew nuts, copra, kapok, sugar, maize, sorghum, castor, sunfloner, cowpea, gram, rice and coffee. The basin of the Rufiji-Ruaha rivers for long attracted attention and various surveys assessed the possibilities of development and flood control. These surveys confirmed the great potential fertility of the basin but showed that its development would be costly. In the 1950s river gauges were installed and pilot irrigation schemes started. Large tracts of the province are tsetse infested, but the keeping of stock on sisal estates increased. and by the early 1960s the Tanganyika Agricultural corporation had about 3.000 head on its ranch on the Ruvu river. Timber is produced, most of which goes to Dar es Salaam; and the mangrove concessions in the Rufiji district are an important asset, worth about £10.000 a year. Some of the finest big-game fishing in the world is to be had in the Mafia channel, between the delta of the Rufiji river and the island.

A minor dairying industry has grown up around Dar es Salaam, which has rice, flour and other mills, and many cotton ginneries. Mica is mined principally in the Morogoro district, although it is found also in the Kilosa and Bagamoyo districts. China clay is obtained at Pugu near Dar es Salaam and building materials are extensively quarried. Salt is produced in considerable quantities, by evaporation from sea water. Graphite, garnets and phosphatic limestones also occur and there are small deposits of copper, vermiculite and gold. (J. P. MT.)

EASTERN QUESTION, a term used to describe the international problem presented by the chaotic condition of the Ottoman empire in the 19th century when it was threatened by internal disruption. The treaties of Paris (1814–15) and the final act of the congress of Vienna (1815) had provided an international system for those areas affected by the French Revolutionary and Napoleonic Wars (*qq.v.*). The Ottoman empire lay outside this system and therefore constituted a field of potential conflict between the great powers. In the first part of the 19th century only Austria, France, Great Britain and Russia were concerned with this question, but the German empire, in virtue of its treaty of 1879 with Austria-Hungary became increasingly occupied with Balkan and Turkish affairs, while toward the end of the century Italy began to entertain ambitions at the expense of Turkey.

In the 18th century France had been the European country with the greatest interest in the Mediterranean. The battle of the Nile (1798) and British occupation of Malta and the Ionian Islands, however. reduced French naval power in that sea. The consequent decline in the prosperity of Marseilles made the French especially anxious to re-establish their prewar position after 1815. The British. having succeeded the French as the dominant power in the Mediterranean, were equally anxious to secure their interests. The basis of British policy was the Chanak peace treaty of Jan. 5, 1809, with the Turks (who in 1806 had been France's allies against Russia, at that time Great Britain's ally). The Chanak treaty laid down the principle that no vessels of war of any power whatsoever should enter the Straits (the Dardanelles and the Bosporus). For practical purposes this meant that Great Britain obtained security against the entry of the Russian fleet from the Black sea into the Aegean, Russia then being as a result of the treaty of Tilsit (1807) in accord with France.

The Russo-Turkish Wars of the 18th century had established the Russians on the Black sea: by the treaty of Kuchuk Kainarji of July 21, 1774 (this and all dates in this article are new style), they had secured the fortresses of Kerch. Yenikale and Kinburn and the independence of the Tatar state in the Crimea; then in 1783 they had annexed the Crimea; and by the treaty of Jassy (Iasi; Jan. 9, 1792) the Russian frontier had been advanced to the Dniester. Moreover, by the treaty of Bucharest (1812) Bessarabia became a Russian province. On their southeastern frontier the Russians had made progress against Persia. The eastern Georgian kingdom of Kartlia acknowledged Russian overlordship as early as 1783 and became part of the Russian empire in 1801; the western Georgian kingdom of Imeretia was joined to Russia in 1810; and all Azerbaijan north of the Aras river together with the khanate of Talysh south of the river was ceded to Russia by Persia in 1813. By 1815 therefore Russia was firmly established in the near and middle east. Russian statesmen furthermore were determined that Russia's frontiers should be covered either by client states or by countries open to legitimate Russian intervention. Under the treaty of Kuchuk Kainarji Russia had obtained the right to protect the Christian population of Turkey, especially that of the Danubian principalities (Moldavia and Walachia), and the treaty of Bucharest made Russia the guarantor of the administrative autonomy of Serbia.

In this respect Russia found that Austria had considerable reservations. Austria could co-operate with Russia in the maintenance of the status quo in central Europe but was very sensitive to events in the Balkans. Having driven the Turks out of Hungary in the 17th century the Austrians had established against them the so-called Military Frontier (*Militärgrenze*), populated largely by Croats and Serbs, who served in the imperial army. In the 18th century this Slav element was loyal to Vienna, but in the 19th the fear arose in the minds of Austrian statesmen that the creatjon of a large Slav state in the Balkans might attract the South Slavs of the Habsburg empire and cause them to secede, thus threatening the empire with dissolution. Austrian policy. therefore, was to preserve the status *quo* in European Turkey. Russian intervention there would lead to the spread of nationalist feeling and thus infringe Austrian interests.

The Eastern Question in the 1820s.—In the first years after 1815 the major powers were anxious to maintain the treaty of

Vienna. There was little desire in the period of postwar reconstruction to raise the problem of the Ottoman empire. A crisis occurred when the Greek leader, Prince Alexander Ypsilantes, crossed the Prut in March 1821 and tried to raise Moldavia and Walachia in revolt against the Turks, hoping that a show of success would compel Alexander I of Russia to support him (see GREEK INDEPENDENCE, WAR OF). Ypsilantes in fact found little support. because he appealed first to the ruling class of Phanariote Greeks, who were as odious as the Turks to the Rumanians. In the meantime, however, there was a rising in the Morea in sympathy with Ypsilantes. Atrocities and reprisals on both sides, culminating with the hanging of the patriarch Gregorios in Constantinople (April 22, 1821), had a powerful effect in rousing Russian public opinion.

Alexander I, valuing Austria's co-operation in western and central Europe, was not anxious to fall out with Austria in the Balkans. The British government instructed its ambassador, Lord Strangford. to prevent a rupture of Russo-Turkish relations, which Strangford interpreted to mean that the Greeks must surrender unconditionally. When a Russian note to Turkey in July 1821, demanding the cessation of atrocities and the observance of the treaties, obtained no satisfactory reply, Russia broke off diplomatic relations with Turkey. The congress of Verona (Oct. 1822) virtually ignored the Greek question; the limit of Lord Londonderry's concessions before his suicide (Aug. 12, 1822) was that if the Greeks established a de facto government it would be difficult not to give them belligerent privileges. His successor as British foreign secretary, George Canning, was willing to concede these rights, but he was equally in favour of nonintervention and worked to restore normal Russo-Turkish relations, to which Russia agreed. In response to a request for concrete suggestions made by Francis I of Austria at Czernowitz (Chernovtsy) in Oct. 1823, Alexander proposed in Jan. 1824 that there should be created three Greek principalities, paying annual tribute to Turkey and garrisoned by Turkish troops. but this suggestion was disliked by the powers on the grounds that it opened the way to excessive Russian influence. It had been rejected in advance by the Greeks themselves who in Jan. 1822 had proclaimed the independence of all Greece.

The situation was changed by Sultan Mahmud II's decision to invoke the help of the semi-independent pasha of Egypt, Mohammed Ali. The latter's son, Ibrahim Pasha, landed first in Crete and then in the Morea on Feb. 24, 1825, acting as if he intended to exterminate the Greeks. Russian feeling in favour of independent action began to revive, and Canning began to evolve a plan of joint action with Russia as a better alternative to independent Russian intervention, but agreement was not easily obtained. On Dec. 1, 1825, however, Alexander died and was succeeded by Nicholas I. It was expected that Nicholas would adopt a more forward policy. Canning therefore sent the duke of Wellington to St. Petersburg with the dual purpose of congratulating Nicholas on his accession and paving the way for agreement with Russia.

Russian policy under Nicholas in fact did exhibit new features. Great Britain and Russia agreed under the St. Petersburg protocol of April 4, 1826, to offer mediation in the Greco-Turkish dispute on the basis of constructing a Greek state tributary to the sultan. Nicholas was careful to keep Greek affairs separate from those of the Danubian principalities and Serbia. In April 1826 a Russian ultimatum was presented to Turkey, demanding the evacuation of the principalities and the meeting of a conference to discuss the Bucharest treaty of 1812. The Turks had to agree and, on Oct. 7, 1826, concluded with Russia the convention of Akkerman. This confirmed the treaty of 1812 and stipulated that in Serbia there should be no Muslims in the administration, while in the principalities native boyars were to be appointed *hospodars* (princes).

The European powers were slow to reach agreement on the Greek question. On July 6, 1827, the treaty of London was signed between Great Britain, France and Russia. This repeated the provisions of the St. Petersburg protocol of 1826, but added that if the Turks did not accept mediation consuls would be sent to Greece and that, if an armistice were not agreed, then the fleets of the three powers would blockade the Morea and intercept Turkish and Egyptian supplies. Canning died on Aug. 8, but his policy was continued by Viscount Goderich (formerly F. J. Robinson). The Turks for their part refused mediation, and the admirals blockaded the Morea — an action which led unexpectedly to the battle of Navarino (q.v.), on Oct. 20, 1827. in which the Turkish-Egyptian fleet was destroyed. Meanwhile Turkey had denounced the convention of Akkerman.

The Russo-Persian War of 1826–28. — While Russia was preoccupied in the Balkans, the Persians seized the opportunity of attacking the Russian positions in the Caucasus (July 28, 1826). The Russians now found themselves acting in concert with the British and French in the Aegean, but alone both in relation to the principalities and to Serbia and against the Persians, who moreover had the backing of the British governor-general of India. In spring 1827. Gen. I. F. Paskevich took over command of the Russian Caucasian corps and laid siege to the Armenian city of Yerevan, which the Persians surrendered in October. Unable to resist the Russians, the shah concluded the peace of Turkmanchai on Feb. 22, 1828, ceding the khanates of Yerevan and Nakhichevan. Russia had now turned the Caucasus from the east.

The Settlement of the Balkans. — In European Turkey the battle of Navarino had solved nothing, because the Greeks could not defeat Ibrahim Pasha by themselves. At the London conference of March 12, 1828, it was agreed that the blockade should continue, but Wellington. now prime minister. was surprised when the Russian ambassador. Prince C. A. Lieven. declared that Russia intended to make war, if necessary, in connection with Turkey's repudiation of the Akkerman convention. On April 26, 1828. Russia declared war on Turkey.

Eventually the French plan to send troops to the Morea was accepted. Under the protocol of July 19, 1828, authority was given for the French troops to land. This virtually assured Greece's independence, for they quickly expelled the Egyptians. All that remained was to decide the extent of the new Greek state. The northern frontier was eventually fixed on the Arta-Volos line, and in Feb. 1832 the powers offered the Greek crown to Otho of Bavaria.

Russo-Turkish relations and the political instability of the Ottoman empire still caused concern. A significant event was the Russian reappraisal of the policy to be adopted in the Balkans and near east. The Russian Gen. I. I. Diebitsch in the Balkans had taken Varna in Oct. 1828 and crossed the Balkan range to capture Adrianople on Aug. 20, 1829. but while the military operations were in progress the problem of Russia's policy toward Turkey was laid before a committee of the emperor's leading advisers and Nicholas accepted its view that Russia should now uphold the Ottoman empire, as a weak state constituting no threat to Russia, rather than let it pass into the hands of other powers. In this spirit a peace treaty was concluded at Adrianople on Sept. 14. 1829. The treaty was not onerous for Turkey: the principalities remained under Turkish suzerainty subject to the Russian guarantee; the Akkerman provisions regarding Serbia were confirmed; Russia obtained territorial access to the mouth of the Danube and was also confirmed in the Caucasus in possession of Anapa, Poti and part of the Georgian pashalik of Akhaltsikh. The terms of the treaty of London (1827), moreover, were accepted by Turkey.

The Principalities, 1829–34. — On the peace of Adrianople, Gen. Count P. D. Kiselev was appointed to supervise administration in Moldavia and Walachia. The *hospodars* were required to rule in collaboration each with an assembly of the higher clergy and boyars. Kiselev, whose policy was to build up a basis for Russian influence. did nhat he could to improve the lot of the Rumanian peasants, whom he tried to protect from exploitation by the boyars. At least he succeeded in bringing about an identity of conditions in Moldavia and Walachia, which was to make ultimate unification possible. After the Russo-Turkish convention of Jan. 1834 (part a fresh departure in Russian policy aimed at conciliating Turkey) the Russians evacuated the principalities.

The Treaty of Unkiar Skelessi and the Münchengrätz Agreements. — The pasha of Egypt, Mohammed Ali, had received

nothing for his efforts on the sultan's behalf in Greece. The sultan could reply that the pasha had achieved nothing to merit reward. Accordingly in Oct. 1831 Mohammed Ali declared the sultan heretical and sent the Egyptian army under Ibrahim Pasha to invade Palestine. The Turks were driven back and the Egyptians occupied Syria, defeating the Turkish army in Dec. 1832 at the battle of Konya in Anatolia. It seemed that the Egyptians would occupy Constantinople itself. Nicholas now offered his assistance to the sultan. Mahmud II had appealed for British help in Nov. 1832, but Lord Palmerston, the British foreign secretary, preoccupied with problems in western Europe, could not respond. The Turks therefore had to accept Russia's offer. In Feb. 1833 the Russian fleet appeared in the Bosporus and on April 3 Russian troops disembarked on the Anatolian shore. Turkey was saved from collapse, but had to surrender Adana to Ibrahim Pasha and the pashaliks of Syria and Tarsus for the lifetime of Mohammed Ali under the convention of Kutahya (April 8, 1833). Before the Russian forces were withdrawn an eight-year treaty of alliance was concluded between Russia and Turkey at Unkiar Skelessi (Hunkiar Iskelesi) on July 8, 1833. In a secret article it was agreed that, in case of need, Turkey's help to Russia should be limited to closing the Dardanelles to all non-Russian vessels of war.

Nicholas, aware that this arrangement with Turkey was open to misinterpretation, took steps to allay the fears of Austria. When he met the Austrian emperor Francis I at Munchengratz (Sept. 1833). he made a secret agreement with him to maintain the existing dynasty in Turkey and to prevent Mohammed Ali from acquiring any portion of European Turkey. His object was to retain for himself an exclusive right of intervention at the Straits. Nicholas and Francis also concluded an agreement, to which Prussia subsequently adhered, for the maintenance of the status *quo* in central Europe. Russia was thus given security both in the south and in the west.

Political Tension in the 1830s.—Palmerston was much dissatisfied by the treaty of Unkiar Skelessi and especially by its secret article, which he took to be a provision for the overthrow of the principle stated in the Chanak treaty of 1809. His reply was to put the British Mediterranean fleet in a state of readiness. In his instruction of March 1834 orders were issued that the fleet might be summoned to Constantinople if the sultan requested aid to ward off a Russian attack, though in no circumstances was the sultan to be informed of this decision. When Wellington in the Conservative administration of 1834–35 discovered the existence of this order he promptly canceled it as being too dangerous an instrument to be left in an ambassador's hands, but it was reissued when Palmerston came back into office. Palmerston moreover formed the quadruple alliance of April 22, 1834, with France, Spain and Portugal to bring stability to the Iberian peninsula and so to leave Great Britain free for the problems of the Aegean and the Levant.

Russia's position in Turkey under the treaty of Unkiar Skelessi was not a strong one, because the Turks might fail to renew it on its expiry. In 1838 a plan to reinforce the Black Sea fleet with ships from the Baltic was considered, but the vice-chancellor, Count K. V. Nesselrode, thought that the passage of Russian ships through the Straits would serve as a precedent for Great Britain and France to demand similar privileges. Nicholas accepted this analysis.

A crisis was eventually produced by the sultan Mahmud, who was determined to punish Mohammed Ali. In April 1839 the Ottoman army invaded Syria only to be decisively defeated at the battle of Nizip on June 24. The Turkish admiral, the kapitan-pasha Ahmed, deserted to the Egyptians and the sultan himself died on July 1, 1839. Palmerston wished to coerce Mohammed Ali in cooperation with France and, if necessary, to compel the Russians to withdraw if they intervened in Constantinople, but the French cabinet would have no part in coercing Mohammed Ali, whom it regarded as a *protégé*. In the meantime Russia formulated a new plan. In Sept. 1839 Count F. I. Brunnow was sent to London with proposals which amounted to an abandonment of the treaty of Unkiar Skelessi: Turkey was to be given a general guarantee and the Straits to be closed against all powers. Palmerston was at first suspicious of the Russian move, but in Jan. 1840 he proposed that Great Britain, France, Austria, Russia and Prussia should send troops to Turkey against Mohammed Ali, if the sultan requested them, and that the Straits should be closed to foreign warships. France, however, refused to agree. The other powers therefore, in London, on July 15, 1840, signed an act for the pacification of the Levant, without French participation. Mohammed Ali was given ten days in which to submit: if he did so, he would receive the hereditary pashalik of Egypt and the administration of southern Syria and Acre for life; if not, he would be coerced and confined to Egypt. There followed a period of acute Anglo-French tension. In the end Louis Philippe decided against war, and Adolphe Thiers, the protagonist of support for Mohammed Ali, was compelled to resign (Oct. 1840).

Mohammed Ali refused to accept the conditions of the powers. An allied expedition under Sir Charles Napier was sent to Syria. Beirut fell on Oct. 10 and Acre on Nov. 3, 1840. On Feb. 3, 1841, the sultan, who had previously declared Mohammed Ali deposed, signed a firman appointing him hereditary viceroy of Egypt. This went some way toward satisfying the demands of French policy.

The Straits Convention of 1841.—Under the London Straits convention of July 15, 1841, France, Austria, Great Britain, Prussia and Russia agreed with the Porte that it should be forbidden for all time for vessels of war belonging to foreign powers to enter the Dardanelles and Bosporus in time of peace, with the exception of light vessels on embassy service. This meant that Russia gave up the exclusive right granted under the treaty of Unkiar Skelessi. In future no one power was to seek exclusive influence in the Ottoman empire. In 1843 Nicholas told the Austrian diplomat, Count K. L. von Ficquelmont, in Warsaw: "I shall never cross the Danube and everything between this river and the Adriatic ought to be yours." In June 1844, in conversations with Sir Robert Peel and Lord Aberdeen at Windsor, he declared his intention of acting in concert with the powers. In Dec. 1845, during a visit to Vienna, he repeated his desire to uphold the Ottoman empire and disclaimed any intention of seizing Constantinople.

The Eastern Question in 1848–49.—During the European revolutionary crisis of 1848–49 Nicholas proved as good as his word. When revolutions broke out in Vienna and in Berlin he took precautions to prevent the extension of revolutionary activity to the Danubian principalities. Troubles in Jassy and in Bucharest were curbed in Sept. 1848 by a Turkish occupation of which Russia approved. A Russo-Turkish convention of May 1849 modified the constitutions of the principalities and provided for a joint occupation. The Russians did not withdraw until 1851.

The Crimean War (1854–56).—The Crimean War (*q.v.*) may here be briefly stated to have resulted from the challenge offered by France to the principle implied in the Straits convention of 1841 that no one power should have exclusive influence in Ottoman affairs. The issue which the emperor Napoleon III chose was the question of the guardianship of the Holy Places in Palestine. Nicholas I took up this challenge and attempted to assert Russia's rights under the treaties of Kuchuk-Kainarji (1774) and Adrianople (1829). Turkish refusal led to a Russian occupation of the principalities in 1853 and then to a Franco-British ultimatum for their evacuation. Russia did subsequently evacuate the principalities as a result of an Austrian demand, but France and Great Britain, having declared war and being committed in the eyes of public opinion to achieving a great success, invaded the Crimea. Hostilities did not end until Jan. 1856, when the new Russian emperor Alexander II accepted an Austrian ultimatum that peace must be made.

The Treaty of Paris, 1856.—The peace conference met in Paris on Feb. 25, 1856, and the treaty of peace was signed on March 30. Russia surrendered part of southern Bessarabia, thus losing control of the mouth of the Danube, the navigation of which was placed under a commission of the riparian states. The Straits convention of 1841 was re-enacted, but with the provision that the Black sea should be neutralized: Russia and Turkey were

permitted to maintain only insignificant naval forces on the Black sea (the Turks or their allies, however, could in fact if need arose easily introduce warships from the Aegean). Russian claims to a protectorate over the Christian subjects of the Porte were set aside in favour of a general European guarantee, while the Danubian principalities received an international assurance of their status.

The treaty of Paris had important consequences for Europe as a whole. It had been the policy of the Austrian foreign minister, K. F. von Buol-Schauenstein, that the general support which Austria had received from Russia in central Europe and which had indeed restored the Habsburg empire in 1849, when Russia had intervened in Hungary, should be replaced by a British and French guarantee of Austrian territory. In fact, all that Austria obtained was an alliance with Great Britain and France on April 15, 1856, for the maintenance of the territorial integrity of the Turkish empire. Thus Austria was left isolated in Europe, which made possible the Franco-Piedmontese successes in Italy in 1859 and the expulsion of Austria from the Germanic confederation by Prussia in 1866. So weakened was Austria that the dynasty was obliged in 1867 to come to terms with the Magyars of Hungary, who achieved administrative autonomy within the Habsburg system. The South Slav question became the major issue of Austro-Hungarian policy. The Magyars were not in favour of annexations at the expense of Turkey which would increase the number of Slavs within the territories of the crown of St. Stephen. It was imperative that the *status quo* should be maintained in the Balkans.

Russia likewise was not anxious to disturb the Balkans after 1856. Alexander II had decided that reform must be carried out in Russia, which led in 1861 to the decree emancipating the peasants, a measure that it would take many years to execute. Moreover, in 1863, Russia's position in Europe was severely shaken by the Polish insurrection.

The Eastern Question, 1856–70.—Between the treaty of Paris and the outbreak of the Franco-Prussian War (1870) important developments took place in southeastern Europe. In Bulgaria national consciousness had grown sufficiently for the Turkish government to create a Bulgarian exarchate (1870–72). In 1859 Walachia and Moldavia joined together to form the new state of Rumania; in 1866 the elected prince, Alexandru Cuza, abdicated and was succeeded by Charles of Hohenzollern-Sigmaringen (Carol I). The principalities were thus virtually detached from the Ottoman empire. In 1856 Serbia obtained a European instead of a purely Russian guarantee. After the Turkish garrison commander had bombarded Belgrade (June 1862), the powers compelled the Turks to evacuate two Serbian fortresses and, in 1867, to remove their troops from the principality.

In Austria-Hungary, the Magyars were alarmed by the growth of South Slav nationalism. The Serbian secret society, the Omladina (founded 1866), gave currency to the idea that Prince Milan Obrenovich was "the uncrowned king of Serbia." The Croats, subjects of the Hungarian crown who enjoyed a measure of autonomy from 1868, were by no means favourable to closer association with Belgrade, but extremists among them began to work for a Greater Croatia.

Russia was active in the Balkans during these years, though military weakness prevented a forward policy; but the defeat of France by Prussia in 1870 altered the balance of power in Europe, and Russia felt strong enough to tear up the Black sea clauses of the treaty of 1856. In Nov. 1870, Prince A. M. Gorchakov, the chancellor, declared that his government no longer considered itself bound by the limitation clauses. The powers gave their formal assent in London in March 1871. In 1874, when universal conscription was introduced, Russia could once more consider armed action. There were two strands of thought within the Russian ministry of foreign affairs: on the one hand the Pan-Slavist and Slavophil elements were strongest in the Asiatic department, which dealt with Balkan affairs and in which Count N. P. Ignatiev had considerable influence; on the other, Gorchakov and his associates preferred to work in concert with the other European powers. Alexander II, with whom the final decision rested, generally supported Gorchakov.

The First Dreikaiserbund, 1873.—Austria, Prussia and Russia each saw the danger of conflict over disputes in the Balkans. The German chancellor, Bismarck, wanted a period of peace in which to organize the new German empire. Russia was equally willing to end tension with Austria-Hungary. Thus a series of agreements were reached providing for mutual assistance and concerted action, which can be said to have created the first *Dreikaiserbund,* or Three Emperors' alliance. of Oct. 22, 1873. The *Dreikaiserbund* was in effect an agreement to avoid war in the Balkans. Subjected to considerable strain during the Franco-German tension of April–May 1875, the alliance was put to the test when insurrection broke out in Bosnia-Hercegovina (*q.v.*) in July.

The European powers attempted to prevent trouble from spreading in the Balkans. The Porte accepted a six-power consular commission to assist in reaching a settlement, but this merely provided a clearing house for information. Proposals by Count Gyula Andrássy, the Austro-Hungarian foreign minister, for the better government of Bosnia-Hercegovina (the "Andrássy note") were accepted in Feb. 1876 by the Porte, which offered an amnesty to the rebels. Russian statesmen were ready to make the Andrássy note a success, but a solution was prevented by the rebels' own attitude. In April their leaders drew up a series of stiff demands which the Porte refused to accept. In May 1876 the visit of Alexander II and Gorchakov to Berlin produced the "Berlin memorandum," which declared that Austria, Russia and Germany required a two months' armistice and that, if proposals of reform failed, they would concert measures. The British cabinet refused to be associated with this measure, lest it become a party to dismembering the Ottoman empire, and the British fleet was ordered to Besika bay, where it arrived on May 26. The British attitude was bellicose,,but Benjamin Disraeli sought to tone down its severity by conducting conversations with the Russian ambassador, Count P. A. Shuvalov, in June. Disraeli's policy was one of wait-and-see, which would leave the Turks and the Christians to fight out their differences.

The situation in the Balkans was out of control. In May 1876 the Bulgars rose in revolt, whereupon Muslim irregulars, the *bashi-bazouks,* took savage reprisals. The Berlin memorandum was due for presentation to the Porte on May 30, 1876, but on May 29 Sultan Abdul-Aziz was deposed by a *coup d'état* and replaced by a nonentity, Murad V. The real ruler of Turkey was Midhat Pasha, who formulated a scheme of reform for the empire. Indignation at the massacres in Bulgaria forced Milan of Serbia to deliver an ultimatum to the Porte, which was followed by a declaration of war on July 1. Montenegro declared war on Turkey on July 2. When the news from Bulgaria arrived in Great Britain, Disraeli was inclined to play down Turkish savagery, but public opinion reacted sharply against Conservative policy. W. E. Gladstone issued his celebrated pamphlet, *The Bulgarian Horrors and the Question of the Orient.*

Alexander II came under pressure from Russian public opinion to intervene in the Balkans, but was inclined to collaboration with Austria. Alexander and Gorchakov met the Austrian emperor Francis Joseph and Andrássy at Reichstadt on July 8, and on July 13 drew up the secret Reichstadt convention. Both parties agreed not to intervene for the moment, but, if the Turks won the war, to concert measures to prevent excesses against the Christians. The *status quo* was to be maintained in Serbia, Montenegro was to be granted full independence and reforms were to be carried* out in Bosnia-Hercegovina on the basis of the Andrassy note. If Turkey were to lose the war, no large Slav state was to be established. Austria-Hungary was to have Bosnia-Hercegovina, while Russia was to obtain southern Bessarabia and Batum in Georgia. In the event of a complete Turkish collapse, Constantinople was to become a free city, Thessaly and parts of Epirus to go to Greece, and Bulgaria and Rumelia to be independent.

The situation became more difficult when the war went against Serbia. In Aug. 1876 Milan asked for the good offices of Russia to bring about an armistice. On Sept. 1, 1876, the Serbs were severely defeated near Aleksinac and Serbia lay at the mercy of the

Turks. Alexander II was then at the Crimean palace of Livadia, where, exposed to the Pan-Slav influences, he began to put pressure on both Austria-Hungary and Germany for action in the Balkan question. On Oct. 30, 1876, Russia took the decisive step of demanding that Turkey grant Serbia an armistice, which Turkey accepted. Then a British proposal for a conference in Constantinople was accepted by the powers. In his Guildhall speech of Nov. 9, 1876, however, Disraeli emphasized Great Britain's interest in the Eastern question in a manner that seemed to threaten war. Returning from Livadia, Alexander II, unaware of Disraeli's speech, himself made a public address in Moscow on Nov. 10, in which he spoke of Russia's "sacred mission." So rare was it for an emperor to make a political speech that public opinion in Russia considered that Alexander had made a retort to Disraeli. Committed in the eyes of public opinion, Alexander gave orders for the mobilization of the army.

There was some modification of the British attitude. Lord Salisbury, nominated to be British representative in Constantinople, was at first instructed to offer only mediation, but further instructions did not rule out the possibility of coercing the Turks. Less Turcophil than Disraeli, Salisbury found it easy to reach an agreement with the Russian ambassador, Count N. P. Ignatiev, during their discussions in Dec. 1876. Ignatiev accepted Salisbury's insistence that there should be no "Big Bulgaria" while it was agreed that in Serbia and Montenegro the *status* quo should be maintained and that in Bosnia-Hercegovina an international commission should be set up. The six powers' proposals of Dec. 22 met with opposition from the Turks. Midhat Pasha declared his intention of granting a new constitution under which Muslim and Christian would enjoy equality. but insisted on maintaining centralized control. The powers modified their demands, but on Jan. 20, 1877, the Turks rejected them and the representatives of the poners left Constantinople. The new sultan. Abdul-Hamid II, dismissed and deported Midhat Pasha on Feb. 5, and issued a *hatti-sherif* promising reforms based on the conference's proposals. The British government was willing to give him a chance to prove his sincerity, but the situation created difficulties for Russia. where the financial strain of keeping a large number of troops on a war footing was heavy. At the end of February it was decided that Russia should demand the implementation of the conference's proposals. whether alone or in concert with the other po ers. Ignatiev toured the western capitals, but his draft proposals were not accepted. At length agreement was reached on the "London protocol" of March 31, which demanded that the Porte put its army on a peace footing and, in the event of failure to comply, announced that the powers would themselves consider the condition of the Christian population of the Balkans. On April 9 the Porte rejected this demand and on April 24 Russia declared war.

Russia went to war in strict understanding with Austria-Hungary, who in Jan. 1877 had agreed to observe a benevolent neutrality and not to invoke the treaty of 1856 with Great Britain and France; Austria-Hungary moreover might occupy Bosnia-Hercegovina, while Russia was to confine military action to Rumania, Bulgaria and Serbia; and Montenegro was not to be entered by either party. In March the limits of the respective annexations were defined: Austria-Hungary was to take Bosnia-Hercegovina, except for the sanjak of Novi Pazar (between Serbia and Montenegro), while Russia was to recover southern Bessarabia. If the Ottoman empire were to break up, the two powers undertook to concert. No large Slav state was to be created, but Bulgaria, Rumelia and Albania were to have their independence, while Thessaly, Epirus and Crete were to go to Greece. Constantinople was to be a free city.

The Russian plan was one of rapid advance. but the Turks were not badly prepared. In June the Russian army crossed the Danube, but was held up at Plevna by the forces of Osman Pasha. Meanwhile a British note of May 6, 1877, had warned Russia that Great Britain could not stand aside indefinitely. In the Russian reply of May 30. 1877. it was proposed that Bulgaria north of the Balkans should be autonomous; that Bulgaria south of the Balkans should have a just administration; that Bosnia-Hercegovina was to have satisfactory institutions; that Russia was to have southern Bessarabia and Batum; and that Rumania was to be independent or have the northern Dobruja. Above all it was emphasized that Russia would not oppose Austro-Hungary in Bosnia-Hercegovina. The Russian government merely repeated in this note its arrangements with Austria-Hungary. A different atmosphere prevailed in the Russian army, where the generals were determined to make the most of the situation and create a "big Bulgaria" north and south of the Balkans. In July the British government warned Russia that it would consider action if Constantinople were occupied. The key to the situation was the Turkish defense of Plevna, which fell on Dec. 10, 1877. On Jan. 20, 1878, Adrianople had fallen. The armistice of Jan. 31 did something to relieve the tension, but on Feb. 13 the British fleet entered the Dardanelles, without permission of the Porte, to protect British life and property in Constantinople. Finally on Feb. 19 Russia and Great Britain agreed that Russia would occupy neither Constantinople nor Gallipoli and that no British troops would be landed on the European shore of the Straits.

On March 3, 1878, the treaty of San Stefano (*q.v.*) was signed between Russia and Turkey. Its two most debatable points were (1) the creation of a "Big Bulgaria" north and south of the Balkan range and extending into Macedonia; and (2) the expansion of Montenegro and Serbia, by which they became contiguous. The opposition of the powers, however, compelled Russia to revert to the spirit of the previous agreements with Austria-Hungary and Great Britain. At the congress of Berlin (*q.v.*) Russia accepted the fact that the treaty of San Stefano mas impossible to execute and agreed to a small Bulgaria north of the Balkan range, while Eastern Rumelia south of the range was to be a semi-autonomous province under a Christian governor. Austria-Hungary occupied Bosnia-Hercegovina and obtained the right to intervene in the sanjak of Novi Pazar. Russia. however. obtained southern Bessarabia, in return for which Rumania received part of the Dobruja.

Russia had good reason to be dissatisfied with the treaty of Berlin and sought an entente with Germany in order to have a stronger position in the interpretation of its terms, but Bismarck preferred to conclude, on Oct. 7, 1879, an alliance with Austria-Hungary.

The Second Dreikaiserbund (1881).—Germany's alliance with Austria-Hungary was valuable to Bismarck as preventing the recreation of the "Crimean coalition" of Austria-Hungary, France and Great Britain, but it presented him with problems in the near east. He did not want to alienate Russia merely to please Austria. Luckily for him, Russian policy aimed at avoiding a clash. Alexander II and his successor, Alexander III, together with N. K. Giers, Gorchakov's successor as foreign minister, believed that an association with Germany was a wiser course than opposition, which could only commit Bismarck more closely to Austria-Hungary. On June 18. 1881, was concluded the second *Dreikaiserbund*, an arrangement for mutual assistance and concert which for Russia was an instrument for avoiding conflict in the near east. Austria-Hungary. however, finding little profit in the *Dreikaisevbund*, went on to conclude a secret treaty of mutual assistance with Milan of Serbia (June 28, 1881), which gave Vienna virtual control over Serbian foreign policy. A similar treaty was concluded with Rumania in Oct. 1883; but the Rumanians insisted that Germany should be a party to this treaty. Bismarck's adherence to this treaty meant that Germany was henceforth closely identified with Austro-Hungarian policy in the Balkans. Even so. the *Dreikaiserbund* was renewed for a further three years in 1884. The Bulgarian crisis of 1885–87, however, broke it up.

The Middle Eastern Question.—The Russo-British conflict over the Straits was complicated by Russian expansion in central Asia. Russia had taken Samarkand and subdued Bukhara in 1868, occupied Rhiva in 1873 and taken Kokand in 1876. As long as it was directed toward Samarkand, this Russian penetration did not threaten British interests in India, because the Hindu Kush presented an insurmountable obstacle; but penetration in the direction of Afghanistan did constitute a danger. The Trans-Caspian railway had reached Ashkhabad in 1885 and was extended

through Merv to Chardzhou on the Amu-Darya (Oxus) in 1886. The Russian position in the middle east could henceforth be quickly reinforced from the Caucasian command. Great Britain had to consider how to protect the Afghan city of Herat, which was thought vital to the defense of India. The current view was that, if war broke out with Russia in the middle east, British vessels would have to force a passage at the Straits to attack Russia in the Black sea and the Caucasus. When the Russians defeated the Afghan army at Panjdeh on March 30, 1885, Great Britain prepared for war. The crisis was solved amicably mainly because German influence in the near east was thrown on to Russia's side. Russia's own willingness to halt in central Asia at that moment was no doubt caused by preoccupation with events in Bulgaria.

The Union of the Two Bulgarias and the Reinsurance Treaty, 1885–89.—On Sept. 18, 1885, as a result of a *coup d'état* at Plovdiv (Philippopolis) Bulgaria and Eastern Rumelia were united. Though Russia had supported the "Big Bulgaria" policy in 1878 Alexander III did not look with favour on the new Bulgarian state, which was by no means subservient to Russian interests. Russia therefore proposed a conference of the signatory powers of the treaty of Berlin. The Serbs, however, were dissatisfied with a situation from which they had obtained little and on Nov. 13, 1885, King Milan, assured of Austro-Hungarian support, invaded Bulgaria—only to be defeated at the battle of Slivnitsa on Nov. 17–19. This led in its turn to a Bulgarian invasion of Serbia. The struggle was ended by the peace of Bucharest on March 3, 1886. Russia obtained some satisfaction from this episode, because Bismarck had informed the Austro-Hungarian foreign minister, G. S. Kálnoky, in Dec. 1885 that there could be no modification of the *status quo* in the Balkans without the consent of the powers and thus refused to support unilateral action by Austria-Hungary. Russia had less success in bringing the Bulgars to heel. Despite the abdication of Prince Alexander (*q.v.*) of Battenberg in Sept. 1886, a Russian mission under N. V. Kaulbars failed to secure Bulgarian acceptance of Russian control, and in November Kaulbars and the Russian consuls were withdrawn from Bulgaria. This step seemed to be the prelude to Russian armed action in the Balkans.

Bismarck, not willing to support Austria-Hungary openly against Russia, encouraged Great Britain to do so instead. Italy, hostile to France on account of Tunisia and (since May 20, 1852) a member of the Austro-German alliance. entered into an agreement with Great Britain in Feb. 1887 for the maintenance of the *status* quo in the Mediterranean, to which Austria-Hungary adhered in March. This accord was enlarged to cover the Straits in December. The so-called Mediterranean agreements of 1887 thus gave Austria-Hungary a powerful accretion of strength in the near east. Meanwhile Alexander III had decided that the *Dreikaiserbund* could not be renewed and that Russia could associate only with Germany. On June 18, 1887, was concluded the "Reinsurance treaty" by which Bismarck undertook to support Russian policy in Bulgaria and at the Straits; Russia was to remain neutral unless Germany attacked France, while Germany was to remain neutral unless Russia attacked Austria-Hungary.

In 1887 Bismarck was in a very difficult position. On the one hand he was required to support Russia at the Straits, on the other he was associated with Austria-Hungary and Italy, whose agreements with Great Britain were designed to frustrate Russian policy. If this situation had been generally known by the contending powers, Bismarck's system might well have fallen to the ground. Indeed, Russia had few illusions about the Reinsurance treaty, which was rather a guarantee against active German hostility than an instrument of policy. Visiting Berlin in Nov 1887, Alexander was confronted by Bismarck with a series of demands amounting almost to an ultimatum to abandon warlike intentions in the Balkans. In December the Russian government informed Austria-Hungary of its peaceful intentions in the Balkans. To make this situation palatable, Russia was allowed in Feb. 1888 to demand that the Porte should declare illegal the election of Ferdinand of Saxe-Coburg as prince of Bulgaria. The sultan agreed to this demand, but took no action to depose Ferdinand. The crisis had nevertheless been so acute that Bismarck, in order to quieten demands for a preventive war against Russia, had published on Feb. 3, 1888. the text of the Austro-German alliance of 1879 in order to show that Germany's commitments were purely defensive.

Thereafter Russia had little faith in the value of German support in the near east. Alexander entered into negotiations for the renewal of the Reinsurance treaty in Dec. 1889. but without serious conviction. After the fall of Bismarck in March 1890, Alexander III and Giers tried to get Germany's support for Russian policy in Bulgaria and at the Straits, but Germany was unwilling to give written assurances.

Changes in Russian Policy in the 1890s.—At the beginning of the 1890s Russian attention began to turn away from the near and middle east to Siberia and the far east. Capital was needed for development, and from 1888 Russia was already borrowing heavily in France. In May 1891 a beginning was made to the construction of the Trans-Siberian railway. In Aug. 1891 Russia concluded an *entente* with France, enlarged into a military alliance which came into force in Jan. 1894. The *entente* in general strengthened the diplomatic position both of Russia and of France. Secured by the French Mediterranean squadron from the risk of British surprise action at the Straits, Russia could concentrate on the far east (the opening of the Chinese-Japanese war in July 1894 was an embarrassment, because Russian influence could not be effective in China until the Trans-Siberian railway was completed). For the time being, however, Russia could not afford to excite suspicion in the near east. By 1895 Great Britain had allowed the Mediterranean agreements of 1887 to lapse, while Germany was ready to concentrate on the colonial field.

The Armenian Question and Crete, 1894–97.—In 1894 the Turkish persecution of the Armenians gave cause for international anxiety. Massacres in Erzurum and Diyarbakir in Nov. 1895 excited fears lest Russia should intervene at the Straits in retaliation. Austria-Hungary was especially anxious that all the powers should act in concert, to which France and Russia refused to agree. In Dec. 1895, however, when the Russian foreign minister, Prince A. B. Lobanov-Rostovski, asked what the French attitude would be if Russia intervened in Turkey, France replied that the matter was of too small importance for France to support Russia. Russia was therefore disposed to caution.

After an outbreak of violence in Canea in May 1896, the powers presented a demand to the Porte for reform on the island of Crete. The sultan appointed a Christian governor for Crete on June 28 and then made proposals for reform, but the Cretan Greeks refused to submit, and the powers had to put pressure on mainland Greece to stop shipment of arms to the insurgents. On Aug. 25 the ambassadorial conference in Constantinople proposed autonomy for Crete. Next day, however, Armenian revolutionaries tried to seize the Ottoman bank in Constantinople—an attempt that provoked the massacre of 6,000 Armenians. whereupon the powers made fresh representations. Because union with Greece, which the Cretan Greeks demanded, would serve as a precedent for the partition of the Ottoman empire in Europe, the powers finally decided to impose their own solution and landed marines at Canea in Feb. 1897. In March 1897 the blockade of Greece was announced and Cretan autonomy under the sultan was proclaimed.

Under pressure of public resentment at this solution the mainland Greek government ordered its army to attack the Turks in the north on April 17. 1897. The Turkish army, however, had undergone reorganization under the German general, Colmar von der Goltz. The Greek army was thrown back and the Turks poured into Thessaly. The Greek government had to renounce Crete and ask for the good offices of the powers to produce a settlement with Turkey, which was achieved in the peace treaty of Dec. 4, 1897.

The eastern crisis of 1895–97 caused the powers to reconsider their attitudes. Lord Salisbury would have been willing to assign the Straits to Russia in return for Russian recognition of the British position in Egypt (occupied since 1882), but the emperor Nicholas II rejected this course on the grounds that it would be the first step in the break-up of the Ottoman empire, the con-

sequences of which Russia was not strong enough to face. After Lobanov-Rostovski's death in Aug. 1896 there was a reconsideration of Russian policy. In November the Russian ambassador in Constantinople. A. I. Nelidov, proposed that Russia should be prepared to seize the Straits and in Jan. 1897 the emperor actually approved the plan of operations, but when the French foreign minister, Gabriel Hanotaux, refused to support the project Russia tried a different course of action. Austria-Hungary, perturbed by the British withdrawal of interest at the Straits. turned to Germany for help in the Balkans, but William II and his advisers suggested conciliation with Russia. Rather than rely on the uncertain aid of Italy alone, Austria-Hungary therefore sought a settlement with Russia. In April 1897 Francis Joseph and his foreign minister, Count Agenor Goluchowski, visited St. Petersburg. Russia and Austria-Hungary then agreed to maintain the *status quo* in the Balkans for ten years. This agreement permitted Russia to concentrate on the far east in order to combat Japanese influence in Korea and Manchuria. It was not until 1908 that Russia again considered forward action in the near east.

The Annexation of Bosnia-Hercegovina.— During 1902 a fresh revolutionary situation arose in European Turkey. Macedonian and Bulgarian guerrilla bands took up arms against the Turks. and the Austro-Hungarian government began to fear that Russia might intervene in spite of the agreement of 1897. Russia, however, had to consider the situation in the far east, on which as yet no final decision had been taken. The Russian foreign minister, Count V. N. Lamsdorff, met Goluchowski in Vienna in Dec. 1902 and declared his readiness to co-operate with Austria-Hungary in pressing the Porte to undertake reforms. Germany, France. Great Britain and Italy approved of this policy, and Abdul-Hamid accepted the proposals made by the powers in Feb. 1903, but the situation deteriorated. In June pro-Russian revolutionaries assassinated the pro-Austrian ruler of Serbia, Alexander Obrenovich, and elected the head of the rival house, Peter Karageorgevich. Nevertheless. Austria-Hungary and Russia continued to co-operate for the maintenance of the *status quo*. On July 13, 1903, a joint *dkmarche* was made in Sofia to prevent the Bulgarian government from giving aid to the Macedonian revolutionaries. In Oct. 1904 Francis Joseph and Nicholas II conferred in the Austrian Alps at Murzsteg and agreed to present a program of reform to the Porte. When the Russo-Japanese War broke out in Feb. 1904 Russia was even more disposed not to exacerbate the situation and therefore in Oct. 1904 signed a fresh accord with Austria-Hungary for the maintenance of the *status quo* in the Balkans. The war with Japan went badly, and Russia was disorganized by internal revolution in 1905. It was therefore in Russia's interest to-play down difficulties in Europe.

The re-entry of Russia into Balkan politics depended upon the diplomatic settlements in the far and middle east. The new Russian foreign minister, A. P. Izvolski, decided that Russia's differences with Japan and Great Britain must be settled. Compromises were reached with Japan by the convention of July 30, 1907, which divided Manchuria into fields of influence, and with Great Britain by the convention of Aug. 31, 1907, which provided for the maintenance of the *status quo* in Tibet, for the recognition of Afghanistan as being outside the Russian sphere of influence and for the division of Persia into three spheres, Russian, Persian and British. With these successes to his credit, Izvolski attempted to apply the same principles of agreement to the Balkans. In Aug. 1907 he conferred with the Austro-Hungarian foreign minister, A. Lexa von Aehrenthal, in Vienna on possible joint action, whereby Austria-Hungary would annex Bosnia-Hercegovina and Russian warships would have passage through the Straits. Nothing was decided, and at a meeting of the Russian council of ministers in Feb. 1908 Izvolski was warned that Russia would not undertake a forward policy.

In July 1908 the Young Turk revolution broke out in Turkey and a constitution was proclaimed. For Austria-Hungary this meant that the Slavs of Bosnia-Hercegovina under Austrian occupation would henceforth have a forum in which to express their grievances. Aehrenthal therefore thought that the time had come for Austria-Hungary to annex Bosnia-Hercegovina in full sovereignty. Accordingly Izvolski, who had already sent an *aide-mémoire* to Aehrenthal on their conversation in the previous year, was invited for further conversations. and the two ministers met at Buchlau (Buchlovice) in Moravia. By a verbal arrangement of Sept. 15–16, Austria-Hungary was to annex Bosnia-Hercegovina and Russia was to have the Straits opened Izvolski, however, had not yet consulted the other countries interested in the Straits. In fact, there was no backing for him either from France or from Great Britain.

In the meantime, on Oct. 6, Aehrenthal announced that Bosnia-Hercegovina would be annexed. Izvolski was furious that Austria-Hungary should have thus stolen a march on him. He had no formal evidence that an agreement had been reached with Austria, and now that Austria-Hungary had acted unilaterally he could scarcely reveal to the Serbs, who were equally outraged by the annexation, that he was prepared to betray their interests. On Feb. 26, 1909, however, Turkey formally recognized the annexation, and on March 14 Germany intervened to invite Russia to agree to the face-saving device, by which Austria-Hungary was to invite international recognition of the annexation provided that Russia promised assent beforehand. In this way it would be possible to avoid giving Russia public humiliation. On March 21 Prince Bernard von Bülow, the German chancellor, instructed the German ambassador in St. Petersburg, F. von Pourtalès, to inform Izvolski that Germany expected an answer—Yes or No. In other words. Russia was informed that Austria-Hungary could invoke the alliance with Germany. Russia submitted, with bad grace.

The Bosnian crisis was of great importance. Germany had taken the decisive step of underwriting Austro-Hungarian policy in the Balkans, a decision which Bismarck had sought to avoid. In March 1909 Serbia promised to follow a good-neighbour policy toward Austria-Hungary but in fact decided to increase propaganda among the Slavs of the Austro-Hungarian empire. The Russians were determined never again to endure humiliation in the Balkans and began to devise methods of retrieving their position. On Oct. 24, 1909, an agreement mas made between Russia and Italy at Racconigi, near Turin, by which the two powers undertook to support the principle of nationality in the Balkans. Italy recognizing Russia's special position at the Straits, while Russia would support Italy's claims on Tripoli and Cyrenaica. the last remaining dominions of Turkey in Africa. Austria-Hungary soon saw that the annexation of Bosnia-Hercegovina had been a mistake: the addition of 2,000.000 Slavs to the Habsburg empire had not solved but enlarged the South Slav question. There was a growing feeling in Austria-Hungary especially in military circles that the integrity of empire was in danger. Thus in 1908–09 there had been created the situation in the Balkans which brought about World War I (*q.v.*).

EASTERN REGION, GHANA, lies in the southeast part of the republic fronting the Gulf of Guinea, being bounded eastward chiefly by the Volta river. Pop. (1960) 1,579,903. Area 8,750 sq.mi. Its dominant features are: (1) the Akwapim ranges of folded Pre-Cambrian quartzites, phyllites, shales and sandstones trending northeast from Accra to the Volta gorge at Ajena; (2) transverse to these ranges, the Kmahu plateau of Voltaian sandstones across a saddle at Koforidua; (3) a range of Pre-Cambrian metamorphics between Kibi and the Kwahu plateau. These highlands (1,000–2,500 ft.) are surrounded southward by the Accra plains, mostly of ancient schists and gneisses, northward by the Afram plains of Voltaian sandstones and below the Kwahu scarp by the Densu and Birim river basins, floored by Pre-Cambrian crystalline and igneous rocks.

Except in the drier Afram and Accra plains, where savanna and scrub occur, the predominant vegetation under a well-distributed annual rainfall exceeding 45 in. is moist semideciduous forest ideally suited to cocoa, oil palm and local staples (yams, plantains, cassava, maize). The forest soils are chiefly loamy, but along the coast ironstone laterites studded with anthills are commoner.

Although there is evidence of earlier habitation, the ancestors of the modern inhabitants appear to have arrived between the 11th and 16th centuries in several distinct ethnic groups. Much of the region's history before the 20th century turns on the internal relations of these groups and their contacts with European powers who established coastal trading posts. In 1879 cocoa was introduced from the Spanish island of Fernando Poo and soon became the chief export.

The region, whose population density is the highest in Ghana, has as its largest town Accra (*q.v.*), the capital of the country from 1876 (pop., Accra municipality [1960] 388,231). Other towns are Koforidua, the regional capital (pop. [1960] 28,000), Nsawam, Asamankese, Teshi, Achiase, Akwatia, Suhum, New Tafo and Nkawkaw. There are eight administrative districts with headquarters at Anum, Mpraeso, Kibi, Koforidua, Asamankese, Oda, Ada and Accra.

Cocoa is the chief product. The Accra plains, comparatively free from tsetse, support numerous beef cattle. Fishing takes place along the coast and in the creeks of the lower Volta. Akwatia in the Birim basin is Ghana's leading diamond-producing centre. There are bauxite deposits on the Kwahu plateau and the range near Kibi and stone is quarried in the Accra plains. Most manufacturing industry is in Accra and Tema, but matches are made at Kade, in the heart of the timber area. Accra has a roadstead port and 17 mi. E. at Tema (pop. 15,000) a new port was opened in 1961. The Volta dam at Akosombo was designed to supply power to an aluminum smelter at Tema and irrigation to the Accra plains. Railways link Accra and Tema with Kumasi and Sekondi-Takoradi, and there is a good road network. Accra has an international airport and airline connections with Sekondi-Takoradi, Kumasi and Tamale. (ER. A. B.)

EASTERN UGANDA (until 1962 Eastern province), Uganda, extends from the Victoria Nile eastward to the Kenya boundary and from Lake Victoria northward to embrace the lake and swamp system of Kyoga. Indeed, most of the region consists of gently undulating land tributary to Lake Kyoga (3,370 ft.). Area 15,366 sq.mi., including 4,395 sq.mi. of open water and swamp. Everywhere in the north the dry season is pronounced, and the characteristic vegetation is a short-grass savanna grading in the larger valleys through seasonally waterlogged grassland into permanent swamp. In the belt marginal to Lake Victoria there are hills rising to 4,300 ft. and, with a rainfall of about 55 in. fairly well distributed through the year, patches of moist, semideciduous forest are in evidence. As a sleeping-sickness area, much of this lakeside belt is devoid of population. In the east the Tertiary volcano of Elgon, rising to 14,178 ft., forms a fertile and well-watered area with montane forest in the 6,000–10,000 ft. zone.

At the 1959 census the total population of the province was 1,902.697 and the density per square mile was 173. District densities were: Busoga 197; Bukedi 254; Bugisu 216; Teso 106. The main tribal groups are Iteso, Basoga, Bagisu, Bagwere, Badama and Banyole. Nilo-Hamitic languages are spoken in the north and Bantu languages in the south; Nilotic-speaking groups are also found in the ethnically complex area of the southeast. The 29,748 non-Africans included 2,038 Europeans, 23,612 Indians, 1,626 Pakistanis, 491 Goans, 1,091 Arabs and 890 others. The main towns, with 1959 figures of total population and (in parentheses) non-African population, are as follows: Jinja 29,741 (9,913); Mbale 13,569 (5,136); Soroti 6,645 (2,027); and Tororo 6,365 (1,547). In 1962 Sebei district was created.

The Eastern region has a higher proportion of land under cultivation than any other part of Uganda. Bananas are important in central Busoga and in Bugisu; while finger millet, though widely cultivated, is especially significant in Teso and Bukedi. Other food crops are sweet potatoes, cassava, peanuts, beans and maize. The major cash crops are cotton and, in the Elgon country of Bugisu, arabica coffee. Teso is the foremost district of Uganda for the rearing of beef cattle, and about 3,000 tons of fish a year are obtained from its swamps and lakes.

Apart from cotton ginning and, in southern Busoga, the manufacture of sugar, industrial developments are confined to the towns. Jinja is the source of hydroelectric power and the site of a copper smelter. At Sukulu, near Tororo, cement and cement asbestos are manufactured. Mbale is a centre for the hides and skins industry, and it has a large, up-to-date coffee-curing works. The various towns have good communications. The railway line from the coast enters the region at Tororo and leaves it at Jinja, and a branch line from Tororo proceeds through Mbale to Soroti (100 mi.), whence in the early 1960s it was being extended to Gulu in northern Uganda. Main roads parallel the railway lines.

(S. J. K. B.)

EAST FLANDERS (Flemish OOST-VLAANDEREN; French FLANDRE ORIENTALE), one of the nine provinces of Belgium, consists of 6 administrative *arrondissements* (Aalst, Dendermonde, Eeklo, Ghent, Qudenaarde and Sint-Niklaas), 34 judicial cantons and 297 communes. Pop. (1958) 1,261,440, nearly all Flemish speaking. Area 1,150 sq.mi.

The province lies within interior Flanders, which rises inland from the coastal plain at about 15 to 150 ft. above sea level. It is drained by the Lys and Scheldt rivers, which converge at Ghent to form the lower Scheldt, itself joined farther east by the Dender. Their valleys are 2–3 mi. wide, filled with alluvium, across which the rivers meander in great loops; many have been cut off naturally or by regularization. Between the rivers, the low interfluves are covered with Eocene deposits, Flanders clay in the south, more sandy deposits in the north and a few patches of Oligocene sands and clays. In the northeast, to the west of the Scheldt estuary, are reclaimed polderlands.

Agriculture is practised intensively, much of it on a horticultural scale, for holdings are small, particularly in the north. The proximity of large towns has encouraged market gardening, and vegetables, hops, potatoes, sugar beet, chicory, flax and even some wheat are grown, often by spade cultivation. On many holdings more than one main crop is grown each season. Yields are high, the result of heavy manuring. Clover and fodder crops are included in the rotations to feed dairy cattle; each holding usually has a herd of a few animals, sometimes stall fed, to produce milk, butter, cheese and veal. In the early 1960s there were about 340,000 cattle (of which less than one-third were dairy animals) and 280.000 pigs. The Waasland or Pays de Waes, west of the Scheldt estuary, is particularly fertile; there market gardens specialize in cauliflowers and tomatoes, and there are orchards of bush fruits, dairy farms and poultry farms.

Inland Flanders has long possessed a flourishing industrial and commercial economy, and industry is carried on in close association with agriculture. Many factory workers live in the country, owning a small holding and traveling daily to work. Textiles are

the chief manufacture. In early times wool was the most important product, then linen developed along the Lys valley, based on local flax and soft water. Later on it was cotton that became pre-eminent. Other textiles (jute, rayon and nylon) are also produced, and yarns and cloths are used by a vast range of associated industries. At one time the industry was largely domestic, then gradually it congregated in the towns. The chief centre is Ghent (*q.v.*), which contains half the country's cotton spindles, but other towns—Deinze on the Lys, Oudenaarde (*q.v.*) and Ronse on the Scheldt, Geraardsbergen (French, Grammont), Aalst (*q.v.*; French, Alost) and Ninove on the Dender and Dendermonde (French, Termonde) at the Scheldt-Dender junction—are important. Many of these towns also have metallurgical (notably textile machinery), chemical, fertilizer, leather and glassware manufactures.

The province is well served with rail and road communications. The rivers are regularized and carry a heavy traffic (lower Scheldt, more than 4,000,000 tons of freight annually), a canal links Ghent with Bruges and Ostend and a ship canal runs north from Ghent to the Wester Schelde at Terneuzen (more than 8,000,000 tons of freight annually).

This has been for centuries one of the most closely settled areas in Europe. The average density of population in 1958 was 1.098 per square mile. Ghent is the biggest city, with 160,669 people in 1958; several contiguous communes bring the population to over 200,000. Of the other textile towns, the largest is Aalst (44,478). There are several market towns such as Sint-Niklaas (*q.v.*; 47,015), the centre of the Waasland, and Eeklo (18,129) in the northwest, and 35 communes with between 5,000 and 10,000 people. Within these communes, many single houses are situated within small holdings; this is an area scheduled for dispersed rural settlement. (F. J. M.)

EAST GRINSTEAD, a market town and urban district of East Sussex, Eng., lies 30 mi. S.S.E. of London by road. Pop. (1961) 15,421. East Grinstead stands on a hill in an agricultural and wooded area overlooking the Medway valley and Ashdown forest to the southeast. The urban district contains East Grinstead and the villages of Ashurst Wood and Kingscote. Agriculture and timber production are the chief occupations of the people, though a few light industries have been established. A great number of houses were built after 1951 and many of the new residents travel daily to work in London.

The buildings in East Grinstead are of all periods from Tudor timber-framed houses onward, the loveliest being Sackville college, built as an almshouse in 1608 or 1609 by Robert, 2nd earl of Dorset, and still used for that purpose. St. Swithin's church, on the site of St. Edmund's (960), was rebuilt between 1789 and 1813 after the collapse of the tower in 1785. It stands on the hilltop and contains unusual fluted, concave pillars and iron grave slabs, the oldest of which is dated 1570.

The Queen Victoria hospital, founded in 1889 to serve the local community, became in 1939 a centre for plastic surgery and treated members of the Allied armed forces during World War II. In 1944 the Canadian government built and equipped a large plastic surgical wing as a memorial to those members of the Royal Canadian Air Force who had been patients of the hospital. Later the British War Relief Society of America provided the American wing surgical unit. The hospital was taken over in 1948 under the National Health Service act, 1946, and made a regional centre for plastic surgery. Pioneering work in the field of corneal graft surgery was done there.

Originally a clearing in the great forest of Andredsweald (see WEALD, THE), Grenestede ("green place") was granted a charter in 1121. Since it lay directly between London and Pevensey, William I included it among the royal domains that went with Pevensey castle. Iron was discovered early and at the time of William the Conqueror there was an iron mine there. Furnaces for the ironaorks were fed from surrounding forests until Henry VIII and Elizabeth I passed laws to preserve the trees. East Grinstead is an ancient borough which from 1307 until 1832 returned two members to parliament. In 1285 the king ordered the market to be held on Saturday instead of Sunday, and in 1516 a yearly fair was granted.

The first Mormon temple in Great Britain was completed in 1958 at nearby Newchapel. Sheffield park lies about 9 mi. S. and is a National trust property (from 1954) famous for its garden and lakes laid out by Lancelot "Capability" Brown in the 18th century and redesigned by Arthur G. Soames in the 20th.

EAST HAM, a municipal, county and parliamentary borough of Essex. Eng., 6 mi. N.E. of London bridge. Pop. (1961) 105,359. Area 5.2 sq.mi. East Ham is bounded north by Wanstead, east by Ilford and Barking (the other side of the river Roding), south by the Thames and west by West Ham. The borough includes all or part of the districts of Wanstead Park, Manor Park, Forest Gate, Little Ilford, North Woolwich. Upton Park and East Ham itself. The northern part is mainly residential but along the Thames are many industries including the Beckton works of the North Thames Gas board; there too are the major portions of the Royal Albert dock and the King George V dock. East Ham is intersected by the two main highways out of east London—the Romford and the Barking roads; a bypass road cuts off the southern angle of the borough nearer the river on the way to Grays and Tilbury. Its growth during the end of the 19th and beginning of the 20th centuries was very rapid, and it now forms, geographically, part of the eastward extension of London. A town development plan (1952) visualized a considerable reduction in population within 20 years. Movement of population would be to Basildon New Town and other towns in Essex scheduled for expansion (*e.g.,* Brentwood where the corporation was developing an estate).

East Ham belonged before the Conquest to Waltham abbey, whose possession of it was confirmed by Edward the Confessor. The parish church of St. Mary Magdalen contains Norman work in the chancel and also a monument to Edmund Nevill, who claimed the earldom of Westmorland in the 16th century. William Stukeley, the antiquary (d 1765), is buried in the churchyard. East Ham was incorporated in 1904, became a county borough in 1915 and has been represented by two members of parliament (for East Ham North and East Ham South) since 1918.

EAST INDIA COMPANY, a company formed for the exploitation of trade with India and the far east. In the 17th and 18th centuries East India companies were established by England, the United Provinces (Dutch), France, Denmark, Scotland, Spain, Austria and Sweden. By far the greatest of these was the English East India company, the subject of this article, although the Dutch East India company (*q.v.*) and for a time the French company were also very powerful.

Early Development.— In Sept. 1599 a group of London merchants formed an association for direct trade with the East Indies, in order to compete with the Dutch and break their monopoly of the lucrative spice trade. A capital of £30,000 was immediately raised, and on Dec. 31. 1600. Elizabeth I granted a charter for 15 years to "the Governor and Company of Merchants trading into the East Indies." conferring a monopoly of the East Indian trade together with limited authority to make laws and punish interlopers. The first 12 voyages of the company, known as the "separate voyages" (1601–13) because they were individually financed and the subscribers took the whole profits, proved very successful. The voyages reached as far as Japan, and factories were established in Java at Bantam in 1602, in India at Surat in about 1612 and on the Indian mainland at Masulipatam (Masulipatnam) and at Pettapoli in the Bay of Bengal. James I proved a firm supporter of the company and in 1609 he renewed its charter "for ever" with a proviso that it could, if necessary, be terminated on three years' notice.

The attempt to break the Dutch monopoly in the spice islands was unsuccessful. A series of conflicts between the English and Dutch companies ended in uneasy truce in 1619, but the Dutch company, with its powerful government backing and territorial bases. was the stronger. When in 1623 some English merchants in the Moluccas were massacred by the Dutch at Amboina, the English company abandoned its attempted intervention, and concentrated on Surat and the other Indian factories. Good relations had been established with the Mogul emperor by Sir Thomas Roe, whom Jatnes I had sent on an embassy in 1615, and the Indian trade in calicoes, indigo, raw cotton and silk, saltpetre and some

spices proved generally profitable. Trading relations were also established with Persia. In England, the company's resources grew. After 1613 capital was raised for several voyages at a time, permitting more flexible enterprises; a permanent joint stock was not created until 1657. The company quickly built up a trading fleet; by 1614 it possessed 24 ships. Throughout the company's history, the armed East Indiamen were world-famous, and their development gave a general stimulus to English shipbuilding and navigation.

Under Charles I the company suffered some reverses. The king did not revoke its charter, but in 1635 gave a licence to an association formed by Sir William Courteen, the "Assada merchants," to trade in India. The piratical methods of this rival syndicate destroyed the company's credit in India, and Courteen's traders continued to harass the East India company until 1649. It was not until Oliver Cromwell granted a new charter in 1657 that the company's monopoly was secured.

Expansion and the "Interlopers." — After the Restoration, the East India company began to develop into more than a merchant association. Charles II granted it five important charters, the first in 1661, which gave it extensive sovereign rights. New and profitable sources of trade were opened up, notably the China trade. The decline of the Mogul empire in India necessitated active protection of the company's settlements, and gradually the original principle of peaceful trade based on local alliances without territorial responsibilities had to be abandoned. The three presidencies of Madras, Bengal and Bombay (which were ceded by Charles II in 1668) had been established by 1680. In 1684 it was found necessary to fortify Bombay, and with fortification came the beginnings of an administrative and fiscal system. From the 1680s the history of the company's Indian settlements becomes that of British India *(see* INDIA: *History).* Here only the company's history in England will be traced.

Sir Josiah Child, who dominated the company from 1674 to 1695, understood and met the changing conditions. With no desire for territorial dominion he appreciated that an active policy was needed for security of trade. He also established excellent relations with Charles II and James II by large gifts of money, and the East India company became closely identified with the court interest. This gave protection against the growing demands of merchants wanting a share in the enormous profits of Indian trade. The revolution of 1688, however, left the company vulnerable both to the Whigs, its political enemies, and to its opponents in the City of London. By 1691 the company's rivals had formed a new society, and demanded a new charter. The dispute between the two factions went on both inside and outside parliament, until in 1698 an act of parliament granted the monopoly of Indian trade to those who contributed to a loan of £2,000,000. The old company retained its supremacy; it contributed 5315,000 and kept its forts and privileges in India, but the new company gained a foothold in the Indian trade. Finally in 1702 it was agreed that the companies should be jointly managed for seven years. By the Godolphin award of 1708, the companies were amalgamated (1709) as the United Company of Merchants trading to the East Indies. The new company's charter was only granted for three years, but in return for loans it was extended in 1711 until 1733, in 1730 until 1769 and in 1744 until 1783.

The constitution of the United company was very similar to that which the old company had gradually evolved. It was governed by a court of 24 directors, with a stock qualification of £2,000. Government was carried out largely by committees, and the chairman, who had great power, and vice chairman were elected annually. From the earliest days of the old company, the general court of proprietors had been active; in 1709 it was laid down that the general court should meet every quarter, or on the demand of nine proprietors. The stock qualification for proprietors was £500 and their decisions could overrule those of the directors. In times of peace and prosperity the system worked well, but the struggle with the "interlopers" left an unfortunate legacy of internal faction and political intrigue.

***The* Ruling** Company. — Under Sir Robert Walpole, the company prospered; it had its established place as a pillar of the London money market, and became an important part of Walpole's governmental machine. The victories over the French in India during the Seven Years' War, however, brought about great changes in the company's functions. and in its relationship with the government. The conquests of Robert Clive (*q.v.*), and his assumption of the government of Bengal by the treaty of 1765 made the East India company the ruler of rich and extensive territories. The government could not ignore the problems this raised. After many intrigues, the company forestalled government interference in 1767 by promising an annual payment of £400,000 which it could ill afford. Further negotiations led to Lord North's Regulating act of 1773 which gave the governor of Bengal the title of governor general. His appointment was subject to government approval, and with his council of four he was given legislative powers. Furthermore a supreme court was established and its judges appointed by the crown. Warren Hastings (*q.v.*) became governor general. The new system soon revealed many flaws; in India the governor general's powers were not clearly enough defined, and in practice inadequate; in England, the government had established no machinery to keep check on Indian affairs. For many reasons—jealousy of the rich "nabobs" returned from India and undue fear of their political influence, evidence of misgovernment in India, and the campaign against Hastings which was powerfully supported by Edmund Burke—the question of the East India company's future became an issue of the first magnitude, an issue in which political faction and individual interests were mixed with a genuine demand for reform.

A solution was found in William Pitt's India bill of 1784. A government department. the board of control for India, was set up to govern British India. The India board ultimately had complete authority over the board of directors. but the directors in practice still retained considerable powers in the inauguration of policy and especially in commercial affairs. Under the board's first president, Henry Dundas, the system was made to work fairly smoothly. Gradually the government tightened its control over the Indian administration. In 1813 an act was passed ending the company's monopoly in India and in 1833 the China trade was opened. The 1833 act left the company with no real administrative or commercial functions, an anomalous position ended by the act of 1858, after the Indian mutiny, when the East India company reluctantly transferred its possessions to the crown. *See* also references under "East India Company" in the Index volume.

EAST INDIES, a term used loosely to refer to the islands of the Republic of Indonesia (formerly known as the Netherlands Indies or Dutch East Indies), to all the islands of the Malay archipelago, or to the foregoing plus all of southeast Asia and India. Modern practice generally limits the term to the Malay archipelago. It is the largest group of islands in the world and extends in a wide belt along the equator for more than 3,800 mi. between Asia and Australia. *See* MALAY ARCHIPELAGO; INDONESIA.

EAST KAZAKHSTAN OBLAST (VOSTOCHNO-KAZAKHSTANSKAYA OBLAST), a province situated in the Altai mountains at the extreme northeast of the Kazakh Soviet Socialist Republic, U.S.S.R. Pop. (1959) 734,924: area 37.568 sq.mi. It is bordered on the east and southeast by China (Sinkiang Uigur autonomous region) and on the northeast by Altai *krai* and the Gorno-Altai autonomous *oblast.* It is drained by the upper Irtysh river and its affluents, the Narym and the Bukhtarma. In the south lies Lake Zaisan (*q.v.*) in the middle of a large depression. The cli-

mate is continental, with high pressure in the winter giving clear cold weather. In the summer the weather in the plains is often hot and cloudless. Precipitation in the foothills is considerably higher.

The capital of the *oblast* is Ust-Kamenogorsk. Other important cities are Leninogorsk, Zyryanovsk and Zaisan.

The *oblast* is an important mining region, the main deposits being zinc, lead and silver, with some copper and gold. The principal mining centres are Ust-Kamenogorsk, Zyryanovsk and Belousovka. The nonferrous industries are powered by hydroelectric plants at Ulba, near Leninogorsk; at Ablaketka, just south of Ust-Kamenogorsk; and at Glubokoye.

Agriculture is mainly, concerned with stock raising, but wheat and beets are also grown. There are considerable fisheries in the rivers and lakes.

The only railway in the *oblast* is the branch from the main Turksib line running through Ust-Kamenogorsk and terminating at Zyryanovsk. The Irtysh river is navigable from May to October.

In the early 1960s there were more than 700 schools in the *oblast*, as well as various technical institutes. (G. E. WR.)

EAST KILBRIDE, a New Town (*q.v.*) built around an old village of the same name in Lanarkshire, Scot., 8½ mi. S.S.E. of Glasgow, from which it is divided by the Cathkin Braes (700 ft.). The town was designated in 1947 to cover nearly 16 sq.mi. and the proposed population was 50,000. Pop. (1951) 5,136; (1961) 31,-972. East Kilbride lies in a dairying area and an annual cattle show has been held there since 1816. Milk bottling and the making of agricultural and mining machinery are old industries; the biggest new ones are aeroengineering and the making of domestic electrical appliances. The town is the site of the new National Engineering Laboratory of Great Britain.

EASTLAKE, SIR CHARLES LOCK (1793–1865), English painter, art historian and museum director, was born at Plymouth, Devonshire, on Nov. 17, 1793. He went to Plympton grammar school (conturrently learning drawing from Samuel Prout) and briefly to the Charterhouse, London. But in 1809 a resolve. "unalterably fixed." to become a painter of "history" (*i.e.*, of scripture allegory. antiquity or literature as opposed to everyday life or portraits) brought him as pupil to B. R. Haydon and to the Royal Academy schools. By 1812 he had finished his first commission, the "Raising of Jairus's Daughter," and in 1815 came the famous "Buonaparte on Board the Bellerophon," the proceeds of whose sale took him to Rome in 1816. There till 1830 he worked in a congenial society that included Sir Thomas Lawrence, J. M. W. Turner. William Etty, Sir Humphry Davy and Thomas Moore. Rome and the Campagna deflected him for a while from history to landscape, his skill in which appears in his later "banditti" pictures; then also were begun his copious notebooks. many of which are preserved in the National gallery, London. He was elected an associate of the Royal Academy in 1827 and to the Royal Academy in 1830; in 1850 he succeeded Sir Martin Archer Shee as president of the Royal Academy and was knighted.

With his appointment in 1855 to the new directorship of the National gallery—whose keeper he mas from 1843 till his resignation in 1847 in face of unjust criticisms—the artist was finally displaced by the writer, administrator and arbiter of national and court taste; and Eastlake is best remembered for his part in raising the status of the gallery and for his books *Materials for a History of Oil Painting* (1847) and *Contributions to the Literature of the Fine Arts* (2 series, 1848, 1870). He died at Pisa, Italy, Dec. 24, 1865.

In 1849 he had married Elizabeth Rigby, author of *Letters From the Baltic* (1841). LADY EASTLAKE (1809–93) was also a considerable diarist and translator of G. F. Waagen's *Treasures of Ast* in *Gveat Britain* (1854–57). Their nephew CHARLES LOCK EASTLAKE (1836–1906) was keeper of the National gallery, 1878–98, and a writer on painting and industrial art.

BIBLIOGRAPHY.—W. Cosmo Monkhouse, Pictures *by Sir Charles Eastlake* (1875); Lady Eastlake, "Memoir of Sir C. L. Eastlake," in his *Contributions,* 2nd series (1870; includes catalogue of his paintings); C. Eastlake Smith (ed.), *Journals and Correspondence of Lady Eastlake,* 2 vol. (1895).

EAST LANSING, a city of Ingham county, in south-central Michigan. U.S. The city has been council-manager governed since 1944. With neither industry nor railroad connections, it grew up around Michigan State university (pioneer land-grant school, 1855) and expanded with the student enrollment. Chartered in 1907 as a college city, its name, a subject of controversy, was settled by the U.S. post office, which designated the postal area East Lansing as it was a few miles east of Lansing (*q.v.*), through which its mail was routed. It became in the 1920s a residential suburb, offering homes to state officials and to Lansing automobile factory executives. To the south of its central avenue lies the mile-square campus, spanning the Red Cedar river, with more than 20,000 students. To the north lies a community of fine homes and quiet streets, participating in all aspects of university life but alert to the index of automobile sales and to the fate of its citizens in state elections. For comparative population figures *see* table in MICHIGAN: *Population.* (M. KU.)

EASTLEIGH, a municipal borough in the Winchester parliamentary division of Hampshire, Eng., 4 mi. N.N.E. of Southampton. Area is 9.8 sq.mi. Pop. (1961) 36,577. Incorporated in 1936. it includes the districts of Chandler's Ford, Allbroke, Bishopstoke and parts of North Stoneham, Otterbourne, Fair Oak and Stoke Park. Lying in well-wooded country, it is in part residential and in part industrial, the chief industry being the works of the British railways (Southern Region).

The church of St. Nicolas at North Stoneham is one of the earliest ecclesiastical foundations in England, though it shows no trace of the old Saxon building. It contains the memorial to Sir Thomas Flemyng. who sentenced Guy Fawkes to death. and for centuries a celebration took place every Nov. 5.

EAST LIVERPOOL, a city of Columbiana county in eastern Ohio. U.S., is noted for its pottery. Nearly equidistant between Pittsburgh. Pa., Youngstown, O., and Canton, O., it is situated on the Ohio river near the intersection of the Ohio, Pennsylvania and West Virginia boundaries.

First settled in 1798 by an Irish Quaker, Thomas Fawcett. the village was variously known as St. Clair, Fawcettstown and Liverpool before its incorporation as East Liverpool in 1834. In the nearby hills an English potter from Staffordshire, Eng., James Bennett, found a clay which was suitable for the manufacture of crude yellowware and established the first kiln in 1840. Other potteries were soon built, but it was not until federal import duties were placed on earthenware goods, commencing with the Morrill tariff of 1861, that the village emerged as one of the nation's foremost pottery centres. The manufacture of whiteware began in the 1870s; of semivitreous china in the 1890s. There is an outstanding collection of pottery ware, ranging from pioneer patterns to modern designs, in the East Liverpool Historical Association museum. Though many of its potteries were transferred across the Ohio river into Newell and Chester, W.Va., the city remains a centre of the industry. In addition to ceramics, East Liverpool produces a wide range of manufactured products, including steel, asphalt roofing, wood and fibre containers, paper, tin and chemicals. A village of 1,308 inhabitants in 1860, its population increased to 20,387 by 1910, after which the city's rate of growth was much slower. For comparative population figures see table in OHIO: *Population.* (P. R. S.)

EAST LONDON (Afrikaans 00s-LONDEN)a city and the fourth port of the Republic of South Africa, lies on the southeast coast of the Cape of Good Hope province, 695 mi. E. of Cape Town and 433 mi. S.W. of Durban by road. Pop. (1960) 113.258, of whom 47,793 were Europeans. It stands at the mouth of the Buffalo river and is built chiefly on the east (left) bank, which rises steeply from the water front. The city has wide straight streets of which the chief is Oxford street; the Esplanade runs northeast along the sea front with beaches for surf bathing. Among the principal buildings are the city hall (1899), law courts (1883) and the fine municipal market (1955). A double-deck road and rail bridge 1 mi. from the river mouth leads to the west bank, where stand Ft. Glamorgan and the old powder magazine, built in 1847. The city has a technical college, art gallery, aquarium and zoo. The museum is notable for a specimen of the primeval fish *Latimeria chalumnae (see* COELACANTH). Queen's park (80 ac.) lies

between the city centre and the river. The mean temperature is 59.4" F. in July and 70.2° in January. with about 32 in. annual rainfall. East London is a popular resort and the South African Grand Prix motor race is held there annually.

East London is a terminus of the South African railways and is linked by air services from Collondale (8 mi. W.) with the main centres of the Republic. The port, on which is based a considerable fishing industry, has wharfage on both banks and a turning basin at the river mouth sheltered by breakwaters, with a 732-ft. dry dock. Mail vessels on the London-Cape Town-Durban route call weekly in both directions. The city is a market and distribution centre for the eastern part of the province. Its chief business is the wool industry and its manufactures include confectionery, furniture, textiles, clothing, footwear, soap, glass, storage batteries, pharmaceuticals, fruit canning and automobile assembly. The port's principal imports are general cargo, petroleum fuels, timber and grain; the main exports are maize, wool and fruit.

The place was first named Port Rex after George Rex of Knysna, whose brig anchored off the estuary in 1836. In 1847 it was used as a supply base for the seventh Kaffir War and in the following year was annexed to Cape colony as the "Port of East London." It became a municipality in 1873 and a city in 1914.

(H. H. DR.)

EAST LOTHIAN (formerly HADDINGTONSHIRE), a south-eastern county of Scotland, one of the three surrounding Edinburgh. is bounded on the north by the Firth of Forth, northeast by the North sea. south by Berwickshire and west by Midlothian. Area 267.1 sq.mi.

Physical Features. — In the south is part of the Lammermuir hills, broad undulating grouse moors, clad in heather or bent grass, or in cotton grass, deer grass and sphagnum over peat. Occasionally there are shelter-belts of conifers. The main plateau surfaces at 1,200–1,300 ft., swelling to 1,733 ft. in Lammer Law and 1,750 ft. in Meikle Says Law. are planed across steeply inclined, tightly folded but lightly metamorphosed Silurian shales and grits. but in the east across Old Red Sandstone conglomerate infilling an ancient valley. Through steep-sided. flat-floored, gravel-bottomed dales, small clear trout streams like Whiteadder and Faseny waters flow south to the Tweed. The northern edge of the Lammermuirs, a steep fault-line scarp of the system flanking the mid-lowland from Dunbar to Girvan, is gouged deeply by hill streams like the Hopes, Birns and Gifford waters, which are tributaries of the Tyne. These streams caused great havoc on Aug. 12, 1948 (rainfall 5.5 in. in 24 hr.), when the Tyne flooded low-lying areas in Haddington. To the north is a plateau at about 500–600 ft., planed across Old Red Sandstone and Carboniferous rocks, mantled in easily tilled red boulder clays and in parts (mainly wooded) stiff intractable boulder clays.

Farther north lies a softly undulating lowland plateau at 200–300 ft., similarly mantled, and then the broad, gently sloping, flat-floored vale of the sluggish river Tyne, running 27 mi. from Borthwick in Midlothian east-northeast across the county, the greatest of many similarly oriented glacial spillways. The northern slope of the vale rises gently to the small wooded crags of the Garleton hills, of andesitic lavas, tuffs and intrusions of Carboniferous age. These rocks separate two synclines in Carboniferous sediments—limestones, sandstones and, in the west, some coal. All the rocks are planed across by the boulder-clay-plastered rolling plateau (200–300 ft.) already noted, and by post-glacial raised beaches mainly at 25 ft. above mean sea level. A fluvio-glacial gravel delta, largely wooded, overlooks the quicksands of the modern Tyne mouth.

The coast has some fine cliffs, as east of North Berwick, facing the bold volcanic crag of the Bass rock (*q.v.*), breeding place of gannets. East and west are some good beaches, a fringe of dunes or links and, inland. a sand-apron. The Aberlady bay nature reserve includes many of the distinctive coastal flora. The northern area is dry and sunny (Dunbar averages 1,400 hr. of sunshine annually), especially in the spring, but the Lammermuirs have 35–40 in. mean annual rainfall. (A. T. A L.)

History. — In the Iron Age, Celtic people lived in the county and left many hill forts, as well as a hill-top town, Dunpender, on Traprain Law, which was occupied until the 4th century A.D. They were succeeded by Angles in the 7th–8th century, and the Lothians formed part of Northumbria. The area was introduced to Christianity by St. Baldred in the 8th century. At the Battle of Carham (c. 1016) the Lothians were finally incorporated in Scotland. In the 12th century much of the land passed to Anglo-Norman families, who developed cereal and fruit growing and the wool trade. Haddington (*q.v.*) was founded by David I, and later royal burghs were Dunbar (1317) and North Berwick (1370) (*qq.v.*). At Prestonpans (*q.v.*) coal mining and salt panning had started in the 12th century.

The county, however, lay in the path of the English invaders and was subject to much destruction during the 14th. 15th and 16th centuries. In this period the feudal castles of Dirleton, Tantallon and Hailes were built. There were also nunneries at Haddington and North Berwick, friaries at Haddington, Luffness and Dunbar, and the Holy well at Whitekirk, a place of pilgrimage. John Knox (*q.v.*) was a native of East Lothian and by 1560 people had turned to the Reformed Church. The last battles fought in the county were those of Dunbar (1650) and Prestonpans (1745).

Conditions were more settled in the 18th century and there was a further development of agriculture. The land was enclosed and drained, industries were started and woods planted. The old settlements of group holdings gave way to centralized farms, each with a slated farm house, large pantiled steading buildings and a group of rubble and pantiled cottages. Mansion houses were built and parks were walled and planted. Some new villages were established (Gifford. 1722, and Ormiston. 1732, are both of architectural interest) and Haddington and Dunbar developed as market towns. Farming reached the height of prosperity in the 1870s. In the last years of the 19th century golfing and holiday facilities were developed at North Berwick, Gullane and Dunbar. Also, deep coal mines were sunk in the west of the county, notably at Prestonpans, which now became a mining town.

Population and Administration. — The population of East Lothian, which was about 30.000 in 1801, rose slowly throughout the 19th century and increased by about 10,000 to 47,487 between 1901 and 1921, mainly as a result of the mining development. By 1961 the population was 52,653. Land tenure is in a state of transition, from mainly tenant occupation of the generally large farms on the estates of such landowners as the earls of Wemyss and Haddington toward a much larger proportion of owner-occupied farms. East Lothian is probably the best-housed rural county in Scotland, and the villages are delightful. There are seven small burghs, those with the largest population in 1961 being Tranent (6,317), Haddington, the county town (5,506), Dunbar (4,003) and North Berwick (4,161). The shire, which returns one member to parliament with Berwickshire, forms part of the sheriffdom of the Lothians and Peebles, and a sheriff substitute sits at Haddington.

Agriculture and Industry. — About one-quarter of the employed population is engaged in agriculture, forestry or fishing, but the proportion is declining. The 400–600-ac. farms are largely arable. Traditionally, cash crops (wheat, barley, potatoes) are produced, together with fodder for bought-in stock which are sold fat after winter feeding and also provide dung vital for high yields of cash crops. Dairying, however, is increasing, as is market gardening. The hill pasture of the Lammermuirs carries one Cheviot or Blackface ewe to every two acres. Fishing is confined to the Port Seton fleet of ring- and seine-net boats, together with local lobster-fishing boats out of North Berwick and Dunbar.

Coal mining declined by the 1960s as the shallower mines closed and is confined to the Prestonpans area. Manufacturing consists mainly of food and drink products, textiles and light engineering. The main trade is carried on with Edinburgh, although North Berwick, Dunbar and Haddington are local retail as well as social centres. By the 1960s traveling shops were replacing the village shops which, with village crafts, were declining.

Cars are the main form of transport but there are good bus services on the radial routes to Edinburgh. The main railway line serves Dunbar. (F. P. TI.)

EASTMAIN, a river of Quebec province, Can., rises south of

Lake Nichicun in central Labrador-Ungava and flows nearly due west for 510 mi., discharging into James bay. The valley is shallow and irregular, and the river is full of falls and rapids. A Hudson's Bay company post (founded 1865) is situated in the tidal section of its mouth, which is 1½ mi, wide and obstructed by' shoals. The river was explored in 1892 by A. P. Low, Canadian government geologist. (J. D. I.)

EASTMAN, GEORGE (1854–1932), U.S. inventor and manufacturer of photographic materials and cameras, was born at Waterville, N.Y., July 12, 1854. While Eastman was still a boy the family moved to Rochester, N.Y., where he was educated in the public schools and then worked briefly in an insurance company and a bank. In 1880 he perfected a process for making dry plates and began their manufacture. He originated transparent film and organized the Eastman Dry Plate and Film company in 1884. The Kodak camera was placed on the market in 1888. By 1927 Eastman had a virtual monopoly of the photographic industry in the United States. He was one of the first to introduce profit sharing as an employee incentive.

One of the most generous philanthropists in America, he gave away half his fortune in 1924. His total benefactions amounted to more than $75,000,000, the University of Rochester and the Massachusetts Institute of Technology being the chief beneficiaries. He died in Rochester on March 14, 1932, by his own hand. (J. R. Lt.)

EASTON, a city in eastern Pennsylvania, U.S., and seat of Northampton county, at the junction of the Lehigh and Delaware rivers, 55 mi. N. of Philadelphia and 70 mi. W. of New York city. The city is connected with Phillipsburg. N.J., across the Delaware river, by two automobile and two railway bridges, and many civic groups and churches have members from both cities. With a population (1960) of 31,955, Easton is a central city of the Allentown-Bethlehem-Easton standard metropolitan statistical area, comprising Northampton and Lehigh counties in Pennsylvania, and Warren county in New Jersey (see ALLENTOWN). (For comparative population figures *see* table in PENNSYLVANIA: *Population.)*

The Easton area is endowed with quantities of limestone and slate, as well as iron ore, lumber and serpentine. The city is surrounded by diversified farm land and is about 50 mi. from large anthracite coal and zinc fields. Among its manufactured products are air valves, cement, crayons, farm machinery, flour and feed, industrial cars and quarry trailers, metal castings, paper cups and containers, pigments and oxides, portable tools, pumps, steel products and textiles. It is also a printing and publishing centre.

Northampton county and Easton were established simultaneously in 1752, and Easton has always been the county seat. Originally the county included most of northeastern Pennsylvania. The streets of Easton were laid out by William Parsons at the request of the proprietor, Thomas Penn, and the city was named to honour the latter's father-in-law, the Earl of Pomfret, whose estate in Northamptonshire, England, was called Easton-Neston. Settlement at the forks of the Delaware had begun even earlier, and the land was obtained from the Indians in the notorious Walking Purchase of 1737. During the French and Indian War Easton was the scene of several Indian treaties; during the Revolution it served as a frontier outpost. In 1826 some local citizens founded Lafayette college, and named it for the Revolutionary hero, who had revisited the United States two years earlier. Easton was incorporated as a borough in 1789, and chartered as a city in 1887. (J. M. Co.)

EAST ORANGE, a city of Essex county, N.J., U.S., adjoining Newark. The site was originally settled in 1666 by 30 families from New Haven, Conn. Along with West Orange, South Orange (*qq.v.*) and Maplewood, it was once a part of Orange (*q.v.*). East Orange was separated from the latter and established as a municipality in 1863; it acquired its city charter in 1909.

It is mainly a residential suburb for commuters to New York and Newark. The industrial section has been called Ampere since Francis B. Crocker and Schuyler S. Wheeler began the manufacture of electric motors there in the 1890s. The city's industry includes electrical equipment, food products, precision instruments, cosmetics, signal and sound equipment, and aeronautical and automotive parts. Upsala college. a Swedish Lutheran institution, was founded there in 1893. Panzer College of Physical Education and Hygiene was founded in Newark in 1917 and eight years later moved to East Orange, where it remained until its consolidation with Montclair State college in 1958.

A source of civic pride is the municipal centre, completed 1929. Pop. (1960) 77,259 by federal census. For comparative population figures see table in NEW JERSEY: *Population.* (E. R. D.)

EAST POINT, a city of Fulton county in north-central Georgia, U.S., originated in 1857 as the eastern terminus of the Atlanta and West Point railroad at its junction with the Central of Georgia. During the American Civil War it was the site of an important military supply depot for the Confederate army. East Point adjoins, but is politically independent of, Atlanta (*q.v.*), of whose metropolitan area it is a part. It comprises a compact industrial area, producing textiles, fertilizers, paper, machinery, furniture, metal products, foods and chemicals, and is also a storage warehouse centre. The principal business area lies along the railroad tracks, and outside this area are attractive residential neighbourhoods. The city schools are operated by Fulton county. For comparative population figures see table in GEORGIA: *Population.* (Js. C. B.)

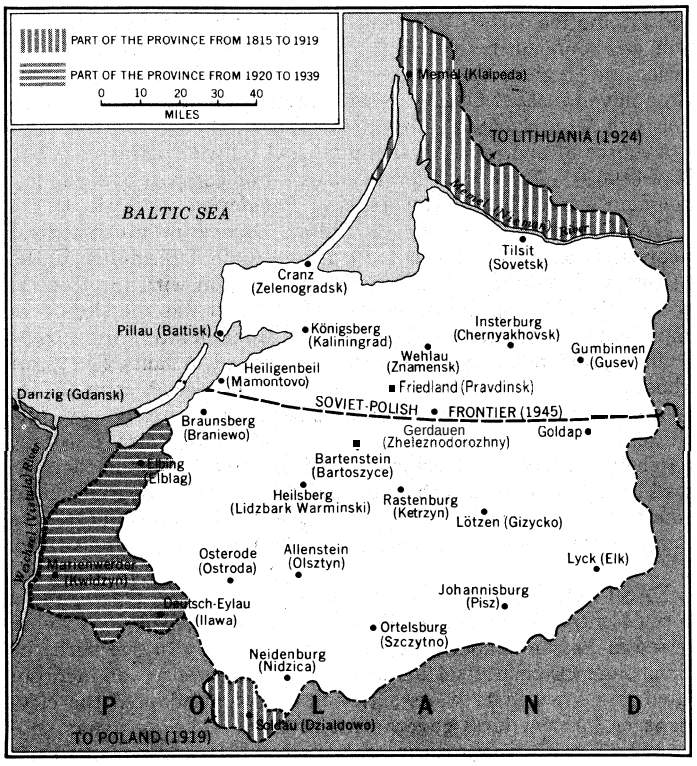
EASTPORT, the easternmost city of the United States, and a port of entry, is located in Washington county, Me., on Moose Island in Passamaquoddy bay, and connected by bridge with the mainland. Originally settled around 1780, Eastport was incorporated as a town in 1798, as a city in 1893 and adopted the city-manager form of local government in 1936. The town was captured by British troops during the War of 1812 and remained under martial law until 1818, when it went to the United States under the terms of the treaty of Ghent. Eastport was the scene of considerable activity during the 1930s when the federal government began work on the Passamaquoddy Tidal Power project, a plan to harness the exceptionally high tides of Passamaquoddy bay for hydroelectric power. The project was abandoned in 1937 prior to completion, due to congressional failure to provide funds, and its facilities were transferred to the War Assets administration, but interest in the development occasionally was renewed.

Eastport's economy is heavily dependent on fishing and fish processing. Herring, the main catch, are canned as sardines and used in making other sea products, such as pearl essence, fish meal and fish oil. It has a population of about 3,000. (H. A. Pe.)

EAST PROVIDENCE, a city of Providence county, R.I., U.S., on the east side of the Seekonk and Providence rivers, opposite Providence. There are four major sections: Watchemoket, the largest; Phillipsdale, containing most of the manufacturing; Rumford, which has a large chemical works; and Riverside, with well-developed summer resorts. Major products include wire and cable, jewelry, machinery and chemicals. Refined petroleum products are stored there for distribution.

Roger Williams (*q.v.*) established himself in East Providence in the spring of 1636, but left when he learned it was within the jurisdiction of the Plymouth colony. About 1644 it was settled by a company from Weymouth as part of the town of Rehoboth in Massachusetts. In 1812 Rehoboth was divided and the west part was made the township of Seekonk. In 1861 it was decided that the west part of Seekonk belonged to Rhode Island and that part was incorporated as the township of East Providence in 1862. In 1958 the town was chartered as a city and adopted a city-manager form of local government. For comparative population figures see table in RHODE ISLAND: *Population.* (G. H. Bs.)

EAST PRUSSIA (OSTPREUSSEN), a former German province bounded, between World Wars I and II, north by the Baltic sea, east by Lithuania and south and west by Poland and the free city of Danzig. The name Prussia is linguistically of Baltic origin; its ancient inhabitants, exterminated by the Knights of the Teutonic Order, called themselves *Prusi* (see PRUSSIA). When the Knights conquered the Polish province of Pomorze in 1308 the name Prussia was extended westward covering the whole territory administered by the Teutonic Order. In 1466 Poland recovered Pomorze (and the region of Warmia, or Ermeland, in the Old



MAP SHOWING THE CHANGING BOUNDARIES OF THE AREA OF FORMER EAST PRUSSIA AND ITS MAJOR TOWNS

Prussia); and between that date and 1701 (when the elector of Brandenburg became king in Prussia) the country held directly by the crown of Poland was called Royal Prussia to distinguish it from the land retained by the Knights as Poland's vassals, which became a secular duchy (Ducal Prussia) in 1525 and was freed from Polish suzerainty by the treaty of Wehlau (1657). From 1815 the name East Prussia was given to the easternmost province of the kingdom of Prussia. The boundaries of this province remained unchanged until World War I. Its area was then 14,284 sq.mi., and its population in 1910 was 2,064,175.

As a result of the treaty of Versailles (1919) the Memel (Klaipeda) territory was taken from Germany (in 1924 it was incorporated into Lithuania); the district of Soldau (Dzialdowo) was given to Poland, while the regency of Marienwerder (Kwidzyn), formerly part of the province of West Prussia, joined East Prussia, now territorially separated from the rest of Germany. The new area of East Prussia (1920–39) was 14,304 sq.mi., and its population (according to the census of 1925) was 2,256,349, of which total 83.8% were Lutheran and 15% Roman Catholic.

After World War II East Prussia was partitioned between Poland (the southern part) and the U.S.S.R. (the northern part), the frontier running north of Goldap, Bartenstein (Bartoszyce) and Braunsberg (Braniewo). With the exception of the Klaipeda territory which was reincorporated into Lithuania, the northern part was incorporated into the Russian federation and colonized by Russians. Konigsberg became Kaliningrad; Insterburg, Chernyakhovsk; and Tilsit, Sovetsk. In the southern part about 400,000 indigenous Poles (whom the Germans had called *Masuren*) remained, and immigrants from pre-1939 Poland replaced the Germans. who either had fled in 1944 or were evacuated after 1945. (K. SM.)

EAST SAINT LOUIS, city in St. Clair county, Ill., U.S., on the Mississippi river. opposite St. Louis. Mo. A ferry station was established on the site in 1797 and 20 years later a village was platted. Originally known as Illinoistown, it was incorporated as a town in 1859 and, after amalgamation with adjacent East St. Louistown, it was reincorporated as East St. Louis in 1865. The first railroad to reach there, in 1855, foreshadowed the city's transformation from an undistinguished river town into a component of a virile industrial region. By 1866 ten railways, seeking the trade of St. Louis, were stopped at East St. Louis by the barrier of the Mississippi river. The completion of Eads bridge in 1874 allowed limited rail traffic across the river but not before the position of East St. Louis as a railway centre and freight depot was established.

The superior transportation facilities and nearby deposits of coal, phosphate rock and limestone began to attract manufacturing in the late 19th century. Between 1880 and 1910 the city's population increased sixfold; the rate of growth slowed thereafter. Pop. (1960) 81,712 by federal census (for comparative population figures see table in ILLINOIS: Population). Rapid development blighted many historic sites in the vicinity, among them the village of Cahokia, founded by a French Jesuit mission in 1698. (See CAHOKIA MOUND.)

Huge stockyards are located at National City (National stockyards), economically a part of East St. Louis. Besides meat packing, the city depends heavily upon the manufacture of chemicals, pigments, steel products, glass, building materials and the refining of oil. (R. E. M.)

EATON, DORMAN BRIDGMAN (1823–1899), U.S. lawyer and civil service reformer, was born in Hardwick, Vt., June 27, 1823. Following graduation from the University of Vermont, Burlington, in 1848 and the Harvard law school in 1850, he became a noted New York lawyer. He retired in 1870 to pursue civil service and municipal reform. His legal work with the New York Citizen's association of 1864, and after, led to creation of the department of health, the fire department, the department of docks, and the police judiciary. These agencies became models for others throughout the country. In 1873 Eaton succeeded George W. Curtis as chairman of the federal Civil Service commission and, defying sharp political opposition, worked for a merit system of government appointments. At Pres. Rutherford B. Hayes's request, in 1877, he studied and later reported upon the British civil service. Among others of his influential writings in the field was The "Spoils" System and Civil Service *Reform* (1881). Eaton helped found the National Civil Service Reform league in 1881. He drafted the Pendleton Civil Service act (1883) and under it served on the U.S. Civil Service commission. He continued to press for municipal reform in New York, where he died Dec. 23, 1899.

EATON, MARGARET O'NEALE (1796–1879), a beautiful and vivacious woman whose marriage in 1829 to a man soon to be appointed to President Jackson's cabinet caused a political uproar in the U.S. She was the daughter of William O'Neale, a Washington tavern keeper. (The name is sometimes also spelled O'Neill or O'Neil.) After an irregular schooling, she married at an early age John B. Timberlake, a navy purser. They had a son and two daughters. When Timberlake was with his ship, his wife, "Peggy," as she was called, often stayed at her father's tavern. There her beauty, wit and vivacity charmed many notables. including Andrew Jackson and his friend John H. Eaton. a wealthy widower, who came to Washington as senator from Tennessee in 1818. Gradually, gossip connected Peggy's name with that of Eaton.

When Timberlake died on sea duty in 1828, rumour had it that he had cut his throat because of his jealousy of Eaton. The latter consulted Jackson, who believed Peggy to be virtuous and advised his friend to marry her. The marriage took place Jan. 1, 1829, and a few weeks later Jackson made Eaton secretary of war.

Floride Calhoun, wife of Vice-Pres. John C. Calhoun, snubbed Peggy, and the wives of other cabinet members followed her example. Jackson was outraged. Secretary of State Van Buren, a widower, was courteous to Peggy, and his stock rose with Jackson as that of Calhoun fell. It was the beginning of the break between Jackson and Calhoun.

Eaton resigned from the cabinet in 1831. In 1836 he was appointed minister to Madrid, and for four years his wife enjoyed the brilliant society of the Spanish court. The Eatons then returned to Washington, where Eaton died in 1856. Not long thereafter

his wealthy widow married a young Italian dancing master, Antonio Buchignani. During the next few years her husband ran through her property, eventually eloping with her granddaughter. Peggy died in Washington, Nov. 8, 1879.

See Queena Pollack: *Peggy Eaton, Democracy's Mistress* (1931); M. L. Eaton, *Autobiography (1032).* (G. G. V. D.)

EATON, THEOPHILUS (c. 1590–1658), co-founder and for many years governor of New Haven colony in colonial America, was born in Stony Stratford, Buckinghamshire, Eng. The son of a minister, Eaton was schooled in Coventry and then apprenticed to a London merchant. He became a wealthy trader, was elected deputy governor of the East-Land company and was once agent of the British sovereign to Denmark. As a wealthy merchant, he became interested in New England colonization, being among the original Massachusetts company patentees. When his friend of boyhood days Rev. John Davenport was persecuted for nonconformist views. Eaton joined with Davenport and others to found the American colony of New Haven. Probably the wealthiest group to emigrate to 17th-century America, they arrived at Boston in 1637, settling in New Haven the following year. After establishing a church and government based on Puritan doctrines in 1639, they annually elected Eaton governor until his death on Jan, 7. 1658. In 1655, Eaton helped prepare a new code of laws for the colony. Eaton married twice and had two children by his first wife and five by his second. Never successful as a merchant in New Haven, he finally devoted himself to agriculture. (B. K. B.)

EATON, WILLIAM (1764–1811). U.S. army officer and adventurer. who in 1805 led an expedition across the Libyan desert in an effort to overthrow the pasha of Tripoli during the so-called Tripolitan War was born in Woodstock, Conn.. Feb. 23, 1764. At the age of 16 he ran away from home to join the colonial army.

After the Revolutionary War ended he alternately taught school and attended Dartmouth college. Hanover. N.H.. until he graduated in 1790. He taught for a time at Windsor, Vt.. and. with Senator Bradley's influence, secured appointment as an army captain in 1792. In that year he married the widow of Gen. Timothy Danielson. of Brimfield. Mass.. and made his home there. near his native Woodstock. Five children were born to them.

In service against Indians and conspirators in Ohio, Georgia and Tennessee. William Eaton distinguished himself in the eyes of Timothy Pickering (*q.v.*) in the war department by his effective investigations, actions and racy reports. In the department of state. Pickering persuaded Pres. John Adams to appoint Eaton consul at Tunis and instruct him to study and report on north African affairs and prospects for trade, a matter of interest in maritime New England.

In north Africa Eaton found the possibilities of trade encouraging, but it appeared that the pashas were dominated by the piratical interests; one. Pasha Hamet Karamanli of Tripoli. had been dethroned. Eaton returned to the Cnited States (1803) and won Pres. Thomas Jeffersori's approval of a plan to restore Karamanli. Back in north Africa. Eaton, with ten U.S. marines and a rabble of Arabs with Karamanli. marched from Egypt westward and. with the help of U.S. naval bombardment. took Derna, Libya, (April 27. 1805). When the pasha at Tripoli agreed to a treaty with the United States. Eaton was obliged to end his operation unfinished. He returned to the United States and died at his home in Brimfield. Mass., on June 1, 1811.

EATON, WYATT (1849–1896), U.S. painter, whose portraits of many of the foremost 19th-century figures were noted for their delicacy and feeling, mas born at Philipsburg, Que., on May 6, 1849. He was a pupil of the schools of the National Academy of Design, New York city, and in 1872 went to Paris, where he studied in the École des Beaux-Arts under J. L. Gérôme. He made the acquaintance of J. F. Millet at Barbizon and was also influenced by his friend Jules Bastien-Lepage. After his return to the United States in 1876, he became a teacher in Cooper institute and opened a studio in New York city. He was one of the organizers (and the first secretary) of the Society of American Artists. Among his portraits are those of William Cullen Bryant and Timothy Cole, who engraved many of Eaton's works. Eaton died at Newport, R.I.. on June 7, 1896.

EAU CLAIRE, a city of Wisconsin, U.S., and seat of Eau Claire county, is situated at the confluence of the Eau Claire (named "clear water" by 18th-century French trappers and traders) and the Chippewa rivers. The village was settled in the 1840s and platted in 1855. From lumbering days persons of Scandinavian descent have been predominant in the population. It was chartered as a city in 1872 and grew rapidly with the development of the northwestern lumber trade between 1870 and 1880. A city-manager form of local government was adopted in 1949.

Eau Claire is the principal trade centre for west-central Wisconsin's dairy land. There is abundant water power, and its diversified manufactures include rubber and metal products, paper and pulp products, meat packing and food processing. Carson park. almost surrounded by Half Moon lake, with Paul Bunyan camp, a replica of logging days. is a local recreational attraction. Winter sports include ice fishing, skiing. especially at Hendrickson hill jump, and skating. The municipal airport provides facilities for commercial and privately owned planes.

It is the location of a Wisconsin State college (established 1915), a county hospital for the mentally ill and a county tuberculosis hospital. For comparative population figures see table in WISCONSIN: *Population.* (F. H. HY.)

EAU DE VIE: *see* BRANDY.

EAVESDRIP (EAVESDROP), that width of ground around a house or building which receives the rain water dropping from the eaves. By an ancient Saxon law, a landowner was forbidden to erect any building at less than two feet from the boundary of his land, and n-as thus prevented from injuring his neighbour's house or property by the dripping of water from his eaves. The law of eavesdrip had its equivalent in the Roman *stillicidium,* which prohibited building up to the very edge of an estate. This prohibition has been adopted by some countries which follow the Roman civil law. From the Saxon custom arose the term "eavesdropper"; *i.e.,* anyone who stands within the eavesdrop of a house, hence one who pries into others' business or listens to secrets. At common law an eavesdropper was regarded as a common nuisance, was presentable at the court leet and indictable at the sheriff's tourn, and was punishable by fine and by having to provide sureties for good behaviour. Though the offense of eavesdropping still exists at common law, there is no modern instance of prosecution or indictment.

EBBINGHAUS, HERMANN (1850–1909), German psychologist, who was primarily responsible for showing that, contrary to the beliefs then prevailing, the methods of science could be applied to the study of the "higher thought processes," was born at Barmen. Jan. 24, 1850. While the "higher thought processes" with which Ebbinghaus was concerned were later called simple rote-learning processes, they were sufficiently more complex than the phenomena with which other psychologists were working to make his contribution a major advance. That memory could be shown to be orderly was viewed as an achievement of the highest order, and, apparently as a consequence of his report of this work (*Über das Gedächtnis,* 1885), Ebbinghaus was made professor at the University of Berlin. Many of the methods and materials developed by Ebbinghaus for the study of memory are still used in research in verbal learning. The nonsense syllable (three-letter unit in which the middle letter is a vowel, the other two consonants, and which does not form a word) is a notable example.

Ebbinghaus was a masterful writer; his scientific prose was lucid and sparkling, retaining nevertheless the rigour and precision expected of a scientist. His textbook (*Grundzüge* der Psychologie, 1897) was a great success. He was an eloquent and forceful spokesman about an important and growing need felt by many psychologists, namely, the need to divorce psychology from philosophy.

After completing his work on memory. Ebbinghaus turned to other topics, most notably to colour vision and to methods for testing mental capacity of children. In 1894 he left Berlin for a post at Breslau and in 1905 went from Breslau to Halle. He died suddenly of pneumonia at Halle on Feb. 26, '1909. *See* also PSYCHOLOGY. EXPERIMENTAL: *Early Period.* (B. J. U.)

EBBW VALE, an urban district in the Ebbw Vale parliamentary division of Monmouthshire, Eng.. 28 mi. W. of Monmouth by road. Pop. (1961) 28.631. The town lies near the head of the Ebbw valley, nearly 1,000 ft. above sea level and. like the mining towns of South Wales built in the second half of the 19th century, it straggles untidily along the valley. Christ Church (1870) is its chief building. Its position on the northern outcrop of the South Wales coal field made it first an important iron-smelting area and later a coal-mining centre.

The extended use of coal and new processes in smelting made Ebbw Vale one of the most important steel centres in South Wales, but distance from the coast and trade depression in the 1930s caused great decline and distress. In 1935, however, a vast new steelworks, covering approximately $2\frac{1}{2}$ mi. by $\frac{3}{4}$ mi., was established on an old but much smaller foundation. It started working in 1938–39 and after 1945 it was enlarged. Its capacity is now about 600,000 tons of sheet steel and tin plate a year. Attached to the Ebbw Vale steelworks are limestone quarries, brickworks and an iron ore field in Forthamptonshire. The industries of the district also include coal mining.

EBEL, HERMANN WILHELM (1820–1875), German Celtic scholar, studied at Berlin and Halle, and. after holding other professional posts, became professor of comparative philology at the University of Berlin. He died at Misdroy on Aug. 19. 1875. His most important contribution to Celtic philology was his revised edition (1871) of Kaspar Zeuss's *Grammatica Crltica. A* selection of his papers was published in English as *Celtic Studies,* edited by Sullivan (1863).

EBEL, JOHANN GOTTFRIED (1764–1830), German-born writer whose affection for Switzerland caused him to settle there and to write the first Swiss guidebook. was born at Zullichau, Prussia, Oct. 6, 1764. He became a scientist and physician with wide interests and the political views of an early liberal. During a stay in Switzerland (1790–92), and influenced by Albrecht von Haller, Rousseau and German philhelvetic trends. he developed a liking for the Swiss people, history and landscape. In 1793 he published his *Anleitung, auf die niitzlichste und genussvollste Art die Schweiz zu bereisen,* which dealt systematically with all aspects of the country. Many revised editions and translations show its great renown for almost 50 years. All his books deal with Switzerland; they include *Schilderung der Gebirgsvolker der Schweiz* (2 vol., 1798–1802) and *Über den Bau der Erde im Alpengebirge* (2 vol., 1808). In 1801 he was naturalized and in 1810 settled in Zurich, where he died on Oct. 8, 1830.

See H. Escher, "J. *G.* Ebel," in *80. Neujahrsblatt zum Besten des Waisenhauses in Zurich* (1917). **(A. Bx.)**

EBENACEAE, a family of dicotyledonous trees and shrubs including the ebony (*q.v.*) and other valuable timber trees. It has 5 genera, with about 325 species, chiefly tropical or subtropical, and especially abundant in Malaya. The fruit is usually a berry. Several tropical species are cultivated for their edible fruits. whereas the oriental persimmon (*Diospyros kaki)* is one of the most important fruits of China and Japan and is also cultivated in various parts of North America. The family is represented in the United States by two species of persimmon (*q.v.*).

EBERHARD (d. 939), duke of Franconia from 918 to 939. was the brother of Conrad, duke of Franconia and German king (911–918). In 915 Eberhard supported his brother's ineffectual action against the rebellious duke of Saxony, Henry the Fowler. On Conrad's death Henry became king as Henry I, probably at Conrad's wish. Eberhard renounced all claim to the kingship. but in exchange was almost completely independent in Franconia. In 938 Eberhard rebelled against Henry's son Otto I (king from 936). but was defeated and fined; he allied himself with Henry of Bavaria, the king's brother, and Giselbert of Lorraine. In 939 he launched a new rebellion. His forces were surprised by King Otto at Andernach on the Rhine and Eberhard was killed in the battle.

EBERHARD IM BART (1445–1496), count and later duke of Württemberg, was born at Urach on Dec. 11. 1445, the second son of Louis I, count of Wurttemberg-Urach (d. 1450). He succeeded his brother Louis II in 1457 under the regency of his uncle Ulrich of Württemberg-Stuttgart (d. 1480) and came of age in 1459. In 1468 Eberhard made a pilgrimage to Jerusalem, returning through Italy. In 1474 he married Barbara di Gonzaga, daughter of Lodovico III of Mantua. Keenly interested in the new learning of the Renaissance, he founded the University of Tiibingen in 1477.

In 1473 Eberhard had acquired the countship of Sulz. The crucial treaty of Münsingen (1482) between him and his cousin Eberhard VI the Younger, of Württemberg-Stuttgart, established the law of primogeniture and made him the sole count of Württemberg as Eberhard I; if he left no heir he was to be succeeded by his cousin. However, the latter was incompetent and irresponsible. and in 1485 Eberhard disinherited him. At Esslingen, in 1492, he provided for a regency by the estates after his own death. Eberhard granted charters to Stuttgart and Tübingen and reformed the convents (secularizing some) and the administration. In 1488 he joined the Swabian league and soon became a leading member. In 1495 the German king Maximilian I constituted Eberhard duke of Württemberg and Teck and confirmed the law of primogeniture in the duchy. Eberhard died at Tübingen on Feb. 24,1496. Despite the settlement of Esslingen, Eberhard the Younger succeeded him.

See F. Ernst, *Eberlzard im Bart (1933).*

EBERHARD, JOHANN AUGUST (1739–1809), German philosopher and lexicographer, a defender of Leibniz' system against Kant's and the compiler of a dictionary that remained in use for 100 years, was born on Aug. 31, 1739, at Halberstadt, where his father was a singing master and schoolteacher. Graduating at Halle, he took holy orders, but became somewhat estranged from orthodox Lutheranism through the influence of Moses Mendelssohn and C. F. Nicolai, whose acquaintance he made in Berlin. In his *Neue Apologie des Socrates* 11772) and in his *Allgemeine Theorie des Denkens und Empfindens* (1776) he advocated (1) the free examination of religious doctrine and (2) epistemological rationalism in the manner of Leibniz and Christian Wolff. In 1778, however. he was appointed professor of theology at Halle. Eberhard attacked Kant's critical philosophy as being superfluous in view of what Leibniz and Wolff had already done. His later philosophical work. including *Sittenlehre der Vernunft* (1781), *Theorie der schonen Kiinste und Wissenschaften* (1783). *Allgemeine Geschichte der Philosophie* (1788) and *Handbuch der Aestketik* (1803–05), is less noteworthy than his German dictionary. *Versuch einer allgemeinen deutschen Synonymik,* 6 vol. (1795–1802). The abridged version of the dictionary, *Synonymisches Wörterbuch der deutschen Sprache* (1802). was republished in the 16th edition in 1903–04. with English, French, Italian and Russian translations. Eherhard died at Halle on Jan. 6. 1809.

EBERSWALDE, a town of Germany which after partition of the nation following World War II became a regional capital of the *Bezirk* (district) of Frankfurt an der Oder. German Democratic Republic. It is situated 61 km. (38 mi.) N.E. of Berlin on the Berlin-Pasewalk railway. Pop. (1959 est.) 31.969. The Finow canal runs through it and about a mile to the north the Oder-Havel canal, which takes large vessels, flows through the heavily wooded area of the Eberswalde forest and the Mönchs heath. A forestry school was founded in Eberswalde in 1830 and the town has the forestry faculty of Berlin university. Eberswalde became industrialized in the 19th century and produces cranes that are exported throughout the world. The town received its municipal charter in 1257 and was sacked during the Thirty Years' War. In the middle of the 18th century Thuringian cutlers settled there. In World War II the town was occupied by Soviet forces in April 1945.

EBERT, FRIEDRICH (1871–1925), German Social-Democratic statesman and president of the Weimar republic from 1919 to 1925, was born in Heidelherg on Feb. 4. 1871, the son of a tailor. By upbringing a Catholic. Ehert later left the church. Apprenticed to a saddler he visited Karlsruhe and Munich as a journeyman and

in 1889 went to Mannheim, where he entered a circle of Social Democrats influenced by Ferdinand Lassalle. He was an active trade unionist and, despite repeated police warnings and spells of unemployment, he established branches of his union in many north German towns, including Bremen. He settled there in 1891 and soon became chairman of the Bremen Saddlers' union. During 1893 he worked on the editorial staff of the Social Democratic newspaper *Bremer Bürger Zeitung*. As an untiring and effective speaker he quickly reached a leading position in the local party organization. Although familiar with the popular writings of Marx and Engels, Ebert went by the 1891 Erfurt program of social democracy. Ideologically he belonged to the Marxist centre and had an optimistic Marxist faith in "progress." His special talent lay in party organization and practice; the fierce theoretical contests within the party hardly interested him.

After his marriage in May 1893, Ebert opened a tavern, which became a centre of political and trade union activity. In 1900 he was elected to the Bremen city council, where he gained a sound grasp of municipal politics and rose to be president of the Social Democratic party (S.P.D.) faction. In March 1900 he became labour secretary to the newly founded trade union cartel in Bremen. As a specialist in social affairs and in labour and insurance law, he won a respected position in Bremen politics. He gave special attention to the feminist movement, the condition of schools and the electoral law. His attempt to abolish the existing class suffrage in Bremen failed; but he won over important Liberal elements for a common struggle against the powerful position of the senate. As co-chairman of the S.P.D. party convention in 1904 he became more widely known, and in 1905 he was elected as secretary to the party central committee in Berlin, where he remained until his death. Always objective in argument and bent on compromise, Ebert won the confidence of all groups in the party (except for the radical left, to which he always felt alien). He was thus able to compose many serious differences between party and trade unions, as well as conflicts with, or within, regional party bodies. He supported close collaboration with the unions, as in the question of mass strikes, and attained their reconciliation with the S.P.D.

As secretary of the party committee Ebert dealt with financial matters and also with the party's youth department (from 1908 he directed the central office for Germany's young workers), but his main work was in party organization. He remodeled the central office and district branches and radically improved the party's electoral machine, thus being partly responsible for the S.P.D.'s great electoral victory of 1912 (from 43 seats in 1907 to 110), when he became *Reichstag* member for Elberfeld-Barmen. In 1911 Ebert had declined the co-chairmanship of the party congress, but accepted when at Jena in Sept. 1913, he was elected by a large majority to succeed August Bebel (d. Aug. 1913) as co-chairman with Hugo Haase. Ebert, though basically opposed to war, supported the S.P.D.'s vote for the war credits in 1914. Shortly before the crucial vote on Aug. 4, 1914, however, he was sent together with Otto Braun, the party treasurer, to Zürich so that they might conduct the party from Switzerland, should it suffer a wartime ban. Back in Berlin by Aug. 6, he resumed the party leadership along with Haase. At first he was not prominent in the *Reichstag* group, where Eduard David and Philipp Scheidemann dominated. Always aiming at compromise, Ebert nevertheless insisted on the block vote once a majority decision in the party group had been taken. When Haase resigned (Dec. 1915) Ebert became chairman of the group with Scheidemann on Jan. 11, 1916. Because of his high office as leader of the party and of the *Reichstag* group Ebert now won dominating influence in the S.P.D. In March 1916, the party's leftist minority voted in the *Reichstag* against the war credits. On Ebert's initiative they were expelled. Then, at Easter 1917, they founded the new Independent Socialist party (U.S.P.D.) under Haase.

Firmly against German wartime annexations, Ebert was equally insistent that the pre-1914 frontiers of the *Reich* should be preserved even in the border lands of Alsace-Lorraine. He upheld compulsory military service throughout the war, though two of his sons were killed in action. In June 1917, Ebert led the German delegation to the Socialist peace conference in Stockholm. From then on, Ebert led his party into close collaboration with the *Reichstag's* so-called majority parties which were aiming at parliamentary government. In this way he restored the S.P.D., weakened by the leftist defection, to a position of influence. He was a leading member of the interparty committee which prepared the peace resolution of July 19, 1917, and took part in the defeat of the chancellor, Georg Michaelis, in October. Dragged against his will into the ammunition workers' strike of Jan. 1918, he successfully worked for its swift resolution.

Ebert's chairmanship of the central committee of the *Reichstag* (from July 1918) further strengthened his own and the party's position. He supported Prince Max of Baden as chancellor from Oct. 3. By the end of October some measure of parliamentary government had been achieved; thus the Social Democrats had attained their longstanding aim. Ebert however continued to advocate the maintenance of the monarchy. At noon on Nov. 9, anticipating the abdication of the emperor William II (Nov. 28, 1918), Prince Max handed over the chancellorship to Ebert, who even now hoped to establish a regency; later the same day, however, Scheidemann, to Ebert's dismay, proclaimed a German republic, and Ebert, fearing that extremists would take charge, accepted the *fait accompli*. To maintain order he allied himself with the army under Chief Quartermaster General Wilhelm Groener, a decision of fatal consequence to the Weimar republic. On Nov. 10, Ebert (with Haase) became co-chairman of the Council of People's Representatives, the new cabinet formed by the S.D.P. and U.S.P.D. He overrode the Independents and pressed for a national assembly, successfully quashing the U.S.D.P. plan for oligarchic rule by the council. After some hesitation Ebert put down the extreme leftist risings of the winter of 1918–19 and later. This led to a further break with the Independents and earned him the hatred of the radical left, who accused him of betraying the workers. On Feb. 11, 1919, the national assembly, meeting at Weimar, elected Ebert provisional president, and in Oct. 1922 the *Reichstag* extended this term until June 30, 1925.

As president, Ebert, frequently present at cabinet meetings, strongly influenced the choice of chancellors and general policy. Supported by Braun, now the prime minister of Prussia, he overcame many crises. Under his leadership the government survived Wolfgang Kapp's ineffective *Putsch* in March 1920, moving to Dresden and then Stuttgart. Determined to maintain the constitution and German national unity, especially during the Bavarian crisis of 1923, he did not hesitate to call in the army's assistance as permitted under article 48 of the constitution. Yet, fully aware of the dignity of his office, he never exceeded its constitutional powers. In foreign affairs he strongly disapproved the treaty of Rapallo (April, 1922) with Russia; over this he fell out with Walter Rathenau, the foreign minister. He supported the policies of Rathenau's successor, Gustav Stresemann, though distrusting the man. Later he took account of the growing trend to the right (visible especially in the election of 1924) by nominating rightist chancellors (W. Cuno, W. Marx and H. Luther).

Through his unobtrusive and objective conduct of office, his conciliatory spirit and his tact and dignity, Ebert won above all the esteem and respect of the educated middle class, but became increasingly estranged from his party. He became the target of a callous and systematic nationalist agitation mainly intended to prevent his re-election. Mocked as the "saddlers' apprentice," he was accused of treason for his part in the ammunition workers' strike of Jan. 1918. A court decision at Magdeburg (Dec. 1924) took up these defamations. This unjust decision was widely and indignantly rejected. Ebert was nevertheless shaken by the course and result of the case; he had received inadequate support even from sections of the S.P.D. where his impartiality was not understood. Though gravely ill he declined to go to a hospital so that he might be available as witness. The postponed treatment caused his death of appendicitis on Feb. 28, 1925.

The death of Ebert, "the Abraham Lincoln of German history" (Theodor Heuss), was a great blow for the young Weimar republic; the civilian was succeeded by the imperial General-Fieldmarshal von Hindenburg. His son F. Ebert published a collection

of Ebert's writings and speeches, *Schriften, Aufzeichnungen, Reden,* 2 vol. (1926).

EBIONITES (Heb. *ebionim,* "poor men"), a title given to an early Christian sect which retained and exaggerated the Jewish interpretation of Christianity probably provided by the "Judaizers" opposed by the apostle Paul. Explicit mention of them is first found in Irenaeus (c. 185), who says that they believed in one God. the Creator. taught that Jesus (son of Joseph and Mary) was the Messiah. used only the Gospel of Matthew, rejected Paul as an apostate from the Jewish Law. interpreted the prophets in a singular fashion and venerated Jerusalem as the house of God. Later writers state that the Ebionites were founded by a certain Ebion and that Jesus became Messiah because he obeyed the Jewish Law. They denied the pre-existence of the *Logos,* although some of them finally accepted the virginal conception of Jesus. By the 3rd or 4th century. when their doctrines are reflected in the *Clementine Homilies* and (to a lesser extent) *Recognitions (see* CLEMENTINE LITERATURE), they were describing Jesus as the "Son of Man" and the true "prophet" of Deut. xviii. 15; they were removing what they regarded as interpolations from the Old Testament in order to uphold their teaching. which included vegetarianism, holy poverty and frequent ritual washings. They rejected sacrifices and the Jewish Temple regarding its destruction as due to God's condemnation of it. At the same time some, at least, among them came to accept Gnostic doctrines of cosmic dualism.

Most of the features of Ebionite doctrine find anticipations in the teachings of the Qumran sect, as revealed in the Dead sea scrolls. It would appear that the movement arose after the destruction of the Temple in A D. 70 and for a time came close to Jenish Christianity; though Christianity, especially under the influence of the apostle Paul. was developing as a universal religion, the Ebionites insisted on views like those held in conservative sectarian Judaism. They finally found the Gospel of Matthew unsatisfactory and developed their own literature, including the Gospels of the Ebionites and of the Nazarenes *(see* APOCRYPHA, NEW TESTAMENT; NAZARENES).

Attempts made in the 18th and, especially, the 19th century to find primitive Christianity reflected among the Ebionites are generally regarded as misguided. While the early church was influenced by sectarian Judaism such as that reflected in the Dead sea scrolls, it contained within itself a more "catholic" germ and, well before the fall of Jerusalem, had turned toward the gentile world. When the Ebionites rejected Paul they were not following the example of the Jerusalem church.

EBNER-ESCHENBACH, MARIE VON, FREIFRAU (1830–1916), Austrian novelist knonn for her sensitive portrayals of Austrian life in village and castle, was born at Zdislavič, Moravia, on Sept. 13, 1830, the daughter of Count Dubsky, and was brought up there. In 1848 she married the Austrian captain, later field marshal, Moritz von Ebner-Eschenbach, and lived first at Vienna, then at Klosterbruck, where her husband had a military appointment. In 1863 she returned to Vienna where she remained until her death on March 12, 1916. Her first literary venture was the drama *Maria Stuart in Schottland,* produced at the Karlsruhe theatre in 1860, but she found her true sphere in narrative. Beginning with *Die Prinzessin von Banalien* (1872). she graphically depicted in *Boiena* (1876) and in her masterpiece, *Das Gemeindekind* (1887; Eng. trans. *The Child of the Parish,* 1893) the surroundings of her Moravian home, and showed a true sympathy with the poor and their problems and an unsentimental understanding of children. *Lotti, die Uhrmacherzn* (1879), *Zwei Comtessen* (1885; Eng. trans. 1893) and *Unsühnbar* (1890) described with equal insight the life of the Austrian aristocracy. She also published collections of aphorisms, parables, fairy stories and poems. Her wit and masterly character-drawing make her one of the outstanding German women writers of her time.

EBONY, the wood of trees of the genus *Diospyros* (family Ebenaceae), widely distributed in the tropical parts of the world. The best kinds are very heavy, deep black. and consist of heartwood only. On account of its colour, durability, hardness and susceptibility of polish, ebony has been used for cabinetwork and inlaying, piano keys, knife handles and turned articles.

Ebony was among the articles of merchandise brought to Tyre (Ezek. xxvii, 15), and Herodotus states that the Ethiopians every three years sent a tribute of 200 logs of it to Persia. By the ancients it mas esteemed of equal value for durability with the cypress and cedar. According to Gaius Solinus in his *Polyhistor,* it was employed by the kings of India for sceptres and images, also, on account of its supposed antagonism to poison, for drinking cups.

The hardness and black colour of the wood appear to have given rise to the tradition, alluded to by Robert Southey in *Thalaba, the Destroyer* (1801), that the tree produced neither leaves nor fruit, and was never seen exposed to the sun.

The best Indian and Ceylon ebony is furnished by D. *ebenum,* nhich grows in abundance throughout the flat country west of Trincomalee. in Ceylon. The tree is distinguished by the width of its trunk, and its jet-black, charred-looking bark, beneath which the wood is perfectly white until the heart is reached. The wood is stated to excel all other varieties in the fineness and intensity of its dark colour. Although the centre of the tree alone is employed, reduced logs one to three feet in diameter can readily be procured. Much of the East Indian ebony is yielded by the Coromandel ebony *(D. melanoxylon),* a large tree attaining a height of 60 to 80 ft., and 8 to 10 ft. in circumference, with irregular rigid branches, and oblong or oblong-lanceolate leaves. The wood of *D. tomentosa,* a native of north Bengal, is black, hard and of great weight. *D. montana,* another Indian species, produces a yellowish-gray, soft but durable wood. *D. quaesita* is the tree from ahich is obtained the wood known in Ceylon as *Calamander.* Its closeness of grain, great hardness and fine hazel-brown colour, mottled and striped with black, render it valuable for veneering and furniture making. D. *dendo,* a native of Angola, is a valuable timber tree. 25 to 35 ft. high, with a trunk 1 to 2 ft. in diameter. The heartwood is very black and hard and is known as black ebony, also as billetwood, Gabun, Lagos, Calabar or Niger ebony.

What is termed Jamaica or American ebony, and the green ebony of commerce, is produced by *Brya ebenus,* a leguminous tree or shrub, having a trunk rarely more than 4 in. in diameter, flexible spiny branches, and orange-yellow, sweet-scented flowers. The heartwood is rich dark-brown, heavier than water, exceedingly hard and capable of receiving a high polish.

EBRO (anc. IBERUS or HIBERUS) is the only one of the five great rivers of the Iberian peninsula to flow into the Mediterranean. It drains the largest catchment area, about one-sixth of Spain. The river rises in springs at the foot of Peña Labra (Reinosa) in the Cantabrians and flows for 5i6 mi. in a southeasterly direction to its delta in the province of Tarragona. To Haro, its upper valley is steep and narrow, but by the time it reaches Tudela it has been joined by powerful affluents. According to the Spanish proverb, "the Arga, the Ega and the Aragon made the full-grown Ebro." Wide terraces flank the river down-

stream and many fast Pyrenean tributaries join it, some exceeding 100 mi. in length (Segre, 160 mi.). Except for the Jalón (145 mi.), the right-bank tributaries from the Iberian mountains are short and unimportant. At Mequinenza the Ebro enters a deep gorge and many defiles through the Catalan mountains, finally entering its delta below Tortosa. Barges can navigate the Ebro to Tudela in the rainy season, but navigation stops at Mequinenza with low water and only small boats can sail up the 15 mi. from the delta to Tortosa.

The Ebro collects 222 tributaries, the largest of which have been utilized for hydroelectric power and irrigation. By the mid-1950s a system of 35 major dams could store 1,673,600,000 cu.m. of water. produce 789,300,000 kw.hr. of electricity and irrigate 919.715 ac. of land. By far the largest dam is the Pantano del Ebro (near Reinosa), followed by those of Tremp and Camarasa and Escales. The right bank of the Ebro valley from Tudela to 5 mi. below Saragossa is irrigated by the Imperial canal (begun by Charles V), and the Tauste canal skirts the opposite bank for a shorter distance.

(J. M. Ho.)

EBROÏN (d. A.D. 680 or 683), Frankish statesman of the Merovingian period, prominent in the struggle between Neustria and Austrasia and also remembered for the martyrdom of St. Leger. Becoming a mayor of the palace for Neustria on the death of the previous mayor Erchinoald (*c.* 664), Ebroi'n forthwith took absolute control of affairs and completely overshadowed the king. Clotaire III. who had just come of age. As certain public offices had been usurped as hereditary perquisites by a feu- old families, Ebroin proceeded to expel the members of these families from court. This policy provoked lasting resentments. which he suppressed ruthlessly. When Clotaire died (673), Ebroi'n, without consulting the assembly of bishops and magnates, took it on himself to designate Clotaire's younger surviving brother Theuderic (Thierry) III as king. but the Neustrians rose in revolt and appealed to the elder brother, Childeric II of Austrasia. Theuderic and Ebroi'n were imprisoned for a time, but Childeric soon lost the affection of the Neustrians and was assassinated (675). Theuderic then recovered his throne. but a son of Erchinoald was appointed mayor instead of Ebroi'n. While Leger, bishop of Autun, influenced the Burgundian nobles to declare themselves for Theuderic, Ebroi'n went over to the Austrasians and put forward a new king, Clovis III. As soon, however, as he had subdued the Neustrians and made himself mayor of the palace again, he broke with Clovis. To save Autun from siege. Leger gave himself up to Ebroi'n, who put his eyes out, cut his tongue off and, two years later: had him beheaded.

On the assassination of Dagobert II. who had been restored to the Austrasian throne in 676, the new Austrasian mayor of the palace. Pepin II. resumed the struggle against Ebroi'n and the Neustrians, but was defeated at Bois-du-Fays near Laon *c.* 679. Ebroi'n was eventually killed bv an act of private vengeance.

Nineteenth-century historians credited Ebroi'n with great projects. but the only ancient author to speak favourably of him was the author of the *Miracles of St. Martial:* "By crushing the proud and the wicked . . . , he restored peace everywhere."

EBURACUM: *see* YORK (England).

EÇA DE QUEIRÓS (QUEIROZ), **JOSÉ MARIA** (1845–1900), the greatest Portuguese novelist. was born on Nov. 25, 1845, at Póvoa de Varzim in the north of Portugal. He was the illegitimate son of a young magistrate, José Maria de Almeida Teixeira de Queiroz, and Carolina Augusta Pereira de Eça, the daughter of a lieutenant colonel. His parents did not marry until 1849: the young Eça de Queirós was brought up by relatives and spent little time at home until his undergraduate days were over. After attending the Colégio da Lapa in Oporto he proceeded in 1861 to the University of Coimbra. where his main interests were reading widely in French and acting in plays presented by the university's dramatic club. On graduating in the faculty of law in 1866. Eça de Queirós went to join his parents in Lisbon where his father, a prominent magistrate. helped him to make a start in the legal profession. Queirós' enthusiasm was for literature, however, and he was busy writing stories, ironic, fantastic, macabre, often gratuitously shocking. and essays on a wide variety of themes for the *Gazeta de Portugal;* many of these were collected later in *Prosas Bárbaras* (1903). In Oct. 1569 he sailed for a tour of the near east with his friend, Count Resende. His impressions of the tour. nhich did much to awaken his passion for exact description, hitherto subordinate to a taste for the fantastic, are to be found in *O Egipto* (1926). He was back in Lisbon on Jan. 3, 1870, and in July was appointed to a post in the municipal service of Leiria. Toward the end of his stay there. in May 1871, appeared the first number of *As Farpas,* pamphlets of social and political criticism written by Queirós and his close friend, Ramalho Ortigão. In 1871 also he was closely associated with the group of fornard-looking intellectuals, often known as the "generation of '70," which organized the Conferências do Casino ("Casino lectures"); one of the lectures. on realism in art. was delivered by Queirós who denounced contemporary Portuguese literature as "unoriginal. conventional, hypocritical and false."

He was appointed consul in Havana. Cuba, toward the end of 1872. His activity in Cuba on behalf of the exploited Chinese labourers. who came under Portuguese protection because they had embarked at the Portuguese south China port of Macao. merits praise, though he nas unable to provide a final solution for their difficulties His reports on the welfare of Portuguese immigrants in the U.S. and Canada whom he visited in 1873 also show his deep concern for social amelioration. Late in 1874 he was appointed consul in Newcastle upon Tyne. The articles he contributed to the Portuguese press on English life and letters during his residence in England from 1874 to 1888 are collected in the *Cartas de Znglaterra* (1903) and *Crdnicas de Londres* (1945). In 1875 there appeared in the *Revista Ocidental* the first version of his powerful novel *O Crinte do Padre Amaro,* a vivid revelation of the ruinous effects of clerical celibacy and a clerical education on a weak nature and of the dangers of ignorant fanaticism in a provincial backwater. Fuller, revised editions appeared in book form in 1876 and 1880. In 1878 came another outstanding novel, *O Primo Basílio* (Eng trans by Roy Campbell, *Cousin* **Bnzilio,** 1953), a biting satire on so-called "romantic" passion and its tragic consequences which recalls the theme of Flaubert's *Madame Bovary.*

Queirós was transferred to the consulate in Bristol in 1879. In 1880 he published *O Mandarim,* a fantasy or satirical farce of less weight and power than the preceding novels. A similar novel, compounded of fantasy and farcical humour, is *A Relíquia,* published in book form in 1887 (Eng. trans. by A. F. G. Bell, *The Relic,* 1954). On Feb. 10, 1886, Queirós married Dona Emília de Castro Pamplona, a sister of Count Resende. In June 1888 appeared what is probably his masterpiece, the long, substantial *Os Maias* In this detailed. broad picture of mainly upper-middle-class and aristocratic society the social satire is still effervescent; the theme, as in the two chief earlier novels, is based on unlawful sexual relations, but the ending is, surprisingly, less calamitous.

Queirós was appointed consul in Paris in Aug 1888. In the last decade of his life his critical verve and his ability to create characters diminished and. in the view of some critics, a sentimentalism crept into his work nhich was alien to the earlier Eqa de Queirós. Nevertheless, his last novels. *A Ilustre Casa de Ramires* (1900) and especially *A Cidade e as Serras* (1901; Eng. trans. by Roy Campbell, *The Czty and the Mountains,* 1955), both extolling the beauty of the Portuguese countryside and the joys of rural life, have many devoted readers.

Queirós died in Paris on Aug. 16, 1900.

ÉCARTÉ, a game of cards. invariably played for a stake. It was probably first played in Paris in the first quarter of the 19th

century. It is one of a family of "short" games developed from *triomphe* or trump and is related to euchre (*q.v.*).

The play is two-hand, though three or more players frequently participate by chouette. or betting with or against either player. The pack of 32 cards is used. the cards of each suit ranking K (high). Q. J, A, 10, 9. 8, 7. Each player receives j cards, and the 11th card is turned for trump. Either player may "stand," whereupon the original hands are played out. If neither player stands, each discards his unwanted cards and receives enough new cards to restore his hand to five. Again each player has opportunity to stand—and so on, until one decides to play. If neither player stands and the pack is exhausted, the hand must be played. The card turned for trump is never changed during the deal. Either player holding the king of trumps may score one point by showing it before the opening lead. The play is largely mechanical, since the second player must win the lead if he can. A trick is won by the higher trump or the higher card of the suit led. The object is to win three or four tricks, counting one point, or all five tricks (vole), counting two. If the original hands are played and the one who stood fails to take at least three tricks: his opponent scores two points. The game is five points.

Skill at écarté consists in judging when to play and in making inferences as to the adverse cards when the opponent does not choose to play. The first matter has been reduced to a complete calculation of the *jeux de règle* ("regulation hands") that have at least a two to one chance to win three tricks. The second point; however, sometimes warrants standing on a weaker hand.

See A. H. Morehead, R. L. Frey and G. Mott-Smith, *The New Complete Hoyle,* rev. ed. (1956). (G. MH.)

ECBATANA (Old Persian HANGMATANA), an ancient city on the site of which stands the modern town of Hamadan (*q.v.*) in the province of Kermanshah. Iran. Situated at the foot of Mt. Orontes (Alvand), Ecbatana was the capital of Media and the summer residence of the Xchaemenid kings, being afterward also one of the residences of the Parthian kings. According to the Greeks it was founded by the half-legendary Deioces (*q.v.;* 8th–7th century B.C.), the first king of the Medes (*cf.* Herodotus i, 96 ff.). Ecbatana is not mentioned in extant Assyrian inscriptions. In the Old Testament it is mentioned in the book of Ezra (vi, 2). A description of the city is given by Herodotus and by Polybius (x. 27). Though surrounded by seven walls and possessing a citadel that was at the same time a treasure house. it was captured by Cyrus the Great from Astyages in 550 B.C. and was taken from the last Achaemenid by Alexander the Great in 330 B.C. Ecbatana is mentioned by Herodotus as the place where Cambyses died, but this is probably a mistake for Hamath (in Syria). The only Xchaemenid kings known to have built at Ecbatana are Darius I and Artaxerxes II. Found on the site were two inscribed foundation plaques of Darius and inscribed column bases of Artaxerxes recording his construction of an audience hall. A quantity of gold and silver jewelry, vessels, plaques and weapons of Xchaemenid date, now in museums and private collections, is said to come from Hamadan. These finds include objects bearing the names of Ariaramnes. Arsames, Xerxes. Artaxerxes I and II and Darius II.

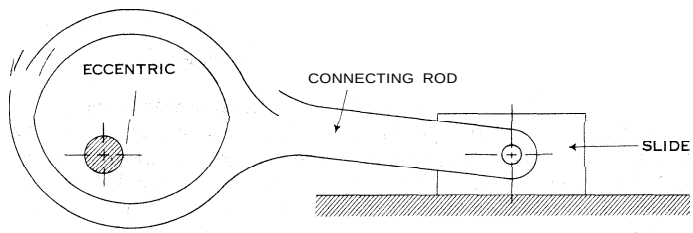
ECCARD, JOHANN (1553–1611), German composer known for his setting of the year's cycle of Lutheran chorales, was born at Mühlhausen in 1553. He was a choirboy at Weimar before becoming a pupil of Orlando di Lasso in Munich in 1571. After serving Jacob Fugger in Augsburg (1577–78), he joined the Königsberg chapel of Prince Georg Friedrich of Preussen-Xnsbach in 1579, becoming *Kapellmeister* in 1604. From 1608 till his death in Berlin in autumn 1611, he was *Kapellmeister* to the electors of Brandenburg.

Eccard wrote in a narrow range of forms, his songs and early Masses recalling Lasso. He favoured short sacred pieces, vocal and instrumental, culminating in the cycle of chorale settings, *Geistliche Lieder uuf den Choral* for five voices (1597). These miniatures represent a masterly fusion of choral song and polyphonic motet and avoid the stark economy advocated by some Lutheran extremists.

See F. Blume, *Die evangelische kirchenmusik (1931).* (B. L. TR.)

ECCENTRIC, from two Greek nords. meaning literally "out from the centre," and thus used to connote generally any deviation from the normal. In ancient astronomy the word denotes a circle round nhich a body revolves. but whose centre is displaced from the visible centre of motion. In early times the ellipses in which the planets revolved around the sun as focus could not be distinguished from circles. but the unequal angular motion due to ellipticity was observed.

A point, however, can be found on the major axis of the ellipse (namely the empty focus) such that the angular velocity of the planet about it is nearly constant. It was therefore supposed



FROM HALL AND AZPELL, "MECHANISM PROBLEMS." BY PERMISSION OF PITMAN PUBLISHING CORP.

DIAGRAM OF AN ECCENTRIC MECHANISM

The eccentric, mounted off centre, rotates inside the connecting rod and gives a reciprocating motion to the slide

that the deferent of the epicycle of the planet moved uniformly in a circle about this point.

In engineering, an eccentric is a disk mounted out of centre on a shaft, to give reciprocating movement to a lever; it is an agent much used in steam engines and other mechanisms. It is fixed with a key or screw onto the crankshaft and moves the valve rod to and fro to control the flow of steam and the exhaust. Using two eccentrics with link motion. the engine can be reversed, and the steam used expansively. *e.g.,* in locomotives. when a good rate of speed has been reached.

A reversing eccentric is one with a slotted fitting whereby it can be moved in relation to the shaft. thus reversing the action of the valve to run the engine in the opposite direction. This is but little used, however, the link motion having preference. Eccentrics are also fitted on the popular drop-valve steam engines, being located then on a shaft running parallel with the cylinder. An eccentric is often employed to work a pump and to operate the slides of certain machines. such as those for shearing and punching. Eccentrics are used to work the jaws of powerful rock and stone crushers, and to close quick-acting clamps and safety mechanisms that check slipping. Where a large offset is desired, however, a linkage generally is preferred.

ECCHELLENSIS (ECHELLENSIS), **ABRAHAM** (*c.* 1600–1664), a learned Maronite. was born at Eckel. Syria. Educated at Rome. he became professor of Arabic and Syriac in the college of the Propaganda at Rome. and in 1646 professor at the Collège de France. Invited to take part in the preparation of an Arabic version of the Bible, Ecchellensis returned in 1652 to Rome. where he died. Qf his Latin translations of Arabic works, the most important was the *Chronicon Orientale* of Ibnar-Rāhib (1653), a history of the patriarchs of Alexandria. With Giovanni Borelli he wrote a Latin trsnslation of the 5th. 6th and 7th books of the *Conics* of Apollonius of Perga (1661). He also published *Eutychius vindicatus, sive Responsio ad Seldeni Origines* (1661). To Le Jay's polyglot Bible he contributed the Arabic and Latin version of Ruth and the Arabic version of the third book of Maccabees.

ECCLES, the name of an English family of musicians the most important of whom are referred to below.

SOLOMON ECCLES (1618–1683) was horn in London. A teacher and composer, he wrote the music for Thomas Otway's *Venice Preserved* (produced in 1682). In 1660 he became a Quaker and

publicly burned his instruments and music, claiming in his most important work. A *Musick Lector* (1667), in the form of a discussion between three churchmen. that only "musick that pleaseth God" can be approved of. In 1671 he joined a Quaker mission to the West Indies led by George Fox and was later expelled from Barbados for speaking seditious words. He returned to England and may have begun composing again but he died in London on Feb. 11. 1683.

JOHN ECCLES (1668–1735). Solomon's eldest son and pupil, succeeded Nicholas Staggins in 1700 as master of the King's Band of Music and in the same year was second in a competition for the best setting of William Congreve's *The Judgement of Paris.* He published three volumes of theatre music and a collection of over 100 songs. He wrote the music for Queen Anne's coronation in 1702 He died at Kingston-upon-Thames, Jan. 12. 1735.

See J. Jeffreys, The *Eccles* Family (1951). (C A. L)

ECCLES, a municipal and parliamentary borough of Lancashire. Eng.. lies on the north bank of the Manchester ship canal. 4 mi. W. of Manchester. Pop. (1961) 43.184. Area 5.3 sqmi.

Before the Reformation the monks of Whalley abbey had a grange there at what is still called Monks hall, and in 1864 many thousands of silver pennies of Henry III and John of England and William of Scotland were discovered near the spot. From early times "wakes" were held at Eccles, and bullbaiting, bearbaiting and cockfighting were carried on. Under Elizabeth I these festivals were abolished but were revived under James I and maintained until late in the 19th century. The church of St. Mary, believed to date from the 12th century, has been much restored. There are several modern churches and chapels and a town hall. Among a variety of industries the chief are engineering and metalworking. Eccles cakes, made of pastry with currants, have a wide reputation. The town was incorporated in 1892. Eccles and the borough of Swinton and Pendlebury form the borough constituency of Eccles, which returns one member.

ECCLESIA, by etymology a gathering of those summoned *(eccletoi),* was the most general word for an assembly of citizens in a Greek city-state, and in the early Christian church became the word for "church." As an institution it had its roots in the Homeric *agora* (*q.v.*), the meeting of the people. All normal Greek city-states probably had something to correspond to it, but its composition and powers differed widely from city to city and from time to time. The most detailed evidence for the development and working of the institution comes from Athens.

Development at Athens.—The earliest recorded activity of the Athenian people as a body was when it nipped in the bud Cylon's attempted *coup d'état* about 632 B.C. It may have given a mandate to Draco for the first codification of the law (*c.* 621) and it certainly did to Solon for his (probably 594). Solon extended membership of the *ecclesia* and of the *heliaea* (in effect the people sitting as a court of appeal) to the *thetes,* the lowest of the four property classes into which he had divided the citizens. As this class probably comprised all who had not enough land to qualify as *zeugites,* the class immediately above, the *ecclesia* became coterminous with the body of male citizens of 18 years or over. Apart from the right to hear appeals (in what type of cases we do not know) in the *heliaea,* the only indisputable powers exercised by the people at this stage were a part in the elections of the chief magistrates *(see* ARCHON) and the conferring of extra-legal rights on individuals. It may have had the final decision in making war and peace. Legislation was at this stage infrequent and administration was largely in the hands of magistrates drawn from the top, or the top two, property classes. But if Solon did set up a new council *(boule, q.v.)* of 400 beside the old aristocratic council of the Areopagus (*q.v.*), his aim must have been to secure for the *ecclesia* a wider share in public business by providing it with a steering committee. After the constitutional interlude of the tyranny (561–510 B.C.) Cleisthenes in 508 revived and increased the power of the *ecclesia* by setting up a *boule* of 500, selected by lot on a genuinely representative basis. Between this date and the completion of Ephialtes' reform in 462 the *ecclesia* became the dominant organ of the state.

Composition, Procedure, Powers at Athens and Elsewhere.—In full democracies all male citizens of age were entitled to attend meetings and sometimes a quorum was required for all or for certain types of business. In Athens a quorum of 6,000 was laid down for a resolution on an individual or for an ostracism (*q.v.*). In Magnesia on the Maeander a quorum of 600 is mentioned, and in Gortyna in Crete one of 300. In some states, for example Iasus and Rhodes, the attendance of poorer citizens was encouraged by paying them. At the beginning of the 4th century B.C. pay was introduced at Athens, at first one obol for each meeting, rising during the century to one and a half or one drachma according to the type of meeting. In order to ensure that the *ecclesia* played its full part, provision was often made for regular, as opposed to specially summoned. meetings. At Athens in the 4th century B.C. four regular meetings were prescribed for each tenth of the year; one of these four was designated the "master" assembly (*kyria*). For each of them there was certain prescribed business, the most important (such as the confirmation of the magistrates in their offices, consideration of ways and means, the safety of the realm) being reserved for the master assembly. Such a provision for regular meetings was widespread, being found for example in Delphi. Delos, Thera, Samos and Miletus.

At Athens the *ecclesia* was summoned. both for regular and for special meetings, by the *prytaneis,* a committee of the *boule,* and they fixed the agenda, insofar as it was not legally prescribed, and advertised it. In the late 5th century one of the *prytaneis* was chosen to be chairman, *epistates,* of the *boule* and the *ecclesia,* holding the position for one day only. In the 4th century nine *prohedroi* were chosen by lot out of the councilors whose tribes were not for that turn providing the *prytaneis* and this board presided over the *ecclesia,* their *epistates,* also chosen by lot, putting the motions to the vote. These extreme steps to prevent a politician from exploiting the chairmanship of the *ecclesia* were not universal. Elsewhere than at Athens, and probably at Athens too at an earlier date, magistrates or politicians presided, generals at Syracuse for example, "leaders of the people" at Argos, polemarchs at Orchomenus. At Athens motions had to originate in the council, which formulated any. proposal made into a preliminary resolution *(probouleuma).* This was then laid before the *ecclesia* either as a recommendation or without prejudice. After discussion, open to all members, a vote was taken, usually by show of hands *(cheirotonia),* sometimes by pebbles (*psephoi*). Whichever method was used the measure was called a *psephisma.* A simple majority determined the result. There was no group voting. The *ecclesia* could amend a *probouleuma* freely, but could only initiate new business by instructing the council to bring a specific matter before the next meeting of the *ecclesia.* In 4th century theory laws *(nomoi)* were more sacrosanct than *psephismata* and the *ecclesia's* power to make or amend them was therefore more rigorously controlled. Changes had to originate in the *boule* or *ecclesia,* but final decision rested with a large panel of jurors, called when so acting *nomothetai.* A similar institution is found at Chios, Samos and Teos among other places. At Athens the distinction was breaking down a few decades after its inception at the end of the 5th century B.C. A more effective check on the *ecclesia's* legislative sovereignty was the suit for illegal procedure (*graphe paranomon)* under which, if the proposer of a *psephisma* or *nomos* was arraigned and condemned, the *psephisma* or *nomos* was annulled. Finally at Athens impeachments *(eisangeliai)* for serious political offenses might be brought before and decided by the *ecclesia.*

Assemblies of this type continued throughout the Hellenistic and Roman periods, though with gradual atrophy of their powers under the Roman empire.

The leagues, which came much to the fore from the 4th century B.C. onward, usually had assemblies, voting either by heads or cities. The Aetolian league (*q.v.*) had a primary assembly called *ecclesia* to which all citizens of the constituent communities belonged. It met at least twice a year, once for the election of magistrates. From the 3rd century B.C. the Achaean league (*q.v.*) had both regular and extraordinary meetings of an *ecclesia,* at which voting was by heads. In Lycia a primary assembly gave way in the 2nd century B.C. to an assembly at which voting was by

cities in proportion to their population.

Early Christian Church. — The word *ecclesia* only gradually acquired the specialized sense of "church." It probably came to the New Testament by way of the Septuagint, uhere it occurs about 100 times, almost always to render the Hebrew *qahal,* "gathering." It is found only twice in the Gospels, in highly controversial passages (Matt. xvi, 18; xviii, 17). In Acts it is frequent, being used of pagan gatherings, of gatherings of Christians in individual places (Jerusalem. Antioch, Ephesus) and houses and of the Christian community as a whole. Where the reference is Christian the attribute "of God" is always to be understood. if not expressed. In Colossians and Ephesians refinements are developed, leading on to the speculations of the Apostolic fathers and concepts like the tnofold nature of the church, as militant and triumphant. (A. R. W. H.)

ECCLESIASTES, one of the wisdom books of the Old Testament (see WISDOM LITERATURE), is a collection of aphorisms divided into 12 chapters. In the Hebrew Bible it belongs to the so-called "festal scrolls" (*megilloth*) and is placed between the Song of Solomon and Lamentations; in the Septuagint and later versions it stands between Proverbs and the Song of Solomon because, like these two books, it was associated with King Solomon.

Authorship and Contents. — Unlike the series of sayings in Proverbs, which belong to different periods and are ultimately popular lore, Ecclesiastes is presented as the work of a single author. The writer uses a pseudonym, which is unusual in the Old Testament, calling himself qoheleth ("preacher"; Gr. *ecclesiastes*). In the first two chapters the author claims to be "the son of David, King in Jerusalem" (i, 1; *cf.* i, 12), which can mean only Solomon. Solomon was of course well known as a wise man, and the author may have identified himself with this famous wise man of the past as a device to give greater authority to the book.

Ecclesiastes consists of nearly 40 loosely arranged aphorisms, varying from 3 to 15 lines in length. They may have been a collection from a sage's notebook, perhaps edited and arranged by the original writer, the preacher. Important skeptical utterances are placed at the beginning (i, 3–ii, 23), followed by advice to enjoy the day (ii, 24–26) before death makes an end of everything (iii, 19 ff.). The key word "death" connects iii, 18–22 with iv, 1–3 and v, 9–17 with v, 18–vi, 9. In vii, 1–ix, 12 there are five maxims on unjust events, each with its own special point but fitting well together. Particular attention is given to the concluding sections: xi, 1–8 is an exhortation to lead a full life though death is the end, and xi, 9–xii, 7 describes allegorically the decay of the aging man and his way to the "eternal home" of the grave. (In xii, 1, "Remember also your creator," the word "creator" is probably a false reading for "pit"; *i.e.,* "grave.")

Main Themes. — First and foremost among the themes of Ecclesiastes is the preacher's skepticism. Claiming the support of experience, he constantly questions the ordering of this world in which a man does not get his deserts; a good example is the early death of a just man. who should have had a long life (vii, 15). The senseless intervention of death makes men like cattle (iii, 19). All the attempts of man to mold his happiness are limited by predestination (vi, 10) and by the chances of time (ix. 11). A man does not know what time is favourable to his purposes (viii, 2–8; ix. 12).

Recognition of these terrible truths, however, does not make the preacher deny the rule of God. On the contrary, he conceives of God as an awful majesty, but hidden and incomprehensible. Though in comparison with the deism of the "enlightened" wisdom writings the preacher approaches the prophetic view of Cod. he is still far removed from it. He advises prudence in visiting the temple and in vows and prayers (v, 1 ff.; iv, 17 ff. in Hebrew text). In contrast to the Book of Proverbs he never uses "Yahweh." the name of God used in worship and prophecy; he always speaks of God in an almost impersonal sense. It may be that God has given his good creation a time plan clear to himself (iii, 11) and unalterable (iii, 14). What troubles man is that he can never comprehend God's plan. God blesses those that please him and lets unhappiness befall those that displease him; it is his pleasure alone that decides to which group a man belongs.

When the preacher speaks of the good fortune of the dead in comparison with the living, and still more of those who (being aborted) have never seen the light of day (iv, 2–3), this extreme phraseology is not intended to drive the hearer to complete nihilism or suicide; its aim is to counteract a naïvely "enlightened" attitude by a call to wholesome sobriety. A man should not give himself up to illusions, but in spite of his basic skepticism should enjoy gratefully his small day-to-day pleasures. Death is the final end (ii, 16; xi, 8); the preacher questions the belief in a life after death in "heaven" (iii, 21). The body is given to dust, and the spirit, which thereby loses its individuality, is taken back by God (xii, 7).

The repeated phrase "Vanity of vanities [*i.e.,* absolute vanity], all is vanity" is often regarded as the keynote of Ecclesiastes and may indeed have been part of the preacher's own teaching, but this maxim on the emptiness of existence, stressed at both the beginning and the end (i, 2; xii, 8), is, like the introductory verse (i, 1), an addition made by a pupil. It corresponds, however, to the preacher's phrase "all is vanity and striving after wind" (i, 14, 17, etc.). But this theme of the emptiness of life is not the keynote of the book, and it would be a mistake to try to attribute to another author all sayings in Ecclesiastes that take a more positive attitude.

The preacher affirms the relative value of wisdom as against foolishness but, in contrast to the tradition of the schools which saw in wisdom security for life, he recognizes its limitations. He cannot countenance the naïve optimism of the schools for he knows the other side of existence: the impenetrability of fate, the incalculability of death, etc. Even if one concedes a certain breadth of range to the aphorisms, that does not exclude the possibility of later alterations, made with the aim of softening maxims which might cause offense. This is shown most clearly by the passage added at the end (xii, 9–14). Here, most probably, two editors have been at work, the first (xii, 9–11) affirming the hard but true sayings of his master and acknowledging himself his master's pupil in the work, the second (xii, 12–11) deeply disturbed by the preacher's skeptical and impious attitude and regretful that such a heretical book should be made public. Reading it is justified only if, by making a great effort, one perceives in it the call to obedience under a God who acts justly. The aphorisms in iii, 17; vii 29–viii, 1; viii, 5; viii, 12b–13; xi, 9c, probably also derive from this second "corrective" editor.

No direct quotations from Ecclesiastes are found in the New Testament.

Sources and Parallels. — Aphorisms often traveled a great distance in the ancient east and were a kind of nomadic possession. Parallels to the preacher's aphorisms — for instance, the call to enjoy life in the face of death, as well as the skeptical utterances — are found particularly in Egypt but also in Akkadian wisdom literature.

Attempts have been made to find traces of Greek philosophy in Ecclesiastes (especially in ch. i), but i, 4–11 is not about the elements discussed by the early Greek philosophers, nor has the eternal sameness in the succession of mankind on earth or of wind, sun and rivers anything to do with Heraclitus' aphorism "all is flux" or with the doctrine of Stoic cycles. In iii, 1–15, too, it is alternative activities, each of which has its appropriate time, that are spoken of, not an ordered rotation. A more probable theory is that Greek gnomic teaching became known in Jerusalem at the time of the preacher through bilingual coastal dwellers. An attempt has been made to trace connections with the aphorisms of Theognis of Medara (6th century B.C.), but this too is hardly successful; Theognis' largely political skepticism is directed against the rise of the lower classes! a point on which the preacher is indifferent. The gulf between Ecclesiastes and Greek wisdom becomes

particularly plain in the light of the demotic wisdom literature of Egypt of the 1st century A.D.; in this are found aphorisms that are indeed Egyptian in form but that none the less breathe the Greek spirit in their fundamental outlook.

Date and Provenance.— The writer's period and origin can be deduced only indirectly. The language is late Hebrew in syntax and vocabulary; there are a relatively large number of Aramaic forms, although the book has certainly not been translated from Aramaic. Attempts have been made to read into iv, 13–14, ix. 13 ff. and x, 16 ff. allusions to certain events under the Ptolemies or Seleucids (3rd century B.C. onward), but these verses may merely be giving typical illustrations unconnected with history. (This of course is no argument against the date as such.) Since there were Greek sympathizers in Jerusalem in the first 30 years of the 2nd century, some scholars, assuming Greek influence, would advance the date to that time. This cannot be categorically refuted but it is improbable because in that same period in Jerusalem Ecclesiasticus (*q.v.*) was produced, a strictly "orthodox" book of maxims expressing a similar attitude to that of the second epilogue to the preacher's work (Eccles. xii, 12–14). In addition, a fragment of Ecclesiastes was found in a cave at Qumran that has been dated mid-2nd century. Ecclesiastes thus must have had a semi-canonical appearance as early as c. 150; otherwise the Qumran Essenes would not have taken it over. That being so, a date around about 250–200 B.C. is more probable.

The book must have been written in Jerusalem. It certainly cannot be derived from Phoenicia and hardly from Alexandria. It was long doubtful whether Ecclesiastes was worthy of inclusion in the Hebrew canon, and an origin outside Jerusalem would probably have been a decisive factor against such an inclusion.

(KU. G.)

ECCLESIASTICAL LAW (ENGLISH) is a body of law concerned with the constitutional position of the established Church of England vis-à-vis the rest of the state and with the church's internal constitution, with the appointment, rights and obligations of its ministers and other officers, with the functioning of the church's courts, with forms of service and with proprietary rights so far as the church's property is concerned. It is administered largely by the ecclesiastical courts.

Within the framework of the divine law. the Church of England claims the right to make regulations, and these cover a wide variety of subjects including matters liturgical, pastoral, proprietary and disciplinary. These form part of the canon law (*q.v.*) and as such were accepted as part of a body of law binding on all Englishmen. In the middle ages it was not doubted that within the realm of England the law of the church and the common law were both of binding force; spiritual courts and temporal courts alike exercised jurisdiction. At the Reformation and with the Act of Supremacy (1534) the authority of Rome terminated, and by the end of the 17th century the royal supremacy thus established had come to mean effectively the supremacy of parliament. But the law of the land and the church's courts continued to function. What is more, the whole of pre-Reformation canon law remained, save insofar as it was expressly or by implication altered by legislation. but legislation by, or by the authority of, the temporal power, and not legislation emanating from Rome. In England, therefore, the ecclesiastical law of the established church includes both pre-Reformation canon law and post-Reformation acts of parliament. It also has to take account of canons passed by the two convocations of Canterbury and York (*q.v.*), which, after receiving the royal assent, have a limited authority over the clergy; and it has to take account of measures of the church assembly which, under the Church of England Assembly (Powers) act, 1919 (the Enabling act), may pass measures which, though subject to parliamentary scrutiny, have, on receiving the royal assent, all the force of an act of parliament.

Ecclesiastical law is for the most part administered in the ecclesiastical courts, which are as much royal courts as are the temporal courts; but, just as a point of temporal law may fall incidentally to be decided in an ecclesiastical court, so may a point of ecclesiastical law occasionally arise for decision in a temporal court. By the Ecclesiastical Courts act (1855) the ecclesiastical courts lost their jurisdiction in defamation; by the Court of Probate act (1857), they lost their jurisdiction in testamentary matters; and by the Matrimonial Causes act (1857) they lost it in matrimonial cases. By far the greater part of their work is concerned with faculties for the introduction or removal of things to or from consecrated buildings or land or for alterations to such buildings. But they still also exercise a criminal jurisdiction over the clergy for ecclesiastical offenses.

The supremacy of the crown in church and state (which, as has been said, means in practice a parliamentary supremacy), resulting in the fact that the law of the church and of the state is one law and that all courts, ecclesiastical and temporal, are alike courts of the land with their decrees enforced by the same temporal power, is perhaps the most obvious distinguishing mark of the establishment. Other religious bodies exist and have freedom of worship and freedom to run their own affairs. In the eyes of the law, however, they are simply associations of like-minded persons, as in a club, whose relationship, *inter se,* is essentially a matter of contract between them. This does not mean that they escape the law. It means that they manage their affairs and determine their own disputes in their own way according to their own rules, insofar as these do not run counter to the law. But. as in the case of any club, in the ultimate resort their rules can be tested and enforced only by recourse to the courts of the land, which involves a secular court in the task of considering doctrinal points, as, indeed, happened in the Scots case of *The General Assembly* of *the Free Church* of *Scotland* v. *Lord Overtoun and others* (1904). Like everyone else, too, they cannot escape parliamentary control, if and insofar as parliament wishes to control them.

The present freedom of non-Anglicans, however, has been conferred upon them by parliament, which has by stages removed from them various disabilities, the two main landmarks in history being the Toleration act (1689). which applies to Protestants, and the Roman Catholic Relief act (1829). Nor have all differences between Anglicans and non-Anglicans been removed. For example, the occupant of the throne may be neither a Roman Catholic nor married to one; a Roman Catholic may not be lord chancellor; nor may a Roman Catholic present to a living in the Church of England; nor (in strict law, not in practice enforced) may Roman Catholics assume various ecclesiastical titles, such as bishop of a diocese. The nonconformist layman is under no legal disability, and such minor disabilities as still in theory apply to nonconformist ministers are a dead letter. Privileges, too, have been conferred on non-Anglicans. Their priests or ministers, for example, are exempt from jury service; and the place of worship of any religious denomination is exempt from rates.

Courts.— In Anglo-Saxon England ecclesiastical causes were heard in the court of the shire or the hundred, in which the bishop (or, in the hundred court, the bishop or archdeacon) sat with the temporal judges. But William the Conqueror removed ecclesiastical causes from the temporal courts and thereafter they were heard in ecclesiastical courts, whose jurisdiction, however, was wide. The main courts were, in ascending scale, those of the archdeacon, of the bishop and of the archbishop, with appeal lying ultimately to the pope or his delegates. There was not, however, a close adherence to this tidy arrangement. Frequently a higher court claimed concurrent original jurisdiction with a lower one, and there were many peculiars that did not fit into any neat scheme.

Originally the archbishop, bishop or archdeacon was the chief. judge in his own court; but from about the middle of the 12th century professional judges, clerks in at least minor orders, began more and more to exercise the judicial function. As such they came to be known as the official principals of the courts over which they presided, and toward the end of the middle ages the bishop's judge mas also his vicar-general with authority to exercise various

administrative functions not demanding the possession of bishop's orders. These ecclesiastical lawyers in the first decade of the 16th century formed themselves into a society, analogous to the Inns of Court and known as Doctors' Commons (*q.v.*). In 1545 Henry VIII removed the necessity for orders as a qualification for ecclesiastical judicial appointment. Henry VIII also put an end to all appeals to the pope (Statute of Appeals, 1532) and substituted a final appeal to the king in chancery (exercised by the high court of delegates). Some causes were in fact entertained at first instance by the court of high commission.

In the 20th century the ecclesiastical courts exercise both a criminal and a civil jurisdiction. The latter, known as the faculty jurisdiction, is concerned with the oversight of consecrated land and buildings and of everything upon or in them. The archdeacon's court is virtually obsolete so far as judicial functions are concerned. Civil causes begin in the consistory court of the diocese, presided over by a judge who in practice is a barrister and who still combines in his person the functions of official principal and vicar-general and who is called the chancellor (or, in the diocese of Canterbury, the commissary). From the consistory court an appeal lies to the court of the province, known in Canterbury as the Court of Arches and in York as the Chancery Court of York. A final appeal lies from the provincial court to the privy council. Some criminal cases against clergymen for ecclesiastical offenses are tried in the consistory court with an appeal to either the provincial court or the privy council; others are tried in the provincial court with an appeal to the privy council.

Apart from the fact that the high court may by a writ of prohibition restrain an ecclesiastical court (including the privy council) from exceeding its jurisdiction, the temporal courts do not exercise control over the ecclesiastical courts. The chief officer (under the judge) of an ecclesiastical court is the registrar, and barristers and solicitors have a right of audience. (E. G. Mo.)

ECCLESIASTICUS (The Wisdom of Jesus the Son of Sirach) is one of the Old Testament books called apocryphal or deuterocanonical. In Hebrew its author is called ben Sira (*i.e.,* the son of Sira); in Greek Sira became Sirach, and the work is often called by this name. The origin of the Latin name Ecclesiasticus, which was given it as early as the time of Cyprian (d. 258), is uncertain.

Contents.—Ecclesiasticus may be divided into four main parts (enumeration according to the Revised Standard version): (1) ch. i–xliii, wisdom as a revelation of God and as a guide to conduct; (2) ch. xliv–l, praise of the ancients of Israel; (3) ch. li, 1–12, appendix, a prayer of thanksgiving for deliverance from mortal danger; (4) ch. li, 13–30, conclusion, an acrostic poem on the rewards of the study of wisdom. In the (Greek) Septuagint the book is headed by a prologue written by the translator (beginning "Whereas many great teachings have been given to us . . ."). In the Authorized (King James) version an additional, spurious prologue is prefixed to this.

Themes.—Ecclesiasticus ranks with the wisdom books of the Old Testament and shows dependence on the Book of Proverbs. Moral commonplaces couched in proverb form and arranged on no clear plan predominate in ch. i–xliii. Interspersed are passages of sustained reflection on the bases of morality and the deeper aspects of wisdom. The principles of a divine moral law imprinted on the conscience of mankind, of free will, of moral responsibility for sin and of divine retribution are emphatically asserted (xvii, 1–12; xv, 11–20; xvi, 6–23; xvii, 15–23). There is no question, however, of retribution after death, ben Sira retaining the older view of Sheol (the underworld, the home of all departed spirits). Characteristic is his insistence that the Law of Moses is the main channel by which divine wisdom comes to Israel (xxiv, 23–34). He is exceptional too, among the wisdom writers, in his expansive admiration for the spiritual value and beauty of the Temple worship with its Aaronic priesthood (xxxv, 1–11; xlv, 6–24; l, 5–21). Passages in his eulogy of wisdom as God's agent in the universe (xxiv) and in his hymn to the creator (xlii, 15–xliii) are worthy to go alongside the corresponding ones in Job and Psalms. In the New Testament, borrowings of Ecclesiasticus' thought and phraseology are found chiefly in the Epistle of James.

Authorship and Date.—A comparison of the data of Ecclus. l, 27 and the Hebrew colophon at the end of the book identifies the author as "Simeon the son of Yeshua, the son of Eleazar, the son of Sira." The words "Simeon the son of" are suspect, and the author's name was probably Yeshua—*i.e.,* Joshua or, in Greek, Jesus. He was called ben Sira, the "son" of Sira, after his grandfather. In his prologue the translator of the Greek version, the grandson of ben Sira, implies that he set about the translation "in the 38th year of Euergetes the king." This is taken to mean the 38th year of Ptolemy VII Euergetes II; *i.e.,* 132 B.C. The grandfather would have flourished 60 or 50 years before, about 190–180 B.C. This fits in with the reference in l, 1 ff. to the high priest Simon the son of Onias (or Ionias), whom the author had known but who was dead at the time of writing. This high priest was Simeon II, who died in 196 B.C., a date which confirms 190–180 B.C. as the approximate period in which ben Sira wrote.

Text and Versions.—Written in Palestine, Ecclesiasticus early won authority in certain Jewish circles, but was expressly excluded from the Palestinian biblical canon about A.D. 100. The original Hebrew text gradually dropped out of sight and was not rediscovered until 1896, when Solomon Schechter and others found extensive manuscript fragments in the genizah of an ancient synagogue at Cairo. The Hebrew manuscripts, which cover in all about two-thirds of the book, help to eliminate false readings of the Greek version, but because of their fragmentary nature and corrupt state they leave many textual problems unsolved.

The Greek version made by the author's grandson was admitted among their Scriptures by the Jews of Alexandria. Through the Septuagint, it passed on to the Christian church. Down the centuries the Greek has held the position of standard text. From it was made the Old Latin version (north Africa, 3rd century) incorporated in the Vulgate. Ecclesiasticus is more extensively used in the liturgy of the Roman Catholic Church than any other Old Testament work except the Psalter and was declared canonical Scripture by the Council of Trent.

The Peshitta Syriac version, made directly from the Hebrew about A.D. 200, is important for textual criticism.

An intriguing problem is raised by the existence of a recension of Ecclesiasticus in an expanded form found in the Hebrew manuscripts and in the versions. The expansions introduce a more advanced theology of the individual soul and its personal relationship to God and supplement the eschatology of ben Sira by insisting on retribution in "the future world." Correspondences of thought and expression between these expansions and certain portions of the Ethiopic Book of Enoch, the Book of Jubilees and the Testaments of the Twelve Patriarchs (*qq.v.*) suggest that they may be of Essenian origin. Moreover, there are similar coincidences between these glosses and the tenets of the Essenes and between them and the literature of the sectaries of Qumran, of whose library Ecclesiasticus formed a part. It is not impossible, then, that this expanded recension of Ecclesiasticus may be the work of the scribes of Qumran (*see* Dead Sea Scrolls). *See* also Apocrypha, Old Testament.

Clamer (eds.), *La Sainte Bible,* vol. vi (1946). (C. Ke.)

ECHEGARAY Y EIZAGUIRRE, JOSÉ (1832–1916), Spanish dramatist, mathematician and statesman, who dominated the Madrid stage during the last quarter of the 19th century and shared with F. Mistral the Nobel prize for literature in 1904, was born in Madrid, April 19, 1832, and died there, Sept. 4, 1916.

He taught mathematics at the school of civil engineering, became an ardent exponent of free trade and held office in several governments during the revolutionary period (1868–74). It was

not until 1874 that he turned to the theatre with the play *El libro talonario,* but during the next *30* years he produced more than *60* plays.

With Echegaray came an extraordinary recrudescence of romanticism. Although not unsuccessful in comedy (*Un crítico incipiente,* 1891) he preferred tragedy: the "period" play (La *esposa del vengador,* 1874; *En el seno de la muerte,* 1879), generally in verse, and contemporary middle-class drama, generally in prose. Of this last. examples are *O locura o santidad* (1877; Eng. trans. *Madman or Saint,* 1907) in which society condemns as madness the overscrupulous conscience; *El gran Galeoto* (1881; Eng. trans. *The World and his Wife*), a study of how calumny corrupts its innocent victims; and *El hijo de don Juan* (1892). a travesty of Ibsen's *Ghosts.* In all his plays. his manner is melodramatic. The clash of violent passions is almost invariably resolved by bloodshed and probability is relentlessly sacrificed to skilfully contrived stage effects.

See A. Martinez Olmedilla, Jose' Echegaray (1949). (H. B. HL.)

ECHIDNA, "snake." a monster of Greek mythology, half woman. half serpent. Her parents were either the sea deities Phorcys and Ceto, or Chrysaor, monstrous son of Medusa, and Calirrhoe, daughter of Oceanus. Among Echidna's progeny, by the hundred-headed Typhoeus, were the dragons of the Hesperides and of the Golden Fleece. the Hydra, the goatlike Chimaera and the infernal hounds Orthus and Cerberus. The Sphinx and the Nemean lion, both sired by Orthus, were also among her offspring. (D. E. W. W.)

ECHIDNA (SPIKY ANTEATER), a common name applied to a group of egg-laying mammals, the Monotremata, the lowest order of the class Mammalia. Spiny anteaters are native to Australia, Tasmania and New Guinea. They are heavy-bodied animals with extremely short tails. The snout is characteristically elongate and very sensitive. Teeth are lacking and insect food is obtained by means of the long. slender, tubular tongue that is coated with a sticky secretion The legs are short and stout. and the feet have long claws used in digging. The skin is covered with short, sharp spines. somewhat like those of porcupines and hedgehogs; hence the name "spiny anteater."

COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

ECHIDNA OR SPINY ANTEATER (TACHYGLOSSUS)

Echidnas often live in sandy, rocky places. When attacked they may roll into a ball. relying on their sharp quills for protection, or may burrow rapidly into sandy soil. They are nocturnal in habits. and have poor eyesight but well-developed senses of smell and hearing. The female lays a single egg that is incubated in an abdominal pouch in which the young remains for some time after hatching. The mammary glands open into the pouch.

The straight-beaked or five-toed spiny anteater (*Tachyglossus*) is found in eastern Australia, Tasmania and southern New Guinea. It varies from 15 to 20 in. in length, has a proportionately short. straight snout and coarse quills. The curve-beaked or three-toed spiny anteater *(Zaglossus)* occurs in New Guinea and adjacent Salawati Island. It attains a length of *30* in., has a relatively long, curved beak and fine quills.

See MONOTREME; MAMMAL. (R. T. O.)

ECHINODERMATA, a phylum of marine invertebrates which includes many prickly-skinned animals familiar to almost anyone who has visited the seashore in the temperate or tropical zones. The sea stars or starfishes (class Asteroidea), sea urchins (Echinoidea) and brittle stars (Ophiuroidea) are the dominant temperate-zone classes; in the tropics one is apt to encounter in addition the sea cucumbers (Holothuroidea) as well as the feather stars (Crinoidea).

These five classes into which the phylum is divided give an idea of how diversified the group is. Several aberrant classes existed in earlier periods of the earth's history but these died out before the end of the Paleozoic era (see *Fossil Echinoderms,* below).

INTRODUCTION

History. — The name Echinodermata, derived from Greek meaning "spiny skinned," was coined by J. T. Klein in 1734 and originally referred to the dry tests. or shells, of sea urchins. The name *Echinus,* still used for a genus of sea urchins, was originally applied by the Greeks to the European hedgehog as well as to the common Mediterranean sea urchins, the latter being about the same size and having spines of similar length and colour as those of their namesake on land. Klein's term, later extended to include all members of the phylum, is quite appropriate for the members of four extant classes but less suited for those of the Holothuroidea. which only rarely have large plates with spiny projections.

Importance. — In the ecology of the sea, echinoderms play an immense role. The crinoids deposit large amounts of lime through the decomposition of their skeleton, and in previous earth periods, when crinoids were dominant, they produced vast beds of limestone. Where they occur in great numbers the rock-boring sea urchins change the shore line. The sand- and mud-swallowing echinoderms remove large amounts of decaying matter that otherwise would accumulate on the sea bottom and thereby keep bacterial activities down. The sea stars are efficient scavengers and regulate the production of certain mollusks. The enormous swarms of microscopic larvae that the majority of echinoderms produce at certain times of the year constitute, with the larvae produced by other groups of invertebrates, an important food element for slightly larger plankton organisms.

For man the sea star also has a negative importance, as destroyer of commercially exploited beds of bivalves. and large sums are spent on finding methods that will curtail its activities. The simplest method has been to collect starfishes, usually by trawls. and destroy them. Recently chemicals have been used, and in some localities it has been contemplated to transfer oyster beds to water less saline than the sea stars can tolerate.

In the tropics sea cucumbers are dried and utilized as Bêche-de-Mer (*q.v.*) in a gelatinous soup, and the ripe ovaries and testes of some of the larger sea urchins are eaten raw or cooked in some parts of the world.

For the student of zoogeography the echinoderms have been most useful. As bottom forms they are restricted to the area where they have settled down, and they are usually sufficiently numerous so that material for study always can be procured. Where strong currents are present the planktonic larvae of echinoderms may be carried along and settle down within the area which is influenced by such currents, thus indicating the course of the current.

For modern experimental biology the eggs, sperm and larvae of many echinoderms have been the perfect material. The bibliography of the work performed on one single species of sea urchin fills an entire volume. Sea stars, brittle stars and sea cucumbers have been excellent subjects for experiments on regeneration (*q.v.*), and much has been learned about the reactions of invertebrates with a primitive nerve system through the numerous experiments performed on echinoderms.

STRUCTURE AND FUNCTION

Adult and Larval Characteristics. — The fundamental characteristics of the recent echinoderms are a free-swimming bilateral larva and an adult having, (1) five-rayed symmetry; (2) an internal calcareous skeleton; and (3) a peculiar hydraulic apparatus, the water-vascular system, derived from parts of the coelomic cavities and having cylindrical projections, the podia, or tube feet, that extend to the surface. As always, there are exceptions. Thus many forms have acquired large eggs that develop directly without forming a larva; a secondary bilaterality is superimposed over the five-rayed symmetry in some sea urchins and in all holothurians; and in some sea cucumbers the calcareous skeleton appears to be lacking.

Adult Echinoderms.—Mature echinoderms are bottom dwellers, living on or in the surface of the sea bottom. Some holothurians are able to swim and a few species are even adapted to an entirely planktonic existence. Certain feather stars are able to swim by raising and lowering the "arms." Most of the recent echinoderms

FIG. 1.— DIAGRAMMATIC SECTIONS OF THE FIVE LIVING CLASSES OF ECHINODERMATA SHOWING THE RELATIONS OF MOUTH. ANUS. TUBE FEET AND SPINES THE DIGESTIVE TRACT IS OUTLINED

are of moderate size. A few dwarfed forms have a body length of one to two centimetres. whereas some holothurians may reach a length of two feet or more. Some of the larger sea stars may have a diameter of about two feet. and the largest sea urchins may measure about 20 cm. in diameter. In earlier geological periods many forms reached a much greater size. Most spectacular were the ancient crinoids, some of which attained a stem length of up to 70 ft.; the few stalked forms that survive today rarely measure more than two feet in height.

The well-developed body cavity that all echinoderms possess marks them as three-layered (triploblastic) animals and thus places them high above the two-layered coelenterates with which earlier zoologists. not unnaturally. lumped them under the name Radiata. Echinoderms are nevertheless rather primitive in several respects. They possess no head and lack higher nerve centres, and their sensory organs are primitive. They have no heart and their blood vessels are lacunae. Their respiratory organs are of the simplest types, mostly thin-walled bladders, extensions from the body cavity or invaginations from the cloaca. They make extensive use of amoeboid cells for the transport of digested food and for the elimination of waste materials, and the sex products are simply shed into the water.

Larval Echinoderms.—Each class has developed a different larval form. Formerly these larvae were considered independent animals and each type was given a special name, but all represent modifications of a fundamental pattern. The fertilized egg divides and produces a typical gastrula—a hollow ball with an invagination, the intestine. In the echinoderms the original mouth becomes the anal opening while a new mouth is formed, a developmental pattern which is present in a number of othergroups, among these the vertebrates, in contrast to worms, crustaceans and mollusks, where the original mouth remains as such in the adult while a new anus is formed. From the upper end of the intestine arises on each side a hollow pouch which extends downward and becomes subdivided into three pairs, from which develop the body cavity and the water-vascular system. In an effort to co-ordinate the echinoderm development with that of the vertebrates these divisions have often been called segments, but this interpretation is no longer accepted.

Externally the early stages of the different larvae are very similar. A ciliated band develops on the anterior side of the larva, forming a loop around the area where the mouth is forming. In the simplest larval type, that of the sea cucumber, the band becomes looped like a double-lined letter H (see fig. 2). Later the outer sides of the loops form several short lobes that give it a fancied resemblance to a human ear; hence the name *Auricularia* for the larva. In the sea star even more pronounced lobes appear, forming short arms; at the same time the ciliated band above the mouth forms an independent loop and the whole end of the larva above the mouth becomes greatly lengthened. This type of larva has been known as the *Bipinnaria*. In the crinoids, where only the comparatively recent stalkless forms have been studied, the larva, known as the *Doliolaria*, is barrel-shaped and has several ciliated bands arranged as hoops. (A similar stage occurs in the sea cucumbers before metamorphosis and is the only larval stage in those forms where the Auricularia stage has apparently been suppressed.) In the three larval types described so far no skeleton is present, except in the case of some of the holothurian larvae, in which a few wheel-shaped spiculae may be found.

In the two remaining groups, the sea urchins and the brittle stars, which represent the most advanced stages within the phylum, the larvae are more complex and surprisingly similar in type. Their similarity is hard to understand when one considers how unlike the adults of the two groups are. In these forms the lobes and arms, short in the larvae described earlier, have extended into enormous slender appendages supported by delicate, reticulated calcareous rods. The early students of these larvae, who fancied a similarity of the appendages to the long legs of a painter's easel turned upside down, called them Pluteus. In modern terminology the prefixes *Echino-* and Ophio- are added to distinguish between the larva belonging to sea urchins and brittle stars. In the sand dollars and cake urchins, which represent the latest evolutionary stage within the sea urchins, an unpaired rod extends downward from the mid-line of the larva, thereby making it possible to recognize the larvae of these forms at a glance.

Metamorphosis.—During metamorphosis the bilateral symmetry of the larva disappears, with the mouth and anus shifting into new positions (often temporarily disappearing and being reformed). At the same time part of the left coelomic cavity becomes the water-vascular system, forming a ring that sends out five radial canals. Other structures, such as nerve bands, blood lacunae, etc., simultaneously develop in a pattern co-ordinated with the water-vascular system.

Five-Rayed Symmetry.— The secondarily acquired five-rayed symmetry is evident in all echinoderms except some of the extinct groups; in some of the recent forms, the irregular sea urchins and the sea cucumbers. it is more or less overshadowed by a superimposed bilateral symmetry. Most of the organ systems, including the water-vascular system, blood lacunae, oral nerve system, radial muscles and skeleton, are centred around the mouth and radiate out; they are superimposed on each other, repeating the same essentially five-rayed pattern. The digestive system, though centrally placed, deviates from this pattern. The sex glands usually show a five-rayed distribution, placed interadially, with some deviations in some of the irregular sea urchins and in the sea cucumbers, in which only one pair of glands are present, presumably the

primitive condition. In crinoids and certain brittle stars the number of arms is increased by forking. and in some sea stars new arms sprout out between the original five. There is rarely more than one madreporite, the porous plate through which water is taken into the water-vascular system. This plate. which is usually quite large and conspicuous. gives a certain irregularity to the otherwise perfect symmetry that most forms display. In sea stars and sea urchins the madreporite is usually large and easily seen on the animals' upper side. whereas in the brittle stars it has shifted to the underside. becoming one of the large plates around the mouth. In the crinoids the plate is lacking. and stone canals. of which there are several, hang free into the body cavity. In the iea cucumbers the madreporic plate lies in the mid-line of the upper side, between the mouth and the opening for the genital pore—a primitive condition—or it forms a round or oblong head that hangs free into the body cavity or is attached to the dorsal mesentery.

Skeleton. — The calcareous skeleton is formed by mesodermic cells in the deeper layer of the skin and is therefore a true endoskeleton. There is a certain similarity between echinoderms and vertebrates in the manner in which the skeleton is laid down and later, during growth, resorbed and reconstructed, but the chemical composition is different. In echinoderms the calcareous particles are laid down inside the cells, not outside them as in the vertebrates. The netlike structure of the echinoderm skeleton, the way the skeletal substance resembles a typical calcite crystal—in cleavage and in optic properties—makes it easy to recognize echinoderm skeletons and fragments of them in fossil strata. The ease with which the skeleton can be identified is one reason why echinoderm remains are so useiul to paleontologists.

Except in the sea cucumbers, the young echinoderm begins by laying down a definite number of primary plates, or ossicles, characteristic of each group. and as the animal grows, more plates are added. The place where new ossicles are added lies, in the forms having arms, behind the terminal, unpaired plate of the arm; in the other forms. sea cucumbers and sea urchins, the growth area lies around the anus. In the groups in which regular plate systems exist. the older ossicles are rebuilt and enlarged so that they keep pace with the growth of the animal. In the sea cucumbers there is often considerable difference in the size of the spiculae of the older part of the animal (located near the mouth) and the newer part (located near the anus). As the animals grow older, new types of spiculae often appear in the deeper skin layer, while the older spiculae near the surface are frequently worn off.

Water-Vascular System. — The water-vascular system, which characterizes all recent echinoderms. was probably incipient even in those extinct forms that had not yet acquired a five-rayed symmetry. The middle part of the left coelomic sac forms the main part of the system'. The anterior part of the sac supplies the madreporic plate, perforated by ciliated pores and connected to the ring canal by another canal. which, because in some forms its wall is stiffened by calcareous matter, is called the stone canal. The middle part of the left coelomic sac forms a ring around the esophagus and develops five blind-ending radial canals from which arise cylindrical outpocketings that push their way to the surface. These outpocketings. covered by skin, become the tube feet, or podia, of the adult echinoderm. In the more primitive forms—the crinoids and sea stars—the supporting skeleton lies beneath the water-vascular system. In the brittle stars the open groove with the radial canal has been roofed over by plates, the plates beneath the water-vascular system having developed into complex structures: reminiscent of vertebrae, with articulations and muscles. In the sea urchins the radial canals have somehow become placed internal to the close-fitting skeleton; the same is true of the sea cucumbers, in which the system lies well below the layer of spiculae. In the echinoderms in which the body is prolonged into arms. the podia are restricted to a band along the radial canals. In the more advanced types of sea stars the number of feet is increased by staggering the rows. In regular sea urchins the bandlike arrangement of the tube feet is retained, but also in these may occur an increase in the number of feet by pushing the plates that carry the pores for the feet into several short rows or arches. In forms like the sand dollars the number of feet on the underside is increased by their spreading over most of the suriace. In many of the more advanced sea cucumbers, some forms! like *Thyone,* the species usu-

ally used for experimental work in the U.S., are covered by a veritable fur of tube feet. In cases in which they are actively used in locomotion the podia often have an inner bladder, the ampulla, extending into the body cavity: when a tube foot contracts, liquid pours into the ampulla; reversely, when a tube foot expands, liquid is poured into the foot from the reservoir of the ampulla. Similar bladders, called Polian vesicles, are often present on the circular canal. In forms in which the podia have no ambulatory function — in the crinoids and brittle stars — no ampullae are present. In irregular sea urchins podia on the central part of the upper side function as simple gills by being flattened into thin leaves. A special function is taken over by the podia around the mouth of the sea cucumbers; these podia are modified as tentacles that take in food, either by shoveling in sand and mud by means of broad, disc-shaped tentacles or by collecting food particles on branching tentacles as in a net. In the burrowing forms the tentacles are fingerlike and help partly in pushing the animal through the mud or sand and partly in stuffing the mud or sand with its organic debris into the mouth. In the highly modified heart urchins, in which the characteristic masticatory apparatus of the sea urchin is lost, long tube feet around the mouth help to gather up food particles lying on the surface of the mud. .

CLASSIFICATION

The following taxonomic outline is the one generally accepted by the majority of invertebrate zoologists (wholly extinct classes are prefaced by an asterisk) :

Phylum Echinodermata
Subphylum Pelmatozoa
"Class Heterostelea
* " Cystoidea (Cystidea)
* " Blastoidea
" Crinoidea
* " Edrioasteroidea
Subphylum Eleutherozoa
Class Holothuroidea
" Echinoidea
" Asteroidea
" Ophiuroidea
* " Ophiocistioidea

Fossil Echinoderms. — For the paleontologist the extinct classes of echinoderms from the Paleozoic strata (a period extending from 200,000,000 to 500,000,000 years ago) are of the greatest interest and an enormous amount of information dealing with these forms has accumulated. Unfortunately, as only the skeletons are preserved, much of what has been written about the soft parts, on the basis of our knowledge of present-day forms and their development, is hypothetical. At the present time five classes are accepted for the subphylum Pelmatozoa, the primitive, attached forms including the crinoids. and the only group which still has living representatives. Of the subphylum Eleutherozoa, the unattached forms. to which most present-day echinoderms belong, only one small extinct class is known exclusively from the Paleozoic period.

FIG. 7.—FOSSIL ECHINODERMS. (A) BLASTOID OROPHOCRINUS FUSIFORMIS, (B) CRINOID BOTRYOCRINUS DECADACTYLUS

The pelmatozoans are characterized by the presence of a cup. or theca, in which the inner organs are placed, and are attached either directly to the substratum or by a shorter or longer stem. The mouth is directed upward and one or more food grooves run toward it. The animals may have arms, enclosing extensions of the body cavity, or shorter or longer articulated projections, the brachioles. Some forms may be without any such appendages.

Heterostelea.—Lowest rank the members of the class Heterostelea, in which no radial symmetry is evident; these had a mostly laterally flattened theca and a stem composed in part of a double row of ossicles. with or without brachioles. It is assumed that these forms had the stem and theca in a lateral position.

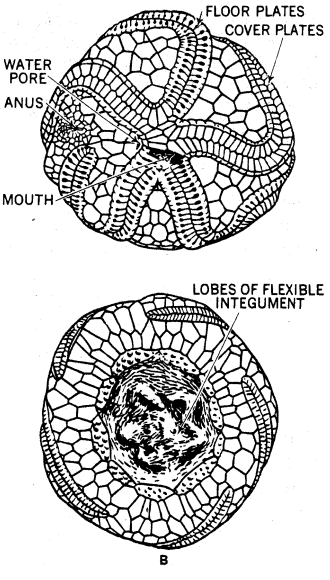
Cystoidea.—In the class Cystoidea the theca was upright, more or less spheroid, but not five rayed, and either attached to the bottom or provided with a stem. Two to five food grooves were present, bordered by simple brachioles.

Blastoidea.—In this class the theca had acquired a five-rayed structure and was directly attached or had a stem. Five food grooves were present, with brachioles along the sides; the latter were in many cases pinnulated like a feather with the grooves extending up along the pinnulae, thereby creating an enormous food-collecting surface. Many of these forms superficially resembled crinoids.

Crinoidea.—Both extinct and extant members of the class Crinoidea are characterized by genuine arms. with or without pinnulae. and usually with a stem — in the modern feather star. however. the stem disappears at an early stage—while the five-rayed pattern is pronounced. Three of the crinoid orders died out in the Paleozoic. but a fourth, which blossomed out in the Triassic period, is still extant, though chiefly represented by stalkless, unattached forms (see Extant *Echinoderms,* below).

Edrioasteroidea.—In the class Edrioasteroidea no stalk was present; the theca, more or less like a bag or a short cylinder, was possibly attached by a sucking disc. The mouth was placed on the upper side with five food grooves protected by marginal plates. The anus, likewise placed on the upper side. was covered by plates. The Edrioasteroidea is of special interest because possibly some if not all of the present-day Eleutherozoa (see below) have originated from forms related to this group.

Ophiocistioidea.—Of the extinct class Ophiocistioidea about ten species are known. They were free living, with the mouth directed downward, and had a shell. or test. reminiscent of that of a sea urchin but composed of fewer and irregular plates. The podia were few and large and formed five short double rows around the mouth. Many speculations have been made about their affinities to sea urchins and brittle stars, but probably the ophiocistioids represent merely a small branch that quickly became extinct.

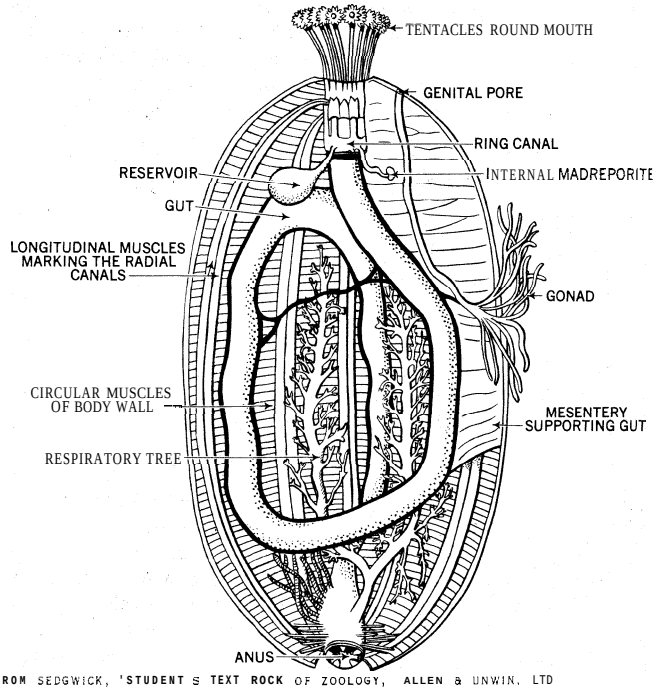


FROM E. R LANKESTER, "TREATISE ON ZOOLOGY," A & C. BLACK

FIG. 8.—FOSSIL SESSILE STAR (EDRIOASTER): (A) UPPER AND (B) UNDER SURFACES

Extant **Echinoderms.**—*Crinoidea* (Sea Lilies and Feather *Stars*).—Among the present-day echinoderms the surviving crinoids represent the most archaic type. They are attached, at least during the early stages. and have the mouth directed upward. They feed on microscopic plankton particles, which are carried to the mouth along ciliated grooves. The larva is of a simple type. and the radial canal of the water-vascular system lies in an open groove above, the arm skeleton. The sex glands are pushed out in the arms or in certain pinnulae and the mature sex products are set free by rupturing of the skin. Most of the attached forms hare a slender stem which justifies the common name sea lily. In the rare West Indian crinoid *Holopus* the stem is reduced to a short cylindrical base.

The arms divide synchronously usually once so that ten arms result; however, many forms repeat the bifurcation so that a larger number of arms are formed. Only in the most archaic species, as *Rhizocrinus,* from deep water off the coast of Norway, is the primitive five-armed condition retained. About 80 species of stalked forms are described from the deep water of present-day seas, although thousands of species populated the ocean bottom in earlier geological periods. In contrast there are now about 550 species of stalkless feather stars occurring in both shallow and deep water.



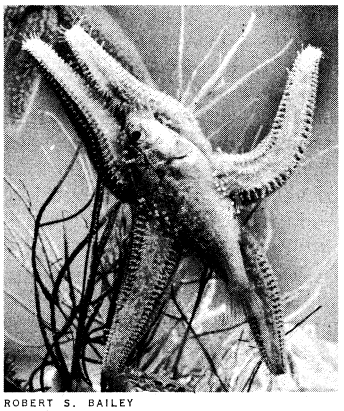
FROM SEDGWICK, 'STUDENT S TEXT ROCK OF ZOOLOGY, ALLEN & UNWIN, LTD

FIG. 9.—A HOLOTHURIAN, OR SEA CUCUMBER, OPENED ALONG THE BACK

Holothuroidea (Sea *Cucumbers*).—Among the recent Eleutherozoa the sea cucumbers look least like echinoderms, with their strong development of muscles and with a skeleton usually reduced to microscopic spiculae or totally lacking. In a few forms larger plates are present, but not in a definite arrangement as in the other groups. Formerly sea cucumbers were considered an evolutionary offshoot from the sea urchins with which they share a lack of free arms; a meridianlike arrangement of the radial canals, which run from mouth to anus; closed ambulacral (podial) grooves; and skeletal elements placed external to the water-vascular system. But the extremely simple larva, the single pair of gonads and, in the more primitive forms, the position of the madreporic plate between the mouth and the genital pore all indicate a phylogenetic position far removed from the sea urchins. In contrast to all other echinoderms the sea cucumbers move with the oral end forward and the lengthened oral-anal axis parallel to the bottom. The underside, with three radial canals, is designated as the trivium and the upper side, with two canals. is called the bivium. The animals develop a bilateral symmetry, and there is usually a pronounced difference between the podia of the underside, which function as in sea urchins and sea stars! and those of the upper side, which often are nipplelike, with the sucking disc reduced. In two orders no tube feet are present. and in one of these orders even the radial canals are lacking. For catching their food the animals use the modified tube feet or tentacles around the mouth. A peculiar respiratory organ is present in three of the five orders: a pair of hollow, branching invaginations from the cloaca called the respiratory trees. or water lungs. Through these water lungs sea water is taken in and is expelled after an exchange of oxygen and carbon dioxide takes place. These organs are lacking in the most primitive order, the deep-water Elasipoda. and in the forms without tube feet and radial canals. the Apoda, a condition possibly indicating a close affinity between these two groups.

About 700 species of sea cucumbers are known. A large number are shallow-water forms; particularly important are the members of the genus *Holothuria,* with about 80 species. which inhabit the tropical reefs.. The primitive Elasipoda, deep-water species, are the most extreme abyssal forms; they have been taken at more than 7.000 m. depth, as the Challenger and later the Galathea expeditions have amply demonstrated.

Asteroidea (Sea Stars or Starfishes).—Sea stars have the ambulacral grooves open and the larval type is simple. Except for the few species that sprout a larger number of arms between the original ones, the five-rayed condition is prevalent. The group is easily recognized by its star-shaped body though the arm length varies from virtually nonexistent in the pentagonal cushion stars to extremely long in other species. In the more primitive forms, like *Astropecten,* the arms are bordered by large marginal plates that give a certain rigidity to the arm; in these species the tube feet are relatively few. In evolutionarily higher starfish the marginal plates are insignificant and the tube feet, often numerous, are placed in three to four rows. Among these forms the stomach can be everted and wrapped around the prey. which is then digested outside the body.



ROBERT S. BAILEY

FIG. 10.— STARFISH (ASTERIAS FORBESI) WITH STOMACH EVERTED. PARTIALLY ENVELOPING A FISH

There are about 1.200 species of asteroids known from all parts of the oceans. Species from deeper water depend mostly on decaying matter for food and use ciliated paths for bringing the food particles to the mouth. In the colder parts of the world, where oysters and mussels abound in shallow water, one finds the more modern. aggressive forms of starfishes. They are particularly numerous in the North Pacific, an area where the lines between related species are not well defined. where great variability is displayed and where hybridization apparently often takes place.

Echinoidea (Sea Urchins, Sand Dollars, etc.).—The sea urchins have a highly developed larval form and the ambulacral grooves are closed. with the entire skeleton lying as a solid wall external to the grooves. The boxlike skeleton with its sharply defined plates. the highly developed articulating spines of all sizes and shapes, the efficient, three-pronged pincers and the complex dental apparatus in most forms all indicate the high developmental stage that the sea urchins have reached. From the regular forms. which live freely exposed on the sea bottom. two aberrant groups have arisen with members that live more or less concealed in sand or mud In both groups the anus has moved out from the central position and the animals have become secondarily bilateral. In the sand dollars the dental apparatus is preserved. whereas in the heart urchins the mouth has become excentrically placed and the dental apparatus is lost: they live in mud and their food is collected by the large tube feet around the mouth. About 700 sea urchins exist at the present time, a fraction of what was found in earlier periods.

FIG. 11.—AN ECHINOID. OR SEA URCHIN. SPLIT HORIZONTALLY WITH THE ORAL HALF TO THE LEFT

Ophiuroidea (Brittle Stars).—The brittle stars! with their slender arms sharply set off from their disc-shaped body, have a complex larva similar to that of the sea urchins, and the ambulacral groove on the arms is closed. They are more active than most other echinoderms because of the strong development of the muscles attached to the vertebralike plates in the arms. The podia, on the other hand, function merely as sensory organs but may also assist in bringing food particles to the mouth. Brittle stars have no intestine or anus and they feed chiefly on microscopic organic debris that is sifted by the numerous spines situated in front of the mouth. The size is moderate to small for the majority. A few species, however, have arms that are more than two feet in length; these giants are usually found clinging to the large six- to seven-foot-long sea pens (certain coelenterates) in deeper water. The smaller, shore forms are found in sand, mud, under rocks, in sponges and among algae. In deeper water, on muddy bottom, brittle stars occur in such quantities that the bottom is literally paved with them. About 1,700 species have been described, an indication that the class is definitely one of the most successful groups of echinoderms.

See also articles on various echinoderms; namely, BÊCHE-DE-MER; SAND DOLLAR; SEA CUCUMBER; SEA URCHIN; STARFISH; and references under "Echinodermata" in the Index volume.

(EL D)

ECHINOIDEA, a class of the Echinodermata (*q.v.*), comprising the sea urchins (*q.v.*), heart urchins and sand dollars.

ECHINUS, in architecture, a convex molding. under the abacus of a column capital, so called from its resemblance in form to a sea urchin (Greek *echinos*). It is universal in both Greek and Roman Doric orders in which it has a profile of circular or elliptical curvature, Roman examples have a *cyma recta,* double curved (*see* CYMA) profile. The convex molding between the volutes of the Ionic order is termed an echinus. as is any similar form in a capital of any style. See MOLDING; CAPITAL; ORDER.

ECHIURIDA (ECHIUROIDEA), a phylum of generally sausage-shaped marine worms that, in spite of an apparent lack of segmentation. must be considered nearly related to the Annelida (*q.v.*). Although formerly considered a class and placed in the obsolete phylum Gephyrea, together with Sipunculida (*q.v*) and Priapulida (*q.v.*), echiuroids have little in common with the former, and it is probable that supposed relationships with the latter can be altogether discounted.

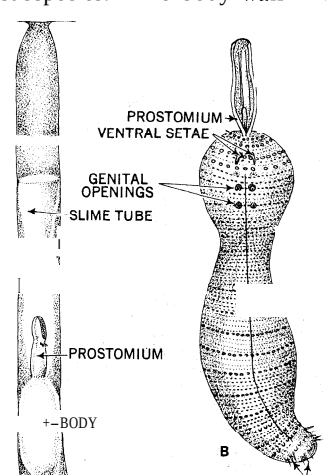
STRUCTURE AND FUNCTION

Typical representatives of the Echiurida are several species that, because of the extended scooplike proboscis (prostomium) overhanging the mouth, are called spoon-worms (fig. 1 and 2). Spoon-worms are moderately large sac-shaped creatures that inhabit U-shaped tubes on sandy mud bottoms. The northern cold water species. *Echiurus echiurus,* is described below as an example.

External Features.— The body consists of a cylindrical trunk which reaches a length of 12 cm or more, and a preoral lobe or prostomium, shaped like a hemispherical fan when fully extended, which is about half as long as the trunk. The prostomium is ciliated on its ventral surface and its margins are fused at the base, forming a funnel around the mouth. During feeding the prostomium is extended over the surface of the surrounding mud, and particles of detritus are swept along ciliary tracks toward the mouth.

The trunk is encircled by rings of mucous-secreting papillae, the slime being used to line the walls of the burrow. The anus is terminal.

Autotomy (Self-Amputation).—The prostomium is readily detached from the trunk, less so in the Alaskan than in the European subspecies. The body wall in the area of detachment is thinned forming a special autotomization ring behind the mouth. and in front of this ring is a powerful sphincter muscle, which upon sudden contraction discards the anterior end. The trunk regenerates the missing parts within a few weeks and feeding is then resumed



(A) AFTER FISHER AND MACGINITIE (B) AFTER GREEF

FIG 1—SPOON-WORMS (A) URECHIS CAUPO IN ITS BURROW; (B) ECHIURUS ECHIURUS

Setae.—At the anterior end, behind the mouth, is a pair of powerful ventral bristles (setae) that are used in burrowing. At the posterior end are two incomplete rings of smaller setae, interrupted ventrally, that are used in cleansing the burrow. The setae resemble those of annelids: each seta is formed by the secretion of a single basal cell; and when an old worn seta is discarded, its place is taken by a new one derived from a reserve follicle Muscles corresponding to the protractors of an oligochaete annelid move the seta forward,

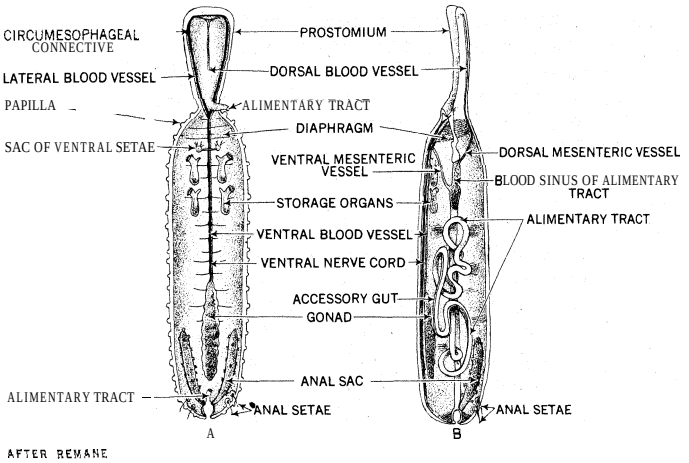


FIG. 2.—ANATOMY OF ECHIURUS: (A) VENTRAL VIEW: (B) SIDE VIEW

backward and sideways; other muscles, including an interbasal one, move the two ventral setae apart.

Body *Wall*.—The skin consists of a simple columnar epithelium that. except on the ciliated regions of the prostomium, secretes a thin cuticle. The subepidermal connective tissue layer contains yellow and red pigment cells. The muscular coat consists of three layers: the strongly developed longitudinal layer lies between the outer circular and inner oblique layers. A thin membrane, the peritoneum, separates the body wall from the spacious coelom or true body cavity (see below).

Internal **Features.**—*Body* Cavities.—The cavity of the prostomium is a system of canals and lacunae that are separated from the coelom by an incomplete partition, the diaphragm. These cavities are provided with an endothelial lining, and coelomic fluid moves freely between the two compartments. It has been shown that the prostomial cavity is derived from the embryonic blastocoele that develops a secondary connection with the coelom (fig. 3). Because of this unusual embryonic development F. Baltzer has likened the body of an echiurid to a chimera in which the anterior part is larval and the posterior part adult.

Coelomic Fluid.—The coelomic fluid contains two types of cells, spherical erythrocytes. which in the Californian species Urechis *caupo* contain a respiratory pigment similar to hemoglobin; and amoeboid leucocytes, often laden with red-brown pigment granules. In all but the youngest individuals, maturing sex cells are also found in the coelomic fluid. The coelomic fluid performs respiratory as well as nutritive and excretory functions. Respiratory exchanges take place in part through the skin, since the worm keeps up a constant flow of water through the burrow by peristaltic contractions of the body. Water is also taken into the anal vesicles and expelled periodically. According to A. C. Redfield and M. Florkin (1931). the properties of *Urechis* hemoglobin are such that it gives up oxygen at low tensions when the worm is confined to its burrow at low tide. This "oxygen reservoir function" is criticized by E. Eliassen (1954), who favours the "low tension transport" function (see also ANNELIDA: *Introduction*).

The coelomic fluid of *Echiurus* is isotonic with the sea water in which it lives and contains no plasma proteins in solution.

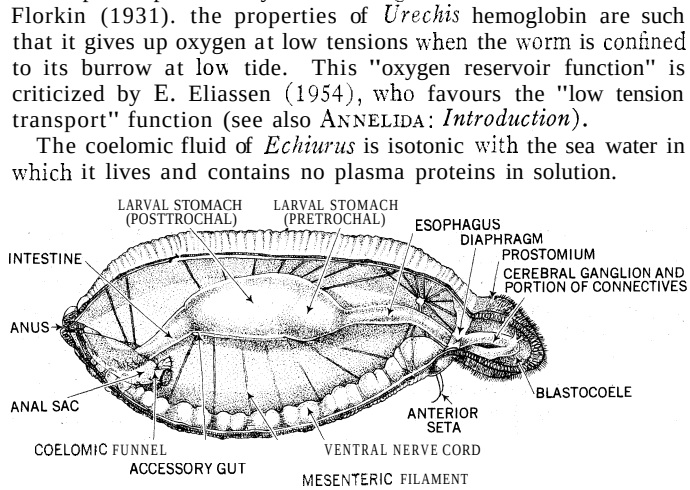

FIG. 3.—60-DAY LARVA OF URECHIS CAUPO; VIEW WITH PART OF BODY WALL CUT AWAY

Digestive System.—The mouth communicates with the pharynx, which makes a double loop in the region of the diaphragm; a thick-walled esophagus is dilated posteriorly to form a crop in which the food bolus is molded. These parts, constituting the fore-gut. are of ectodermal origin. The endodermal mid-gut, separated from the fore-gut by a sphincter, is divided into three regions, the pre-, mid- and postintestine. The midintestine is accompanied by a narro er accessory tube, which is continuous before and behind with an open ciliated groove. This accessory tube or siphon is of unknown function and. although similar structures occur in unrelated groups. as for example among polychaetes (Capitellidae) and in sea urchins, its presence is considered to be one of the more distinctive features of the Echiurida The postintestine opens into a short anal tube, also of endodermal origin. Both mid- and postintestine are strongly coiled and convoluted. The intestinal juice is alkaline and contains a powerful protein-digesting enzyme. A fat-splitting enzyme is also present, but evidence for a starch-digesting one is inconclusive.

Excretory Organs.—The anal tube receives a pair of endodermal sacs; in the newly metamorphosed larva these sacs communicate with the coelom, each by a single funnel, the nephrostome; in the adult the number of nephrostomes is greatly increased. The anal vesicles are highly characteristic of the phylum. They subserve both excretory and respiratory functions and. since they are provided with typical nephrostomes, they probably represent a posterior pair of metanephridia.

Vascular System.—The vascular system is closed; a ventral vessel runs the whole length of the trunk above the nerve cord and forks anteriorly to form a ring around the margin of the prostomium. A short dorsal vessel, confined to the anterior part of the body. receives blood from the ventral vessel by way of a sinus surrounding the mid-gut. It pumps the blood forward into a median prostomial vessel that communicates anteriorly via the marginal loop with the ventral vessel. The blood is colourless and contains only phagocytic amoebocytes.

Nervous System.—There is a ventral nerve cord in which, in the adult. no separate ganglia can be recognized. It divides anteriorly. and the circumpharyngeal connectives form a long drawn-out loop that follows the margin of the prostomium There are no special enlargements or cerebral ganglia. The ventral nerve cord arises embryonically by the union of two ectodermal thickenings and. in *Echiurus,* exhibits 16 transitory ganglionic masses. In *Urechis* the number of these supposedly primary trunk ganglia is only 12 (fig. 3).

Sense Organs.—Groups of sensory cells. nhich may be either tactile organs or chemoreceptors. underlie the epidermis and are especially abundant along the margins of the prostomium. Special sense organs are lacking in the adult, but eyespots are present in the larva.

REPRODUCTION AND DEVELOPMENT

Reproduction.—In *Echiurus* the sexes are separate but superficially alike. The gonad is suspended from the ventral vessel, and the maturing sex products are shed into the coelom. The naked eggs grow from 0.01 to 0.2 mm. in diameter, nourished by the coelomic fluid. and are then taken up by the ciliated funnels of the storage organs. In some genera, like *Bonellia,* the developing ovum is enclosed in a follicle and nutrition is mediated by a special cap of nurse cells. In males the sperm clusters also develop in the body cavity and the liberated spermatozoa are collected as they become mature and free-swimming.

There are two pairs of gonoducts that act as storage organs. They are regarded as modified metanephridia and although they perform no excretory function, are confusingly termed "nephridia" by some authors. Each of these ducts is provided with a bilobed ciliated funnel that gathers up the mature sex cells, and a large thin-walled sac that serves as a storage chamber. In *Echiurus* the funnel opens into the gonoduct close to its external end. but the presumably more primitive condition in which the funnel is at the internal end of the sac occurs in some other genera (*see* below).

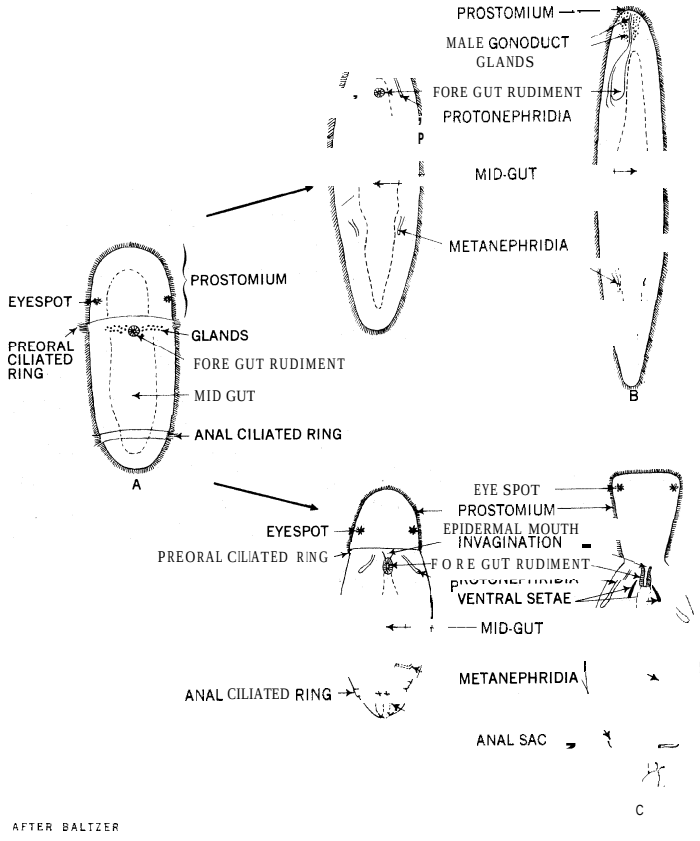
Development.—The most complete study of echiurid development is that of W. W. Newby on *Urechis.* Fertilization is ex-

ternal and the early stages show a spiral cleavage similar to that of Platyhelminthes, Mollusca and Annelida. A typical "annelidan cross" is formed from the first four cells, the first quartet, but the later stages show a predominance of supposedly molluscan features. Thus the blastopore, pushed forward ventrally by the expansion of the somatic plate, forms only the mouth. In typical annelids the somatic plate. as it grows downward on each side. unites ventrally to divide the blastopore into a mouth-forming and an anus-forming region. Mesoblastic teloblasts are absent in the better known European and North American species. Growth in length is achieved by expansion of the trunk region and not by the teloblastic addition of segments at the posterior end, as in the Annelida. However. C. N. Dawydoff described the appearance of two teloblasts and a transient metamerism in the giant larva of an unidentified echiurid from Annam. The body cavity is a schizocoele, that is, formed by splitting of the mesoblast into layers.

The embryo develops into a free-swimming trochophore of the annelidan type, provided with a pair of larval protonephridia.

Sex Determination in **Bonellia.**—Zoologists have long been interested in this problem and many outstanding contributions have been made, especially by Baltzer and C. Herbst. The trochophore becomes transformed into an indifferent larva (fig. 4). If it finds the prostomium of a female it becomes attached and remains for several days (B. *viridis*) during which period a gradual metamorphosis toward the male condition takes place. It then migrates to the fore-gut and thence to the antechamber of the female storage organ where it remains for at least one breeding season On the other hand larvae that develop in sea water uiually become females However, the presence of female extracts, from the fore-gut or prostomium, will stimulate male transformation. The active principle. which resists boiling and is probably not a protein, has not been identified Moreover, a diversity of foreign agents such as acids potassium ions, heavy metals glycerine and even shaking or transference from Mediterranean to North sea nater have been shonn to induce masculinity

The simple facts, outlined above, appear to justify the view that all larvae are potentially bisexual and that the male response is elicited by a variety of different stimuli and is therefore. fundamentally, a response to an irritant. The investigations of Baltzer have shown that when larvae are removed prematurely from the female prostomium they exhibit various stages of male transformation. The degree of intersexuality is approxiinately correlated with the duration of the attachment period, but, since extracts also elicit a graded series of transitional types, it appears probable that organs in the mouth region have a lower threshold toward the male-inducing substance than have those situated more posteriorly. Baltzer advanced the view that male transformation is essentially an inhibition. The stimulating action of potassium ions led Herbst to suggest. in view of the known effect of these ions in increasing cellular permeability, that an increased water uptake might be the masculinizing agent. and this hypothesis received support from the experimentally proved antagonistic action of calcium ions. Later Herbst suggested that glycerine derived from the metabolism of fat in the larval gut must play some role. R. Goldschmidt attempted to bring the facts in line with his famous theory of sex determination. and M. Hartmann pointed out similarities with the phenomenon of sex reversal in the polychaete Ophrytrocha. The theory that all eggs are potentially bisexual has been challenged by J. Z. Wilczynski (1960).



AFTER BALTZER

FIG 4.—LARVAL DEVELOPMENT OF BONELLIA VIRIDIS DEPENDING UPON ENVIRONMENTAL CONDITIONS THE (A) INDIFFERENT LARVA TRANSFORMS INTO A (B) YOUNG MALE OR (C) YOUNG FEMALE

CLASSIFICATION AND RELATIONSHIPS

The Echiurida is a small phylum. with over 30 genera and about 80 species Several systems of classification have been proposed; that adopted below is essentially identical with that of Dawydoff (1959):

Phylum Echiurida (Echiuroidea)
Family Echiuridae
" Urechidae
" Thalassematidae
" Ikedidae
" Bonellidae

Echiuridae.—As now restricted, this family comprises the single genus *Echiurus,* described above

Urechidae.—W K Fisher placed the genus *Urechis* in a separate order Xenopneuita on account of the absence of a vascular system There is only one ring of anal setae The small prostomium is not uied as a feeding organ; food is captured by means of a finely netted slime tube (fig 1[A]), secreted periodically by a glandular girdle, that filters the water as it is suept through the burrow by peristaltic contractions of the body. The slime tube, together with its catch, is then eaten It has been estimated that the net must have a meih with pores of 36 to 40 Angstrom (Å) units (Å = 1/10 000 000 mm), since molecules of ovalbumin can pass through, whereas those of serum globulin are partly retained and those of hemocyanin completely retained Another peculiar feature of Urechidae is the absence of a definitive gonad; the sex cells are found free in the coelomic fluid from their earliest identifiable stage There are two or three pairs of gonoducts with external funnels in which the lips are drawn out into spirally twisted, whiplike processes

Thalassematidae.—Members of this predominantly tropical and subtropical family were separated from the Echiuridae by S. Bock on account of the absence of anal setae There are seven genera. comprising some 50 species. Some thalassematids inhabit shells of sea urchins or sand dollars. *Thalassema dendroi hynchus,* from Chilka lake, a brackish bay on the northeastern coast of India, is tolerant of low salinities; both this species and a related one have gill-lie processes on the margins of the prostomium. *Anelassorhynchus abyssalis* has been taken at a depth of 1,083 fathoms off the coast of California A presumably primitive metameric arrangement of the gonoducts is found in some species of *Ochetostoma,* with three to five pairs in sequence. More usually the number is restricted to one or two pairs On the other hand *Ikedosoma* has 6 to 14 pairs, some of which are represented by groups of organs, reflecting a local, nonmetameric multiplication of the embryonic rudiment

Ikedidae.—Fisher placed the remarkable Japanese species *Ikeda taenioides,* which attains a length of over one metre in a separate order Heteromyota because, unlike the arrangement in

other echiurids, the longitudinal muscle layer is external to the circular layer.. The excessively long prostomium is readily discarded. and this part was formerly mistaken for a nemertean worm. The trend to multiplication of the gonoducts, noted above in the thalassematid *Ikedosoma,* has advanced so far in *Ikeda,* with 200 to 400 organs, that all traces of metameric paring are obliterated. The funnels are situated at the internal end—a primitive feature.

Bonellidae.—This interesting family. with over 20 genera. is characterized by a pronounced sexual dimorphism. Females are typical echiurids. distinguished primarily by the structure of the excretory organs: the nephrostomes are not sessile. but communicate with the anal vesicles, or rarely communicate directly with the cloaca by slender tubules. The prostomium is usually long and ribbonlike, but in *Nellobia* it is short and truncated; frequently it is deeply cleft or forked, as in *Bonellia* (fig. 5). In *Prometor* the margins of the prostomium unite to form a cuplike funnel at the base. There are usually two ventral setae, but they are lacking in some genera: anal setae are absent. *Acanthobonellia* has two clusters of small ventral setae on muscular pads. In *Acanthohamingia* minute ventral spinelets. without musculature, are situated in the genital groove (*see* below). There may be a single gonoduct, as in *Bonellia,* but more frequently the primitive paired condition prevails. The funnel may be apical or basal. *Archibonellia* retains a pair of supposedly larval metanephridia. and *Australobonellia* has a single such organ between the gonoducts. The siphon, rudimentary in *Achaetobonellia,* is said to be absent in *Sluiterina.* The majority of species are of an intense green colour; the pigment, known as bonelline. is a mesopyrrhochlorine. chemically a degradation product of chlorophyll. It is highly toxic to other organisms and may therefore have a protective function; the green tissues are usually rejected by predators. The lytic properties of bonelline solutions toward echinoderm larvae are enhanced by simultaneous exposure to light; it may be, for this reason, that *Bonellia,* which avoids light and is nocturnal. cannot tolerate appreciable illumination.

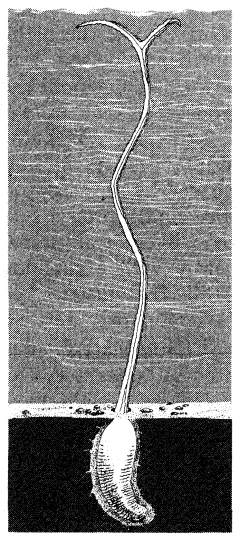


FIG. 5.—BONELLIA VIRIDIS IN ITS BURROW, WITH DIVIDED PROBOSCIS, OFTEN A YARD LONG, PROTRUDED

In the late 1950s specimens of four hitherto undescribed genera were recovered from Pacific deeps by a Soviet expedition; among these are *Vitjazema,* taken at 5,500–9.950 metres.

The males are usually minute, 1–3 mm. in length, and live as parasites upon or within the body of the female Immature stages may be found developing in the fore-gut, on the prostomium or attached to the skin. Mature males of *Bonellia* migrate into the muscular antechamber of the gonoduct; in *Achaetobonellia* this region forms a thick-walled bulbous expansion. The androeiium, or male tube, of *Pseudobonellia* is situated betneen the genital pores. Males of *Amalosoma* are found in an androecial groove in front of the genital openings; in *Acanthohamingia* this groove is set with setae. A relatively large male of *Acanthobonellia miyajimai,* 28.5 mm. in length, nas found by I. Ikeda (1907) in the body cavity of the female. Except in the possession of functional reproductive organs, the dwarf males present a combination of degenerate and persistent larval characteristics. Setae may be present or absent. There is no prostomium and the mid-gut is closed at both ends *(Bonellia)* or degenerate (*Acanthobonellia*). The single collecting funnel of *Bonellia* opens into the blind fore-gut that functions as a sperm reservoir and spermatozoa are discharged through the mouth. The *vas deferens* of *Acanthobonellia* has four funnels. The excretory organs are a pair of larval metanephridia.

Doubtful **Genera.**—Two genera formerly placed among the Echiurida are non definitely excluded *Sternaspis* is a polychaete, and "*Epithetosoma*" a nemertean of the genus *Micrura. Poeobius meseres* regarded by its discoverer, H. Heath, as a connecting link between Echiurida and Annelida. is clearly an aberrant polychaete. *Sactosoma* (= *Saccosoma*), placed by Fisher in the echiurid class Sactosomida, has not been seen since its original discovery and is of uncertain status. It is said to possess one pair of gonoducts but to lack prostomium, setae, anal vesicles and blood vessels.

Relationships.—The Echiurida have many features in common with the Annelida. Distinctive features of the group are the apparent lack of segmentation and the persistent "larval" anterior end that forms the proboscislike prostomium. It is by no means certain that the lack of segmentation is primary, although W. W. Newby favoured this view. Evidence of suppressed segmentation may be derived from the appearance of transitory ganglia in the ventral nerve cord. from the varying number of setal groups and from a metameric interpretation of the gonoducts and excretory organs. Molluscan features are evident in early development and for this reason it is difficult to regard the Echiurida as a degenerate class of the Annelida.

Molluscan affinities have also been suggested for the Sipunculida, another unsegmented phylum remotely related to the Annelida but widely different from the Echiurida. Echiurids are clearly more primitive, as shown by the half-larval character of their body, and more annelidian than the sipunculids, as shown by the possession of setae and by the terminal position of the anus.

Relationships with the Priapulida are extremely doubtful since the body cavity of the latter is probably a pseudocoele.

(G. E. P.)

ECHMIADZIN, a monastery in the Armenian Soviet Socialist Republic of the U.S.S.R. is situated in the plain of the Aras (Araks) river, 860 m. (2,821 ft.) above sea level, 33 km. (21 mi.) W. of Yerevan and 64 km. (40 mi.) N. of Mt. Ararat. It is the seat of the Supreme *catholicos* (Katholikos) or primate of the Armenian Church. The name, which means "where the only begotten Son descended." was adopted because, traditionally. St. Gregory the Illuminator (*q.v.*), the founder of the Armenian Church, there beheld his vision and erected the first church in 309. The neighbouring small town of Vagharshapat, renamed Echmiadzin in 1915, dates from the 6th century B.C.; it took its name from King Vagharsh (Vologaeses III), who in the 2nd century A.D. chose it as his residence and walled it. In 344 it ceased to be the Armenian capital and in 353 the patriarchal seat was removed to Dvin. then to Ani and later to Hromkla and Sis in the medieval kingdom of Cilicia. In 1431 the primate George brought back the seat to the original see.

The monastery comprises a complex of buildings surrounded by brick walls 30 ft. high, looking. with their loopholes and towers, like a fortress. A modern college and seminary, a type foundry, a printing press and a bookbinding establishment are attached to the monastery.

The present cathedral. on the site of the original church, goes back to the 7th century; although considerably restored later, it retains the main elements of the structure—a cross inscribed in a square. with four salient apses and a dome resting on four piers. The recently excavated remains of two earlier churches show that the original church was a vaulted basilica and that it was replaced in the late 5th century by a domed church, which had projecting apses like the present one and free-standing piers supporting the dome. Large quantities of glass cubes found during the excavations proved that this older church had mosaic decorations.

The red porphyry porch and the belfry were added in the 17th century. The interior walls are decorated in Persian style, in part the work of Armenian painters of the early 18th century and in part modern imitations. In the cathedral treasury are numerous silver and gilt church vessels, medieval gilt bookbindings, vestments. hangings and other works of art, the sacred hand (relic) of St. Gregory, with which the primate confers the episcopal consecration, and the silver basin for the preparation of the holy oil. The rich collection of manuscripts, including some handsome illustrated copies going back to the 10th century, is housed at the

Matenadaran at Yerevan, but since their transfer a new collection has been started and is steadily growing.

Half a mile to the east of the monastery stands the church of St. Hripsime (618), a niche-buttressed square in which the dome rests on the projecting walls of the four axial and four diagonal niches; these, in the form of three-quarter cylinders, give access to subsidiary chambers at the four corners. The third church, that of St. Gayane, was built in 630; its plan is that of a cross inscribed in a square, with three apses and free-standing piers supporting the dome. The porches of both churches are later additions.

Echmiadzinski *rayon* (administrative division)' of the Armenian S.S.R. has a mainly rural population of which Echmiadzin is the centre. The district suffers severely from drought, but an irrigation project was inaugurated which has greatly increased the production of the region. (S. D. N.)

ECHO, a sound reflected from an obstacle *(see* ACOUSTICS OF BUILDINGS), personified in later Greek mythology as a mountain nymph or oread (not before Euripides). In Ovid's *Metamorphoses* she offends Hera by keeping her talking and thus preventing her spying on an amour of Zeus; in punishment, she is deprived of speech, save the power to repeat the last words of another. A hopeless love for Narcissus (*q.v.*) makes her fade away to a voice only.

In Longus, Echo rejects Pan's advances; he thereupon drives the shepherds mad, and they tear her in pieces. Earth buries her limbs and allows them still Echo's power of song.

ECHO SOUNDER, a device that measures the depth of water by producing a sound just below the surface and detecting the return of the sound or echo from the bottom. The depth of the water is indicated by the time required for the sound to travel from the ship to the bottom and back to the ship.

One of the first practical echo sounders came into being in 1919. This was the Hayes sonic depth finder developed at the U.S. Naval Engineering Experiment station. It consisted of an electromagnetic device that sent sound waves to the ocean floor, received the reflection and indicated the depth by a timer calibrated at 4,800 ft. per second, the basic speed of sound in sea water. About 1927 the Submarine Signal company was producing a similar device that was given the trade name of Fathometer. Echo sounder design was later improved but the basic principles used in these earlier developments were not changed materially.

The echo sounder system consists basically of three parts: (1) the transducer, mounted on the underwater skin of the ship, which converts electrical to acoustic energy and vice versa; (2) the transmitter, which generates high-level electrical energy to feed the transducer; and (3) the receiver-indicator, which amplifies the very weak echo received by the transducer, displays it visually or aurally as an indication of depth, and controls the time at which the pulses are transmitted.

Operation of the echo sounder is comparatively simple. When the transmitter supplies a powerful pulse of electrical energy, the transducer converts this pulse into an acoustic pressure wave in the water directed downward. This wave strikes the ocean floor: is reflected back and received by the transducer. The echo is converted there from acoustic to electrical energy, then amplified in the receiver and applied to the indicator. The indicator is usually a neon light rotating at the proper speed (determined by the speed of sound in water) around a dial calibrated in feet or fathoms.

The echo sounder's operation is entirely automatic and indications are given on every revolution of the dial. This method of taking soundings has many advantages over the older methods (such as by lead line). For example, the soundings shown by the echo sounder indicate the depth directly beneath the vessel whether it is moving or stationary; ordinary speeds have no effect on the operation of the device. Older methods were much slower, and frequently depth information came after the ship had moved from the spot. Furthermore, the echo sounder can be left in operation for indefinite periods. resulting in thousands of soundings being indicated per hour. Most echo sounders are equipped with devices that automatically make a permanent record of such lines of soundings.

The chief use of the echo sounder is to insure that the ship is in safe water and not in danger of going aground. It may also be used in navigation by comparing a series of soundings obtained against those recorded on available charts. A good comparison fixes the ship's position and track with some degree of accuracy. Hydrographers use echo sounders in charting the oceans of the world and in survey work. The echo sounder is indispensable in charting the ocean's bottom and in discovering hitherto uncharted pinnacles and shoals. Echo sounders have even been used by fishermen to locate large schools of fish. Echo sounders are in operation on practically every important class of ship, naval and merchant. and are also found on small craft. (M. M. EL.)

ECHTERNACH, a town in Luxembourg. is situated on the Sûre river! 18 mi. N.E. of Luxembourg city. Pop. (1960) 3,389. In Roman times it was a resort of Trier merchants but the town itself grew around a Benedictine abbey, founded in the 7th century by the English St. Willibrord, who introduced Christianity from there. The surviving 18th-century buildings are partly used as a school, while the 11th-century church (basilica). where St. Willibrord was buried. was damaged in 1944 and later rebuilt. The town hall (Denzelt), originally a court of justice: is a beautiful example of 15th-century architecture.

Echternach is known for its religious dancing procession on Whit-Tuesday, in honour of St. Willibrord. The participants, headed by the bishop of Luxembourg and accompanied by the village bands, progress slowly from the Sûre to the basilica. dancing to a lively traditional tune. The town is an attractive tourist centre with excursions to the impressive natural scenery of the Müllerthal district, popularly though inappropriately known as Luxembourg's "Little Switzerland." (K. C. E.)

ÉCIJA, a city of southern Spain, in Seville province, is situated on a terrace overlooking the Genil river, 86 km. (53 mi.) E.N.E. of Seville by road. Pop. (1950) 41,621. It is the ancient Astigis and the Roman *colonia* Augusta Firma. Named Estedja by the Moors, it was recaptured from them by Ferdinand III in 1240. During the 16th century it enjoyed great prosperity stemming from trade with the West Indies, but it declined in the 19th century. Henry III granted it the status of a city. Écija is in an area of large estates and many of the inhabitants are farm labourers. The main crops are olives. cotton and cereals. There are sawmills and lime quarries, and textiles, soap and meat products are manufactured. (M. B. F.)

ECK, JOHANN (1486–1543), German theologian and principal Catholic opponent of Martin Luther (*q.v.*), was born of peasant stock on Nov. 13, 1486, in the Swabian village of Egg (Eckj, a name he later utilized instead of or along with his family name Mai(e)r (Mayr or Slayer). He studied the humanities, philosophy and theology at Heidelberg (1498), Tiibingen (1499), Cologne (1501) and Freiburg im Breisgau (1502), where he was ordained to the priesthood in 1508 and became doctor of theology (1510). In Nov. 1510 at the University of Ingolstadt Eck began a lifelong career as professor of theology, supplemented by several terms as dean, prorector and rector. During many of these years he also served conscientiously as local pastor. His active pen soon attracted attention. Worthy of mention among his early productions are the theological treatise *Chrysopassus* (1514), on predestination, free will and grace, and a series of philosophy textbooks. In public debate and writing he departed from medieval notions on usury by defending interest-taking up to 5% on productive capital.

Luther's break with the Catholic Church proved the turning point in Eck's life. Thereafter his numerous writings, sermons, public debates, speeches at diets and conferences, and diplomatic missions concentrated on religious controversy. Eck was friendly with Luther until the appearance of the latter's 95 Theses (1517), which Eck assailed as heretical in *Obelisks* (1518). Luther retorted with his *Asterisks.* His disciple Karlstadt joined the fray, which culminated in the celebrated public disputation at Leipzig (June 27–July 15, 1519) held in the presence of Duke George of Saxony, his court, the local university faculty and many others. To this popular form of intellectual tourney Eck brought a reputation as a matchless debater whose gigantic frame and stentorian voice

augmented the impression created by his vast knowledge: prodigious memory, quickness of mind and tongue. Karlstadt, with whom Eck contended for five days, cut a poor figure. Argument with Luther filled the remaining period. Chief topics were the divine institution of the papal primacy and the infallibility of ecumenical councils, both of which doctrines Luther denied. Here too the audience rated Eck victor. Neither conceded defeat; both proceeded to seek and gain sympathizers.

To speed proceedings Eck visited Rome (March–July 1520), where he played an important role in the deliberations prior to the solemn papal pronouncement *Exsurge Domine* (June 1520), censuring 41 of Luther's theses and threatening him with excommunication. Leo X created Eck an apostolic protonotary, and delegated him, along with Jerome Aleander, as special emissary to publish and enforce the bull in Germany. Eck's second journey to Rome (Oct.–Dec. 1521), coming at the time of the pope's death, was uneventful, but during a final trip (March–December 1523), at the request of the Bavarian dukes. Eck treated successfully with Adrian VI on several matters of ecclesiastical polity concerning Bavaria, informed the pope about German religious conditions and proposed reforms.

At the *Reichstag* at Nürnberg and Regensburg (Ratisbon) Eck was prominent in promoting a union of Catholic powers. At the diet of Augsburg (1530) he headed a theological committee which drafted a refutation of the Lutheran creed known as the Confession of Augsburg. When the Zwinglians also presented there a profession of faith, *Confessio Tetrapolitana,* Eck himself prepared the rebuttal. Previously he had gone to Switzerland as leading debater on the Catholic side at the Baden disputation (May 21–June 8, 1526), where he was judged winner against John Oecolampadius (*q.v.*) and other outstanding Zwinglians. Again Eck was the main Catholic orator at the indecisive religious colloquies at Haguenau (1540); at Worms (1541), where he faced Philipp Melanchthon (*q.v.*); and at the diet of Regensburg (1541). His labours carried him as far as England (1525), where he conferred with King Henry VIII, who had written a criticism of Luther. In the negotiations preliminary to the Council of Trent both Emperor Charles V and Pope Paul III consulted him. He died at Ingolstadt on Feb. 10, 1543.

As a writer Eck was prolific. His published titles exceed 100; many others remain in manuscript or have disappeared. Mostly composed in Latin, they are striking more as learned defenses of the traditional faith than for style or originality of thought. The most important tracts include: *On the Primacy of Peter* (1520); *On Penance* (1522); *On the Sacrifice of the Mass* (1526); *Enchiridion Against the Lutherans* (1525), a summary of contested Catholic beliefs, Protestant objections to them and answers to these difficulties. Counting translations into German, Flemish and French, this most popular of Eck's works saw 91 editions up to 1600, ranking it the best-used Catholic polemical handbook of the century. He was less proficient in his native language, and his German version of the entire Bible (1537) was so stiff that it merited only restricted acceptance.

Those intimately acquainted with the "Catholic .Achilles" praised his tireless zeal and laboriousness. sincerity, frankness, blunt joviality, simplicity of life, disdain of ecclesiastical dignities and material gain. At the same time they found him impetuous, uncompromising, overcontentious and tending to arrogance. The tone of his polemics. bitter and coarse as it seems nowadays. was that customary in his time; his adversaries more than repaid him in kind. There was created a voluminous counterpolemical literature, in which the virulent lampoon *The Planed-down Eck* (*Eccius dedolatus*, 1520), probably by the famous humanist Willibald Pirckheimer, was but the best-known example. Its vilifications of his character, motives, virtues and manner of death were frequently repeated later. but these serious charges must be discounted as largely unfounded.

BIBLIOGRAPHY.—The best list of works by Eck and about him is in *Corpus Catholicorum,* vol. xvi (1930). In English see *Catholic Encyclopedia,* vol. v (1909), and *New Schaff-Herzog Encyclopedia of Religious Knowledge,* vol. iv (1909). All histories of the Reformation and lives of Luther refer to Eck. (JN. F. B.)

ECKENER, HUGO (1868–1954), German aeronautical engineer and airship pioneer. commander of the first airship to fly around the world. Born at Flensburg on hug. 10. 1868, he was educated at the universities of Munich. Berlin and Leipzig. He took a keen interest in airship construction, joined Count Zeppelin's firm. and was instrumental in developing the rigid airship in the early 1900s. During World War I, Eckener trained airship pilots and directed the construction of 88 Zeppelins for the German navy. Returning to commercial construction in Nov. 1918. after Zeppelin's death. he achieved great success in temporarily popularizing airship travel. He commanded the "ZR-3," built for the United States as a war reparations payment and later named "Los Angeles," in its flight across the Atlantic in 1924. He also commanded the "Graf Zeppelin" on its epic around-the-world flight in 1929 and on its polar exploration flight in 1931. In 1937 he was in command of the "Hindenburg" when it burned with heavy loss of life on May 6, at Lakehurst, N.J.—a tragedy that virtually ended international airship travel. Eckener spent the last years of his life as head of a machine plant in Germany and wrote several books. He died at Friedrichshafen, Ger.. on Aug. 14, 1954. *See* AIRSHIP. (D. CR.)

ECKERMANN, JOHANN PETER (1792–1854). German writer, chiefly remembered ior his association with Goethe. was born at Winsen, Hanover, Sept. 21, 1792. Brought up in great poverty, he served in the War of Liberation (1813–14), and became a clerk in the war department at Hanover. subsequently studying for a year at Göttingen. He published a book of poems in 1821. and in 1823 attracted Goethe's attention by sending him the manuscript of his *Beiträge zur Poesie mit besonderer Hinweisung auf Goethe.* Goethe invited him to Weimar and he there became Goethe's unpaid literary assistant. also acting as tutor to the grand duke's son, and, in 1838, acquiring an appointment at court and the position of librarian to the grand duchess. He died there, Dec. 3, 1854.

Eckermann's most valuable work was his *Gesprache mit Goethe in den letzten Jahren seines Lebens, 1823–32,* 3 vol. (1836–48), a source of information on Goethe's life and ideas. It was based on notes taken with Goethe's permission and is comparable in importance with Boswell's *Life of Johnson.* It has been translated into every European language: English translations (*Conversations with Goethe*) include those by S. M. Fuller (1539). J. Oxenford (1850) and R. O. Moon (1951). Eckermann also acted as Goethe's literary executor and published his posthumous works (1832–33), and, with F. W. Riemer, prepared the first complete edition of Goethe's works.

BIBLIOGRAPHY.—J. Petersen, *Die Entstehung der Eckermannschen Gesprache* (1924); H. H. Houben, *J. P. Eckermann, sein Leben für Goethe,* 2 vol. (1925–28) and *Goethes Eckermann* (1934).

ECKHART (ECKHART VON HOCHHEIM, called MEISTER ECKHART) (1260?–1328?), the greatest German speculative mystic. was born at Hochheim. near Gotha. He joined the Dominican order. probably entering the local friary of Erfurt. In 1293 he went to St. Jacques in Paris to complete his theological studies, but he did not graduate as master till 1302. In 1303 he was appointed provincial minister of his order in Saxony and proved a very successful administrator. Between 1314 and 1322 he was teaching and preaching in Strasbourg. After this he was lector at Cologne and the most popular preacher in Germany. But he was not without his critics. He was summoned to appear before the archbishop of Cologne on a charge of heresy in 1326. He vigorously defended his innocence and appealed to Pope John XXII. In 1327 proceedings were opened in Avignon, where ~ ~ k - hart appeared in person. Eckhart recanted and soon afterward died. A papal bull of 1329 condemned 28 propositions from his works.

Modern scholarship tends to judge Eckhart charitably. to make allowances for his obscurity, his love of paradox and hyperbole, his tendency to startle his congregation. In philosophy he followed the Aristotelian tradition, including that of the Arabic commentators. His theology has close affinities with that of Thomas Aquinas, but there are differences of emphasis. His favourite writer was St. Augustine. from whom he borrowed his speculations about time and eternity. He was also influenced by Plotinus,

Pseudo-Dionysius and Moses Maimonides. Like Pseudo-Dionysius, Eckhart refers to God as "Nothing." This implies, not that God does not exist, but that he has a fuller existence than any created being. If we are to affirm anything positive about God. the most important statement we can make is that he is (Ex. *iii*, 14). With Aquinas, Eckhart adds that, whereas the creature *has* being, God *is* being. In a sense he is above being, since he created being.

When Eckhart asserts that all created beings are *unum purum nihil,* he does not ,deny the existence of the world, but means that in comparison with God the world is as nothing. His cardinal doctrine is that of the birth of the Son in the soul. which signifies the mystical union of the human and divine, the highest goal of man. This is attained by a process of purification. It is union of wills. not of essences. It is given by grace. not acquired by merit. The organ or faculty in. or through, which it takes place is the "spark of the soul." When dealing with mystical experiences Eckhart often used the language of Neoplatonism, hence the charges of pantheism. But his most daring observations can be interpreted in a Christian sense. He never taught that God can be reached without the aid of the sacraments and other religious observances. His attitude was that pilgrimages, fastings, physical austerities and external works in general are of no avail unless the soul is well disposed; which is perfectly orthodox.

Eckhart did not create medieval German prose: a tradition already existed, thanks to the great preachers of the 13th century and others. But he contributed in a marked degree to German vocabulary by the addition of many abstract terms. The standard edition (including the trial documents) is by J. Quint *et al., Meister Eckhart: die deutschen und lateinischen Werke* (1936–), with a modern German translation. There are English versions with bibliographies in J. M. Clark, *Meister Eckhart, an Introduction to the Study of His Works* (1957) and J. M. Clark and J. V. Skinner, *Meister Eckhart, Selected Treatise:. and Sermons* (1958), including extracts from the Latin works.

ECKHEL, JOSEPH HILARIUS (1737–1798), founder of the science of classical numismatics. was born at Enzersfeld in lower Austria and educated at the Jesuit gymnasium in Vienna, where he had entered the order at the age of 14. He taught grammar at various collegiate schools, but because of ill-health gave up teaching to devote himself to his early interest in numismatics. In 1772 he was sent to Italy where he had access to important collections in Bologna. Rome and Florence, and in 1776. two years after his return. was appointed chief curator of the imperial cabinet of coins and professor of antiquities and numismatics at the University of Vienna. He died at Vienna on May 16. 17'38.

Eckhel's great work is the *Doctrina numorum veterum (8* vol., 1792–98), in which he established basic 'principles for the classification of coins by region, chronology and type that became the model and standard for later systems.

ECKMÜHL (EGGMÜHL), **BATTLE OF,** an engagement of the Napoleonic Wars (*q.v.*), fought on April 22, 1809, at Eggmühl 13 mi. S.E. of Regensburg between the French and their allies under Napoleon and Davout and the Austrians under the archduke Charles. A week alter his invasion of Bavaria. the archduke reached the Landshut area with 126,000 men on April 16. A further 49,000 Austrians, in two corps, had been sent 30 mi. N. of Regensburg on the Danube, where Davout's 60.000 lay exposed. On April 17, Napoleon arrived at Donauwörth and hastened to close up Davout's and Masséna's forces (still 75 mi. apart). He intended to hold the Austrians on Davout's front while to the south Masséna came up on their rear to cut them off from Landshut. On April 19, Davout marched from Regensburg across Charles's front. his rearguard successfully engaging at Teugen with one of Charles's three columns. Masséna now stood 30 mi. W. of Landshut. where J. Hiller commanded the two remaining Austrian columns that Napoleon had taken to be the bulk of Charles's army. On April 21 these were threatened by the French centre converging with Masséna, who arrived too late to take them in reverse. Hiller now retired, with considerable losses. to the Inn. Charles, however, reinforced by one of the corps previously north of the Danube, decided to attack the heavily outnumbered French left wing under Davout and Lefebvre next day. He began his outflanking movement against Davout's left at midday on April 22, but Napoleon's approach enabled Davout to launch his own attack on the Austrian left wing about 1 P.M., an hour before the French vanguard from the south debouched. Promptly suspending the right wing's advance in the face of Napoleon's threat to his rear. Charles withdrew over the Danube during the night. He had lost about 10,000 killed, wounded and captured. the French about 3.000 killed and wounded. (J. H. N.)

ECLAMPSIA, a disease condition of unknown cause, characterized by convulsions and coma and occurring chiefly in pregnant women. *See* OBSTETRICS; PREGNANCY: *Toxemias of Pregnancy.*

ECLECTICISM, in philosophy or in theology, is the practice of selecting doctrines from different systems of thought without adopting the whole system from which each doctrine was derived (Gr. *eklektikos,* "selective"). It is distinct from syncretism (*q.v.*) in that syncretism is the attempt to reconcile or to combine systems, whereas eclecticism leaves the contradictions between systems unresolved. In the sphere of abstract thought eclecticism is open to the objection that. insofar as each system is supposed to be a whole, of which its various doctrines are integral parts, the arbitrary juxtaposition of doctrines from different systems is likely to result in fundamental incoherence. In practical affairs, however, the eclectic spirit has much to commend it.

A philosopher, no less than a statesman, may be eclectic not on principle (though he can defend as a principle his right to be eclectic) but because he perceives the intrinsic merit or the utility of doctrines that happen to have been advanced by opposite parties. This tendency is naturally most apt to manifest itself when established systems are losing their novelty or having their defects revealed by changes of historical circumstance or by scientific discoveries. In antiquity, for instance. from the beginning of the and century B.C. onward, a number of philosophers professedly attached to long-established schools—the Greek Academy. the Peripatetics. or the Stoics—were ready to adopt views from schools to which they did not belong; and Roman philosophers in particular. to whom all Greek philosophies were enlightening, often did not want to commit themselves to a rigid partisanship which Greeks themselves were abandoning (Cicero is eclectic par excellence). Very little purpose, however, is served by attempting to group the numerous ancient eclectics together as if they formed an "Eclectic school." In the 19th century, however, the name *éclectisme* was specifically adopted as the designation of his own system by the French philosopher Victor Cousin (*q.v.*).

ECLIPSE is the complete or partial reduction of visibility of a celestial body by the passage of a second celestial body (from Gr. *ekleipsis,* "forsaking"). The many eclipse phenomena known to astronomers are of two distinctly different types. In the first. the eclipsing body comes between the observer and the eclipsed object. and the latter appears to the observer partly or completely covered by the eclipsing body. Eclipses of the sun, occultations of stars by the moon, transits of Venus or Mercury across the sun's disk and eclipses of binary stars are of this kind. Eclipses of the second type affect only planets or satellites that are not self-luminous; here the eclipsing body intervenes between the sun and the eclipsed object. The latter remains in view of the observer. but its illumination by the sun is interrupted, and it becomes darkened by entering into the shadow of the eclipsing body. Examples of this case are eclipses of the moon and eclipses of the satellites of Jupiter.

To the general public, eclipses of the sun and of the moon are

of considerable interest since they are readily observable without a telescope and offer an impressive spectacle. Primitive people are struck with fear by the falling darkness during a total solar eclipse or by the weird sight of the eclipsed moon; even animals are disturbed or frightened. Accounts of such eclipses are found among the oldest records of history. battles have been decided by their unexpected advent and the successful prediction of eclipses constitutes one of the earliest triumphs of the scientific investigation of nature.

ECLIPSE PHENOMENA

Eclipses of the Sun.—An eclipse of the sun takes place when the moon, revolving in its orbit around the earth, comes between the earth and the sun so that the moon's shadow sweeps over the face of the earth *(see* fig. 1). This shadow consists of two parts: the umbra or total shadow. a cone into nhich no direct sunlight penetrates; and the penumbra or half shadow. which is reached by light from only a part of the sun's disk.

To an observer who is within the umbra the disk of the sun appears completely covered by the disk of the moon; such an eclipse is called total. To an observer within the penumbra. the moon's disk appears projected onto the sun's disk so as to overlap on it partly; the eclipse is then called partial.

As the umbra cone is narrow at its intersection with the earth, a total eclipse is observable only within the narrow strip of land or sea over which the umbra passes. A partial eclipse. on the other hand, is visible over the large area covered by the penumbra.

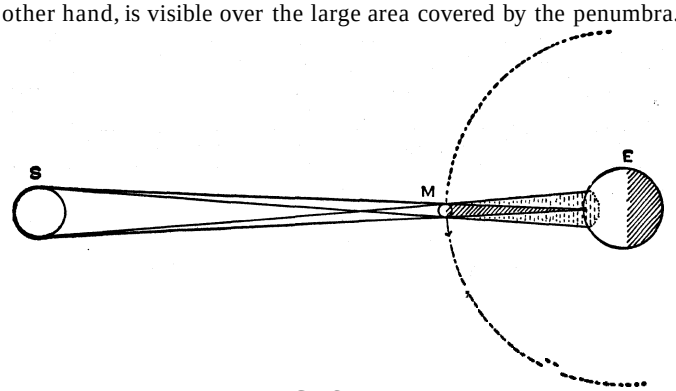

FIG. 1.—ECLIPSE OF THE SUN

The shadow of the moon M sweeps over the surface of the earth E. In the darkly shaded region (umbra) the eclipse is total, in the lightly shaded region (penumbra) the eclipse is partial

Sometimes the earth intercepts the penumbra of the moon but is missed by its umbra; only a partial eclipse of the sun is then observed anywhere on the earth.

By a remarkable coincidence, the sizes and distances of the sun and moon are such that they subtend very nearly the same angle (about $\frac{1}{2}°$) at the earth, but their apparent sizes are not constant. Since the earth revolves around the sun in an elliptical orbit. the distance of the sun varies slightly during the year, and this involves a small change in the angular diameter of the solar disk. In a similar way the apparent size of the moon's disk changes somewhat during the month because of the elliptical shape of the moon's orbit. Thus when the sun is nearest to the earth, and the moon is at its greatest distance. the apparent disk of the moon is smaller than that of the sun. If an eclipse occurs at this time the moon's disk passing over the sun's disk may enter completely inside the latter, leaving the rim of the sun visible all around it. Such an eclipse is called annular.

The various phases observable at a total solar eclipse are illustrated in fig. 2(A). "First contact" designates the moment when the invisible disk of the moon just touches the disk of the sun. The partial phase of the eclipse then begins as a small indentation in the western rim of the sun becomes noticeable. The dark disk of the moon now gradually moves into the sun's disk and the sun appears in the shape of a crescent. After about $1\frac{1}{4}$ hours the crescent grows very thin and daylight appears somewhat dusky. At the "second contact" the last trace of the sun's crescent disappears and the total phase begins. Within a few seconds all direct

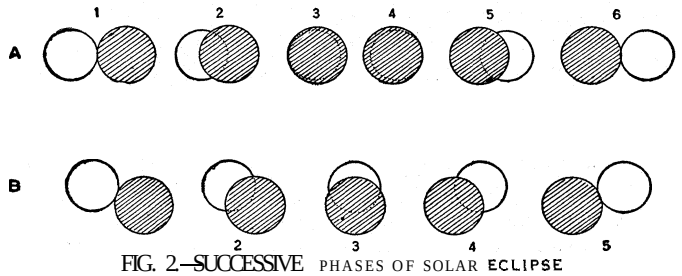

FIG. 2.—SUCCESSIVE PHASES OF SOLAR ECLIPSE

The dark disk of the moon gradually moves across the disk of the sun from west (right) to east (left). (A) Total eclipse: (1) first contact; (2) partial phase; (3) second contact, beginning of totality; (4) third contact, end of totality; (5) partial phase. (6) fourth contact. (B) partial eclipse: (1) first contact; (3) maximum phase; (5) last contact.

sunlight vanishes. it suddenly grows dark, the brightest stars become visible in the sky and the dark disk of the moon is seen projected onto the pale halo of the sun's corona—an unforgettable spectacle. The general landscape illumination during totality is considerably brighter than on a night of full moon, but the sudden transition from daylight is most impressive.

Totality never lasts very long, $7\frac{1}{2}$ minutes at the utmost. It ends at the "third contact" when the following limb of the moon begins to uncover the western rim of the sun. Daylight returns as suddenly as it vanished; the thin crescent of the sun gradually widens, and about $1\frac{1}{4}$ hours later the second partial phase of the eclipse ends at the "fourth contact," when the last encroachment made by the moon on the sun's rim disappears.

In a partial eclipse *(see* fig. 2[B]) the motion of the moon's disk is such that its centre does not pass across the centre of the sun. After the first contact the visible crescent of the sun decreases in width until the centres of the two disks reach their closest approach. This is the moment of maximum phase, and the latter is measured by the ratio between the smallest width of the crescent and the diameter of the sun. After maximum phase the crescent of the sun widens again until the moon passes out of the sun's disk at the last contact.

When observing a partial or annular eclipse it is necessary to protect the eyes against injury by the intense brilliance of the sun. The sun should be viewed only through a dark smoked glass (much darker than that of ordinary sunglasses) or a darkened photographic plate or film.

Eclipses of the Moon.—When the moon moves through the shadow of the earth *(see* fig. 3). it loses its bright direct illumination by the sun. although its disk still remains faintly visible. This phenomenon is called an eclipse of the moon. As the shadow of the earth is directed away from the sun, a lunar eclipse can occur only at the time of full moon, that is, when the position of the moon is opposite to that of the sun.

To describe the progress of a total eclipse of the moon a cross-cut of the earth's shadow cone, both umbra and penumbra. is drawn at the distance of the moon, as shown in fig. 4. The moon's path relative to the shadow is indicated by the dotted line. and successive positions of the moon are marked by $M_1, \ldots M_6$. At M_1 the full moon enters the penumbra, and while it moves from M_1 to M_2 a penumbra eclipse occurs. But the dimming of the moon's illumination by the penumbra is so slight as to be scarcely noticeable, and penumbra eclipses are rarely watched.

After the moon has reached the position M_2, a part of its surface is immersed in the umbra and is darkened; the moon is in partial eclipse. About an hour later the eclipse becomes total

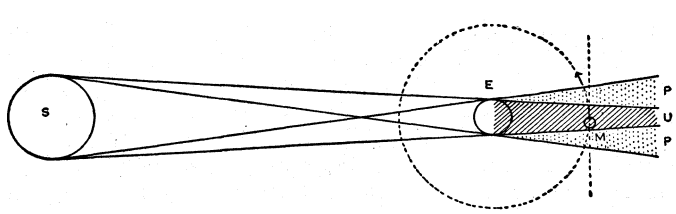

FIG. 3.— ECLIPSE OF THE MOON

The moon revolving in its orbit around the earth passes through the shadow of the earth. U (umbra) is the total shadow, P (penumbra) the partial shadow

when (at M_3) the whole disk of the moon is within the umbra. However, the moon's surface is never completely darkened by an eclipse: even at the middle of totality it is visible, with a peculiar dull ruddy hue. This illumination is caused by sunlight refracted in the earth's atmosphere and reddened by its passage through the air.

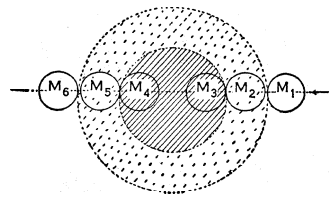

FIG. 4.—SUCCESSIVE PHASES OF A LUNAR ECLIPSE

The large circle of light shading is a crosscut of the penumbra at the distance of the moon, the smaller circle of dark shading a crosscut of the umbra. $M_1 \ldots M_6$ are successive positions of the moon as it crosses the shadow

If the moon's path leads through the centre of the umbra the total eclipse lasts about $1\frac{3}{4}$ hours. At M_4 the moon emerges from the umbra: there follows a partial eclipse ending at M_5, then a penumbra eclipse ending at M_6.

An eclipse of the moon is visible and presents the same features at all places on the earth where the moon is above the horizon. Because of the earth's atmosphere the edge of the umbra is rather diffuse. and the times of contact between the moon and the umbra cannot be observed accurately. The progress of a lunar eclipse can be adequately followed with the naked eye, field glasses or a small telescope. It is an interesting experience for the layman but of little value for astronomical research.

Eclipses of the Satellites of Jupiter.—Eclipses of the four large satellites of Jupiter provide a frequently occurring and fascinating spectacle to the telescopic observer. The orbits of these satellites lie nearly in the same plane as Jupiter's orbit around the sun, and at practically every revolution of each satellite the following four eclipse phenomena take place: (1j eclipse of the satellite when it passes through Jupiter's shadow; (2) occultation of the satellite when it disappears behind the planet, as seen from the earth; (3) transit of the satellite across the disk of Jupiter; (4) transit of the shadow of the satellite across the planet's disk. Fig. 5 illustrates the occurrence of these phenomena; it shows Jupiter

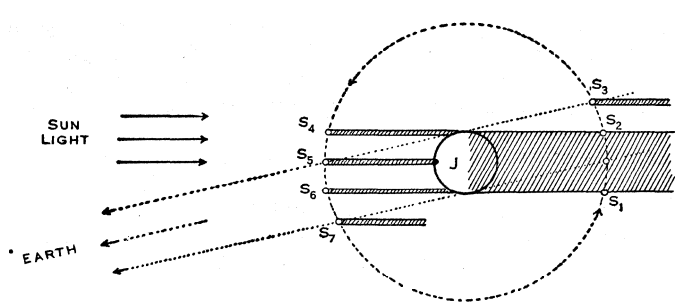

FIG. 5.— ECLIPSES OF THE SATELLITES OF JUPITER

J represents the planet Jupiter, St . . . S_7 mark successive positions of one of its satellites as it revolves in its orbit around Jupiter. The system is illuminated by sunlight from the left but is observed from the direction of the earth

and the orbit of one of its satellites. the direction of the sunlight illuminating the system and the direction toward the earth from where the observation is made.

When the satellite in its revolution arrives at S_1, it enters into Jupiter's shadow (eclipse) and vanishes from lack of illumination. At S_2 it comes out of the shadow, but to the terrestrial observer it is now hidden behind the planet (occultation) until at S, it reappears at the limb. When the satellite reaches the position S,, its shadow falls on Jupiter causing a small dark spot on its surface. Seen from the earth the satellite is to the left of Jupiter approaching its limb. while at the same time its shadow spot passes across the planet's disk (transit of shadow). At S_5 the satellite starts to pass in front of the planet (transit of satellite) following its shadow spot. Since both Jupiter and the satellite turn their illuminated sides toward the earth. they differ little in surface brightness. Near the limb the satellite is somewhat brighter than the planet's surface on uhich it appears projected. but near the middle of the disk it is hardly distinguishable. At S_6 the shadow leaves the planet, and at S_7 the satellite emerges at the limb.

Historically the eclipses of Jupiter's satellites are important for they provided one of the earliest proofs of the finite velocity of light. It is possible to calculate with considerable precision the times of disappearance and reappearance of a satellite undergoing eclipse. Ole Roemer (1675) noticed discrepancies between the observed and calculated times which he explained as being the result of changes in the travel time of light when the earth is nearest to Jupiter or farther away from it.

Other Eclipse **Phenomena.**—*Occultations* of *Stars* or Planets by *the Moon.*—From the earth the moon is seen projected onto a background of distant stars. As the moon moves eastward across the constellations it occasionally passes in front of one of the brighter stars or a planet. causing an occultation. At the moment when the eastern limb of the moon reaches a star. the latter suddenly disappears (immersion). In about an hour or less the moon will have passed over the star and the latter will reappear at the western limb (emersion). Between new moon and full moon the immersion takes place at the invisible (or faintly visible) dark limb; the emersion takes place at the bright limb.

The suddenness with which a star disappears and reappears without fading or flickering is conclusive proof that the moon has no appreciable atmosphere. Accurately timed observations of occultations are used to study the orbital motion of the moon.

Transits of *Mercury and Venus.*—The two planets Mercury and. Venus. which are nearer to the sun than the earth is. do sometimes pass between the earth and the sun. With a telescope properly equipped to reduce the overpowering light of the sun, either of these planets is then seen as a small dark circular disk projected on the brilliant disk of the sun. crossing it slowly. The four contacts of the planet's disk with that of the sun are observed similarly as for a solar eclipse.

Transits of Mercury take place at irregular intervals of 3 to 20 years, on an average 14 times per century. Tranists of Venus are rather rare; they have been of great astronomical importance for the accurate determination of the solar parallax. Many expeditions were organized to observe the transits of Venus of 1761, 1769. 1874 and 1852 from distant places on the earth. The next transits of Venus will occur on June 8, 2004. and June 6, 2012.

Eclipsing *Binaries.*—These are stars that vary in brightness periodically, the most famous of which is Algol (*q.v.*), or β Persei. The .explanation of the light change is that there are two stars, not resolvable with the telescope, revolving round one another in an orbit whose plane nearly passes through the solar system. Thus one star passes periodically in front of or behind the other as seen from the earth, and two eclipses take place during each revolution. From the way in which the light from the double system varies it is possible to calculate the orbit and relative sizes of the two components, and to obtain certain other information (see STAR).

Prediction and Calculation of Solar and Lunar Eclipses.—The problem may be divided into two parts. The first seeks to find out when an eclipse will occur, the other to determine its circumstances: whether or not it is visible at a given place on the earth, its type (total or partial), etc.

It is convenient to consider the earth as fixed and to suppose the observer situated at the centre of the earth. To this observer, O (fig. 6), the sun and moon appear projected on the celestial sphere, a large sphere which he imagines surrounding him. While this sphere appears to him to rotate daily around the line PP' (the earth's axis of rotation), the sun's disk, S, appears to travel slowly along the great circle EE' (the ecliptic), making a complete revolution in one year. At the same time the moon's disk, M, revolves along the circle LL' once during a lunar month. The angular diameters of the two disks S and M are about $\frac{1}{2}°$, but vary slightly (see Eclipses of *the* Sun, above).

Every month the moon's disk revolving along LL' will once overtake the more slowly moving sun; this moment of overtaking is called the new moon. In general the moon's disk will pass above or below the sun's disk. Overlapping of the two disks results in an eclipse of the sun; it will occur only when the new moon happens at a moment when the sun is near the points ☊ or ☋, where the circle LL′ intersects EE'. These points are called the ascending and descending nodes of the moon's orbit.

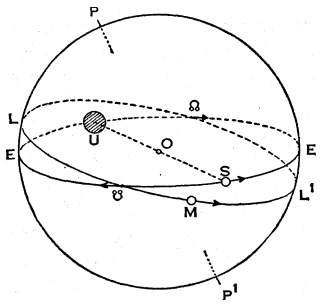

FIG. 6 —APPARENT MOTIONS OF SUN AND MOON ON THE CELESTIAL SPHERE

The observer O imagines himself at the centre of a large sphere. The sun S appears to move around the circle EE' (the ecliptic) once a year, the moon M around the circle LL', its orbit, once a month. The crosscut U of the earth's shadow is always opposite to the sun S. The intersections (nodes) ☊ ☋ of the moon's orbit and the ecliptic revolve along the ecliptic once in 19 years

The moon will suffer an eclipse when it enters into the shadow cone of the earth. The crosscut of the umbra at the distance of the moon (as shown in fig. 4) may be projected like a disk U onto the celestial sphere. It subtends an angle of about 1.4°; its centre will always be opposite to the sun's disk and travel along EE'. An eclipse of the moon takes place whenever the moon's disk overlaps the shadow disk; this happens only when the shadow disk is near one of the nodes, or the sun is near the opposite node. The passage of the sun through the lunar nodes is therefore the critical time for both solar and lunar eclipses. The moon's orbit plane, represented by the circle LL', is not fixed, and its nodes move slowly along the ecliptic in the direction indicated by the arrow. making a complete revolution in about 19 years. The interval between two successive passages of the sun through one of the nodes is termed an "eclipse year," and since the moon's node moves so as to meet the advancing sun, this interval is about 18.6 days less than a tropical (or ordinary) year.

In fig. 7(A) the region of the ascending node as seen from the centre of the sphere is much enlarged. Here the node is kept fixed and the apparent motions of the sun and the moon are taken relative to the node. To the imaginary observer at the centre of the earth the sun's disk will travel along the circle EE', the moon's disk along LL'. The sun is so distant compared with the size of the earth that from all places on the earth's surface the sun is seen nearly in the same position as from the centre. But the moon is relatively near and its projected position on the celestial sphere is different for various observing stations on the earth; it may be displaced as much as 1° from the position in which it is seen from the centre of the earth. If the radius of the moon's disk is enlarged by 1°, a circle C, is obtained which encloses all possible positions of the moon's disk seen from anywhere on the earth. Conversely, if any circle of the moon's size is drawn inside this "moon circle" C. there is a place on the earth from which the moon is seen in that position.

Accordingly, there will be an eclipse of the sun somewhere on the earth whenever the moon overtakes the sun in such a position that the moon circle passes over the sun's disk; when the latter is entirely covered by the moon circle, the eclipse will be central (total or annular). From fig. 7(A) it is evident that a solar eclipse will take place if a new moon occurs while the sun moves from S_1 to S_4. This period is called the eclipse season; it starts 19 days before the sun passes a node and ends 19 days after. Since there is a new moon every month, at least one solar eclipse, and sometimes two, occur during every eclipse season. When the new moon falls within 11 days of the node passage (between S_2 and S_3), the eclipse will be central.

Fig. 7(B) illustrates the condition for a lunar eclipse. If a full moon occurs within 13 days of a node passage of the sun (when the shadow disk passes the other node) the moon will be eclipsed. Most eclipse seasons, but not all, will thus also contain a lunar eclipse. Eclipses of the sun are evidently more frequent than those of the moon, but the former are visible only from a very limited region of the earth, the latter from a whole hemisphere. Any particular town or city would on the average experience about 40 lunar eclipses and 20 partial solar eclipses in 50 years, but only one total solar eclipse in 400 years.

The sun returns to the same node after each eclipse year; new moons (or full moons) recur at intervals of an ordinary month. Nineteen eclipse years (6585.7806 days) are nearly equal to 223 months (6585.3211 days). After this interval of 18 years 11 days, which is called the saros, the moon and the sun come nearly to the same relative positions again and eclipses will repeat themselves. Thus the solar eclipse of Oct. 2, 1959, was a repetition of that of Sept. 21, 1941, which was a repetition of that of Sept. 10, 1923, which was a repetition of that of Aug. 30, 1905, and so on (see Table). In ancient times the saros was used for the prediction of eclipses.

Since the coincidence of the two periods is not exact, the repetition of an eclipse after a saros will be of different circumstances. Suppose an eclipse of the sun takes place while the sun is at S_3 (fig. 7[A]) and the moon at M_3; it will be visible on the earth in high northern latitudes from where the moon's disk is projected into the lower part of the moon circle. After 223 months there will be another new moon with eclipse. As this period is shorter by 0.4595 days than 19 eclipse years, the moon will now overtake the sun before the latter has quite returned to S_3, while it is 28° farther to the right, nearer to the node. The sun will be closer to the centre of the moon circle, and on the earth the eclipse will be visible nearer to the equator or farther south than the previous eclipse. After every saros the meeting of the moon and the sun will be a little farther to the right, until it takes place near S_1 M_1, after which the eclipse returns no more. Solar eclipses may thus be ordered into series. each of which contains 68 to 75 eclipses (about 18 total), at intervals of a saros extending over 13 to 14 centuries.

The fraction of 0.3211 days in the period of the saros has the effect of making each successive eclipse of a series visible about 110° of longitude farther west on the earth. and after three saroses it returns nearly to the same longitude, but farther south if at the ascending node or farther north if at the descending node. Eclipses of the moon, of course, also occur in similar saros cycles.

During a solar eclipse the shadow cones (umbra and penumbra) of the moon sweep across the face of the earth (fig. 1), while at the same time the earth is rotating around its axis. The circumstances of a solar eclipse are best illustrated by a map which shows the intersections of the shadow cones with the earth's surface and their tracks across continents and oceans resulting from the combined effects of both motions. Fig. 8 illustrates the circumstances of the total solar eclipse of Nov. 1, 1948. The narrow double line marks the path along which the umbra travels in $3\frac{1}{2}$ hours from central Africa across the Indian ocean toward New Zealand. Within the area of this lane, 50 mi. wide, the eclipse is total. The wide surrounding region bounded by the full line is that covered by the penumbra, where the eclipse is partial. Within the lune at its extreme left the sun is already in partial eclipse when it rises, within the lune at the right the sun sets during the partial eclipse. In the intermediate region the whole progress of the partial eclipse can be observed, and from the dotted lines the time of its beginning and end at any particular place can be read.

The astronomical ephemerides published for each year give such

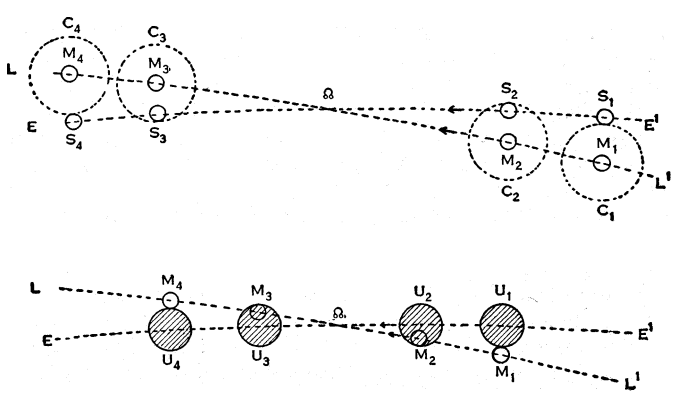

FIG. 7.— ASCENDING NODE OF THE MOON'S ORBIT AS SEEN FROM THE CENTRE OF THE SPHERE

(A) A solar eclipse occurs somewhere on the earth whenever the circle C overlaps the sun's disk S. The circle C encloses all positions of the moon seen from anywhere an the earth at a given moment

(B) A lunar eclipse occurs when the crosscut U of the earth's shadow overlaps the moon's disk M

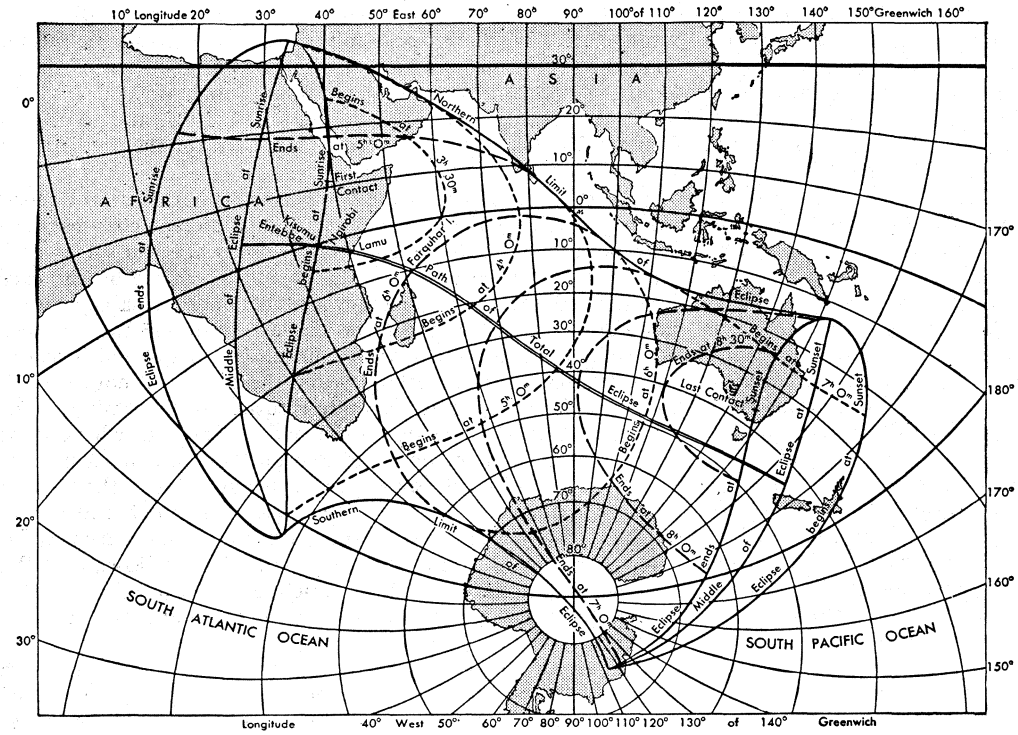

FIG. 8.— MAP SHOWING THE SOLAR ECLIPSE OF NOV. 1, 1948

Within the narrow double line a total eclipse is observed; in the large area outlined the eclipse is partial. Reproduced from the American Ephemeris and Nautical Almanac by permission of the Nautical Almanac Office, U.S. Naval Observatory

maps for the more important eclipses as well as data for accurate calculation of the times of contact at any observing station.

It is possible with the aid of modern tables to predict solar eclipses several years ahead with an accuracy of a few seconds. For predictions of longer range the main uncertainty is that of the moon's motion. Eclipses can. of course, be "predicted backward" as well as forward, and the calculation of ancient eclipses has been of value in historical research. (R. J. TR.)

INFORMATION YIELDED BY SOLAR ECLIPSES

Partial solar eclipses give little information of astrophysical interest. Total eclipses. however, contribute much knowledge concerning the nature of the sun's external layers. regions that are usually lost in the brilliant sky glare from the sun's shining surface. At total eclipse. the disk of the moon acts as a screen outside the earth's atmosphere, cutting off the direct rays from the photosphere. as the bright solar surface is known. The brilliance of the sky is thus enormously decreased and the fainter appendages of the sun become visible. The astrophysical value of eclipse observation. however, may be said to be decreasing. as a result of the invention of such instruments as the coronagraph (see below). even though there are still some problems that can be solved only at eclipse. Observations can be secured every clear day with the coronagraph. whereas eclipses are relatively rare phenomena. usually occurring in distant locations and lasting for only a few minutes.

Chromosphere. — The chromosphere (*q.v.*), the sun's atmosphere, extends upward from the photospheric surface, growing more and more rarefied with increasing height. The chromosphere has no well-defined upper boundary, but it has been traced to a height of about 10,000 mi. above the surface. It is filamentary in structure, being composed of myriads of streamers of luminous gas projected from the solar surface. An individual small streamer. or spicule. is very short lived; from its beginning as a bright eruption on the surface until its fading out as a thin. iaint, ribbonlike spurt is a period of only 10 or 15 minutes.

The sun's atmosphere thus in no way resembles that of the earth. Not only is the structure of the chromosphere nonuniform but the temperature is extremely high. Elements such as iron, calcium or aluminum. which are solids on the earth. are completely vaporized on the sun and appear as important constituents of its gaseous envelope. Determination of the chemical composition of the atmosphere and of the temperatures and pressures obtaining there is best done from spectroscopic observations made at the time of total eclipse. (See SPECTROSCOPY; SPECTROSCOPY. ASTRONOMICAL.) Each individual chemical substance — element or compound — when vaporized and heated to incandescence, sends out its own characteristic radiations. Thus. when the spectrum of some unknown substance is matched with the radiations from known substances, the chemical cornposition of the sample can be determined. The relative intensities of the lines of a given element give further information concerning temperatures and pressures in the luminous material.

The ordinary spectrum of the sun contains a brilliant background of all colours — a so-called continuous spectrum. This radiation emanates from the lower levels of the solar atmosphere, where the pressure of atoms and electrons is high enough to inhibit the previously mentioned characteristic radiations. The atoms in the upper levels, however. absorb these radiations. so that the solar spectrum consists of the bright rainbow background. with many fine gaps where the light has been absorbed. These gaps appear as dark lines — absorption lines — on the bright background.

At the moment of totality. when the moon obliterates the last trace of the bright photosphere. with its dark-line spectrum, the upper, rarer layers of the atmosphere flash into view with the characteristic bright-line spectrum of a luminous gas. This spectrum disappears within four or five seconds, as the moon moves over the sun. and a second flash occurs at the end of totality. Because of its evanescent character. it has been called the "flash spectrum."

Analysis of flash spectra has led to some surprising results. The spectrum matches the dark-line spectrum only roughly. The lines of the neutral metals are of comparable strength in the two spectra. but those of the ionized metals (*i.e.*, atoms that have lost one electron) are markedly enhanced in the flash spectrum. The difference is attributed, in part, to lower pressures in the upper layers, but elevated temperature appears to contribute to the increased excitation. Especially is this true for the flash lines of ionized helium. which do not appear at all in the ordinary dark-line spectrum. These require excitation temperatures of at least 25.000° K. for their production. whereas the temperature required to produce the observed quality and quantity of bright emission from the surface is only 6.000° K.

Prominences. — Extending upward from the chromosphere. and probably closely related to it. are the so-called prominences, one of the striking features of a total eclipse, which project outward into space. sometimes as far as several hundred thousand miles. They appear as rose-coloured patches of flame, projecting well beyond the limb of the moon. Despite their resemblance to fire: prominences cannot be referred to as flames. They consist of long interlacing filaments of incandescent gas. Their rosy colour arises from the predominant gaseous radiations, the red of hydrogen and the violet of ionized calcium. Prominences appear to have a temperature slightly in excess of that associated with the chromosphere.

The spectroheliograph (*q.v.*) enabled astronomers to record the prominences outside eclipse. Indeed, something of their form and structure is disclosed by an ordinary spectrograph, with the slit wide open. A special spectroheliograph, built at the McMath-Hulbert observatory. with motion-picture recording, was the first instrument to depict graphically the spectacular motions exhibited by some of the prominences. The objects often hang for days, suspended.like clouds above the solar surface. Their internal motions are extremely complicated; a characteristic effect is the downward streaming of the filaments, which descend to the surface in long graceful arcs. Occasionally the great clouds erupt with violent explosions and rapid motions. Velocities in excess of 100 miles per second are not uncommon.

Corona. — During totality there appears one of the most beautiful of natural phenomena, the so-called solar corona, which shines like finely etched white frost against the deep blue of the eclipse-darkened sky (*see* CORONA). The form of the corona presented at different eclipses is almost infinitely variable. On occasion, usually near sunspot minimum, long streamers extend four or five solar diameters away from the sun. At other appearances. especially close to maximum, the corona is more nearly circular, but with jagged, flowerlike petals. The corona is faint, 500,000 times or so less brilliant than the sun itself. Consequently the ordinary sky glare surrounding the sun hides the faint coronal glare, and before the development of the coronagraph it was believed to be impossible to record the corona except at the time of eclipse. The coronagraph produces in effect an artificial eclipse of the sun inside the instrument, and under conditions of very clear sky, usually attainable only at high altitudes, makes it possible to record the corona with some degree of regularity.

The corona presents many interesting problems. The greatest mystery of all — the nature of its composition — was solved by B. Edlén. The spectroscope had revealed numerous lines, radiations that could not be matched with those from any known terrestrial element. For years astronomers theorized about "coronium," a supposedly new element existing on the sun. There was precedent for such a hypothesis. Helium had been discovered in the corona during the eclipse of 1868, and it was not isolated on earth until 27 years later. But as chemists filled in gap after gap in the periodic table of the elements, hope faded of finding coronium as a new substance.

A somewhat similar mystery, that of the bright emissions from gaseous nebulae, was meanwhile solved by I. S. Bowen, who showed that the lines were due to "forbidden" atomic transitions. In other words, they arose from changes within the atom that were contrary to rules for normal lines. Under laboratory conditions these forbidden lines are extremely faint. Under conditions of low density and special excitation, however, the normal radiations can be almost completely suppressed and the forbidden lines will then appear. Indeed, both nebular lines and coronal lines have been observed in the spectra of two variable stars of the recurrent nova class.

The coronal lines were also proved to result from forbidden transitions. But where the nebular atoms have lost but from two to four electrons, those responsible for the coronal radiations have had as many as 13 torn away. The substances identified are iron X (*i.e.*, iron with nine electrons missing), XI, *XIII* and XIV. Similar emissions from calcium and nickel also appear.

The import of this discovery is staggering. Reference has already been made to the high excitation of the chromosphere and prominences, which led to estimates of temperature as great as 25,000" K. This figure is in itself enormous compared with the 6,000" K. value usually ascribed to the solar surface. But 25,000°, in turn, is insignificant compared with the minimum figure of 500.000" required for the observed ionization of the coronal atoms. Some estimates have been higher than 1,000,000".

These high temperatures are caused by the impact of gases explosively ejected from the sun, especially in the vicinity of active sunspot groups. The energy of the shock waves degrades into heat in the corona.

There is a further implication from this knowledge of the solar atmosphere. It can no longer be assumed that the solar radiation has a quality similar to that of a black body heated to 6,000° K. There must be in addition quantities of radiation in the far ultraviolet and even in the region of soft X-rays, far in excess of that from an incandescent globe at 6,000°. These short-wave radiations must enter the earth's upper atmosphere, where they produce the ionosphere, a high layer of electricity that makes possible long-distance radio transmissions. But the atmosphere so compietely absorbs these wave lengths that none of the energy reaches the surface. Existence of the radiation is revealed only from study of flash and coronal spectra and from evaluation of the effects in the earth's atmosphere. Variability of the earth's magnetic field is an associated phenomenon. So, also, is the aurora, produced by streams of corpuscular radiation interacting with and penetrating the earth's magnetic field. The earth's upper atmosphere glows under the effect of an electric discharge. The continuity provided by coronagraphic observations shows that the corona is not uniform in brilliance around the sun and that it rotates with the solar surface. The corona shows many bizarre pulsating forms, clearly associated with the presence of magnetic fields and electric currents in its boundaries.

Deflection of Light by a Gravitational Field. — One of the most famous, and the first. of the tests of Einstein's theory of relativity was that of observing the bending of a ray of light passing close to the sun. During a total eclipse the brighter stars are visible to the naked eye. and many more can be photographed near the sun. Einstein's theory predicts that the stars near the sun should be found not in their true places but displaced away from the sun by a small but measurable amount varying inversely as the distance from the centre of the sun. This test was first carried out in 1919 and has been repeated since with results on the whole in favour of the theory.

Baily's Beads. — Totality does not begin or end quite suddenly, as it should if the sun and moon were of perfectly smooth outline. There exists for a moment or two a crescent of minute gleaming points of light, called Baily's Beads. These are due to the irregular outline of the moon (*i.e.*, its mountains and valleys), because of which the sun is left uncovered here and there for a moment after the disk representing the size of the moon, if smoothed out, would have covered it.

Shadow Bands. — When totality is nearly due and only a small crescent of the sun remains, there can often be seen on the ground or on the walls of buildings striations of light and shade, indefinite in outline but something like a sheet of corrugated iron, moving moderately rapidly perpendicular to their length. These, termed the shadow bands, are due to corrugations introduced into the nearly plane waves of light reaching the earth from the sun through irregularities in the refraction of the earth's atmosphere. They are of no great scientific import. (D. H. M.)

ECLIPSES IN HISTORY

In ancient times eclipses were regarded as portents; hence it is not surprising that many eclipses are mentioned in history and in literature, in addition to those which are recorded in astronomical treatises or on astronomical tablets.

The value of these records may be classified as follows: (1) literary and historical, depending on the interest which they aroused, the notice taken of them and their connection with events; (2) chronological, insofar as they make it possible by computing their dates to verify chronological systems resting on other evidence and to supply dates for events connected with the eclipses; (3) astronomical, including the determination by ancient astronomers of the periods and motions of the sun and moon, and by modern astronomers of the mean rate of change of those motions.

Literary and Historical **References.**—*Chinese.*—In the *Shu Ching* or *Book of History* it is stated that Hsi and Ho (semidivine figures sent by the legendary emperor Yao to the four corners of the earth to keep the sun on its course and to prevent eclipses) had neglected the duties of their office and were abandoned to drink in their private cities. The king, Chung K'ang, placed the marquis of Yin in command of an army with instructions to punish them. The marquis issued a florid address to his troops in which he referred to Hsi and Ho as having neither heard nor known anything

on a recent occasion when "the sun and moon did not meet harmoniously in Fang." This phrase is taken by all Chinese scholars, ancient and modern, to mean an eclipse. It would therefore appear that a military expedition was sent to punish Hsi and Ho for failing to observe, or to prevent, an eclipse. There are good reasons for believing that this part of the *Shu Ching* is a literary restoration dating from the 4th century A.D., but sufficient is found in a quotation in the *Tso Chuan (Tso Conzmentary* compiled between 430 and 250 B.C.) and in statements in the *Bamboo Annals* to prove that the reference to the eclipse is authentic, though its relation to the supposed offense of Hsi and Ho is doubtful. It is probably based on a comminatory ritual directed against these neglectful magicians. Attempts have been made to identify this eclipse, but the necessary data are wanting. The received Chinese chronology places the accession of Chung K'ang in 2159 B.C. The *Bamboo Annals,* whose chronology is probably nearer to the truth, place it in 1952 B.C. The *Shih Ching,* or *Book of Poetry,* contains a lamentation caused by an eclipse of the moon, followed by an eclipse of the sun. The dates are clearly defined and are found to agree with events in 734 B.C. The earliest eclipses that have been definitely identified are (for the moon) that of 1361 B.C. and (for the sun) that of 1217 B.C., both derived from inscriptions on ancient oracle bones. The eclipses recorded in the *Ch'un Ch'iu* or *Spring and Autumn Annals* possess chronological and astronomical rather than literary interest.

Assyrian.—The Assyrian eponym canon, which preserves the names of the annual magistrates who gave their names to the years, records under the year which corresponds to 763–762 B.C.: "Insurrection in the city of Assur. In the month Sivan the sun was eclipsed." The reference must be to the eclipse of the sun on June 15, 763 B.C. A reference to the same eclipse has been found in the Bible: "'And on that day,' says the Lord God, 'I will make the sun go down at noon, and darken the earth in broad daylight' " (Amos viii, 9).

Greek.—Homer, in the *Odyssey,* twice makes the unrecognized Odysseus predict that Odysseus will return "as the old moon wanes, and the new appears," that is. at new moon, when alone an eclipse of the sun is possible. In one of these passages he predicts vengeance on his wife's suitors. On the day when Odysseus was to become known and slay the suitors, the seer Theoclymenus notes among other portents of gloom that "the sun has perished out of heaven, and an evil mist has spread over all." This was interpreted by Plutarch and Eustathius as a total eclipse of the sun. Some modern scholars have regarded it as merely a vision of the seer. An identification with the solar eclipse of April 16, 1178 B.C., which was total in or near Ithaca, has been suggested. But it is not improbable that this story belongs to legend rather than to history.

In a fragment of a lost poem by Archilochus occur the words: "Nothing there is beyond hope, nothing that can be sworn impossible, nothing wonderful, since Zeus, father of the Olympians, made night from mid-day, hiding the light of the shining sun, and sore fear came upon men." This phenomenon has been identified as the total eclipse of the sun on April 6, 648 B.C.

Small fragments survive of other poetic descriptions of eclipses, and the ninth paean of Pindar, addressed to the Thebans, takes an eclipse of the sun as its theme, as follows: "Beam of the sun! O thou that seest afar, what wilt thou be devising? O mother of mine eyes! O star supreme, reft from us in the daytime! Why has thou perplexed the power of man and the way of wisdom, by rushing forth on a darksome track?" Pindar then proceeds to speculate on the meaning of the eclipse as a portent. The poem probably refers to the solar eclipse of April 30, 463 B.C., which was nearly total at Thebes.

The most famous of ancient eclipses was a total eclipse of the sun which happened, according to Herodotus, during a battle between the Lydians and the Medes. The portent induced them to conclude peace. Herodotus further says that Thales of Miletus predicted this eclipse to the Ionians for the very year in mhich it happened. Babylonians were certainly predicting eclipses at about that time by means of the 18 years' cycle known as the saros *(see* below). But, as that cycle gives eclipses for every year, the statement about Thales must, if true, mean that he predicted that an eclipse of that particular year would attain a great magnitude. Such a prediction can be made by the 18 years' cycle without any mathematical computation. The eclipse was certainly that of May 28, 585 B.C., and must have been predicted by means of the eclipse of May 18, 603 B.C. Several ancient writers have preserved 585 B.C. or some neighbouring year as the date of the eclipse.

Thucydides comments on the frequency of eclipses during the Peloponnesian war. The most interesting of these were the solar eclipse of Aug. 3. 431 B.C., when "the sun assumed the shape of a crescent and became full again, and during the eclipse some stars became visible" (a statement that agrees well with modern computation) and the lunar eclipse of Aug. 27, 413 B.C. That date had been selected by the Athenian commanders Nicias and Demosthenes for the departure of their armament from Syracuse. All preparations were ready, but the signal had not been given when the moon was eclipsed. The soldiers and sailors clamoured against departure and Nicias in obedience to the soothsayers resolved to remain thrice nine days. This delay enabled the Syracusans to capture or destroy the whole of the Athenian fleet and army.

Aug. 15, 310 B.C , is the date of a total eclipse of the sun said to have been seen by Agathocles and his men the day after he had sailed from Syracuse on his way to Africa. Modern computations of the eclipse track render it probable that he sailed to the north of Sicily.

In Plutarch's dialogue *De facie in orbe lunae* ("the face on the moon's orb"). one of the characters, called Lucius, deduces from the phases of the moon and the phenomena of eclipses a similarity between the earth and the moon and illustrates his argument by means of a recent eclipse of the sun, "which, beginning just after noon, showed us plainly many stars in all parts of the heavens, and produced a chill in the temperature like that of twilight." A little further on Lucius refers to a certain brightness which appears round the moon's rim in total eclipses of the sun. The identification of this eclipse with that of March 20, A.D. 71, was confirmed by F. K. Ginzel after a very exhaustive discussion. There are numerous other references to eclipses in Greek literature.

Roman.—A large number of eclipses were recorded in Roman history. One which has attracted the attention of students of astronomy and of the Roman calendar alike is stated by Cicero to have occurred in what may have been the 350th year from the foundation of Rome. He also says that it was described by the poet Ennius: "On the Nones of June the sun was covered by the moon and night." This would appear to have been the solar eclipse of June 21, 400 B.C., which reached a total or almost total phase at Rome a few minutes after sunset. It seems to show that in that year the calendar month of June began 16 days later than it did after the Julian reform. The eclipse of the moon on June 21–22, 168 B.C., has attracted much attention. The Romans were at that time at war with Macedonia, and Polybius says that this eclipse was interpreted as an omen of the eclipse of a king and thus encouraged the Romans and discouraged the Macedonians.

Use of Eclipses for Chronological Purposes.—Although no continuous era has been used since ancient times, dates are frequently expressed in terms of regnal years, or are named after consuls or other officials of whom lists have been preserved. In these cases it is important to be able to equate certain specific years thus defined with years before the Christian era. This can be done whenever the date of an eclipse or other identifiable and calculable astronomical phenomenon is given in an ancient record.

The received Chinese chronology can be confirmed accurately by eclipses from the Shang dynasty *(c.* 1766–c. 1123 B.C.) onward. The chronology of Ptolemy's canon of kings, which gives the Babylonian series from 747 to 539 B.C., the Persian series from 538 to 324 B.C., the Alexandrian series from 323 to 30 B.C. and the Roman series from 30 B.C. onward, is confirmed throughout by eclipses. The eclipse of 763 B.C., recorded in the eponym canon, makes it possible to carry the chronology back with certainty through the period covered by that canon to 893 B.C. Assyrian, Babylonian and Persian chronology provide a stable chronology for the countries with which Assyria, Babylon and Persia came into contact, but there is no check from eclipses on Greek or Egyptian historical chronology before the Persian period. Identifiable eclipses re-

corded under named Roman consuls extend back to 217 B.C. The dated solar eclipse of Ennius, the lunar eclipse seen at Pydna in Macedonia on June 21–22. 168 B.C. and an eclipse of 190 B.C. can be used to determine the position of Roman calendar months in the natural year; and occasionally eclipses help to fix the precise dates of a series of events, such as those connected with the Athenian disaster at Syracuse.

Use of Eclipses for Astronomical Purposes.—In Ancient Astronomy.—It would appear that at least from the time of King Nabonassar (747 B.C.) a dated canon of astronomical observations was preserved at Babylon, including all eclipses. This rendered it possible to determine accurately the intervals between eclipses and must have facilitated the discovery of the 18 years' cycle (more exactly the cycle of 6,585⅓ days, which the 10th-century Greek lexicographer Suidas calls the saros) and its multiple, the 54 years' cycle of 19,756 days. These two cycles govern the recurrence of eclipses. It has been seen that Thales probably used such a cycle. In a Babylonian observation tablet of 568 B.C. mention is made of failure to observe a predicted eclipse of the moon, which is found by computation to have been real but invisible at Babylon. It was doubtless predicted by cycle. Tables based on the saros go back to the 4th century B.C. Eclipses of the moon give more accurately than any other kind of observation the actual time when sun and moon are in opposition. From an early date the Babylonian astronomers must have deduced from them not only the mean interval between two conjunctions but also the principal inequality in the motion of the moon and the similar inequality in the motion of the earth (or, as on their geocentric theory they conceived it, of the sun) and they were able to define the periods of these inequalities, which astronomers call the anomalistic month and year.

In the same way, since eclipses happen only when the two luminaries are stationed at intersections of their orbital planes called nodes, and since the path of the shadow in a lunar eclipse depends on the position of the centre of the sun in relation to the node, the Babylonians were also able to determine the position and motion of the nodes. By assuming, what is approximately true. that the saros of 6,585⅓ days contained an exact number (1) of synodic months. or revolutions of the moon measured from the sun, (2) of anomalistic months. or revolutions of the moon measured from its apogee or perigee (*i.e.*, from its farthest distance from and closest approach to the earth), and (3) of draconic months, or revolutions of the moon measured from its node. the early astronomers, perhaps in the 6th century B.C., computed the relative motions of the sun and moon, the lunar perigee and apogee and the nodes. About 500 B.C. Naburiannu, apparently from a more accurate study of eclipse observations, obtained improved values which for the motion of the moon from the sun were 10″ per annum too small, from the moon's perigee 20″ per annum too great and from its node 5″ too small. Still more accurate values were obtained by Kidinnu about 383 B.C., from whom they passed to the Greek astronomer Hipparchus. In the system of Naburiannu the distance of the moon from its node was used for the prediction of the magnitude of lunar eclipses.

In Modern Astronomy.-Ancient eclipses are of the highest value for the determination of "secular accelerations," *i.e.*, for the determination of the progressive, as distinct from the periodic, changes in celestial motions. Edmund Halley asserted in 1693 his belief that the moon's motion was subject to acceleration, but did not specify the amount of the acceleration. In 1749 Richard Dunthorne demonstrated from a comparison of the recorded with the computed times of eclipses distributed over 2,000 years that such an acceleration existed and assigned to it the value of 10″ a century. By this is meant that the effect of the acceleration is to produce an advance of 10″ in the moon's longitude in the course of a century. P. S. Laplace in 1787 showed that such an acceleration should be the gravitational effect of the secular diminution in the eccentricity of the earth's orbit; but according to J. C. Adams in 1853 the acceleration due to this cause amounted to 6″ only in a century. The residue must be explained by other causes.

This acceleration is mainly due to tidal friction, which has two consequences: (1) the earth's rotation is slowed down by the pull of the moon on the oceans at a rate that has averaged some 2″ per century per century since ancient times; *i.e.*, the total angle turned

Solar Eclipses During the 20th Century*

Date of eclipse at noon point	Duration of totality (minutes)	Node and series	Regions crossed by belt of totality
1900 May 28	2.1	D 5	Mexico, S.E. United States, Portugal, Spain, N. Africa
1901 May 18	6.5	D 6	Sumatra, Borneo, Sew Guinea
1904 Sept. 9	6.4	A 7	S. Pacific ocean

*Those eclipses that are visible only in polar regions or are of exceedingly short duration are omitted.

through every century has decreased by an average of 2″ every century. so that the day increases in length; (2) the orbital angular momentum of the moon is increased, pushing the moon farther away from the earth and thus lengthening the lunar month. The first effect would by itself lead to an apparent acceleration in the moon's motion of about 26″ per century per century; the acceleration actually observed is only 5.2" per century per century because the second effect counteracts the first.

ECLIPTIC, in astronomy, is the great circle on the celestial sphere which forms the apparent path of the sun in the course of the year. The twelve constellations or signs of the zodiac are arranged along the ecliptic. The plane of the ecliptic is the plane of the earth's orbit, or more strictly the plane in which the combined centre of gravity of the earth and moon revolves around the sun; it meets the celestial sphere in the great circle mentioned above.

ECLOGITE, a typical member of a small group of garnet rocks including both igneous and metamorphic representatives, and of special interest because of the variety of minerals they contain and their geological relationships. Under the name griquaite, eclogites are found as blocks or boulders in the kimberlite "pipes" of the diamond fields of South Africa *(see* DIAMOND). This eclogite is of special interest inasmuch as diamonds have been found as enclosures of the garnet of the rock, and according to one view eclogite is the parent rock of the diamonds of the South African fields, the diamonds of the "pipes" being derived from the explosive disruption of deep-seated masses of diamantiferous griquaite or eclogite.

The eclogites (from the Greek word *ekloge,* "a selection") are mostly coarse-grained and massive aggregates of green monoclinic pyroxene and red garnet, but some varieties possess green hornblende wholly or partly replacing the pyroxene, thus giving rise to the two important groups—the pyroxene and the hornblende eclogites. The minerals associated with these essential constituents include rutile, apatite and iron ores, and, less commonly, quartz. muscovite, zoisite, cyanite, albite, bronzite, olivine and chlorite.' The eclogites correspond closely in bulk composition with gabbro and diabase (*qq.v.*), but are characteristically assemblages with high density (specific gravity 3.2 to 3.6 as compared with gabbro 2.9 to 3.0).

The pyroxene (*q.v.*) in eclogite shows considerable variation in composition, and includes both nonaluminous and aluminous varieties. The latter contain significant proportions of the jadeite and aegirine molecules and correspond to omphacite, a green variety of diopside. The red garnet (*q.v.*) is a pyrope-rich variety containing almandine and grossular, but is not so magnesia-rich as the garnet found in serpentines and peridotites. The hornblende *(see* AMPHIBOLE) is usually a green variety—smaragdite, or alkali-hornblende sometimes approaching glaucophane in composition.

Whether of metamorphic origin or considered as igneous rocks consolidating under excessive pressures, the almost complete absence of plagioclase feldspar makes these rocks of peculiar interest. The omphacite-garnet assemblages appear to have crystallized under high pressures: in place of augite, olivine and plagioclase. Magnesian garnet appears in place of olivine-anorthite, and a jadeite-chloromelanite-bearing pyroxene in place of the augite-plagioclase combination of the gabbros.

That some eclogites are of metamorphic origin is clearly revealed by their geological associations and microscopic structures. Such often appear as lenses intercalated among crystalline schists and show unmistakable crystalloblastic structures, that is, resulting from solid state crystallization.

Others, such as those of western Norway, occur as lenticular masses in granite gneiss or bands in olivine rocks (peridotites, dunites or their. serpentine derivatives). These rocks possess no true crystalloblastic structure, and are believed to be unaltered igneous rocks. Probably some eclogites from other areas previously believed to be transmuted gabbros are of similar origin.

The amphiboles of the eclogites may represent either a direct crystallization from the magma. or arise by metamorphic processes from original pyroxene, and it is not improbable that many of the so-called "garnet-amphibolites" are transformed eclogites. The recognition of eclogites as primary magmatic consolidations under high pressures has led to the conception of an eclogite zone in the earth's crust immediately below the more acid silicate shell *(see* GEOCHEMISTRY: *Geochenzical Structure of the Earth).* At considerable depth magma of basaltic or gabbroid composition may exist stable as solid eclogite, and it is possible that in this zone is to be discovered the source of the eclogite blocks of the kimberlite "pipes." The geological associations of some eclogites appear not to accord with the prevailing conception of the group as a high-pressure mineral facies. In a seemingly anomalous environment are certain eclogites and, indeed, the mineral jadeite itself, found in intimate association with low-grade metamorphic schists or serpentine~in France, California and the Celebes. Though some of these associations may be the result of tectonic transport, that is, movement of the earth's crust, there remain occurrences to which such an interpretation is inapplicable. The chief localities for eclogites are Pre-Cambrian and Paleozoic metamorphic-igneous complexes. They are known from Scotland. western Norway, Saxony, Bavaria. the Alps, Austria, Greece and California. (C. E. T.)

ECLOGUE, a pastoral poem usually in dialogue but perhaps originally signifying no more than a short poem (Gr. *ekloge,* selection). The term was originally applied specifically to pastoral dialogues and was equipped at the Renaissance with various fanciful etymologies, notably "goat-speech" (Gr. *aix,* goat; *logos,* speech), which accounts for the frequent English spellings "eglog" or "aeglogue" and the French *"églogue."* 'The form, widely used during the Renaissance by neo-Latin and vernacular poets, later became increasingly rarer. There are eclogues in English in Spenser's *Shepheardes Calendar* (1579) and Collins' *Persian Eclogues* (1742) and four in Louis MacNeice's *Collected Poems* 1925–1948 (1949).

See BUCOLICS; PASTORAL. (J. F. RE.)

ECOLOGY, ANIMAL, is concerned with the interrelations between animals and their environments. It is a subdivision of the science of ecology. or that branch of biology that embraces the interrelations between plants and animals and their complete environments. Ecoldgy is a basic approach to the conservation of natural resources and—together with several other biological sciences, such as biochemistry, genetics. cytology and general physiology—cuts across the sciences of zoology and botany, that is, ecology is concerned frequently with general principles that apply to both animals and plants.

This survey is divided into the following sections:

I. GENERAL

1. Introduction. — The content of ecology may be divided in several ways. First, where attention is directed to the type of environment, ecology is divisible into terrestrial interrelations (terrecology), fresh-water interrelations (biological content of limnology) and marine interrelations (biological content of oceanography). Second, where emphasis is upon plants or animals, we speak of plant or animal ecology. Third, where the point of departure deals with the level of the complexity of interrelations, me have to do with autecology, or the interrelations of the individual plant or animal with its physical and biotic environments, or with synecology, which is the study of progressively complex interrelations of natural assemblages of organisms, such as populations and communities.

These groups of ecological categories are seldom wholly separable. They are united both by the application of common principles and by natural intergradations between any two. For example, fresh-water marshes merge with grassland or forest; areas may be covered with a temporary pond at a particular season of the year; river mouth and the sea meet at the estuary. A complete understanding of an animal is impossible without considering its relationships with plants. Similarly, such an understanding is not possible without considering its interrelations with others of the same kind and with animals of different kinds. Consequently, the study of the entire natural assemblage of plants and animals and their environment is desirable in any complete investigation.

The technique of ecology is both experimental and descriptive. The science has many important interrelations with other branches of basic and applied knowledge. Several examples are notable.

In basic biology one problem is that of the origin and establishment of species. When a new species arises, its particular adjustments of structure, function and behaviour must be such that the population may live in a particular environment or series of environments. It must adjust both to the physical influences that are in operation and to biological factors already established. Under such conditions the new population may do one of three things: It may adjust to the total environment; it may emigrate to another environment; it may die. If the organisms adjust, this implies that they can compete or co-operate with other species for food and shelter. Consequently, the establishment of a species is the result of ecological selection of a particular heredity.

Interrelations between ecology and sociology were summarized by J. W. Bews (1935).

There are many ecological aspects of man's industrial and agricultural production. These include the relations of economic plants to soil types, diets of farm and range animals, pollution, overlumbering, overgrazing, overcultivation, dust storms, floods, forest fires and game conservation. Often a man-made catastrophe has its origin in the unconscious application of ecologically unsound practices. For additional information the summaries of P. B. Sears (1935) and I. N. Gabrielson (1941) may be consulted.

The importance of general conservation, whether of oil and coal or of timber. soil, migratory birds or whales, cannot be emphasized too much with reference to the future well-being of mankind. Plants and animals are interrelated in highly complex natural communities and they must be manipulated or replaced with scientific care. Here the application of ecological principles ranges from those involved in the stocking of a small lake to a national program of reforestation. Basic research and the training of personnel should precede attempts at conservation since the solution may require answers to a number of inconspicuous yet important questions. For example, the bighorn or Rocky Mountain sheep formerly ranged over high mountains from Arizona into British Columbia and Alberta but is now absent or present only in reduced numbers in many parts of that territory. Herd reduction may be a consequence of many adverse influences. including (1) shooting of bighorn by hunters; (2) insufficient forage plants; (3) inadequate range; (4) scarcity of water; (5) disease; (6) parasites; (7) competition for food with domestic cattle; (8) competition for food with other game such as mule deer; (9) predation by such hunters as the bobcat and puma.

It will be seen that ecology has many interrelations with other branches of learning and that its applications are inextricably involved with man's destiny. As information accumulates in regard to the requirements of species populations and community relations, such data become available to animal husbandry, agriculture, conservation and public health The danger is that the information mill not be available in an integrated form soon enough to ensure broad conservation of natural resources.

Solution of many problems in public health and medicine involve ecology. Thus, the effective control of a variety of diseases is achieved by control of the vector rather than by control of the disease-producing agent or pathogen. Such vectors include malarial mosquitoes, mosquitoes carrying the virus of yellow fever and jungle yellow fever, rats and rat fleas infected with plague bacteria, ticks and mites carrying pathogens responsible for such diseases as certain relapsing fevers, forms of typhus. and many more. Control of the carrier is an ecological problem since the program involves the interrelations of the vector with its environment.

2. History. — In this brief survey of animal ecology only a small portion of the science can be dealt with. Historically, the subject is old in that some of its material is derived from natural history dating to Aristotle. In modern terms ecology is of recent origin as an organized science. It was established at about the time that the science of genetics was recognized.

In the 18th and early part of the 19th centuries there was considerable fact and fancy in natural history. In 1869 Ernst Haeckel stated that the individual was a product of co-operation between the environment and organismal heredity. This relationship he termed "oecology."

Haeckelian "oecology" was more or less forgotten in the activity that resulted from publication of Charles Darwin's theory of natural selection in 1859. This was a strange turn of events, since Darwin's theory was primarily an ecological theory of evolution, stressing the environment as a selection agent over long periods of time. Ecology was placed on a modern basis, more or less, by F. A. Forel in Switzerland in 1892, E. B. Warming in Denmark in 1896 and by the Americans E. A. Birge, H. C. Cowles and F. E. Clements between 1891 and 1905.

Thereafter, research in ecological subjects tended to stress population and community analysis. Quantitative and statistical methods increased the scope of the science, and more interrelations became apparent between ecology and taxonomy, physiology, biochemistry and geography. Study of microclimate and microhabitat became increasingly important. There was a growing emphasis among ecologists to evaluate their data in terms of evolution and of conservation.

II. BASIC REQULREMENTS OF ANIMALS

Organisms have three basic physiological requirements to meet if they are to live as individuals and perpetuate the species. These drives are nourishment, recuperation and reproduction. Their ecological counterparts are food, shelter and certain problems involving territory. The particular ways in which species satisfy these drives involve modification of structure, functions and behaviour that are known as adaptations or adjustments. The better adjusted the organism, the better its chances of living with other members of its species population and with members of other species populations. Consequently, there are recognized three general categories of adjustments: feeding, sheltering and reproductive.

1. Food. — Organisms must obtain nourishment to live; and since food must be obtained from the environment, it becomes a

fundamental ecological factor. Certain basic aspects of plant nourishment are discussed in the treatment of communities.

As a rule, the food types that make up the bulk of a species' diet are associated with definite feeding adjustments. The first feeding category is that of plant eaters, or herbivores, only a few examples of which can be mentioned here. Numerous insects, such as aphids, feed upon plant sap; and their mouth parts are in the form of a tubular, sucking beak. Other insects, including certain ants, have thick crushing jaws for cracking seeds. Although lizards as a group are meat eaters some species eat vegetation and have rounded and broadened teeth. Among mammals the domestic cow and horse. as well as the deer, have some teeth flattened for grinding their plant food.

The second feeding category is that of the carnivores, or flesh eaters. Within this group are two subdivisions. The first are the predators. These stalk their food, kill it by direct assault and then feed upon the victim. Their feeding adjustments are for overtaking and holding prey. Here may be mentioned the long, highly modified mouth parts that enable cychroid ground beetles to feed on certain snails while the latter are withdrawn into their shells; the sharp claws of cats; the recurved teeth of the black snake; and the protrusible tongue of the toad. The second group of carnivores contains the parasites. These differ from predators in that they feed on the flesh of their prey, the host, while it is vigorous and at liberty, whereas predators feed after their prey has been subdued and is dead or dying. It is to the biological advantage of parasites that the host is not killed, so that the parasite may continue to feed upon it. Here are numerous types of feeding adjustments, including ectoparasites and endoparasites, living on or within the host's body, respectively. An entire branch of biology, parasitology *(see* **PARASITISM AND PARASITOLOGY),** is concerned with these animals. Many parasites are adjusted to feed on a special kind of food. The blood diet is such a particular case, and feeders on blood are known as sanguinivores. Such animals generally have specialized saliva that is anticoagulant and anesthetic in its action. Common sanguinivores are fleas, the majority of female mosquitoes, bedbugs, leeches and ticks. Common endoparasites include the tapeworms and flukes.

Then there are the omnivores, feeding on a variety of both plants and animals. Man is an omnivore; his dentition enables him both to cut and grind his food. There are many aquatic omnivores. The majority of these feed on minute organisms in the water and consequently must be collected by specialized conveying and straining mechanisms. Whalebone whales, rotifers, sponges, numerous marine worms, clams, oysters and barnacles collect and devour minute, usually floating, often microscopic plants and animals (collectively called plankton) in the water. Obviously, within and between these three major feeding categories there are many differentiations and intergradations.

2. Shelter. — Turning to the second of the three basic organismal drives, it is found that continuous physiological activity leads to exhaustion and finally death. Therefore, animals must undergo physiological recuperation or rest. Frequently this is accomplished during sleep or its physiological equivalent. Such resting periods, during which an animal is characterized by relative inactivity and relatively slower responses to external stimuli, are dangerous since the individual is more exposed to attack from its natural enemies. Consequently the majority of animals undergo periodic rest in some protected or sheltered spot, such as the mud on the bottom of a pond, a hollow tree, beneath a log, in a subterranean burrow, beneath a leaf or deep within a flower. These "homes" are known as habitat niches. They are restricted portions of larger areas known as habitats.

3. Habitats. — Habitats may be classified as follows:

I. Habitats occupied by free-living organisms
  A. Salt water or marine (polar, temperate, tropical)
    1. Littoral or shore
      a. Rocky
      b. Sandy
      c. Muddy
    2. Pelagic or surface waters of seas
    3. Abyssal or deep sea
  B. Brackish water, such as an estuary
  C. Salt lakes, such as the Dead sea of Palestine and Great Salt lake of Utah
  D. Fresh water
    1. Standing water
      a. Marsh
      b. Bog
      c. Ponds and lakes (polar, temperate, tropical)
        (1) Paralimnic, or fresh-water littoral
        (2) Limnetic, or fresh-water "pelagic"
        (3) Profundal, or deep-water, and pedonic, or lake-bottom
    2. Flowing water
      a. Springs
        (1) Cold-water
        (2) Thermal, or hot-water
        (3) Chemical, such as sulfur springs
      b. Streams (including small brooklets and large rivers)
        (1) Rapids or waterfalls
        (2) Relatively quiet pools
  E. Terrestrial
    1. Epigean, or aboveground
      a. Flood plains
        (1) Gravel
        (2) Sand
        (3) Silt
      b. Grasslands
        (1) Tall grass
        (2) Short grass
      c. Forests
        (1) Deciduous
        (2) Evergreen
          (a) Tropical
          (b) Coniferous
      d. Desert
        (1) Sandy
        (2) Rocky
      e. Ice desert
    2. Hypogean, or subterranean, such as caves
II. Habitats occupied by parasites
  A. Ectoparasitic
  B. Endoparasitic

This general classification can be expanded almost indefinitely. For example, the societies of ants, termites and certain wasps and bees, and the towns and cities of man are habitats of a great array of plants and animals. Again, each category in the above list is subject to considerable variation with respect to latitude and altitude and to the differential action of numerous environmental influences. Obviously there are many intergradations between habitats. For example, grassland and desert intergrade in semidesert; a shore may consist of sandy mud; or a pond may be present only during the spring months.

A habitat may be occupied continuously by the same animals, termed permanent residents, or occupied at a particular period by animals known as temporary residents. Within an American elm and oak deciduous forest, chipmunks are permanent residents, whereas the migratory black and white warblers are temporary residents.

Many permanent residents undergo special periodic sheltering adjustments associated with dormancy. One of the adjustments associated with winter is termed hibernation (*q.v.*). It is accompanied by a relatively low temperature and physiologically inaccessible water in the form of snow and ice, and the habitat niche is termed a hibernaculum. One of the adjustments associated with summer is termed estivation. It is accompanied by a relatively high temperature and physically inaccessible water or drought, and the habitat niche is termed an estivaculum.

Hibernation and estivation are broad seasonal adjustments. There are many sheltering adjustments of a more limited nature. A familiar example is the periodic occupation of habitat niches for a part of each 24-hour cycle of day and night. Often the same niche is occupied by different populations at different times. Many nocturnal animals inhabit the carpet of decomposing leaves of a forest by day and feed on the living foliage of the trees during parts of the night; their ecological counterpart, the diurnal animals, are active by day and inactive during the night, and many of these pass their period of rest in the same layer of leaf mold.

It must also be remembered that often the several stages in the life cycle of an animal occupy a series of different habitat

niches and often a series of different habitats. For example, the common fresh-nater clams have minute young known as glochidia; these, when discharged by the parent, have a brief period in the water of the stream or lake during which time they must become attached to fishes to live. If they can attach to a fish. they become parasitic for a time and are dispersed in this manner. Eventually, however, the further developed glochidia leave the host and settle to the bottom, where they continue their development and become free-living clams. Again. the familiar May flies, stone flies and dragonflies hatch from eggs laid in fresh water, lead herbivorous or carnivorous aquatic lives as naiads and then transform into aerial adult insects.

Members of a particular kind or species of animal tend to have common structural, functional and behavioural adjustments; consequently the population occupies a series of similar habitat niches throughout the range of the species. These niches may be identical, or ecologically equivalent, if the range is great or the species is tolerant of a variety of conditions and habitats. This ability to tolerate environmental variations is known as vagility. The puma, with a range from sea level to high elevations in mountain ranges, from Alaska to Patagonia, has a high vagility; sloths, restricted to certain kinds of tropical American forests, have low vagility.

The environment is constantly selecting the inherited adjustments of animals, and animals are constantly modifying their environment through feeding, burrowing, respiration, depositing their feces and excreta and eventually their bodies. Consequently, through long periods of time, populations evolve with better adjustments to existing conditions through natural selection, and the habitats and habitat niches change through the influence of physical and biological factors.

In this almost constant process of change, the species that inhabit the same habitat compete for food and shelter and often cooperate for these necessities. Such competitions and co-operations among populations are both direct and indirect. and their proper study is a vast subject (see POPULATION ECOLOGY). The sheltering adjustments that allow a species to inhabit several habitat niches over its life history is such a large subject that only a few examples can be given here.

In the first place, there are the broadest levels of adjustment to media: for example, aerial, aquatic and terrestrial adjustments for locomotion as well as respiration in air or water; more specialized adaptations for life in the relatively fresh waters of inland lakes and streams in contrast with a life in the salt water of oceans. Within these broad adjustments are progressively more specialized features that allow a species to occupy a particular habitat and even a particular portion of its habitat.

Stream animals illustrate this process. They are adjusted to the whole stream in a general way, but some species (fishes. May fly naiads) obtain their oxygen through gills, whereas others (dytiscid beetles) carry a supply of fresh air with them when they dive and periodically replenish this supply by returning to the surface. Furthermore, certain types of animals tend to inhabit quiet pools. where the current is relatively slow and the amount of dissolved oxygen relatively small, whereas others tend to inhabit rapids, where the current is swift and the dissolved oxygen abundant. Consequently. there are pool mores and rapids mores, indicating that such animals have a collective type of adjustment to a special portion of the stream.

Then there are still more special adjustments to a part of such a habitat. For example. there are adjustments to the surface film of the water. Water striders (Gerridae) skate over the surface on the finely haired tarsal segments of their legs. Certain species of the staphylinid beetle of the genus *Stenus* have an anal secretion that lowers the surface tension of the water; because of the greater tension of the film on which the anterior parts of the beetle rest the insect is pulled rapidly forward. Still others, such as the larvae and pupae of mosquitoes, lie just beneath the water surface; the contact of the film with certain parts of their bodies supports them without expenditure of muscular energy.

Since most aquatic animals are heavier than water, those animals that inhabit the upper layers rather than move over the bottorn must hold their spatial position against the pull of gravity. Such buoyancy or flotation adjustments are very diverse. The swim bladder of many fishes aids in this maintenance of position. Many minute single-celled animals or Protozoa achieve buoyancy by the presence of oil globules in their protoplasms. Certain marine snails have egg masses that are kept afloat by a mucous pad that is infiltrated with air bubbles. One marine group of protozoans, the Radiolaria, despite a dense skeleton of silicon, lives near the sea surface. In certain radiolarians this flotation is accomplished by the secretion of carbon dioxide that accumulates as gas bubbles in the protoplasm of the animals. Numerous surface dwellers, including some rotifers, many small crustaceans of the order Cladocera and protozoans of the genus *Ceratium* undergo a seasonal change in form in apparent correlation with the density and viscosity of the water. The warmer water of summer offers less resistance to sinking. The summer populations of these animals are characterized by individuals having the surface expanded in proportion to their mass, the winter populations by individuals having a relatively compact form with fewer or shorter projections.

Over long periods of time most organisms are chiefly responsible for the formation of a rich, organic soil. Activities of civilized man usually lead to strong modifications of habitats; for example, pollution of streams and lakes, soil erosion, destruction of watersheds, dense smoke clouds and increased radioactivity are but a few ways in which some habitats deteriorate.

4. Reproduction. — Another basic drive, reproduction, has many ecological implications. Climate and weather have both long-range effects and more immediate effects upon such diverse aspects as courtship behaviour, time of mating. laying of eggs and development of the larval or immature stages. Most higher plants are pollinated by an environmental agency. This agency may be a physical factor, as in the wind-pollinated trees, or it may be a biological agency, as in the transfer by insects of pollen for many fruits and vegetables. Growth of species populations through reproduction involves the problems of both food and shelter, attack by predator and parasite, disease, co-operation and numerous other aspects of general ecology. See also REPRODUCTION.

III. PRINCIPLE OF COMMUNITY

Even this brief survey of food, shelter and reproduction demonstrates that no organism can live wholly alone and be independent of other organisms. Herbivores must be associated with their food plants, and carnivores and parasites must be associated with their prey. Consequently, since no plant or animal can live in a foodless biological vacuum, species populations form natural gatherings with other populations. Such assemblages are of various sizes, composition and complexity. They have been called biocoenoses. if the interrelations are especially closely knit. but they are more generally known as communities. L. R. Dice (1952) distinguished between the nonliving environment and the community (living environment) and combined both as the ecosystem.

Since each species inherits a particular heredity that allows it to tolerate certain environmental conditions but not others, it follows that the populations of a community can tolerate the normal environment at that place. This environment is complex. It consists of two kinds of influences: (1) the physical factors, such as light intensity and quality, temperature, precipitation, evaporation, quality of the medium, substrate, salinity, air or water pressure and many others; and (2) the biological factors, including food, biotic aspects of shelter, population pressure, predation, parasitism, disease and many more.

1. Major Community. — When a community is relatively self-sustaining and self-regulating. it is at the level of survival for its component species populations. Such a community is called a major community. The major community is one of the fundamental concepts in biology. Normally single-celled organisms such as algae and protozoans cannot exist apart from their food supply. Similarly, the separate cells of many-celled organisms are unable to live apart from the tissues of which they are vital units. The tissue is similarly unable to exist apart from other tissues of the organismal whole. Finally. the complete organism cannot exist without food. Therefore the populations involved

must live together in a major community if they are to exist at all. This is the level at which survival is possible.

Given radiant energy from the sun, the major community is a self-maintaining. self-regulating, independent assemblage. There are few exceptions to this principle. A possible exception is found in certain kinds of caves, where the initial food supply is derived largely from external sources. A forest is a major community, as is an adjoining grassland, and each is independent of the other for survival. Similarly, a lake is a major community and the vast oceans are collectively a continuous: self-sustaining major community.

Within any of these major communities are almost innumerable smaller communities that are not self-sustaining; for example, tree holes and decaying logs in forests, cattle droppings in grasslands, the lake-bottom or profundal community and the coral-reef community in the sea.

Major communities have three basic features in common: (1) a fundamental structure, known as stratification; (2) systems of interchange and recombination of foodstuffs, known collectively as community metabolism; and (3) a common system of periodicities.

2. Stratification. — with respect to stratification, the species populations are in a vertical series of horizontal layers, termed strata, and usually also in a series of concentric layers, termed zones, from the periphery to the centre of the community. Major communities, then, are separable into both horizontal and concentric layers. Since a major community is always in contact with one or more major communities at its boundaries, there is always a marginal zone where the communities intergrade. This intergrading area is known as an ecotone. The seashore is a much-studied ecotone between the marine and terrestrial communities. Obviously the ecotone is not a major community since it is not self-sustaining; that is, it could not exist in its present form without being a part of, and dependent upon, the communities that it connects.

The principle of stratification will be examined again in the discussion of the marine biome, and forest stratification will be used as an illustration of community structure. **A** forest usually has the following strata: (1) subterranean; (2) floor; (3) herbaceous; (4) shrub and small tree; (5) canopy. Each stratum, dependent upon the other four, may be thought of as a community in the genera1 sense but is not a major community. Each stratum has its own microclimate, its particularly adjusted stratal animal life and its peculiar organization. Stratal adjustments are abundant and suggest that the stratum places a positive selection value upon certain kinds of adjustments to maintain position or to procure food and shelter. Generally, stratal adjustments for a particular stratum are similar in widely separated forests over the world. Species occupying a given stratum in two such forests may be widely separated taxonomically but still have similar requirements. This phenomenon is termed the principle of ecological equivalence.

The subterranean stratum, at the bottom of the forest's vertical gradient. is most similar ecologically to the subaqueous stratum of aquatic gradients. Its matrix of soil particles is relatively continuous and homogeneous. Light is absent, and the soil temperature and soil moisture are relatively stable in contrast to higher forest strata. Living here are myriads of bacteria, fungi, soil protozoans. nematode worms, earthworms, almost countless mites, numerous insects, moles and the extensive root systems of trees, shrubs and herbs. Moles are good examples of animals adjusted for life in a certain stratum. They have large, horny forefeet for tunnelling, short tails. minute ears and vestigal eyes. These features are adjustments for a life of digging, and are shared more or less by numerous other ecologically equivalent mammals.

The floor is the second stratum. It is less homogeneous and less continuous than the preceding stratum but much more so than all higher strata. Similarly, it is intermediate between higher strata and the subterranean stratum in its physical and biological conditions. In contrast to the higher strata, the floor is slightly colder in winter, slightly warmer in summer, dimly lit during the day and more easily injured by forest fire and flood. The forest floor is an insulating layer, retarding erosion and accumulating diverse foodstuffs. Its matrix consists of leaf mold and log mold. In this layer are included fallen leaves in all stages of decay—providing a characteristic aspect to the stratum — rotting stumps and prostrate logs, twigs, nuts. fallen fruit and flowers, animal feces and the dead and decomposing bodies of animals. In evergreen forests the leaves tend to fall throughout the year, whether in tropical jungles and rain forests or in temperate coniferous forests. In deciduous forests the leaves tend to be deposited in the autumn season.

In addition to numerous animals that live their entire life cycle in the floor stratum, such as many mites and insects. there are others that spend a part of their life in the floor. For example, ladybird beetles (Coccinellidae) move from the herbaceous stratum of grassland communities, as well as from higher forest strata, to form large overwintering aggregations that hibernate in the leafy floor stratum; other animals nest or shelter there but feed by day or by night in higher strata; still others feed in the floor stratum but have their habitat niches elsewhere.

The three succeeding strata differ markedly from the floor. They are structurally discontinuous since the herbs, shrubs and trees rise separately from the soil. The essential matrix is made up largely of animate material in contrast to the largely inanimate matrix of the floor and soil. These higher strata provide large amounts of food for herbivorous insects, such as the leaf-feeding chrysomelid beetles, wood-boring buprestid and cerambycid beetles, sap-sucking aphids and the numerous scale insects (Coccidae); and for herbivorous birds and mammals, as well as for the predators that feed upon this multitude. Many animals shelter in the shrub and tree strata. Deer mice occasionally nest in shrubs and many predators visit shrubs and trees. In these strata tree frogs search for their insect food and the pilot black snake hunts for bird eggs and small mammals.

The leafy crowns of the topmost stratum, the canopy, interlock to form a forest roof that receives the full force of weather and that serves to modify such physical influences as light intensity, light quality, temperature, wind velocity, relative humidity and evaporation rate from the canopy progressively downward to the subterranean stratum. Along the ecotone the canopy often continues downward to within a few feet of the ground and is often secondarily interlocked by vines. In equatorial forests there may be several strata of trees, and true rain forests have three tree strata with correspondingly complex canopies.

All the five basic forest strata briefly discussed above contribute to the well-being of the whole major community. During the seasonal growth period the forest climate is relatively cool, dark and moist, and the air is relatively still, in contrast to conditions external to the forest. These physical influences are only a few of those that operate from canopy to subterranean stratum and from the peripheral ecotonal zone to the centre.

3. Community Metabolism. — Such stratified major communities, whether forest, grassland, lake or sea have a basic system of food interrelations. This community metabolism is separable into two interlocking phases: (1) an anabolic phase, in which foods are formed; and (2) a catabolic phase, in which foods are broken down.

Community anabolism is divisible into two basic "key industries." These are: the microbiological industry, and the photosynthetic industry. Generally speaking, both of these anabolic phases are dominated by plants.

Dead plants and animals are broken down into organic compounds by many kinds of bacteria and fungi, known collectively as heterotrophs. Other bacteria, known as autotrophs, reduce these organic compounds further into inorganic salts. Essentially this is the microbiological key industry. It is fundamental to the life of a community and consequently fundamental to the constituent plants and animals. It is these inorganic salts that are finally absorbed by higher or "green" plants, through their root systems in the subterranean stratum of terrestrial communities, or by algae in the surface layers of aquatic communities.

The photosynthetic key industry is carried out chiefly by green plants and to a lesser degree by the poorly known photoauto-

FIG. I.— FOOD CHAIN OF THE FOREST FLOOR

The producers of the first trophic level include forest litter, diatoms and algae, and provide food for the microscopic decomposers, which are bacteria and fungi, and for some primary consumers. Primary consumers include single-celled animals and lower invertebrates, and are fed upon by secondary consumers, which include microscopic lower invertebrates and larger invertebrates. Secondary consumers are, in turn, fed upon by small vertebrates

trophic bacteria. Plant carbohydrates, manufactured in the photosynthetic process, are combined with inorganic salts. absorbed by the plants, to form plant proteins. These plant proteins in the form of plant tissues are available for the catabolism of the community.

The catabolic phase of a community is carried out chiefly by animals and fungi. The herbivores, which feed upon the plants, are in turn available as food to the predators, parasites and hyperparasites in several grades of carnivorism and scavengerism. Consequently all organisms are either directly or indirectly dependent upon the microbiological and the photosynthetic key industries; these two processes are entirely dependent upon each other and all of the intermediate stages in the food cycle of the entire community.

4. Food Web.—In any given community the circulation of foods is an interwoven system of feeding interrelations. The whole system is spoken of as the food web, and the separable strands of food and feeder are termed food chains, although it is apparent that a food chain. as such, is an arbitrary device for studying a few directly related portions of the food web.

Many examples of food chains are available but almost none are known completely. A simple example may be cited from a prairie community: the sap of grasses is eaten by aphids; the aphids are eaten by larvae and adults of ladybird beetles; the ladybird beetles are eaten by predaceous ground beetles, such as *Carabus* and *Calosoma;* the ground beetles are in turn devoured by such birds as dickcissels, horned larks and grasshopper sparrows; finally, the smaller birds may be eaten by marsh hawks. In this chain the several links are in relative balance. When the marsh hawk dies, its body is decomposed by bacteria, and eventually the resulting inorganic salts are available for absorption by the prairie grasses, completing the food cycle in a single food chain of the prairie food web.

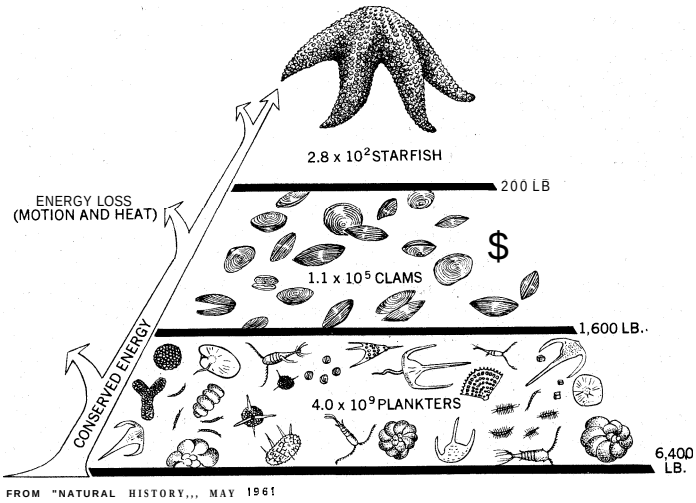
There are several other points to be noted concerning food chains. A species may eat different foods (1) in different parts of its geographic range, (2) in different stages of its life history and (3) at different times of the year.

5. Pyramid of Numbers.—When the food web is examined quantitatively, by counting or estimating the number of animals present per given area or volume of environmental medium, it is found that not only are there many more small animals than larger ones but that the size classes involved form a triangular figure when size is plotted against abundance (fig. 2). Charles Elton in 1927 called this relationship the "pyramid of numbers." Small animals have a higher reproductive potential than larger ones. Since the energy value of food eaten must eventually balance the physiological energy expended in obtaining and assimilating this food. predators generally eat animals in the next lowest size level or thereabout to conserve this energy expenditure. For example, in the prairie food chain cited above) the marsh hawk could probably assimilate the aphid protoplasm, but the energy expended in eating such minute prey would be greater than the potential energy of the food.

Pyramids of numbers have been investigated carefully for only a few communities. The pyramid has been figured for an Illinois deciduous forest by Orlando Park. W. C. Allee and V. E. Shelford (1939). for an equatorial forest in Panamá by E. C. Williams. Jr., (1941), for tree holes by Orlando Park. S. I. Auerbach and Glenna Corley (1950) and for certain Wisconsin lakes by Chancey Juday (1942). The food and feeder relationships in the pyramid were examined mathematically by R. L. Lindeman in 1912, and his formula was extended and modified by Allee, A. E. Emerson, Orlando Park. Thomas Park and K. P. Schmidt in 1949.

***6.* Trophic** Levels.—The community pyramid of numbers may be considered to have four or five trophic levels (levels of feeding interrelations), each level containing a variable number of species and each species population containing a variable number of individuals.

Thus the first trophic level consists of the photosynthetic plants (either green plants or photoautotrophic bacteria or both). These organisms are the producers which manufacture carbohydrate material. The second trophic level comprises the herbivores, the primary consumers, which feed upon photosynthetic plants. The third trophic level includes the carnivores, that is. the secondary consumers. which feed upon herbivores and other carnivores. The fourth trophic level includes saprophagous organisms, such as heterotrophic bacteria and fungi; these are the tertiary consumers, drawing nourishment from the decaying organisms of the first three levels noted. Finally there is a fifth trophic level, consisting of the chemoautotrophic bacteria; these are the quaternary consumers, which further simplify organic compounds formed by the activities of the fourth level. This terminology is one of several devised to clarify major feeding patterns within the whole corn-



FROM "NATURAL HISTORY,,, MAY 1961

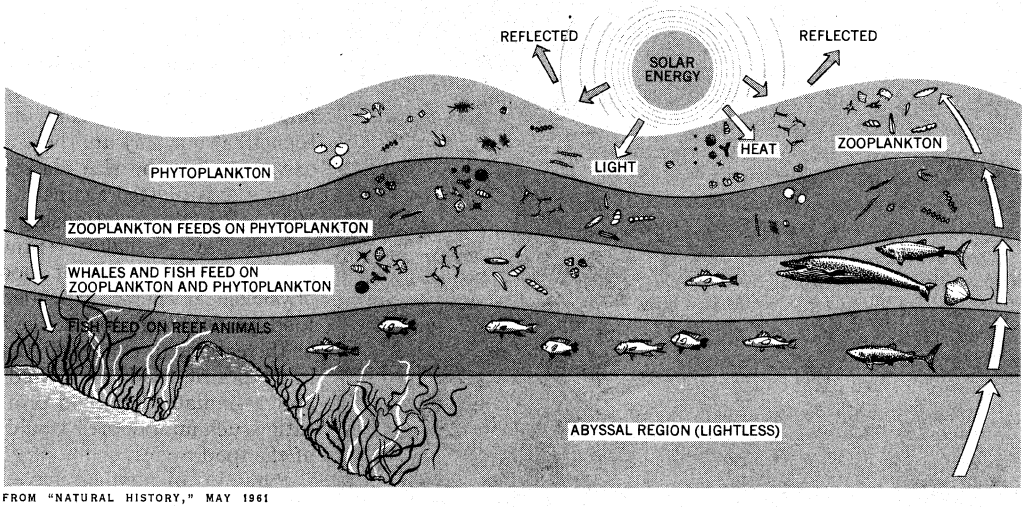
FIG. 2.— PYRAMID OF NUMBERS OF ONE PART OF A SEA COMMUNITY

Yearly food movement from plankton through clams (*Chama*) to starfish (*Pisaster*). Efficiency of production and energy transfer is indicated by the numbers of individuals and by the total weights or biomass that each level contributes to the next higher level

munity or ecosystem. Naturally, every organism consumes, transforms, produces and otherwise rearranges and reorganizes its protoplasm and its habitat.

Two items need amplification. First, omnivores encompass herbivores and carnivores in their food supply and alternatively feed upon the second and third trophic levels. Second, within the carnivore level are several grades of predation. that is, several size classes of predators. This tends to further complicate the secondary consumer category.

There are exceptions to the pyramid of numbers. These are generally found in animals that have special feeding adjustments that enable them to concentrate on small prey. The whalebone whales strain enormous numbers of minute organisms from the sea, and the paddlefish strains small crustaceans from the waters of the Mississippi valley.



FROM "NATURAL HISTORY," MAY 1961

FIG. 5.— SIMPLIFIEDMARINE FOOD CYCLE

Phytoplankton is directly dependent upon solar energy and nutrient salts dissolved in water. The nutrient chemicals in dying phytoplankton sink to bottom (arrows at left) and are carried back to surface by currents for reuse in new cycle (arrows at right)

7. Biomass.— When a species population is weighed in part or as a whole, the weight of the population can be examined in relation to other parts of the pyramid or food web. Walter Pickles in 1937 developed this concept in relation to ants and defined biomass as the total weight of a species population per unit of area Obviously the biomass could be determined for each link of a food chain, for each stratum of a community or for the whole community.

8. Productivity.— When pyramids, or numbers of animals, and biomasses, or weights of animals, are discussed, the production potentials for a given area or volume of a given habitat become important. Productivity can be thought of in several ways. There is the annual crop production as well as the standing crop production, this latter meaning the amounts of protoplasm or protoplasmic products present at a given time and place. In these two concepts amounts are involved. as bushels of corn, board feet of lumber or pounds of beef or herring per acre of prairie, forest or sea surface.

A second way of thinking of productivity is in terms of the efficiency of production. For example. E. N. Transeau calculated that the photosynthetic efficiency of field corn (10.000 plants per acre) is only 1.6% in terms of the total solar energy that is available for one acre; in other words over 98% of the available sun energy is not utilized by these plants. Corn production is usually thought of as high, yet the actual efficiency is low, and the relative efficiencies of animals feeding on this staple food are important to man and his domesticated animals.

A third way in which production can be viewed is in direct energetic terms, calculating the rate of production and amount of production in gram calories (g. cal.) per unit of area per unit of time, using the solar energy as the total amount available. G. L. Clarke discussed this aspect of productivity for a part of the North Atlantic in 1946. His general conclusions are applicable broadly to community metabolism. On Georges bank, off the coast of New England, the energetic input for the marine community in terms of light energy is 3.000.000 g. cal. per day per square metre of sea surface. The diatoms are plant plankton (phytoplanktonic), important organisms in the photosynthetic industry. These abundant, minute algae had a net production rate of from 0 to 9,000 g. cal. per day per square metre of sea surface; that is, the efficiency of diatom production was 0.3%. The animal plankton (zooplankton) feeds primarily upon the phytoplankton. The net production rate of these minute, free-floating animals was from 0 to 440 g. cal. per day per square metre of sea surface; that is. the efficiency of zooplankton production was only 0.015%.

In turn, fishes feed directly on zooplankton, or on bottom-dwelling organisms, or are indirectly dependent upon these animals in the case of predaceous fishes at higher predator levels. Ultimately both zooplankton and fishes are dependent directly or indirectly upon the phytoplankton. These latter organisms are directly dependent upon the light energy from the sun and upon nutrient salts dissolved in the water, as previously discussed. Data concerning Georges bank were obtained on the weight of whole fishes of all species landed annually. Weight of the catch varied from 63.000.000 to 289,000,000 lb. per year over the 10,000,000 ac. of Georges bank. This represents a yield of from 7 to 33 lb. of fish per acre per year. Assuming an energy content of 740 g. cal. per pound for raw fresh fish; the yield of fish landed per acre per year is equivalent to a production rate of 1.6 to 7.7 g. cal. per day per square metre of sea surface. That is, the efficiency of production was from 0.00005 to 0.00025%.

Stated simply: on every trophic level, when one animal eats another animal or a plant, only a tiny fraction of the energy stored in the tissues of the organism eaten actually becomes available energy for the eater—by far the greater portion of the potential energy is lost to the environment as heat, as a result of the numerous metabolic activities of the eaten and the eater.

From this analysis it is clear that production efficiencies decline rapidly from lower to higher trophic levels in the pyramid of numbers of a major community. Naturally, the details will vary as between parts of the same community, between different communities of the same type and between different types of communities.

Ecological research is essential in productivity problems. Obviously, much more solar energy is available than is being utilized by plants and animals. Man himself uses more and more food as his population increases but returns relatively little available energy to the food cycle. When his global population cannot be supported by the available food supply, the problem of overpopulation will adversely affect the conservation of natural resources. Loss of natural resources will in turn adversely affect the food supply.

9. Periodicity.— Another basic feature in community organization is that of periodicity. The activities of animals, in their search for food. shelter and mates, fall into one of two categories. These are periodic activity and aperiodic activity.

Periodic Activities.— Most of the large activities of communities are periodic and are correlated with such physical recurrent influences as relative length of day and night, daylight intensity, air temperature and distribution of precipitation. In fact, correlation of community activity in the large with the periodic physical environment is essential for survival.

Periodic activities are of three general kinds at the level of the major community; they are seasonal, lunar and daily. Sea-

sonal activities involve the growing season of plants; mating periods of animals; several aspects of dormancy, including hibernation and estivation; correlations in photoperiodicity, or the relation between leafing, flowering and fruiting of many plants with the relative length of day and night throughout the year; and migration. The study of periodic, seasonal events is known as phenology. When a sequence of phenological changes is followed through the annual cycle and related to environmental factors, the general process is termed seasonal succession, or aspection. The pear is often divided into a series of periods that are correlated with seasonal phenomena, such as the peaks of abundance of certain populations that are characteristic of a particular community or type of community. The seasonal population peak of typical species, which are frequently known as index species, or the appearance of some characteristic behaviour or structural change may serve as an index of the time of year as well as of the kind of community under examination.

Within this seasonal frame, certain animals exhibit reproductive phenomena that are correlated with tidal or lunar events Such animals include the palolo worms, certain marine annelids that swarm and spawn at definite times of certain months. All such phenomena are embraced by the term lunar periodicity.

Finally, there are the changes in community activity that are correlated with the regular march of day and night. These changes, broadly termed diel activities, are divisible into diurnal (day) and nocturnal (night) events. Community activities characteristic of the twilight periods, dawn (auroral) and dusk (vesperal), are grouped broadly as crepuscular events. Probably the most important diel activity is the diurnal manufacture of carbohydrates by a photosynthetic plant. The complementary nocturnal process is the distribution of much of this carbohydrate material throughout a terrestrial plant. Another diel phenomenon is the vertical migration of many minute animals that inhabit the surface stratum of the sea. These animals. including many protozoans and copepod and cladoceran crustaceans, move to the surface during the night and move downward during the day. This migration is apparently brought about actively, by the animals' direct or indirect response to light intensity, as well as passively, by the animals' being carried by diel convection currents.

Communities commonly have a well-defined diurnal animal life and a well-defined nocturnal animal life. Xumerous special adjustments allow animals to compete and co-operate within this diel periodism of the physical influences. The vertical pupil of the eye of many snakes, such as rattlesnakes, is an adjustment to their nocturnal habits. Some diurnal tree squirrels have slightly yellowish eye lenses, which adaptation reduces the intensity of bright daylight; whereas the lenses of the nocturnal American flying squirrels (Glaucomys) are perfectly translucent and allow all available light to filter upon the retina. Again, most nocturnal cats have a reflecting layer, or tapetum, back of the retina, and a similarly light-reflecting layer is found in the eyes of certain nocturnal moths and beetles. The tapetum is the structure that causes the eyes of such animals to glow when exposed to a light in the dark. The bioluminescent organs of the common fireflies or lightning bugs (lampyroid beetles) are adjustments that enable these nocturnal beetles to mate at night.

Almost all communities can be divided into two periodic animal groups, the diurnal and the nocturnal. As a consequence, the number of available habitat niches as well as the population is increased. This in turn increases the number and kinds of possible interrelations and renders the community more biologically complex. By this more complete utilization of the space-time lattice, the whole community considered as a unit approaches aperiodicity with respect to day and night in a physically periodic environment.

Aperiodic Activities.—In the second category of activity, the aperiodic type, there is no rhythmic correlation with the 24-hr. cycle of day and night. Instead, in aperiodic species populations some individuals are active and some inactive at any given time.

Aperiodic patterns are of two kinds. First. there are those species that inhabit relatively stable environments that are removed from direct periodic diel influences. These include the cave crayfish (Cambarus pellucidus) of Mammoth cave, Ky.; certain animals that inhabit the relatively constant subterranean stratum of terrestrial communities or the interior of decaying logs on forest floors, such as the subsocial beetle, *Popilius disjunctus;* the flour beetle (*Tribolium confusum*), which lives in the relatively stable habitat of stored food products. Second, some of the social animals are aperiodic, such as many kinds of ants and termites. Also, as man's social organization becomes more complex, his activities as a whole tend to become arrhythmic. Although other social species are not completely aperiodic, as for example many bees and wasps and some ants it is difficult to conceive of a wholly social species having its activity rigidly controlled by the periodic environment.

Whether animals such as man evolved sociality first and became aperiodic as an adjustment to social life, or were aperiodic first and became social later is an unanswered question. At least the aperiodic pattern is correlated with a relatively constant environment, whether this is the complex social medium or a habitat that is removed from direct control of diel factors.

IV. PRINCIPLE OF SUCCESSION

Turning from community organization, another important aspect is the growth and change of communities through time. This process, known as ecological succession, can be separated into two components: physiographic, influenced by all the physical features of the environment; and biotic, determined by the animals and plants comprising the community itself.

1. Physiographic Succession.—This form of succession was described by H. C. Comles in 1901 with respect to the series of communities that gradually arose as postglacial Lake Chicago drained away leaving the smaller Lake Michigan and the Chicago plain in its place.

The effects of physiographic influences were summarized by H. C. Cowles in a classic statement ("The Plant Societies of Chicago and Vicinity," The Geographic Society of Chicago Bulletin No. 2 [The University of Chicago Press, 1901]):

> Having related the vegetation largely to topography, we must recognize that topography changes, not in a haphazard manner, but according to well-defined laws. The processes of erosion ultimately cause the wearing down of the hills and the filling up of the hollows. These two processes, denudation and deposition, working in harmony produce planation; the inequalities are brought down to a base level. The chief agent in all these activities is water, and no fact is better established than the gradual eating back of the rivers into the land and the wearing away of coast lines; the material thus gathered fills up lakes, forms the alluvium of flood plains, or is taken to the sea. Vegetation plays a part in all these processes, the peat deposits adding greatly to the rapidity with which lakes and swamps are filled, while the plant covering of the hills, on the contrary, greatly retards the erosive processes. Thus the hollows are filled more rapidly than the hills are worn away. As a consequence of all these changes, the slopes and soils must change; so, too, the plant societies, which are replaced in turn by others that are adapted to the new conditions.

Successional changes of this kind are widespread and basic. Erosion and deposition of soil by both wind and water profoundly modify the earth's crust within a given climatic period. These changes alter the structure of terrestrial and fresh-water communities to such an extent that established populations of plants and animals are unable to cope with the changed conditions, and their place is taken by other species that can adjust; hence, communities succeed each other through time.

2. Biotic Succession.—The second component in ecological succession signifies changes in community structure brought about through biological action of the plants and animals constituting the community. These processes and their effects collectively have been termed community development. For example, waste products, feces, decay of dead organisms. formation of organic soils, filling up of lake and pond bottoms with organic sediments and other influences gradually change a community so that, again, residents are unable to tolerate the changed conditions and are replaced by different species populations.

This type of succession can be demonstrated in the laboratory. Thus. L. L. Woodruff in 1912 demonstrated the regular sequence of protozoan species that occurred in a flask of hay infusion chiefly as a consequence of food and waste product factors over a period of several weeks.

3. Sequence **of** Community Changes.— Together, physiographic and biotic factors induce and regulate the process of community change. Research showed that such changes may be described, are relatively continuous and to some extent are directional, hence predictable Community changes continue until a stable end product is reached. A sequence or series of communities is termed a sere; the early stages are knoxn as pioneer communities and the relatively stable end product is the climax community. This latter community is a climatic climax in that, for a given latitude, altitude and climatic period, the physiographic and biotic changes have become relatively stabilized and can be tolerated by resident populations. At high latitudes the substratum of the climax community may be very unstable.

Normal community succession may be modified. deflected or arrested within any sere. The normal tendency of ponds to fill up to form marshes, and of marshes to form pioneer grasslands or forests, and these latter to form a climax high-grass prairie or a climax beech and maple forest in a certain area occurs over a long period of time. This has Important practical significance for the formation of man's food supply, his fisheries, duck populations corn and wheat yields or lumbering activities. Scientific management is clearly indicated rather than hasty action in attempting to alter natural processes. A community originated and maintained by human disturbance is an artificial community termed a disclimax When succession and development take place relatively unmolested by man or his indirect influences, the sequence is a primary sere (prisere); when development and succession are controlled by man or his indirect influences, the sequence is a secondary sere (subsere).

Succession and development of a sere are also frequently controlled by local conditions primarily, rather than by the prevailing climatic conditions. Local effects are termed edaphic, and edaphic seres are common Two powerful edaphic influences are soil and water. The edaphic aquatic sequences are of two general kinds (1) the flowing water sere in which the change is from small swift brooks with high velocity to the edaphic climax of an old, meandering river that has cut its bed to the base level and winds across a silted flood plain; and (2) the standing water sere in which the change is from bare-bottomed ponds and lakes to marshes or bogs and finally the pioneer stages in a terrestrial sere, either grassland or forest as a rule. depending on the seasonal distribution or rainfall and other climatic factors.

FIG 5 — SUCCESSIONAND DEVELOPMENT OF A SAND SERE IN THE DUNES OF NORTHERN INDIANA

(A) Grass takes hold on the beach; (B) as humus accumulates, cottonwoods appear; (C) these are replaced by pines and beeches, which in turn. (D) give way to maples. As one location reaches a climax away from the beach (to the left of the boulder), earlier stages are beginning on the newly developing beach, which is continuously being built up by wave and wind action

As the community as a whole undergoes succession intracommunity sequences take place. These latter are knonn as microseres and include changes that take place in cattle droppings in the prairie community in the decaying bodies of animals, in decomposing fallen logs and stumps, in tree holes and in disintegrating fungi in the forest community All these microseres follow a regular sequence of biochemical, structural and biotic changes, but are without a climax stage, since they are incorporated into the major community as it matures.

V. PRINCIPLE OF CONVERGENCE

An important principle emerges at the level of community maturation. This is the principle of convergence, which states that there is a general tendency for edaphic seres to run their course, for microseres to uax and wane and for climatic seres to mature from pioneer to climax In the end, often over many centuries, an entire region tends to develop into the regional climatic climax

Convergence was emphasized by H C. Cowles in 1901 With Cowles' aid, V. E Shelford applied the principle to the Chicago area in 1913 It was generally treated by F. E. Clements and V. E. Shelford in 1939.

The principle is illustrated well in northern Indiana. where four major seres are evident These are sand clay flood plain and pond The pond eventually fills, passing through a marshy cattail stage, the flood plain is exploited by a series of terrestrial communities; and the sand and clay seres accumulate humus. In the end honever, all four seres meet in the common development of a beech and maple forest This latter is a climatic climax for this particular area Even though the animal and plant life of the climax varies with latitude and altitude, the principles of convergence has many broad implications.

VI. BIOMES

A. Terrestrial

1. Extension. — Communities and major communities, whether edaphic or climatic, pioneer or climax, are distributed over the terrestrial parts of the world in a series of broad belts ,from the poles to the equator. In general, although edaphic influences alter the regularity of these belts, they are correlated with similarly broad climatic zones. The communities that occupy any one of these zones. including the extensions caused by the altitude factor, are known collectively as a biome. The biome is the largest ecological unit. It is seldom continuous, covers a large area of the earth and is subject to considerable intrabiomal variation. The biome consists of a single climax type, which usually varies in composition with latitude and altitude, and many subsidiary seres. It holds almost innumerable major communities. each self-sustaining and each consisting of many dependent communities and species populations. Convergence operates over any given biome through time.

2. General Characteristics. — The table gives the major details about the terrestrial biomes. This highly condensed summary does not stress the obvious fact that there are many intergradations between biomes. The study of biomes is an important aspect of ecological animal geography. Discussions of the latter are found in Animals, Distribution of and Zoogeography.

B. Marine

The terrestrial biomes, with their numerous alpine extensions and interbiomal intergrades. cover only about 30% of the world's surface. The remaining 70%, covered by ocean waters and their adjacent seas, has been called the marine biome.

This vast expanse, which contains numerous communities, is but a single, self-sustaining, independent, major community. Consequently. whereas terrestrial biomes each have many major communities, the marine biome and major community are synonymous. For example, given radiant energy from the sun, two oak iorests 100 mi. apart are independent of each other and of adjacent meadows and lakes. Each forest is a major community. Two coral reefs 100 mi. apart are independent of each other but are dependent upon the minute organisms in the adjacent sea water for their initial food supply. The coral reefs are communities, but the whole sea is the major community.

The marine biome has the same basic structure as any other major community. It possesses both vertical and horizontal strata and zones; its metabolism is based upon the photosynthetic and microbiological key industries; its food cycle involves the same general principles; and finally. its activities in lighted regions are primarily periodic, involving seasonal, lunar and diel rhythms.

1. Aquatic Organisms.—Aquatic organisms are separable into three ecological categories. These are plankton, nekton and benthos.

Plankton. — Plankton comprises feebly swimming and free-floating organisms that cannot move against a current. On the basis of size, planktonic organisms are separable into: (1) macroplankton, organisms that are visible to the unaided human eye; (2) net plankton, organisms secured by a plankton net with meshes between 0.03 and 0.04 mm. wide and (3) nannoplankton or microplankton, minute planktonic components that pass through the meshes of a plankton net.

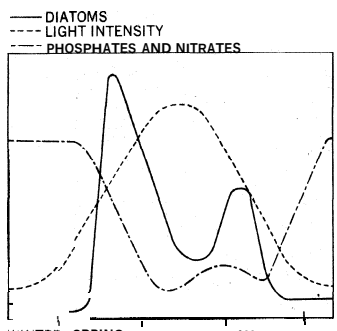
As noted earlier under Productivity, plankton is also commonly divided into phytoplankton and zooplankton. Phytoplankton consists of the minute, unicellular plants and animal-like plants. This important group forms the major part of the photosynthetic key

Terrestrial Biomes

Biome	Distribution	Climate	Typical animals and generalities
Equatorialforest (jungle; rain forest)	Range about 20" S.–20" S. About 6,000,000 sq. mi., mostly less than 1,000 ft. elevation. Indo-Malaysia, Congo basin, Amazon and Orinoco basins, much of Central America and Mexico on either side of Central plateau to Tropic of Cancer	Rainy low latitudes. Humid and warm, rainfall 50 in. to 150 in. per year, evenly distributed, but with some areas having one or more "wet" and "dry" seasons	Monkey, lemur, ape, sloth, tapir, elephant, army ant, driver ant, many termites, arboreal snail, *Peripatus* and allies, toucan, parrot and parakeet. Mammals typically thin haired; animals 40% diurnal and 60% nocturnal; 11% amphibious, 39% cursorial, 50% arboreal. Communities with many strata; *e.g.*, true rain forest, at least 70 in. rain annually, with three tree strata and arboreal adjustment extensive
Temperate Grassland (steppe, plains, prairie, pampas, llanos)	Bordering deserts of Asia Minor and central Asia. North America from Texas northward into Canada and eastward to the 100th parallel	Great temperature extremes in minter and summer. Annual rainfall 20 in. to 40 in. for tallgrass, and 12 in. to 20 in. for short grass	Asia: saiga antelope, Mongolian gazelle, wild ass, two-humped camel. North America: bison (buffalo), prongbuck (pronghorn antelope), prairie dog. Grasshopper typically abundant. Many adjustments to hibernation and estivation. Steppe mammals 47% subterranean and 53% floor residents, in general, gregarious, swift, migrate or hibernate, high fertility. Many running and digging animals
Tropical Grassland (savanna, pampas, llanos)	Tropical areas in Africa, Australia and South America	Generally warmer, with shrubby plants or trees scattered over grassy floor	Australia: kangaroo. South America: pampas deer; armadillo abundant. Africa: certain baboons, lion, hyena, certain buffalo, giraffe, zebra, square-lipped rhinoceros and many genera of antelope (eland, kudu, addax, wildebeest, hartebeest, blessbok, bontebok, etc.
Desert (vegetation, when present, usually thinly scattered)	Many areas over the world: Death valley in United States; parts of southern South America; Sahara and Kalahari in Africa; Syrian, Arabian, Thar and Gobi in Asia; a part of Tasmania and interior of Australia	Annual rainfall less than 10 in. Death valley and Sahara have July means of 95" F., January means of 64" F., with usually cold nights and hot days	If semidesert and desert are combined, this biome would cover about one-fifth of terrestrial area, or 11,500,000 sq. mi. Estivation common, and nocturnalism typical. Characteristic desert forms include: Gila monster, sidewinding rattlesnake desert fox and desert jack rabbit. Prongbuck; desert monitors (Australia): horned viper (North Africa and Arabia)
Temperate deciduous forest (variety of trees; well-developed herb and shrub layers)	North temperate zone of eastern North America, Europe, western and eastern Asia, Japan. Parts of northeast China; eastern coastal areas in Australia; New Zealand	Annual rainfall of 20 to 60 in., usually well distributed. Winter and summer well-defined, with at least four months with a mean temperature more than 50" F.	Wisent (Europran bison) and red deer. In the United Statqs: Virginia deer, black bear, bobcat, flying squirrel, tree squirrel and chipmunk; numerous snails (*Polygyra*), carabid beetle (*Dicaelus purpuratus*), certain salamanders (*Plethodon cinereus*), common box turtle and the pilot black snake are typical. The biome has numerous types of climax forests, the chief trees being red oak, beech, sugar maple, tulip, chestnut, black cherry, magnolia, live oak and cypress
Taiga (coniierous forest; scant herb and shrub layers)	Circumpolar in the subarctic and north temperate zone of America, Europe and Asia	Annual precipitation between 20 and 40 in., much of which is snow. Winter season long and severe	This vast forest is notable for lumber and furs, and in many areas its fauna intergrades with the deciduous forest fauna (*e.g.*, in North America tree squirrel, flying squirrel, chipmunk, Virginia deer, bobcat, black bear). Moose, caribou or reindeer, lynx, snowshoe hare, wolf, fox, marten, weasel or ermine are characteristic for both Eurasia and North America. The maral deer, wild dog and tiger are Siberian. Canada has the skunk and puma. There are numerous woodpeckers; crossbills and snowy owls are especially typical of coniferous woods
Tundra (snow and ice deserts; scant low vegetation, chiefly lichens)	Polar and alpine regions of the northern hemisphere, treeless and barren for most of the year. Generally irom northern limit of taiga to Polar sea. Southern hemisphere: alpine zones of Andes, and certain mountains in Australia	Annual precipitation small, not more than 10 in., except for part of Greenland. Winter long, and summer short. Temperature of narmest month never exceeds 50' F.	Birds and mammals are either migratory, or depend on sea for food supply, with the exception of few birds including the redpoll and ptarmigan. Typical mammals include the reindeer (including the caribou), musk ox, ermine, arctic hare, arctic fox and lemmings

industry of the marine biome as a consequence of the diatoms, dinoflagellates and their allies; since this biome also includes many kinds of bacteria. it plays an important role in the bacterial key industry previously discussed.

Phytoplankton is so important to the food cycle and numerous related problems in productivity that some mention must be made of the seasonal abundance of diatoms. In arctic and temperate upper waters the diatom population is relatively low in winter, increases rapidly in the spring, falls off in summer, increases slightly in autumn and falls again to the winter low.



O. PARK, W. C. ALLEE AND V. E. SHELFORD, "A LABORATORY INTRODUCTION TO ANIMAL ECOLOGY AND TAXONOMY," THE UNIVERSITY OF CHICAGO PRESS

(Adapted with permission after F. S. Russell and C. M. Yonge, "The Sea: Our Knowledge of Life in the Sea and How It Is Gained," Frederick Warne & Co.)

FIG. 6.—INTERRELATION OF THE SEASONAL CYCLES IN ABUNDANCE OF DIATOMS, LIGHT INTENSITY, PHOSPHATES AND NITRATES IN THE OPEN NORTH ATLANTIC

Many ecological influences are involved in this population cycle; for example. light intensity, water temperature, nitrate and phosphate salts and winds. Sea water is enriched constantly by inorganic salts that have been formed by bacterial action; these salts are utilized by phytoplankton in building their protoplasm. In the winter the concentration of these salts is high, but the light is insufficient for maximum photosynthesis, thus the diatom production is low. In the spring the production is rapid. since salts and light are ample; but meanwhile, the upper layer of water is warming rapidly and a discontinuity layer forms between the upper warmer and lower colder layers of water. This interposed layer, because of its electrical properties. prevents upwelling of nitrate and phosphate salts in sufficient amounts to be utilized by the rapidly growing diatom population. Consequently as summer approaches, the production begins to fall rapidly: the diatoms have exhausted the supply of these salts in the upper level. above the discontinuity layer. Summer, then. has a lowered population, even though light is ample for photosynthesis. (This. incidentally, is an illustration of J. von Liebig's "law of the minimum." which states that growth is limited by the factor that is operating in minimal quantity. As summer draws to a close, the falling temperature of the upper water approaches that of deeper waters, the discontinuity layer disappears and phosphate and nitrate salts are diffused upward by partial pressures, as well as by the mixing of waters that occurs during autumnal gales. Since the light intensity is still sufficient for photosynthesis, and since salts are again becoming available for metabolism. there is a second (autumnal) peak of diatoms. This latter does not equal the spring (vernal) peak since the approaching winter, with its lowered light intensity, interferes.

The production of vernal and autumnal peaks or pulses of phytoplankton in the temperate zones of the sea are paralleled by similar peaks in large lakes, but not necessarily in smaller bodies of fresh water.

Zooplankton consists of many groups of animals, most of which feed upon the phytoplankton. Zooplankton commonly is divided into several categories. There is the temporary plankton (meroplankton) consisting of planktonic eggs and larvae of nonplanktonic adults of both fishes and invertebrates. Permanent plankton (holoplanktonj, animals that live all their lives as planktonic individuals, makes up the rest of the zooplankton. Holoplankton includes protozoans, especially radiolarians and foraminiierans, many worms, jellyfishes and siphonophores, certain molluscs, such as the pteropods and heteropods, and especially crustaceans. These latter, being to the sea what the insects are to terrestrial habitats, include chiefly copepods. ostracods and amphipods. The copepod *Calanus finmarchicus* is an especially important member of the surface-water community since its numbers provide suitable food for many animals higher in the pyramid of numbers.

Nekton.—The nekton consists of animals that can move against currents. These are generally larger animals, including fishes and squids. Most commercially important fishes are nektonic; they feed upon plankton or prey upon other fishes, as the sharks. Marine mammals such as seals. porpoises and whales are nektonic.

Benthos.—This last division of marine animals includes those forms that inhabit the sea floor and subaqueous strata of the community. They consist of active benthos, such as many crabs and snails that move over the floor or burrow through the bottom substrate, and passive benthos, such as numerous colonial coelenterates and sponges that remain attached to the bottom as benthonic adults.

2. Layers of the Sea.—The sea is stratified both vertically and horizontally. The major divisions and some of the subdivisions will be characterized below.

Pelagic Division (The *Water Mass of* the Sea).—The water of the sea can be divided into two general zones on the basis of available light, the euphotic (lighted) and the aphotic (unlighted).

The euphotic zone. the upper 200 metres or so of water, is illuminated by daylight that is reduced gradually in intensity and spectral quality with increasing depth. The plankton inhabit this zone primarily: the phytoplankton must stay in the upper stratum of this zone to carry on photosynthesis and the zooplankton feed chiefly on these minute plants. Most nekton live here as well, since they too are directly or indirectly dependent upon the phytoplankton for food.

Below the euphotic layer is a deep aphotic zone. where light gradually fades out, the water pressure gradually increases and the temperature is relatively constant at a few degrees above freezing.

Benthic Division (*The Entire* Sea Floor).—This division consists of a series of more or less concentric zones that begins at the ecotone between terrestrial and marine, or fresh-water and marine, communities and extends seaward. The sea floor is divisible primarily into two subdivisions: the littoral system. extending from the shoreline to the edge of the continental shelf; and the deep-sea system. continuing from the continental shelf to the ocean deeps.

The littoral system is again subdivisible into two zones. The first of these is the eulittoral zone, from high-tide level on the shore seaward to a depth of about 40 to 60 m. This seaward limit coincides with the photosynthetic limit beyond which attached plants cannot grow. This photosynthetic limit naturally varies with latitude. Within the eulittoral zone is a relatively well-defined intertidal zone, which is bounded by high-water and low-water extremes of tide.

The eulittoral zone as a whole is rich in life, having an abundance of both floating and attached plants and animals. Its substrate is also highly variable; there are three chief types—sandy, rocky and muddy—as well as intergrades. such as sandy-mud.

The second littoral zone is known as the sublittoral. This extends from the seaward limit of attached plants to about the 200-m. line. The seaward limit of the sublittoral coincides more or less with the depth of the water at the outer edge of the continental shelf and also more or less with the depth that divides the aphotic and euphotic zones noted previously.

The deep-sea system is similarly divisible into two zones. The first of these is known as the archibenthic zone. and extends from the seaward limit of the sublittoral zone downward to about the 1.000-in. line. Its exact lower limit is variable. From about this latter depth to the sea bottom is the second deep-sea zone, the abyssal region.

The archibenthic zone is more or less physically uniform. Daylight is absent and the temperatures vary from about 5° to −1° C. Since there are no seasons: the seasonal rhythms so typical of the previously mentioned eulittoral zone are absent. Since there are no attached plants and no phytoplankton, the animal populations consist of parasites, carnivores and scavengers.

The abyssal zone is generally similar in physical conditions to the deep-sea zone, except for increasing water pressure. The abyssal populations are sparse. decreasing in numbers with increasing depth and with increasing distance from the shore. The animal life is thought to be endemic, that is. limited to the area, rather than impoverished ecological extensions from higher zones. Scar-

city of food appears to be the chief limiting factor. These grotesque animals that inhabit this zone are predators, scavengers or parasites. Since plants are absent, save possibly for bacteria: the abyssal forms are entirely dependent on the "rain" of food from the upper levels. However, this food is sparse, since the decomposing animals falling from the surface layers are broken down by heterotrophic bacteria in the upper and intermediate strata. Food input for the abyssal region, then, must be derived largely from the floating animals of intermediate depths. These latter animals are, in turn: dependent on the surface layers above them. The abyssal animals exhibit numerous structural adjustments t~ the great pressures of their habitat, and many deep-sea and abyssal fishes are provided with bioluminescent organs.

(O P.)

ECOLOGY, HUMAN. Human ecology is the study of the structure and development of human communities and societies in terms of the processes by which human populations adapt to their environments taking account of the technological systems and patterns of social organization through which this adaptation is effected. As a discipline it represents an application of the perspectives of the biological sciences to the investigation of subjects included in the social sciences. The consistently naturalistic approach that this requires only became possible with the reappraisal of man's place in nature occasioned by the impact of Darwin's theory of evolution in the latter part of the 19th century. (See also ECOLOGY. ANIMAL; POPULATION ECOLOGY.)

Aspects of an ecological viewpoint are implicit in the observations of early thinkers like Plato and Aristotle on the relation of population size to the structure and stability of political institutions and, for example, in the contrasts between urban and rural modes of existence set forth by the medieval Arab scholar. Ibn Khaldun. Systematic work in human ecology, honever, had to await the accumulation of geographic. ethnographic, and demographic data which got underway in the efforts of the 19th-century investigators. By the end of that century. it was possible to suggest theories dealing with such ecological problems as the determinants of population growth, the location of cities and the spatial pattern of economic activities, regional variations in disease and death rates and the evolution of the social division of labour. Although the idea of human ecology as a discipline gained currency only after 1920. the basis for its conceptual framework was laid by 1900 in such proposals as those of Friedrich Ratzel concerning "anthropogeography," Émile Durkheim concerning "social morphology" and C. H. Cooley concerning "territorial demography." The term "human ecology" was popularized in the 1920s in connection with the work in urban sociology of the so-called Chicago school—R. E. Park and his followers. It was perhaps a mere accident. however, that the first thorough elaboration of concepts and techniques in human ecology occurred in the context of studies of the contemporary metropolitan community. Specialists in disciplines related only remotely to urban sociology also found it fruitful to interpret differences among societies as reflections of varying environmental and demographic conditions and the modes of adaptation thereto. Ethnographic studies of tribal groups, for example, disclosed hitherto unsuspected connections among the sustenance technology, kinship structure, systems of social rank and the size and organization of settlement units.

Without reviewing the voluminous results of such specialized studies, it is possible to suggest in broad outline how the interrelations of population, environment. technology and social organization develop. As has been learned from research in prehistoric archaeology, the rudimentary technology of the Stone Age afforded a meagre return to efforts at gaining subsistence and provided a precarious protection against environmental hazards. Population groups were small and dispersed, with the consequence that only the most elementary division of labour based on age and sex differences could be effected. The transition to Neolithic agriculture in effect increased the carrying capacity of the land with a resulting augmentation of numbers. (See AGRICULTURE. PRIMITIVE: *Early Agricultural Communities.*) The sedentary mode of existence and the production ot a small economic surplus beyond minimum subsistence needs provided opportunity for the perfection of craft techniques and a modest elaboration of specialized social roles.

Metallurgy, irrigation and other technological achievements of Neolithic villagers prepared the way for the urban revolution. Aggregations of population transcending the village in size and complexity of organization could be supported when the agricultural population of sizable regions was brought under the hegemony of centers of military power, and when caravan routes and sailing ships made possible extensive trade among cities. The early urban civiljzations, however like their imperial and feudal successors, remained low-energy societies.

Although the first phases of the Industrial Revolution may be said to have begun in the 18th century in England with mechanical inventions in the textile industries operated by water power, the effective multiplication of per capita energy supply awaited the application to machinery of steam power derived from fossil fuel; this innovation led to widespread industrialization and large-scale urbanization.

A salient feature of this sequence is that each stage represented a significant expansion over the preceding one in each component of the ecological complex. Populations increased, not only in the sense of increasing density within fixed areas but also in the territorial scope of the effective population unit. The environment was enlarged as the increasing capacity of technology created new resources and magnified the efficiency with nhich old resources were exploited. Organization underwent growth in numbers of units—specialized social roles, groups and strata—and in the ramifications of their interrelations.

The 20th century has witnessed no slackening of the rate of expansion. The population of the world, like that of most of its major regions, has grown at higher rates of increase than earlier history records. Technological innovation, ranging from the tapping of a new fundamental energy source. the atomic nucleus, to countless applications of new materials and processes, has proceeded at a seemingly accelerated pace. The scope and intensiveness with which the planetary environment is exploited have been without precedent. Organization on a world scale has become an economic reality, and world-wide international conflict has been followed by efforts toward a world polity. Meanwhile, within the nation-state new organizational forms and elaborations of old ones have co-ordinated ever more numerous and more diversified kinds of activities. whether the nominal locus of authority is government

bureaucracy or semipublic corporate enterprise. It is hardly surprising that such swift and radical changes should impinge unequally upon the areas and peoples of the world. The significant consequence. however, is that the several stages of the historical sequence are paralleled by contemporary differences among human communities, ranging from isolated groups in inaccessible regions still living under virtual Stone Age conditions, though increasingly brought within the orbit of development, to the pulsing metropolitan centres of the high-energy societies in which the leadership and impetus for change are concentrated.

Human ecology has its most significant contacts with plant and animal ecology at the point of common concern with the structure and dynamics of the total complex of community-habitat interactions. called the ecosystem. The diagnosis of a problem like soil erosion, for example, requires that patterns of human occupancy and exploitation of land be analyzed from the standpoint of their impact on the physical and nonhuman biotic components of the system. Changes in these necessarily alter—for better or worse—the conditions to which human activities must be adapted. The consequence of technological progress is man's growing capacity to make far-reaching modifications of the ecosystem, with a concomitantly increasing probability that these modifications will affect human welfare in complicated ways, difficult to anticipate. As the unique animal with the potential capacity to comprehend its own role in the ecosystem, however, man has the opportunity to develop ecological study so as to realize the advantage of foresight.

The holistic emphasis implied by the very idea of human ecology has been a continual threat to the unity of the discipline. Comprehensive treatises on the subject typically have represented expressions of social philosophy rather than empirically grounded statements of scientific theory. Indeed, numerous commentators have put forth the view that human ecology must remain primarily a philosophic viewpoint rather than aspire to the status of a systematic discipline. By the middle of the 20th century, however, promising attempts at scientific synthesis were beginning to appear, as in A. H. Hawley's Human Ecology (1950) and Julian Steward's ecologically based Theory of Culture Change (1955). At the same time, researches in an increasing number of problem areas were manifesting the influence of ecological thinking, establishing human ecology as one of the most vigorous of the various intellectual movements cutting across traditional academic disciplines.

ECONOMETRICS, the empirical testing of economic theories and the expression of economic relationships in mathematical form. It was developed during the 1930s when, as a consequence of the economic crises in various countries, exact quantitative information was needed about the possible consequences of measures of economic policy. Though economic theory provides the government with ideas about the process which determines the economic magnitudes it does not quantify these ideas. Moreover, without empirical verification it is impossible to find out what economic laws are valid in a specific situation. It is the task of econometrics to carry out this empirical verification and to establish quantitatively the relationships which appear to be valid. If, for instance, economic theory points out that changes in the demand for certain consumer goods are determined by changes in income and prices, the econometrician tries to find out whether in fact this relationship exists. He also tries to describe it by calculating income and price elasticities, which are defined as the ratio between a percentage change in income and price respectively and the induced percentage change in demand. Only when all relevant relationships between economic variables have been quantified has knowledge been obtained which can be used as a guide for economic policy. In this way, J. Tinbergen (one of the first econometricians) carried out a statistical testing of the business cycle theories developed in economics and collected many coefficients describing the interdependencies among economic phenomena.

The statistical description of economic phenomena made great advances between 1920 and 1960. In several countries a complete picture of all economic activities could, by the early 1960s, be given every year. This is usually carried out by means of a system of national accounts on which the flow of goods and services between various sectors of the economy are recorded. As a rule the following sectors are distinguished: households, enterprises, government, foreign countries and capital formation. (*See* also NATIONAL INCOME.)

Economic quantities are as a rule measured in money units. If, honever, the development of a certain quantity in several successive years must be shown, it is easier to make use of index numbers. The value of the item in one of the years, the basic year, is put equal to 100 and those of the other years are expressed as a percentage of it. These percentages are called index numbers (*q.v.*).

A well-known index number in many economic problems is that of retail prices. It is a weighted average of the price indices of various consumer goods. In the United Kingdom, for instance. it contains 10 main groups of goods; *viz.* food, alcoholic drink. tobacco, housing, fuel and light, durable household goods, clothing and footwear, transport and vehicles, miscellaneous goods, and services. Each group consists of a number of sections. There are 91 such sections. The weighting coefficients are the shares of each commodity in the total consumers expenditures derived from surveys of 11,638 households. (See COST OF LIVING.)

The main task of econometrics is to express in quantities the relationships which, according to economic theory, exist between economic phenomena. Attempts are made to express these relationships in mathematical equations. or. in other words, to "explain" the historical development of a certain economic variable by writing it as a function of other economic or noneconomic quantities, the explanatory variables. As all economic variables are mutually dependent, it is not sufficient to construct isolated equations. A complete system of these equations must be set up by means of which all important variables can be described simultaneously. Such equation systems are called econometric models. The greater part of the activity of econometricians had, until the early 1960s. been devoted to such "model building."

The first step in an econometric analysis is to specify the equation to be used for the description of a certain variable. This means that the economic and noneconomic quantities to be used as explanatory variables, and the mathematical form of the equation, must be determined by theoretical reasoning. As a rule, linear or logarithmic linear forms are chosen as a first approximation. So, for example, it can be deduced from the theory of consumer's behaviour that total national consumption in a certain year depends, among other things, on the national income and the price level.

A simple linear function to express this relationship can be twitten as:

$$C_t = a_0 + a_1 Y_t + a_2 p_t + u_t$$

If a logarithmic linear function looks more adequate the equation $\log C_t = a_0 + a_1 \log Y + a_2 \log p_t + v_t$ can be used. In these equations the symbols have the following meaning: C_t = consumption in year t; Y_t = national income after taxes, in year t; p_t = average level of consumer's prices in year t; u_t and v_t = error terms. The parameter a_0 is a constant term and has, in general, no economic meaning; α_1 (in the first equation). the marginal consumption quota, shows what percentage of a given change in income will be consumed and a_2 measures the influence of price on consumption. In the second equation α_1 gives the ratio between the percentage changes of consumption and income. The variables u_t and v_t are introduced because the equations. given Y_t and p_t, do not determine exactly the quantity consumed. C_t. There are several reasons why the equations. used for practical purposes, are only approximations. In the first place they do not include all the variables which influence C, only the most important. So, for instance, income distribution is left out. Furthermore they are only linear approximations whereas in reality the relationships might well be curvilinear. Finally the equations may be disturbed because the variables C, Y and p may contain errors of measurement. The error term of an econometric equation is considered as a stochastic variable. which means that it can take on a number of different values each with a certain probability. When specifying the equation the properties of the probability distribution of the error term, which seem adequate in any special case, must also be given because they are needed in the next stage of the analysis, the estimation of the parameters. As a rule this distribution is supposed to be normal with zero mean and a certain finite standard deviation which is independent of the explanatory variables, and constant in time.

When the equation has been specified the parameters can be estimated. In practice this is done in most cases with the help of data on the recent development of the variables concerned. In that case such parameters are chosen that an equation is obtained which fits as well as possible the historical development of the variable to be explained. The concept "fits as well as possible" must be interpreted statistically. A criterion for the accuracy of fit which is very often used is that the estimates must be such as to minimize $\Sigma_t u_t^2$. This criterion is known as "the method of least squares."

When equations have been established in this way for all important variables of a certain economy, they form together an econometric model of that economy. Though, as already mentioned, all economic quantities are mutually dependent, the interdependency is not equally strong in all sectors. For a small economy, for instance, the economic development in other countries is very important; on the other hand the business situation in a small country will not have any influence on, say, world trade. The same phenomena can be found within a domestic economy. So, for instance, certain items of government expenditure will influence the economic process without being determined by economic variables. Therefore, in an econometric model two kinds of variables must be distinguished; *i.e.*, dependent or endogenous variables and independent or exogenous variables. The endogenous variables are determined by each other and by the exogenous variables. whereas the latter are fixed by noneconomic factors or by factors outside the economy.

A model is called complete when there are as many equations as there are endogenous variables. The endogenous variables can then, by solving the equation system, be expressed as functions of the exogenous variables. These functions are called reduced form equations. By means of these equations the impact of changes in the exogenous variables on the endogenous variables can be analyzed.

Among the exogenous variables there may be some which can be determined by the government. Government expenditure has already been mentioned; other examples are tax rates, interest rates and some kinds of investment expenditure. In certain situations these variables, as instruments of economic policy, can be used by the government to adjust undesirable economic developments to the targets of economic policy. The reduced form equations provide the quantitative information about the possible consequences of economic policy measures which is then needed.

In the description given much attention has been paid to macroeconomic phenomena. The examples given refer to quantities such as national consumption, national income and so on. Econometrics deals also with microeconomic analyses. So, for instance, much uork has been done in the field of analysis of household surveys, which give insight into the structure of consumers' expenditure. The same is true with regard to investment behaviour of entrepreneurs.

ECONOMIC ANTHROPOLOGY. Economic anthropology, a branch of social anthropology (*q.v.*), is the comparative study of the relations between the system of allocation and management of the resources of societies of various types and the structure and values of those societies. For a major part of its basic analysis economic anthropology relies upon the principles of economics. But the concrete generalizations of economics deal primarily with the institutions of western-type industrialized societies; *e.g.,* business firms, banks, wage-labour. Most of the economic systems which anthropologists first studied, in Oceania and Africa, were involved only peripherally with such institutions or lacked them entirely—some were completely ignorant of money—and hence the description of such systems had to be worked out largely without the help of economists. The earlier name of "primitive economics" often given to the study reflected the emphasis on its separate, exotic character. But as "primitive" communities all over the world have come more closely into contact with civilization. their economic life has taken over many western forms; and modern economic anthropology has developed correspondingly, in order to deal with these and also with the economics of a range of peasant communities with relatively complex institutions, such as those in Latin America and the orient.

The first task in economic anthropology was to demonstrate the existence of economic data and problems in primitive communities and their relevance for an understanding of the social life of the people. In the 19th century K. Biicher, an economist, and H. Schurtz, a sociologist, showed how primitive forms of labour, exchange and wealth were related in function to modern western forms, and in 1915 W. Koppers gave a synthesis of material and views over the whole field. But such work was necessarily based mostly on second-hand, fragmentary data; it often confused economic with technological problems; and it was couched in terms of the preconceived formal schemes of an evolutionary or quasi-historical character that were then current. The next task was to examine the economic institutions of primitive peoples by systematic investigation on the spot. Various fieldworkers, notably B. Malinowski and W. E. Armstrong, showed the economic effects of magical beliefs and practices, the social as well as the commercial significance of primitive systems of exchange and credit, and the general functional interdependence between systems of mobilization and control of wealth and systems of social status and social grouping. The more general significance of some of this work for the typology of societies was developed theoretically, as by R. Thurnwald and M. Mauss.

Later studies described the economic systems of particular communities or analyzed particular institutional forms comparatively. The major factors responsible for stimulating or inhibiting productivity in primitive and peasant economic systems have become fairly clear Studies of incentives to labour, co-operation in work, and distribution of the product hare brought out the delicate interplay between individual and social factors, such as personal ambition, community standards of industriousness, economic obligations attaching to kinship and household ties, and the sanctions of ceremonial and ritual performance *(see* LABOUR, PRIMITIVE). Studies of land tenure have shown the complex sets

of rights that may be held regarding particular parcels of land and the special significance in many societies of land rights attaching to membership of a descent group such as a clan or a lineage *(see* LAND TENURE, PRIMITIVE). They have also explained how, for ritual or symbolic reasons, land is frequently regarded as an asset which is not transferable by ordinary purchase and is therefore in a special economic category. Studies of capital formation have shown how even in the technologically simplest economic systems some types of capital goods occur and some principles of prudent management of assets are in operation. But the importance attributed to disbursement in primitive economic systems and the close relation between expenditure and social status has also been demonstrated. Saving for specific purposes is approved, but the object of saving is often to provide for a "feast of merit," a "potlatch" (*q.v.*), a wedding celebration or other ceremonial occasion for mass consumption of wealth. Participation and especially leadership in such a ceremony may represent the most significant avenue for achievement of status in the community, and productivity of the economic system may be geared in large degree to this socially defined aim.

Much attention has been paid in economic anthropology to examination of processes of exchange, which are often very complex and usually exemplify the intricate interrelationship between economic and social procedures and values. Primitive communities are hardly, if ever, self-sufficient and may engage in elaborate exchange of material goods, or of goods and services, including those associated with intermarriage. In this sense a purely "subsistence economy" is hardly ever found; even the most isolated community usually manages to have some trade in ornaments or raw materials, or exchange of women as wives, with its neighbours. But as Malinowski and Mauss showed, much exchange is for symbolic, not material, ends. The acts of transfer of goods and services, while affecting the concrete resources of the parties involved, also strengthen their social and political ties and represent, even in a mystical way, basic principles of social structure and social unity.

Analyses in economic anthropology are for the most part qualitative, but there has been an increasing tendency, illustrated, *e.g.,* by the work of R. Firth, S. Tax and C. S. Belshaw, to reinforce the analysis by quantitative data. The significance of such data is not simply to illustrate the theoretical propositions advanced but to show the magnitude of the economic system and the degree of possible variation in the factors involved. For instance, from a certain ascertained level of productivity, making allowance for maintenance of equipment and for a stated set of household and community wants to be met, the limits of capital accumulation can be estimated fairly closely. Quantitative data have also revealed the range of peasant household consumption and the relative importance of the management role of a wife in a domestic unit in which the husband is ostensibly the dominant partner.

The trend in later economic anthropology has been to study societies no longer "primitive" but using some institutions of western type. Studies have been made of peasantry growing cash crops such as cocoa or rubber for the international market or supplying labour to industrial concerns; or of peoples who have abandoned their traditional rural life for an urban market economy. Such studies can have an obvious practical interest. Moreover, growing interest in the economic development of communities that have been technologically backward has turned the attention of economists more closely to the social factors involved and hence to economic anthropology.

ECONOMIC DEVELOPMENT. Although economic development has been defined in various ways, two definitions vie for prominence: (1) the growth of aggregate output of a country; and (2) the growth in per capita output. At the outset it is worth observing that it is possible to have increases in aggregate output without at the same time enjoying any growth in per capita output. For example, if the rate of growth in aggregate output is 2% per year and the rate of population growth is also 2% per year, the economy is growing from the aggregate point of view but not from the point of view of output per person. For some problems a knowledge of changes in aggregate output might be the only factor that is significant while for others the per capita value might be the one that is of major importance. For example, if a country has limited foreign exchange, an increase in aggregate output may imply an equal increase in the demand for foreign exchange. With such a problem in mind, looking at development from the aggregate point of view would be the correct approach. On the other hand, if we are concerned with planning for development, and our aim is to raise the standard of living of the mass of the population, then a per capita index is clearly the more pertinent one. In this discussion we shall employ per capita output as our index of development.

Other indexes of development have been suggested from time to time. For example, the level of per capita consumption is considered significant since it is closely related to some notions of the welfare of the mass of the population. However, this does not take into account the extent of investment taking place currently. If me consider two countries that have the same level of per capita consumption but differ in their levels of per capita investment, then it would appear that the country with the higher per capita investment is developing more rapidly than the other because it is creating capacity for greater future output. From this point of view, per capita output would appear to be the more pertinent concept.

In discussions of development it is real output and not simply the money value of output that is of significance. Changes in real output reflect the changing capacity of the economy to produce goods and services, while a change in the money income may reflect nothing more than a fluctuation in the value of money. Thus, an index of development should be one in which money values have been deflated (or inflated, as the case may require) to account for changes in the price level. Also. normally it is net rather than gross output that is considered. That is, we must deduct from gross output for the year the amount necessary to replace the capital goods that have worn out during that period.

If we look at statistics of per capita output in different countries it becomes apparent that there are enormous gaps between the per capita output of advanced countries and of underdeveloped areas. For example, the United Nations' estimates of per capita output for various countries for the years 1952–54 revealed that the per capita output for the United States was $1,870, while that of Burma was only $50. Although it has been argued that in any real sense the level of income in the United States was not really 37 times higher than that of Burma, it is nevertheless true that the gap between these two countries was unquestionably large. The majority of non-European countries have a level of per capita income of less than $200 per year per person. In fact. such per capita estimates exaggerate the standard of living of the typical person in such countries. both because they include investment funds and because they do not take into account the fact that there is a skewed distribution of income so that the typical worker receives a wage below the average income level.

In a sense the problem of the underdeveloped countries is a problem of recent history. In all ages some countries have been richer than others but the great gaps that exist in the 20th century are larger than those of earlier centuries. It is likely that before the Industrial Revolution (*q.v.*) in the west very few countries had per capita outputs that were more than three or four

times that of any other country.

Among the reasons why some countries enjoy very high per capita incomes is the flood of inventions and technical knowledge that followed in the wake of the Industrial Revolution. The knowledge necessary to produce relatively large outputs per head is today available to all countries. Such was not the case two centuries ago. In other words, two centuries ago the maximum output achievable irrespective of the amount of capital available was very much lower than it is today. Hence, the problem of underdeveloped countries is not one of achieving increases in knowledge but rather one of accumulating capital and improving the quality of the work force to the degree necessary to employ the techniques required to attain high levels of output. Furthermore, we shall see below that it is possible, although unlikely in many cases, to bridge the gap between low and relatively high levels of output in less than half a century.

Characteristics of Backward Economies.—Backward economies usually exhibit a number of characteristics that are in part a reflection of the state of backwardness and in part help to explain why the state of backwardness may persist for long periods of time. The major characteristics may be summed up as follows:

In all backward economies a high proportion of the population, often above 70%, is employed in or dependent upon agriculture. This contrasts sharply with the less than 10% of the population dependent on agriculture in a country like the United States. It is usually believed that there is absolute overpopulation in the agricultural sector, so that one could reduce the number of workers in agriculture and still obtain approximately the same total output. There is normally very little capital per head and often only the crudest equipment is employed in the agricultural sector. The large mass of the people have practically no savings; there is among them a relatively high level of indebtedness in comparison to income. Savings are usually achieved by a landholding class whose personal values are often not conducive to investment in industry and commerce. Most consumption expenditures are on basic foods and necessities. Output in agriculture consists mostly of cereal grains and primary raw materials with exceedingly low amounts of protein foods. This is in part due to the fact that if one acre devoted to cereals produces a certain number of calories, it usually takes between five to seven acres of equally good land to be used as pasture in order to produce the same number of calories in meat products. The level of education in underdeveloped areas is, for the vast majority of the people, exceedingly elementary. Over half the adult population is usually illiterate. Such economies usually lack a strong and numerous middle class. The status of women is considerably inferior to that of men and their occupational opportunities are usually limited. For the bulk of the population, economic and social behaviour is determined by tradition.

Patterns of Development.—As might be expected, the process of economic development normally leads to a change in all of the characteristics we have mentioned. To begin with, development inevitably implies a shift of the labour force away from agriculture. For example: a highly developed European economy will normally have no more than 20% of its work force in agriculture. about 40% in industry, and the rest in various types of trade and service activities. This is true even for countries that continue to be exporters of ioodstufis after they industrialize, as in the cases of Denmark, the Netherlands and New Zealand. This simply reflects the fact that economic development is accompanied by the introduction of labour-saving machinery in the agricultural sector. The other side of this coin is the growth of the manufacturing segment of the economy, up to a point, as the per capita income of a country increases.

The changing pattern of tertiary industry in the course of development is not clear. Some authorities, such as Colin Clark and A. G. B. Fisher, have argued that the tertiary sector (trade, transport and services) increases indefinitely at the expense of agriculture in the course of economic growth. However, others, such as P. T. Bauer and B. S. Yamey, have claimed that there is usually a significant amount of minor trading activities carried on by the bulk of the population in backward economies, and that with the introduction of a factory system there may actually be a diminution of the proportion of the population engaged in such activities. Hence, the Clark-Fisher generalization is based on a statistical illusion. in part, due to the fact that such trading activities in backward economies are carried out by women whose husbands are engaged in agriculture, and who themselves live on the land and hence are usually classified as dependent on agriculture. But be that as it may, tertiary industry as a well organized and specialized activity does appear to increase in the course of development.

One of the main manifestations of development is capital accumulation. Indeed, both the quantity of capital and its quality will increase with increases in per capita output. In addition, the rate of savings of the majority of the population is also likely to increase as income increases. However. this aspect of the pattern of growth must not be exaggerated. Most nongovernmental savings in any capitalistic economy are not made by wage earners but rather by business firms in the form of undistributed profits. or by recipients of property income in the form of dividends, interest earned and rents.

Consumption patterns are also inevitably altered as a country's per capita income increases. The proportion spent on foodstuffs declines while that spent on manufactured products and services increases at a greater rate than the increase in the level of per capita income. Also. the nature of foodstuffs consumed shifts away from cereal grains toward high-protein foods.

The level of education and the quality of the population inevitably increases as a result of development. By the quality of population we have in mind only the acquired characteristics and not innate capacities.

In countries where development has taken place the status of women has usually risen considerably. Also, women have come to participate in a wider variety of occupations. This factor generally has had two definite influences. First, with a high proportion of women in the work force, output per capita has increased. Second, it has been claimed that this phenomenon has helped to induce the reduction in the birth rate that usually accompanies industrialization. It has also been argued that in advanced countries socio-economic behaviour is less tradition-bound than in underdeveloped economies. This in part may be due to the gradual movement of the population from rural to urban areas and to the simultaneous increase in the variety of occupational opportunities.

In addition. the scale of economic undertakings usually increases in the course of development. This is especially likely to be true in the nonagricultural sector. Not only is manufacturing shifted out of small cottage industries into factories, but the size of factories of various types generally increases with the expansion of the economy.

Capital Accumulation and **Development.**—By capital accumulation we mean the increase in the man-made equipment useful for economic production—machinery, tools and implements of various sorts, buildings and other structures, and inventories of goods. The process of development involves the accumulation of capital at a more rapid rate than the increase in the labour force so that there is an increase in the amount of capital per worker.

The analysis of development has been carried out with the aid of the concept of the incremental capital-output ratio. By the incremental capital-output ratio we mean the addition to capital required to obtain an additional unit of net output. For example, in the United States the capital-output ratio for many decades has averaged around 3:1. This means that a $3 addition in the capital stock pill yield a $1 increase in net output. Thus, if an economy saves 9% of its income, and has a capital-output ratio of 3:1, it could expect a 3% increase in output per year.

Using this concept we can compute the rough relationship between required rates of savings (and investment) and the consequent rates of output that may occur. For example, a rate of net savings (out of net national income) of 21% per year, and a capital-output ratio of 3:1, would enable such an economy to grow in aggregate output by 7% per year. Such a rate of growth, when compounded, implies a doubling of an economy's output

about every decade. To make this example more striking, we might consider that an underdeveloped country would have a per capita income of roughly $100, while a developed European economy, such as Belgium, would have a per capita income of about $800. Now, if our underdeveloped economy grew at the rate of 7% per year, and if its population remained stationary. it could reach the level of income of an advanced European economy within three decades. Of course, rates of savings of 21% per year are exceedingly high and almost unknown, although not impossible.

In many underdeveloped economies, rates of net savings are less than 8% per year and rates of population growth are often above 2% per year. Given a rate of savings of 8%, a capital-output ratio of 4:1 and a rate of population growth of 2% per year, we would have an economy that had no growth at all in its per capita output. Hence, to find the reasons for a lack of economic development we must discover the reasons for low rates of savings, for relatively high capital-output ratios and for relatively high rates of population growth.

Various reasons have been suggested for the low rate of savings (and investment) in underdeveloped countries. First, it has been argued that the simple fact that per capita incomes are very low implies that the bulk of the population has to live close to the level of subsistence and that as a consequence there is little left for savings. Second, since underdeveloped countries lack a significant middle class, and it is in this class that we usually find the entrepreneurial groups in most advanced economies, there is a very limited amount of investment activity to induce adequate savings. Third, it has been argued that the landlord class, out of whose income savings could come, is not interested in improving the nature of its landholdings and hence saves little for that purpose. It has further been suggested that the landlord class is generally motivated toward conspicuous consumption in such areas. All of this is not to suggest that net savings do not take place in such economies, but that the savings are not sufficiently large to offset the rate of population growth.

Population Growth and Development. — Historically, high rates of population growth have always accompanied economic development. The reasons for this may be gleaned from our knowledge of the usual patterns of demographic change. In underdeveloped countries both birth rates and death rates are usually quite high. However, the improvement of sanitation and the growth in the general level of public health, which are a consequence of development, bring about a reduction in the death rate. However, these same phenomena do not initially affect the fertility rate, and the increasing gap between birth and death rates manifests itself in an increasing rate of population growth. Indeed. in many countries, e.g., Mexico and Malaya. the rate of population growth is above 2.5% per year. However, any country that has developed successfully has experienced at some point in its history the onset of sustained fertility decline. It is this phenomenon that has reduced the population hurdle to growth and has facilitated further development in advanced countries.

The discovery of powerful insecticides and advances in public health techniques have led to the development of inexpensive means for the eradication of epidemic diseases. This has enabled some underdeveloped countries to reduce their death rates considerably, even in the absence of general economic improvements. The effect of such measures has been to increase actual and potential rates of population growth, and it has tended to magnify the population hurdle to development.

The importance of sustained fertility decline can be seen from two points of view. First, a reduction in the rate of population gronth makes it easier to overcome the obstacles of fixed or not easily expandable factors of production, such as land. Second, a falling fertility rate alters the age composition of the population; it reduces the number of children per adult and hence decreases the burden of dependency. Indeed, it has been estimated that the reduced burden of dependency as a result of reasonably falling birth rates may enable such an economy to increase its investment and output to such an extent that the consequent per capita output would be higher by some 30% within three decades than would be the case in the absence of fertility decline.

The Strategy for Development. — There is no complete agreement among economists as to the best strategy to foster economic development in backward economies. Some have argued in favour of gradual development. This group views population growth as a factor that is dependent upon sociological considerations and that is independent, for the most part, of what happens in the economy. They argue that economies would naturally develop if left alone and recommend the introduction of institutional changes that would release the productive powers within it. Thus they advocate the removal of such restrictions on enterprise as tariffs, currency controls and export quotas, and restrictions on the mobility of either capital or labour. They believe that given such a restriction-free atmosphere, an economy would develop gradually of its own volition.

While not against such institutional changes, the opposing school argues that certain necessary types of economic activity must be engaged in on a fairly large scale if they are to be effective. For example, the introduction of a modern transportation system and the building of dams for the irrigation and reclamation of land are, by their very nature. large-scale projects which may often require much larger amounts of capital than would normally be obtained through voluntary savings. Furthermore, they maintain that since the rate of population growth is likely to increase as a consequence of development, the rate of capital accumulation must be sufficiently large to overcome the population hurdles in the earlier stages of economic growth. Therefore it has been argued that only with a fairly large initial effort can we hope to induce a rate of change sufficient to foster sustained growth.

ECONOMIC FORECAST. An economic forecast, also known as a business forecast or trade forecast. is a statement predicting economic aspects of future events. Some forecasts cover the whole range of economic affairs and others are limited to specific industries or to the effects of certain economic policies. When an economic forecast deals with all branches of activity it may be described as an analysis of the business outlook. Such over-all forecasts are of value in answering broad questions of public policy and in serving as background for special forecasts of limited scope.

In making detailed analyses the forecaster may be concerned with any of the specific events or variables of interest to businessmen, individual investors or government officials. In business planning, forecasting enters into current operations. as in scheduling production for the months immediately ahead. It also helps to determine longer-range programs, such as deciding upon new products or new plant locations. Forecasts by government units are specialized in varying degrees; they may predict numbers of school-age children in future years, traffic burdens on designated highways or revenues from existing or proposed taxes.

Attempts to put economic forecasting on a scientific basis have met with only partial success. The most rigorous forecasters work with quantitative measures of activity or position, such as national income, business inventories and money supply, and they specify in terms of causal influences or relationships why the predicted result is to be expected. In a complex economy, however, many factors have to be considered; interrelations between them are often not fully understood; and disturbances originating outside the system frequently affect the outcome. Hence, the actuality never quite coincides with the forecast.

Development of Forecasting. — Through the centuries, personal judgment was the primary resort of the business executive. His decisions were based on his own forecasts, whether or not they were consciously worked out. Success was dependent upon his ability to sense the implications of the situation without explicit

definition or measurement of the forces making for change. Striking results were sometimes achieved, but extreme variations in accuracy occurred. Although still widely used. the process is subject to imaginative and emotional elements. and this kind of prediction commands little confidence today.

Not until the early years of the 20th century had statistical techniques or the theory of economic fluctuations developed sufficiently to make scientific forecasting possible. Then forecasters began to apply both statistical techniques and the theory of economic fluctuations with great enthusiasm. Cnfortunately. the problem nas oversimplified in various ways, and three decades of effort culminated in nidespread disillusion. Although most of the elements of accepted business-cycle theory appeared in this early period of trial and error, the very multiplicity of theories led to confusion. Some nere couched in terms of real production and consumption, others treated monetary and credit developments as decisive, and others focused on psychological phenomena. such as naves of optimism and pessimism.

Shortcomings of statistical analysis were also revealed. Using available time series, or indexes obtained by combining such series, statisticians attempted to segregate various components of past movements—such as trends and cycles—and then applied these components in projecting future movements. Long and short cycles of great regularity were established; most widely accepted nere a long cycle averaging 18 years and a short cycle averaging 3⅓ years in duration *(See* BUSINESS CYCLE.) These cyclical patterns were used, alone or in combination with trend lines and other components of economic change. to predict the next movement However, actual economic fluctuations did not display sufficient regularity to give these methods much value as forecasting devices. Moreover, both theory and practical analysis were hampered in this early period by lack of data on over-all economic activity and on such important segments as Investment and consumption.

In the late 1930s two developments were largely responsible for a rebirth of forecasting. the formulation of an improved theoretical framework following the publication of J. M. Keynes, *General Theory of Employment, Interest and Money* (1936) and the compilation of national income and gross national product data. These new theories and data systems were brought into use as aids to planning and control by the United States and Great Britain during World War II. The importance of these tools in analysis and policy formation also gained official recognition in other countries, notably Sweden and the Netherlands. and advisory or planning agencies were set up by the governments concerned to ensure against any lack of preparedness for dealing with future recessions in their early stages.

Analysis of Economic Causes.—After World War II, forecasters focused their attention on patterns of economic causation. Each forecast was treated as a research problem in which the objective was to evaluate the importance of the causes that would be operating in the period ahead and from this analysis to formulate a hypothetical projection describing what was likely to happen. Among the "causes" commonly relied upon were: automatic economic processes, including both growth and cyclical movements or relationships; planned and controlled activities; and disturbances.

The older method of projecting growth by means of a fixed trend line has largely fallen into disfavour. Neither time itself nor the growth rates experienced in the past are causal factors. The causes of economic progress are of two kinds—the technical, including innovations. research and capital accumulation; and the demographic, including population and rates of participation in the labour force. By taking a certain number of workers, working a certain number of hours at a projected level of efficiency, an estimate of future output is derived. Since the underlying causes operate slowly, the method is of use only in making long-term forecasts. Like the trend line, it abstracts from short-term influences and requires an assumption that full employment will prevail at the target date.

Inflexible cyclical patterns have also been discarded. Modern business-cycle analysis in this tradition relies not on the periodicity of the cycle, but on observed sequences in the movements of specific variables related to it. Some variables consistently lead, so that their reversals may be judiciously interpreted as indicators of the approach of turning points. However, for an improved account of business cycles in causal terms, forecasters have turned toward the development and use of relationships between variables, particularly stock-flow relationships. The latter explain how cyclical movements develop from successive imbalance? in the position of stocks and in the flows by which the stocks are created and used. In combination, these relationships can be used to project a pattern of changes in the variables considered. The most rigorous application of this approach utilizes equation systems called econometric models. The model expresses the interrelations between variables in such a way that. given current knowledge of some variables and future estimates of a limited number of others, called exogenous variables. a forecast can be obtained by simultaneous solution of the equations. The strong point of this method involves a weakness: rigorous mathematical treatment forces the exclusion of much that could readily be utilized by other procedures.

Among the variables often treated as exogenous in econometric models are business investment in new plant and equipment and government purchases of goods and services. Statistical methods are widely mistrusted in forecasting such variables because discretionary elements are considered more important than automatic responses. Forecasters therefore resort to analysis of plans and programs as a guide to future rates of expenditure. Quarterly surveys of a large number of business concerns are taken to determine their planned capital outlays in the quarter or year ahead. Detailed studies of the federal budget, of legislative enactments and of other current developments are made to obtain clues to future rates of government spending. However, plans are generally subject to change without notice, so the outcome can rarely be considered assured.

In addition. results may be seriously affected by disturbances not taken into account when the forecast was prepared; these include international military or political developments, labour disputes and unusual weather. Because neither these nor the autonomous elements in key variables can be handled in equations, many forecasters prefer a flexible form of quantitative analysis. As a rule, the forecaster proceeds by analyzing and projecting the expenditures of important groups. such as government, business and consumers. He then translates this preliminary forecast into income and employment and checks the various projections in terms of the known interrelationships between variables. Finally, successive approximations are taken to obtain a forecast that takes account of everything known about the specific variables and at the same time combines them into an internally consistent pattern of change.

ECONOMIC MAN, a concept traceable back to the writings of the classical economists, especially to the works of Adam Smith and David Ricardo (*qq.v.*). It was assumed by most of the classical writers that political economy was a study of wealth and that mankind was occupied solely in acquiring wealth. While John Stuart Mill, one of the classical economists, did not use the term "economic man." he described the nature of the principal hypothesis which makes the abstraction of the "economic man" possible. It is generally recognized that Mill wrote the clearest statements of the body of doctrine identified as classical economics. "Political economy," he said, ". . . does not treat of the whole conduct of man in society. It is concerned with him solely as a being who desires to possess wealth. and who is capable of judging of the comparative efficiency of means for obtaining that end. It predicts only such of the phenomena of the social state as take place in consequence of the pursuit of wealth. . . . Political economy considers mankind as occupied solely in acquiring and consuming wealth." *(Essays on Some Unsettled Questions of Political Economy,* pp. 137–140).

It was assumed that, under the influence of these strictly eco-

nomic motives, man mould express himself in economic decisions that would always maximize his returns; that he would prefer the greater to the lesser gain, pay the lowest price for all things purchased and exert every effort to lower costs and increase profits; sheer accumulation of wealth would know no limit. Ethical and moral considerations were negated to the one absorbing passion and motive, the desire for wealth. This concept created an unethical, unscrupulous, money-minded person who lacked the attributes necessary to live in a society made up of persons with other motivations. The behaviour of the "economic man" together mith the gloomy forebodings that population would increase faster than food supply, helped create the impression that economics was indeed "the dismal science."

The concept has long since lost its appeal. There is no economic man any more than there is a social or a political or a religious "man." Economists of the 20th century, as Alfred Marshall remarked, are concerned "with man as he is; not mith an abstract or 'economic' man, but a man with flesh and blood."

The values that determine human behaviour are vastly more complex and varied than they nere when the concept was developed. The utilitarian emphasis on "good" and "happiness" helped to change the emphasis from the wealth or pecuniary motivation. It has been shown that man has many interests other than his interest in money; that his convictions, feelings and passions are determining factors; that he desires security, leisure, independence, justice and freedom in many forms. The virtually unlimited human wants and the efforts expended to satisfy them from limited resources is a much broader concept than conceived by the classical writers. In fact, economics is a science that studies human behaviour as a relationship between ends and scarce means. which have alternative uses. This is a far more comprehensive view than that which gave birth to the "economic man" (J. F. BE.)

ECONOMIC PRODUCTIVITY. Productivity has long been used by economists as a theoretical and interpretive concept, and its measurement has found varied applications. Economic productivity is the ratio of the output of a good or service, or collection of goods or services, to the input of one or more of the factors producing it. This ratio may be in the form of an average, expressing the total output of some category of goods divided by the total input of a factor or factors. Or it may be incremental, expressing the ratio of a change in output to the associated change in input. Most available productivity data are of the first type.

This article is organized according to the following outline:

In principle, any of the inputs associated with a given productive effort can be used in the denominator of the productivity ratio. Thus, one can speak of the productivity of land, labour, capital or subcategories of any of these factors of production (*q.v.*). One may also speak of the productivity of a certain type of fuel or raw material, or combine inputs to determine the productivity of labour and capital together, or the productivity of all factors combined.

Labour is by far the commonest of the factors used in measuring productivity. One reason is that. in terms of value, labour represents the largest input. Although great variation exists from product to product, labour absorbs, on the average, from two-thirds to three-fourths of the value added in economic activity. A second reason is that labour inputs are more easily measured than certain other factors, such as capital. This is especially true if by measurement one means simply counting heads and neglecting differences among uorkers in levels of skill and intensity of work. In addition, data relating to numbers of workers are often readily available, while information on other productive factors may be difficult to obtain. Not least important in explaining the emphasis on labour as an input is the fact that, historically, technological advance has made itself felt through the displacement of labour—that is. through increases in labour productivity—rather than through the displacement of other factors. Some kinds of labour productivity measures are thus valuable as indicators of this process and of the resulting improvements in man's material well-being.

The productivity of land, though it receives considerably less attention than the productivity of labour, also has been of historical interest. In ancient and preindustrial times the products of the soil comprised the bulk of total output, and hence the productivity of land constituted the major ingredient in a people's standard of living. Soil of low productivity could, and over much of the earth still does, mean poverty for a region's inhabitants. However, it is no longer generally believed, as it was in past centuries, that a country's economic well-being is inevitably tied to the fixed productive powers of the land. The productive potential of the land has proved not to be fixed but to be susceptible of great expansion through the use of modern agricultural methods. Moreover, industrialization, where it has taken place, has greatly reduced man's dependence on agriculture. These circumstances, together with expanding opportunities for trade, have enabled some countries to overcome in substantial degree the handicaps of a meagre agricultural endowment.

The productivity of capital—plant, equipment, tools and other physical aids—is a subject of long-standing interest to economists. though concern with its empirical aspects is of more recent origin. Improved statistical reporting and the availability of data in a few industrially advanced countries, notably since World War II, have encouraged systematic efforts to measure the productivity of this factor. Compared with achievements in measuring labour productivity, however, the progress realized has been quite limited. The theoretical and practical difficulties to be overcome are appreciable.

I. USES OF PRODUCTIVITY MEASUREMENTS

The most outstanding use of productivity measurement has been as an index of economic growth and of the level of technological development. A nation or an industry advances by economizing its inputs for a given output. Labour productivity is an especially sensitive indicator of this economizing process and is one of the major measures used to chart a nation's or an industry's economic advance. An over-all rise in a nation's labour productivity signifies the potential availability of a larger quantity of goods and services per worker than before and, accordingly, a potential for higher real income per worker. Countries with high real wages are usually also those with high labour productivity, while underdeveloped countries have low productivity and low wages. If, for the moment, other productive factors are neglected, it can readily be appreciated that the facts could hardly be otherwise, for the wage level will then be equal to the total national product divided by the number of workers; that is, it will be equal to the level of labour productivity.

The change during any interval in a nation's over-all labour productivity represents the sum of changes in the major economic sectors and industries. Some sectors and industries move ahead more rapidly than the over-all average while others gain more slowly or even decline. In the movement of a country from a level of low productivity and low income to one of high productivity and high income a strategic role is played by the industrial, rather than by agricultural and other sectors. In the late 18th and early 19th centuries the effect of the Industrial Revolution was felt first in the manufacture of woolen and cotton textiles, power generation, the metal trades and machine-making industries. Along with the development of new processes came the development of new products and services which formed the basis for new industries. An outstanding feature of these changes was increased labour productivity, which in turn laid the foundations for an enormous expansion of output. Technological change exerted and continues to exert its influence irregularly and unevenly.

In the compilation of over-all averages this diversity is concealed because high rates in some industries offset low rates in others.

Thus the rate for the economy as a whole varies within narrower limits than the spread among individual industries would suggest and. aside from erratic short-term movements, it may appear fairly stable over extended periods. A surge of labour-saving innovations would cause the over-all average to move higher, while a technological lull would depress it. History suggests that the surges tend to be associated with basic technological changes such as the steam engine. the gasoline engine, the electric motor and standardization of parts. Once introduced, such inventions or developments are used in many different industries. These surges tend also to be associated with such developments as employment of the open-hearth furnace in steel manufacture or the introduction of the steam railroad.

Besides its use as a means of measuring over-all growth and technological development, productivity is valuable also as an indicator of comparative rates of change among industries and products. Understanding of over-all growth is promoted by a knowledge of the contributions made to it by individual industries and of the circumstances underlying the pattern of movement of each of these industries.

Productivity has a third use, as a technical aid in measuring efficiency, planning and forecasting. and assessing resource allocation and its changes. While its validity as an efficiency measure is rarely definitive, a rough accuracy suffices to make it serviceable in various ways.

Related to the use of productivity as an efficiency indicator is its use as a performance standard or goal. Production quotas for men and machines set in terms of a specified volume of output per hour or per day may serve as yardsticks for evaluating the effectiveness of productive operations. They may also provide the basis for supplemental or premium payments to workers. Where compensation to workers is based on piecework alone, labour productivity becomes the sole determinant of labour income. Use of productivity as a standard may serve also as a basis for grading and evaluating any group of workers performing common tasks, distinguishing the more productive from the less productive. Applied to equipment, productivity standards can help to show when the performance of a machine or other mechanical aid is deteriorating and in need of special service or repair.

The role of productivity in forecasting stems from the fact that productivity is or can be made a variable in many forecasting problems For example, a forecast of total output for some future year might be made by projecting both the size of the labour force and the level of labour productivity for that year and multiplying the tno. A variant. common to planning in underdeveloped countries, arises from the desire to boost productivity. and with it per capita income to higher target levels by a given future date. Information on the target level of labour productivity, together with expectations about growth in the labour force and some understanding of the relation between capital per worker and output per worker, facilitates preparation of an estimate of the capital investment needed to reach the target. Again, an estimate of the probable annual gain in labour productivity, together with an estimate of the probable annual increase in output. will permit an estimate to be made of the availability of future employment opportunities.

Output per unit of labour or other input has further value as a tool in analyzing resource allocation patterns and trends. The extent to which resources flow to various uses depends, among other things, on their productivity in each of those uses. Changes in productivity in the course of time alter the pattern of use and cause the quantities of resources required in particular uses to change. The resulting trends depend on several things. On the one hand. an increase in the productivity of, for instance, labour, since it means a decrease in labour requirements per unit of output, tends to reduce the demand for labour. But it also implies a cheapening of labour relative to the cost of other competing factors of production. Hence there will be a tendency to substitute labour for other factors. Where labour cost represents a large fraction of total cost, a productivity increase will contribute tonard a reduction in the price of the product. thereby expanding sales and with them the demand for labour. The net result depends upon the sum total of all these separate effects. It is by no means uncommon to find that the expansionary effects predominate, and many economists consider this to be the normal outcome. In any event, the productivity concept and data on productivity trends can contribute importantly to an understanding of resource and output flows.

A final area in which productivity occupies a strategic place is covered by the term "prices, wages and productivity." Economists are far from a full understanding of the relations among these variables but there is substantial agreement on the follo ing points:

1. The large increases in real wages that have come about over the long term in many countries are closely associated with large increases in labour productivity in these countries,
2. In the absence of increases in labour productivity, a stable price level is inconsistent with persistent increases in money wages.
3. An increase in labour productivity or in the productivity of other factors usually brings with it a reduction in costs and henck tends to result in price reductions, wage increases or both.
4. In industries where sales of products are comparatively insensitive to price changes, increases in labour productivity will tend to reduce employment and possibly also reduce wages.
5. Wage increases in individual plants and industries may induce productivity increases by encouraging the substitution of capital and other factors for labour.

This last statement forms the basis for an explanation sometimes offered of the apparently high rate of mechanization in the United States. Abundant economic opportunities for labour on the land and in the frontier west, it is said, resulted in a scarcity of labour in industry, and hence in high wages and intensive mechanization. The same logic, with a reverse twist, is sometimes used to account for low labour productivity in underdeveloped countries. Here the argument runs that very low wage rates make it economical to rely heavily on labour and to use little capital. While there is much that these explanations leave out of account, they are valid within limits.

II. FACTORS THAT DETERMINE PRODUCTIVITY LEVELS

The many factors that help to determine the level of productivity in a country, industry or enterprise can be classified in various ways. Virtually every listing would include, in one or another form, supplies of labour, land, raw materials, capital facilities and mechanical aids of various kinds. Included also would be the education and skills of the labour force, the level of technology. methods of organizing productivity activity, the energy and enterprise of managers and workers and a range of social, psychological and cultural factors that underlie and condition economic attitudes and behaviour. Some of these factors are physical in nature, like land or capital facilities, while others are nonphysical. Some are essentially man-made nhile others represent in one or another degree an endowment of nature. All possess qualitative and quantitative aspects, both of which are important for productivity.

These variables, however classified, interact and mutually condition one another in determining productivity levels and their changes. Thus, in any country one expects the level of technology, the skills of the work force, the quantity of capital and the capacity for rational economic organization to be positively correlated. A country with low productivity is likely to show deficiencies on all counts; a country with high productivity is likely to score high on all of them. To put it differently, the numerous productivity-determining factors behave as variables in a system of simultanrous equations, with all acting concurrently to shape the outcome. Within this system, there are no grounds for assigning causal priority to one or a few variables. All interact mutually to determine the outcome. Within certain problem frameworks, however. it may be entirely appropriate and indeed essential for explanatory purposes to emphasize certain variables over others.

Two broad problem frameworks may be distinguished, both of perennial concern to students of productivity and growth. One of these involves changes in production over time, the other involves differences in productivity levels among enterprises, industries and countries at a given time. Within these frameworks are countless problems and subproblems, each of which may lead to a somewhat different selection and emphasis of variables.

Explanations of long-term productivity changes in a country, region or industry usually stress technological change and, as an adjunct, changes in the quality and quantity of capital. Other variables are not ignored but are regarded as playing a passive role and are given a subordinate position. The justification for this is that change in technological knowledge and the capital embodying it is not only essential to substantial gains in productivity but is the factor most immediately associated with those gains. It ordinarily is perceived as the leading and moving force in the process. When technological change occurs. the quality of capital improves and the amount available to aid each worker usually increases. The kinds of raw materials used may change, better grades being required or the use of lower grades becoming possible. Changes occur in the way productive factors are organized and production is carried on. Although in some periods and in some circumstances work may have become harder and more tedious following technological advance, and while the transition from land to factory has often entailed special hardships, the dominant trend has been toward shorter hours and a diminution in the arduousness of labour.

Emphasis on technological change and capital accumulation as primary forces arises also from a recognition that they are essential, in ways that other factors are not, to large and systematic advances in productivity. Gains that can be obtained solely through a reorganization of work or use of better raw materials or the breakdown of restraining attitudes or practices are occasionally dramatic but always limited. By contrast. very substantial gains can follow from growing technological knowledge and increasing supplies of capital. If allowance is made simply for adaptive changes in other factors, the prospects for advance become almost unlimited. Only these two factors can fairly be singled out as constituting the engines of productivity growth.

There is a tendency in formal theories of economic growth to stress capital accumulation as a primary variable while treating technological change more as an implicit and omnipresent background force. There are several reasons for this tendency. One is that capital is the central transmission factor for technological change and the major medium through which advances in technological knowledge are given economic expression. It also is tangible and in certain respects measurable. while knowledge cannot be measured as easily. In addition. capital results from the investment process, which in turn is linked to the saving process, and both of these play a strategic role in most theories of growth. Hence, emphasis on capital rather than technological knowledge makes it easier to draw on an established body of economic thought in seeking to explain productivity gains.

It has been noted that both the quantity of capital and its quality change as productivity increases, and it is not possible adequately to separate the two in terms of their effects. Increases in capital per worker through the accumulation of more and more of the same kinds of equipment and tools would not lead continuously to proportionate or more than proportionate increases in output per worker. They would. after a point. lead to diminishing increases, and eventually even to a decline. in output per worker. The onset of a decline would be far distant in an industry or economy possessed of a high level of technical knowledge but starting near the bottom of the accumulation ladder and affected by an acute scarcity of capital instruments. But an ultimate decline would be expected on the basis of the principle of diminishing returns.

Qualitative changes in capital. reflecting advances in knowledge and skill and leading to the design and construction of improved capital instruments, offer an escape from this principle. If capital can be steadily improved over time, its expansion need not entail diminishing returns. In countries for which data are available for broad sectors and for many individual industries there is a rough correlation between growth in the quantity of capital per worker and growth in labour productivity.

III. HISTORICAL TRENDS

Man's use of capital as an aid in production is, strictly speaking, as old as his use of primitive tools of wood and stone. But the introduction of power-driven machinery, its systematic improvement and its progressive substitution for labour are a set of much more recent phenomena. (See INDUSTRIAL REVOLUTION.)

1. Industrial Development. — The influences of technological change and industrial development have touched virtually all regions of the world since the latter half of the 18th century, though in different ways and in widely differing degrees. Some areas were involved only through trade, receiving manufactured goods in exchange for raw material exports. Others developed industry to a limited extent that served principally as an adjunct to foreign trade and did not penetrate deeply into the domestic economy. Still other countries, like Great Britain and the United States, mere more fundamentally affected as their economies underwent progressive advance and transformation. At the close of the 19th century, France, Italy, Germany, Russia, Japan and Canada, among others, also possessed substantial manufacturing capability. The transition was most evident in western and northern Europe and in North America, and least in the middle east. Africa, Asia and South America.

The countries that stood in the industrial forefront by the first decade of the 20th century remained there up to World War II, though their relative positions shifted. Most conspicuous was the forward surge of the Soviet Union, following the inauguration of the five-year plans in 1928. After World War II large strides were made in other countries of eastern and southern Europe. China and India also moved ahead, as did several South American countries.

TABLE I.—Long-Term Trends in National Output per Worker
(index numbers, 1890=100)

Year	Country			
	United States	Great Britain	Germany*	Japan
1890	100	100	100	100
1900	122	107	100	144
1910	138	110	107	166
1920	142	100	—	228
1929	172	116	90	366
1938	182	132	127	547
1948	223	132	—	314
1960	295	161	166	747

*For 1948 and later, German Federal Republic (West Germany) only.
Sources: Figures adapted and assembled by the author from data in numerous sources, including the following: Solomon Fabricant, *Basic Facts on Productivity Change*, National Bureau of Economic Research, Occasional Paper 63, Table 4 (1959); Joint Economic Committee, 85th congress, 1st session, *Productivity, Prices, aitd Incomes*, Tables 1 and 2; Colin Clark, *The Conditions of Economic Progress*, 3rd ed., ch. 3 (1957); Kazushi Ohkawa, *The Growth Rate of the Japanese Economy Since 1878*, Appendix Table 6 (1957); M. Frankel, "Some Implications of International Postwar Productivity Trends," *The 1958 Proceedings of the Business and Economic Statistics Section of the American Statistical Association*, Table 2 (1959).

The consequences for labour productivity of the changes under discussion — industrialization, mechanization and capital accumulation — are summarized in Table I for the United States, Great Britain, Germany and Japan. Because of the difficulties inhering in productivity measurement, the figures are rough approximations. They nonetheless suffice for distinguishing the rates of change among the four countries. It should be noted that in 1890 each of the countries occupied a different rung on the ladder of industrial development. By certain yardsticks. Britain already was a mature country. The United States and Germany were less advanced while Japan stood in a comparatively early stage of industrialization. Equally important, each country was differently endowed in terms of skills and resources, possessed different social and economic institutions, and was differently situated geographically. As a result. the potential for further growth differed among the four countries.

The figures show great unevenness in the rate of gain for each country from period to period. The differences among the countries are also marked, both for individual subperiods and for the entire 70-year span. These differences reflect the variety of forces that contribute to productivity change. their varying importance at different times and in different places and the complex ways in which they interact. Britain experienced no perceptible gain from 1890 to 1920. but moved ahead significantly during the next 18 years. The United States gained during the 1938–60 interval at a rate much above the rates prevailing over the preceding 50 years Japan's rate during the 18 years following 1920 was about 80%

higher than its rate for the preceding 30 years. The very high rate in Japan between 1948 and 1960 was the result of recovery and restoration following World War II. A similar phenomenon is observable in a number of other countries, including Germany, though the figures in the table do not show it. Britain and Germany are noteworthy for their low average rates over the long term. Japan, in contrast, is unique for the high average rate attained over a very long period.

2. Labour Productivity. — An index of output per worker, like any single productivity index, provides only limited information on the process of productivity change. Some other features of that process deserve mention. Long-term increases in labour productivity have usually been accompanied by reductions in the number of hours worked per day and per week. In Britain or the United States, for example, a 60-hour week was not uncommon in 1850 but a century later 40 hours was a familiar figure. Hence, if the data in Table I were put on a man-hour basis, the rates of increase would, in general, be much higher.

A reduction in hours worked is simply one of the ways in which a people may benefit from productivity increases. Such reductions as have taken place probably have not entailed proportionate sacrifices in the quantities of goods and services that, with constant hours, might otherwise have been obtained. For when hours of work are very long, worker efficiency tends to be low. Within limits, as hours are reduced, efficiency rises. There is substantial evidence that the decline of the working day from very high levels has brought compensatory gains of this kind.

Systematic long-term increases in labour productivity have been accompanied also by changes in the quality of labour and changes in the quality and quantity of other inputs. Generalizations about these other changes are, however, difficult to make. In many fields of production, for many classes of work, introduction of machines has entailed a downgrading of skills. Loss of many traditional handicraft skills during the early stages of mechanization is a case in point. This type of loss has been repetitive throughout the history of mechanization. A machine replaces one class of skills and at the same time generates requirements for other skills of a lower order.

But the sequence is by no means one-directional. Machines are complex, and over the decades their complexity has increased. This growing complexity has created a need for skills of a high order for machine development and for the installation, servicing and operation of machines. Organizational requirements for the effective use of machines also have become more complex, thereby increasing the need for a large array of highly trained specialists. As a result, the downgrading and displacement of some skills have been accompanied by upgrading of others and the emergence of new ones. There is little doubt that the latter tendency has predominated over the long term. The general educational and technical qualifications of an industrial, highly productive labour force are very much higher than those of a low productivity labour force engaged largely in agricultural and handicraft pursuits.

3. Productivity of Other Factors. — Changes in the productivity of other factors have accompanied the more or less regular, long-term increases in labour productivity. Unfortunately the record is far less comprehensive and in some respects less clear as to the nature of these changes than in the case of labour productivity. By introducing constant improvements in farming methods, farm machinery and fertilizers, technological change has led to large increases in the productivity of land as measured by the output of foods and fibres per acre. But it should be noted that, unlike output per worker, output per acre does not correlate well with living standards because of the varying intensity with which cultivation is carried on in individual countries. This circumstance accounts, for example, for the fact that output per acre for a particular commodity sometimes is higher in a poor country than in a rich country. Technological change has also made it possible to economize in the use of some raw materials in production and thus raise output per unit of raw material consumed But in practice higher productivity, while possible. may not result, since with a cheapening of this factor it often proves economical to use it more liberally than before. Sometimes, also, more'mechanized methods of production are inherently more wasteful of raw materials than less mechanized ones.

In some countries, at least for some periods. the productivity of capital has risen. In the United States, from 1900 to 1960, output per unit of tangible capital increased about 80%, or at an average annual rate of just over 1%, with the bulk of the increase occurring after 1929. On the other hand, it barely changed between 1890 and 1920. As between the two factors, labour and capital, it is clear that over the long term the major savings have been in labour. Both theoretical considerations and statistical data suggest that continued technological change will bring further large gains in labour productivity but the probable trend with respect to capital is uncertain.

From the standpoint of the individual enterprise, all reductions per unit in factor inputs are important. The economic benefit is the same whether a given net reduction in cost results from the saving of labour, capital or raw material. But from a world-wide or economy-wide point of view, labour savings occupy a unique place. This is so because labour, interpreted in the broadest sense, is not only an input in the productivity process but also represents the goal of that process. Ultimately, goods and services are consumed by people. An increase in output per worker or per capita signals the availability, or potential availability, of increased quantities of goods and services for each individual. An increase in output per unit of capital or raw material does not necessarily carry this connotation. If the objective is to attain ever-rising living standards. then it is labour productivity that. over the long term, must be increased.

4. Trends in Productivity. — Trends in over-all productivity are composites of trends in the several sectors and subsectors of the economy and, in the last analysis, of trends in individual industries and enterprises. Trends at these subordinate levels often differ widely, both from one another and from the broader economy-wide averages. Some of this diversity may be seen by comparing the trend in output per man-hour in the total United States private economy with similar trends in the farm and nonfarm subsectors. For the entire period of 1909–56 production in both subsectors moved ahead about the same amount and roughly in line with the over-all movement. Between 1909 and 1929, however, the increase in the farm sector mas far below that in the nonfarm sector, while for the period of 1938 to 1948 the reverse mas true. The periods of 1929 to 1938 and 1948 to 1956 show a slightly higher trend in the farm sector than in the nonfarm sector.

The figures serve to qualify the popular impression that agriculture is a persistent laggard in the technological march. In the United States, during the 19th and early 20th centuries, the nonfarm sectors — including mining, manufacturing, communications and utilities — were certainly in the vanguard. But in later decades, productivity in agriculture rose. The farm surpluses of the 1950s and 1960s symbolized the results.

These productivity movements do not exhibit a close relation to movements in output. For all periods increases in farm output, though relatively low, averaged close to 1% per year. At the same time productivity increases varied widely. ranging from under .5% to over 3%. For the nonfarm sector an annual 2% productivity increase was registered between 1929 and 1938, a period when output declined by 1% a year. By contrast, much the same productivity increase occurred from 1938 to 1948 when output advanced at 6% per year. This outcome is perhaps not surprising in view of the fact that the sources of output and productivity increases are not identical. Productivity increases will result in output increases provided the quantity of resource inputs does not decline. But output increases may also result independently of productivity increases, from an expansion of resource inputs or from an increase in the intensity with nhich resources are used.

To gauge the contribution of any sector to the production total it is necessary to consider the size of the sector and its productivity level. Because agriculture in the United States contributes less than 5% of the national product and employs less than 9% of the labour force, even a large change in output per worker would have but a nominal effect on the total. The outcome may be very different if the sector is large and if its productivity level,

measured by value of output per worker, is high relative to other sectors. In that case, and depending on the method of measurement, a redistribution of labour in favour of the high productivity sector can produce large productivity changes in the total even though sector productivity changes little. This source of productivity gain, while important for all dynamic economies, is especially so for one that is in the early stages of industrialization. In such economies, low productivity agricultural pursuits absorb the bulk of the labour force, and hence the potential gain from their transfer to more productive occupations is very large. Traditionally, students of productivity have shown greater interest in the industrial sector than any other. The reasons for this, already touched on, have to do with the early and sustained influence of mechanization on this sector and the consequences for productivity that followed.

5. Relation Between Productivity and Output. — In comparing countries some association is observable between changes in productivity and output; countries showing large increases in one variable tend also to show large increases in the other. But the relationship is, at best, very loose. Coincident movement of the two variables would mean that gains in output had arisen exclusively because of labour savings. (Strictly speaking. this is true only if the productivity figures relate to output per manhour.) By contrast, an increase in output accompanied by no change in productivity would indicate that the advance was attributable solely to the use of greater manpower or other resources. The data for the years following World War II show that both rising productivity and greater manpo er contributed to the advances in output in all countries but that the influence of the former was generally greater. In Japan, Italy. France and Austria, for example, productivity was more important while in Poland, West Germany, the Soviet Union and Canada manpower increases played a larger role.

It is ordinarily preferable that increases in output be obtained through productivity growth rather than through a larger labour force, for this implies not only more product, but also more leisure, or at least a potential for more leisure. A tacit assumption here is that the leisure is voluntary. If it is not, then the problem of unemployment must be reckoned in the balance. Italy is a case in point. Between 1948 and 1957 industrial productivity in Italy rose at a rapid rate and in doing so accounted for almost the whole increase in output. But industrial employment expanded only slightly and contributed little to the relief of a serious unemployment problem.

6. Rates of Growth. — Performance during a span of over two decades. 1938–60, contrasted greatly for many countries with performance over the shorter postnar intervals. Indeed, one is left by the long-term data with a quite conservative impression of the progress made by the several countries, both individually and as a group. The amazingly high growth rates common in the postwar years are not in evidence and the order in which the countries are ranked from high to low is very different.

The contrast between growth rates over the long term and the short term reflects the impact of war and the efforts to recover from it. Japan and Austria are excellent illustrations. The high rates of increase in productivity realized in the postwar period by Japan and Austria did little more, by 1960, than restore those economies to their prewar levels. Much the same thing could be said of West Germany and of Britain, though in the latter case the gap between long-term and short-term growth rates is more modest. Other west European countries — France and Italy, for example — had by 1960 surpassed their 1938 levels by more substantial margins. though these economies also were obliged to devote a major fraction of their energies to overcoming wartime arrears. This applies also to the east European countries, the Soviet Union. Poland and Czechoslovakia. Within the intercountry structure of rates, and in contrast to its position in the postwar structure, the U.S. registered an average advance in excess of 2% from 1938 to 1960. A notable feature of the U.S. trend, in contrast with trends for most other countries. was its stability. Gains in the 1948–60 period were appreciably greater than for the longer interval but, comparatively speaking, the gap was small. The comparative closeness of long-term and short-term rates for the U.S. reflects its good fortune in escaping the physical destruction and economic disorganization of war suffered by other countries.

IV. COMPARISONS OF PRODUCTIVITY LEVELS

Besides knowing productivity trends over long periods of time, it is frequently useful to know productivity levels and differences in productivity levels at a given time. One problem in this category involves comparing output per worker, or worker-hour, among plants producing similar goods for the purpose of assessing the relative efficiency of each and explaining the differences among them. Another problem relates to determining differences in value productivity among subsectors and industries. Such knowledge is essential, for example, to an understanding of the effects on the national product of a change in the distribution of the labour force. The potential uses for data on productivity levels are manifold.

Comparisons of productivity levels of different countries, whether on an economy-wide or industry-wide basis, have attracted much interest because they serve, among other things, as a point of departure for appraising and understanding differences among countries in technology, resource utilization and living standards. Table II compares, on an economy-wide basis, output per worker and per capita for 16 countries. The fact that some of the figures are for 1950 rather than a more recent year is of minor importance because over-all data of the kind given tend to change only slowly. Neglecting small intercountry differences, the basic impressions conveyed by the table were doubtless still valid in the early 1960s. Yet it must be stressed that the figures are to be treated as only rough approximations.

TABLE 11.—Comparison of Levels of Output, About 1960
(in both columns the figure of 100 represents C.S. output)

Country	Real output per worker	Real output per capita
Argentina	35*	27
Australia	62*	72
Brazil	21*	20
Canada	92*	74
Chile	29*	24
Denmark	62	62
France	52	52
Germany, West	46	51
Great Britain	50	58
Ireland	36	39
Italy	37	29
Japan	31	27
New Zealand	88*	90*
Soviet Union	25*	25*
Sweden	57*	65
United States	100	100

*About 1950 rather than 1960.

Note: A countrv's output per capita, relative to that in the U.S., exceeds its output per worker, relative to that in the U.S., if the fraction of its population in the employed labour force is greater than the corresponding fraction in the U.S.

Sources: Data developed from Colin Clark, The *Conditions of Economic Progress*, 3rd ed., ch. 3 and 4 (1957); *Statistical Yearbook* (United Nations); *Yearbook of Labour Statistics*, International Labour Organization: *Economic Survey of Denmark*, Secretariat of the Government of Denmark: *Survey of Current Business*, United States Department of Commerce; *United States Income and Output*, United States Department of Commerce.

The general level of productivity in the United States is the highest of those shown by a wide margin, and a more comprehensive listing of countries would not alter its position. New Zealand and Canada are not far behind the United States but the gap betueen them and the others is fairly wide. Australia, Sweden and Denmark bracket the high side of what might be called a middle productivity range, while Britain, France and — with allowance for incomplete postwar recovery — West Germany fall on the lower half of this range. The remaining countries, with productivity levels of between one-third and one-fifth that in the U.S., are located still lower on the scale. A large group of excluded countries, belonging in the underdeveloped class, would occupy still lower positions. This group would embrace the bulk of the peoples in Africa, Asia, the middle east and South America. It is well to keep in mind that these people comprise a majority of the world's total population and, accordingly, that the average productivity level for the world as a whole is, by western standards, very low.

Differences among countries in the relation between the output per worker and output per capita figures are attributable to differences among countries in the percentage of the total population at work. If the proportion of those seeking and finding gainful

employment was the same in all countries. the relation between each pair of figures in Table II would be the same. One might expect that with higher output and income levels there would be a tendency for the percentage of the population seeking work to decline. Entrance into the labour force would be delayed by longer schooling. and fewer family members would be obliged to work in order to maintain any given income level. The table suggests a relationship of this sort, though it is not a strong one. It may be that the tendency in this direction is stronger than appears but that it is offset by the more abundant and attractive occupational opportunities existing in countries with high incomes. In any case, the differences that exist between the two series are not large and do not alter the over-all intercountry pattern. The close correspondence between them affirms the overriding importance of productivity levels for living standards.

At least two broad approaches can be taken in seeking to explain such productivity differences as are found in Table II. One of these map be termed cross-sectional. It seeks to identify the chief factors associated with the observed differences and to ascertain their relative importance. Measurement and analysis of the degree of association between intercountry differences in output per worker and corresponding differences in, say, size of plant is an example of this approach. It does not of itself tell us the direction of cause and effect between two variables nor even that a causal relationship is present. Neither does it tell us anything about the time-trend of the relationship — whether it has always existed, whether its form has changed over the years or why it may have changed. Nonetheless, the approach is helpful in suggesting which factors may contribute significantly to productivity differences.

The other approach might be called developmental, since it involves an assessment of the process of economic change as it affects productivity levels. It goes beyond the cross-sectional approach in that it endeavours to explain how certain causal factors came to be important and how they have interacted with other factors to cause shifts in labour productivity over time. Necessarily in this approach the question arises of where and how to apportion responsibility for change. The answers supplied by economists have varied. T. R. Malthus (*q.v.*) selected population growth as his key variable. J. A. Schumpeter (*q.v.*) emphasized the role of entrepreneurship in a country's development. In much contemporary literature, whether concerned with industrialized or underdeveloped countries: the process of capital accumulation is regarded as of overriding importance. Despite their differences, all these treatments may be characterized as developmental since they give attention to the movement and influence of particular factors over time.

The two approaches are complementary. While useful hypotheses might be built wholly from one or the other, the value of each is enhanced by their joint use. The cross-sectional approach, in identifying factors of probable significance, facilitates the application of the developmental or historical approach. At the same time, the latter helps to amplify the meaning and significance of the factors found to be associated with productivity differences.

Needless to say, each country's current circumstances and its development, as these bear on productivity levels, possess unique characteristics. For this reason no single, simple hypothesis, whether rooted in one approach or in a combination of approaches, is likely to go very far in accounting for the wide range of differences in Table II. One probably valid generalization seems north making, however. Differences in growth rates are essential to an understanding of most large productivity differences among countries. Almost without exception, the countries with high productivity are those that have succeeded in mastering improved technology; with the aid of capital accumulation they have diffused this mastery through the several sectors of the economy and have continuously improved it. Only by continued productivity advances over a fairly long period is it possible for a country ? achieve such levels as prevail among the high-income countries.

V. PROBLEMS AND LIMITATIONS OF PRODUCTIVITY MEASUREMENT

Many difficulties, both theoretical and practical, attend the development in any area of an organized, consistent body of productivity data. Some of the difficulties are specialized and unique to a specific inquiry. Others are more general in character and affect many different kinds of productivity studies. The few remarks that follow treat difficulties of this latter type.

A basic difficulty arises from the heterogeneity of inputs and outputs that make up the productivity ratio. Ordinarily such ratios are computed not for a single. homogeneous type of output, but for product categories that embrace a host of subproducts. Thus the output of the steel industry consists of sheets, wire. rods, structural shapes of various kinds and a great many other items. Computation of satisfactory productivity data for an industry usually requires, therefore. that account be taken of the diversity of output and its changing composition. This can and often is done by weighting the subproducts in accord with their relative values and then adding them together. Unfortunately, however, relative values change over time, raising the question of what weights to use. Should they be initial year weights or terminal year weights or some combination of the two? The question is not academic, since difierent weights sometimes produce significantly different amounts of change between the initial and the terminal years.

There is a parallel problem on the input side. Strictly speaking, the labour force is not homogeneous. It is made up of a range of skills and specialties that embody varying amounts of education and training. and it is reasonable to suppose that their contributions to the production process vary accordingly. Weights may be used in aggregating. though in practice this is done less frequently than is the case with output. Where it is done. there is again the option of using different methods with different results. The weighting problem is not avoided by first computing productivity ratios for subproducts and then combining these ratios. For the individual ratios must be weighted before they can be aggregated, and in most suitable weighting systems the relative importance of the weights changes over time.

A second basic difficulty relates to the susceptibility to measurement of inputs and outputs. Labour inputs are relatively easy to measure, particularly if one is content simply to count heads. But if one wishes to take account of differences in the quality and intensity of labour inputs, the question of measurement immediately arises. At what rate should one type of labour be converted into another? Wage rates often are used for the purpose, not because of a belief that they are correct but because they are the most readily available yardstick.

Measurement problems are equally difficult in connection with capital inputs. Plant and equipment lose their value gradually over time. and in any one year contribute but a part of this value in production. There is no universally acceptable procedure for measuring this contribution. There exist a few recognized accounting practices but no one of them is recognized as superior to the others. It probably is true that no one procedure is best in all situations but that each has unique advantages for certain applications. Measurement is further complicated by the diverse composition of capital instruments, a fact that rules out any counterpart to headcounting for labour inputs.

Moreover, the composition of capital changes over time with the result that the kinds of machines and facilities used in one year may differ markedly from those employed a generation earlier. Any one of these circumstances would alone suffice to make measurement difficult.

For some inputs, such as organization or enterprise, an acceptable method of measurement is wholly lacking. The quality and very likely the quantity of each has changed greatly over the years and their importance relative to other inputs has changed. But no reasonably rigorous means for evaluating these changes is available.

On the output side, measurement difficulties are especially apparent with regard to services. In contrast to commodity outputs, which are tangible and divisible into identifiable units, some service outputs are very difficult to define and measure satisfactorily. In concrete terms. what is the output of an enterprise engaged in business consulting? Of an organization dispensing banking services? Of a government agency exercising regulatory functions? More is

involved here thdn the fact that each of these activities embraces a mixture of distinguishable services. The main trouble is lack of any acceptable standard by which to measure such outputs.

This problem is not unique to service outputs, but it shows itself most clearly in the service sphere. Lacking a suitable direct measure of service outputs the student will often use inputs as a substitute measure, the assumption being that inputs and outputs are equal or will move together over time. Whatever its merits for gauging output. this method is unsuited to measuring productivity. For the validity of a measure oi productivity depends on a clear separation of outputs from inputs. Considering the nature of the problems, it is not surprising that the bulk of available productivity information relates to commodity production.

The availability of satisfactory sources and data constitutes a third major problem in developing productivity information. Censuses of production and population, national income series and their components, series regularly published on industrial and farm output, on wages, hours and the labour force. and data provided by regulatory and other government agencies are among the basic source materials that may be used. The scope and quality of these materials vary nidely among countries, and tend to be more comprehensive and reliable in the more advanced, industrialized countries. With few exceptions, unfortunately, such data are not collected for the purpose of providing information on productivity. Special studies often must be undertaken either to supplement what information is available or, for certain input-output areas. to obtain any data at all. Even where information for recent periods of time is extensive the researcher may find it difficult to prepare productivity tables that extend back very many years. For no country can our knowledge of productivity trends in the 19th century be described as better than meagre. The situation for many underdeveloped countries is still less satisfactory.

A miscellany of other difficulties affect productivity measurement. One of these is the choice of a time period over which to measure changes in productivity. Another involves determination of the inputs of the productivity ratio. If the input is labour, should it cover all employees or only production workers? Should it be on a man-hour or a man-year basis? Yet another problem relates to determining a suitable output classification; that is, to determining the content of the output category and the breadth or narrowness with which it is defined. Decisions on these problems that are both theoretically sound and practical are often very hard to reach. See also ECONOMIC DEVELOPMENT; PRODUCTION, CENSUS OF.

ECONOMICS (ARTICLES ON). The history of economic thought, which reflects the great transitions of social history, is summarized in the survey article ECONOMICS. This article outlines the views of the economic philosophers who mere spokesmen for their eras; describes the emergence of economics as a scientific discipline; and discusses the methods used by economists.

CAPITALISM discusses the evolution of private enterprise, the variations by which it has been adapted to changing societies, and the outlook for the future of the system as indicated by current tendencies. Historic forms of private enterprise are treated in GUILD; LAISSEZ-FAIRE; MERCANTILE SYSTEM; and PHYSIOCRATIC SCHOOL. INDUSTRIAL REVOLUTION deals with the series of 18th and 19th century innovations that set much of the pattern of 20th century enterprise.

SUPPLY AND DEMAND describes the factors that must be taken into account in gauging the interaction of these forces in specific situations. INFLATION AKD DEFLATIOn discusses the causes of these phenomena and their bearing on the economic climate in which business is conducted. BUSINESS CYCLE analyzes dominant theories as to the nature of these broad upswings and downturns of business activity.

ECONOMIC FORECAST describes the methods that have been used, with varying degrees of success, to predict the occurrence and duration of business cycles.

COMPETITION, ECOKOMIC deals with the advantages and disadvantages of this aspect of private enterprise. Attempts to eliminate competition are treated in CARTEL; CO-OPERATIVES; and MONOPOLY. The legal regulation of competition is discussed in FEDERAL TRADE COMMISSION, and self-regulatory measures in TRADE ORGANIZATION.

Among the articles on individual phases of business activity are ACCOUNTING; ADVERTISING; BOOKKEEPING; BUDGET. BUSINESS; CREDIT; INSTALLMENT CREDIT; INSURANCE; MANAGEMENT SCIENCES; MARKETING; MASS PRODUCTION; OFFICE MACHINES AND APPLIANCES; OFFICE MANAGEMENT; PRODUCTION MANAGEMENT; PUBLIC RELATIONS; RESEARCH, IXDUSTRIAL; RETAILIKG; and SALESMANSHIP. Related articles of importance are listed in FINANCE, ARTICLES ON.

Among the articles dealing with broad areas of economic theory are CONSUMPTION; DEMAND; DISTRIBUTION; ECONOMIC MAN; LAND; MARKET: *Economic Theory;* PRICE; RENT; STANDARD OF LIVING: VALUE; WEALTH AND INCOME.

Articles concerned with statistical interpretations of economic conditions include BIRTH RATE; COST OF LIVING; ECONOMETRICS; NATIONAL INCOME, ACCOUNTING; MARRIAGE RATE; POPULATION; PRICES. STATISTICS OF; ECONOMIC PRODUCTIVITY; etc.

Among the articles dealing with the relationship of government to business are FAIR TRADE LAWS; IKTERSTATE COMMERCE; PUBLIC ENTERPRISE; SALES TAXES; TARIFFS; and TAXATION.

Articles on various phases of the economics of labour include AMERICAN FEDERATION OF LABOR–COKGRESS OF INDUSTRIAL ORGANIZATIONS; APPRENTICESHIP; CASUAL LABOUR: CLOSED SHOP; EMPLOYMENT AGENCY (EXCHANGE); GENERAL STRIKE; HOURS OF LABOUR; INDUSTRIAL ACCIDENTS; INDUSTRIAL RELATIONS; LABOUR LAW; PENSIONS; STRIKES AND LOCKOUTS; TRADES UNION CONGRESS; TRADE (LABOUR) UNIONS; WAGES; WORKMEN'S COMPENSATIOS; UNEMPLOYMENT INSURANCE.

Among the articles involving problems of international economics are AGRICULTURE; COMMERCE, HISTORY OF; ECONOMIC DEVELOPMENT; ECONOMIC UNION; FOOD SUPPLY OF THE WORLD; FREE TRADE; NATURAL RESOURCES; SHIPPING, HISTORY OF; STATISTICAL ORGANIZATIONS, INTERNATIONAL; TARIFFS; TRADE, INTERNATIONAL. Also. sections on economics are included in the articles on the major nations of the world.

Articles dealing with the social and ethical implications of economic problems include HOUSING; LUXURY; PHILANTHROPY; POVERTY; SOCIAL SECURITY; UNEMPLOYMENT. Phases of economics are discussed within the framework of the other social sciences in PSYCHOLOGY, APPLIED; MATERIAL CULTURE; SOCIAL ANTHROPOLOGY; and SOCIOLOGY.

Article: on collectivist schools of thought include COLLECTIVISM: COMMUNISM; GUILD SOCIALISM; MARXISM; SOCIALISM: PRINCIPLES AND OUTLOOK; and SYNDICALISM.

Biographical articies set. the background of the work of such

molders of economic thought as Adam Smith, Friedrich List, Thomas Robert Malthus, etc.

The lists given above should be taken merely as examples of the *Britannica's* coverage of economic topics. The Index volume cites articles and sections of articles on many additional phases of economic theory and practice

In view of the key role of economics in the contemporary scene. the *Britannica's* articles on the subject have been planned with the general reader in mind as well as the student, and the style is essentially nontechnical, except for sections on mathematical procedures in such articles as ECONOMETRICS The following articles are suggested as a minimal reading list for an introduction to the elementary principles of economics: ECONOMIC MAN; ECONOMICS; INDUSTRIAL REVOLUTION; MARKET. *Economic Theory;* and *SUPPLY* AND DEMAND.

ECONOMICS. The term economics came into general use in the 20th century, replacing the older "political economy" as the name of a somewhat vaguely defined branch of social science The change of name reflected changes in the discipline itself. uhich had become subdivided into a number of specialties. One separation had been made between economics as a pure science and economics as the study of public and private problems of policy; another separation was made between empirical economic facts—historical or statistical—and economic theory.

The word economy comes from two Greek roots referring to the management of a household or estate. But in the past two centuries or so the meaning has become generalized to cover all uses of means in such a way as to husband them. to make them go as far as possible. Political economy itself is a modern term. It was introduced about the beginning of the 17th century to describe the study of the problems of the princely states which at the close of the middle ages in Europe replaced the feudal-ecclesiastical political order. It referred to the economic affairs of the state or principality—the raising and use of revenue and increase of resources—treating the state as the estate of the ruler. But this study never was generally known by this name. After the nationalistic epoch gave way to individualism or liberalism, at the time of the enlightenment in the late 18th century, political economy was adopted as the name of a science based on the new moral and political world view, and the older state-oriented literature came to be designated as mercantilism.

Epochs in the Development of Economic Thought.—The sketch above suggests four main periods or epochs in the evolution of economics, corresponding to those usually recognized in European history. They are the Greek (or classical in the meaning of general history, but the Roman contribution was minor), the medieval, the early modern (16th to late 18th century) and the modern, roughly the 19th and 20th centuries. Each corresponds to a distinctive political order and to distinctive conceptions of man and society; and it is an important fact that books were written by and for different social classes in the different periods. The Greek literature was written by aristocratic philosophers and publicists, and related to the problems of the city-state, which was nominally democratic but was based on slave labour and excluded the merchant and financier from civic life Such writers as Plato and Aristotle commented on many obvious facts and principles. such as the importance of division of labour and the use of money. But their interest centred in such moralistic and metaphysical notions as the condemnation of lending at interest as unnatural. Modern knowledge of the economic and industrial life of ancient Greece is derived mainly from other sources, incidental references in literature and archaeological remains. Many of the ideas were in fact survivals of primitive attitudes; they are found also in the older parts of the Bible, and survive as a strong influence even today.

Medieval economic thought is still more moralistic and alien to the modern outlook. The dominant social organization was the church, and recorded thought was more of the nature of preaching or theology and metaphysics than of science, as words are used now. For that world, the accepted ideal was a static or customary society and civilization. every man working out his lot in the situation to which he had been called. Trade was frowned upon, beyond limited routine exchange at "fair"—meaning customary—prices, corresponding with a customary standard of living for each social class, and interest-taking was condemned outright. In the later middle ages, however, numerous evasions of the prohibition against interest-taking, achieving the same result through other contractual arrangements, came into use and were recognized as legitimate. Men's interests were shifting to the concerns of earthly life, cultural, aesthetic and scientific, as well as material; *i.e.,* political and economic. The evolution of economics must be seen as integral with that of economic life and of European civilization as a whole.

The third period is best designated as that of economic nationalism. but the economic thought is usually called mercantilism. (*See* MERCANTILE SYSTEM.) It dealt with the economic policies of the national monarchic states which displaced the feudal order at the close of the middle ages. The distinctive writings on economic matters were produced by political pamphleteers. It was the age of the commercial revolution; the monarchical states saw wealth obtained through foreign trade as the basis of political power, and money as the embodiment of wealth. Europe was flooded with silver and gold, especially from the new world, chiefly by way of Spain; and the northern countries, which had no mines at home or in their colonies, centred attention on sharing in the treasure through a favourable balance of trade, an excess of exports over imports.

Mercantilism flourished from the 16th century to the 19th century. and was exemplified in innumerable writings and in the restrictive and regulative policies of such statesmen and rulers as Jean Baptiste Colbert. Lord Burghley, Oliver Cromwell and Frederick the Great. Besides attempting to secure a favourable balance of trade (an excess of exports. bringing in money or bullion), other aims were low interest rates, low wages, encouragement of population growth and colonies. It has been interpreted as nation building and as an advance toward free trade, which was promoted within the national domain, in contrast with the application of similar restrictive policies by smaller units in the medieval towns. Whether the measures advocated met the immediate needs of the times is still a disputed question. In economic terms. the fallacies have long since been exposed, but the general attitude survives today in protectionism.

Transition to Modern Political Economy or Economics.— Modern economics started out essentially as the theory of free enterprise. It is interesting to observe that the great mercantilist writers of the later 17th century in England (contemporaries of John Locke in political philosophy) were in substance free traders. Thomas Mun's famous booklet, *England's Treasure* by *Forraign Trade* (published posthumously in 1664 but in circulation much earlier), sophistically used the balance of trade argument in favour of freedom to export specie. Other writers, such as Charles Davenant, Nicholas Barbon, Sir Josiah Child and especially Sir Dudley North, aorked out the theoretical argument for freedom in foreign trade about as explicitly and clearly as did Adam Smith nearly a century later. North argued that the wealth of a nation is that of its citizens and that the businessmen, traders and producers are the best judges of when trade involves a net gain. It remained for someone to apply the same reasoning to internal policy, against the surviving guild restrictions or national control of apprenticeship, of wages and interest, grants of monopolies and the like.

All through the later mercantilist period, economic relations were gradually becoming more free and controls were falling into disuse, particularly in England. In notable respects the statement of free-trade doctrine came earlier in France, where the movement itself was much sloner. It was here, of course, that the phrase "laissez faire" originated in the first half of the 18th century. The kingdom of France was still subdivided into many districts with customs frontiers until after the Revolution. About the same time there appeared one of the most notable of the books anticipating the liberal point of view, the somewhat mysterious *Essai sur* la *nature du commerce en général,* by Richard Cantillon. It is apparently a translation, perhaps by the author himself, of an English manuscript which has disappeared. Cantillon showed

a fairly clear insight into the mechanism by which a free market will direct resources into the production of the goods most in demand. Similar insights were conspicuous in the nearly contemporary essays of David Hume, though he wrote no systematic treatise. Early in the second half of the 18th century much attention was attracted by the writings of a French school, the members of which called themselves *les économistes* but who are now referred to as the physiocrats. The word is practically equivalent to law (or rule) of nature. The leader was the court physician François Quesnay. Like many of the mercantilists, these writers used rather absurd if ingenious arguments; and it has been pointed out that their position was connected with the self-interest of certain groups that had achieved wealth and power in the disturbed conditions in France after the death of Louis XIV, especially in consequence of the ambitious schemes of John Law and the famous "Mississippi Bubble." But the physiocrats are to be credited with an attempt to see and analyze a national economy as a whole. Their most characteristic doctrine was the view that only agriculture yields a surplus beyond what is required for the support of the workers; hence land rent alone is available for the support of the state and higher culture or the increase of wealth, and is the only proper subject for taxation. These ideas survived in part in the work of Adam Smith and the British classical economists. The pre-Revolutionary statesman, Anne Robert Jacques Turgot, renowned for his courageous but abortive economic and fiscal reforms, was to some extent a disciple; his work. *Réflexions sur la formation et la distribution des richesses* (1766–70), is an exceedingly able treatise.

The Classical Political Economy.— In 1776 Adam Smith published *An Inquiry into the Nature and Causes of the Wealth of Nations*, a work in which wisdom, learning and the power of analysis are joined to an extraordinary degree. As already noted, Smith shared many of the popular prejudices that were evident in the writings of the physiocrats. He held that "in agriculture nature works with man,"—as though this were not true of all other pursuits—and that only labour is productive. He also held that the interests of businessmen, as a class, are more often opposed to the interests of the community than are those of landowners. Nevertheless, Smith gave the world a new view of the advantages of trade as a mechanism for working out the division of labour, and a new philosophy of commerce. But he saw in commerce, as well as internal trade, a means to welfare! not merely to the aggrandizement of the state. His book was, in one leading aspect, a formidable tract directed against mercantilism. Money, from the communal point of view, he held to be merely an instrument. a wheel of trade. The real source of a country's wealth, he said, is its annual labour, and its wealth or well-being could be increased only by making its labour more effective, particularly by extending specialization and accumulating product in the form of capital. (For "labour" we should now say "productive resources.") "The division of labour is limited by the extent of the market" is one of his most famous sayings.

These were Adam Smith's fundamental principles. He elaborated them with great skill in relation to concrete problems, showing unusual powers of fresh observation in his selection and use of illustrative material, and passing large sections of economic history and the whole range of the contemporary commercial and fiscal problems of Britain under survey. Although his book is the most influential brief ever formulated for unimpeded trade, neither hampered nor coddled by governments, its greatest importance lies not in that circumstance but in the general picture, at once simple and comprehensive, which it gives of the economic life of a nation. It shows how the apparent chaos of competition, the welter of buying and selling, is resolved or transmuted into an orderly system of economic co-operation by means of which, under individual freedom in contrast with central direction, the community's wants are supplied and its wealth increased. This general picture has been in the minds of economists ever since, whatever their opinions with respect to the efficiency or morality of the competitive system, and its general outline is admitted even by collectivists to be valid for their systems. Despite some sweeping phrases which invite another interpretation, Smith was no doctrinaire advocate of a hands-off policy by governments in respect of economic matters. His treatment must be understood against the background of conditions of his day, in which so much was a holdover from the period of mercantilism and even the middle ages. He was opposed to monopoly, exclusive combinations and special privileges of all kinds, quite as much as he was opposed to the type of legislation which aims at fostering a country's prosperity by restricting its trade. He is often styled the "apostle of self-interest." but he took no pains to conceal his dislike for some of the forms in which self-interest manifests itself in trade and industry, and had no aversion to legal measures wherever they actually promised to be beneficial. What his attitude would have been under the later conditions of the 19th and 20th centuries toward the factory acts, social insurance. and particular measures intended to foster equality of opportunity, we cannot tell. But there is nothing in the aims of these newer types of legislation which runs counter to his principal contentions or is inconsistent with his general economic philosophy.

Adam Smith's work had a profound influence not in Great Britain alone but in almost every part of the western world. It was partly responsible for some radical changes in the commercial policies of governments, though its influence cannot be measured. because the current of the times was moving in the direction of his contentions. Its effect upon scientific thought and upon the character and quality of public discussions of economic questions cannot be questioned. Men like Jean Baptiste Say in France and Karl Heinrich Rau in Germany based their work very largely on Smith's and helped to diffuse his influence. Say, however, was more than a mere popularizer. He had some clear-cut views of his onn and developed Smith's work in directions other than those it took in the hands of Smith's British successors. In the United States, Say's work came to be about as widely read as Smith's.

The particular trend which the development of economics took in Great Britain after Smith was largely determined by the character of the economic problems which confronted the nation, partly by reason of rapid changes in its own industrial structure (the industrial revolution) and partly in consequence of the French Revolutionary and Napoleonic wars. Population increased rapidly and foreign trade expanded. The changes were accentuated by the wars and by governmental effort to maintain self-sufficiency in food (or to benefit the landed interest. which controlled the government); land rents rose aith the increase in agricultural prices; the currency was depreciated (a practically universal accompaniment of any major war); rates of interest and of profits nere disturbed; and. after the peace, both industry and agriculture experienced depression conditions. Some of these conspicuous and important phenomena engaged the attention of parliamentary committees; all of them attracted the interest of thoughtful men who, with Adam Smith's picture of the mechanism of organized economic life in their minds, thought of them as interrelated and attempted to explain them in some consistent and comparatively simple way. Out of the discussions of the period, in pamphlets and controversial tracts, there emerged a formal system of political economy. It owed much to Smith, but it stressed matters to which he had given little or no attention, and emended his views at a number of important points. This newer political economy mas concerned more largely with abstract general relations, but it dealt with real problems.

For convenience, the period of which we are now speaking may be taken as definitely beginning with the publication of David Ricardo's *Principles of Political Economy and Taxation* in 1817, and as culminating with the publication of John Stuart Mill's *Principles* of *Political Economy* in 1848. One who compares the economic tracts and the systematic treatises of that period with the *Wealth of Nations* will be impressed with the increased importance given to a group of problems which have continued to be principal concerns of economics, problems now commonly grouped under the head of theory of value *(see* VALUE, THEORY OF) and distribution (*q.v.*). The theory of value attempts to explain nhy goods exchange at particular prices. why some are expensive and others cheap. The modern theory of distribution is really a part of value theory, dealing with the prices of produc-

tive services, with a view to explaining the sharing of the national income or social dividend. or why some are poor and others rich. The classical economists found it useful for analytical purposes to classify the total product into three distributive shares—wages of labour, profits of capital and rent of land. Later on, the conception of a fourth share, the profits of enterprise. or of the successful direction of production, was taken over from the French economists (Say and his followers); the earnings of capital, separated from the entrepreneurial functions of management and responsible risk-taking, came to be called interest (whether actually paid out for borrowed money or imputed to that of the owner, an individual or a group).

The clasiical theory of value stressed chiefly the tendency of the prices of goods produced and sold under competitive conditions to be proportionate to the costs of producing them. However, costs meant not the money outlays of the producers (entrepreneurs) but the "real" costs, human sacrifice or pain. For Ricardo this appeared to mean quantity of labour Some of his writing seems to suggest that labour alone is really productive, other factors only assisting. This extreme form of the labour theory of value, which doubtless was never held by Ricardo, was taken over in a variety of modified forms by the various schools of socialists and economic radicals, notably by Karl Marx (*q.v.*) in his theory of surplus value. which maintained that all distributive shares other than wages must come out of the difference between what labour produces and what it earns, *i.e.*, that rent, interest and profits must all represent exploitation of labour. Later. the notion that the abstinence involved in saving and accumulation of capital is also a true cost was introduced by Nassau William Senior in An *Outline* of *the* Science of *Political* Economy (1836). The socialists, of course, scornfully rejected this innovation.

The classical economists did not see clearly that what is economized is the use of resources, both human and nonhuman, and that the ultimate meaning of the cost of any product is the nonuse of resources for some other end. This fact is now known as the alternative cost principle. But the alternative end sacrificed is not always and entirely a quantity of another marketable product; it may be the leisure use of time and labour, or some direct (nonmarket) use of any other resource. It should be noted that, as all modern economists have recognized. the cost explanation of value applies only in a long-run view, over time sufficient to adjust production to demand. The classical economists freely recognized that over short periods price depends on demand and supply, *i.e.,* the demand for the existing supply already produced, or for which commitments have been made. For example, the price of a commodity in short supply is likely to rise well above its cost of production until its output has time to catch up with demand.

A similar division between short-run and long-run views was inevitable in connection with the theory of distribution. Neither theory has stood up well under later criticism, though many important facts and principles were recognized.

In the long-run theory of distribution, the idea that the standard of living determines wages is in effect a cost-of-production theory of the price of labour. This doctrine rested upon the theory of population associated with the name of Thomas Robert Malthus (*q.v.*), though it was clearly stated in general terms by Adam Smith and by still earlier writers. In the later form, the notion of subsistence, as a physiological minimum, was replaced by, or interpreted to mean, a standard of living, a scale or level which labourers think of as necessary in order to undertake family life. If wages fall below that level, it was thought, the rate of growth of the working population will be negative (births fewer than deaths), and the decline in the labour supply will raise wages. If wages are above this level, population will increase and wages mill fall—unless a higher standard of living becomes effective as a control of marriage. Somewhat similar reasoning was applied to profit. the rate of return on capital. The supply tends to increase as long a5 the return is above what savers generally consider sufficient to compensate for the abstinence required to save, and will decrease when it is below such a level; hence the rate of profit tends toward this level as a position of equilibrium.

The rent of land, however, was held not to be affected by the principle of cost. Land was thought to be permanently fixed in supply; it was defined by Ricardo as "the original and indestructible powers of the soil." Hence, a rise in rent will not tend to counteract itself by bringing forth an additional supply—or reciprocally for a decline. Correspondingly, rent mas not supposed to be a part of or to influence the price of its produce, which in this view is determined by the cost (wages plus profit) on land barely north using and yielding no rent—or by the cost at the intensive margin. Changes in rent were thus the effect, not the cause, of changes in product prices.

In the classical system of distribution as a whole a very important place was ascribed to the "law of diminishing returns," in a particular long-run or historical interpretation. As the theory ran, the growth of population, itself dependent on growth of capital, required resort to poorer land and also to more intensive cultivation of land already in use. In either case, the increase of product would not be proportionate to the increased amount of labour (and capital). Manufactures, in contrast, were thought to be subject to increasing returns, because of larger opportunities for the economies of the division of labour and for invention and for the application of the fruits of scientific progress to industry. Agriculture also benefited by technical progress, but here the possibility of improvement was thought to be smaller and to be more than counterbalanced by the increasingly disadvantageous proportioning of labour and capital to land. Since labourers must always get the same real wages—the means of subsistence—the profits of capital must decline, until the growth of population and wealth would come to an end in a stationary economy. Taken as a prophecy, this doctrine has not been entirely disproved by the course of events. It is true that the possibilities of improvement in agricultural technique were underestimated by the classical economists; new lands of good quality have been brought under cultivation and their produce brought to market by cheap transportation; and the Malthusian "principle" has been partly falsified by some at least temporary declines in birth rates. But in recent years increasing concern has been felt about the continued rapidity of population increases, particularly in the so-called underdeveloped areas, and the Malthusian prediction has to some extent returned to fashion. (See ECONOMIC DEVELOPMENT.)

Any general system of value theory must have something to say about the value of money or the general price level. This problem was of especial concern to Adam Smith because of the price revolution which had swept over Europe after the discovery of America and of its startling effects. Later this interest was nourished by the monetary and price changes of the period of the great wars of the French Revolution and of Napoleon. On this point the classical school held to the doctrine later known as the quantity theory of money: other things being equal, the value of money (and reciprocally the price level) depends on its quantity in relation to the volume of production and trade. (See QUANTITY THEORY OF MONEY.) Allowance would also be made for the use of money substitutes, such as bank credit, already familiar in Europe. As a long-run view, this doctrine was supplemented by the notion that the quantity of money is determined by the costs of mining the precious metals. Among different countries, whether or not they possess mines of precious metals. prices would tend to be equalized by a flow of money or bullion from countries in which foreigners would buy less to those in which they would buy more.

It would be an error to think of these earlier economists as altogether preoccupied with abstract theories, or not to recognize that their interest in these matters was born of an interest in practical problems. And in general, they were not such uncompromising opponents of any sort of interference by government in industry as some later critics and pretended expounders of their views have made them out to be.

The Critical Schools.—Before reviewing the later progress of economics, especially the developments of the later 19th century, it will be helpful to look at the principal types of criticism which have been directed against the older political economy and at the conceptions which have been proposed as replacements. In the

first place, romanticists like Adam Müller in Germany and John Ruskin in England intensely disliked the new individualistic economic mechanism. the workings of which the economists were trying to probe. They particularly disliked the defense of this mechanism of economic laissez faire, which the economists in general did defend, by statement or implication. They preferred an ordered society with economic values subordinated to moral or religious or aesthetic values, such as they thought had been more or less fully embodied in the social structure of the middle ages. Work, they inclined to insist, is not merely a means to an end, particularly what are called economic ends; good work is worth doing for its own sake and for its effect upon character. They did not impugn the fitness of economics as an instrument of attack upon its special problems so much as they belittled these problems.

Another group of writers, for whom there is no better descriptive name than "the critical school," came much closer to meeting the orthodox economists upon their own ground. One of the earliest and the most influential of them was Simonde de Sismondi (*Nouveaux principes d'économie politique* [rev. ed. 1827] and other works). Other able writers, notably Thorstein B. Veblen in the United States, took a similar position. These critics urged that more attention be given to the defects of the competitive economic mechanism, even viewed merely as a means of providing for material needs. They contended that the economists, contemplating the long-run or normal tendencies and the theoretical beauties of the automatic processes by which the pursuit of individual economic interests becomes organized into a vast scheme of economic co-operation, forget how often the mechanism breaks down and normal economic life is interrupted by crisis and depression; how unemployment, chronic as well as epidemic, is a disease of this economic order; how unequally the aggregate product is distributed among individuals or families; and how many of the things men do for their own economic advantage are in fact inimical to the interests of the community. As later critics have put it, businessmen are interested primarily in making money, which does not always mean making more goods. The picture of the economic harmonies (the title of a mid-19th century French apologetic work) requires, it is urged, rationalizing of the facts to an unwarranted degree. These criticisms also undoubtedly go too far. They unduly play down the role of the abstract principles stressed by the older economics in the general course of the economic activities of the community. And no economist of the first rank has ever been a devotee of the pure automatism of the market. But the critical school has had a wholesome influence on the progress of economic science. It should be observed that this school occupied a position between that of the orthodox school and that of the socialists who denounced the works of the latter as mere apologetic, a product of the existing economic order and prompted by the interests of those who benefit by its iniquities.

Another line of attack was adopted by the historical school, or more accurately, schools, since the term covers several different groups. This position has been represented in all countries, but it has been most influential in Germany. The most important of its early exponents were Friedrich List (*Das Nationale System der politischen Ökonomie* [1841]) and Wilhelm Roscher (*Grundlagen der Nationalokonomie* [1854] and other works). The form of a nation's economic life, said these critics, is a historical category, peculiar to a given nation at a given time, a product of its past and. therefore, only to be understood through a study of that past. The wisdom of particular economic policies is relative to conditions of a place and time, and the supposedly universal laws of abstract economics need to be supplemented by or even subordinated to study of concrete facts of the national situation. If they had gone no further, the historicists would have found many to agree with them. But they tended to make of the historical method something arbitrary and doctrinaire. (Karl Knies, whose work *Die politische Ökonomie vom Standpunkte der geschichtlichen Methode* appeared in *1853,* is a notable exception.) Not content with looking to history for the causes of these concrete differences of economic structure in which they were interested, they proposed to derive from history itself universal and binding laws, akin to those of the physical sciences. They were fond of schemes of stages of economic development through which they thought every nation must pass. In these speculations they were really elaborating suggestions found not in historical research but in the Greek speculative historians. They regarded the forms taken by economic life, past and present, as inevitable products of historical forces; and at the same time, unconscious of the inconsistency, they advocated a rather heavy-handed control of economic activities by the state.

The British and French economists had looked upon the organization of economic life as being shaped and determined by the interplay of the interests and rational activities of individual men, and had viewed the state as an instrument of individual purposes—well-being as judged, in the main, by each person for himself. The spokesmen of the historical school, in contrast, were strongly influenced by the philosopher Georg Wilhelm Friedrich Hegel, nho ascribed a prior and independent value to the state, with individuals somewhat in the role of means, on the analogy of cells or organs in the human body; the view is related to that of the mercantilists though-more sophisticated. Although they pushed their views to extremes, they gave a needed emphasis to what has come to be called the institutional view of economic activities, as contrasted with the individualistic or contractual aspect. But both the older historicists and the later institutionalists (largely a U.S. movement of the early 20th century) slurred over the contrast between two kinds or meanings of institution; *i.e.,* patterns of action moving in predestined grooves under the influence of relatively unconscious social forces versus those embodying deliberate organization and control, such as the political organs of the state. The state, in turn, was conceived by the older schools in what would now be called totalitarian terms, while the institutionalists, like the socialists (in contrast with the communists), thought of it as democratic. Historical economists have also been more ready to think of change, as contrasted with finality. in the pattern of economic organization, and they give a useful impulse to the study of economic history, which is valuable both in itself and as a complement to economic theory. Under the influence of historical study the old dogmatism of the historical economists gradually gave way to a realization of the variety and complexity of the fabric of economic history; and the newer schools of historical economics under the leadership of such scholars as Gustav von Schmoller in Germany and Ashley and George Unwin in Great Britain were primarily devoted to historical research. The movement also broadened out, particularly in Germany, under such leaders as Max Weber and Werner Sombart, into what is often called sociological economics, a position also well represented in France (François Simiand, Maurice Halbwachs, C. Bouglé).

The Marginal Utility Analysis.—The older classical economists, as we have seen, centred their attention on the long-run relations between value and costs and were generally content to dispose of short-run variations of price by merely invoking the formula of demand and supply. This was used without careful analysis of the short-run situation, particularly of the role of demand. Work directed toward filling in this gap had important effects in changing the whole conceptual picture. Similar steps introducing the new analysis were taken independently and almost simultaneously in the early 1870s by William Stanley Jevons (*q.v.*) in England, Karl Menger in Austria and Marie Esprit Léon Walras (*q.v.*) in France and Switzerland. (It presently became known that they had been in part anticipated by earlier writers who were ignored and forgotten.)

Adam Smith, in a famous passage, had contrasted value in use with value in exchange, noting that the former is high for water and low for diamonds, and conversely for the latter. The new discovery was that there is nonetheless a definite relation between value in use (or utility) and exchange value, hence price. The value in use is not properly measured by the difference between having the normal supply of a good and having none at all but by the difference it makes to have a little more or a little less. Thus where water is scarce its value—both use and exchange value—is exceedingly high, because the marginal use meets an intense desire or need; that is, because an addition to our supply

of water on a desert trip can add very substantially to our well-being. If diamonds were abundant enough their value would be small because we would benefit very little from further additions to our stock of diamonds. Goods, however important, that are superabundant, the supply being unlimited by any cost, have no economic utility or economic value, though to common sense this seems a paradox.

Perhaps the most important feature of the new views, considered as theories of demand and of price, was not the psychological explanation but clarification of the nature of what Adam Smith called the "effective demand." It was seen that the demand for a commodity by any consumer or in any market is not a definite magnitude but a functional relation showing the different quantities that will be purchased as the price changes. It is assumed that in most cases a higher price will reduce the quantity demanded. The actual quantities depend on both the tastes of the consumers and on their purchasing power, and in addition, on the availability of other products competing for the consumers' income and the price of these other items.

This idea served to clarify the relation between price determination in the short run and that in the long run. In the former case. the supply is typically the amount already on the market, and the price is the marginal demand price for this amount. But in the longer run, production itself responds to price and price to supply, so that the long-run or normal or equilibrium price is that at which the amount consumers will take is equal to the amount which producers find it profitable to produce. This advance is largely to be credited to Alfred Marshall (Principles of Economics [1890] and numerous later editions, considerably revised).

It was also gradually recognized that costs of production consist of the payments which at the same time constitute the shares in the distribution of the product among the different productive agents. Thus a rational conception of production in terms of the allocation of productive capacity among alternative modes of use, through the competitive bidding of business units (or their managers or entrepreneurs), explains at the same time the prices of final products. the costs of production and functional distribution. Personal distribution depends in addition on the amount as well as the value of the productive services of all kinds that are owned or controlled by the various participants in economic activity.

Goods are usually produced by the co-operation of various kinds of productive services. and the special problem of distribution, in modern terms, is that of the division of this joint product among the different kinds of co-operating productive services or agents. (See DISTRIBUTION.)

At the end of the 19th century a number of writers (especially John Bates Clark and Philip Henry Wicksteed) sought to analyze distribution in a manner analogous with the marginal utility theory of consumer demand. It was argued that a business firm, too, would be willing to pay a productive agent only what he adds to the firm's well-being. It is clearly unprofitable to buy, *e.g.*, a man-hour of labour if it adds less to its buyer's income than the labour cost him. This marginal yield of a productive input came to be called the value of its marginal product, and the resulting theory of distribution which states that every type of input mill be paid the value of its marginal product is called the marginal productivity theory of distribution, a theory which still has its place in current economic literature.

This theory, or principle, that every agent tends to get what it produces does not mean that each person gets what he deserves and in fact tells us little about the ethical quality or social desirability of the result. It must be remembered that differences in training and opportunity greatly affect men's productive capacities as workers, and that institutions, especially that of inheritance, enter into this picture as well as into the ownership of property and the opportunity to accumulate. And the swift process of change in technology and demand often robs men of the fruits of skill acquired at great cost—and also of the savings committed to particular industries. In particular, such innovative activities as invention and exploration for minerals may yield anything from zero to a reward quite disproportionate to the outlay in effort or money.

The rate of interest received much attention in the discussion of this period. Controversy was stimulated in particular by the publication in the 1880s of two books by Eugen Bohm-Bawerk, a disciple of Karl Menger. He propounded two views of interest, both foreshadowed a half century earlier in the work of N. W. Senior. One is a reworking of the abstinence theory into one of postponement or waiting, or discount of the future. Interest is viewed as the reward or necessary inducement for saving, hence as the measure of the superior attraction of present over future consumption. The other view regards interest as the yield or productivity of investment due to the greater efficacy of more roundabout processes, *i.e.*, processes in which raw materials are first transformed into producers' goods which are in turn used to make consumers' goods.

The interest rate on loans tends to equal the yield obtainable on investments; *i.e.*, the ratio of the net rental on capital goods (after provision for maintenance and eventual replacement) to their cost; and the cost is the value of consumable goods sacrificed in using productive capacity to create them. (See CAPITAL AND INTEREST) The theory of interest is of the greatest importance in the general system of value theory, since the value of all durable goods bought and sold is immediately determined by the capitalization of the expected future income. This tends to be the same as their cost. since no such good will be produced, or long maintained. unless it is expected to yield at least the going rate on its costs, and if it yields more, new supply will lower the rate. But errors and unexpected changes in conditions often cause capital goods to be worth more or less than cost (to yield less or more than interest on cost).

The discussion of distribution at the beginning of the 20th century also produced significant contributions to the theory of profit, particularly by Frank H. Knight and Joseph A. Schumpeter. In ordinary business usage, profit is a mixed form of income, containing elements of interest and of wages for that vaguely distinguishable part of management activity which may be treated as labour; and both the amount of the owner's capital and the proper rate of interest to allow are also uncertain. The distinguishing mark of profit is that its amount is not stipulated in any agreement or fixed in an exchange but is contingent upon the success of a particular enterprise or undertaking. According to Knight, profit arises from error or imperfect foresight on the part of the responsible entrepreneur, in making policy decisions or in delegating these to salaried managers as his agents (in a corporation, the agents of the voting stockholders as a group). Pure profit is the amount left over after making all stipulated payments for productive services, raw materials, etc., and after deduction of the going rate of payment for the entrepreneur's own capital and services. It may be a negative as well as a positive sum. and. Knight suggests, it is impossible to say conclusively whether the gains are greater or less than the losses in the aggregate for a whole economy. Pure profit is, of course, increased in any individual case by greater accuracy in the ultimate managerial decisions, and tends to be decreased by excessive optimism on the part of entrepreneurs.

According to Schumpeter. whose views are compatible with the preceding discussion, profit is the reward to the entrepreneur for successful innovation. To him the primary task of the businessman is not the running of routine operations, but the putting of new ideas into effect. He is always seeking new products, new sources of supply and new productive technology, and if he can effect these innovations before it is done by his competitors, he obtains a profit over and above the regular interest on his investment and the wages of his day-to-day managerial labour.

The end of the 19th century produced another important contribution which continues to occupy the attention of economists. Even more than from his work on marginal utility theory, Léon Walras' influence today stems from his invention of general equilibrium analysis. This approach is characterized by its recognition of the interdependence of the various parts of economy. For example, a fall in meat prices is not only likely to affect sales of poultry and fish but also to change the amount of money con-

sumers have left over for the purchase of all other goods. Indeed, a change in practically any economic variable has direct or indirect effects on innumerable other magnitudes. and it is this complex network of interrelationships which general equilibrium theory undertakes to analyze. This analysis is necessarily of such complexity that the use of mathematical equipment becomes absolutely essential. In the simplest general equilibrium systems demand and supply relationships are expressed as functions of all prices in the economy, and the requirement that demand for every commodity in the economy be equal to its supply thus constitutes a system of simultaneous equations which can normally be solved to obtain the unknown magnitudes of the prices. Subsequent work in the area has involved more complications and more advanced mathematical techniques.

A number of concrete economic phenomena can be explained meaningfully only in such a general equilibrium context. This is true of any problem involving the allocation of national resources, such as the production of guns or butter in wartime, because any increase in one output can be evaluated only in terms of possible reductions of production of other items. Similarly, the analysis of monetary and, in particular, of interest rate phenomena must involve general equilibrium considerations because they materially affect every sector of the economy. Most recently. general equilibrium theory has also led to the input-output analysis of Wassily W. Leontief (*The Structure of American Economy, 1919–1929* [1941]) in which the technological interrelationships of production in entire economies are investigated empirically and interpreted as a system of simultaneous equations which can be solved for the total input and output requirements involved in the production of any particular collection of consumers' goods.

Recent Contributions to Economic Analysis.— It is possible to list the main developments in economic analysis since the 1920s under four headings: welfare economics, the theory of monopolistic competition, the theory of the determination of national income and employment and mathematical economics. All of these grew out of earlier work but their systematic analysis and the widespread attention they have received are fairly recent.

This is particularly true of welfare economics whose subject matter has to some extent been discussed throughout the history of economics but which has only in the 20th century been established as a separate and well-defined branch of the discipline. Welfare economics may be interpreted as the theory of economic policy. It investigates the effects of various economic phenomena and governmental policies on the well-being of the community. Its emphasis has largely been on the consequences of various market forms such as monopoly and competition for the allocation of the economy's resources and its relation to the desires of the public. The effects of various types of taxes, import duties, price controls, rationing devices, nationalization and socialism have also been studied. The first systematic work in this area nhich perhaps is still the most important contribution is that of Arthur Cecil Pigou (*The Economics of Welfare* [1920]). Work in the late 1940s turned more to quasi-philosophical issues involved in the foundations of welfare economics, but more recently interest has swung back primarily to applications of the subject to problems such as those involved in investment decisions by government agencies.

The second major recent development of economic theory, the theory of monopolistic competition, gave full recognition to the range of market structures in between the extremes of pure competition and pure monopoly to which earlier writings had largely been devoted. (*See* COMPETITION, ECONOMIC; MONOPOLY.) Important earlier contributions to the subject had been made by many economists including Jacob Viner, Roy F. Harrod and Frederik Zeuthen. But the attention of the profession was fully captured by tno works, Edward Hastings Chamberlin's *The Theory of Monopolistic Competition* (1933) and Joan Robinson's *The Economics of Imperfect Competition* (1933). The theory encompassed a variety of market phenomena including product differentiation, a situation in which each seller carries goods which have some unique properties in the view of the consumer (brand names, special ingredients, accompanying customer services, etc.) so that the seller may be considered to have a partial monopoly. Also analyzed were oligopoly, which is characterized by an industry composed of a small number of large firms; discriminating monopoly, where a given item is sold at different prices to different customers; and monopsony, that is, a single (monopolistic) buyer. Since the bulk of business in developed capitalist economies is conducted under conditions of product differentiation or oligopoly the enthusiasm with which the analysis was received was understandable. Unfortunately, the theory involves difficult problems which have so far prevented its complete integration into the body of economic analysis.

The third of the major recent developments, the theory of income determination, is associated primarily with the work of one man—John Maynard Keynes (*q.v.*) who published his fundamental volume, *The General Theory of Employment, Interest and Money* in 1936. The Keynesian analysis takes the position that, at least in the short run, the level of effective demand for consumers' and producers' goods may either fall short of or exceed a nation's capacity to produce. In the former case the result will be unemployment and depression, while the latter event (where effective demand exceeds productive capacity) will lead to inflation. The important Keynesian analytic innovation consists in his discussion of the determinants of effective demand. Over-all consumer demand is, on this view, determined largely by national income, that is, by the amount of purchasing power which flows into the hands of consumers. Over-all demands for producers' goods, on the other hand, depend primarily on profit prospects and the terms on which businessmen can finance their purchases of equipment, inventory and other inputs. If rates of interest are high it will be expensive to borrow the funds used to construct new plants and equipment and so high interest rates will reduce the demand for producers' goods.

This at once suggests a number of policy instruments for the control of unemployment or inflation. For example, in an inflationary period it may be appropriate to reduce effective demand by use of one or more of the following actions: (1) reduce the money supply, which will tend to raise rates of interest and so decrease the demand for producers' goods; (2) reduce governmental expenditure. thereby directly decreasing total demand for goods; (3) raise taxes or sell government securities to the public, thereby reducing the purchasing power in the hands of consumers. Of course, none of these techniques is without its drawbacks but if problems of unemployment or inflation become sufficiently serious, action of this sort is likely to be worth the price.

One characteristic of these policy measures is particularly noteworthy. It provides the means for the government to help combat inflation or unemployment without detailed central direction. Basically, the method consists in additions to or withdrawals of purchasing power and it is left entirely up to consumers and businessmen to decide to what uses these funds will be put (or from what types of expenditure they will be withdrawn). Keynes also emphasized that wage reductions are not an effective and dependable cure for unemployment. They result, at least in the first instance, in a reduction in costs of production, but they also reduce the public's purchasing power.

Keynes' work is important analytically because it provides a systematic explanation of the determination of over-all effective demand and hence of the level of production (national income). It is very much in the spirit of general equilibrium analysis, with the interdependence of production and monetary phenomena playing a crucial role. However, Keynes achieves a considerable amount of simplicity and analytic power by his exclusive attention to broad categories; for example, the category of consumers' goods is never discussed in terms of the specific industries and products of which it is composed. Economic analysis conducted at this level of aggregation has proved particularly helpful in the systematic investigation of policy problems and has been given the name *macroeconomics* in contrast with *microeconomics*, the study of the individual units which compose the economy.

A fourth major recent phenomenon is the expansion of the field of mathematical economics. This is a far more complex and

heterogeneous development than those which have just been discussed and its origins go back at least to the first half of the 19th century. Though there are even earlier writings in the area, the first systematic work is probably that of the French economist. mathematician and philosopher, Antoine Augustin Cournot (*Recherches sur* les *principes mathématiques* de la *théorie* des *richesses* [1838]). Cournot recognized that if businessmen adopt policies nhich yield them maximum profits, the differential calculus permits the prediction of the nature of their price and output decisions, the reaction of their prices to changes in taxes, etc. For the differential calculus is the classical mathematical tool of maximization and minimization computations, so that given enough information it can tell us what levels of outputs and prices are necessary to obtain maximum profits for the firm. Largely on this basis, Cournot was able to develop a rich and informative theory.

For the next half century mathematical analysis received little attention from economists. Only with the work of the marginal utility theorists did interest in this area become more widespread. An outstanding example is the role of mathematics in Walras' general equilibrium analysis which has already been referred to.

Until recently, the differential calculus was the most important tool of mathematical economics. Eugen E. Slutsky in 1915, John Richard Hicks and R. G. D. Allen in 1934, and Paul A. Samuelson in 1947 all made important contributions to the analysis of the behaviour of the consumer and the business firm. Using the so-called higher order maximum conditions of multivariable functions under constraints they were, for example, able to derive fruitful theorems about the reactions of the utility maximizing consumer and the profit maximizing firm to price changes.

More recently, mathematical economics has turned to other types of problems and other types of mathematical techniques:

1. *Economic* Dynamics.—With this technique the structure of economic processes and economic developments over time is studied in detail. Particular attention has been paid to the sequence of developments involved in business fluctuations and to the analysis of the long-run mechanism of expansion of an entire economy. The mathematical techniques which most frequently have been employed here are difference and differential equations. Roughly, a difference equation may be described as a relationship between the current value of some variable and the values of this and possibly some other variables at various dates in the past. These are obviously a suitable instrument for economic dynamics, particularly because economic data are reported and acted upon at discrete intervals (perhaps once a month) rather than continuously as a differential equation would imply.

2. Activity Analysis.—Economic problems are frequently characterized by what the mathematician calls inequality constraints. For example, the total output of the economy is limited by the available mineral resources, its labour supply, etc. The amount of any such resource actually employed must aways be less than or equal to the total amount available. Any attempt to use a nation's resources in an optimal manner must take these constraints into account. The analysis of maximization or minimization problems involving such inequality constraints required a new set of mathematical techniques called mathematical (or in a special simple case linear) programing, which are most closely associated with the work of mathematician George Bernard Dantzig. These methods have been employed to extend the theory of welfare economics, general equilibrium analysis and the theory of economic growth, in all of which such constraints play an obvious role. These applications of mathematical programing, many of which are the work of Tjalling C. Koopmans, have been given the name "activity analysis."

Game Theory.—The analysis of problems of oligopoly and other related market situations underwent a major reorientation as a result of the work of John von Neumann and Oskar Morgenstern (Theory of Games *and Economic* Behavior [1944]) in which the analogy between business competition and rivalry in games was exploited as an analytic tool (see GAMES, THEORY OF). Work in this area and the other problems of mathematical economics which have just been described continues to be a major preoccupation of economic theorists.

This discussion has been confined almost entirely to economic theory nith no attention to the large variety of empirical. institutional and applied work which has become important. As in other' disciplines, work in economics has become increasingly specialized into such areas as international trade, labour economics, money and banking. and public finance, each with its large and growing body of literature. Moreover, work in the collection and analysis of statistics has developed rapidly. Reliable records of economic activities are brought together and published by governments and private organizations on a scale which would have excited the envy of the earlier economists. Analytic statistical techniques and the investigation of their foundations have evolved from the primitive political arithmetic of the 17th century into the complex and sophisticated methodology which is known as econometrics (*q.v.*). All of these developments together constitute the discipline of economics which continues to be in a state of ferment and rapid growth.

ECONOMICS, PRIMITIVE: see ECONOMIC ANTHROPOLOGY.

ECONOMIC UNION. In the widest sense this term designates any form of co-operation in the economic field between two or more countries. The Universal Postal union (*q.v.*), for example, or the former European Payments union (*q.v.*) may be regarded as economic unions. though each was confined to a limited and specific set of problems. The concept is used more frequently for the establishment of a common market between two or more countries; this. in turn, is a special form of customs union. A customs union is an agreement between two or more countries stipulating: (1) the complete elimination of tariffs and other trade barriers between the member territories; (2) the establishment of a uniform tariff and other rules regulating imports from outside the union; and (3) apportionment of customs revenue between the members in accordance with an agreed formula. An economic union goes further in that it normally also embraces agreements on the flow of investment between the member countries and may include provisions regarding other aspects of economic relations such as the migration of labour among the members of the union.

History.—Preferential arrangements relating to international

trade were concluded in the middle ages and even earlier, but the idea of a genuine customs union did not arise until the early 19th century. Only after the end of the Napoleonic wars did the idea of a customs union take hold. The German Zollverein, formed in 1834, is the most important customs union of the pre-World War II period and has often served as a model. In the course of the 19th century various countries which acquired colonies practised customs assimilation, a policy which has many similarities with a customs union. Customs assimilation involves the establishment of a uniform trade area between the mother country and the colonies, with free trade within the customs area and a common tariff barrier to the outside. Among the chief protagonists of colonial customs assimilation were the United States and France. Great Britain and Germany did not practise assimilation but treated their colonies as separate entities for customs purposes, though in some cases they accorded them preferential treatment.

In the period between World War I and World War II several unsuccessful attempts at forming regional customs unions were made, but the first effective customs union to come into existence was Benelux (*q.v.*), the union of Belgium, the Netherlands and Luxembourg, formed in 1944 by governments at that time in exile in London. The Benelux union did not begin operations until Jan. 1948. A customs union between France and Italy (Francita) was projected, but negotiations for this union were dropped in favour of the establishment of a wider union, the European Economic Community (E.E.C.), which included France, Italy and the German Federal Republic in addition to the Benelux countries.

The European *Economic Community.*—This community, known as the European Common Market or sometimes abbreviated to "Euromart," was formed by a treaty signed in Rome on March 25, 1957, among six countries which had already been united in the European Coal and Steel Community. The treaty provided for the gradual abolition of tariffs and quotas among the six member states over a period of from 12 to 15 years. One year after the signing of the treaty the six countries were obliged to reduce their mutual tariffs uniformly by 10%, 18 months later by another 5%–10% and one year after that by another 5%–10%, so that by the end of the first phase their tariffs were to be reduced by 25%. The complete removal of trade barriers was to be accomplished during a second and third period. At the same time a common tariff was to be worked out which would be equal to the average of tariff rates as they existed before the treaty. However, in 1959 negotiations carried on among the countries tended to lead to a reduction in tariffs on 70% of their trade items, an increase on 15% and unchanged rates on another 15%. The treaty of 1957 provided! in addition, for setting up a bank designed to finance investment schemes, expenses due to reconversion needs and basic industrial developments in the less developed areas of the community. A special fund of close to $600,000,000 was also to be made available during the first five years of the union for development of the overseas territories of the member states.

The formation of the European Economic Community had an immediate and strong impact upon the other countries of western Europe. Negotiations were carried on with other countries, especially with Great Britain, relating to their accession to the community. But because of its desire to maintain a policy of imperial preference, Britain did not join, nor did certain other countries. The main objection of the other countries was the joint tariff of the E.E.C.

During 1958 and 1959 negotiations among the European countries continued. and during 1959 it became clear that Great Britain, the three Scandinavian countries: Switzerland and Austria would join a common market area. Finally on May 4, 1960, the European Free Trade association (E.F.T.A.) was formed by a treaty signed by seven countries—Austria, Denmark, Norway, Portugal, Sweden, Switzerland and the United Kingdom. The purpose of the E.F.T.A. (often called "the seven" to distinguish it from "the six," or E.E.C.) was to move gradually toward free trade among its members and to reduce trade harriers to other countries in step with the E.E.C. while maintaining such preferences as those enjoyed by the members of the British commonwealth.

During 1960 the two unions extended various concessions to one another. Five nations—Greece, Iceland, Ireland, Turkey and Spain—belonged neither to E.E.C. nor E.F.T.A., though they were members of the Organization for European Economic Cooperation (*q.v.*) and expressed interest in joining one or the other of the European trading groups. Greece's application to join the E.E.C. as an associate member was approved in 1961, and Finland became an associate member of E.F.T.A. in the same year.

The idea of a common market was taken up with alacrity in other parts of the world. After 1957 talks on the formation of a common market in Asia and Africa went forward. In Latin America a treaty establishing a free-trade zone among Argentina, Brazil, Chile, Mexico, Paraguay, Peru and Uruguay was signed in Feb. 1960. None of these organizations, however, was a genuine customs union such as the German Zollverein.

Economic Aspects of Economic **Unions.**—The main advantage that the participating countries expect to derive from an economic union is an improvement of the level of income. The greatest benefits are derived if the countries forming the union have complementary production patterns, *i.e.,* if one group of countries is predominantly agricultural and another predominantly industrial or if their resources supplement one another in other ways. An economic union produces an increase in internal trade and in time a higher degree of specialization, and hence brings cheaper costs of production in the various parts of the union. But an economic union surrounding all its members with a common tariff wall does not necessarily lead to optimum specialization of production on a world scale, and some members of the union—especially those with low tariffs before the formation of the union—may be worse off with respect to certain goods. In general, the larger the number of countries in a common market the greater the benefits, and it may sometimes be preferable to have a partial lowering of tariffs among many countries rather than a complete removal among a few and the maintenance of high tariffs against nonparticipating countries.

Political Aspects.—The main political problems associated with the formation of economic unions concern the obligations which participating countries may have toward third countries under most-favoured-nation agreements (see MOST-FAVOURED-NATION TREATMENT). Political problems also concern the question of whether the formation of an economic union is a step toward closer political unification.

Countries forming an economic or customs union do not have to extend to third countries the benefits they extend to each other. This principle is based in part on the customary exception in commercial treaties of customs unions from most-favoured-nations obligations. But the point has been contested in cases in which tariffs were not removed completely between participating countries. In the case of the formation of the European Common Market the claim was made by the U.S.S.R. that under its most-favoured-nation rights the participating countries should grant the same reductions to Soviet goods as they did to the commodities of the members of the union. This claim was rejected but, as noted above, political pressure by the U.S.S.R. on Finland was strong enough to induce that country to refrain from joining the E.F.T.A.

More important than the most-favoured-nation claim is the expectation that an economic union may lead eventually to political unification. This issue was prominent, for example, in the proposed customs union between Germany and Austria of 1931, which was seen by some as a first step to political unification. The same issue played an important role in the formation of the E.E.C. U.S. support for this form of economic integration of the major countries of the European continent was motivated largely by the expectation that it would lead to greater political unity, and the reluctance of the Scandinavian countries to join the common market may partly be explained by their close economic relations with Britain and partly by their fear that they might lose more political autonomy than they were willing to give up.

Finally, economic unions tend to create new supranational political and administrative agencies. Even in a simple customs union a supranational body to supervise the collection and imposition of joint tariffs must be created. In the Zollverein this task mas assigned to the *Zollparlament,* which may be regarded as the

forerunner of an all-German parliamentary body. In the E.E.C. five supranational institutions were formed: (1) the assembly. which forms the parliament of the union; (2) the council, which is the main decision-making organ; (3) the committee. which administers the treaty; (4) the court of justice. which performs judicial functions; and (5) the economic and social committee. which is charged mainly with research and advisory functions. As can be seen. the general administrative framework of the union is modeled on the organization of the United Nations. *See* also PAN-EUROPEAN MOVEMENT.

Strauss, *Common Sense About the Common Market* (1958); Political and Economic Planning, *European Organisations* (1959). (B. F. H).

ECONOMIC WARFARE. This term has been variously defined—by some on the basis of the measures employed, by others on the basis of the objectives sought. In both Great Britain and the United States it was used originally to refer to all measures—diplomatic; military, economic—taken to impair an enemy's support of his war effort. In the United States, the Industrial College of the Armed Forces in 1956 sought a definition that would result in a manageable administrative task for the agency to be assigned responsibility for waging economic warfare; the proposal was that economic warfare be defined as "the use of economic measures for attack on economic targets." Such a definition, it was explained, would not preclude the economic warfare agency from working closely with the diplomatic. military and psychological warfare agencies in planning other kinds of attack on economic targets. In strategic bombing, for example, the economic warfare agency would establish the desired priority of targets in the light of economic warfare strategy, but actual operations would be entirely the responsibility of the military. If economic mobilization. *i.e.*, a nation's mobilization of its resources for war, may be considered as one side of the coin, the reverse side would be economic warfare; *i.e.*, disruption of the enemy's economic mobilization. (See also MOBILIZATION, ECONOMIC.)

The term first came into common use in Great Britain during the years immediately preceding World War II. It reflected an evolution from the earlier concepts of blockade (*q.v.*) and interception of contraband (*q.v.*) in light of the radical changes brought about by aerial and submarine warfare. In the 1930s the British government laid plans for creating a new department, the ministry of economic warfare, to take the place of its World War I ministry of blockade. Instead of limiting itself to the traditional practice of blockading enemy ports and intercepting ships on the high seas. the new ministry. according to plan, would seek to control enemy trade at the source and thus shift the focus of control "from the seas to the quays." The aim of the proposed ministry. as stated in the plans. was "so to disorganize the enemy's economy as to prevent him from carrying on the war."

The essentially military character of economic warfare has been recognized both in England and in the United States. The British doctrine. as cited by W. N. Medlicott in *The Economic Blockade*, was as follows (by permission of Her Britannic Majesty's Stationery Office):

Economic warfare is a military operation, comparable to the operations of the three services in that its object is the defeat of the enemy, and complementary to them in that its function is to deprive the enemy of the material means of resistance. But, unlike the operations of the Armed Forces, its results are secured not only by direct attack upon the enemy but also by bringing pressure to bear upon those neutral countries from which the enemy draws his supplies. It must be distinguished from coercive measures appropriate for adoption in peace to settle international differences without recourse to war, *e.g.* sanctions, pacific blockade, economic reprisals, etc., since unlike such measures, it has as its ultimate sanction the use of belligerent rights.

In the United States: Pres. Franklin D. Roosevelt, in implementing the act of July 2. 1940, authorizing the control of exports, declared the administration of the act to be essentially a military function and issued a military order, in his capacity as commander in chief, instead of the usual executive order.

Economic warfare measures include export and import controls. trade agreements with neutral nations, shipping controls (navicerts. ship navicerts and ship warrants), black-listing. pre-emption (or preclusive buying). financial measures, the blocking of enemy exports. prevention of smuggling and other measures.

Export and Import Controls.— Export control is usually the first measure of economic warfare or economic sanctions to be taken by a nation at war or when war is imminent. The control may be employed to prohibit or regulate the export of commodities to destinations from which they or similar goods may reach the enemy: to prevent the accumulation of war materials by potential enemies: to bring pressure to bear on neutral nations: and to implement war trade agreements. The licensing of exports may also be used for purposes other than economic warfare; *e.g.*, the conservation of needed materials. Export controls were applied in Great Britain at the outbreak of war in 1939. and had been in effect to a limited extent before that time. After the fall of France and the Low Countries in 1940. when the enemy shore line was vastly extended and British naval forces were spread thin, effective physical blockade and naval interception became impractical. The British. seeking to control the flow of goods at the source. appealed to the United States to adopt export controls. By the act of July 2. 1940, congress authorized the president to prohibit or curtail the export of munitions. military equipment and related machinery and supplies whenever he determined that such action was necessary in the interests of national defense. While at first the emphasis was on conservation of materials for defense needs, the policy also was influenced by economic warfare considerations; *i.e.*, denial of critical materials to the Nazis.

Import controls have a much more limited use in economic warfare. Their primary purpose is to conserve shipping space and foreign exchange. but they may also be used in economic warfare to bring pressure to bear on neutrals. In a "cold war" they may be employed to deny a prospective enemy the opportunity to earn foreign exchange.

War Trade Agreements.— In war. neutral countries are a coveted source of. or channel for, the supply of critically needed materials. and thus become important battlegrounds of economic warfare. From the beginning of World War II Great Britain sought to arrange trade agreements with various neutrals and during the war conducted negotiations with Norway. Sweden. Denmark. Iceland. Belgium. the Netherlands. Switzerland, Hungary, Greece. Italy. Spain. Portugal and the Soviet Union. The efforts met with varying degrees of success. Even where agreements were consummated. there was almost continuous negotiation throughout the war concerning proposals for amendments. protests for alleged violations. and the details of supply-purchase agreements supplementing the trade agreements. The degree of neutrality varied from country to country and from time to time, according to the progress of the war and the position of the neutrals in relation to the belligerents. The United States on its entry into the war became a party to certain of the agreements and negotiated new agreements with the Latin-American countries in an extensive, preclusive buying campaign.

Shipping Controls.— The principal instruments for control of shipping were the navicert. the ship navicert and the ship warrant. Collectively they were referred to as the "paper blockade." but the term was not applied in any derogation of their power or effectiveness. The system of licensing automobile drivers furnishes an analogy. It would be physically impossible in modern highway traffic to stop every vehicle to inspect the driver's licence. Yet the fact that a driver may be stopped. and that the penalties for violation are severe. is an effective deterrent to unlicensed driving. So in modern commerce it is impractical to intercept all shipping on the high seas to determine whether or not the cargo has been licensed or navicerted. But the fact that a vessel might be intercepted. and that the naval forces were able to concentrate on vessels known or suspected to be carrying unnavicerted cargo, facilitated the enforcement. Thus the mere threat of interception was a strong deterrent to unnavicerted shipping. and the extent and effectiveness of the controls were far greater than could have been achieved by naval power alone. The navicert. an abbreviation for "navy certificate." was devised by the U.S. consul general in London in World War I to facilitate the passage of U.S. shipments through the British blockade. In effect. the ship navicert was a

form of commercial passport covering all or part of a ship's cargo. In World War II navicerts were made compulsory in July 1940, thus in effect making all unnavicerted cargo contraband and subject to seizure. Similar documents — the mailcert and the aircert —were designed for shipments by mail and air.

A ship navicert permitted a vessel to make a single voyage through naval controls. It was issued when all the items on the vessel's manifest had been approved. It required a description of the ship and its proposed itinerary. approval of its cargo. passenger list and crew, and an agreement for the examination of mail. A ship warrant entitled a vessel to use Allied and Allied-controlled facilities for bunkering, ships' stores. repairs, insurance and other services. It was issued only after the owner or master had agreed to certain terms, including an agreement that no ship owned or controlled by him would sail to or from the navicert area without a ship navicert. The compulsory navicert, restrictions on insurance and port facilities and rationing of adjacent neutrals were interrelated and mutually supporting economic warfare measures.

Business Controls. — Black-listing was a powerful weapon of economic warfare directed against individuals. In Great Britain the black list was known as the "Statutory List" and in the United States as the "Proclaimed List of Certain Blocked Nationals." In Great Britain and also in the United States after Pearl Harbor. the persons on these lists were regarded as enemy nationals and thus became "untouchables." No .Allied national could trade with them; if they or their property came within Allied control, they were subject to seizure. There was also the threat of postwar reprisal. Not only was the actual black-listing effective but the fear of it was a deterrent. Originally the British list consisted chiefly of enemy nationals located in the neutral countries of Europe. and the U.S. list, those in the Latin-.American countries. After the United States entered the war the tn-o lists were closely co-ordinated. At one time there were over 15,000 names on the two lists. The number had declined to approximately one-third that figure when the lists were abolished in 1946.

Pre-emption (or preclusive buying, as it is designated in the United States) is a method of acquiring supplies in neutral areas to prevent their acquisition by the enemy. In general, it is a useful instrument of economic warfare only in cases where the supply of the item is limited or where there is an agreement to limit production or prohibit or curtail exports to the enemy. In the absence of such an agreement. attempted pre-emption may defeat its purpose by stimulating further production.

Financial measures may be used in economic warfare to interfere with the enemy's foreign trade, to prevent the building up of the enemy's external assets, to seize such assets as exist or to immobilize them by preventing their transfer. and to bring financial pressure on neutral nations and their nationals. These objectives may be accomplished by foreign exchange controls, transactions controls and the export and import licensing of gold, silver and currency. But the detection of disguised transactions and accounts in neutral banks and trading firms is often difficult if not impossible.

The first financial control measure taken by the United States in World War II was the freezing of all Danish and Norwegian assets in the United States on April 10, 1940. All Dutch. Belgian and Luxembourg assets were frozen on May 10, and French assets were impounded on June 17, following the invasion of those countries. The primary purpose was to protect the property of their citizens. On June 14, 1941, all German and Italian assets in the United States were frozen. and in July Japanese assets were frozen by both the United States and Great Britain. These measures and the publication of the Proclaimed List marked the final commitment of the Cnited States in the economic warfare which had begun a year earlier with the passage of the Export Control act. The economic battle line was thus drawn between continents and the means of more effective control at the source had been achieved.

Prevention of Enemy Exports. — The primary purpose of preventing exports by the enemy is to deny him foreign exchange to finance his agents abroad. This goal was achieved in part in World War II by paper controls, hacked by naval interception. Certificates of origin and interest were required for all exports by the European neutrals. These certificates nere issued by the Allied blockade authorities only on evidence that neither the item nor any substantial part of it was of enemy origin and that no enemy national nas interested directly or indirectly in the transaction.

Prevention of Smuggling. — The foregoing measures were designed primarily to control the movement of bulk cargo and the regular mails. There were, however, many less bulky but highly strategic commodities, such as industrial diamonds, platinum, quartz crystals and certain drugs. which lent themselves to smuggling operations The fantastic prices prevailing in the black markets of the European neutrals for these commodities made this a lucrative business. The possibilities seemed limitless with the obscure and devious channels and devices that were employed. The countermeasures applied by the Allies with partial success included the use of undercover operatives, diligent search and preemption.

Strategy and Tactics. — Of the foregoing measures, control of exports, war trade agreements and pre-emption were used in an effort to stop the enemy's supplies at the source; black-listing and financial controls to hinder the trading for supplies; the navicert and the ship warrant to prevent their transport; and, finally, interception of unnavicerted ships and apprehension of smugglers to prevent penetration of the blockade. The sum of these measures formed the economic warfare strategy of World War II. Tactically they were applied in planned campaigns against particular areas, commodities or firms and individuals. Simple in concept. they were tremendously complicated in execution. Their adoption even belatedly was a significant contribution to victory.

Organization. — In Great Britain during World War I an attempt was made to carry out the blockade by interdepartmental co-ordination, but this failed completely and resulted in the establishment of the ministry of blockade to which the relevant departments of the foreign office were transferred. As a result of the planning in the critical years preceding World War II, a subcommittee of the committee of imperial deiense in 1938 proposed the plan for a ministry of economic warfare, that name having been adopted as more expressive of the broader concept of the measures designed to restrict the enemy's support of his war effort. The ministry came into being at the outbreak of war and functioned effectively throughout.

U.S. participation in the blockade in World War I was centred in the War Trade board. which in 1917 rapidly developed an effective organization, collaborating with the ministry of blockade in the Allied Blockade committee. In World War II economic warfare planning was begun in a small unit in the Army Industrial college (later the Industrial College of the Armed Forcesj in 1940. When the Export Control administration was established, the economic warfare unit was transferred to that agency. The Export Control administration later was transferred to the Economic Defense board, which became the Board of Economic Warfare, later the Office of Economic Warfare, and finally was merged with the Foreign Economic administration. None of these successive agencies. however, was devoted entirely to economic warfare, nor were all economic warfare activities delegated to one agency. In both the Cnited States and Great Britain, economic warfare activities and the responsible personnel were about equally divided between intelligence and operations, and these two functions were closely integrated.

Economic Defense. — This term usually is applied to measures taken in peacetime to limit the war-making potential of a possible enemy or aggressor nation. The effectiveness of such measures depends on collective action by the international community. Collective economic sanctions were hopefully envisioned by the League of Nations after World War I as a preventive of war, but they were applied only falteringly and belatedly in the Italian invasion of Ethiopia and not at all in the Japanese invasion of Manchuria. Germany and Japan were practically unhampered in their preparation for World War II and continued to receive strategic materials from the western hemisphere through the greater part of 1941. In the Korean War the United Nations resolution of May 18, 1951. called for embargoes on shipment of certain categories of strategic materials to Communist China and North

Korea. The resolution met with varying degrees of compliance which fell far short of economic blockade. As part of its "cold war" strategy the Cnited States in 1948 adopted strict controls on exports to the Soviet bloc and in 1950, after the outbreak of hostilities in Korea, imposed a strict embargo on goods and services to Communist China. In 1950 a number of the western nations. acting through an informal co-ordinatinp committee at Paris, adopted controls on the export of certain strategic materials to the Soviet bloc. The restriction of trade between the Soviet bloc and the free world. however. was a highly controversial issue. and the list of controlled materials was shortened in 1954 and from time to time in the years that followed.

ÉCOSSAISE, a dance in quick 2/4 time, similar to a *contre-danse* and first known in France in the early 18th century where its popularity rivaled that of the *anglaise* and the minuet. The Scottish origin of the French *écossaise* is unproved, though Scottish tunes are believed to have accompanied the dancing of *écossaises* in England toward the end of the 18th century. In the early 19th century the *écossaise* flourished in Germany where it was succeeded by the *schottische,* a round dance which had an affinity with the polka. The vogue of the *kcossaise* inspired compositions for piano bearing this name by Schubert and Chopin, and by Beethoven. who also wrote *écossaises* for military band and small orchestra.

ECTON, a small village in Northamptonshire, Eng., lies off the main road from Northampton to Wellingborough. Pop. (1962 est.) 443. It is famous as the birthplace of Benjamin Franklin's father. Josiah. a soap and candle maker by trade, who emigrated to Boston, Mass . in 1683. The family, which had lived for several centuries in the village, owned a small freehold and were also the village blacksmiths. In 1758 Franklin visited Ecton, saw the family house (no longer standing) and inspected the tombstones of his uncle and aunt, Thomas and Eleanor Franklin, which are still in the churchyard.

William Hogarth, the painter, often stayed at the beautiful rectory (rebuilt in 1693). In the church (13th century, with 14th-century tower) is a monument with a bust by J. M. Rysbrack to John Palmer, archdeacon of Northampton. rector from 1641 to 1679. The hall has associations with Thomas Percy. editor of the *Reliques of Ancient English Poetry,* the manuscript of which was formerly preserved there. In the village Henry Bagley, who cast the bells in many local churches, had a foundry from 1687 to 1703. (P. I. K.)

ECUADOR (officially LA REPÚBLICA DEL ECUADOR), next to Uruguay the smallest independent state in South America. is bounded on the west by the Pacific ocean, on the north by Colombia and on the east and south by Peru. The country derives its name from the fact that the equator passes through it. Until 1830 the name of the region in which the present nation is located was Quito, named after an Indian group that occupied a part of the highlands. Geographically Ecuador is a region of great contrast. It has semidesert lands and steaming tropical jungles. low-lying coastal belts and Amazonian plains separated by mighty ranges of the Andes which provide a galaxy of snow-capped peaks within a few miles of the equator. The economy of the republic is overwhelmingly agricultural, and farm and forest products constitute its principal exports. The inhabitants are largely of American Indian and Indian-European (mestizo or cholo) extraction. A majority of this group lives at subsistence or below subsistence level as farmers, farm hands. servants and day labourers in the cities. Next to Paraguay. Ecuador in the early 1960s had the lowest per capita income of any state in South America. A large share of the cultivated lands and urban properties are controlled by those of European backgrounds who represent only a small percentage of the total population. Ecuador traditionally has been one of the strongholds of the Roman Catholic Church in Latin America. The political history of the republic has been marked by turmoil and tyranny punctuated by periods of able and statesmanlike leadership. (J. J. J.)

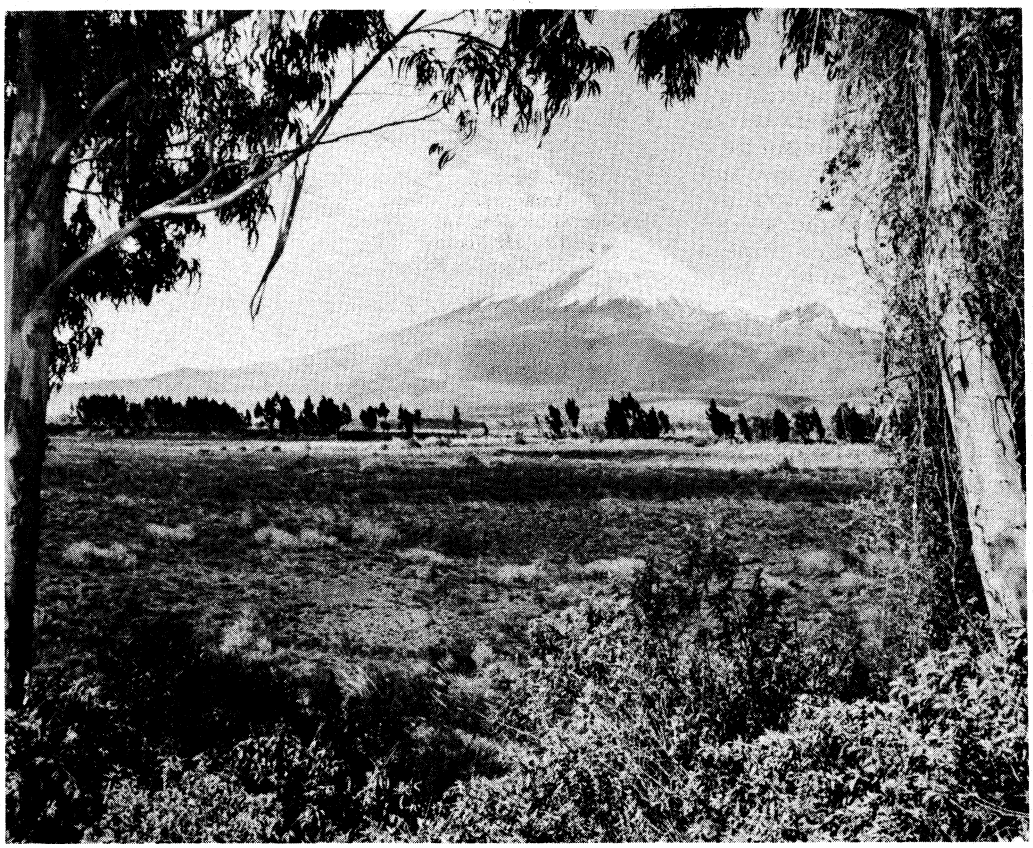
Following are the main divisions of this article:

I. PHYSICAL GEOGRAPHY

1. **Geology and** *Structure.— Sierra Region.—The* dominating physical feature of Ecuador is the great range of the Andes that runs north and south across the country from the border of Colombia to the border of Peru. The uplands of the Andes form the Sierra or highland region. and present a formidable barrier to east-west movement. The Andes are composed of two distinct cordilleras, joined in several places by ridges or spurs which separate some 10 intermontane basins. The Eastern Cordillera is made up of gneiss, mica schist and other crystalline rocks, similar to the geological formations underlying the Cordillera Central of Colombia. The Western Cordillera, on the other hand, is made up of porphyritic eruptive rocks of Mesozoic Age, and some Mesozoic sedimentary strata chiefly Cretaceous.

In the Andes of Ecuador there is one of the world's chief concentrations of volcanic activity. The highest peak in the country is Mt. Chimborazo, an inactive, cone-shaped volcano that stands boldly above the Western Cordillera southwest of Xmbato. Its peak is 20,702 ft. above sea level. Between Mt. Sangay (17,464 ft) in the Eastern Cordillera and the northern border of Ecuador there are about 20 active volcanoes. The world's highest active volcano is Mt. Cotopaxi (19,498 ft.), in the Eastern Cordillera about midway between Ambato and Quito. Other well-known volcanic peaks include Antisana, Cayambe, Tungurahua and Pichincha. All these volcanoes are acidic, explosive and cone-shaped. Earthquakes occur frequently, and sometimes with great violence, such as the one that completely destroyed Ambato in 1949.

Between the two cordilleras there is a string of intermontane basins. Those that lie north of latitude 2° S. are deeply filled with volcanic ash, blown from the volcanoes and carried by the prevailing wind westward into the basins. The ash fill is recent in origin. and in a few places contains plant fossils. These basins are quite complex in surface form. In the northernmost basins there is a terracelike rim of higher surface around the margin, with a lower inner basin excavated by river action. In the basin of Ibarra, for example. the terrace remnants stand between 7,000 and 8,000 ft. above sea level. The town of Ibarra and numerous



A SHELL PHOTOGRAPH

other small villages stand on this terrace. Far below, at an altitude of only about 2.500 ft.. is the flat valley bottom along the Rio Chota, a tributary of the Rio Mira A similar situation exists in the Quito basin. Quito itself is built on the lower slopes of the volcano Pichincha and on a terrace remnant of volcanic ash standing about 9.300 ft. above sea level. At the eastern edge of the city of Quito the terrace ends with an abrupt scarp which drops to the floor of the basin, about 7,500 ft. above sea level. The lower part of the basin has a level floor across which the headwater tributary of the Rio Guaillabamba winds. This river, like the Rio Mira farther north, passes through the Western Cordillera in a deep gorge and crosses the western lowlands to the Pacific.

Just south of the Quito basin there is a ridge of high country that connects the two cordilleras. South of that is the basin of Latacunga, drained by the headwaters of the Rio Pastaza which runs eastward to join the Marañón. In this deeply dissected basin are the towns of Latacunga and Ambato. To the south this basin is cut off by the massive pedestal of Mt. Chimborazo from the basin of Riobamba, which is also drained by one of the headwaters of the Rio Pastaza. South of this the basin of Alausi is formed along one of the west-flowing tributaries of the Rio Naranjal. The large basin of Cuenca is drained by the headwaters of the Rio Saptiago. a tributary of the Marañón. Still farther south are the small river basins of Oña, Loja and Zaruma. The basin of Alausi, and the others farther south, are not filled with volcanic ash.

There are no low passes over the Andes in Ecuador north of latitude 4° S. In southern Ecuador and northern Peru the Andes are deeply dissected by the Rio Marañón and its tributaries. and there passes as low as 7,000 ft. exist, but they are not used.

Coastal Region.—The coastal region is made up of a mixture of low crystalline hills. with a maximum elevation of 2,500 ft. west of Guayaquil, swampy alluvium along the river flood plains, and huge alluvial fans along the western Andean piedmont. The crystalline hills are low and rounded in form. The alluvial fans. in many cases made up of porous volcanic ash eroded from the high-land basins. spread out from the major river mouths, especially those rivers that have cut back into the intermontane basins. At Guayaquil the drainage of the low country through the Rio Guayas is collected in a single channel, confined on the west by a spur of the crystalline hills, and on the east by the huge fan built by the Rio Naranjal and the Rio Chimbo. Upstream the lowland widens and is drained by four tributaries of the Guayas that meander through a maze of oxbow lakes and natural levees. West of Quito the little frontier town of Santo Domingo de los Colorados stands almost at the apex of the alluvial fan built by a tributary of the Rio Esmeraldas. The elevation of the fan where it emerges from the mountains is nearly 2,000 ft. above sea level. North of Esmeraldas the coastal region is low and swampy. similar to that of southwest Colombia. In the south the coastal region is embayed by the Gulf of Guayaquil.

Oriente.—The third major physical division of Ecuador is the Oriente, the part that lies east of the Andes. The boundary of Ecuador and Peru was drawn about 50 mi. above the head of launch navigation on the Amazon tributaries. The Oriente, therefore, is a little-known area, difficult of access from either west or east. Compared with the country farther east in Peru. this Andean piedmont is somewhat higher in elevation Along the eastern base of the mountains there is a zone of upended strata forming cuestas (steep ridges facing the Andes), and in the midst of the dense forest east of the cuesta belt there are isolated mesas.

2. Climate.— The climate of the highlands varies with the elevation and with the exposure to rain-bearing winds Because of the mountainous terrain there are sharp climatic contrasts between nearby areas. For example. although most of the highlands receive abundant rainfall, immediately to the north of Quito there is a dry area that is not reached by the rain-bearing winds. On the trip that tourists often take to the equatorial line, the road out of the city enters the dry area abruptly and the monument on the equator is in the midst of arid country.

The vertical zones of climate are similar to those of Colombia. From sea level to about 3,000 ft. is the tierra *caliente,* with temperatures averaging between 75° and 78° F. and with a range of only 3° or 4" between coldest and warmest month. From 3.000 to about 6,500 ft. is the tierra templada, with temperatures averaging between 65° and 75°, and with a range of only 2° or 3°. Between 6.500 and about 10,000 ft. is the tierra *fria,* with temperatures averaging between 55° and 65°, and with a temperature range of less than 1°. Still higher are the paramos (high, bleak plateaus) with temperatures averaging under 55°. The lower limit of permanent snow is about 14,500 ft. above sea level. The very slight differences of temperature throughout the year are characteristic of tropical high-altitude climates. The differences between day and night, or between sunshine and shade, are much greater.

In the coastal lowland of Ecuador there is a zone of transition from the wet north to the dry south. From the town of Esmeraldas northward the climate is rainy, warm and humid throughout the year. There are two rainy seasons separated by two seasons of someuhat less rain. There are never any heavy ninds or storms. South of Esmeraldas there is one rainy season (January to May),

and one really dry season the length of which increases as one proceeds southward At the tip end of the Santa Elena peninsula, west of Guayaquil. the climate is arid; and this arid condition is found east of the Gulf of Guayaquil in southern Ecuador.

The Oriente has a climate typical of the equatorial Amazon basin. Its temperatures are not excessively high—never over 100°; nor are they ever low. The rainfall of this area, however, exceeds 80 in. and humidity is always high.

3. Vegetation.—The vegetation of Ecuador reflects the climatic differences among the regions. The wet lowlands of the Oriente, and of the Guayas lowland and the coastal area north of Esmeraldas, are covered with a tropical rain forest containing many different species of trees, some of great size, and many epiphytes and lianas. At higher levels the forest becomes thicker in the zone of maximum rainfall—about 4,000 to 5,000 ft. above sea level. Here there is a montane rain forest that is very difficult to penetrate. Still higher is the *ceja* de la *montaña,* or eyebrow of the forest. a moss-covered thick growth of woodland similar to the vegetation described elsewhere in the tropics as an "elfin forest." Above the upper limit of trees—between 10,000 and 11.000 ft.—there are tall mountain grasslands that extend up to the snow line There are parts of the intermontane basins where the ash fill is so porous that the grasslands or brushlands extend much farther down than is generally the case. For example, in the basin of Latacunga at an elevation of only a little over 8,000 ft. the original vegetation cover was a scrub woodland. In the dry area north of Quito there is drought-resistant vegetation with bare ground betneen the plants.

4s one goes southward along the Pacific coast from Esmeraldas the rain forest gives way to deciduous scrub woodland that drops all of its leaves during the dry season. Between Esmeraldas and Manta there is a narrow zone of tropical semideciduous forest in which some of the trees drop their leaves during the dry season. There is a fringe of thick mangrove forest all along the Pacific ocean wherever there is a swampy coast, especially around the Gulf of Guayaquil and the islands in the mouth of the Guayas river. Swamp forest is also found on the flood plains of the rivers. In the forests of Ecuador there are a number of species of plants that are of economic value, and some are actually exploited. In the Guayas valley and on the lower Andean slopes there is the balsa tree *(Ochroma lagopus).* which furnishes the world's lightest lumber. In the scrub woodland of the coastal region there are scattered palms that produce ivory nuts (*phytelephas macrocarpa*) used in the manufacture of buttons. There is also the plant *(Carludovica palmata)* that furnishes fibre for the manufacture of Panama hats. This plant is not a palm, although it is often described as such in popular terminology. On the rainy eastern slopes of the Andes the forests contain cinchona trees, formerly of great value as a source of quinine. The cinchona belongs to the family Rubiaceae, closely related to the coffee tree and to the tree that produces ipecac. It is native to the eastern Andean slopes of this part of South America. Several species of trees in the rain forests east of the Andes were once used for the production of rubber. These forests include a great variety of useful species, but the forests of Ecuador have not been exploited much because of their isolation.

4. Animal Life.—The fauna of Ecuador is closely related to the vegetation cover. In the tropical rain forests there are relatively few mammals but a wide range of species. There are, for example, numerous species of monkeys. The flesh-eating animals include the jaguar, puma, ocelot, fox, weasel, tayra, otter, skunk, grison, raccoon, coatimundi and kinkajou. The hoofed mammals include the tapir, deer and peccary. There are numerous rodents and a variety of bats, including some vampire hats.

Ecuador is rich in the variety of its bird life. About 1,500 species have been identified. The bird population varies with altitude. and in the lowlands is distinctive in the rain forests, the scrub woodlands and the dry areas. Also, Ecuador is the winter home of a number of well-known North American species of birds. Among them are the Carolina rail. the blue-winged teal, the kingbird. the barn swallow. the red-eyed vireo. the redstart, the rose-breasted grosbeak, and the scarlet tanager.

The fishes and reptiles of Ecuador include a great variety of species. The fishes are similar to those of the Amazon region, but the Pacific side lacks such species as the electric eel and the piranha. All the major groups of reptiles have been found, including a variety of dangerous snakes. Two species of large marine turtles are hunted. one for meat and the other for tortoise shell. Lizards are abundant and variable.

Ecuador also ahounds with insects. There are many kinds of butterflies. moths, beetles, grasshoppers, bees and ants. There is one species of giant beetle that grows to a length of five inches; and there are many beetles that are interesting because of the phosphorescent light they emit. Many species of insects in Ecuador harass man, his crops and his domestic animals; they bite, sting, suck blood and carry disease.

The Galápagos Islands (*q.v.*) between 500 and 700 mi. W. of the coast of Ecuador, became famous when they were visited by the English naturalist Charles Darwin in the 1830s. The unusual native animals, including giant turtles, had never developed fear of man because the islands had been isolated throughout the course of history. Bathed by the cool Peru current, the islands have a cool temperature and limited rainfall. They contain a notable fauna quite unlike that of the mainland, and serve as a wildlife sanctuary.

II. GEOGRAPHIC REGIONS

Of Ecuador's three geographic regions the area of chief commercial production is the coastal area. It is occupied by people who take their politics seriously and includes Ecuador's chief city, Guayaquil. The Andean highlands, in the Sierra region, are occupied mostly by people of pure or nearly pure Indian ancestry who are little interested in commerce or politics. The highland population is grouped in about ten intermontane basins, each more or less isolated. It is in the midst of this high country that Ecuador has its capital, Quito. The third physical division of the country, the Oriente, is so thinly inhabited that it remains largely outside the effective national territory of Ecuador.

1. The Highlands.—The highland region is made up of a series of more or less separate clusters of people each located in and around the margins of one of the intermontane basins. These basins, described above, are between the two cordilleras of the Andes at elevations between 7,000 and over 9,000 ft. Outside of Quito and Cuenca. the second and third cities of Ecuador in terms of size, the population is predominantly Indian. In Quito and Cuenca are concentrated the relatively small proportion of people of pure or nearly pure Spanish ancestry. These people own large tracts of land in the high basins, usually the most productive parts of these basins. The pure-blooded Indians are concentrated on the poorer lands or work as tenants or as wage labourers on the large properties. The poorer lands that are left to the Indians are the more porous soils and the drier areas of the basins, and the steep slopes of the bordering mountains.

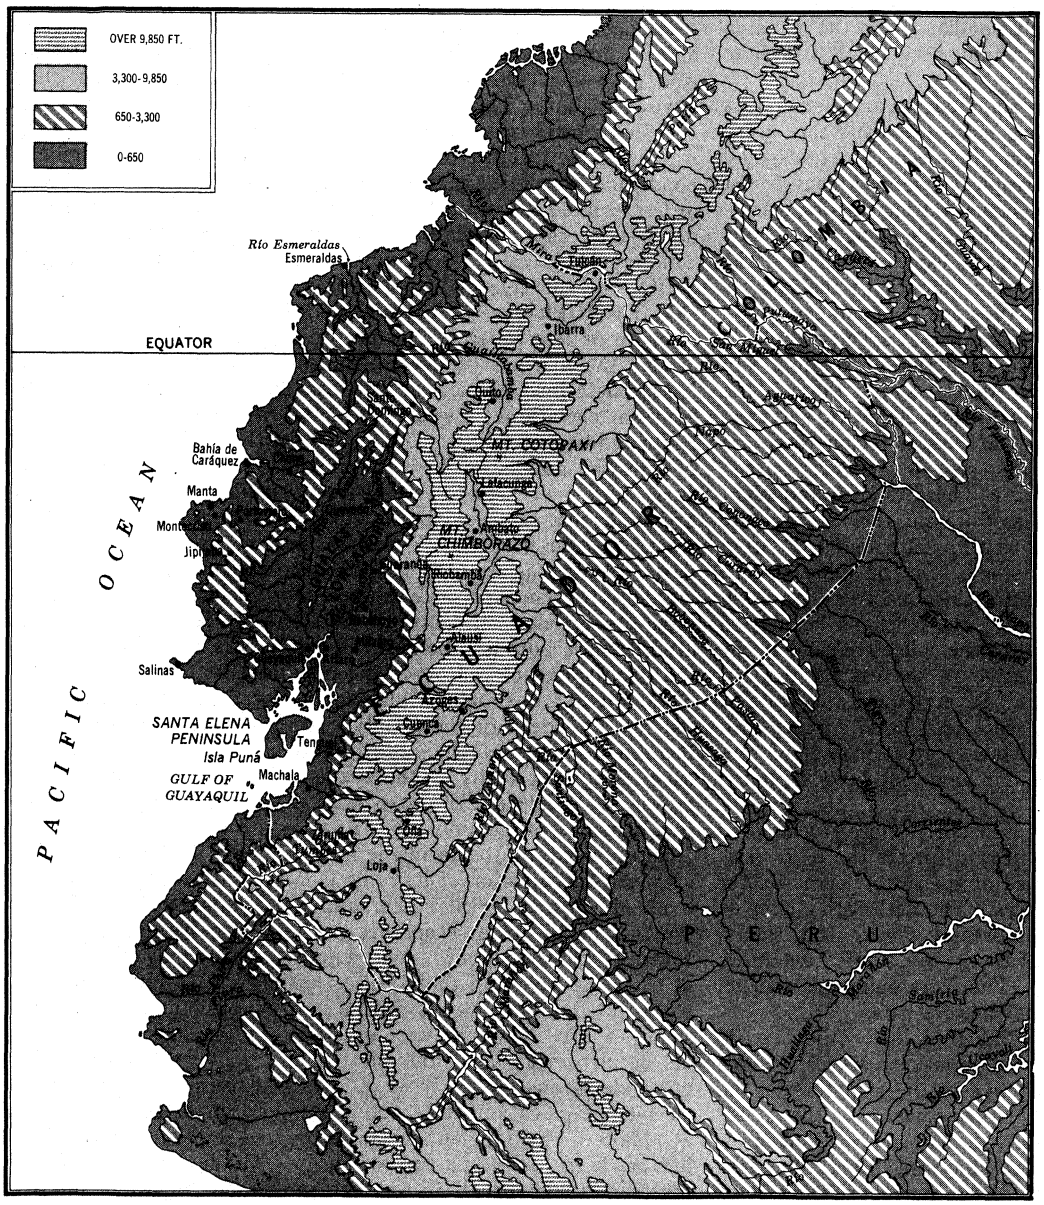
Land use throughout the highland region depends to a great extent on altitude. In the deeply cut valleys that lie well below the general level of the basins there are plantations of sugar cane. The best lands of the basins, however, are used for the growing of maize and the pasture of dairy cattle. This combination of maize production and dairy pasture is found all the way from the basin of Ibarra in the north to Loja in the south. The greatest concentration of dairying is in the basin of Quito and the basin of Cuenca. Still higher and on the poorer lands left to the Indians the chief crops are potatoes and barley, which the Indians use for their own food supply. So great is the pressure of people on the land that these crops are grown high above the basins on the steep slopes of the bordering mountains. On the slopes of Mt. Pichincha west of Quito, Indian subsistence farmers occupy every available bit of land above the Quito basin up to elevations of nearly 12,000 ft. Potatoes can be grown to an average elevation of 10,500 ft., and to an extreme elevation of 11,800 ft. Still higher, the grass-covered slopes below the snow line are used for the pasture of sheep. The high basins are tied together by a railroad, all-weather automobile highways and airplane service.

2. The Coastal Region.—The second of the two major regions into which Ecuador may be divided is the coastal region, which lies between the western base of the Andes and the Pacific ocean. Within this region there are two major subregions and two smaller subregions. The largest concentration of people, and the area in which most of Ecuador's export products originate, is in the lowland of the Guayas and along the eastern side of the Gulf of Guayaquil. This region centres on Ecuador's largest city, Guayaquil. The population of this area is predominantly mestizo. a mixture of Spanish and Indian. Production comes chiefly from large estates on which there are tenant farmers or on which workers are paid wages. The wet lowland upstream from Guayaquil, drained by the four tributaries of the Rio Guayas, has long been used for the production of cacao. In fact this is one of the best places in the world for the growth of the cacao tree. But long neglect of methods of cultivation and resulting high costs of production make it difficult for Ecuador to compete with the cacao areas of Africa and Brazil. This is still one of the cacao-producing areas of the world, but no longer a major one.

The crop that brought speculative prosperity to Ecuador after 1940 was the banana. Banana plantations invaded the cacao area and extended southward along the western piedmont of the Andes, east of the Gulf of Guayaquil. The United Fruit company established a large demonstration plantation in this area, near Tenguel, but most of the bananas are produced on small, independently owned plantations. No banana-loading facilities were built in Ecuador during the 1950s, for the stability of this product remained to be proved. Bananas are brought down the Rio Guayas in barges, and are loaded on the banana ships which lie at anchor in the quiet waters of the Gulf of Guayaquil. After 1940 there was a considerable increase in the land devoted to rice and to sugar cane in this same area. Bordering the agricultural lands there is a large area of grass pasture on which beef cattle are prepared for market—mostly for use in Ecuador, but some to be exported.

The second of the major subregions of the coastal region is between Manta and Chone on the Pacific ocean. The population of this area is almost pure Indian—but it is lowland and not highland Indian. A fairly dense population of farmers working their own small pieces of land occupies this subregion. There in the zone of transition between semideciduous forest and scrub woodland, the Indians have been able to compete successfully with Negroes migrating southward from Colombia. In the hilly country to the east there are small plantations of coffee. But the chief crop of this area is cotton. In the scrub woodland south of Manta much land is used for the grazing of goats.

The two smaller subregions are pioneer zones of new settlement: one is around Esmeraldas, the other inland at the base of the mountains around Santo Domingo de los Colorados. The latter place was opened up as an area of settlement when the road to Quito was completed in 1947. Bananas, the first crops to be produced there, were sold in the Quito market. More recently cacao, also sold only in Quito, has proved more profitable than the banana. The land is divided into medium-sized properties, and during the 1950s Indians from the highlands replaced Negroes as the hired workers.



SURFACE FEATURES AND MAJOR TOWNS OF ECUADOR. SOUTH AMERICA

Esmeraldas is the focus of another area of new settlement, but this one is almost exclusively Negro. In the tropical rain forests the Negroes have proved to be better subsistence farmers than the lowland Indians. Bananas have been planted all along the highway that connects Santo Domingo with Esmeraldas; but the product is sent by truck to Esmeraldas only from the plantations within less than 100-mi. of the coast. At the port the bananas are loaded on ships from lighters, while the ships lie at anchor in the open ocean. The Negro farmers have at times produced a little gold by washing the stream gravels inland from Esmeraldas.

The chief use of the land, however, throughout the coastal lowland is for the pasture of beef cattle. Even beyond reach of the all-weather roads, cattle can be driven to market on the hoof.

(P. E. J.)

III. THE PEOPLE

1. Historic Racial Elements.—The estimated 800,000 Indians living in Ecuador when the Span-

iards arrived were, like all other American Indians: members of the Mongoloid stock. The Spanish conquest saw the introduction of two new racial elements: the Caucasian Spaniards and Negroes who were brought in as slaves. Neither settled in Ecuador in large numbers. The non-Indians in the country are still a minority. The white population of Ecuador has been estimated at between 8% and 27%, with the lower figure probably being more nearly correct. The Spaniards and Negroes first settled on the coast, displacing many Indians who moved to the highlands. Unlike the Spaniards, the Negroes remained almost entirely on the coast. Those who escaped from slavery either formed small communities of their own or intermarried with the local Indian population. By mid-20th century the proportion of the coastal population having Negro blood was estimated to be as high as 45%. Besides pure-blood Negroes and mulattoes, there are also *montuvios,* who are persons of Negro-Indian ancestry. The Indians of the coast are much reduced in number and racially mixed. All have lost their tribal identity except for the Cayapa and Colorado, who together number no more than 2,000.

The composition of the highland population is estimated at 28% white, 30% pureblood Indian and 40% mestizo. Many so-called mestizos are probably pure Indians physically because the word mestizo is commonly used to refer to a person of mixed Indian and Hispanic culture, regardless of his race.

The Oriente is peopled almost exclusively by full-blooded Indians.

2. Languages. — Several families of languages were spoken in coastal and highland Ecuador before the arrival of the Incas. But, except for Chibchan. which was spoken by several tribes in the north, it has not been possible to identify any of these early languages with certainty. After the Inca conquest, Quechua, the language of the empire, was introduced and became well established. The Spaniards found Quechua useful for administrative purposes and promoted its spread at the expense of the surviving native languages. By the end of the 18th century Quechua was universally spoken in the highlands. While Spanish is the official language of modern Ecuador, Quechua is spoken by the greatest number of people.

Several indigenous languages survive in the Oriente, the three most important families represented being Jivaroan, Zaparoan and Tucanoan. Some tribes, such as the Canelo, Cofan and Auishiri, speak languages that have not been linked to any recognized families.

3. Cultures.—When the Spaniards arrived the most important peoples of Ecuador were the Esmeralda, Manta, Huancavilca and Puná on the coast, and the Cara, Panzaleo (Quito), Puruhá and Cafiari in the highlands. While most of these groups had been incorporated into the Inca empire they still maintained a measure of cultural identity. Politically they were organized into petty states and confederacies ruled by chiefs renowned for their military prowess. The chiefs owned much wealth and had many wives and retainers, some of whom were buried with them at their death. The basis of subsistence was intensive agriculture, which in some areas involved irrigation.

The principal crops were maize, quinoa, beans and potatoes. In the warmer valleys fruits such as pineapples and avocados mere grown and sweet manioc was raised on the coast. The women did most of the farming because the men were frequently occupied with war. When not fighting the men engaged in arts and crafts such as weaving, metallurgy and stone carving. They used spears, slings, clubs and axes of stone and copper in warfare. Houses had wooden frames daubed over with mud and roofed with thatch. The typical dress consisted of a long sleeveless shirt or wrap-around skirt with a blanket thrown over the shoulders.

Marriage was monogamous for commoners, but a noble or chief could have many wives and concubines. Class differences existed and were reflected in the fine raiment and jewelry worn by the upper classes. Religion was based on a belief in gods and spirits, many of whom were associated with volcanoes. Shamans and priests interceded with the deities on behalf of the people. Animal and human sacrifice was practiced on important occasions.

Trade flourished, especially along the coast where items of maritime commerce were carried in dugout canoes and in large rafts with sails. From the wild tribes of the Oriente the highland peoples obtained *achiote* (a red dye), parrots and monkeys; they gave blankets. salt and dogs in return.

Following the Inca conquest, oca, sweet potatoes and peanuts were added to the cultivated crops of Ecuador. The llama was raised more widely and its wool was used for weaving. The chewing of coca. previously absent, became prevalent. To facilitate civil administration the Incas built fortresses and extended their highway system as far north as Quito.

The Spanish conquest led to the final breakdown of the Ecuadorian chieftaincies, a process that had already begun under Inca domination. With the establishment of the *encomienda* system the exploitation of the Indians began. The Spaniards established haciendas in the lower and more fertile valleys and those Indians who were not forced to work these holdings retreated to less favourable farming areas in the highlands. By the 1960s the number of Indians who lived in native villages and engaged in subsistence farming was less than the number who made their living in whole or in part by working for white *hacenderos.* Some Indians and mestizos worked for wages on haciendas, but migrated seasonally, as from the highlands to the coast at rice harvest time. Others were tenant farmers who worked a *patrón's* land and were paid partly in money and partly in the crops they could grow on the small parcels of land allotted to them. In the highlands many Indians worked a certain number of days a week for the *patrón* in exchange for the rights to pasture their sheep on his land. or obtain water or firewood from it.

The tribes of the Oriente have cultural affinities with the Indians of the Amazon basin rather than with those of the Andes. The Incas made no attempt to conquer these tribes, and Spanish efforts to pacify them proved unsuccessful. Disease and the abuses of rubber gatherers and other exploiters reduced their number from 200.000 to about 80.000, but those that survived retained their political autonomy into the 20th century.

These tribes have many culture traits in common. All of them practice slash-and-burn agriculture, with sweet manioc as the staple crop. Hunting is carried out chiefly with spears. blowguns and traps. Fish are drugged with barbasco. Villages generally consist of a single communal house of pole-and-thatch construction. Nakedness is common. but some tribes wear garments of cotton or bark cloth. The hammock is in general use, but the Jivaro employ the platform bed. Watercraft consist of dugout canoes and balsa wood rafts. Warfare is declining but is still not uncommon, especially among the Jivaro and the Auishiri. The lance is the principal offensive weapon, and shields are sometimes used for defense. The commonest motivation for war is revenge, and the taking of trophy heads occurs among some tribes, notably the Jivaro.

The chewing of coca does not occur in the Oriente, but tobacco smoking is important, especially as an adjunct of shamanistic curing. The hollow log drum is employed by some tribes for communication.

Of the tribes of the Oriente the Jivaro are unquestionably the best known, principally because of their use of blowguns and poisoned darts and their custom of shrinking the heads of slain enemies. The Auishiri or "Auca," came into prominence in Jan. 1956 when they killed five American missionaries. (R. L. C.)

4. Religion. — Roman Catholicism is the traditional religion of Ecuador, having been established with the Spanish conquest. For a time after the middle of the 19th century the government was so closely tied to the church that only practising Roman Catholics were recognized as Ecuadorian citizens. Ecuador dedicated itself to the Sacred Heart of Jesus in 1873. both by church council and by act of congress. The importance of the church was shown in 1950, when a 17th-century devout Ecuadorian, Mariana de Jesus, was canonized as a saint. Further, in 1952, the first Ecuadorian cardinal was appointed by the Vatican.

Since the advent of the Liberals to power in 1895, church and state have been separate. Education has been secularized, though the church has been granted the right to conduct schools; church property has been confiscated; and freedom of religion is guar-

anteed by the constitution. Extremely friendly relations, however, continued to exist between church and state, and Roman Catholic religious orders have been particularly active in Ecuador. Quito. the seat of the archbishopric, has often been cited for its numerous churches. with their treasures of art and sculpture. Protestants first went to Ecuador after 1395, and they achieved some success in Guayaquil. Both Catholic and Protestant missionaries have been active among the Indians of Oriente.

IV. HISTORY

1. Pre-Spanish Era. — Before the advent of the Spaniards, the Ecuadorian highlands and adjacent lowlands mere occupied by aborigines of comparatively primitive cultures. They were located between the more highly developed Chibcha-speaking groups to the north in central Colombia and the Quechua-speaking groups to the south in highland Peru and Bolivia. The Ecuadorian highland basins were inhabited by six linguistic groups — the Pastos. Caras, Panzaleos, Puruhás, Cañaris and Paltas (from north to south in the order named). Their languages, now extinct, were mutually unintelligible; their customs and beliefs differed significantly. However, these groups shared a basic Andean culture in their adaptations to the highland environment. They were sedentary agriculturists, cultivating maize. beans, potatoes, squash and quinoa. a pigweed cereal. The only domesticated animals were dogs and guinea pigs. Among some of the peoples, handicraft was especially well developed in the making of gold and copper objects and pottery. (See also ANDEAN CIVILIZATION; SOUTH AMERICA: *Archaeology*.)

The prehistoric aborigines of the coastal region and of Oriente were more primitive than the highland peoples. The coastal inhabitants lived mostly by fishing and hunting and traded salt and fish with the highland tribes for cloth and gold and silver. The large island of Puná near the Guayas estuary mas inhabited by a particularly vigorous tribe. The islands of La Plata and Santa Clara, off the coast of Manabi, were considered sacred and were used as sites for burial of tribal chieftains. Except for the Cayapás and Colorados, who live in the upper reaches of the northwestern coastal rivers, the coastal aborigines disappeared or mixed thoroughly with white and Negro to form the *montuvio*. The tribes of Oriente, on the other hand, remained little changed by time, largely because of the effective isolation of the Amazonian region. Antagonistic to western civilization, they live by hunting and fishing and by tilling the soil in a primitive way. The Jivaros and Záparos have been particularly warlike.

By the first part of the 15th century the Caras had conquered the Quitus and had taken possession of northern Ecuador. The kingdom of the Shyri, the ruler of the Caras, was then extended southward to the middle part of the Sierra. This kingdom, along with the tribes to the south in highland Ecuador, was conquered by the Incas in the second half of the 15th century. The southern tribes were brought under control of the Inca empire by 1480, after long struggles, and the tribes farther north finally were subdued after several more years of bitter struggle.

Where resistance was especially strong, the Incas uprooted a great part of the population and replaced it with forced colonists from Peru or Bolivia; and these transplanted foreign groups served as centres of Inca influence among the native peoples. The Incas established the Quechua language and introduced new plants, llamas as beasts of burden, irrigation projects and a road system. (*See* INCA.)

The Inca Huayna Capac divided his empire, before his death in 1525, between his sons Atahualpa, the Shyri heir on his mother's side, and Huáscar, his son by an Inca princess. Atahualpa inherited the northern part of the empire, the so-called kingdom of Quito. and Huáscar received the Cuzco domain in Peru and Bolivia. In the war that ensued, Atahualpa was victorious over Huáscar, who claimed the entire empire. His victory, however, was short-lived. He was seized by newly arrived Spaniards and in 1533 was put to death by his captors. (D. R. D.)

2. Spanish Colonial Period. — Modern Ecuador was first sighted in 1526. In that year a ship outfitted on the isthmus by Francisco Pizarro and his partners and captained by the pilot Bartolomé Ruiz cruised along the coast to a point south of the equator. Ruiz discovered three large settlements of Indians, who received him in a friendly manner. The Indians possessed wealth in jewels and gold in large quantities. During the next several years the Spanish made a number of landings in Ecuador as the final preparations for the conquest of the Inca empire were carried out.

Pizarro landed his forces at the Bay of San Mateo in Ecuador early in 1532. It was from there that the Spaniards began their devastating march down the coast on the way to the heart of the Inca civilization.

The conquest of Ecuador fell to Sebastián de Benalcázar (Belalcázar), a lieutenant of Pizarro. Starting from San Miguel, rhe base founded by Pizarro in what is now northern Peru, Benalcázar moved north intc the highlands of Ecuador against limited Indian opposition. He founded the Villa de San Francisco de Quito in 1534 on the site of the Cara town left in ruins by the retreating Indians. Guayaquil was founded by Benalcázar's forces in 1535.

In 1539 Gonzalo Pizarro, brother of Francisco. was made governor of Quito, the name by which the territory was known. When the first viceroy to Peru, Blasco Núñez Vela, arrived in Ecuador on the way to Lima he found the colonists in revolt under Gonzalo Pizarro. The viceroy's forces were defeated by Gonzalo near Quito in 1546. Gonzalo was in turn defeated in 1548. Ecuador thereupon settled down to a peaceful existence. Land and Indians had been divided among the conquerors immediately following the conquest. Institutions were implanted in much the same fashion as in the remainder of the Spanish colonies of the new world. The conquerors initially acquired considerable wealth in jewels and gold. but within a short time the colony began an essentially agricultural existence based on large estates and Indian labour. European animals for work and food, in addition to plants, were imported to supplement the relatively wide variety of indigenous crops that the Indians cultivated.

By 1600 a half-dozen towns had been founded. Quito, however, had clearly established itself as the administrative, economic, cultural and religious centre of the colony. In 1563 Quito had been made the seat of a royal *audiencia*, a judicial agency which in certain instances was constituted into a legislative body. Quito enjoyed the advantage of being on the overland route between Cartagena. on the Caribbean in present-day Colombia, and Lima, capital of the viceroyalty of Peru, of which Ecuador was a part throughout the 16th and 17th centuries. In 1545 the bishopric of Quito was founded; from that point forward Quito remained the religious centre of the *audiencia,* and largely as a result of that circumstance, the cultural and intellectual centre. The religious edifices of Quito possessed some of the outstanding examples of painting and sculpture found anywhere in America. In 1594 the Jesuits established the Seminary of San Luis and in 1622 the University of San Gregorio Magno. In 1688 the Dominicans founded the University of Santo Tomás de Aquino. The quality of instruction in those schools was not equal to that offered by the "major" universities of Spanish colonial America, but they did give the colony an intellectual tone. The three centres of higher learning were fused in 1769 to form the institution known as the Central University of Ecuador (Universidad Central del Ecuador). The exploration and discovery concomitant to missionary activities from Quito into the Amazon territory added to scientific and geographic knowledge throughout the 17th century.

In 1717 the *audiencia* was removed from the viceroyalty of Peru and made a part of the viceroyalty of Nueva Granada, created to tighten Spain's control over its colonies as the competition with Great Britain for empire mounted. In 1723 Ecuador was returned to Peru when the viceroyalty of Nueva Granada was temporarily suppressed. When it was reconstituted in 1740, Ecuador was returned to it. Ecuador henceforth remained a part of Nueva Granada until independence was achieved.

In the late 18th century Ecuador began to feel the developments that led to discontent and finally rebellion throughout the Spanish empire. There was fear of future oppression, dissatisfaction of

the Creole elements with their share in government, the dissemination of foreign ideas — English, French and North American — and the invasion of the Iberian peninsula by the forces of Napoleon. Francisco Eugenio de Santa Cruz y Espejo, a doctor and journalist of part Indian extraction, and Juan Pío Montúfar provided the intellectual and organizational leadership for those who were becoming increasingly restless under Spanish domination.

The "Patriots," composed of both Creoles and *Peninsulares* (Spaniards), raised the "first cry" of Ecuadorian independence on Aug. 10, 1809, in Quito. This uprising was put down in late October of the same year. and as the first anniversary of the revolt approached, the imprisoned leaders were executed. On Oct. 11, 1810, a Quito group proclaimed the province to be independent. That attempt at independence failed by Dec. 1812. when the authority of Spain was reaffirmed. Meanwhile the independence movement swirled about the *audiencia* borders as the struggle between Spaniards and patriots gathered momentum. In 1821 it reached again into Ecuador when forces from both Colombia and Peru entered the *audiencia*.

Antonio José de Sucre. the trusted and able lieutenant of Simón Bolivar. with soldiers from at least a half-dozen future countries of South America in his ranks, at the battle of Pichincha on May 24. 1822. won Ecuador's freedom from Spain. Two days later the last president of the *audiencia* formally capitulated.

Both Colombia under Simón Bolivar and Peru under the Argentine general José de San Martin vied for control of Ecuador. At the historic meeting of the two at Guayaquil on July 26, 1322. Bolivar triumphed. Under the name "department of the south," Ecuador joined with Venezuela and Colombia in the confederacy known as Gran Colombia. From the time Ecuador became a part of Gran Colombia until 1830 it was in an almost perpetual state of agitation. It was caught in the engulfing tide of continental history as Bolivar fought to sustain his authority over Peru and Bolivia as well as Gran Colombia. (J. J. J.)

3. Early Republican Period. — In Sept. 1830 Ecuador withdrew from Colombia. as Venezuela had done in Nov. 1829, and began its independent existence. A national constitution was adopted and the first president, Venezuelan Gen. Juan José Flores, was elected. The first 15 years of the republic were fraught nith the strife and difficulties associated with the development of a new nation. Flores dominated political affairs, holding office from 1831 to 1835 and from 1839 to 1845. His persistence in keeping power by changing the constitution, which originally prohibited presidents' succeeding themselves immediately, ended in revolution and exile of the "foreign" general. During the administration of Vicente Rocafuerte (1835–39) some progress was made in the legislative framework, public education, religious freedom and freedom of the press and social welfare of the Indians.

From 1845 to 1860 five presidents held office during the most turbulent years in Ecuador's history. Foreign relations were troubled by wars with Peru and Colombia. anticlericalism was rampant and the country was disintegrating internationally as a result of establishment of independent town governments. Out of the breakdown of any semblance of a national government emerged a strong leader, Gabriel Garcia Moreno, who served as president for two periods (1861–65 and 1869–75). Under Garcia Moreno. crop production was increased and eucalyptus trees were introduced into the treeless highlands. Roads were improved and the Guayaquil-Quito railway started. The educational system was extended and prison reforms were introduced. Discipline was enforced among the members of the clergy and the army. Garcia Mareno, an austere Roman Catholic himself, sought to create a strong. united Ecuador by means of religious discipline. The church received complete charge of education. and a concordat with the Vatican (1863) guaranteed the church strong control in civil affairs. Under the constitution of 1869 only persons who were practising Catholics qualified for citizenship. Such a strong program was attained by dictatorial powers. which, however, were unable to stop the slowly growing liberalism in the country, typified by the writer Juan Montalvo. When Garcia Moreno attempted to win re-election for a third term in 1875, he was assassinated.

For 20 years following the downfall of Garcia Moreno, Ecuador experienced considerable turmoil. The Conservatives, essentially the feudalist-Catholic regime of the Sierra, managed to retain control most of the time; but liberalism, fostered by international connections through the expanding export economy of the coast, gained momentum. Sectionalism — represented by *costeños* ("people of the coast") and *serranos* ("people of the Sierra") — entered strongly into the picture. Finally the Guayaquil Liberals came under the leadership of Eloy Alfaro, who had been engaged in liberal movements in Central America. Alfaro (a *costeño*) succeeded in gaining control of the government in 1895 after a year of civil war, and was elected president under the constitution of 1897.

4. Later History. — The Liberal movement received great impetus during the terms of Alfaro (1897–1901 and 1906–11) and of Leonidas Plaza (1901–05 and 1912–16). The main object of the government's attention was the Roman Catholic Church, which was separated from the state and divested of its exclusive control over education. Action was taken to guarantee freedom of worship, of thought and of the press. Civil registry of marriage was made obligatory and divorce laws were enacted. Real property owned by the church that was not directly used for religious purposes was confiscated in 1908, and the state assumed control of large estates. Material achievements of the period included improvements in public health, educational institutions and utilities, such as water, sewer and electric service. Construction of the Guayaquil-Quito railway was continued until that transportation link between lowland and highland was completed in 1908. Extensions of the railway system were made during Plaza's second term, and the telegraph and telephone lines were extended. A start was made also on improvement of sanitation in Guayaquil, which had suffered loss of trade due to endemic conditions of yellow fever and plague at the port. Alfaro was killed by a mob when he tried to return to power in 1912. Plaza managed to finish his second term in spite of formidable opposition.

From 1916 to 1925 the political life of the nation was dominated by coastal financial interests, particularly the Commercial and Agricultural bank at Guayaquil. The country's economy expanded rapidly as the sugar industry and the petroleum industry were developed, new manufacturing industries were established and labour unions were formed. Troubles appeared, however, in the cacao industry as diseases took their toll and the post-World War I business recession caused widespread unrest. The army (composed chiefly of *serranos*) ended the coastal bank's domination in 1925 and created juntas to govern.

Serious economic and social problems faced the governments that held office during the world depression of the 1930s. From 1935 to 1940 seven chief executives — presidents, provisional presi-

dents or dictators — headed the government.

Carlos Arroyo del Rio, a Liberal, was elected president in 1940. Peru invaded Ecuador in the following year and, after a short campaign, succeeded in annexing a large part of Oriente by the protocol signed at the Pan-American Foreign Ministers' conference at Rio de Janeiro in 1942 (see *Boundaries,* below). The administration was criticized for the loss, but under wartime powers Arroyo del Rio held tight control of the nation and vigorously suppressed his opponents. A loose coalition called the Democratic Alliance, comprised of various extreme elements, including Communists, formed an underground opposition. When it seemed apparent that Arroyo del Rio would try to control the next presidential election to ensure the election of his candidate, a revolution overthrew the government and José Maria Velasco Ibarra was brought back as president in 1944.

Velasco Ibarra had been elected president previously in 1933 as an official Conservative candidate, though he was supported by most Liberals. When he tried to dissolve congress, however, he was deposed before the completion of his first year in office. His accession to office in 1944 was supported by the Democratic Alliance, but he soon alienated his Socialist and Communist supporters, particularly after his suspension of the 1945 radical constitution in 1946. He retained thereafter the support of only the Conservatives, who formed the constituent assembly which wrote the constitution of 1946 (see *Administration and Social Conditions; Constitution* below). The apparent contradictions and shifts in Velasco Ibarra's policies alienated other groups, moreover, and economic difficulties immediately following World War II caused considerable unrest. As a result, in Aug. 1947 the army ousted Velasco from office. A series of provisional governments followed until free elections here held in 1948, resulting in the election of Galo Plaza, son of former Pres. Leónidas Plaza.

Galo Plaza was supported by a group composed of individuals from several parties — a departure from the traditional party politics. He attempted to follow a moderate course, aimed at businesslike and democratic administration and recognition of public opinion and the rights of the individual. Action was taken to improve crops and livestock strains, to extend soil conservation practices and irrigation programs and to encourage Ecuadorians to move from the densely settled Sierra basins to the coastal lowlands along new highways. Galo Plaza finished his term in 1952 without spectacular achievements, though progress had been made on several basic problems.

Velasco Ibarra was returned as president in 1952. A $50,000,000 four-year road and railroad construction program was inaugurated in the following year, with the basic aim of linking Sierra and coast together more effectively. Foreign trade increased significantly and higher government budgets were balanced in the mid-1950s. Camilo Ponce Enriquez, the candidate of the Conservative party, which obtained a majority in congress, was elected president by a narrow margin in 1956. He became the third president in succession to take office constitutionally.

In 1960 former president Velasco Ibarra, who had gone into exile in Argentina in 1956, returned to Ecuador and was elected president for a fourth term. He ran as an independent and defeated the candidates of the traditional parties. He resigned in Nov. 1961 in the face of public unrest under inflation, new taxes and declining trade and was succeeded by his vice president, Carlos Julio Arosemena Monroy.

5. Boundaries. — Ecuador's boundaries were set by the protocol of Rio de Janeiro, to which Ecuador agreed after defeat by superior Peruvian forces in 1941; under it Ecuador lost about 70,000 sq.mi. of territory. The area of the country in 1960 was 105,684 sq.mi. (including the Galapagos Islands, an area of 3,028 sq.mi.).

In principle. Ecuador has always maintained rights to the area of the former presidency of Quito. According to the royal cedula of 1740, the presidency of Quito was assigned limits within the viceroyalty of Nueva Granada; such limits encompassed territory amounting to approximately 400,000 sq.mi., including a large part of what is now southern Colombia. Following the successful revolts for independence, the Spanish regions of north estern South America formed the confederation of Gran Colombia, consisting of three large districts — Venezuela, Nueva Granada and Quito. The confederation lasted only a few years, however; and, as a result of separation in 1830, the boundaries agreed upon with the republic of Colombia following the provisional agreement of 1832 resulted in the loss of more than 125,000 sq.mi. leaving Ecuador with an area of approximately 275.000 sq.mi.

The 20th-century boundary problems of Ecuador have focused upon relations with Peru. In 1904 Ecuador was obliged to yield about 27,000 sq.mi. of Amazonian territory to Brazil by the Tobar-Rio Branco treaty and in 1916 yielded nearly 65,000 sq.mi. of Amazonian territory to Colombia by the Muñoz Vernaza-Suárez treaty. Part of these actions stemmed from Ecuador's desire to gain friends in its struggle against more ambitious Peru, but part also reflected the fact that Ecuador had not penetrated nor settled the vast eastern regions as effectively as had Colombia and Brazil. By 1916 Ecuador's national territory had been reduced to approximately 180,000 sq.mi.—less than one-half the size of the original claim.

The accession of large tracts of Ecuador-claimed territory in the Amazon basin by Peru was prefaced by Peruvian accession of Colombian territory in 1922 and by the brief Peruvian-Colombian war of 1932. By 1941 relations between Ecuador and Peru had become severely strained over territorial claims. The United States, Brazil and Argentina offered to serve as mediators in the dispute, but Peru invaded southern Ecuador in 1941, overwhelming the poorly equipped Ecuadorians. As noted previously, Ecuador ceded to Peru more than 70,000 sq.mi. of territory — nearly two-thirds of Ecuador's Oriente or Amazonian hinterland. The loss of territory was agreed upon in the protocol (of peace, friendship and boundaries) of Rio de Janeiro in 1942 during a conference of western hemisphere foreign ministers. The task of fixing the new boundary line in difficult, unexplored areas was continued for many years by an Ecuadorian-Peruvian commission, but the boundary still had not been completely surveyed by the latter 1950s. In 1960, when Velasco Ibarra became president, he declared that Ecuador would no longer recognize the 1942 treaty boundary. (D. R. D.)

V. POPULATION

The first national census for Ecuador was taken in 1950 and recorded a population of 3,202,757. An official estimate made in 1962 stated that the figure at that time probably was 4,653,000. The coastal region contained about 43% of the country's population, the Sierra about 55% and the Oriente about 1.5%. The remainder (less than .5%) of the population lived in the Galapagos Islands.

Although the people of Ecuador are frequently referred to, in popular parlance, as belonging to different "races," it is more accurate to describe their social groups as classes rather than races. The distinctions among them are based not on skin colour or other physical characteristics but rather on the languages they speak, the cultures in which they participate, their styles of dress, whether they live in rural or urban areas, and, to a certain extent, the region in which they live. Also, it is possible, although not easy, for a person to move from one class to another. For example, when intermarriage occurs, husband and wife usually become members of the same class. The "whites" are people who, regardless of their skin colour, speak Spanish, participate in the Spanish rather than the Indian culture, and usually live in the cities. Mestizos participate in both cultures. Indians speak indigenous languages rather than Spanish and tend to be rural rather than urban dwellers. Thus defined, Indians account for about 60% of the national population, mestizos 25% to 30% and "whites" at most 15%.

Immigration statistic? indicate that, since the achievement of its national independence in 1830, Ecuador has not attracted significant numbers of European immigrants, although the country has on occasion made official attempts to draw new citizens from Europe. During World War II, war refugees were invited to settle in the country; and, throughout the period of Hitler's rule in Germany (1933–45), about 1,000 Europeans, many of them Jews, came to Ecuador as immigrants. All in all, however, there was

All are in the Oriente. separate data not available.

probably a smaller proportion of new blood brought into Ecuador after independence than into almost any other country of South America. (G. I. B.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

Ecuador, the smallest and weakest of the states formed from the breakup of Gran Colombia, during its turbulent political history as a constitutional republic developed a conservative centralized government giving considerable power to the president. Its history has been marked by the conflict of Conservatives and Liberals, represented in large part by sectional differences between the Sierra and the coast, and the conflict of the state with the strong temporal power of the Roman Catholic Church.

1. Constitution. — The constitution of Ecuador adopted in 1946 was largely the work of Conservatives, though it maintained all of the basic Liberal principles and social goals. It provided for a unitary republic with the usual legislative, executive and judicial branches. It also provided for a council of state to represent congress when the latter is in recess and to act as liaison between the president and congress. The senate and the chamber of deputies comprise the congress. Senators, totaling 45, are elected for four years. The 15 main provinces elect two senators each, the two eastern provinces and the Galapagos Islands (Archipiélago de Colón) one each; and, in addition 12 "functional" senators are elected by special economic or cultural groups, representing education. coastal and Sierra agriculture, business, industry and labour, the armed forces, journalism and learned societies. Deputies are elected for two years. The three smallest provinces elect one deputy each and the remainder of the nation has one deputy for each 50.000 inhabitants or fraction in excess of 25.000. The president and vice-president are elected for four years and are not eligible for immediate re-election. All candidates for national offices must be Ecuadorian-born citizens; the minimum-age qualifications are 25 years for deputies, 35 years for senators and 40 years for the president and vice-president. All are elected by direct. secret vote. Suffrage is granted to all literate men and women over 18; voting is compulsory for men and optional for women. Members of the armed forces and the national police force do not enjoy suffrage, however.

2. Local Government. — In 1960 there were 19 provinces and the territory of the Galapagos Islands. The provinces were divided into 97 cantones, which, in turn, were divided into 791 *parroquias* ("parishes") — 168 urban and 623 rural. Each province is ruled by a governor, each canton by a jefe politico and each parish by a teniente politico. The Galapagos Islands are administered through the ministry of national defense and are, technically, a naval command. Ten of the provinces belonged essentially to the Sierra and five to the coast. The largest in area were Napo-Pastaza and Santiago-Zamora. the two sparsely populated Oriente provinces which were divided into four separate provinces, and Guayas and Manabi in the Pacific coastal region. The largest Sierra provinces were Pichincha, which includes considerable Pacific lowland area, and Loja. The largest in terms of population were Guayas (876,000), with Guayaquil; Manabí (649,000); and Pichincha (533,000), with Quito.

3. Public Health. — Ecuador's public health program has made remarkable improvement through national efforts and international co-operation. The eradication early in the 20th century of yellow fever, which had retarded the development of Guayaquil, was the beginning of progress in improving health conditions. Considerable progress also has been made in combating malaria and tuberculosis. In co-operation with the United States Institute of Inter-American Affairs, Ecuador virtually eliminated malaria as a cause of death (as late as 1942 nearly 25% of all deaths were caused by that disease). In co-operation with the World Health organization, the country also introduced programs to prevent and control tuberculosis, which in recent times caused one-fifth of all deaths. Public health measures were also instituted to control venereal diseases, smallpox, typhus and plague. The increased availability of potable water has contributed appreciably to the health of the republic.

Ecuador has a high rate of infant mortality. It has been estimated that about 140 out of each 1,000 infants die in their first year and that only about 40 of every 100 children born survive the age of five. Some progress was made in the reduction of infant mortality, however, through various general public health measures and through the establishment of a few maternity hospitals and child-health clinics in Guayaquil, Quito and some of the larger towns.

Malnutrition is also prevalent in Ecuador. The diet of the vast majority is not only deficient in proteins, yitamins and minerals, but the total intake of food is extremely low. A great majority of the inhabitants can afford only about one-half the daily intake of calories considered necessary by health authorities. The lack of roads to open up new food-producing areas, the relatively low literacy rate and poor habits of hygiene contribute to malnutrition in a country apparently well suited to support a relatively high level of health. Such foods as milk, eggs and vegetables are luxuries for the people who produce them.

Ecuador has a social security program providing for health and maternity benefits, compensation for workmen injured during the course of their employment and old-age pensions.

4. Education. — Though primary education is free and compulsory for children from 6 to 12 years of age, opportunities for school attendance were limited in the 1950s by the shortage of schools and of teachers, especially in rural areas. About 300,000 children of school age, for example, were unable to enroll in any of the primary schools in 1955. During that year, however, a sizable school construction program was initiated, and the need for increased aid to education was reflected in the national budget.

Ecuador's five universities are autonomous. The most important are Central university at Quito and Guayaquil university. The universities of Cuenca and of Loja serve the southern sections of the Sierra. A Catholic university, headed by Jesuits, was opened in Quito in 1946. The National Polytechnic school, a government-supported institution, opened in 1946.

The illiteracy rate is high. According to the 1950 census, 43.7%

of all inhabitants over ten years of age were illiterate. Probably not more than 20% to 25% of the population possessed the academic skills ordinarily associated with commerce and "factory" industries.

5. Defense. — Although the armed forces have had a strong voice in politics throughout its history, Ecuador has had fewer military regimes than many other Latin-American countries. After 1948. moreover, only civilians were appointed to the post of minister of defense. The armed forces are charged with defending the constitution and the country from attack.

Approximately two-thirds of the defense expenditures go to the army. a little less than one-fifth to the navy and about 15% to the air force. Military training for one year is coinpulsory for all men 20 years of age. A standing army of from 7.000 to 9.000 men is maintained. The Military college enrolling about 200 cadets and an aviation cadet school are at Quito; an aviation officers' training school is at Guayaquil. The naval school is at Salinas.

VII. THE ECONOMY

A. Production

Economic development in Ecuador has been regional and often local rather than national in scale. Contrasts are especially apparent between the Sierra and the coast. The Sierra lacks the agricultural land needed for expanded production and suffers from a surplus of unskilled labour. The coast, on the other hand, has an abundance of land but lacks the labour force needed for its efficient utilization. The Sierra produces mostly grains. fruits and vegetables, chiefly for domestic consumption, whereas coastal agriculture is commercialized and enters extensively into international trade, the principal exports being bananas, cacao, coffee and rice.

1. Agriculture. — Although only about 5% of the land is under cultivation, Ecuador is predominantly agricultural. About one-half of the economically active people are employed in agriculture, with the next largest group (one-fourth) employed in handicrafts and manufacturing industries. Cultivated land is about equally divided between the Sierra and the coast. amounting to approximately 650,000 ha. (one hectare equals 2.471 ac.) in each region. The Sierra, however, contains a larger percentage of land unsuited for cultivation because of cold: ruggedness and aridity.

The principal staple foodstuffs grown in the Sierra are maize, potatoes, barley, wheat and beans. Maize, which along with barley constitutes the basic diet of the Sierran working population, is the most extensively planted crop, though it is exceeded by potatoes in quantity of production. It is also a principal staple foodstuff grown in the coastal region, along with bananas, rice, sugar and sweet potatoes. Fifteen per cent of all land under cultivation is devoted to maize and barley. Barley grows at elevations up to 11,500 ft., as do potatoes. Wheat production is concentrated in the zone from 7,000 to 10,000 ft. Wheat yields are extremely low as a result of inefficient methods, lack of fertilizers, irregularity of rainfall and other factors. In fact, yields of nearly all Sierra crops are low. The most productive inter-Andean basins are those around Ibarra, Quito, Anibato and Cuenca. Some irrigation systems have been built to modify problems of water supply and porous volcanic soils.

Although bananas had been exported from Ecuador from the 1920s. large-scale commercial production did not take place until after 1945, stimulated by high prices and production decreases in Caribbean countries caused by plant diseases, hurricanes and labour trouble. The construction of new roads in the Pacific coastal region aided the industry greatly. Most of the new banana farms are small holdings; foreign-owned plantations account for only a small percentage of total production. The exporting centres are Guayaquil. Puerto Bolivar and Esmeraldas.

Beginning about 1870, Ecuador produced significant quantities of the world's finest cacao and occupied first place in production until the mid-1920s. In the peak year of 1916 nearly 50.000 metric tons were produced. Serious outbreaks of monilia disease in 1916 and of witches'-broom disease in 1922, however, caused the abandonment of many of the huge plantations in the Guayas lowland. The development of cacao-producing areas in other tropical regions, notably west Africa and Brazil, also affected Ecuador's position. By 1940 Ecuadorian production had reached its lowest point. accounting for only about 14.000 tons, less than 2% of the world's production and only a little more than 10% of the nation's total export value. With the rise of cacao prices after World War II the industry began to recover and Ecuador again became a major producer.

The largest coffee-producing areas of Ecuador are the hilly sections near the coast northwest of Guayaquil and the flanks of the Andes to about 5.000 ft. elevation southeast and east of Guayaquil. In contrast with cacao, coffee trees are planted usually in small plots rather than on large plantations. Production more than doubled during the two decades preceding the mid-1950s especially in response to the sharp rise in world market prices after 1945.

Rice, a staple food in the coastal region and also much in demand in the Sierra, has fluctuated greatly in its role as an export crop. It figured significantly in the national economy when cacao failed, though its value was erratic. In 1926 and 1937, for example, it accounted for less than 1% of the exports. A peak in production (112,000 tons) was reached in 1947, even though the maximum area under cultivation was not reached until 1949. Rice held first place among Ecuador's exports during and for a short time after World War II but thereafter dropped behind bananas, cacao and coffee.

Ecuador's production of sugar for export is not important. In fact, domestic production occasionally has not been sufficient to meet domestic demands. About two-thirds of the sugar cane is grown in the coastal region, where two large mills located on the Guayaquil-Quito railway produce nearly all of the refined sugar. Cane is also grown rather extensively in the lower Sierra valleys, and is used chiefly for the production of *aguardiente,* the white rum sold through government monopoly.

Attempts have been made to satisfy domestic demands for cotton by local production, but crops have been poor except in a few years. The main area of production, the drier part of the coast near Manta, is beset by difficulties of plant disease and erratic rainfall. Successful production requires irrigation and the use of mineral fertilizers.

The livestock industry, though not well advanced in Ecuador, is especially important in the highlands, where grazing haciendas occupy large tracts. The Sierra supplies Guayaquil with much of its meat.

2. Forestry. — Forests, which cover an estimated 65% of Ecuador's land area, provide a number of products of economic importance. Lack of transportation, coupled with other problems associated with tropical logging, hindered the development of a significant export lumber industry. The forests, however, yield a considerable amount of material for domestic construction materials, including the giant bamboo which grows profusely along tropical riverbanks. Balsa wood proved to be a significant export product, especially during World War II. It comes chiefly from the northeastern tributaries of the Guayas river.

Tagua, or vegetable ivory, comes from the seeds of a small palm fern which grows wild in the tropical forests of western Ecuador and Colombia. Although the tagua industry suffered from competition with substitute products for the manufacture of buttons, it still held a basic place in the early 1960s.

The forests of Manabí and Esmeraldas also are the source of *toquilla,* a long fibre used for the fabrication of Panama hats and other straw products, which is in great demand. Kapok, a light fibre that is moisture resistant, also has had strong demand, especially during World War II. Rubber is gathered in the western lowlands and, to some degree, in the Amazonian lowland as well. Cinchona bark. yielding quinine, is an Ecuadorian forest product of importance, but it felt the competition of synthetic rivals. It is gathered chiefly from the forests of the middle western slopes of the Andes.

3. Mining. — Mining has not played as important a role in Ecuador's economy as it has in the other Andean countries. The most extensive mineral exploration was done in Oriente, where potentialities of petroleum deposits are considered favourable.

Between 1937 and 1949 two companies worked in association in the Amazonian basin, but withdrew because their findings did not warrant the construction of costly pipelines to transport oil from that isolated region.

Petroleum deposits have been exploited, however, in the coastal region. Petroleum was discovered before World War I on the arid Santa Elena peninsula, north of the Gulf of Guayaquil. British and Canadian oil companies started work after 1918 and one of the British companies first exported crude oil in 1925. The Canadian company finally abandoned its concessions in 1947. The other British company also had little success and its concessions were taken up in 1951 by a United States company, which opened a small refinery in 1953. Several Ecuadorian oil companies have also been active. Nearly 90% of the country's oil production was controlled in the early 1960s by the British concern, which constructed an 11-mi.-long pipeline from Ancón to the port of La Libertad.

Gold has been the chief mineral mined in Ecuador. Placer mines were in operation along some of the streams flowing eastward from the Andes and in the rivers of the northwestern coastal region in the latter 1950s. The first large company to enter the field (1895) was a United States concern, which obtained a gold-mine concession at Portovelo, in the southernmost province along the Gulf of Guayaquil. By 1950 the concession, about 35 mi. back in the Andes, was abandoned because of exhaustion of the ore, which consisted of silver and copper as well as gold. From 1940 to 1946 copper, as well as some gold, silver and lead, were produced from a mining concession in western Cotopaxi province.

4. Industries. — Industrial development in Ecuador has been confined largely to the manufacture of consumer goods for a relatively small domestic market. Manufacturing embraces principally the preparation of foodstuffs, textiles, shoes, furniture and small wares destined for local markets. Apart from many small factories located in various parts of the country. there are two large sugar mills, a large flour mill using imported wheat and two relatively large edible-fat factories in the coastal region. The brewery at Quito uses Sierra-produced barley, whereas the Guayaquil plant uses barley imported from Chile.

The textile industry is the most important in the country in terms of number of workers employed, capital invested and volume of production. Quito is the centre of most of the textile factories; there are a few at Ambato, Riobamba and a few other Sierra towns. Lack of raw materials has plagued the industry at times. Handicraft textiles, especially the woolen goods of the Indians of Otavalo, are notable.

Ecuador is famous for the handicraft manufacture of Panama hats, so named because they were first distributed for sale in large quantities in Panamá. *Toquilla* fibre was first used for straw hats in the coastal province of Manabí, where the finest hats are still made in the towns of Jipijapa and Montecristi. The centre of production later shifted to the southern Sierra provinces, which account for about 80% of all hats exported. Several thousand weavers, mostly women, are engaged in part-time work at home making straw hats. The centre of the industry is Cuenca, where middlemen obtain the fibre from the coastal region and distribute it to the weavers. and where the finishing stages of washing, bleaching, ironing and shaping are done, generally in large workshops run by export companies.

B. Trade and Finance

1. Trade. — Ecuador, like many other Latin-American nations, is essentially an exporter of raw materials, chiefly agricultural, and an importer of manufactured goods. It regularly has the lowest value of trade per capita among the South American republics. The United States holds a dominant position in both the import and export trade of the country.

Exports. — The total value of Ecuador's exports, which had averaged about $12,000.000 annually between 1936 and 1940 and about $25,000,000 between 1941 and 1945, amounted to approximately $140,000,000 by 1960. Some of the increase was attributable to inflation, but the quantity of the leading export products. particularly bananas, increased significantly. Cacao, coffee, crude petroleum and gold were the main exports in the latter 1930s. Rice assumed first place among exports during and for a short time after World War II but dropped and became erratic in the export trade after 1950. Agricultural products amount to about 90% of all export value, followed by manufactured products, minerals and forest products.

During the 1930s the Cnited States and western Europe, particularly Germany, shared about equally as markets for Ecuador's exports, each region taking more than one-third of the exports. The remainder was taken by Latin-American nations and by Italy and Japan During World War II Ecuador's export trade shifted almost entirely to the United States (nearly 60%) and to Latin America. The ascendancy of rice exports during that period was largely the result of Ecuador's provision of rice to Latin-American countries whose traditional supplies from the far east had been cut off. After World War II. western Germany, Italy and Japan resumed trade nith Ecuador but not on as large a scale as before.

Imports.—The value of imports folloued more or less the same pattern as exports. From an average of $11,000 000 annually between 1936 and 1940, imports increased to about $17,000,000 between 1941 and 1945 and exceeded $100,000,000 in the early 1960s. Machinery and vehicles accounted for 30% of all import value folloned by food. drink, tobacco and textiles. The large importation of foodstuffs, particularly wheat flour, wheat, milk and fish, indicates the limited development of some segments of domestic agriculture. Lack of raw cotton is indicated by the sizable imports of cotton and textile materials, as well as clothing. Imports of metals and metal manufactures of chemicals and pharmaceuticals and of other industrial products are significant.

Trade Relations — Ecuador's balance of trade has been favourable for the most part. The government occasionally restricts the export of certain items in order to assure supplies for the home market. Export duties are imposed on many products. No direct restrictions were imposed on imports in the 1950s, though import permits were required to conserve foreign exchange. The system of selective imports in effect in the early 1960s involved a threefold classification of imports. Essential goods. such as certain foodstuffs. machinery and tractors. mere not taxed nor were surcharges levied. Less essential goods (groap B imports) were taxed 33%; yet, like essential goods (group A), they mere bought with foreign exchange supplied by the Central bank at the official rate. Luxury goods (group C). such as radios, refrigerators and silk and nylon goods, were taxed 44%; moreover, the importer was required to surrender to the Central bank foreign exchange purchased in the free market (at a higher cost than the official rate).

2. National Finance. — The basic unit of the Ecuadoran monetary system is the sucre. named in honour of the hero of the independence movement. Antonio José de Sucre. The main source of revenue for the national government is commerce and transportation taxes, especially customs duties This is clearly reflected in the fact that the coastal province of Guayas alone contributes about one-third of the revenue. Almost every economic activity and every transaction is taxed. State monopolies provide nearly 10% of the government's revenue. Losses of the alcohol monopoly are made up by profits from the tobacco, salt and match monopolies.

The largest part of the foreign debt of Ecuador in the early 1960s was due the bondholders of the Guayaquil-Quito railway, mostly United States investors. Although no payment had been made on the principal for many years. the debt was being serviced. The other large item — loans from the Export-Import bank — was being punctually serviced. Ecuador's internal debt increased in the 1950s through issues of bonds and through loans from the Central bank to cover budget deficits.

The Central bank, a private institution from 1927 to 1948 when it was nationalized, heads the banking system. It controls credit and foreign exchange, extends loans to the government and controls monetary policy. It is the sole bank of issue. A system of development banks, headed by the Banco Nacional de Fomento. was created in 1943 to make loans for the promotion of commerce, agriculture and industry.

C. Transport and Communications

Difficulties arising from extremely mountainous topography and dense tropical forested lowlands have hindered the development of both transportation and communications. Approximately 8,500 mi. of telegraph lines link the principal cities and towns but nearly all of the equipment was in need of repair and modernization in the latter 1950s. A major problem facing both telegraph and radio communications within the country was the exemption of more than three-fourths of the communications from payment. In 1953, however, free transmittal of government business, which accounts for the majority of messages, was abolished.

Natural and financial difficulties have hampered the development of lines of transportation in Ecuador. In turn, inadequate means of transportation hindered the development of the nation by continuing isolation of the two main regions of the country—coast and Sierra—and by preventing widespread participation in international trade.

Considerable use of watermays is made in the lowlands. The several large streams of the Guayas system are much used by rafts. launches and canoes. Most of the rivers of the northwestern coastal region are navigable for considerable distances and are major transportation ways. In Oriente the rivers are primary means of transportation.

There are approximately 830 mi. of railways, all narrow gauge. The main line is the Guayaquil-Quito railway, which extends 288 mi. from Durán to Quito. Built by foreign enterprise and opened to traffic in 1908, it was nationalized, along with all of the other railroads, in 1944. The Guayaquil-Salinas railway, extending for 95 mi. directly west from Guayaquil, was finally closed to traffic in 1953 because of unsuccessful competition with an excellent highway running almost parallel to it. In 1957 the Quito-San Lorenzo line mas officially opened.

By the early 1960s more than 6,000 mi. of roads were in operation; however, only a little more than one-half were all-weather highways. Particularly in the coastal region, where at least four months of unfavourable weather occur, most roads are impassable for a part of the year. During the 1950s the World bank made large loans to Ecuador for road construction and for a new port at Guayaquil that would be more accessible to ocean-going ships.

The principal road is the Pan-American highway, extending about 680 mi. from the Colombian border through the inter-Andean basins to the Peruvian border. The highway averages 20 ft. in width, has a maximum gradient of 8% and consists of cobblestoned and unpaved sections. The Pan-American highway has been complemented by several main roads leading westward down to the Pacific coast. The northernmost (built between 1946 and 1957) links Quito to the port of Esmeraldas by way of Santo Domingo and has a total length of 192 mi. The longest (224 mi.) connects the port of Manta to Quevedo in the Guayas lowland and to Latacunga on the Pan-American highway.

Ecuador joined with Colombia in the ownership of the merchant ship line Flota Mercante Gran-Colombiana and holds a 20% interest in the enterprise. Large seagoing vessels cannot dock alongside piers in Ecuadorian ports because of shallow water. Guayaquil, the chief port, is 30 mi. from the mouth of the estuary. Other ports, where large vessels also must anchor offshore, are Puerto Bolivar, La Libertad, Manta, Bahía de Caraquez, Esmeraldas and San Lorenzo.

Ecuador is served by several national and international airlines.

Current history and statistics are summarized annually in *Britannica Book oj the Year.* (D. R. D.)

ECUMENICAL MOVEMENT, the name given to a movement for co-operation and unity among most Christian churches other than the Roman Catholic. The English word "ecumenical" is derived from the Greek participle *oikoumene* ("inhabited"), used in classical times as a noun to mean the "inhabited world." Later an ecumenical council was so called because its members represented churches throughout the inhabited world; it could thus claim to be general or universal (see Council). About the middle of the 19th century, mainly through the influence of a particular usage of the word *oecuménique* in French, the word ecumenical acquired the significance of "that which is concerned for the unity and renewal of the church." It is in this special sense that it is used throughout this article.

Earlier Centuries.—Concern for the unity and the renewal of the church is not a matter of one time of place; it is a thread that runs through the whole of church history. From the beginning there have been elements of division in the church, and at all times there have been persons concerned to safeguard the unity or to restore it if it has been broken. Until the 16th century the great instrument of unity was the council. Many councils produced more divisions than they healed. but this should not throw doubt on the desire of many of the bishops who attended the early councils, and of the emperors who convened them, to see division brought to an end and unity restored. One of the last great attempts on this line was the Council of Ferrara-Florence (*q.v.;* 1438–45), in which for a brief space the Western and the Orthodox halves of the church were brought together in fellowship.

When the Reformation was threatening Christendom with a deep doctrinal division, great hopes were placed in the convening of a council. The Council of Trent (*q.v.*) served only to deepen the divisions. Yet this was the great century of the theologians, in which leaders on the Catholic and the Protestant sides met frequently, notably in the colloquies of Ratisbon (1541) and Poissy (1561). Little but frustration came of these meetings, yet they served to indicate that in some sense Christendom was still a reality and a unity.

In the 17th century the most notable work was done by individuals, of whom the Scottish Protestant John Dury is typical. Wholly consecrated to the ideal of the unity of the church, Dury traveled tirelessly, attempting to influence leaders in church and state, writing, arguing and preaching. But the 17th century was a time of inflamed theological passion; the failure of the Anglicans and the Presbyterians in England to agree at the Savoy conference in 1661 indicates the almost universal inability even of men of good will to come together in that century. In the 18th century the rulers took a hand. Under the influence of Daniel Ernst Jablonski a plan was launched to introduce episcopacy into the church of Prussia and to bring it into unity with the Church of England. These and similar negotiations led to nothing, and it was not until 1817 that Frederick William III of Prussia produced, in the Prussian Plan of Union between Lutherans and Calvinists (a loose and very undogmatic unity), the first example of a real union of churches in modern history.

The 19th century was the great age of the voluntary Christian societies (see Missions; Bible Societies). Mainly as a result of the evangelical revival, missionary societies and such corporate efforts as the British and Foreign Bible society, the Young Men's Christian association and the Young Women's Christian association brought Christians together for a variety of specific purposes. But these were unions of heart and feeling rather than of doctrine. Loyalty to Christ was felt to be so all-important that questions of denomination were rarely raised, and differences of denominational loyalty were not felt as a hindrance to co-operation. In

all these movements there had hardly been any official co-operation of the churches as such. The modern ecumenical movement began when the churches themselves began to be engaged in the search for the unity and renewal of the Body of Christ.

Beginning of the Modern Movement. — The modern ecumenical movement is generally held to have taken its rise from the first World Missionary conference, held at Edinburgh in 1910. This movement was the offspring of the widespread missionary activity of the time. Living as a tiny minority amid vast populations of non-Christians, missionaries and their converts had found themselves driven into alliance with one another. Where the church was less highly organized and less rigid than in the west, many forms of co-operation had proved possible. The world-wide sense of lellowship had found expression in a series of conferences, which had created a deep impression but had been loosely organized and had no permanence. Edinburgh was different from all that had come before in three vital ways. First, it had been well organized under the direction of J. H. Oldham, who was later to have a hand in the organization of many other ecumenical gatherings. Second, though from the church point of view an unofficial conference, it had taken steps to draw in the churches insofar as possible It was significant that the Society for the Propagation of the Gospel, which, with its strong church sense, had tended to hold aloof from all interchurch movements, agreed to be represented, and the archbishop of Canterbury. Randall Davidson, addressed the conference. Third, the conference established the very first permanent instrument for international Christian work outside the Church of Rome, the continuation committee of the conference. Out of this grew in 1921 the International Missionary council (I.M.C.). John R. Mott, an American Methodist who had been chairman of the Edinburgh conference, became first chairman of the I.M.C., contributing greatly to the development of ecumenical confidence and mutual trust, particularly in the formation of national Christian councils in many parts of Asia and Africa.

From one field Edinburgh had been debarred by common consent. Nothing had been said about problems of faith and order, but it was clear that they could not remain forever undiscussed. Under the inspiration of Charles H. Brent the American Episcopal Church took up the call for a world conference on faith and order, at which the churches should meet precisely to discuss those things about which they differed. The secretary of the commission was a layman, Robert H. Gardiner. Immense difficulties had to be overcome. A great many church leaders believed that such a meeting might do more harm than good. There were no precedents and no assurance that such a conference could in fact be held.

The first conference met in Lausanne in 1927, under the chairmanship of Brent. If the conference had done nothing else, it would at least have shown how necessary it was; it revealed the extent to which the churches had lived in separation from one another and how ignorant they were of one another's beliefs and practices. But the conference did much more than this. It appointed a continuation committee and set in motion a process of joint theological study. Further world conferences on faith and order were held at Edinburgh (1937) and Lund (1952).

It is to be noted that the Church of Rome declined to have anything officially to do with the Lausanne conference, but that the Orthodox churches, which had not been present at Edinburgh in 1910, were well represented.

Yet a third stream of ecumenical activity was beginning to develop during and after World War I, under the leadership of Nathan Soderblom (*q.v.*), at that time archbishop of Uppsala. During the war Soderblom had made heroic but largely ineffective efforts to mobilize the churches in the cause of peace. When peace returned. he felt that the time had come to ask whether the churches had a word to say to the world of men outside its own narrow limits, or a practical, social message to give. Similar questions were moving in many men's minds. They had inspired, for instance. in England the Conference on Politics. Economics and Citizenship held at Birmingham in 1924. The first Universal Conference on Life and Work met at Stockholm in 1925, with Soderblom as chairman and G. K. A. Bell as editor of the report of its proceedings. A survey was made of the great problems of man in modern industrialized society. The size and complexity of these problems was realized. This conference, like the others, appointed a continuation committee, which accomplished much in the education of all the churches as to the social responsibilities implicit in the gospel.

There were now three ecumenical bodies, each with a standing or continuation committee, and the expectation of a succession of world conferences organized by each of the three. There was considerable overlapping of personnel and an increasing duplication of effort. At the meetings of Faith and Order at Edinburgh, of Life and Work at Oxford, both in 1937, and of the International Missionary council at Tambaram near Madras in 1938, the question was raised of the formation of a World Council of Churches, in which the first two movements would merge, the third being associated with it. The proposal met with little opposition and much ready acceptance. A provisional committee was appointed to plan for formation of the council, with William Temple (*q.v.*) as chairman and W. A. Visser't Hooft as secretary. It was intended that the first meeting of the council should take place in 1941, but it was postponed by the outbreak of World War II. During the war years the World council, though still only "in process of formation," made contacts with the churches on both sides of the barrier of war, and, through its service to prisoners of war and refugees and later to the devastated countries, made itself a living reality to the world.

The World Council of Churches. — All this preparation reached its fulfillment in the official formation of the World Council of Churches on Aug. 23, 1948 (*see* WORLD COUNCIL OF CHURCHES. THE). One of the principal achievements of the third assembly of the World council (1961) was the integration of the World council and the International Missionary council into one single great ecumenical body. There had been considerable opposition to this step in conservative circles and in the Orthodox world; but the steady support of the younger churches and the widespread conviction in the Christian world that it is unreasonable to have two major ecumenical bodies in existence made it almost a foregone conclusion that this further step toward unity would be taken. Another achievement of great significance for the ecumenical movement was the admission of the Orthodox Church of Russia (and with it the Orthodox Churches of Bulgaria, Rumania and Poland) to membership in the World council.

It is necessary to recognize the limits of the World council. It does not include the Roman Catholic Church or certain great Protestant bodies, such as the Southern Baptist Churches in the United States. But it does include representatives from the separated Eastern Churches, from the Orthodox Churches of Greek, Arabic and Slavonic speech, the Old Catholics, all the Anglican Churches in the world; the great churches that stem from the Reformation — Lutheran (though not all), Reformed, Congregationalist, Baptist (again, not all); many of the churches of more recent development, such as the Methodists and the Disciples of Christ; some of the Society of Friends, and the Salvation Army. The enthusiasm with which the more recently founded churches in Africa and the east have adhered to it is notable; these churches seem to feel very strongly the value of a great international fellowship, in which they are welcomed on terms of full spiritual equality.

The World council is not, does not aspire to be and should never become a church or a superchurch. It can issue no instructions to its member churches, which retain their full autonomy. Its declarations or utterances on public affairs have no authority other than that which may accrue to them in view of the wisdom with which they have been made.

The World council increasingly commands the confidence of the churches; it has not interfered in their internal affairs; it has continued to work for the two great objectives, the unity and the renewal of the church; it is recognized by churches throughout the world as providing a better instrument than they have ever had before for frank discussion, for consultation and for cooperation in practical service for the well-being of mankind.

Other Forms of Ecumenism. — It would be a mistake, how-

ever, to identify the ecumenical movement with the World Council of Churches or to limit the use of the word to this particular form of ecumenism. At least four other lines have to be taken into consideration.

Roman Catholic Church.—This church on its own principles refuses to have official dealings with other churches or movements. But it is deeply concerned about unity and pursues its own way toward it, especially by the development of the annual week of prayer for unity (Jan. 18–25), forwarded by Paul Couturier of Lyons and officially adopted by the Faith and Order section of the World Council of Churches in 1941. The appointment in 1960 by the pope of a special commission for ecumenical affairs. with Agostino Cardinal Bea as president, the first official recognition by the Roman Catholic Church of the existence of the ecumenical movement, was of the greatest importance.

Movement for Church *Union.*—Between 1910 and 1961, 42 mergers of churches took place in various parts of the world, the most striking being the Church of South India. Only one of these, the union of the French Protestant churches (1938), took place directly under the influence of Faith and Order; the other movements occurred independently. Yet they profited by the ecumenical climate of the 20th century and contributed to its strength.

Denominational Ecumenism.—Every one of the main confessional groups has its international organization (the earliest, the Presbyterian alliance, 1875). This movement could become a danger to the wider ecumenical movement; but the denominations defend themselves by saying that, if ecumenism is not to be a lowest-common-denominator fusion, they can make their best contribution by understanding better their own denominational treasures and bringing them undiminished into the movement.

Evangelical *Ecumenism.*—Small groups are engaged in bitter warfare against the World Council of Churches; these can be disregarded here. But other large groups, of mhich the International Fellowship of Evangelical Students (1947) is typical, continue the 19th-century tradition of fellowship, demanding only loyalty to Jesus Christ as the qualificaton for membership, and are suspicious of the wider ecumenical movement.

ECZEMA, a chronic form of dermatitis. See SKIS DISEASES: *Dermatitis and* Eczema; ALLERGY AND ANAPHYLAXIS: Manifestations of Allergy.

EDAM, a town in the province of North Holland, Neth., is situated on the shores of the IJsselmeer, 21 km. (13 mi.) N.N.E. of Amsterdam by road. Pop. (1959) 4,212. The little town is dominated by the large church of St. Nicholas, rebuilt after a fire in 1602 that destroyed almost the whole town. The town hall (1737) has interesting wall paintings and furniture; the city museum (1895) has a floating cellar; and the tower of the former Ons Lieve Vrouw church contains a very old carillon made by Pieter van den Gheijn of Malines. In the Nieuwenkamp museum, named after the well-known painter and etcher (1874–1950), are etchings, and art treasures from Bali. The famous Edam cheese (zoetmelks kaas, "sweet milk cheese"), made throughout North Holland, is the town's chief product; others are earthenware, packing materials (jute, paper, plastics), coal brushes, tools, door and window furniture and ladies' underwear. Edam took its name and origin from the dam built on the Ye, which joined the Purmer lake with the Zuider Zee (*q.v.*). It became an important harbour and shipbuilding centre when a large dock was built on the Zuider Zee in 1357; in the same year Edam received its civic rights from William V of Bavaria. count of Holland. In the 17th century most of Adm. M. A. de Ruyter's fleet was built in Edam, as well as "de Halve Maen" (the "Half Moon"), the ship Henry Hudson used in 1609 in his search for the northwest passage. When Philip II of Spain ordered a sluice to be built into the dock in 1567 to prevent flooding into the reclaimed land, the inhabitants opposed it in vain. The sluice caused the harbour to silt up and commercial and industrial activity waned. (C. G. M. v. B.)

EDBERT (EADBERHT) (d. 768), king of the Northumbrians from 737 to 758, succeeded on the resignation of his cousin Ceolwulf. He was a strong king whose reign was regarded by Alcuin as a golden age. He fought the Picts in 740, conquered Kyle in 750 and with Pictish help he forced the Britons to come to terms at Dumbarton in 756, though his army met with disaster nine days later. His brother Egbert became bishop of York in 732 and, receiving the pallium in 735, was the first archbishop of York. Church affairs prospered under the care of the two brothers, and York became a famous centre of learning. A letter from Pope Paul I, remonstrating with them for giving three monasteries to a noble, suggests that they had suppressed some spurious monasteries, as Bede had advised. Edbert was in contact with the Frankish kingdom, and received gifts and letters from Pepin the Short.

Edbert resigned in 758 and became a cleric at York. He and his brother Egbert were buried at York, in the same chapel. His son Oswulf, who succeeded him, was killed within a year and the throne passed to a nobleman called Aethelwald Moll.

EDDA, the name given to two books written in Iceland in the 13th century. These are commonly distinguished as the Prose Edda and the Poetic Edda. The name Edda was applied first to the Prose Edda and belonged originally to that book alone.

The Prose **Edda** (also called the *Younger* Edda, Snorri·s Edda) was written by the Icelandic chieftain Snorri Sturluson (1179–1241), probably during the years 1222–23. It is preserved in several medieval manuscripts, the oldest of which, written about 1300. is kept in the library of the University of Uppsala, Swed., and bears the colophon "this book is called Edda, and was put together by Snorri Sturluson . . ."

The meaning of the name Edda has been disputed and many interpretations have been offered, although few deserve to be repeated. According to one interpretation, the name is identical with the Icelandic word edda, "great-grandmother," and implies that the book is a collection of ancient tales. Others suggest that Edda is derived from *Oddi,* the name of the farm where Snorri was brought up and educated. An equally plausible explanation is that the name Edda is derived from *óðr,* "poetry," and that it means "poetics." Whatever the meaning of-its name, the Prose Edda is, in fact, a handbook of poetics.

The Prose Edda is divided into four sections, Prologue, *Gylfaginning,* Skdldskaparmdl, Hdttatal. The last section, the Hdttatal (List of Verse Forms), was probably written first; it consists of a poem in three parts addressed to King Hákon (1204–63) and Earl Skúli (d. 1240), the rulers of Norway. The poem contains 102 strophes, which exemplify 100 different forms of verse. The distinctive features of each form are explained in a running commentary, which makes the Hdttatal an invaluable source for the study of early Norse measures and verse forms.

Interesting as it is for the student, the Hdttatal is of little value as literature. It is preceded by the Skdldskaparmdl (Speech of Poetry), in which Snorri explains the diction of poetry, and especially that of the poetry of the scalds. The chief characteristic of scaldic diction was in its kennings, or periphrases, many of which are obscure. These kennings might be based upon similes drawn from the world of nature, for example, the ship could be called the "horse of the sea." Alternatively, they might be based upon allusion to an incident in myth or legend, in which case the kenning could be explained only by telling the story. To take one example, gold is called the "corn of Fýrisvellir" or the "corn of Kraki." These kennings were based on a legend about a raid nhich Hrólf Kraki, king of the Danes, was supposed to have made on the king of the Swedes in the 5th century. The king of the Danes and his champions had seized the Swedish treasure and, as they rode away over the plains of Fýrisvellir, they escaped capture

by strewing gold behind them, as if it were corn, causing the Swedes to stop and pick it up.

In other chapters of the *Skáldskaparmál,* Snorri retells legends of Sigurd. Brynhild, the Burgundian heroes and the Norse gods. He includes the story of the origin of poetry, the precious mead brewed by the dwarfs, and afterward stolen by Odin (Óðinn). It is largely for stories such as these that the *Skáldskaparmál* is read today. but it also contains much information about the history of Icelandic and Norwegian poetry. The various types of kennings are illustrated with examples from the works of poets who had lived between the 9th and 12th centuries. This poetry had been preserved orally and much of it is recorded nowhere else.

The *Skáldskaparmál* is preceded by the *Gylfaginning* (Beguiling of Gylfi), which is the most interesting section of the *Prose Edda,* serving as an introduction to the *Skáldskaparmál* and the *Háttatal.* Both the diction and the subjects of poetry were closely associated with myths of the gods and poetry could not be properly understood without some knowledge of mythology. The *Gylfaginning* is an account of the Norse gods and, like many learned works of the middle ages, it is cast in the form of dialogue.

Gylfi, described as king of the Swedes, comes to Ásgard, the citadel of the gods, intending to discover the source of their power. The gods, by virtue of their magic, deceive his eyes. and Gylfi is brought into the presence of three figures, High. Equally High and Third, all of them emanations of Odin. Answering his questions. they tell Gylfi about the beginning of the world. the adventures of the gods and the fate in store for all in the Ragnarok (Doom of the Gods) The sources which Snorri used for the *Gylfaginning* were chiefly lays about the gods, many of which are preserved in the *Poetic Edda,* although others are lost.

The Prologue of the *Prose Edda* stands somewhat apart. In it the descent of the Norse gods is traced from heroes of Greece and ultimately from Adam. The influence of European and especially of early English genealogies is patent.

The *Prose Edda* has won universal admiration as a masterpiece of narrative art, but its value as a record of mythology has been much questioned and some critics of the early 20th century rejected it altogether. In recent years, however, scholars have seen reason to place greater faith in Snorri's knowledge of pagan tradition, even though he was educated as a Christian and worked more than two centuries after Iceland had been converted to Christianity.

The Poetic Edda (also called *Elder Edda, Saemund's Edda)* is the name given to a manuscript written in the second half of the 13th century and preserved in the Royal library. Copenhagen. Den. It belonged formerly to the Icelandic bishop Brynjólf Sveinsson (1605–75), who gave it the title *Edda Saemundi multiscii* (Edda of Saemund the Learned), thereby showing that he believed it to be the work of the Icelandic historian Saemund Sigfússon (1056–1133). It is plain, however, that the book was compiled at a much later period than that of Saemund, although some of the poetry contained in it is among the oldest preserved in a Scandinavian language.

The poetry of the *Edda* falls into two groups, the mythological and the heroic. The mythological poetry consists of lays in various metres and of various ages about northern gods. The first in the book is the *Völuspá* (Sibyl's Prophecyj, a lay of some 60 strophes, in which the story of the world and of the gods is told from the beginning until the Ragnarok. when the gods will face death. There is no poem in all Germanic literature of greater scope and magnificence.

The *Völuspá* is followed by the *Hávamál* (Words of the High One), which consists of fragments of various poems, all of which are didactic and supposed to be spoken by Odin. The god discourses on social conduct. and speaks finally of the runes and the power of his magic. Other didactic poems in the *Edda* are the *Vafþrúðnismál* (Words oi Vafthrúdnir). the *Grímnismál* (Words of Grímnir) and the *Alvíssmál* (Words of the All-knowing). In the *Lokasenna* (Flyting of Loki), Loki, the demon, bandies words with the gods. taunting them with coarse jests. In the *Þrymskviða* a tale is told of Thor and in the *Skírnismál* a love story about Frey (Freyr), the god of fertility.

The ages and origins of mythological poems in the *Edda* have been disputed. While it is nearly certain that the *Völuspá* dates from the end of the 10th century and was composed in Iceland, there can be little doubt that many sections of the *Hávamál* as well as the *Skírnismál* and several other poems are considerably older and of Norwegian origin. Some of the lays may well have been composed by Norse settlers in the British Isles.

A number of mythological poems comparable with those of the *Edda* are found in other manuscripts. Among these may be mentioned the *Baldrs Draumar* (Dreams of Balder [Baldr]) and the *Rígsþula* (Song of Rigr).

The second half of the *Poetic Edda* comprises lays about ancient Germanic heroes. The hero of the first of them, *Völundarkviða,* is Wayland the Smith, who was famous as a craftsman in legends of England and Germany as well as of Scandinavia. The heroes of three of the lays are Scandinavians, but those who figure in the rest are all continental Germans. Searly all of the lays are associated with legends of Sigurd, Brynhild and the Burgundian heroes. Like the mythological lays, the heroic ones are of various ages and origins. Some of them. such as the *Hamðismál* (Words of Hamdir) and the *Atlakviða* (Lay of Atli) appear to be derived from continental poems as old as the jth and 6th centuries, although later recast in the Sorse language. Others appear to have been composed in Norway and in Iceland between the 10th and the 12th centuries. and one, the *Grípisspá* (Prophecy of Gripir), can hardly be older than the 13th century. *See* also ICELANDIC LITERATURE.

BIBLIOGRAPHY.—The *Prose Edda* has been published in many editions, among which may be mentioned *Edda Snorra Sturlusonar,* ed. by Jón Sigurdsson and others (1848–87); *Edda Snorra Sturlusonar,* ed. by Finnur Jónsson (1931). Facsimiles of important manuscripts have been published in *Corpus Codicum Islandicorum Medii Aevi,* vol. ii, xiv, xvii (1931–45). The best translations in English are those of A. G. Brodeur, *The Prose Edda, by Snorri Sturluson* (1916), and of J. I. Young, *The Prose Edda of Snorri Sturluson* (1954).

There are many editions of the *Poetic Edda* and among the best are *Norræn Fornkvæði,* ed. by S. Bugge (1867); *Die Lieder der Edda* I–IV, ed. by B. Sijmons and H. Gering (1888–1931); G. Neckel, *Edda* I–II (1927 and 1936), vol. *i* rev. by *H.* Kuhn (1962); J. Helgason, *Eddadigte* I–III (1951–52). Facsimiles: *Codex Regius af den Ældre Edda,* ed. *by L.* Wimmer and Finnur Jónsson (1891); *Codex Regius of the Elder Edda (Corpus Codicum Islandicorum Medii Aevi,* vol. x), introduction by A. Heusler (1937). The best English trans. is that of A. Bellows, *The Poetic Edda* (1923). (*G.* T.-P.)

EDDI (EDDIUS or **AEDDI**) (c. 650–c. 720), also known as Stephanus, a Kentish monk and choirmaster, was employed by Wilfrid bishop of York, to organize services in Northumbria. The *Life* of Wilfrid is ascribed to him, though without any very strong evidence. It is of great value, though very partisan in feeling, and was used by Bede.

See B. Colgrave (ed.), *Life of Wilfrid* (1927), with introduction and Eng. trans., and "The Earliest Saints' Lives Written in England," in *Proceedings of the British Academy,* pp. 55–60 (1958). (PL. GN.)

EDDINGTON, SIR ARTHUR STANLEY (1882–1944), British astronomer. particularly known for his studies of stellar motion and composition and for his support of the theory of relativity. was born at Kendal, Westmorland, on Dec 28, 1882. He nas educated at Owens college, Manchester. and at Trinity college, Cambridge, nhere he nas senior wrangler in 1904 and Smith's prizeman in 1907. In the latter year he was elected a fellow of Trinity. From 1906 to 1913 he held the post of chief assistant at the Royal observatory at Greenwich. In 1913 Eddington was elected to the Plumian professorship of astronomy and experimental philosophy at Cambridge as successor to Sir George Darwin, and in the following year he became director of the university observatory, succeeding Sir Robert Ball.

Eddington's earliest papers dealt with problems of stellar motions and distribution. and in 1914 his first book. *Stellar Movements and the Structure of the Universe,* was published. A model of scientific exposition. it contains what is probably the best general discussion of moving star clusters. Its final chapter, entitled "Dynamics of the Stellar System." marks the foundation of an important branch of astronomical research. Eddington was the father of dynamical stellar astronomy.

In 1916 Eddington began the fundamental researches which cre-

ated the present-day theory of the internal constitution of a star. His crucial hypothesis was that the energy emitted as light and heat from the stellar surface was transmitted throughout the interior in the form of radiation also. He concluded that most stars were gaseous throughout and he made the major discovery that the mass and the luminosity of a star were related. The great densities of the "white dwarf" stars and the nature of the interstellar medium were also illuminated by his work. Eddington drew his researches together in *The Internal Constitution of the Stars* (1926), a book which became one of the classics of astronomy.

Concurrently with these investigations Eddington had, from the year 1917, become deeply interested in Einstein's theory of relativity. He led one of the expeditions to observe the total eclipse of the sun of May *29.* 1919. The data he obtained at the island of Principe (west Africa) verified one of the predictions of general relativity, namely, that the positions of stars seen just beyond the eclipsed solar disk should be slightly displaced away from the centre of the disk. The existence of this phenomenon had not been suspected until it was revealed theoretically by general relativity. Eddington's books *Space, Time and Gravitation (1920)* and *The Mathematical Theory of Relativity* (1923) did much to make relativity known to the English-speaking world. From 1930 onward he worked on a unification of general relativity and the quantum theory. He believed that he could calculate mathematically. and without appeal to observation, the values of those constants of nature which are pure numbers, for example, the ratio of the mass of the proton to that of the electron. This notion. which has not won general acceptance, was derived from his attitude to the philosophy of science. Eddington believed that a great part of physics simply reflected the mode of interpretation which the scientist imposes on the data of observation. This view was developed mathematically in the *Relativity Theory of Protons and Electrons* (1936), *Tlte Combination of Relativity Theory and Quantum Theory* (1943) and in a posthumous volume edited by Sir E. T. Whittaker, *Fundamental Theory* (1946), works in which an astonishing number of the constants of nature were calculated. Eddington's main philosophical writings are *The Nature of the Physical World (1928)* and *The Philosophy of Physical Science* (1939).

Eddington's influence on modern astronomy was great—not only because of the actual results that he obtained, but also because of the stimulating effect of his writings on the thought and research of other workers. He was. moreover, extraordinarily gifted in popular exposition. He received many honours during his lifetime; he was made a knight bachelor in 1930 and received the order of merit in *1938.* He died on Nov. 22, 1944.

Sue the obituary notice by H. Spencer Jones and E. T. Whittaker in vol. 105 of the *Monthly Notices of the Royal Astronomical Society; A.* Vibert Douglas, *The Life of Arthur Stanley Eddington* (1956).

(W. W. M.; **A.A.;** G. C. McV.)

EDDY, MARY BAKER (*1821*–1910), discoverer and founder of Christian Science (*q.v.*), was born July *16, 1821,* at Bow, near Concord, N.H., the sixth and youngest child of Mark and Abigail Baker, both Congregationalist descendants of old New England families. Because of frequent interruption due to illness, Mary's formal education was quite limited, but she read and studied at home, aided by her brother Albert. She early began to write both prose and poetry. Her first husband. George W. Glover, whom she married in *1843,* died before the birth of their son, George, the only child she was to bear. Because of his mother's ill-health the boy was reared largely by others and had little contact with her.

Suffering almost constantly from a spinal malady, Mrs. Glover was much preoccupied with questions of health. She experimented with homeopathy and in *1853* married Daniel Patterson, a dentist. who shared this interest; the union, which was not happy, ended finally in divorce. Before this occurred, however, Mrs. Patterson had heard of Phineas Parkhurst Quimby (*q.v.*) of Portland, Me., who was performing remarkable cures without medication or surgery. She sought him out and was healed. She was warm in his praise, thought that he had rediscovered the healing method of Jesus, studied his notes, lectured on his method and wrote of it in regional periodicals. How much, if anything, her later discovery of Christian Science owed to the influence of Quimby is one of the moot questions of scholarship. Quimby died, and after a time there was a recurrence of her illness. Then in *1866* she had a bad fall; she asserts that her case was hopeless. She turned to her New Testament, and in reading it was healed. This she regarded as the discovery of Christian Science. Separated now from her husband, she lived for a number of lonely years in rented rooms, all the time seeking to put down in writing her slowly evolving system of Christian Science. She discussed it with some, taught it to Hiram Crafts, Richard Kennedy and others who became successful healers. She began to take students on a fee basis, and her fortunes began to improve. In *1875* she published *Science and Health,* which with many revisions and additions before her death became *Science and Health With Key to the Scriptures,* regarded by her followers as divinely inspired, and, along with the Bible, forming the scripture of the new faith. In *1877* she married Asa G. Eddy, one of her followers.

Mrs. Eddy's first public meetings were held in Lynn, Mass., then in Roxbury and Boston. First formal steps to organize The First Church of Christ, Scientist, were taken in *1879.* In *1881* she founded the Massachusetts Metaphysical college, where she taught till it was closed in *1889,* to be succeeded by a gradually developed system of primary and normal class instruction. Meetings in Boston were held first in rented halls, but in *1895* The Mother Church was dedicated; it was quickly outgrown, and in *1906* the imposing "extension," still one of the outstanding landmarks of Boston, was completed. Members of branch churches may and many do belong also to The Mother Church. It was governed during her lifetime according to directives issued from time to time by Mrs. Eddy, and these, collected and revised many times by her before her death, form the *Church Manual.* Like *Science and Health,* it is regarded as divinely revealed. The self-perpetuating board of directors, set up by Mrs. Eddy, became the ruling authority after her passing, operating, they affirm, according to the *Manual,* which cannot be amended. In *1883* she founded the monthly *Christian Science Journal;* in *1898* the weekly *Christian Science Sentinel;* and in *1908* the *Christian Science Monitor,* one of the great daily newspapers of the United States. Other machinery for the administration of a growing movement Mrs. Eddy created as needed: the Christian Science Publishing society, the board of education, the board of lectureship, the committee on publication.

Mrs. Eddy made her home for a time in Lynn, then moved to Boston, later to Concord, and finally to Chestnut Hill, where on Dec. 3, *1910,* at the age of *89,* she died.

Her philosophy and that of Christian Science is a pure idealism. There is only one reality: Mind, God, Good. Matter is unreal; so also is evil. Other idealisms had existed both in the orient and in the west, but few had drawn from the philosophy the practical corollary of healing that Mrs. Eddy drew and made central in her system.

A list of Mrs. Eddy's writings may be found in most editions of *Science and Health.* Among her major works, in addition to those cited, are *Miscellaneous Writings* (1896), *Retrospection and Introspection* (1892), *Unity of Good (1908)* and *Rudimental Divine Science (1908).*

BIBLIOGRAPHY.—Officially approved are: Sibyl Wilbur, ***The Life*** *of Mary Baker Eddy* (1908), various revisions; Lyman P. Powell, *Mary Baker Eddy* (1530). *See* also Edwin F. Dakin, *Mrs. Eddy* (1929), and Charles S. Braden, *Christian Science Today* (1958), both of which include extensive bibliographies, including all of Mrs. Eddy's own writings, and most other basic sources, published and unpublished.

EDDY: *see* WHIRLPOOL.

EDE, a town in the province of Gelderland, Neth., lies 11 mi. N.N.W. of Arnhem. Pop. *(1957* est.) *54,253* (mun.). The museum in the National park, *De Hoge Veluwe,* contains the modern-art collection of Kroller-Miiller, particularly paintings by Vincent van Gogh. Ede, which is a garrison town. has five public parks, the Doesburger mill dating from *1507* and an open-air theatre. There is a rayon-yarn factory and other industries include metallurgy and the making of pianos. The surrounding district has a con-

siderable number of dairy and poultry farms and in Ede are factories for processing dairy products and also a dairy research institute. (H. M. OL.)

EDELINCK, GERARD (1640–1707), Flemish copperplate engraver, who with Robert Nanteuil and Antoine Masson formed the great triumvirate of the best period of French portrait engraving, was born in Antwerp on Oct. 20, 1640. He learned the rudiments of the art in his native town under Gaspard Huybrecht. He then went to Paris in 1665 and worked under F. de Poilly. On the recommendation of Charles le Brun. he was appointed teacher at the academy established at the Gobelins to train workers in tapestry. In his engravings Edelinck excelled in rendering light and shade, colour and the texture of surfaces. He was the first to execute prints in the lozenge shape. Among his works. which number 341, are a "Holy Family" after Raphael, a "Penitent Magdalene" after Le Brun, "Alexander at the Tent of Darius" after Le Brun, a "Combat of Four Knights" after Leonardo da Vinci. "Christ Surrounded by Angels," "St. Louis Praying" and "St. Charles Borromeo Before a Crucifix"—the last three after Le Brun. Edelinck engraved portraits of Louis XIV. Le Brun, Hyacinthe Rigaud. Philippe de Champaigne (which the engraver thought his best), Santeul, La Fontaine, Colbert, Dryden, Descartes, etc. He died in Paris on April 2, 1707. His two brothers, Jean and Gaspard François, and his son Nicolas were also engravers, but did not attain to his excellence.

EDELWEISS (Leontopodium *alpinum*), a perennial plant of the family Compositae (*q.v.*), native of the Alps and the Andes. It is a small ornamental herb about six inches high, with narrow white woolly leaves. and terminal flower heads enveloped in woolly bracts. The woolly covering is assumed to protect the plant, in the exposed situations in which it is found. by preventing its drying up through excessive loss of moisture. It is much sought after by visitors to the Alps. Although rather sporadic in its distribution it is not rare and grows readily in gardens under lowland conditions.

J HORACE MCFARLAND COMPANY

EDELWEISS (LEONTOPODIUM ALPINUM)

EDEMA is a swelling due to effusion of watery fluid into the intercellular spaces of connective tissue. Edematous tissues are swollen and, when punctured, secrete a thin incoagulable fluid. This fluid is essentially an ultrafiltrate of serum but also contains small amounts of protein. Minor differences in composition are found in various diseases with which edema is associated. The fluid is also called a transudate to distinguish it from the protein-rich, leucocyte-containing exudate of inflammation (*q.v.*). Generalized edema (dropsy, hydrops) may involve the cavities of the body as well as the tissues with the excessive accumulation of fluid. Edema is usually a symptom of disease rather. than a disease in itself and may have many causes, most of which can be traced back to gross variations in the physiological mechanisms that normally maintain a constant water balance in the cells, tissues and blood. Among the causes may be diseases of the kidneys. heart. veins or lymphatic system; malnutrition; or allergic reactions. The treatment of edema generally consists of correcting the underlying cause, such as improving kidney or heart function. Edema may be a purely local condition (e g., hives) or a general one (*e.g.*, nephrotic edema). A swelling of the limbs, face or some other region of the body is sometimes called anasarca. The terms dropsy, hydrops and anasarca are somewhat archaic, however, and edema has come to be the preferred term. A related term, ascites (*q.v.*), is used to describe excess fluid in the peritoneal cavity.

Maintenance of Normal Fluid Balance.—The amount of water in the body at any one time is the balance between intake and output. In healthy parsons, water is lost through the urine, sweat, breath and skin and is gained through the intake and metabolism of food and drink. In healthy adults, water makes up from 40% to 60% of body weight. The percentage is higher in infants and children, greater in lean than in fat individuals and higher in men than in women. When the water content rises about 10% above normal, edema becomes noticeable. Body water is considered to be distributed in three compartments or spaces: (1) the intracellular (approximately 70% of body water); (2) the interstitial (22.5%); and (3) the vascular (7.5%). The interstitial and vascular compartments together make up the extracellular space. In addition there are potential serous cavities (*i.e.*, those lined by a membrane whose surface is moistened by a thin fluid derived from the serum or lymph) in the body, such as the pericardial sac, the pleural and peritoneal cavities and the joint spaces, that can become edematous. Normally the serous cavities contain only a few millilitres of lubricant fluid.

Another view of body water distribution does not recognize rigid compartments. The interstitial tissue, or ground substance, is considered to be a gel continuum in which gradients of solute and moisture content normally exist. These "water-poor" and "water-rich" phases of ground substance are in dynamic equilibrium with water in cells, in the body cavities and in the circulation.

Renal control of the amount of water in the body depends on the kidneys' ability to vary excretion and retention of water and solutes, particularly sodium ions, according to circumstance. A highly complex, integrated mechanism assists the kidney: this mechanism involves nervous control of the kidney; blood flow to it; the integrity of renal cellular structure and function; the activity of pituitary, adrenal and other endocrine glands; and a possible regulating system of hypothetical sensing organs (*e.g.*, volume, stretch or chemical receptors). The action of hormones typifies the integrated nature of the supplemental regulators. Steroid hormones (*e.g.*, aldosterone) cause the kidney to retain sodium and other minerals, while pituitary antidiuretic hormone causes the kidney to retain water. A hormone that induces the kidney to excrete minerals also has been suggested. (See also EXCRETION [KIDNEY]; KIDNEY, DISEASES OF.)

Other factors, in addition to renal control, that affect the distribution of water in the body are those whose actions (1) regulate the passage of water and electrolytes through the capillary wall; (2) affect the permeability of basement membrane. endothelial and other cells; and (3) maintain tissue turgor (interstitial tissue pressure). Among these factors are intravascular hydrostatic pressure; gravity; cardiac output; the resistance of the vascular bed; environmental temperature; the effects of poisons, toxins and chemical substances such as histamine on permeability; the degree of polymerization of interstitial tissue; lymph flow; nutrition; and the osmotic pressure and distribution of the plasma proteins and electrolytes. The plasma proteins — particularly albumin — exert a continuous osmotic pressure in the circulation because the capillary wall is practically impermeable to them.

Translocations of water within the body can be explained only partially by known physical and chemical forces, but it appears that chemical hydration and electric potentials effect the exchange of water within the organism. It has also become apparent that living cell membranes participate actively in fluid exchange, causing water and solutes to move in a direction opposite to their concentration gradient.

Edema in Health.—Swelling due to an accumulation of fluids in the tissue spaces, such as in the feet and ankles late in the day or after standing or walking for lengthy periods, is a common experience. "Shipboard edema" may break out in healthy travelers when they enter the tropics. Edema of these types results from the combined effects of gravity, pressure on veins and distention of peripheral vessels; such edema is likely to occur when pressure in the veins is somewhat higher than normal; *e.g.*, as a result of pregnancy or varicose veins. Normal endocrine activity may also produce accumulations and translocations of water because of its effect on connective tissue and its control of renal function. In women the normal cyclic ebb and flow of hormones associated with menstruation sometimes causes the kidney to re-

tain water and sodium. Total body water increases and a premenstrual weight gain is noted.

Edema Associated With Disease can be divided into three groups: (1) generalized edema; (2) local edema; and (3) collections of fluid in the body cavities.

Generalized Edema.—In cardiac, renal, nutritional, endocrinologic and all other forms of generalized edema there is an increase in total body water; a complex process is invoked to explain its development. For example, in cirrhosis of the liver associated with alcoholism fluid usually collects in the peritoneal sac (ascites) and may collect in the legs, scrotum and pleural cavities. The scars, fibrous tissue bands and regenerating cells in the damaged liver squeeze the portal vein in the liver and raise its interior pressure. This increases the permeability of the portal capillaries and causes water to escape into the peritoneal cavity. In addition, the damaged liver cannot synthesize albumin, and the albumin level in the blood falls. There is consequently a drop in plasma osmotic pressure, and fluid escapes from the blood into the tissues. The loss of appetite causes malnutrition, and the tissues waste. Tissue turgor (interstitial pressure) lessens, and water takes up the slack. The damaged liver cannot inactivate steroids as usual, and they accumulate. Adrenal steroids consequently appear in excess, perhaps through stimulation by a volume receptor that may sense the change in blood volume because of albumin depletion. These steroid excesses increase renal retention of sodium and water. Thus it can be seen that many mechanisms work separately and together to produce edema and ascites. Edema also appears in other types of liver disease, such as schistosomiasis, hepatoma, Chiari's disease and hepatitis. (See also GALL BLADDER, BILIARY TRACT AND LIVER, DISEASES OF: Liver.)

Cardiac failure is often accompanied by edema. If the patient is up and about, the edema settles in the legs; if the patient remains in bed, the edema collects in the sacral skin and subcutaneous tissues. Congestive or backward heart failure is commonly seen with valvular defects. High-output or forward heart failure results from anemia, hyperthyroidism, uremia, cholemia and beriberi. Acute (left-sided) heart failure produces pulmonary edema, which may also result from changes in the permeability of lung capillaries brought about by the inhalation of chemicals such as mustard gas. (See also HEART, DISEASES OF.)

Renal disease frequently manifests itself through the development of edema, usually in the eyelids and face as well as in the dependent parts; it is most noticeable after lying down for several hours. The reasons why the face and eyelids are involved are not clear. Edema develops commonly in acute Bright's disease (*q.v.*), the nephrotic syndrome and, less commonly, in chronic renal failure. It appears in acute renal failure when excess fluids are ingested. Water intoxication, due to impairment of the kidneys' ability to excrete water, is seen after operations, in acute renal failure and as a terminal event in some cases of liver or heart failure.

Nutritional edema occurs most frequently in one of two forms: (1) starvation, or famine, edema and (2) edema due to a low level of protein intake. Vitamin B_1 deficiency (beriberi) and potassium deficiency also can produce edema. Starvation edema (caused by famine, anorexia nervosa, cancer, etc.) is usually the result of loss of tissue turgor, but other factors, such as renal sodium retention, contribute to the development of edema. Initial treatment of starved patients with salt-containing fluids or food may be dangerous, as the ingested salt may produce edema and heart failure. Protein malnutrition may be due to poor dietary intake, as in tropical malnutrition (kwashiorkor), or to loss of proteins from the skin (as in burns) or their loss through the urine (nephrotic syndrome) or gut (enteropathic hypoalbuminemia).

Edema also may occur in either natural or man-made endocrine disturbances. Generalized edema also occurs in pregnancy as a part of the clinical picture of pre-eclampsia or toxemia. It may appear cyclically in women who have psychoneurosis. It is commonly produced as a side effect of treatment with steroid hormones and may be seen in the newborn children of diabetic mothers.

Local edema usually results from translocations of fluid; the total volume of body water remains unchanged or is increased only slightly. It may result from local changes in capillary permeability due to many types of injury, such as (1) introduction of toxins (*e.g.*, local swelling after mosquito bites); (2) introduction of allergens followed by allergic reactions associated with the release of histamine in the tissues (*e.g.*, angioneurotic edema of lips, tongue and throat); (3) obstruction to venous return (*e.g.*, thrombophlebitis or pressure of tumours on veins); (4) lymphatic obstruction (*e.g.*, elephantiasis due to filariasis). (See also LYMPH AND LYMPHATIC SYSTEM: Diseases of the Lymphatic System.)

Collections of *fluid* in the body cavities may occur when the cavities become inflamed or are invaded by cancer; these conditions, however, are not considered to be edematous. Pleural and pericardial effusions are common in states of general edema (see also PLEURA, DISEASES OF: Pleural *Effusion*), but effusions into joints (hydrarthrosis) are rare except in rheumatic disorders. Obstructions of veins (*e.g.*, due to portal vein thromboses) or lymph channels also produce effusions of fluid. The accumulation of excess fluid within the ventricles of the brain (hydrocephalus, *q.v.*) is thought to be the result of inflammatory obliteration of the subarachnoid channels through which the cerebrospinal fluid normally circulates.

See E. H. Starling, "The Fluids of the Body," Herter Lectures (1909); J. H. Moyer and M. Fuchs (eds.), Edema: Mechanisms and Management, a Hahnemann Symposium on Salt and Water Retention (1960). (R. M. K.)

EDEN, SIR (ROBERT) ANTHONY: see AVON, (ROBERT) ANTHONY EDEN, EARL OF.

EDEN, a legendary area where, according to the Old Testament, God planted a garden (translated "paradise" in the Septuagint) for Adam, the first man, to inhabit; there grew the tree of knowledge and the tree of life and there the fall of man took place (Gen. ii–iii). Eden itself lay east of Palestine (Gen. ii, 8), or at the source of the Tigris and the Euphrates (Gen. ii, 10–14) or on a mountain in the south (cf. Ezek. xxviii, 13, 14; Isa. xiv, 13).

The pentateuchal source "J" (see PENTATEUCH) of Gen. ii–iii worked the material of an older creation myth into his story of the garden of Eden without reconciling some contradictory elements. Thus, in the Genesis story Adam is not totally ignorant (Gen. ii, 20) and being created out of the earth (Hebrew adama) he is naturally mortal (Gen. ii, 7). The story of the garden of Eden attempts to explain man's progression from the innocence and state of bliss in which he was created to his present condition of knowledge and misery. It attributes the fall to ambition (hubris), whereby man is not merely content with obedience to the will of God but also desires the "knowledge of good and evil" (a classic expression for all knowledge) which is the prerogative of God and which in addition has been expressly forbidden to him (Gen. iii, 5). The act of disobedience suggested by the serpent, a subtle tempter (Gen. iii, 1), brought a triple punishment from God: the serpent is to be hated by mankind, the woman is to have painful childbirth and the man is to till the earth, which is henceforth cursed (Gen. iii, 14–19). Death, being the natural result of Adam's earthly nature (Gen. iii, 19), is not part of the punishment. But the tree of life could give him immortality, so Adam has to be driven out of the garden where it grows (Gen. iii, 22–24). Immortality was a stake of the game, lost by the free choice of Adam (his sin properly speaking) for a knowledge which would bring him to an equality with God, but which in fact had a laughable conclusion: the discovery that he was naked (Gen. iii, 7 Thus the story of paradise lost gives a pessimistic verdict on the human race, and shows a fundamental religious distinction in Israel: the distance in essence between man and God, the radical conflict between man's ambition and God's absolute sovereignty. See also ADAM AND EVE.

See Hans Schmidt, Die *Erzählung* von *Paradies* und *Sündenfall* (1931); P. Humbert, *Études sur* le *récit* du *paradis* et de la chute *dans* la *Genèse* (1940). (P. HT.)

EDENBRIDGE, a market town and civil parish in the Seven-

oaks rural district of Kent. Eng., 11 mi. S.W. of Sevenoaks by road, and with two railway stations. Pop of civil parish (1951) 3 533. It lies on the Eden. an affluent of the Medway, near the Surrey border, and has considerable agricultural trade. The church of St Peter and St Paul is principally Perpendicular. The Crown inn dates to' the 15th century Stangrove park (48 ac.) and another 47 ac have been developed to house some of London's overspill population. Light industries were also introduced

Hever castle 2 mi. S.E., is a beautiful moated mansion of the 15th and 16th centuries on the site of an earlier structure rebuilt by Sir Geoffrey Boleyn. the great-grandfather of Anne Boleyn. who spent much of her life there before her marriage to Henry VIII and was visited there by him. There is a Boleyn chapel in the church of Hever. Near Edenbridge is the modern Chiddingstone castle on an ancient site.

EDEN RIVER, in northern England, rises in the fells that connect the Lake district and the Pennine highlands and flows 90 mi. NW through the counties of Westmorland and Cumberland to its estuary in the Solway firth west of Carlisle. From Kirkby Stephen, nhere its narrow, steep-sided upper valley opens out into the lowland vale between the Pennine and Lake district highlands, it flows in a meandering course among the hummocky moraine surface of the vale past Appleby, which is sited in a river peninsula It receives short, swift right-bank tributaries from the great Pennine escarpment. and longer left-bank tributaries from the Lake district and its flanking limestone hills Its main tributary, the Eamont, collects drainage from the heart of the Lake district. including the discharge from Ullswater, and flows into the Eden near Penrith Where the Eden turns west above Carlisle it receives the Irthing which collects the drainage from the fells lying north and south of the Tyne gap near the Northumberland border. In its lower course, past Carlisle. the river flows in sweeping meanders across alluvial flats (holms). Carlisle commands the lowest bridge from a defensive site on the south bank, flanked by left-bank tributaries. the Petteril and Caldew, the latter floning from the northern slopes of Skiddaw. The river, even below Carlisle, is not navigable and discharges by shifting channels through the tidal flats at the head of the Solway firth. Just below Carlisle Hadrian's wall crosses the river toward its western end at Bowness on Solway. (AR E. S.)

EDENTATA, the mammalian order comprising modern tree sloths, true anteaters and armadillos and extinct ground sloths, glyptodonts and palaeanodonts. Edentates, like man, are placental mammals; that is, the pregnant mother and its developing young are united by a nutritive tissue. the placenta. These mammals, wholly new world in origin, range from southern Argentina northnard through South America and Central America to southern Mexico One species. the nine-banded armadillo, is found as far north as the southern part of the United States. Palaeanodonts appeared in the North American Paleocene epoch about 60,000,000 years ago and died out about 20,000.000 years later, during the Oligocene; their remains have been found in the Bridger formation of Wyoming and the Bad Lands of South Dakota. Ground sloths spread from South America into North America and the Antilles about 10 000,000 years ago and reached Pennsylvania on the east and southern California on the west.

The name Edentata, meaning toothless, is misleading. Only true anteaters are actually toothless. All other edentates lack the first tno or three front teeth, or incisors, of each jaw; otherwise they are provided with a series of simple degenerate cheek teeth covered with little ii any enamel. I1 tree sloths the foremost tooth of the series on each side of th upper and lower jaws is a canine-like tusk, but in ground sloths the tusk may be present or al t Palaeanodonts had similar t

Zoologists of th late 18th and 19th centuries included the African aardvark and old world pangolins (scaly anteaters) in the Edentata. There is no evidence, however, that either group descended from the original edentate stock that gave rise to new-world forms. The resemblances between pangolins and edentates are the result of similarities in their diets. Even the scales of the armature of pangolins are quite different from those of armadillos In pangolins the scales are overlapping. erectile and formed of cemented hairs. In armadillos the individual scales are rigid bony structures. The aardvark had been associated with new-world anteaters because of its feeding habits. long snout, extremely long tongue and degenerate dentition. But these characters alone prove no relationship. Pangolins are now placed in the order Pholidota, and the aardvark is in an order by itself, the Tubulidentata.

EARLIEST EDENTATES (PALAEANODONTA)

The suborder Palaeanodonta comprises the oldest and structurally the most primitive of known edentates. Their history extends from the Upper Paleocene to the Middle Oligocene (roughly. from 60.000.000 to 35,000.000 years ago). The known distribution is wholly North American, but the ancestral form may have come from Asia. A distinct branch of the old stock must already have entered South America during the earliest Paleocene and have given rise to the Xenarthra (true anteaters, sloths, etc). Although armadillolike in form and possibly in habits, palaeanodonts differ from all other edentates in having a normal (nomarthrous) type of articulation between the vertebrae of the posterior dorsal and lumbar regions.

The genus *Palaeanodon* of the Lower Eocene and Upper Paleocene has a reduced number of armadillolike cylindrical teeth; a partially ossified auditory bulla; a small. simple brain; slender limbs not greatly modified for digging; and, judged by the uncomplicated vertebrae. no hardened shield (carapace) or bony dermal plates (scutes). *Palaeanodon* may well have been ancestral to *Metacheiromys,* ahich lived about 50,000,000 years ago, during the Eocene.

Metacheiromys was about 18-in. long, including the tail, or about the size and proportion of a half-grown nine-banded armadillo (see *Dasypodidae,* below). The limbs were short. the front ones having been armed with strong claws. The high processes of the dorsal and lumbar vertebrae may have served as support for a carapace. Such a covering, if present, might have been horny rather than bony because scutes have never been found with the remains of palaeanodonts. The teeth of *Metecheiromys* mere reduced in number and, except for the tusklike canines, vestigial and nonfunctional.

SLOTHS, ANTEATERS AND ARMADILLOS (XENARTHRA)

General Features

The fundamental character of the suborder Xenarthra is the presence of one, two or three pairs of supplementary articular facets on the front and on the back part of each lower dorsal and lumbar vertebra. This condition is called xenarthrous ("strange jointed"), hence the subordinal name. In all other mammals, including palaeanodonts, each vertebra has the usual single pair of articular facets (the prezygapophyses) in front and a single pair (the postzygapophyses) in back. In the three-toed sloths the supplementary facets are poorly defined and do not articulate with the corresponding elements of the adjacent vertebrae. In

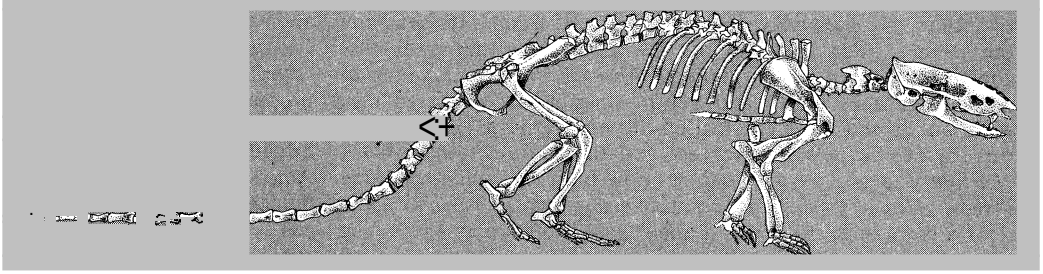

FIG. 1.—METACHEIROMYS, FOSSIL SKELETON OF AN ANCESTRAL EDENTATE OF THE SUBORDER PALAEANODONTA
Restored parts of skeleton are in outline, hypothetical parts are dotted

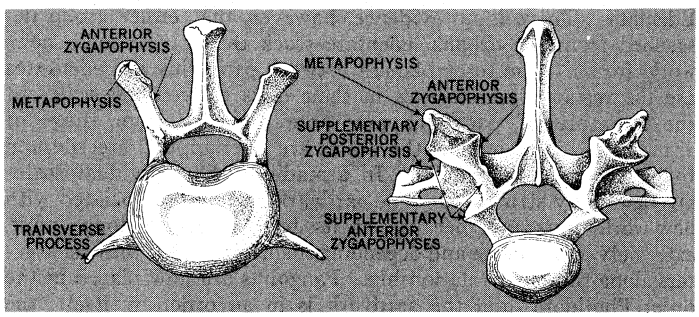

FIG. 2.— COMPARISON OF FIRST LUMBAR VERTEBRAE IN LION AND GREAT ANTEATER

(Left) Nomarthrous vertebra bf a lion, with one pair of anterior zygapophyses that articulate with the posterior pair of zygapophyses of the adjacent vertebra; (right) xenarthrous vertebra of a great anteater, with supplementary pairs of anterior zygapophyses that articulate with the corresponding supplementary posterior zygapophyses of the adjacent vertebra. Figures are front views

two-toed sloths supplementary articular facets are vestigial or absent. In all Xenarthra the sacrum is attached to the hipbones at two points instead of one as in other mammals. Still another complication of the vertebral column is the presence of six cervical vertebrae in the two-toed sloth (incidentally, the same number as in the manatee) and eight to ten cervical vertebrae in the three-toed sloth. In all other mammals the normal number of cervical vertebrae is seven.

The body may be clothed with hair. or the greater part may be covered with a body armour. The forefeet are provided nith strong claws adapted for digging, climbing or hanging. The tail, which may be short or long, is either covered with hair or scales or nearly naked; it is prehensile in the two smaller species of anteaters. The skull is globular in sloths. elongate in armadillos and almost tubular in the greater anteater; the interparietal bone is absent, and the tympanic bone annular and either partly free or completely fused with other elements in a well-developed auditory bulla. An entepicondylar foramen. or opening, is present in the humerus, and the third trochanter is absent in the femur. The placenta is deciduate, the uterus simple and the testes abdominal. Generally one young is produced at a birth. but in some armadillos the single fertilized egg secondarily develops into more than one embryo. The young are well developed at birth.

Hairy Edentates: Sloths and Anteaters

The infraorder Pilosa, or hairy edentates, comprises the ground sloths, tree sloths and anteaters, all South American in origin. Appearing about 40,000,000 years ago. during the Eocene, ground sloths were the dominant mammals from the Middle Eocene to the end of the Pleistocene, a span of about 25,000,000 years. Ground sloths spread into North America and the Greater Antilles about 10,000,000 years ago and persisted in forested areas until the very beginnings of the Recent epoch. Although ground sloths combine the characteristics of anteaters and true sloths, they have several features peculiar to themselves. All three groups were evidently derived from a common ancestor. Anteaters, as mentioned earlier, lack teeth. The dental formula for each upper and lower jaw in tree sloths is: incisors $\frac{0}{0}$, canines (caniniforms) $\frac{1}{1}$ premolars (molariforins) $\frac{4}{3}$; for ground sloths: I $\frac{0}{0}$, C $\frac{0}{0}$ or $\frac{1}{1}$, M $\frac{4}{3}$.

Megalonychidae.—The family of extinct ground sloths typified by *Megalonyx* originated in Patagonia about 40.000.000 years ago, but the genus in North America is known only from the Pleistocene. *Megalonyx* was about the size of an ox. Its head and teeth were similar to those of tree sloths but the lower jaw projected as a spout. The smaller *Nothrotherium* was common to the Pleistocene of North and South America and persisted into the Recent in southwestern United States. As in *Megalonyx* the structure of the pelvis. hind feet and tail indicates that *Nothrotherium* was capable of standing on its hind legs while browsing on trees. *Hapalops,* a more primitive ground sloth, was about the size of a large dog; it appeared about 25.000.000 years ago in the Patagonian Miocene. The West Indian ground sloths, which lived during the Pleistocene. may have been exterminated by early man. Ground sloths walked with the forefoot resting on the knuckles of the three middle digits, quite the same way as dces the present-day giant anteater. *Myrmecophaga tridactyla.*

Megatheriidae.—The family of extinct ground sloths typified by *Megatherium* includes the largest and most massive of edentates. The genus. known from the Upper Pliocene and the Pleistocene of Argentina, was the first of the ground sloth group to be discovered. One species, *M. americana,* was larger than a modern elephant, and the hind limbs were of extraordinary bulk. The "hand" had four functional digits and a vestigial thumb. The three middle toes bore long sharp claws that may have been partly retractile. The hind foot had three functional digits. the middle one of which bore an enormous claw. *Megatherium* walked on the knuckles and the outside edge of his front feet and on the turned-in sides of its hind feet. As in the Megalonychidae, *Megatherium* assumed an erect posture when feeding on leaves and twigs of tall trees

Mylodontidae.—Ground sloths typified by *Mylodon* nere intermediate in size between megatheres and megalonids They predominated in the Pliocene and Pleistocene of South America and were common in the Pleistocene of North America. The skull of *Mylodon* nas short and broad without a sagittal crest. the orbit widely open behind, the muzzle broad and truncate and the lower jan nith lower border straight and without spout A related genus. *Neomylodon,* which survived in Patagonia until the Recent epoch, had an internal layer of bony scales in the skin. The remains of the animal—consisting of the skull; large pieces of hide covered with coarse, yellow hair; and some dung—may have been but a few centuries old.

Myrmecophagidae.—Anteaters range throughout most of tropical America from northern Argentina to Guatemala and British Honduras The head is prolonged into a tubular muzzle through the small gape of uhich extends the long, slender. worm-like tongue.

The giant anteater. *Myrmecophaga tridactyla,* is the largest of living edentates It stands about two feet high and is about four feet long from the tip of the snout to the base of its bushy tail.

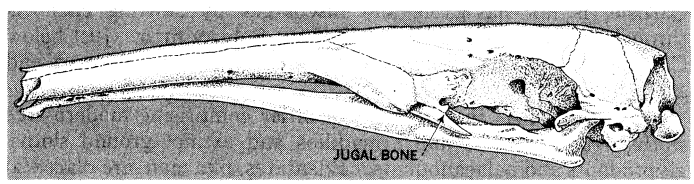

FIG. 3 — SKULL OF THE GREAT ANTEATER (MYRMECOPHAGA TRIDACTYLA)

The jugal and lower jaw bones, which serve for attachment of chewing muscles, are degenerate in anteaters

The tail itself adds about two feet more to the over-all length. Each hind foot has four or five toes; each forefoot has a strongly developed middle digit. the remaining digits being greatly reduced or vestigial. The claws of the front foot are hooked backward and serve the animal for ripping into ant and termite nests as well as for climbing and fighting. The enormously developed salivary glands of anteaters secrete the sticky substance that coats the tongue and traps the insects. The single young produced at a birth is carried for a time on the mother's back. The giant anteater walks clumsily on the soles and in-turned claws of its front feet. Though chiefly terrestrial, it can climb trees when necessary.

The lesser anteater. or tamandua, *Tamandua tetradactylu,* is about two feet long; the tail is nearly as long. sparsely haired and prehensile. The tamandua is mainly arboreal but frequently forages for ants on the ground. The two-toed or tiny silky anteater, *Cyclopes didactylus,* is about ten inches long, has a long, prehensile tail and is strictly arboreal.

Bradypodidae.—Tree sloths are the slowest moving and most arboreal of mammals. They inhabit the forested parts of tropical America from northern Argentina to Nicaragua. Although of undoubtedly very ancient lineage, tree sloths are unknown as fossils. The head is relatively small. short and rounded. and the eyes are placed low on the face. The tail may be either short or vestigial. Each of the extraordinarily long limbs. with the front ones longer than the hind, has two or three toes bound together in

BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM

FIG. 4.— RECONSTRUCTION OF A GROUP OF GIANT ANTEATERS (MYRMECOPHAGA TRIDACTYLA)

The young individual in front has ripped open a termite mound with the powerful claws of his front feet

a common integument and ending in long hooked claws. There are two mammary glands, located on the chest. A canine-like tusk is present in each jaw, the upper tusk closing in front of the lower (the reverse of the canine-tooth relationship in other mammals).

Sloths sleep during most of the day and feed on leaves, fruits and young shoots during the night. They hang back downward from the branches to which they cling with their hooked claws, or they assume a vertical position by embracing the tree trunk or upright branch with their legs. Sloths often sleep in a sitting posture. with the head hidden between the legs. The grav or drab colour of the sloth's pelage renders the animal inconspicuous during the dry season. In rainy periods, however, algae lodged on the surface of the hairs of the sloth's coat turn green and make concealment even more effective against the lush green background.

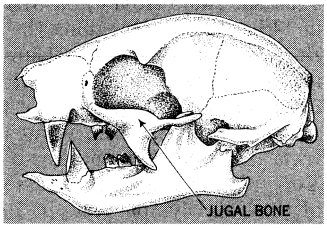

FIG. 5.— SKULL OF THE TWO-TOED SLOTH (CHOLOEPUS DIDACTYLUS)

This edentate is well provided with teeth but, unlike other mammals, its upper tusks close in front of the lower. The shape of the jugal bone in sloths is like that of extinct ground sloths and glyptodonts

The three-toed sloth (*Bradypus*) and the two-toed sloth (Choloepus) are the only members of the family. *Bradypus* has three toes on each front and hind foot. *Choloepus* has two toes on the front feet and three toes on the hind. Bradypus has 5 teeth in the upper jaw and 4 in the lower. 8–10 neck vertebrae, 14–16 thoracic vertebrae, 3–4 lumbar vertebrae and 11 tail vertebrae. The extra vertebrae in the neck permit the three-toed sloth to turn its head through three-quarters of a circle. *Bradypus* has little control over its body temperature; during a cold day its internal temperature may vary with the outside temperatures from 2S° to 35" C. In extremely cold weather the body temperature of *Bradypus* may drop to as low as 20° C. and the animal becomes torpid. *Choloepus* has the same dental formula as *Bradypus* but has a different vertebral ucture: 6–7 cervical r: 5 thoracic v ebrae, 3–4 lumbar vertebrae, 7–8 sacral vertebrae and 4–6 tail vertebrae.

The Indian names for *Bradypus* and *Choloepus, ai* and *unau,* respectively, are sometimes commonly used in other languages as well. Both animals are generally called *preguiça* in Brazil and *perezoso* (literally "lazy one") in other Latin-American countries.

ARMOURED EDENTATES

The infraorder Cingulata, or armoured edentates, contains the armadillos and glyptodonts, all of South American origin.

Dasypodidae.—All extant armadillos are characterized by shields of bony (ossified) dermal scutes which cover the head, back and sides of body and often the tail. The individual scutes are covered by a layer of horny epidermis.

Dasypodinae.—In typical armadillos, subfamily Dasypodinae, the head covering (cephalic shield) is separated from the body covering (carapace) by skin. The basketlike carapace is divided into an immovable shoulder (scapular) shield, an immovable rump (pelvic) shield and, between these, the dorsal field, consisting of a number of movable bands. Irregular bony scutes are scattered over the exposed parts of the limbs, whereas the face and inner sides of the body and limbs are soft and more or less clothed with hair. The tail and ears are usually well developed. Each forefoot has three to five toes and powerful, curved claws adapted for digging; the hind feet are plantigrade, each having five toes terminating in nails.

As in anteaters the tongue of armadillos is long, extensile and covered with sticky saliva secreted by the large submaxillary glands Two or four cervical vertebrae are fused to form the mesocervical bone. With the exception of Dasypus, all existing armadillos have but a single set of functional teeth In Dasypus all but the last of the nine permanent teeth have a two-rooted milk predecessor that remains in use until the animal is nearly full grown.

Armadillos escape from enemies by swift running or by burrowing with astonishing rapidity into the ground. They are omnivorous, feeding on insects, worms, roots, fruits, small vertebrates and carrion. Armadillo flesh is esteemed by the native hunters. and the carapace is sometimes used for making decorative baskets.

The nine-banded armadillo, *Dasypus novemcinctus,* is the best known and most widely distributed living member, of the family. It has a continuous range from northern Argentina to Kansas and Florida and from sea level to 10,000 ft. high in the Andes. Though not so adept at burrowing as most other armadillos, Dasypus can nevertheless dig itself out of sight in hard ground in about two minutes.

The apar (apara), or three-banded armadillo, *Tolypeutes,* has rounded shoulder and pelvic shields and from two to four movable bands between the shields. This arrangement permits the animal to roll itself into a ball, with its armoured head and tail fitting snugly against each other. It lives in northern Argentina, Paraguay, eastern Bolivia and eastern Brazil.

Priodontes, the giant armadillo, measures about 3 feet in total length, the tail occupying about 20 in. It also has 11 to 13 movable bands and bears an extremely large middle claw on each front foot. From 20 to 25 teeth may be found in each upper and lower jaw. The giant armadillo is confined to South America east of the Andes, from the Caribbean coast to Argentina.

Cabnssous, the large so-called eleven-banded armadillo, has 11 to 13 movable bands, a soft tail and powerful claws on its forefeet. It ranges from Argentina into Central America.

FIG. 6.—(LEFT) GROUND SLOTHS (MEGATHERIUM) AND (RIGHT) GLYPTODONTS (DOEDICURUS) OF THE PAMPEAN FORMATION IN ARGENTINA. ABOUT 500.000 YEARS AGO

The ground sloths were leaf eaters the size of elephants. The armadillolike glyptodonts, also plant eaters, used their spiked tails for protection against predators. Restoration from fossil skeletons by Charles R. Knight

Euphractus, Chaetophractus and *Zaedyus* are armadillos characterized by long abundant hairs projecting between the movable bands. *Euphractus,* the six-banded armadillo, is 20 in. long from snout to base of tail; *Chaetophractus,* the hairy armadillo, is 13 in. long; and the *pichi, Zaedyus,* is only 10 in. long. All three genera are found in South America east of the Andes and south of the Amazon.

Chlamyphorinae.—The Chlamyphorinae is the second subfamily of living armadillos. It differs from the Dasypodinae by having less completely ossified scutes; continuity between the shields of the head and back; the carapace of the back completely movable; the pelvic shield vertical to the long axis of the body and entirely separated from the dorsal carapace; the remainder of body clothed with long silky white hair. One species, the lesser *pichiciego, Chlamyphorus truncatus,* is about five inches long, with its dorsal shield attached along the mid-line of the back. Another species, the greater *pichiciego, Burmeisteria retusa,* has the entire dorsal shield attached to the skin of the back. These armadillos, natives of eastern Bolivia and northern Argentina, are the smallest and the most capable burrowing members of the family.

Fossil Armadillos.— Armadillos first appeared in southern Argentina about 55,000,000 years ago, during the Paleocene. Only a few fossil dermal scutes represent these animals. *Utaetus buccatus,* one of the best preserved of fossil armadillos, lived in the same region but about 5,000,000 years later. It combines the basic xenarthran and armadillo characters with a close resemblance to palaeanodonts. *Utaetus* may well be regarded as a descendant of palaeanodonts and nearly or actually ancestral to modern armadillos.

Stegotherium was a highly evolved armadillo that appeared later, during the Miocene. The reduction of its teeth to virtual obsolescence, together with extreme elongation of the muzzle, surpasses anything found in modern armadillos.

Another highly specialized armadillo is the Pleistocene *Chlamytherium,* which was equal in bulk to a rhinoceros. This genus was the culmination of a line of herbivorous armadillos that began with *Proeutatus,* during the Miocene.

Peltephilidae.—The Patagonian horned armadillos appeared about 30,000,000 years ago, during the Upper Oligocene, and disappeared a few million years later, in the Lower Miocene. The most conspicuous character of this family, typified by the genus *Peltephilus,* is the pair of high, cone-shaped horn cores located on the nasal and maxillary bones. *Peltephilus* differed in many respects from true armadillos. The pattern of its head shield is unique: its muzzle was short and broad; the teeth were arranged in a continuous series, with one incisor on each side of the mid-line of each of the two jaws; and the middle digit of each of the hind feet had a hooflike claw.

Glyptodontidae.—Glyptodonts, or turtle armadillos, are among the most bizarre of all mammals. Most glyptodonts are characterized by large size, the largest being about 14 ft. long and over 15 ft. high; the solid, immovable single carapace; the usually present ventral shield, or plastron; the retractability of the head into the body armour; and the complete fusion of the dorsal, lumbar and sacral vertebrae into a solid tube. Glyptodonts appeared in the South American Eocene about 40,000,000 years ago and spread into North America during the Pliocene and Pleistocene.

Early glyptodonts were rather small and not too different from their ancestors. The greatest diversification, particularly of the tail, took place during the late Pliocene and Pleistocene. In *Glyptodon* the tail had about ten heavy rings of dermal plates, the edges of which bristled with long, pointed projections. In *Doedicurus* the basal half of the tail was covered with six overlapping rings; the terminal portion of the tail was smooth and the tip thickened into a huge club-shaped mass studded with long sharp horns.

CLASSIFICATION

The order Edentata, with old-world forms excluded, is a natural assemblage. The principal subdivisions, to the family level, are arranged as follows (extinct groups are prefaced with an asterisk):

*Suborder Palaeanodonta
  *Fam. Metacheiromyidae
  *Fam. Epoicotheriidae
Suborder Xenarthra
  Infraorder Pilosa, hairy edentates
    *Superfam. Megalonychoidea, ground sloths
      *Fam. Megalonychidae
      *Fam. Megatheriidae
      *Fam. Mylodontidae
    Superfam. Myrmecophagoidea, true anteaters
      Fam. Myrmecophagidae
    Superfam. Bradypodoidea, tree sloths, sloths
      Fam. Bradypodidae
  Infraorder Cingulata, armoured edentates
    Superfam. Dasypodoidea, armadillos
      Fam. Dasypodidae
      *Fam. Peltephilidae
    *Superfam. Glyptodontoidea, glyptodonts
      *Fam. Glyptodontidae

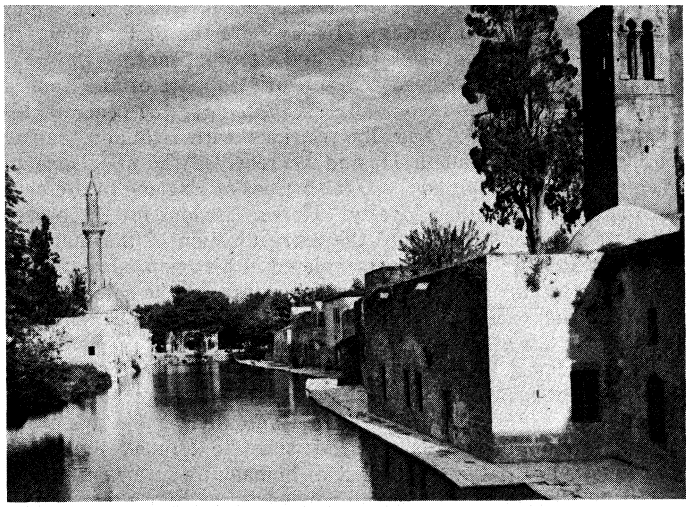
EDERLE, GERTRUDE CAROLINE (1906–), first woman to swim the English channel, was only 19 when on Aug. 6, 1926, she swam from Cape Gris-nez to Dover, a distance of 35 mi., in 14 hr. 31 min., breaking the world record by 1 hr. and 59 min. Born on Oct. 23, 1906 in New York city, "Trudy" won her first major international race at 14. She was a leading exponent of the 8 beat crawl *(see* SWIMMING: *Crawl Stroke).* In the early 1920s she set world and U.S. women's free style records for distances from 100 to 880 yd. and was a member of the championship New York Women's Swimming association free style relay teams and of the U.S. Olympic team in 1924, becoming a professional in the 1925–26 season. After her channel triumph she became a swimming instructor and fashion adviser. (J. D. McC.)

EDESSA, the chief city of the *nomos* (department) of Pella in Greek Macedonia, is the seat of the metropolitan bishop of Edessa and Pella. Pop. (1951) 14,940. The town is located 111 km. (69 mi.) W.N.W. of Salonika by railway and is on the main road from Salonika to Bitola, Yugos. It stands on a rocky height above the valley of the Loudhias river. The proliferation of its orchards and vineyards caused Edessa to be called in antiquity the "Garden of Midas," and the abundance of running water and streams, which pour down the rocks into the plain in a cascade on the eastern side of the town, gave it its medieval name of Vodena (Slav. *voda,* "water"). Rugs and carpets are manufactured there.

Under the name of Aegae, Edessa was the original capital of ancient Macedonia and remained the cult centre of the Macedonian kings even after the capital was moved to Pella at the end of the 5th century B.C. Philip II was assassinated there in 336 B.C. In Roman times it was one of the stages on the Via Egnatia. Later its possession was disputed between the Bulgarians and the Byzantines and, in the 13th century, between the rival Byzantine kingdoms of Thessalonica and Nicaea. In the 14th century it fell to the Serbians, but was recovered by John VI Cantacuzenus in 1349 before being conquered by the Turks. It passed into the kingdom of Greece in Oct. 1912, was occupied by German troops during World War II and was the scene of fighting during the subsequent civil war. (D. M. N.)

EDESSA, an ancient city on the northern fringe of the Syrian plateau, the site of which is now occupied by the town of Urfa in the Urfa *il* of Turkey. Its modern name is derived from its early Aramaic title, Urhai, which was officially replaced by the appellation of Edessa when it was refounded, probably early in the 3rd century B.C., by Seleucus I. Traditions of its earliest foundation refer to the legendary king Nimrod, and Muslim legend



BY COURTESY OF THE CONSULATE GENERAL OF TURKEY

MOSQUE OF IBRAHIM AL-KHALIL AND THE POOL OF SACRED FISH, EDESSA (URFA), TURKEY

associates the place with Abraham, whose birthplace is still shown there, in a cave under the citadel. It is certain that the city was a centre of the cult of the Syrian goddess Atergatis in pre-Seleucid times, for a pool of sacred carp of the kind associated with her worship is still to be seen there, and the fish are even now regarded as sacrosanct.

Remains. — The main remains of the ancient city are the castle, which stands on a steep bluff to the west of the site; the Romanesque tower in the precincts of the medieval mosque of Ibrahim al-Khalil; parts of the city walls, especially on the south side; and the dam and rock-cutting of Justinian.

The castle provides a commanding view of the modern city. Its medieval walls are still substantially intact, and rise sheer from steep hill slopes on the east side. On the west they are defended by an immense ditch cut from the solid rock. Two Corinthian columns that stand within the citadel are conspicuous from most parts of the city. They were associated in popular tradition with the cult of the Dioscuri, and according to Muslim legend they formed the arms of a catapult from which the tyrant Nimrod projected the prophet Abraham.

In the hillsides beyond the citadel are numerous grottoes, often with ornamental entrances, which penetrate deep into the rock, and are sometimes furnished with cisterns. In one cave is a fine mosaic of the 2nd or 3rd century A.D.

The handsome square tower set among trees in the confines of the mosque of Abraham, by the pool of sacred fish, just under the shadow of the citadel, is probably a relic from the crusader occupation. The city walls are in a decrepit condition, though there is a fairly continuous stretch and one quite complete gate on the south and southwest sides.

The most striking remains of ancient Edessa, however, are those of the flood-prevention works of the emperor Justinian. Edessa, like its modem successor, was watered by a stream, the ancient Scirtus (modern Daisan), which rises in a deep pool, under a rock with an Armenian inscription, about 4 mi. N. of the city. It was probably from this watercourse that Edessa received its alternative name of Antiocheia-Callirrhoes ("beautiful-flowing"). This stream, though normally of modest scale, is liable to sudden flooding, and it was responsible for several devastations of the place before Justinian undertook its control in the 6th century A.D. He constructed a low dam across its course, just before it enters the city, and, from there, an impressive channel, about 100 ft. deep, round the east side of the site, which was used to lead away the surplus water in time of flood.

To the south of Edessa stretches the wide valley of the river Belikh. This river rises in the springs of Ras al-Ain al-Arus about 30 mi. below Edessa, but doubtless before the city of Edessa drew off the waters of the Scirtus this stream formed a headwater of the Belikh and supplied the ancient city of Harran, the decline of which seems to have begun with the foundation of Edessa upstream.

History.—Edessa was called after the Macedonian city of the same name, whence according to tradition its first colonists arrived. It remained, however, incompletely Hellenized, and the principality of Osroene (*q.v.*), of which it was capital, was one of the main strongholds of Syriac culture in Roman imperial times. Lying on the main military highway from northern Mesopotamia to the Mediterranean, Edessa was continually involved in the conflicts between Parthia and Rome. Its deliverance from the siege by Khosrau I Anushirvan in A.D. 543 was attributed to its possession of a veronica of Christ, which henceforth became regarded as the palladium of the city. It fell, however, to Khosrau II in 608, and later in that century to the Arabs.

In 1098 Baldwin detached himself from the main body of the first crusade to capture the city of Edessa and founded a countship, which throve there until the place was recaptured in 1144, after a siege of 25 days, by the Muslims. This crusader principality held only local sway, its influence extending as far as Samsat and Seruj. But the discovery of a fine Norman arch built in a chamber of the Saracen castle of Harran has shown that this city, too, was held at this period by the crusaders. Edessa was captured by the Turks in 1637. For later history see URFA.

(WM. C. B.)

Edessene Christianity. — Christians in this small city-state saw three events never seen before: a king baptized. a church building erected and the Greek New Testament translated into another language. Eusebius in his ecclesiastical history records correspondence between King Abgar and Jesus. Abgar (*q.v.*) asked Jesus to come and heal him, adding, "I have heard that the Jews murmur against you and wish to harm you. The city I have is very small and stately. It would do for us both." Jesus replied sending his blessing. Eusebius adds that after the ascension "Judas Thomas sent Thaddaeus (Addai), one of the seventy," who healed the king and preached to all his people. This legend is an antedating and romanticizing of a real event. Christianity reached Edessa *c.* A.D. 150 and the missionary may have been called Addai. By 190 the Easter controversy reveals several bishoprics in the region. The king may have been baptized about this time. A cross appears on the headdress of Abgar VIII in coins issued within the period 180–192. The church building is mentioned in the 6th-century Edessene Chronicle as destroyed by flood in A.D. 201. The translation of the Greek New Testament was into Syriac, Edessa being the home of Syriac literature (see SYRIAC LITERATURE).

Tatian was born in Edessa in the 2nd century, as was Bardesanes (*q.v.*). Bardesanes was later considered a Gnostic heretic, but the reason for his unorthodoxy might be the fact that his was the first native expression of Edessene Christianity. Another product of Edessa at about this time (with a Gnostic taint) was the Syriac Acts *of Judas* Thomas, an imaginative account of St. Thomas' mission to India. It contains the "Hymn of the Soul," considered the gem of Syriac literature: and ends with the apostle's martyrdom and the bringing back'of his bones. Edessa from c. 350 claimed his tomb. Ephraem Syrus (*q.v.*) lived his last ten years in Edessa.

The 4th-century Doctrine of Addai says that Palut was made bishop of Edessa by Serapion of Antioch (c. 190). This may represent an attempt to bring Edessene Christians into line with Greek. Bardesanites, however, long outnumbered "Palutians." Incorporation of Edessa into the Roman empire in A.D. 216 brought a share in persecutions. There were martyrs under Decius and Valerian in the mid-3rd century, most famous being Bishop Barsamya, and in the final persecutions (303–311), when Shamona, Guria and Habbib came to be commemorated.

Rabbula, bishop from 411 to 435, ended Edessene irregularities. He brought Bardesanites to conform, and ousted the *Diatessaron* (*q.v.*) of the heretical Tatian in favour of the Peshitta (Syriac) New Testament. The Christology of Nestorius was condemned by the Council of Ephesus (431). Ibas, head of Edessa's theological school and a leading Nestorian, succeeded Rabbula as bishop in 435, making Edessa for a time the centre of Nestorian-

ism. In 489, however, the school was closed on grounds of heresy and the Nestorians fled across the Persian frontier. The church in Persia, thus strengthened and freed from the restraints of its western connection, began to spread eastward and reached the capital of China in 635. Edessa, the real home of Syrian Christianity, had been brought to conform to the Greek west and was robbed of its share in this great missionary achievement.

EDFU (IDFU, BEHDET; Egyptian DJEBA, Coptic ATBO), a town in upper Egypt, 484 mi. S.S.E. of Cairo by rail. Once the capital of the second upper Egyptian nome, it lies on the west bank of the Nile. The chief god of the city of ancient times was Horus (*q.v.*) of the Winged Disk, called the Behdetite, whom the Greeks identified with Apollo, hence the classical name for the city, Apollinopolis Magna. His consort was Hathor of Dendera, whose statue during the late empire was brought to Edfu annually by boat on a ceremonial visit; Harsomtus, "Horus uniter of the Two Lands," was the child of their union and the third member of the triad of Dandarah and Edfu. The legend of the Winged Disk related the battle of Horus against the forces of evil symbolized by hippopotami and crocodiles; on certain feast days the priests of Edfu performed a symbolic harpooning ritual.

The chief monument of ancient Edfu is the great sandstone temple of Horus, 451 ft. long and 250 ft. wide. It stands on the site of an earlier temple of the Ramesside period, and there were probably yet earlier shrines of Horus on the same spot. The present building, the most perfectly preserved large Egyptian temple, was begun by Ptolemy III Euergetes I in 237 B.C. The main structure was completed by his successor, Ptolemy IV Philopator, in 212 B.C.; the portico, court, pylons and surrounding wall were added by succeeding Ptolemies. The decoration of the walls, comprising scenes in relief which form a unique collection of priestly lore and temple liturgy, was not finished until 57 B.C., in the reign of Ptolemy XII Auletes. Generations of craftsmen thus took part in the construction of this temple, yet it forms a harmonious whole, simply planned along one main axis, so that although late in date it serves as the classic example of an Egyptian temple.

Extensive mounds covering the ancient city and cemeteries of Edfu were excavated, largely between World Wars I and II, by members of the French Archaeological institute in Cairo and of the University of Warsaw. Mud-brick houses of the Greco-Roman, Coptic and Byzantine periods yielded a rich harvest of ostraka and papyri. In the necropolis west and north of the town were found mastaba-tombs of Old Kingdom officials and a number of Middle Kingdom burials.

(M. S. DR.)

EDGAR (EADGAR) (943 or 944–975), king of the Mercians and Northumbrians from 957 to 959, and king of the English from 959 to 975, was the son of Edmund I and Aelfgifu. The Mercians and Northumbrians rejected his elder brother Edwy in 957 and made Edgar their king. He recalled Dunstan (*q.v.*) from exile and made him bishop of Worcester and of London. When he became king of England he deposed Byrhthelm, since 958 archbishop of Canterbury, and intruded Dunstan in his place. Edgar was a keen supporter of the monastic revival, insisting on the return of many estates alienated from monasteries and granting to them some lands which should not have been alienated from royal possession. With his concurrence, secular priests were driven from several houses. He placed as bishop of Winchester the most violent of the reformers, Aethelwold, who refounded the fenland abbeys of Ely, Peterborough and Thorney, while Oswald, bishop of Worcester and archbishop of York, gradually replaced priests by monks at Worcester and founded the abbey of Ramsey. Edgar instigated the composition of the *Regularis concordia*, to ensure uniformity of observance in monasteries. His laws are the first to mention penalties for nonpayment of tithe and Peter's pence.

Monastic writers believed that Edgar's support of the monasteries won him divine favour and accounted for the peace of his reign. He maintained friendly relations with Scotland, ceding Lothian to King Kenneth II, and he received the allegiance of Welsh rulers. He allowed the Danish areas of England to preserve their laws, and won their loyalty. He was anxious for the proper administration of justice, and the reorganization of the hundred, borough and shire courts was completed in his reign. He encouraged trade and instituted an important reform of the coinage. He received embassies from foreign rulers, including the emperor Otto I. He left a reputation for efficient rule.

Edgar delayed his coronation until 973, when he was in his 30th year, probably because he saw a parallel between the royal and priestly offices and wished to be anointed at the age when priests were normally ordained. His splendid coronation at Bath was followed by a spectacular act of homage by foreign rulers of Britain at Chester. In the many panegyrics on him, there is only one criticism, in an 11th-century addition to the Anglo-Saxon Chronicle, that he favoured heathen customs and enticed foreigners to England. He died on July 8, 975, leaving two sons, Edward the Martyr and Aethelred (afterward Aethelred II), and an illegitimate daughter, Edith, who became abbess of Wilton and was venerated as a saint. Edgar's death was the signal for a reaction against his ecclesiastical policy.

(D. WK.)

EDGAR (c. 1075–1107), king of the Scots from 1097 to 1107, was probably the second son of Malcolm III and St. Margaret. He was given "the kingdom of *Scotia* and the land of Lothian" by William II of England in 1094 or 1095. As vassal to William he seized the kingdom from Donaldbane in 1097. He conferred on Durham cathedral extensive lands in Berwickshire, which were later the endowments of Coldingham priory, a cell of Durham. He revived the Benedictine priory of Dunfermline, but the see of St. Andrews was probably vacant throughout his reign. He ceded the Western Isles to the king of Norway in 1098. Edgar died unmarried at Edinburgh on Jan. 8, 1107.

(A. A. M. D.)

EDGAR (EADGAR), THE AETHELING (d. *c.* 1125), English prince, was the son of Edward, a son of Edmund II Ironside, and Agatha, a kinswoman of the emperor Henry II. After the battle of Hastings. Aldred, archbishop of York, and the earls Edwin and Morcar wished to make him king, but he and his supporters submitted at Berkhamsted to William I, who took him to Normandy in 1067. He fled to Scotland in 1068, where his sister Margaret married King Malcolm III. By 1069 rebellions in his favour were crushed. When William and Malcolm made an agreement in 1072, he took refuge in Flanders. He returned to Scotland and in 1074 he was shipwrecked when on his way to France at the invitation of King Philip I, and sought William's protection. He led an expedition to Apulia in 1086. Deprived of his Norman lands in 1091, he went to Scotland, where he acted as intermediary between Malcolm (d. 1093) and William II, who sent him in 1097 to put Malcolm's son Edgar on the throne. He won honour on a crusade, probably in 1102. He was taken prisoner at the battle of Tinchebrai in Sept. 1106, fighting for Duke Robert of Normandy against King Henry I, but was released, and lived in obscurity until his death in about 1125.

(D. WK.)

EDGEWORTH, MARIA (1767–1849), Anglo-Irish novelist, is chiefly known for her children's stories and for her portrayal of Irish life and the general stimulus this gave to the handling of national and regional characteristics in fiction. She was born at the home of her maternal grandparents at Blackbourton, Oxford-

shire, on Jan. 1. 1767, the second child and eldest daughter of Richard Lovell Edgeworth (*q.v.*) and his first wife, Anna Maria Elers. Until she was 15 she lived and was educated in England but in 1782 the family went home to Edgeworthstown, about 60 mi. N.W. of Dublin, and there Maria acted as her father's chief assistant in the management of the estate. In this way she gained knowledge of the difficulties and triumphs of ordinary life, and of Irish peasant life in particular, that was to be the backbone of her novels. The Edgeworths had a wide acquaintance among the gentry; one of Maria's friends was Lord Longford's daughter, "Kitty" Pakenham, who subsequently became duchess of Wellington. Domestic life at Edgeworthstown was busy and happy. Maria helped to educate her young half-brothers and sisters who provided an eager audience for the stories she readily invented. In 1786 these stories were published as *The Parent's Assistant.* They moralize but are lively. The children who appear in them are the first living and breathing children in English literature since Shakespeare. Frequent appearances are made by the impetuous and delightful Rosamond, most memorably in *The Purple Jar.*

hlaria's first publication, however, came out in the previous year. *Letters for Literary Ladies* (1795) is a somewhat tepid plea for reform in women's education, expressing views ivhich were largely those of her father. Mr. Edgeworth's influence over Maria's work was enormous. It took the form of encouragement, collaboration, the providing of plots for novels and the inserting of lengthy passages. This influence is usually deplored. But for Mr. Edgeviorth, it was argued, Maria's writing would have been free from the moralizing which undoubtedly mars it. Maria herself thought that but for her father she would never have written at all. There is no doubt that she loved him uncritically and adopted his utilitarian precepts on life and literature without question.

Castle Rackrent (1800) was Maria's first novel and, as it happens, Mr. Edgeworth had no hand in it. Thady, the steward, stands before us in his long greatcoat to tell the story of the estate and its owners, the Rackrents, who came to ruin. This short narrative was an immediate success. It is free from moralizing and since it launched her into the writing of her Irish stories may be counted among the most influential works of fiction written between the death of Tobias Smollett and the publication of *Waverley.* In his postscript to the original edition of *Waverley,* Scott described his aim as being "in some distant degree to emulate the admirable Irish portraits drawn by Miss Edgeworth." *Belinda* (1801) is a society novel particularly admired by Jane Austen whose heroines may owe something of their naturalness to Belinda, the type of sensible young lady that Mr. Edgeworth himself believed the right education would inevitably produce. *The Essay on Irish Bulls* (1802) is the happiest result of Maria's collaboration with her father as *Belinda* was the most unfortunate. He robbed the latter of greatness by urging a happy ending. In the same year (1801) appeared *Early Lessons* and *Moral Tales for Young People* which were expressly designed, after a theory of Mr. Edgeworth's, for the younger members of the upper classes. *Popular Tales* (1804) made a bid to corner the youth of less elegant society.

The peace of Amiens (1802) made it possible for the Edgeworths to visit first Brussels and then Paris where they were admitted to literary and scientific circles and Maria received an offer of marriage from M. Edelcrantz, a Swedish gentleman "of superior understanding and mild manners," which she refused. She never married. *Leonora* (1806) was reputedly written to please Edelcrantz but she never knew whether he read it. *The Modern Griselda* appeared in 1805. *Tales of Fashionable Life* were issued in six volumes, the first three in 1809 and the second three in 1812. The moral earnestness that lies behind them would have crippled a lesser writer but Maria's exuberance and inventiveness repeatedly rescue her from the most unpromising situations. The *Tales* were popular and for the first time she began drawing big royalties. The best of these novels is *The Absentee* which appeared in the second series. It sprang from a great contemporary abuse—that Irish landowners lived in London while their agents extracted from the peasantry rents that would eventually be thrown away in gaming—and together with *Castle Rackrent* is generally reckoned to be Maria's most enduring work. In 1813 Maria and the family spent some time in London where she enjoyed considerable social success and made a favourable impression on, among others, Byron. Before her father's death in 1817 she was to publish three more novels, two of them, *Patronage* (1814) and *Ormond* (1817), being of considerable power.

After 1817 she wrote less. She completed her father's *Memoirs* (1820) and, from 1826, largely ran the estate. For some years now she had enjoyed a European reputation and when she visited Paris in 1820 she received a particularly warm welcome. The great experience of her later years was Scott. She had at once recognized the authorship of *Waverley* when it was published anonymously in 1814 and their relations were always cordial. They exchanged visits. Her only considerable work after 1817 was *Helen* (1834), a distinguished novel in which Lady Davenant represents one of the first attempts to put a female politician into fiction.

The Irish famine clouded her last years and she worked strenuously for the relief of the stricken peasants. She died at Edgeworthstown on May 22, 1849.

Her literary reputation has suffered in the inevitable comparison with Jane Austen but her achievement was nevertheless considerable. In spite of the tedious moralizing much of her writing is as fresh as paint. Her humorous and well-balanced young women, her realistic children, her dignified and shrewd peasantry and her scenes of regional life were all new things in fiction and where she had shown the way others followed.

V. Barry, and containing some letters not available in the 1867 or 1894 volumes; P. H Newby, *Maria Edgeworth* (1950) in "The English Novelists Series"; Elisabeth Inglis-Jones, *The Great Maria* (1959). (P. H N.)

EDGEWORTH, RICHARD LOVELL (1744–1817), made contributions to the theory of pedagogy and was the dominant influence on the writings of his daughter, Maria Edgeworth (*q.v*). He was born at Bath on May 31, 1744, and was educated at Trinity college, Dublin, and Corpus Christi college, Oxford. While still at college he married Anna Maria Elers of Blackbourton, Oxfordshire. Scientific interests brought him the friendship of Erasmus Darwin whom he visited at Lichfield where he also met Anna Seward and her cousin, Honora Sneyd, whom he married in 1773 on the death of his wife. When Honora died in 1780, Edgeworth married her sister. Elizabeth. She died in 1797 and he married Frances Beaufort the following year. By his four wives he had 22 children.

Practical Education (1798), written in collaboration with Maria, is of value in the history of education. Inspired by Rousseau, Edgeworth argued that education should be based on an understanding of the child's mind and this could be obtained by treating the subject as an experimental science in which the conversation of children was noted down. This work had been initiated by Honora and continued by the authors after her death.

From 1782 onward Edgeworth lived on his estate at Edgeworthstown. Longford. Ireland, where he was an enterprising and enlightened landlord. In 1798. when the Defenders were roaming the countryside and the French landed an expeditionary force. he organized a troop of yeomanry. He took his family to Paris in 1802 and was received in literary and scientific circles. In 1806 he became a member of the board of commissioners to inquire into Irish education and from 1807 onward found time, in addition to his estate management, scientific experimenting and the encouraging of Maria's novel-writing. to aork at his autobiography. He dictated three passages in Maria's novel *Ormond* during his last illness He died at Edgeworthstown on June 13, 1817. His works include *Poetry explained for the Use of Young People* (1802), *Essays on Professional Education* (1809) and *Readings on Poetry* (1816).

EDGEWORTH DE FIRMONT, HENRY ESSEX (1745–1807), last confessor to Louis XVI, was the son of Robert Edgeworth, rector of Edgeworthstown in Ireland, who emigrated to Toulouse, where the boy was brought up by the Jesuits. On taking orders he assumed the additional surname of De Firmont. from the family estate of Firmount near Edgeworthstown. In 1791 he became confessor to the princess Elizabeth, sister of Louis XVI, and then to Louis himself. After Louis's condemnation he obtained permission to celebrate Mass for him and attend him on the scaffold. The legend that at the moment of execution the abbe' uttered the words, "Son of St. Louis, ascend to heaven," was denied by him. Edgeworth continued to correspond with Elizabeth. In 1795, his mother having meanwhile died in prison, where his sister was also confined, he escaped to England, carrying with him Elizabeth's last message to her brother, the future King Charles X. He later went with some papers to Monsieur (Louis XVIII), then at Blankenburg in Brunswick, and was induced to accompany him to Mittau. where, on May 22, 1807, he died.

EDINBURG, a city of Texas, U.S., and seat of Hidalgo county, is about 50 mi. W.N.W. of Brownsville. Originally located at the site of Hidalgo village, it was founded and named by John Young of Edinburgh, Scot. In 1908, by popular referendurn, the county seat was moved to Chapin which was established in 1890 and named for D. B. Chapin. In 1911 the county commissioners' court changed the name of the county seat to Edinburg, and old Edinburg took the name of Hidalgo. The city-manager form of local government was adopted in 1946.

Edinburg, gateway to the irrigated section of the lower Rio Grande valley, is a citrus and vegetable packing-shipping centre. Other industries include a creamery, ironworks, planing mills and cotton gins. There are many oil and natural-gas fields in the vicinity, and Moore air force base is nearby. The city operates one of the nation's most scattered school districts embracing about 945 sq.mi. of grove, farm and ranch development. Pan American college, founded in 1927, is located there. For comparative population figures see table in TEXAS: Population.

(O. Mo.)

EDINBURGH, PRINCE PHILIP, DUKE OF (1921–), husband of Queen Elizabeth II of the United Kingdom of Great Britain and Northern Ireland, was born at Corfu on June 10, 1921, the youngest child and only son of Prince Andrew of Greece, who was a younger son of King George I of the Hellenes, and of Princess Alice, eldest daughter of Prince Louis of Battenberg. The monarchy in Greece was then in eclipse, and he was in consequence brought up abroad and educated in Great Britain—at Gordonstoun, under Kurt Hahn, and at the Royal Naval college, Dartmouth. He served with the Royal Navy from Jan. 1940 to the end of World War II, taking part in the sharp and victorious action at Cape Matapan (1941), the Sicily landings (1943) and the war in the Pacific. On Feb. 28, 1947, he renounced his right to the Greek throne (he was fifth in succession) and took British nationality, adopting his mother's name of Mountbatten. His engagement to Princess Elizabeth was announced on July 9, 1947, and their marriage took place in Westminster abbey on Nov. 20, 1947. On the eve of his wedding he was created a royal highness, with the titles Baron Greenwich, earl of Merioneth and duke of Edinburgh.

Soon after his marriage, the duke of Edinburgh continued his service with the Royal Navy, commanding the frigate "Magpie" in the Mediterranean in 1950–51. At the suggestion of King George VI he took the presidency of the National Playing Fields association in 1948, which brought him into contact with local affairs in all parts of the country. In 1951 he revealed the scientific and practical bent of his mind by his presidential address to the British association on the British contribution to science and technology. After the queen's accession to the throne on Feb. 6, 1952, he had to abandon his naval service to share her official and public life, accompanying her on numerous tours in Great Britain, the commonwealth and foreign countries. In the winter of 1956–57 he made an important world tour, after which the queen conferred on him the titular dignity of a prince of the United Kingdom.

Prince Philip went around the world again in 1959, rejoining the queen for their visit to Canada to open the St. Lawrence seaway on June 26. His concern with industry and national efficiency was shown by the conference on the human problems of industry which he organized at Oxford in 1956, inviting participants from both labour and management throughout the commonwealth. Prince Philip has met with some criticism from traditionalists because of his free and easy approach to the ceremonial side of his work and has had difficulties with the popular press, whose photographers annoyed him and whose owners tended to emphasize his foreign connections. However, the queen's personal decision in 1960 to link the name of Mountbatten with her dynasty was well received by public opinion, and revealed Prince Philip's widespread popularity. (R. T. B. F.)

EDINBURGH, the capital of Scotland, county of a city, royal burgh and county town of Midlothian, stands on the south side of the Firth of Forth, having its seaport at Leith, 2 mi. N.E. from the centre of the city. It is 44 mi. E.N.E. of Glasgow by road and 373 mi. N.N.W. of London, and is bounded north by the Forth, south by the Pentland hills, east by Edgebucklin brae, Musselburgh and west by the Almond river, West Lothian. Pop. (1961) 468,378. Seen from Arthur's Seat, a hill to the east, the Old town lies low in front of the castle. The "witch's hat" turrets give the Old town the impression of a medieval burgh, though most of the stone buildings are not earlier than the 16th century. Most houses in the Georgian New town north of Princes street, the main thoroughfare, are of gray Craigleith stone.

Edinburgh has long been the cultural centre of Scotland. In 1947 the annual Edinburgh international festival, comprising music, opera, ballet, drama and art exhibitions, was established. During the festival, which lasts for three weeks at the end of August and the beginning of September, a military tattoo is staged on the floodlit castle esplanade by the Scottish Command, whose headquarters are at Edinburgh.

Geology.—Quarries of limestone at Burdiehouse and of sandstone at Slateford, Hailes, Granton and Craigleith furnished many of the city's buildings. Earth movements caused upheaval of igneous rocks to form the Pentland hills (1,898 ft.), Braid hills (698 ft.), Blackford hill (400 ft.) and Salisbury crags. Volcanic eruptions produced Arthur's Seat (822 ft.) and Calton hill (355 ft.), which later, in the Great Ice Age, were smoothed by a glacier several thousand feet thick, moving from west to east to produce the crag and tail features conspicuous in the Castle rock (445 ft.) and Salisbury crags.

General Description.—From the castle, dominating the city, the Old town dips eastward down the narrow ridge of Castlehill, Lawnmarket, High street and Canongate to the abbey and palace of Holyroodhouse. From the deep valley south of the Castle rock, the ground rises steeply to Lauriston, then declines to the Meadows, and rises again to the Blackford, Braid and Pentland hills. North of the castle is the ravine where until 1816 lay the Nor' loch, now Princes Street gardens, with railway lines running east and west in the centre. Beyond them on the northern embankment the imposing Princes street has offices and shops on its northern side only. From Princes street the ground northward rises slightly to George street, then descends steeply to Canonmills and Inverleith row in stately Georgian streets, terraces and crescents. Beyond, streets and open spaces stretch to the shores of the Forth. Princes street is prolonged eastward by Waterloo place, built in 1815, and containing government offices, including St. Andrew's house (1937) opposite Calton hill, the Royal High school, and a magnificent terrace of houses high up on the left hand with the older houses of the Canongate deep in the valley on the right. Holyrood palace lies east of the Canongate beneath the majestic Salisbury crags. From the east end of Princes street a road runs south by the North bridge over the valley between Princes street and the High street of the Old town. There, at the point from which the town was first extended northward by the building of the bridge in 1764, another extension was made in 1786 by a bridge

over the valley of the Cowgate leading south to Newington, Grange, Craigmillar and Liberton. Southwest from Princes street lie Haymarket, Murrayfield, Dalry, Gorgie and Saughton; and west are Corstorphine and Tumhouse airport. Queensferry street, at Princes street, runs northwest over the Dean bridge, built by Thomas Telford in 1833, 106 ft. below which is the picturesque village of the Water of Leith, with the river flowing past toward its mouth at Port of Leith. In Queensferry road Daniel Stewart's college for boys looks across toward the fine buildings of Fettes college to the northeast. The road passes through Blackhall, Barnton and Cramond to South Queensferry and the south terminus of the Forth railway bridge, just west of which is the Forth road bridge. From the west end of Princes street, Lothian road leads south through Fountainbridge, Tollcross, Bruntsfield and Merchiston to Morningside and the foot of the Pentland hills. The "Royal Mile" is the popular name for the street that links the castle with Holyrood palace.

Open Spaces.—Public parks and gardens are in every region; the oldest, largest and most historic, Holyrood park (5 sq.mi.), contains Arthur's Seat, Salisbury crags and the lochs of St. Margaret's, Dunsapie and Duddingston. Other open spaces include Calton hill, Princes Street gardens, rich in flowers, the Saughton park, the Meadows, Bruntsfield links, Inverleith and Craigentinny. The Royal Botanic garden is at Inverleith row and the Zoological park on Corstorphine hill, a forest park of 100 ac.

(C. A. MM.; X.)

History.—The name Edinburgh is derived from the Gaelic Dun-eideann ("hill fort of Eidin") and is not, as was once thought, connected with Edwin of Northumbria. Nothing is known of a settlement there during the Roman occupation, and, although there is evidence of a hill fort in the 6th century, the history of the town must be reckoned as beginning in the reign of Malcolm III (Canmore; 1058–93), who, with his queen, St. Margaret, seems to have resided occasionally on the castle rock. Certainly she died there, and the chapel dedicated to her in the castle probably dates at the latest from the early 12th century. It is thought that in the reign of David I (1124–53) the burgh rose, at a bowshot's distance from the castle walls, on the sloping ridge, bounded by streams to north and south. On the low ground farther east David founded the Augustinian abbey of Holyrood, granting it the right to erect the burgh called Canongate. Before the end of the century Edinburgh was one of the four burghs that in their court administered a special code of law for their burgesses. But the first extant charter to Edinburgh was granted as late as 1329 by Robert I the Bruce (*q.v.*), who gave to the burgesses the burgh with the port of Leith, mills, etc., for a yearly sum of 52 merks (a merk was worth 13s. 4*d.*). The Wars of Independence involved constant ravaging of southeast Scotland, and in 1341 Edinburgh was described in the exchequer rolls as totally devastated. There was some recovery under David II, who built a new tower in the castle and for whose ransom in 1357 the burgh pledged itself along with Perth, Dundee and Aberdeen. The town, however, was again laid waste in Richard II's invasion of 1385. Thereafter it prospered once more, though in the reign of James I (1406–37) Perth rather than Edinburgh was the chief town of the kingdom. It was in the reign of James II (1437–60), who was born and crowned at Holyrood, that Edinburgh emerged as the undoubted capital of Scotland. It was now the usual meeting place of parliament; it had a municipality of provost, bailies and council. A second street, known as the Cowgate, had been built to the south, and the earliest wall of which traces remain was begun by James II's orders, though this was superseded by another, of wider compass, after the battle of Flodden (1513). In 1482 James III rewarded the loyalty of the burgesses by granting the provost in perpetuity the office of sheriff with the appropriate jurisdiction. The years 1473–1517 saw the incorporation of ten craft guilds which throughout the 16th century strove with the merchants for control of the burgh council, until in 1583 the decree arbitral of James VI settled its composition and the method of its election for the next 250 years. The town's precedence was confirmed by the foundation of the College of Justice in 1532 and, after further destruction by the earl of Hertford's English army in 1544, by the inauguration of the General Assembly of the Church at the Reformation. For these bodies it has been the meeting place in normal times. The removal of the court to England at the union of the crowns (1603) involved some loss both of prestige and of prosperity, but in 1633 Charles I conferred on the town the dignity of a city and made St. Giles's church a cathedral. Soon afterward the town council, alarmed by his threat to move the law courts elsewhere, erected with the help of individual subscriptions the Parliament house to the south of the High street. Other buildings of the time included Heriot's hospital, for which an extension of the Flodden wall, known as Telfer's wall, was made. Beyond the ancient royalty three neighbouring burghs were acquired. In 1636 the Canongate with Broughton (including North Leith) became a burgh of barony under Edinburgh's superiority. South Leith having been acquired in 1605, the whole of Leith became a burgh of barony for Edinburgh also in 1636. The district outside the West and Bristo ports, known as Portsburgh, was added in 1649. In 1650 the town was besieged by Cromwell and was occupied after the battle of Dunbar. With the increase of mercantile prosperity after the Restoration there was much building, especially of the high tenements which are still a feature of the Old town. After a setback through the abolition of the Scottish parliament by the Union of 1707 with England, the town came near to losing its charter through the Porteous riots of 1736 (see PORTEOUS, JOHN), but it entered on its "Augustan Age" in the second half of the 18th century. This was not only the time of its eminence in art and literature, represented by such names as Allan Ramsay, Sir Henry Raeburn, Robert Adam, David Hume, Principal William Robertson and Henry Mackenzie (*qq.v.*) but of its extension south and north. To the south George square was begun in 1766 by a builder, James Brown, and some adjacent streets were added in the next few years. More important was the expansion to the north, where the New town was commenced, in accordance with an act of 1767, on the gridiron plan of James Craig (?–1795), with its main streets—George street, Queen street and Princes street—culminating in Charlotte square. Communications between the new districts and the Old town were made by the erection of the North and South bridges before 1800 and a little later by the Mound, built up, where the Nor' loch had been drained, with earth removed from the foundations of the Princes street houses. Further building followed in the 19th and the 20th centuries, sometimes well planned, as in the regions of Regent terrace and Moray place, sometimes less happily as in Dalry and Gorgie. Many new housing areas came into being after World Wars I and II.

(E. W. M. B.-M.)

The Castle.—Edinburgh owes much of its importance to its commanding position near the mouth of the Forth river. The medieval town grew upon the crest of the long massive rock which is dominated by the castle. The Castle rock has been a fortress from very early times, certainly from the 6th century A.D., but continual use of this strategic site has obliterated all material evidence of occupation before the 11th century. The principal surviving buildings have been altered to suit changing needs. They are of greater historical than architectural interest, and they date mainly from the 16th century and the reign of Mary, queen of Scots (1542–87). They are grouped as the restrictions of space have permitted and in architecture as varied as its date and purpose. The tiny chapel of St. Margaret, the queen of Malcolm III (Canmore), on the highest point of the rock, is the oldest surviving building. It dates from the 12th century but may incorporate within its walls some undefined masonry of the chapel she founded and in which she heard her dying mass in 1093. The chapel is a simple oblong, with a small nave and a semicircular chancel (square externally) entered through a Norman chancel arch. The building is complete and somewhat restored; occasional services are still held within it. During the middle ages the castle was frequently occupied by the English. Buildings erected before and during this stormy period, many of which in any case were probably of timber and clay, have almost entirely vanished.

Near St. Margaret's chapel are substantial remains of an early example of the characteristic later medieval Scottish castle, the "tower-house." This example was erected in 1367–79 by David II and is known as David's tower. Its massive ruins are accessible,

although entirely engulfed by the Half-Moon battery of 1574. Outside St. Margaret's chapel is the famous bombard "Mons Meg," built for James II about 1450, weighing five tons and of 19½ in. calibre, one of the most notable pieces of ordnance in Britain. Buildings are arranged in a quadrangle about Palace yard or Crown square which occupies much of the summit of the Castle rock. The range on the east is the Palace block or "king's lodging" and looks down the High street. It contains the Scottish regalia (the "Honours of Scotland") which consist of the crown, sceptre, sword of state, all of 16th-century date, and other treasures. In the same block are the apartments of Mary of Guise (Lorraine) and her daughter Mary, queen of Scots, and the small room in which James VI of Scotland (James I of Great Britain) was born in 1566. On the south side of Palace yard is an imposing early 16th-century banqueting hall. Although comprehensively restored in 1888 it presents the essential features of a great medieval hall, with hooded fireplace, minstrel's gallery and buffet hatches to the kitchens. The richly carved hammer-beam roof is original. On the north side, on the site of a 12th-century church, is the Scottish National War memorial (1927), designed by Sir Robert Lorimer. The Scottish United Services museum, with Jacobite relics, Highland weapons and uniforms, is also among the buildings of Palace yard. The descent from these buildings upon the summit of the Castle rock is by a winding road passing under the portcullis gate erected in 1574 by the regent, James Douglas, 4th earl of Morton, who built the Half-Moon battery. The exit to the spacious esplanade or parade ground in front of the castle precincts is by way of a dry ditch and other fortifications of the 18th century. At that time extensive ramparts with sentinel turrets were added, which, following the rise and fall of the precipitous rock, invest the castle with picturesque profiles.

Holyrood Abbey.— An abbey for Augustinian canons from Merton in Surrey, Eng., was founded near the castle by David I in 1128 and rebuilt in about 1220. This work, of which much remains, must be numbered among the most imaginative and successful exercises in early 13th-century composition in Britain. The west front is a particularly imposing faqade, with a deeply recessed doorway originally flanked by boldly projecting towers of which only one remains. The nave incorporates substantial parts of its 12th-century predecessor and stands complete to the wallhead, but the transepts and east end have been reduced to their foundations, and of the cloistral buildings nothing remains.

The Palace of Holyroodhouse.— The destruction of much of the abbey was due to the erection of royal palaces upon the site. The earliest surviving palace, associated closely with Mary, queen of Scots, is a great square tower with a projecting round tower at each corner. It was built for James IV and was completed about 1505. Extensive additions which encroached into the abbey were made in 1671 for Charles II; these were designed on a quadrangular plan by Sir William Bruce (d. 1710), the first Scottish architect in the modern professional sense. The old palace (the northwestern tower of the present complex) contains the Historical apartments with furnishings and other features particularly associated with Mary, queen of Scots, and her times. This old tower is truly medieval, but the new palace of the Restoration period conforms to the more sophisticated style then popular. This is evident in the interiors and in the refined use of superimposed classical orders on the courtyard faqades. The palace is still a royal residence, but is normally open to the public.

Buildings of the Old Town.— Between the castle and the abbey the houses of the medieval burghers rose to great heights upon the high and narrow spine of rock. They had narrow frontages facing the street and even narrower closes or vennels (gaps) between them, and long gardens falling away to the rear. Originally those buildings, or "lands" as they are called, were heavily timbered, with overhanging galleries and gables. There is little left that is earlier than the 17th century, but much of that period remains, and the more modern buildings are lofty and clifflike and preserve the ancient canyonlike aspect of this renowned thoroughfare. Opening off it are picturesque closes leading to unsuspected courtyards with towering buildings behind the main frontages. Many lands and closes retain their descriptive names, such as

BY COURTESY OF PAN AMERICAN WORLD AIRWAYS

PALACE OF HOLYROODHOUSE, EARLY 16TH–17TH CENTURIES, WITH HOLYROOD ABBEY (1128) ON THE LEFT. IN HOLYROOD PARK AT THE FOOT OF THE ROYAL MILE OF EDINBURGH

Shoemakers' land, Bible land, Playhouse close, Advocates' close, World's End close (at the city gate); and names such as Lawnmarket, Grassmarket, Cowgate and Canongate indicate the original function of these areas. In several of the late 16th- and 17th-century dwellings are painted timber ceilings, profusely decorated with foliage, biblical scenes and inscriptions and heraldic and mythical subject matter. Good examples exist in Gladstone's land and in John Knox's house.

The early town, close against the protection of the Castle rock, was further defended by a wall. Parts of the Flodden wall of the early 16th century survive; it crossed the long incline of the Royal Mile about halfway down, and the site of the eastern gatehouse, called the Netherbow port, is marked in the roadway just below Knox's house. East of this, outside the wall, lay the Canongate, between the gatehouse and the abbey, and so-called because it was the "gate," or way, of the canons between their abbey and the town and castle.

Within the medieval precincts the historic church of St. Giles' has dominated the old town for about 800 years. In its eventful history it has been a parish church, a collegiate church and for five years (1633–38) an Episcopal cathedral. It is in use for Protestant worship. It is notable for its magnificent lantern tower (c. 1500), an open spire with a high central feature supported by eight flying buttresses which impart a crownlike effect. It contains many chapels of late medieval dates, and a modern one of great distinction (opened in 1911) designed by Sir Robert Lorimer for the Order of the Thistle. Nearby is the Tron church, begun about 1637 by John Mylne (1611–67), master mason to the crown, and farther down the High street is the Trinity College chapel, founded about 1460 by Mary of Gueldres in memory of her husband James II of Scotland. Its site being threatened in 1848 by the construction of the Waverley railway station, it was taken down and partly rebuilt on its present site behind John Knox's house. It consists of the choir without the aisles, and, with an unusually lofty stone vault and much excellent carving, is one of the most accomplished examples of late medieval architecture in Scotland. Two panels of its large altarpiece in the National Gallery of Scotland, Princes street, are attributed to the Flemish painter Hugo van der Goes (*c.* 1470). In Holyrood park is a small 15th-century well with miniature stone vaulting. It was removed from the district of Restalrig nearby and rebuilt in the park in the 19th century when threatened by railway construction.

The Canongate until 1856 remained a separate burgh and the parishioners worshiped in the nave of the abbey church until this was appropriated by James VII of Scotland (James II of Great Britain) for the Order of the Thistle in 1686. Two years later a new parish church of considerable merit was designed by James Smith; it is still in use. Immediately adjacent to the old Canongate tolbooth (1591) was the civic hall and prison on the Canongate; the tolbooth is now a museum. Opposite are Huntly house (1570), Moray house (1630), with fine plaster ceilings and period details, and Acheson house (1633) in Bakehouse close, all notable buildings. Farther down the Canongate is White Horse close, a unique survival of a 17th-century coaching inn with overhanging timber gables and outside stairs, which has been converted into dwellings. At the foot of the Canongate the Royal Mile (which comprises the Lawnmarket at the top, the High street in the middle and the Canongate at the bottom) widens into an open space before the gates of Holyroodhouse. This space was the sanctuary area of the abbey in medieval times, and within it debtors and delinquents could seek refuge from civil law for a time. The 16th-century abbey sanctuary house, also called the abbey strand, stands within the sanctuary precincts. Summer exhibitions illustrating Scottish ancient monuments are held within it. Incorporated in the walls of the building opposite are the remains of the abbey gatehouse. The Greyfriars church (1614), in which the National Covenant of Scotland was signed in 1638 by men and women resolved to worship God after the established custom and not in the manner laid down by the English archbishop William Laud, has a historic churchyard with many notable tombs, including that of the Adam family of architects.

Buildings of the New Town.—By the mid-17th century the old town was overcrowded; moreover, there were no civic building of fitting importance for a capital city. The Royal exchange on the north side of the High street, opposite St. Giles's, was erected from the plans of the brothers John and Robert Adam in 1753; but it was not until access by bridge and road across the valley and loch north of the castle hill was begun in the 1760s that a comprehensive new town was planned for the open ground beyond the valley. The loch was drained and the valley now forms an extensive open public garden at the foot of the Castle rock, separating the Old town from the New. Thus the skyline of the medieval town, with castle, ramparts, spires and lofty houses perched upon the crest of the rock, affordsa striking view across the valley from the boulevard of Princes street. Most of the New town was built between 1768 and 1850; its showpiece is Charlotte square at the west end laid out by Robert Adam in 1791. The layout is simple—in spacious squares, terraces and crescents, with wide roads serving houses of characteristic Georgian urbanity. It is seen at its sophisticated best in Charlotte square (especially the north side), Moray place and vicinity, Great King street (1820) and the monumental St. Bernard's crescent of 1828. Melville street. Queen street and Heriot row are notable examples of residential thoroughfares with buildings on a smaller and more domestic scale. The New town forms a grid whose three parallel main thoroughfares (Princes street, George street and Queen street) are regularly linked by crossroads at right angles. George street in the middle was planned as the chief axis, with large garden squares at each end, but Princes street, a terrace with open outlook to the south, is the principal promenade. At the east end of it the General Register house (1772–90), by Robert Adam, is the public record office of Scotland. St. Andrew square at the east end is distinguished by the headquarters of the Royal Bank of Scotland, originally built (1772) as a private residence by Sir William Chambers (1726–96). The New town was residential and much remains so, its Georgian buildings having characteristic railings, doorways, fireplaces, plaster ceilings and the like.

Later Buildings.—In Edinburgh the Greek and Gothic revival of the 19th century was particularly active in church and public buildings. Of Greek Revival civic architecture the Royal Scottish academy off Princes street and the adjoining Scottish National gallery by William Henry Playfair (1789–1857), the Royal High school by Thomas Hamilton (1784–1858) and the Surgeons' hall by Playfair are notable exercises in the Doric and Ionic styles. The classical style is also well represented on the summit of another of the many hills upon which Edinburgh stands (the appellation "the Modern Athens" derives from this predominance of hills and classical architecture). The City observatory (1818) on the Calton hill is by Playfair in the Roman Doric manner. The National monument nearby is correct Greek Doric, like the splendid Royal High school which it overlooks. The National monument is all that nas built of a church originally intended to be an exact copy of the Parthenon and a national memorial of the Napoleonic Wars. By 1830 only 12 columns had been erected, when funds ran out.

Among many churches in the classical style are St. Andrew's, George street (1782–89); St. Mary's, Bellevue crescent (1824); St. George's, Charlotte square (1814); and St. Bernard's, Claremont street (1823). Among neo-Gothic churches St. John's at the west end of Princes street is outstanding, with a fine fan vault. It was designed in 1816 by William Burn (1789–1870), who demonstrated characteristic versatility in John Watson's school (1828), a severe but impressive Greek Doric building. St. Paul's, York place (1816), by Archibald Elliot, is late Gothic, but his Regent bridge (1815) is classical, as is Regent road itself, a remarkable example of street façade designing caused by a civic desire to dignify the formal exit from Edinburgh at the east end of Princes street. The pseudo-castellated Governor's house (1815) at the old Calton jail is also by Elliot. The old University building by Robert Adam was begun in 1789, completed in 1834 and received its dome in 1884. The noble University library in the classical style, by Playfair, is about 200 ft. long and covered with a coffered barrel-vault. Even better is the library of the Writers to the Signet, by William Stark (1813). About 140 ft. long, the building is lined with lofty Corinthian columns supporting a shallow barrel-vault, whose length is interrupted by a saucer dome. This library was ingeniously heated by hot air rising through the legs of cast-iron tables which are still in place. Adjoining is the old Parliament house (1632–39), whose hall retains its hammer beam roof. St. Mary's Episcopal cathedral in Palmerston place (1879) is by Sir George Gilbert Scott with western towers of 1917. The National Portrait Gallery and Museum of Antiquities of Scotland (1885) in Queen street is a four-storied building in the Gothic style. Niches in the façade contain statuettes of famous Scots.

Monuments.—Erected in honour of kings, queens and distinguished subjects, monuments are conspicuous in George street, Princes Street gardens and sundry streets and public buildings. The oldest, a leaden statue of Charles II astride his horse ("Bandy-legged Charles on his tun-bellied charger"), has been in Parliament square by St. Giles's church since 1685; the largest is the Sir Walter Scott monument in East Princes Street gardens (1846). Its Gothic spire is 200 ft. high with successive tiers of finials and niches; in each niche is a statuette of a character in the works of Scott, while a marble statue of the author by Sir John Steell is in the open base. In the centre of St. Andrew Square gardens is a Trojan column 136 ft. high surmounted by a 14-ft. figure of Henry Dundas, 1st Viscount Melville, friend of Pitt and "uncrowned king of Scotland." The statue of the statesman W. E. Gladstone by Pittendreich Macgillivray was removed to Coates gardens in 1955.

In Parliament house are statues of Sir Walter Scott, Lord President Robert Blair, Henry Dundas, Lord Cockburn and Lord President Duncan Forbes of Culloden by L. Roubillac, considered one of the finest pieces of statuary in Scotland. St. Giles's church has a large number of memorials, including a statue of John Knox, recumbent effigies in marble of the marquesses of Argyll and Montrose and mural effigies of the novelist R. L. Stevenson and other famous men. Outside, a few yards west of the church, is the statue of the 5th duke of Buccleuch by Sir J. E. Boehm, with sculptured sketches of episodes of the Buccleuch family history.

On the Calton hill the monuments include the unfinished memorial to the Scots sailors and soldiers who fell in the Napoleonic wars, the 102-ft.-high Nelson tower and the small Greek temple commemorating the philosopher Dugald Stewart (1753–1828). East of the hill, in Regent road, is a Robert Burns memorial in the shape of a Greek temple. In the cemetery of the Old Calton are

memorials to the philosopher David Hume and to the political "martyrs" of 1793, together with the fine monument (1893) to Abraham Lincoln, which is also dedicated to the Scottish-American soldiers who fell in the American Civil War. Of memorials of World Wars I and II—in addition to that in the castle—the two best known are in Princes Street gardens, one erected in 1927 to the American-Scottish soldiers and the other to The Royal Scots, the oldest "line" regiment of the British army. The most extraordinary monument is the marble sarcophagus at Craigentinny, showing the "Overthrow of Pharaoh and his Egyptians at the Red Sea" and the "Song of Moses and Miriam." The monument stands over ground 40 ft. below which was buried William H. Miller (1789–1848), famous bibliophile, who left £300,000 and £20,000 to be set aside for burying him at that depth with a suitable monument. (S. H. C.)

The University. — Edinburgh university, the youngest of the Scottish universities, was founded by a royal charter dated 1582, granted by James VI. Although the college in the past was occasionally referred to as the College of King James, and James VI considered himself its founder, it really originated in the liberality of the town council of Edinburgh. William Little of Craigmillar and his brother Clement Little, advocate, along with James Lawson, the colleague and successor of John Knox, may justly be regarded as the true founders. In 1580 Clement Little gave all his books, 300 volumes, for the beginning of a library, and this was augmented by other valuable benefactions which included the 16th-century library of the poet William Drummond of Hawthornden.

The old buildings of the university occupied the site of the ancient collegiate church of St. Mary in the Fields (the "Kirk o' Field"), the scene of the murder of Lord Darnley. The present Old college on the same site, designed by Robert Adam, dates from 1789. The Royal Scottish museum is structurally united to the university, and nearby are the Heriot-Watt college, affiliated to the university since 1933, and the dental school. The renowned medical school stands in Teviot row, adjoining George square and the Meadows. Beside the University Union and the Reid School of Music stands the magnificent McEwan hall (1897), which is used for academic and public functions. Closely associated with the medical school, and separated from it by the Middle Meadow walk, is the Royal infirmary, designed by David Bryce (1803–76). Its wards are lodged in a series of turreted pavilions and cover a large space of ground on the margin of the Meadows, from which, to make room for it, George Watson's college—the largest of the Merchant Company schools—was removed to a site farther west, while the Sick Children's hospital was moved to the southern side of the meadows. George Watson's college was moved again (to Colinton road) in 1932 to make room for a further large extension (a maternity wing) to the Royal infirmary, one of the largest hospitals in Great Britain. In 1951 the Royal (Dick) Veterinary college was embodied in the university, and the university is associated in greater or lesser degree also with the Moray House College of Education, the Edinburgh College of Agriculture and the Edinburgh College of Art. Most of the faculty of science is housed in the King's buildings at Liberton. Adam house, the examination halls in Chambers street, is equipped as a university theatre.

Scientific Institutions. — The old observatory (1774) stands on Calton hill; nearby is the city observatory (likewise disused), and on Blackford hill is the Royal observatory (1896). The Royal College of Surgeons, which occupies a classical building in Nicolson street, is an ancient corporate body, with a charter of the year 1505. The Royal College of Physicians, with a charter granted by Charles II in 1681, has in its hall (1844) in Queen street a valuable library and a museum of *materia medica.* The school of medicine of these two Royal colleges was incorporated in the faculty of medicine of Edinburgh University, and undergraduate medical instruction is now given only by the university. The Royal colleges, however, continue to be closely associated with the faculty in the work of the postgraduate board for medicine.

Other Educational Facilities. — After the disruption in 1843 and the formation of the Free Church, New college was founded in connection with it for training students in theology. After the amalgamation of the United Presbyterian and the Free Churches, as the United Free Church of Scotland, New college was utilized by both bodies and now houses the faculty of divinity.

The Royal High school, among whose pupils were James Boswell and Alexander Graham Bell, is an ancient foundation, and the Grecian buildings (1829) south of Calton hill are its third habitation. Edinburgh academy was opened in 1824. Fettes college and Merchiston Castle school (now at Colinton) are organized on the model of the great English public schools. Foremost among the city's charitable foundations was George Heriot's hospital (1628–50), now a boys' school, founded for the maintenance and teaching of poor fatherless sons of freemen by George Heriot (1563–1624), the goldsmith and banker of James VI. This quadrangular building in Lauriston is one of the noblest in the city. The Mary Erskine School for Girls (until 1944, the Edinburgh Ladies' college) was founded in 1694 by the Company of Merchants and Mary Erskine to give daughters of merchant burgesses similar advantages to those which Heriot's secured for burgesses' sons. George Watson's college for boys was opened in 1738. The Trades' Maiden hospital for craftsmen's daughters, John Watson's, Daniel Stewart's, the Orphans', Gillespie's and Donaldson's hospitals, and other institutions, in which poor children of various classes were lodged, boarded and educated, were founded by successful merchants. George Watson's and Daniel Stewart's hospitals were converted to day schools. George Watson's Ladies' college was founded in 1871. The Edinburgh College of Domestic Science (1889) is in Atholl crescent.

By the 1960s the Education authority administered more than 80 primary and 20 secondary day schools, including the Royal High school and James Gillespie's High School for Girls. The authority also provides educational facilities for adults and young persons over school age—formally in day and evening classes and informally through youth and community groups. A wide range of playing fields is available to the public schools of the city. (J. SR.; X.)

Environs. — On the shores of the Forth lie pleasant suburbs: Cramond, farthest west and once a Roman station, has some old historic houses and has literary associations with R. L. Stevenson. Granton, with a large harbour used by fishing and pleasure craft, lies farther east. Newhaven still has 16th-century fishermen's houses with wooden outside stairs, and its fishwives in voluminous blue-and-white-striped petticoats were for many years familiar spectacles on the streets of Edinburgh where they cried their "caller herrin!" (fresh herring). The village adjoins Port of Leith, which, though now a busy district of Edinburgh (which absorbed it in 1920), had in 18th-century days wide stretches of sand where horse racing took place and a reputation as a fashionable seaside bathing resort. The latter distinction passed to its eastern neighbour, Portobello, while the horse races were transferred to Musselburgh, 2 mi. E. of Portobello. Musselburgh, long famed for its mussels and the distich

> Musselburgh was a burgh when Edinburgh was nane
> Musselburgh'll be a burgh when Edinburgh's gane,

has been misunderstood. The "burgh" of Musselburgh meant mussel bank, not burgh in the sense of "town."

Southeast of the city are Duddingston with its 12th-century church and its old manse and garden frequented by the poet and novelist Sir Walter Scott; Craigmillar with its fine 14th-century castle, once the county seat of Scottish sovereigns; and Liberton and Gilmerton, once medieval sergeanty lands and now suburban townships. Colinton, in the southwest, is picturesquely situated with woods and a popular dell and has intimate associations with R. L. Stevenson. There also were the snuff mill and the mansion of James Gillespie, 18th-century founder of Gillespie's hospital and school. Merchiston castle (15th century onward), in Colinton road, a towerlike, thick-walled house, was the birthplace of John Napier (*q.v.*), the inventor of logarithms. At Restalrig, a northeastern suburb, are substantial remains of the vaulted octagonal King's chapel of the collegiate church, founded by James III in the 15th century. In Corstorphine to the west the 15th-century collegiate church is a fine example of its type. (C. A. MM.; X.)

Population. — In 1801 the population was 67,288; in 1881 it

was 228,357; in 1931, 439.010; and in 1961, 468,378. In 1896 portions of the parishes of Liberton and Duddingston and the police burgh of Portobello were incorporated, and in 1900 a further addition was made including Granton, Restalrig and parts of South Leith and Duddingston. In 1920 the burgh of Leith was amalgamated with the city, and the parishes of Corstorphine, Cramond, Liberton and Colinton were incorporated. In 1955 a further: small extension of the city was effected by incorporating parts of the county of Midlothian at Moredun and at Corstorphine.

Government and Administration. — For parliamentary purposes Edinburgh includes Musselburgh and Port of Leith and is divided into seven divisions. each returning one member. The departments of the secretary of state for Scotland are housed chiefly in St. Andrew's house. The town council, which meets in the City chambers, consists of 71 members. 69 of whom are popularly elected; the remaining two (the lord dean of guild and the convener of trades) are ex officio members elected by the guildry and convenery, respectively. The lord provost, ten bailies and the honorary treasurer are elected by members of council from among their number. By the Burgh Reform act of 1833, passed at a time when the city was bankrupt, the method of appointing the town council in force since 1583 gave place to election of one-third each year by owners and occupiers. The town council exercises all the functions of a local authority within the city. The corporation has a water committee to administer a water supply plan covering city and county, and is represented on the regional committee controlling the fire service and on the joint board responsible for the Forth road bridge. The probation committee is also regional in character.

Industries and Communications. — Long-established industrial activities include brewing and distilling, printing, bookbinding. rubber manufacture, biscuit baking and confectionery and the manufacture of glassware, drugs and fine chemicals. Mention should also be made of shipbuilding and repairing, marine engineering. steel constructional work, wire drawing and wire rope manufacture, the making of paper, glue and gelatin, printing ink, rope and sailcloth. A more recent development is the electronics industry. By the early 1960s Edinburgh had developed rapidly as a tourist centre, its annual total of about 750.000 visitors exceeding that of any other city in the United Kingdom except London. About 90,000 visitors are attracted to the annual international festival. Edinburgh is also popular as a conference centre for international and other congresses.

The city is served by British railways; of the two large railway stations, Waverley served the former London and North Eastern railway, and Princes street formed a terminal point of the former London, Midland and Scottish railway. Scottish Omnibuses Limited operates passenger services from the city linking up with most parts of Scotland, as well as with London and the south. Edinburgh's civil airport is 6 mi. W. at Turnhouse. (J. SR.; X.)

Port of Leith.—The harbour and docks of Leith form one of the largest ports on the east coast of Scotland and are situated in the sheltered waters of the Firth of Forth, approximately 30 mi. from the open sea. The undertaking is vested in a body of commissioners set up by act of parliament. The port consists of an outer and inner harbour (used by coasting vessels), six enclosed docks and a modern western harbour of 203 ac. All classes of goods are handled, but grain, cement, timber, iron and steel, fertilizers and foodstuffs are the principal imports and coal, paper, beer, spirits and wines the principal exports.

A vessel of more than 13,000 tons gross register has entered the docks, and cargoes of more than 10,000 tons have been loaded and discharged. The entrance to the harbour is 400 ft. wide and that to the Imperial (the largest) dock 70 ft. wide. The depth of water on the sill of the Imperial dock is 30½ ft. at mean high-water springs and 27 ft. at neaps. The dock gates are normally opened three hours before high water and closed at high water, but there are facilities for locking in and out. In the tidal Western harbour, vessels drawing up to 30 ft. can remain afloat at the deep-water quay. Four dry docks are available, the largest. the Imperial, being 550 ft. long. Excellent facilities are available for the loading and discharging, the docks being liberally equipped with cranes ranging from 1½ to 120 tons' capacity. All the discharging berths have shed accommodation, and there are special facilities for the handling of grain in bulk. Reclamation undertaken just north of the Imperial and Edinburgh docks in the 1960s provided land for additional industrial sites.

EDIRNE (formerly ADRIANOPLE), a town and capital of the *il* (province) of Edirne in west European Turkey, is situated near the Greek frontier on both banks of the Tunca (Tundzha) river, at its confluence with the Maritsa (Meriç) 234 km. (145 mi.) W.N.W. by road of Istanbul. Pop (1960) 31,865

The site of Edirne was probably determined by its bridgehead location, and a historic road from Europe via the Balkan countries to Istanbul which crossed the Maritsa at Edirne. The largest and oldest part of the town occupies a meander of the Tunca around an old citadel. Its plan is irregular except for the south-central part which was replanned after a fire in the 19th century. The centre of the town has many beautiful mosques, including that of Selim II, built by Sinan and completed in 1574, and those of Ucserefeli and Murad. Other historic buildings include Dar el Hadis (a religious college) and caravansaries. There are many fine bridges over the rivers.

Edirne is on the railway from Belgrade (Yugoslavia) and Sofia (Bulgaria) to Istanbul and is also linked with Salonika in Greece. Main roads connect it with central Europe and with the rest of European Turkey. A bus service runs to Istanbul. The town manufactures cheese. soap, leather, tapestry, woolens, linens and cotton but the once-important raw silk industry has declined. The chief products of the il are cereals (principally wheat) and fruits. Rice is cultivated in the Maritsa plain. Stock-raising is an important activity and Edirne produces its well-known white cheese and meat for the Istanbul market.

Adrianople or Hadrianopolis, originally known as Uskadama or Uskodama, was renamed and enlarged by the Roman emperor Hadrian (117–138). It was the scene in 378 of the Roman defeat by the Goths *(see* below). Conquered successively by the Avars. Bulgars and crusaders, the town was captured by Murad I in 1362 and from 1365 became the residence of the Turkish sultans until the fall of Constantinople in 1453. Under Turkish rule the town flourished as an administrative, commercial and cultural centre, attaining a population of about 100.000 in the 19th century. but the foreign occupations and devastation brought its decline. It was occupied by the Russians in 1829 and 1878 *(see* RUSSO-TURKISH WARS).

During the first Balkan War, Adrianople was taken from the Turks by the Bulgars, with Serbian assistance, in 1913 after a siege of 155 days. The Turks reoccupied it during the second Balkan War and by the treaty of Bucharest (Aug. 10, 1913) it was returned to Turkey. The Greek army, sent to restore order in Thrace, entered Adrianople in July 1920 and the town was ceded to Greece on Aug. 10 by the treaty of Sbvres. The town was again restored to Turkey by the Mudanya convention of Oct. 1922, confirmed by the treaty of Lausanne, July 24, 1923.

(N Tu.; S. ER.; E. TU.)

Battle of **Adrianople.**—Adrianople was the site of two battles. In the first, in A.D. 323, Constan-tine the Great defeated Licinius *(see* CONSTANTINE). The second and more famous engagement, in 378, was the crushing defeat by the Goths of the Roman imperial forces under the emperor Valens (*q.v.*).

The Visigoths had been allowed, in 376, to move inside the

Roman frontier to escape the pressure of the Huns. A year later they revolted, and in 378 Valens determined to subdue them. When the attack was made (Aug. 9) the Gothic cavalry was away foraging. To gain time to recall them, Fritigern, the Gothic leader, made offers of surrender, and, while Valens negotiated, the Roman troops remained stationary without water for several hours under a blazing sun. After some of the Roman officers began to fight without orders, the Gothic cavalry returned and the Romans, exhausted and dispirited, were forced into a disordered mass too dense to allow them to use their weapons. Their main body was massacred: two-thirds of the army fell, including the emperor; his corpse was never found.

This Gothic victory was one of the milestones of history: the Roman empire's barriers were breached so gravely that they could be restored only temporarily, by taking the barbarian tribes inside the imperial frontiers and charging the new settlers with defending the provinces against other barbarians. According to the traditional view the battle also marks the changing relative values of infantry and cavalry in that henceforth cavalry was to have increasing predominance; but the account of the battle by the 4th-century historian Ammianus Marcellinus hardly supports the conclusion that it was a great cavalry victory.

See Ammianus Marcellinus, *Res Gestae,* xxxi, 12–13. (E. A. T.)

EDISON, THOMAS ALVA (1847–1931), U.S. inventor best known for his development of the phonograph and the incandescent lamp, was even more notable for the wide range of his interests. Born at Milan, O., Feb. 11, 1847, Edison's education was limited to three months in the public school of Port Huron, Mich. At 12 he became a railroad newsboy and after 15 earned his living as a telegraph operator in various cities, always studying and experimenting in his spare time. In 1868 he took out his first patent, for an electrical vote recorder. During the next few years he devised stock tickers, duplex, quadruplex and automatic telegraph systems and the electric pen, which was the forerunner of the modern office duplicating machine. His invention (1877–78) of the carbon transmitter, in which compressed lampblack buttons were used to translate sound into a varying electrical signal and back again, marked a real advance in the science of telephony and aided materially in bringing the Bell telephone into practical use.

Most modern inventions result from the contributions of many minds, and it is often difficult for the courts to determine priority, but when Edison made application in 1877 for a "phonograph or speaking machine," the U.S. patent office could discover no previous record of this sort. The original model, costing $18, recorded on a cylinder covered with tin foil and turned with a hand crank. Ten years afterward Edison developed a motor-driven machine with cylindrical wax records, and this speedily became popular. Later he invented a disc form for reproducing music with a diamond point as well as the "Ediphone" for office dictation.

On Oct. 21, 1879, after expending more than $40,000 in fruitless experiments, he succeeded in making an incandescent lamp in which a loop of carbonized cotton thread glowed in a vacuum for more than 40 hours. The following decade was devoted to the invention and exploitation of methods for the generation and distribution of electricity, including the three-wire system, underground mains, improved dynamos and motors and an electric railway for carrying freight and passengers. From 1891 to 1900 he was chiefly engaged in the advancement of a magnetic method of concentrating iron ores and from 1900 to 1910, in the development of a new kind of storage battery, using an alkaline solution with nickel hydrate as the positive material and iron oxide as the negative. In 1891 he applied for a patent on a "kinetescopic camera" for taking motion pictures on a band of film to be viewed by peeping into a box; this was later improved to project the pictures on a screen.

In the *Scientific American,* Dec. 25, 1875, he described an unknown "etheric force," which manifested itself by sparks passing between carbon points at a distance from an interrupted current, In 1883 he patented what became known as "the Edison effect," the passage of electricity from a filament to a plate of metal inside an incandescent lamp globe (a forerunner of the electron tube), and in 1885 a method of transmitting telegraphic signals from moving trains or between ships by induction. During World War I he worked on naval problems for the government and on the production of phenol and other chemicals. In 1927 he was admitted to the National Academy of Sciences.

In his combined workshop and laboratory at Menlo Park, N.J., and later at West Orange, N.J., Edison was incessantly engaged in various forms of invention for more than 50 years and took out 1,033 patents up to April 1928. He died at West Orange, Oct. 18, 1931.

EDMER (EADMER) (c. 1064–*c.* 1141), English historian and biographer of St. Anselm, was of English parentage. probably a native of east Kent. He was placed when a boy in the convent of Christ church, Canterbury, and in due course became a monk there and eventually precentor. When Anselm was made archbishop of Canterbury in 1093, Edmer became his chaplain, and as the archbishop's intimate friend and adviser wrote an authoritative biography of him *(De vita et conversatione Anselmi),* about 1124. Edmer was also closely associated with Anselm's successor Ralph d'Escures, and was active in the prolonged dispute between Canterbury and York over ecclesiastical supremacy in Britain. In 1120, with Henry I's permission, he was appointed bishop of St. Andrews by King Alexander I of Scotland, but returned unconsecrated the next year because Alexander refused to recognize Canterbury's claims to ecclesiastical supremacy over Scotland. Edmer's chief work was his history of England, the *Historia Novorum in Anglia,* and in addition to that of Anselm he wrote biographies of several English saints. Edmer's account of the Canterbury-York controversy is partisan to the point of being disingenuous and even dishonest, but although Archbishops Lanfranc and Anselm are his heroes, his work remains a first-class source for the history of England and the English church between 1066 and 1122. Edmer died probably about 1141.

(G. W. S. B.)

EDMONTON, a city and capital of the province of Alberta, Can., and a trade and transportation centre for much of northwestern Canada, is in the meadow and aspen-grove country of central Alberta at an altitude of 2,182 ft.; the city is located 150 mi. E. of the Rocky mountains, on the wide, impressive valley of the North Saskatchewan river. It is named after Fort Edmonton, a Hudson's Bay company trading post built in 1795, 20 mi. downstream, opposite a North West Fur company post built the previous year. After 1807 the trade of the far northwest was conducted from the present site; the furs were shipped out via the North Saskatchewan river. A few Métis settled in the area, but it did not grow appreciably until the 1870s, when pioneers arrived in anticipation that the transcontinental railway then being built would follow the wooded park belt. That did not happen, but steady agricultural settlement began when a railway connection with Calgary was secured in 1891. In 1905 the transcontinental Canadian Northern railway reached Edmonton on its route to Yellowhead pass in the Rockies. That same year Edmonton was selected as the capital of the newly organized province of Alberta, and in 1906 the University of Alberta was founded there; the city quickly became the undisputed centre of northern Alberta. Edmonton is the wholesaling and retailing centre of a rich mixed farming area that includes the Peace river country 175 mi. N.W.

Some of Canada's largest meat-packing plants were established

in Edmonton, and they comprised its most important industry in the early 1960s. Fuel is obtained relatively inexpensively from nearby coal deposits and natural gas reserves. The whole development of Edmonton was changed in 1947 with the discovery of one of the world's great oil fields at Leduc, 20 mi. S. Thereafter a number of other important fields. including Redwater and Pembina, were discovered within 75 mi. of Edmonton, and the city experienced a sustained boom. Its population more than doubled after 1941, when it was just under 100,000. The population was 281,027 in 1961 (metropolitan area, 337,568).

Edmonton became the leading oil refining centre of western Canada, with three large oil refineries. An important petrochemical industry was developed in the second half of the 20th century, and there were plants producing polyethylene, cellulose acetate and various industrial chemicals. Other industries such as pipe mills and steel-fabricating plants also serve the oil industry. Near Edmonton a large nickel refinery utilizes natural gas as a fuel; commercial fertilizers are an important by-product. Only 235 mi. N.W. in the valley of the Athabasca river, are the famous oil-saturated tar sands, a great potential source of petroleum.

Edmonton is served by two transcontinental railway lines; railways radiate from Edmonton to the Peace river country, where the Alaska highway continues northward, and to the town of Fort McMurray in the northeast, which is on the Mackemie water system that serves the area to the Arctic ocean. Thus the city functions as the distributing and collecting centre for the rapidly developing north. Edmonton is in a strategic position for international flights in the northern hemisphere; there are daily transcontinental flights, as well as flights to Alaska and the rest of the United States, and to the Canadian Arctic. (JN. H. W.)

EDMONTON, a municipal (1937) and parliamentary borough of Middlesex, Eng., 9 mi. N. of London bridge by road. Pop. (1961) 92,062. Edmonton, consisting of Upper and Lower Edmonton, lies near the Essex border along the Old North road (Ermine street) between Tottenham and Enfield, with the river Lea for its eastern boundary. Also running through the borough are the New river (an artificial cut, 1613), the London-Cambridge arterial road and the North Circular road. Timber wharves on the Lea Navigation supply a considerable furniture industry. Textiles and clothing are made, but the chief product is equipment for gas production. The oldest factory is a gasworks (1845). There is ample evidence of Roman occupation around Edmonton, and it was a Saxon township (Eadhelmes tun) as early as the 8th century. The part of Middlesex called Edmonton hundred has existed for 1,000 years with boundaries unchanged. Near the centre of the town with its village green, where the market is held, is Pymmes park (53½ ac.); there are several Georgian houses, and Salisbury house is of the 16th–17th century. In the churchyard of All Saints is the memorial of Charles Lamb, who lived and died (1834) at Edmonton, and his sister Mary. William Cowper and John Keats were also residents, and the Bell inn is famed through Cowper's poem "John Gilpin."

Other literary allusions include the play *The* Merry *Devill of Edmonton* (published 1608) and the joint play of William Rowley, Thomas Dekker, John Ford, etc., *The Witch of Edmonton* (published 1655). The public library (1897) is a Lamb and Keats memorial.

EDMUND, SAINT (EDMUND RICH) **(c. 1175–1240),** archbishop of Canterbury and a distinguished scholar, was born at Abingdon, near Oxford, on Nov. 20, probably in 1175. His father, Reginald of Abingdon, a fairly prosperous merchant earned for himself the nickname of "the Rich," which apparently became hereditary in the family. Edmund began his education in a grammar school at Oxford, and at the age of 12 took a vow of perpetual chastity in the Virgin's church at Oxford. After graduating at Paris, he lectured for six years in the liberal arts, partly in Paris and partly in Oxford, where he was the first to lecture on Aristotle. He returned to Paris to study theology, on which subject he then lectured at Oxford. In 1222 he accepted the treasureship of Salisbury cathedral, and little is known of his life for the next ten years. But he attracted the notice of the Roman court and during 1227 he preached the crusade in England.

In 1233 Edmund was elected archbishop of Canterbury at the express suggestion of Pope Gregory IX, after the monks of Canterbury had in vain suggested three other candidates for the pope's approval. Edmund at once leaped into prominence by the outspoken manner in which he rebuked the king for following the advice of foreign favourites. In common with the baronial opposition he treated Henry III as responsible for the tragic fate of Richard Marshal, earl of Pembroke *(see* PEMBROKE, EARLS OF), and threatened the king with excommunication. The king bowed before the storm, dismissed the foreign counselors, made peace with Marshal's adherents and was publicly reconciled with the barons. But it was in part at least in the hope of emancipating himself from Edmund's control that the king asked the pope to send him a legate (1236).

Matthew Paris, who heartily disliked the pope's envoy, paints a picture which was accepted as true until modern research showed it to be grossly exaggerated. According to him, on the arrival (1237) of the legate, Cardinal Otto, the archbishop felt himself thwarted at every point: the marriage between Simon de Montfort and the princess Eleanor, which Edmund had pronounced invalid, was ratified at Rome upon appeal; the king upheld the monks of Canterbury in their opposition to the archbishop's authority, a common occurrence at the time, and the legate, if he did not actually favour the king's moves, kept silent. In fact, however, there are several indications that the two prelates remained on food terms and trusted each other. Nevertheless, Edmund duly laid a protest before the king and excommunicated in general terms all who had infringed the liberties of Canterbury. These measures, the least he was expected to do, led to no result; he possibly had anticipated this. In 1240 the English clergy were required to pay the pope a subsidy for the war against Frederick II, and simultaneously 300 Romans were "provided" with English benefices.

In Aug. 1240 the pope, Gregory IX, summoned a general council. Edmund, who in any case was bound to his triennial visit to Rome, seems to have anticipated the normal date in order to discuss personally with the pope the affairs of Canterbury and of England in general. He crossed the channel and stayed for a little rest at Pontigny, but the state of his health drove him later to Soisy (near Provins), where he died on Nov. 16, which is his feast day. His candnization, demanded at once by his admirers, was delayed (till 1247) through the opposition of Henry III.

Edmund is one of the most saintly and attractive figures of the English church. It mas his misfortune to be placed at the head of the national hierarchy in a crisis for which he had not been prepared by practical training or experience. As archbishop he showed no great capacity or force of character, but the purity of his motives and the loftiness of his ideals commanded universal respect.

Some scholastic treatises are claimed as the work of Edmund. Assuredly authentic is the once widely known *Speculum ecclesiae,* a devotional treatise which belongs to the end of his career; it appeared in *Bibliotheca,* vol. v (1609), edited by M. de la Bigne (Eng. trans. by F. M. Steele, 1905).

EDMUND (EADMUND), **SAINT,** THE MARTYR (d. 869), king of East Xnglia, was killed by the Danes on Nov. 20. 869. The Annals of St. Neots date his accession 855, but contemporary authorities record only his death. The Anglo-Saxon Chronicle says that he fought the Danes and was defeated and killed. The belief that he was killed, not in battle, but unresisting, must have arisen early, for the St. Edmund pennies afford evidence of his cult before the end of the 9th century. The oldest life, written by Abbo of Fleury about 985, claims to repeat the story as Dunstan had heard it told to King Aethelstan by Edmund's sword-bearer. It tells how he was shot at with arrows and eventually beheaded by the command of the Dane Ingwar for refusing to desert Chris-

tianity. He was ultimately buried at Beadoricesworth (now Bury St. Edmund's; *q.v.*), where his shrine became famous. Later, fictitious, versions make him a continental Saxon, born at Niirnberg, and adopted by Offa, king of East Anglia, when on his way to Rome. They also invent names for his parents, Alkmund and Scivare. His feast is celebrated on Nov. 20.

Arnold (ed.), *Memorials of St. Edmund's Abbey* (1890–96), including the *Passio S. Eadmundi* by Abbo of Fleury; Lord Francis Hervey, *The History of King Eadmund the Martyr* (1929). (D. WK.)

EDMUND (EADMUND) **I** (921–946), king of the English from 939 to 946, was the son of Eadgifu, third wife of Edward the Elder, and was half brother of King Aethelstan, alongside whom he had fought at the battle of Brunanburh in 937. On Aethelstan's death in 939, Olaf Guthfrithson, the Norse king of Dublin, occupied Northumbria, and in 940 raided the midlands as far as Tamworth. A peace made at Leicester left him in possession of Northumbria and of the territory of the Five Boroughs of Lincoln, Stamford, Nottingham, Derby and Leicester, but Edmund recovered all except Northumbria in 942 after Olaf's death, and in 944 regained Northumbria, driving out the Norse kings Olaf Sihtricson and Raegnald. He captured Strathclyde in 945 and entrusted it to Malcolm I of Scotland in return for a promise of his support on sea and land. He thus inaugurated a policy of establishing a secure frontier and peaceful relations with Scotland, which was followed by his son Edgar also. Early in his reign he received an embassy from Germany, and just before his death he intervened in Frankish politics in support of King Louis IV, who had been foster son of Aethelstan.

His short reign produced three law codes, apart from the Hundred ordinance which may be his or Edgar's. The hundred is first mentioned in his laws. He aimed at curtailing the practice of the blood feud and at suppressing cattle thieving. One code enjoins celibacy on the clergy, perhaps at the instance of Dunstan, whom he made abbot of Glastonbury.

Edmund was killed on May 26, 946, in his royal hall at Pucklechurch, Gloucestershire, by Leofa, an exiled robber, and he was buried at Glastonbury. By his first wife, Aelfgifu, he left two sons, Edwy and Edgar, and he was succeeded by his brother Edred.

EDMUND (EADMUND) **II** IRONSIDE (c. 993–1016), king of the English from April 23 to Nov. 30, 1016, was a son of Aethelred II and his first wife, Aelfgifu. When, in 1015, after the murder of two leading thegns of the northern Danelaw, Sigeferth and Morcar, King Aethelred confiscated their estates and imprisoned Sigeferth's widow, Edmund seized and married her against his father's will, took possession of the estates of Sigeferth and Morcar and was accepted as ruler by the people of the Five Boroughs (Lincoln, Stamford, Nottingham, Derby and Leicester). When Canute invaded later in 1015. Edmund raised the northern forces, while Ealdorman Eadric of Mercia collected an army in the south, but then deserted Edmund for Canute. Edmund assembled the English army late in the year, and again early in 1016, but on both occasions it disbanded because it would not fight without King Aethelred being present. Then Edmund and Earl Uhtred of Northumbria laid waste the northwest midlands which would not come out against the Danes. Meanwhile Canute ravaged in the east and finally reached York, thus causing Uhtred to return north and submit. Edmund joined his father in London, and after Aethelred's death some councilors with the citizens of London elected him as king, while a fuller gathering of the witan at Southampton chose Canute. From then until Oct. 18, Edmund led a strong resistance against the Danes. He recovered Wessex, relieved the siege of London and forced the Danes, who had been raiding Mercia, to take shelter in Sheppey. Ealdorman Eadric now rejoined Edmund; but when, on Oct. 18, Edmund intercepted the Danish army at Ashingdon, Essex, Eadric again deserted and Canute was victorious. Peace was made at Alney, Gloucestershire, Edmund retaining Wessex and Canute the lands north of the river Thames. When Edmund died on Nov. 30, 1016 (probably from natural causes, since only late authorities say he was murdered), Canute became king of all England. Edmund was buried at Glastonbury. His stout defense against Canute earned him the epithet "Ironside," recorded from the late 11th century. His infant sons were brought up in Hungary, and one of them, Edward, became the father of Edgar the Aetheling and of his sisters Margaret (afterward queen of Scotland) and Christina.

EDMUNDS, GEORGE FRANKLIN (1828–1919), U.S. senator and noted constitutional lawyer, was born in Richmond, Vt., on Feb. 1, 1828. He had little formal schooling but studied law and was admitted to the bar in 1849. He served as a Republican member of the Vermont house of representatives (1854–59) and the Vermont senate (1861–62). He was appointed to a vacancy in the U.S. senate in 1866 and served until 1891 when he resigned to devote full time to the legal profession. He was chairman of the senate judiciary committee from 1872 to 1891 except for one two-year period, and was president pro *tem.,* 1883–85. He took an active part in the impeachment proceedings against Pres. Andrew Johnson and supported the Tenure of Office act limiting the president's power to make removals. Edmunds was influential in establishing the electoral commission to decide the disputed presidential election of 1876 and became one of its members. He was a candidate for the presidential nomination in 1880 and 1884, receiving 93 votes in the Republican convention in the latter year. The act for the suppression of polygamy (1882) bears his name and he was responsible for the final form of the Sherman Anti-Trust act (1890). He was admired for his legal acumen, independence and inflexible integrity but feared for his barbed wit. He died in Pasadena, Calif., on Feb. 27, 1919.

See W. *H.* Crockett, *Vermont: the Green Mountain State* (1923), *A Book of Biographies* (1932). (E. H. Ro.)

EDO, the vernacular name for the city of Benin (*q.v.*), is used to designate those Negro peoples in Southern Nigeria who speak dialects of Bini, one of the Kwa group of Western Sudanic languages. Their territory, a little west of the Niger river, extends from hilly country in the north to swamps in the Niger delta about 150 mi. southward and makes up the four administrative divisions, Kukuruku, Ishan, Benin and Urhobo (Sobo). Altogether the Edo in Nigeria number just over 500,000 (1952 census). Benin Division (pop. 292,081) was once the nucleus of the former Benin empire; the other divisions do not correspond to indigenous political units, the latter being far smaller, mostly petty kingdoms or chiefdoms of one or more villages and a few single autonomous villages without chiefs.

Today many Edo are Christians or Muslims, but traditionally they believe in a rather remote high god, the Creator. Lesser gods have cults everywhere; local heroes and the spirits of parents are also worshiped, and witchcraft beliefs are distinctive. The village is the basis of political organization. The men are associated in age grades, and patrilineal descent is combined with primogeniture in the inheritance of offices. These customs are modified by other features—*e.g.,* titled political, military and priestly offices, title societies and, in the south, women's age grades—which differ in complexity and relative importance from place to place. See also NIGERIA.

(1910). (P. M.-W.)

EDO (YEDO), the ancient name for Tokyo, the capital city of Japan. Edo was a small fishing village at the end of the 16th century but soon thereafter became important under the shogun Tokugawa Ieyasu, who made it his capital. In less than a century the population of Edo exceeded 1,000,000. In 1868 it was pro-

claimed the residence of the emperor and official capital of Japan, and was renamed Tokyo. In the 20th century it continued to grow in spite of fires, earthquakes and air raids during World War II. By 1960 the population of Tokyo had reached 8,310,027, and the city had become known as one of the most modern in the world. *See* also TOKYO.

EDOM refers variously to a land (Gen. xxxvi, 31, 32), equated at times with Seir (Gen. xxxii, 4); a person, identified with Esau (*q.v.*); and a people (Num. xx, 21).

In the pre-exilic period, the territory of Edom lay solely east of the Dead sea and the (Wadi) Araba, the great rift extending between the south end of the Dead sea and the Gulf of Aqaba, the east arm of the Red sea. It consisted mainly of the southern continuation of the high, rolling, fertile plateau, of which Moab (*q.v.*), immediately north of it, formed one segment. Oriented north-south, it measured 82 by 33 mi. The t o lands were separated by the wide and deep canyon of the Zered river (Wadi Hesa) (Num. xxi, 12) which, rising in the reaches of the desert to the east, flowed westward, emptying into the southeast end of the Dead sea.

Edom was bounded on the north by the Zered, on the west by the Araba and on the east by the desert; the southern boundary was formed by the edge of the tableland which drops suddenly to meet the Wadi Hismeh, a part of the great Arabian desert. On this high plateau, rising in places to above 3,500 ft., with its temperate climate, abundant natural resources and strategic position astride the trade routes between Arabia and Syria, numerous civilizations arose and fell from earliest historical times onward, with sometimes fallow periods lasting as long as 500 years intervening between the destruction or collapse of one and the development of another. The historical memory contained in the account in Gen. xiv of the destruction wrought by the kings of the east has been corroborated by the discovery of a whole series of Bronze Age sites which were destroyed no later than the 19th century B.C. and were never again reoccupied. Thereafter, for more than five centuries, till the establishment of the kingdoms of Edom and Moab and the related kingdoms of eastern Palestine in the 13th century B.C., nomads roamed the land. In the Negev and Sinai the gap in sedentary, agricultural civilization lasted between the 19th and the beginning of the 10th century B.C. It is significant in connection with this particular gap in the history of permanent, sedentary civilization in Edom, as in Moab, that neither the Egyptian lists of towns nor the Tell el-Amarna letters refer to them or to eastern Palestine in this period between the 20th and 13th centuries B.C. Edom and Seir, for instance, are first mentioned in the records of Merneptah (*c.* 1234 B.C.) and of Ramses III (1198–67 B.C.). There are no archaeological traces of Horites (Deut. ii, 12, 22) in either the hill country of Edom or in the Araba or in the Negev. It may be that under the Horites are to be understood purely nomadic groups such as the Edomites must have found and conquered when they seized the territory to which they gave their name. They may originally have been descended from the Hurrians (*q.v.*) who, to judge from archaeological finds at Nuzi, played an important role in the ancient near east during the 2nd millennium B.C.

The heyday of the Edomite kingdom extended from the 13th to the 8th centuries B.C., although it continued to exist several centuries longer. Its civilization was of a high order, Agriculture, animal husbandry, mining and metallurgy, architecture. pottery making and commerce were among the sophisticated activities. The land was dotted with well-built stone villages and towns and fortresses. The literature of Edom, like that of Moab, was in all probability of no mean order, if inferences may be drawn from the related Moabite inscription of Mesha. Edomite pottery, like Moabite pottery of the 13th to 6th centuries B.C., was possessed in part of outstanding and distinctive excellence. Archaeological investigation has revealed pottery figurines indicative of the worship of fertility gods, which prevailed throughout the entire ancient near east.

The beginning of Edomite as of Moabite pottery antedates that of the closely related Israelite pottery. This precedence has a direct relationship to the account in Gen. xxxvi, 31–39, which lists "eight" Edomite kings who reigned in the land of Edom before the Israelites had a king. This archaeological fact harmonizes with the biblical information that the Edomite and Moabite kingdoms were established before the advent of the Israelites, who begged in vain for perniission to travel through these kingdoms via the "king's highway" en route to the Promised Land (Num. xx, 14–21; Judg. xi, 17). These well-established kingdoms with their strongly fortified frontiers refused permission, and the Israelites were compelled to go east around their territories, and finally succeeded in forcing their way westward on the north side of the Arnon, through what at that time was part of the territory of Sihon, king of the Amorites. Had this particular Exodus of the Israelites taken place before the 13th century B.C., they would have found neither Edomite nor Moabite kingdoms whose rulers could have given or refused them transit permission through their territories.

Throughout most of their history, Edom and Judah were engaged in war with each other, primarily to determine which was to control the Araba rift that stretched between them and that was of great importance because of the trade route which followed its length and especially because of its copper and iron deposits (Deut. viii, 9). Long before the outbreak of Judaeo-Edomite hostilities, the copper and iron in the Araba were mined by the Kenites and then by the Edomites, to whom they were related through the Kenizzites (Gen. xv, 19). David defeated Edom and enslaved many of the Edomites (II Sam. viii, 13–14). Solomon was able to capitalize on David's gain and organized the copper-mining industry on a large scale. He probably compelled many Edomites to work for him in the copper mines in Araba. When the tables were reversed, the Edomites probably did the same with Judaean prisoners. They are known to have engaged in the slave trade (Amos i, 6, 9), and whenever opportunity offered took slaves from Judah (II Chron. xxviii, 17). Solomon, although he had to contend with the Edomite prince Hadad (I Kings xi, 14 ff.), held undisputed control over the Araba itself. He exploited its mines and exported copper on his Tarshish ships sailing from his port city Ezion-geber to Ophir (I Kings ix, 26–28; x, 11, 22; II Chron. xx, 36–37). When next heard of, Edom was ruled by Jehoshaphat through a deputy governor (I Kings xxii, 47). Jehoshaphat attempted but failed to revive the sea trade from Ezion-geber (I Rings xxii, 48). During the reign of his son Joram, Edom regained its independence (II Kings viii, 20–22).

For somewhat more than half a century, Edom was undisturbed. Then Amaziah of Judah in 800 B.C. captured Sela, the main stronghold of Edom, and renamed it Joktheel (II Kings xiv, 7). His son Uzziah (Azariah) completed the reconquest of Edom, recovering Ezion-geber (which had become known as Eloth or Elath) from Edom and establishing it as a port (II Kings xiv, 21–22; II Chron. xxvi, 1–2). Edom then remained subject to Judah till the time of Uzziah's grandson, Ahaz, when it regained control of the Araba and of Elath by taking advantage of Ahaz' distress during the Syro-Ephraimitic war in 734 B.C.

To the first part of this final period of Edomite control over Elath belong pottery jars discovered in excavations there, stamped with a royal seal in ancient Edomite (Hebrew) characters reading: "Belonging to Qosanal, the Servant of the King." Qosanal is a typical Edomite name, the first part of which, Qos, is the name of a well-known Edomite and then Nabataean deity.

Following its recovery of Elath, Edom, like Judah, experienced a progressive decline. The long struggle with Judah, plus the extended period of aggrandizement by Assyrian and Babylonian armies against Edom and Moab, in addition to whatever events may have transpired during the very first part of the rise of the Persians to power. coupled with the growing strength of the Nabataeans who had appeared upon the scene, resulted in the weakening and destruction of the Edomite state. By the 4th century B.C. the Nabataeans dominated the former territory of Edom as they did that of Moab.

Many of the Edomites, pushed out of their former territory by the Nabataeans, drifted westward across the Araba and established themselves in southernmost Judah. There, during the Hellenistic period, they became known as Idumaeans. The possibility that

Edomite territory once extended into parts of southern Palestine is suggested by a number of biblical verses which definitely locate Edom-Seir on the west side of the Araba. All of these verses, however, in their present form must be dated to the exilic period or later, after the collapse of the Edomite kingdom on the east side of the Araba. They reflect the Idumaean settlement in southernmost Judah, which the author of Deut. xxiii, 7 probably had in mind when he said: "You shall not abhor an Edomite, for he is your brother," meaning those Idumaeans who had been Judaized and had become worshipers of Yahweh. The close relationship of the Idumaeans and Judaeans in Judah and the Nabataeans in the former territory of Edom and Moab as well as in the Negev and Sinai can be no better illustrated than by the marriage of Herod Antipas, the son of the Idumaean Herod the Great, king of Judaea, to the daughter of the Nabataean king Aretas IV.

EDRED (EADRED) (d. 955), king of the English from 946 to 955, was the son of Edward the Elder and his wife Eadgifu. He succeeded his brother Edmund in 946, and received the submission of Northumbria and took oaths from the Scots. In the next year, Archbishop Wulfstan I of York and the Northumbrians pledged themselves to him at Tanshelf, Yorkshire, but soon afterward accepted as king Eric Bloodaxe, a son of Harald I Fair-hair of Norway. Edred ravaged all Northumbria in revenge (948), burning the minster at Ripon. His rear guard was overtaken and defeated at Castleford, and Edred was prevented from utterly destroying the land only by the Northumbrians' desertion of Eric and payment of compensation. Yet they accepted in 949 another Scandinavian, Olaf Sihtricson, as king; they drove him out in 952 in favour of Eric Bloodaxe, who was expelled and killed in 954. Henceforward the West Saxon kings ruled Northumbria. Archbishop Wulfstan was suspected of disloyalty and imprisoned in 952; he was restored in 954, but apparently not allowed to return to Northumbria. Edred was a close friend of Dunstan and a supporter of monastic revival. He gave Abingdon to Aethelwold (afterward bishop of Winchester) for him to refound the monastery there. Edred suffered from continuous ill-health. He died at Frome on Nov. 23, 955, and was buried at Winchester. His will sheds light on the constitution of a king's household. He left a large sum of money for his people to buy off heathen armies if required.

EDUCATION (ARTICLES ON). Educational methods are presented in the context of the cultures from which they arose, from those of ancient India, China, Greece and Rome to the world of today, in EDUCATION, HISTORY OF. This article outlines the concepts of the great leaders of educational thought, and the rise and development of national school systems. A supplementary article, WOMEN, EDUCATION OF, deals with the traditional prejudice against academic and professional training for women, its social sources and its conquest.

Theories as to the purpose of education, both in democratic and nondemocratic societies, are analyzed in EDUCATION, PHILOSOPHY OF; various kinds of control, management and direction of matters related to schools are discussed in SCHOOL ADMINISTRATION. Practical applications of educational philosophy are treated in TEACHING, METHODS OF and TEACHERS, TRAINING OF. The educational pioneers whose contributions are described in articles of this type are represented also by biographical articles.

Current methods of education on various age levels in Great Britain and the United States are the subject of a series of articles: PRE-ELEMENTARY EDUCATION; ELEMENTARY EDUCATION, which is supplemented by PAROCHIAL SCHOOLS; SECONDARY EDUCATION; and HIGHER EDUCATIOK. Also, sections on educational administration are included in many articles on nations and states —*e.g.*, FRANCE: *Education;* OHIO: *Education;* etc.

SCHOOL AND CURRICULUM discusses the content of education, including extra-class activities, at various age levels in the school systems of the major nations of the world; the social objectives that determine the curriculum; and the main types of curriculum, in terms of orientation—child-centred, community-centred, etc. Articles on specific types of subject matter include ART EDUCATION; CLASSICAL EDUCATION; FOREIGN LANGUAGES, TEACHING OF; HUMANITIES; MUSIC, TEACHING OF; PHYSICAL EDUCATION; READING; and SCIENCE, TEACHING OF. Techniques that have contributed to teaching effectiveness in many areas are described in AUDIO-VISUAL EDUCATION and in TELEVISION: *Closed-Circuit Television.* Discussions of testing methods include EXAMINATIONS and PSYCHOLOGICAL TESTS AND MEASUREMENTS.

Problems of special groups of students are treated in BLIND, TRAINING AND WELFARE OF and DEAF AND HARD OF HEARING, TRAINING AND WELFARE OF.

UNIVERSITY outlines the development of the first universities from the centres of instruction known as *studia generale;* the rise of the University of Paris, Oxford and Cambridge and the spread of centres of higher education in Europe; and the establishment of modern universities in various parts of the world. This article is supplemented by COLLEGE; LAND-GRANT COLLEGES AND UNIVERSITIES; UNIVERSITY COLLEGE; and individual articles on many colleges and universities. Also, information on colleges and universities is included in many articles on the cities in which they are located.

Education for professional careers is discussed in ARCHITECTURAL EDUCATION; ENGINEERING EDUCATION; LEGAL EDUCATION; MEDICAL EDUCATION; etc. Education for the armed services is treated in MILITARY, NAVAL AND AIR ACADEMIES. Among the articles dealing with specialized fields are AGRICULTURAL EDUCATION AND RESEARCH; TECHNICAL EDUCATION; and VOCATIONAL EDUCATION. Also, articles on various careers—for example, ACCOUNTING; JOURNALISM; and PHARMACY—contain sections on education in these areas.

Articles dealing with institutions and methods adapted to special needs include ADULT EDUCATION; CORRESPONDENCE INSTRUCTION; EMPLOYEE TRAINING; RURAL EDUCATION; SUMMER SCHOOL; and UNIVERSITY EXTENSION.

Among the articles concerned with the professional interests of teachers are ACADEMIC FREEDOM; EDUCATION, SOCIETIES OF; EDUCATIONAL ARCHITECTURE; PARENTS AND TEACHERS, NATIONAL CONGRESS OF; SCHOOL ADMINISTRATION; and TEXTBOOKS.

Scholarships, fellowships and other forms of financial aid to students are discussed in STUDENT AID. Additional articles of general interest include COEDUCATION; DEGREE, ACADEMIC; EDUCATION, INTERNATIONAL; FRATERNITY AND SORORITY; and PARENT EDUCATION.

In many cases, articles in related fields will be found helpful in setting educational problems in perspective—for example, ART; BOOK; the articles cited in CHILDREN (ARTICLES ON); CIVILIZATION AND CULTURE; INTELLIGENCE; PHILOSOPHY AND PHILOSOPHICAL STUDIES; PSYCHOLOGY (ARTICLES ON); SCIENCE; and SOCIOLOGY. For a comprehensive view of *Encyclopædia Britannica's* resources on any topic, the Index should be consulted.

While some of the articles referred to in the above paragraphs are of special importance to the teaching profession, all are essentially nontechnical and within the grasp of the intelligent layman. The following articles are recommended as a minimal reading program for those who wish an introduction to the aims and methods of the educational world: CIVILIZATION AND CULTURE; SCHOOL AND CURRICULUM; EDUCATION, HISTORY OF; HUMANITIES; SCIENCE.

EDUCATION, HISTORY OF. This article deals with the history of educational thought and practice from early historical times to the present day. Emphasis is placed on the history of elementary education rather than on that of secondary, technical and university education *(see* SECONDARY EDUCATION; TECHNICAL EDUCATION; UNIVERSITY). Descriptions of modern educational systems are in general to be found in the educational sections of the country articles: and there are also articles treating the different aspects of education *(see* COEDUCATION; ELEMENTARY

EDUCATION; SCHOOL ADMINISTRATION; etc.).

The educational programs of underdeveloped countries and of countries achieving independence after World War II have been primarily concerned with the pressing problems of illiteracy and of providing elementary education for children and functional education and technical training for adults. Programs to meet these problems are discussed in the country articles. (See also ADULT EDUCATION; AGRICULTURAL EDUCATION AND RESEARCH; AUDIO-VISUAL EDUCATION; ELEMENTARY EDUCATION; ILLITERACY; READING.)

The article is arranged as follows:

I. THE WESTERN WORLD

It is usual to regard ancient Greece as the cradle of western education and as the starting place of its history. Earlier cultures — Mycenaean, Minoan and Egyptian — contributed to Greek development, but all too little is known about them, whereas the Greeks have handed down a rich store of knowledge about their educational thought and practice during the 5th and 4th centuries B.C., the great days of their civilization. Ever since, this remarkable heritage has been a formative and creative influence in the shaping of educational policy, especially in western countries.

1. Ancient Greece.—Living in city-states, the Greeks regarded education as a major service of the state and an essential instrument for the training of citizens. Frequently engaged in life-and-death struggles against powerful enemies and, in addition, often in peril from within the city-state itself, they looked to education to provide citizens capable of defending the city in any crisis. But theirs was an exclusive citizenship, for Greek civilization rested on a basis of slavery, the slaves outnumbering the citizens. Trade and manual work, regarded as degrading, were left to slaves and Greek education did not, therefore, include technical and commercial studies.

Each city-state had its distinctive character and its own conception of good citizenship, with consequent differences in educational aims, a characteristic well illustrated by the contrast between Spartan and Athenian ways of educating children and young people. The Spartans were always a minority in their territory and to retain their position as the dominant race had to be strong enough to enforce their authority over the subject majority. They had also to be able to garrison their frontiers effectively against possible invaders. Their principal aim, therefore, was military efficiency and their education was designed to promote soldierly qualities such as courage and obedience. Xenophon and other Greek writers have described the system in some detail, revealing the ruthlessness with which young people were conditioned to make them brave soldiers. Physical fitness was the paramount objective. Babies with weak constitutions or physical defects were killed by exposure and those allowed to live were, at the age of seven, taken from their mothers for a course of rigorous training. This training continued with increasing severity for the next 11 years. Grim austerity was the keynote of their lives during this long apprenticeship, the memory of which survives in our use of the word "Spartan." They were organized in "packs," each under the leadership of a boy picked for his ability and courage. Corporal punishment was an important feature of the discipline and it was imposed not only as a penalty but also as a test of endurance. Boxing and other pastimes calculated to foster fighting instincts were encouraged, and boys were kept fully occupied by an exacting round of activities. At the age of 18 they became ephebi (cadets) and for two years were trained in garrison duty. When they were 30 they became full citizens, but their military education did not cease until they were too old to fight.

Whether in the course of their training they learned to read is uncertain. Unlike other Greek states Sparta cared little for poetry and the arts. It made an exception, however, of the works of Homer and poems of war, especially those "in praise of the men who had died for their country." And the Spartans loved dancing, particularly when it reproduced movements of battle or of gymnastic exercises like wrestling. A notable feature of Spartan education was the care taken in the upbringing of girls. In other Greek states girls were given no education other than the domestic training that home life provided. But in Sparta girls were also taught to be active out-of-doors and to regard physical fitness as a main objective. They were allowed to live at home but in other respects their training was similar to that of the boys; they had their own playing field where, under strict discipline, they joined in various games and practised physical exercises designed to make them strong and healthy so that they might grow up to become the mothers of brave and sturdy soldiers. Motherhood and the careful rearing of children were set before them as the highest ideals, and the women of Sparta were renowned for their excellence as mothers and nurses. Within its narrow range, education in Sparta was certainly efficient and fulfilled the main task assigned to it, that of helping to produce loyal and courageous soldiers. But it was a poor training for political leadership, and Sparta suffered for lack of distinguished citizens with political insight.

Although as concerned as Sparta about defense, the Athenians had a very different attitude toward life and this was reflected in their education. Their boys were prepared for peace as well as for war, and more was expected of them than of their Spartan contemporaries — wisdom no less than courage. Their aim in education was to rear well-balanced individuals, physically sound and

intellectually alert with a moderate outlook on affairs—"nothing in excess" was a maxim to which they attached much importance. Education in Athens had no clear-cut political aim and was much less a state enterprise than in Sparta. The educative process was divided into two stages which. using modern terminology, may be described as: (1) primary, with an age range from 6 to 14; and (2) secondary, from 14 to 18. At the age of 18 boys began a period of two years' compulsory service as an ephehos, or cadet. taking the customary oath to defend the city and the gods. Later, when Athens fell under the power of Macedonia, the need for military training ceased and the ephebic years were devoted to courses in philosophy and literature. In the primary and secondary stages a principal study was music which included much that we should call literature and art. Gymnastics also had a wide connotation and was designed not only to secure physical fitness but also to promote poise and graceful movement. We have no sure knowledge of the detail of the curriculum but it generally included reading. writing, simple arithmetic, poetry repetition, music and physical exercises. Girls did not share in this education; they were trained at home mainly in housekeeping. This was because women mere not of great account in Athenian society; Pericles suggests their modest role in the saying: "Great is the glory of the woman whose name is not in the mouths of men for either good or evil."

As Athenian culture developed, more attention was paid to intellectual studies, especially by students during their ephebic years. There was a corresponding decrease of attention to physical pursuits. hence the complaints of satirists like Aristophanes about growing luxury and the corruption of youth. Such complaints were apparently based on a comparison of the worst features of the present with an idealized picture of the past. But some criticism was well justified, especially when directed against the influence of the less reputable Sophists, itinerant pay-receiving lecturers who helped to gratify the Athenian's appetite for discussion. They have given the word "sophistry" to our vocabulary, and it furnishes a clue to the type of adult education they provided. Often repudiating the claims of citizenship they were a disintegrating force harmful to the morale of the state. Some Sophists, however, were great teachers and one of them. Socrates, as we see him through the eyes of his disciple Plato, stands out as one of the noblest and wisest men of all time. Although a Sophist he was a fierce enemy of the shallow and pretentious rhetoric with which some of these lecturers misled their hearers.

The Athens and Sparta of their day provided Plato and Aristotle with a useful background for their discussion of educational principles But the quality of their thought transcends limits of time or place, and some of the problems that they examine belong as much to the 20th century AD. as to their own. While Plato discusses education in several of his dialogues, his major pronouncement., about it are in his *Republic* and in his *Laws.* "If you want to know what is meant by public education," said Rousseau in his *Émile* (Eng. trans.. Everyman ed., 1955), "read Plato's *Republic.* Those who merely judge books by their titles take this for a treatise on politics, but it is the finest treatise on education ever written." Both Plato and Aristotle regarded politics and education as inseparable: for in their view education. with its main purpose the training of good citizens, should be the basis of any political structure. But the emphasis on citizenship did not involve disregard of the individual, for to be a good citizen it was necessary to be a good man. "If you ask what is the good in general of education," Plato observed in his Laws, "the answer is easy; education produces good men and good men act nobly. . . ."

But Plato distrusted democracy—the trial and death of his master. Socrates, was one reason for this, and he taught at a time when some brake upon excessive individualism was necessary So he advocated a kind of communism that has been likened to that of a monastery. with education as the main creative force in the community life But this community life involved the destruction of the family as a social unit and the elimination of parental control in the upbringing of children. This feature of Plato's utopia has had many critics including several in general sympathy with his views—Aristotle, for example, and Rousseau who asks in his *Émile:* (Eng. trans., Everyman ed., 1955): "Can devotion to the state exist apart from the love of those near and dear to us? Can patriotism thrive except in that miniature fatherland, the home? Is it not the good son, the good husband, the good father who makes the good citizen?"

Another much-criticized feature of Plato's educational scheme was that it confined the benefits to a governing class neglecting the industrial, artisan elements. Members of the governing class were to be sorted into two categories during their educational course. Those who showed practical ability but lacked philosophical insight would be given a training to fit them for military service or for subordinate positions in the task of government. But those nho were outstanding in wisdom would be given a prolonged training to equip them for the highest service to the state, namely that of ruler or guardian. At the age of 20 those who showed promise of this kind were to undergo, for approximately ten years. an advanced course of study in which the mathematical sciences were an important element. At 30 there was a further selection and those chosen would be called upon to study dialectic or philosophy for five years and at the end of that period would be assigned various duties to enable them to gain experience as leaders in military and civil affairs. Finally, at 50 they would be required to spend their lives in contemplation of "the good," and to be ready "when their time comes to toil also at politics and in ruling for the public good." These guardians were the elite of Plato's utopian state, the finest products of an elaborate education designed to promote as its principal aim human goodness "intimate with the eternal order."

While it is quality of thought and vision that makes Plato's plan for education remarkable, some of the details are interesting and important. His view that women should receive the same education as men did not gain general acceptance in Great Britain until late in the 19th century, and his insistence upon it is the more surprising because in the Athens of his time women were treated as inferior beings to be educated only in household affairs. Similarly advanced was his appreciation of the role of adult education and his belief that some studies, such as philosophy, need a background of experience and maturity. Plato's conception of education was concerned to impart values, taking as a guiding principle in their selection the view that all education should conduce to the promotion of goodness. Sir Richard Livingstone has described this notion of education as a training for goodness as the most important truth that can be learned from Plato. It has had a profound influence on educational thought in the western world, and many great teachers have consciously or unconsciously based their philosophy of education upon it. Thomas Arnold, for example, mas echoing Plato when he defined education as "teaching our understandings to know the highest truth, teaching our affections to love the highest good. . . . The great work of education is to make us love what is good, and therefore not only know it but do it."

Aristotle mas one of Plato's pupils and shared many of his opinions about education. Like his master hewbelieved that education should be controlled by the state and that it should have as a main objective the training of citizens. The last chapter of his *Politics* (B. Jowett's trans., 1905) opens with these words: "No one will doubt that the legislator should direct his attention above all to the education of youth. . . . The citizen should be moulded to suit the form of government under which he lives." He shared some of Plato's misgivings about democracy, but after discussing various forms of government he declared his preference for limited democracy. He recognized, ho ever, that it could only succeed if the citizens were of high quality and contended that education should have two principal aims—training for citizenship and the development of personality. His conclusion about the purpose of education is, therefore, not unlike the twofold British aim as expressed in the Hadow report (1926) on the *Education of the Adolescent,* namely, to attain "social individuality." Aristotle anticipates another modern trend when stressing the emotional factor in education: discussing the training of citizens he urges the importance of developing a sense of "affection" for the state and the community.

2. Hellenization of the Western World.—Although on many issues Aristotle's views resemble those of his master, there are some features of Plato's ideal commonwealth of which he strongly disapproved, especially the disruption of family life. In his *Ethics* he describes the family as a centre of friendship and a powerful force for good. He was no recluse but a man of the world acquainted with public affairs; as a tutor to the young prince who became Alexander the Great he had an opportunity of influencing one who later wielded immense power. History does not record what impression he made on his famous pupil, but in due course Alexander by his conquests and his policy of planting Greek cities and towns in conquered territories succeeded during his short reign in bringing Hellenic civilization to the countries bordering the Mediterranean and farther afield. Within ten years (334–324 B.C.) he brought under his sway Asia Minor, Syria, Egypt, Babylonia and Persia, and his vast empire stretched as far as the northern territories of India. Education was encouraged throughout the Hellenic world and new centres of learning rivaling Athens developed in Alexandria, Pergamum, Antioch, Rhodes and other places.

Of the cities founded by Alexander the most famous for its learning was the one which bore his name, Alexandria. It continued to flourish under the Ptolemies, the dynasty that ruled Egypt after Alexander's death in 323, until its conquest by Rome in 30 B C. Alexandria had a famous library founded by the first of the Ptolemies which was reputed to house 700,000 manuscripts, and there was a museum provided by his son with a residence for scholars and research workers. Researches carried out in Alexandria covered a wide field; the pioneer work done in mathematics and science was outstanding, Euclid and Archimedes being two of Alexandria's famous students. "Euclid's Elements," observes Lord Russell in his History of Western Philosophy (1946), "is certainly one of the greatest books ever written, and one of the most perfect monuments of the Greek intellect." Hellenic civilization continued to expand its influence in a variety of ways and eventually, in Cicero's words, it "poured in a great flood from Greece to Rome."

3. Ancient Rome.—During the early centuries of the republic, before coming under the influence of Greek culture, Rome relied upon parents to provide what were regarded as the essentials of education, namely character training, healthy upbringing and a grounding in civic traditions. Fathers were expected to ensure, as far as possible, that their sons grew up healthy in mind and body, that they revered the gods, knew how to conduct public business competently, and were capable of serving their country in the field in time of war. On the mothers rested the responsibility of training their daughters to be modest, virtuous, industrious and skilled in household duties. In training his sons the Roman father contrived to combine a fairly grim severity with a large measure of paternal affection. No attempt was made to arouse cultural interests or to cater to them; it was essentially a practical training, civic and moral, but its intellectual outlook was extremely narrow. It was, however, remarkably effective in producing in its youth a devotion both to the family and to Rome.

It is uncertain when Greek culture began to penetrate into Italy beyond the early southern colonies, but by about 250 B.C. Hellenism was flowing in like a rising tide. Teachers (*grammatici*) set up schools in which they taught their pupils to read and write Greek, basing their instruction on the works of great authors, especially Homer. These authors were soon being translated into Latin, and knowledge of Greek literature increased rapidly. In time, schools of rhetoric and philosophy were established, attracting students preparing for a career in public life or the law. This higher education in rhetoric, characteristic of hellenized Roman education, was not without its critics who feared that it would widen the gulf between the social classes. Theodor Mommsen (*Roman* History, Eng. trans., Everyman ed., 1911), describing it as "an exclusive humanitas," maintains that it "eradicated the last remnants of the old social equality." Cicero deals at length with the training of the orator in his De *Oratore,* contending that the w-ell-educated citizen should be versed in both philosophy and rhetoric. In the next century Quintilian (born about A.D. 35), the most famous of Rome's teachers of rhetoric, wrote his *Institutio oratoria,* in which the conception of rhetorical culture is seen at its best. His ideal was "the good man skilled in speech."

His *Institutio* is not just a monograph on the teaching of oratory, but a comprehensive treatise covering many aspects of education. It came rather late to have a significant effect on Roman education but had a great vogue during the Renaissance, influencing especially the development of the grammar school. Although its education was so much affected by Greek thought, Rome never took kindly to the intervention of the state in educational affairs. It was not until the later phases of the empire that the central government attempted to systematize education. Vespasian (A.D. 9–79) was the first emperor to subsidize it, and eventually subsidizing led to control. Later emperors intervened over the appointment and remuneration of teachers, and Diocletian (A.D. 245–313) fixed the rate of payment for the teaching of various subjects. In A.D. 425 an imperial edict made the government the controlling education authority and, subsequently, persons wishing to keep a school had to obtain consent. From the subsequent passing of the schools from secular to ecclesiastical control until comparatively modern times—certainly for well over 1,000 years—the idea of the state as the seat of authority in education was dormant.

As Alexander the Great had done, the Romans usually planted their culture and their institutions wherever they established their rule. They installed their system of education throughout their empire and, although the subject population' included people of several races with wide differences in degrees of civilization, the education provided followed much the same pattern everywhere. Grammar schools were to be found in most areas, giving pupils between the ages of about 7 and 14 an education in language and literature, while in towns of any size there were also schools of rhetoric. In the western parts of the empire the grammar schools usually taught Latin and Greek but eastward Greek was generally the only language. Ambitious and wealthy students wanting a university type of education went to Athens, Alexandria, Rome or Constantinople; but higher education, as understood by the great majority, meant the grammar and the rhetoric schools. While Roman education was spreading, Christianity was also gaining such strength that its relationship to the schools with their pagan culture became an issue of growing importance. (See also SCHOOLS, ANCIENT.)

4. The Beginnings of Christian Education.—At first Christianity found most of its adherents among the poor and illiterate, making little headway, as St. Paul observes (I Cor. i, 26), among the worldly wise, the mighty and those of high rank. But during the 2nd century and afterward it appealed more and more to the educated class and to leading citizens. These naturally wanted their children to have at least as good an education as they themselves had had, but the only schools available were the grammar and rhetorical schools with their Greco-Roman, non-Christian culture. There were different opinions among Christian leaders about the right attitude to this dilemma that confronted all Christians who sought a good education for their children. The Greek fathers, especially the Christian Platonists Clement of Alexandria (c. 160–c. 215) and Origen (c. 185–c. 254), regarded Christianity as the culmination of philosophy, to which the way must be sought through liberal studies. Without a liberal education the Christian could live a life of faith and obedience but could not expect to attain an intellectual understanding of the mysteries of the faith nor to appreciate the significance of the gospel as the meeting ground of Hellenism and Judaism. St. Augustine (354–430) and St. Jerome (c. 340–420) also encouraged the use of the secular schools by Christians, maintaining that literary and rhetorical culture is valuable so long as it is kept subservient to the Christian life. Tertullian (c. 155–*c.* 222), on the other hand, was suspicious of pagan culture, but he admitted the necessity, though deploring it, of making use of the educational facilities available. Most Christians who wanted their children to have a good education appear to have sent their children to these secular schools; this practice seems to have continued even after 313 when Constantine stopped the persecution of Christians, giving them the same rights as other citizens. Christians also set up catechetical

schools for the religious instruction of adults who wished to be baptized. Of these schools the most famous was the one at Alexandria which had a succession of outstanding heads, including Clement and Origen. Under their scholarly guidance it developed a much wider curriculum than was usual in catechetical schools, including the best in Greek science and philosophy in addition to Christian studies. Other schools modeled on that at Alexandria developed in some parts of the near east, notably in Syria, and continued for some time after the collapse of the empire in the west. The gradual subjugation of the western empire by the barbarian invaders during the 5th century led to the breakup of the educational system that the Romans had built up. Among the ruins of this great civilization the Christian Church survived, and one of its most important tasks was to build, when this became possible, a new educational order.

For about four centuries the western world was plunged in intellectual darkness. The church, however, was able to provide some teaching of a religious character, especially for its clergy; and on those modest foundations a new educational system took shape gradually and fitfully. Learning that had no religious significance was rarely encouraged, and monastic and other teachers were directed to avoid what Pope Gregory the Great (*c.* 540–604) stigmatized as "the vanities of worldly learning." But even during the darkest days there were exponents of wider conceptions of education and among them were such scholars as Boethius, Cassiodorus, Isidore and Bede. There were, too, monasteries in which the lamps of learning burned brightly. "We may," says Spencer Leeson in his *Christian Education* (1947), "remember with special thankfulness Bede, the monk of Jarrow, *praeceptor Angliae,* . . . . Not only did Bede by teaching and translation spread the knowledge of his faith: he also in his great *Ecclesiastical History of the English Nation* gave us, as it were, the first consciousness of our nationhood." But it was in Ireland that monasticism made its greatest contribution to the preservation and enrichment of culture during the 6th, 7th and 8th centuries. In pre-Christian times there had been an educational tradition in Ireland, as in other Celtic regions, which the Irish monks took advantage of by developing schools open to the laity as well as to the clergy. They were keen students of the classics as well as of their native language and literature, and, when they crossed to the continent as missionaries, they carried with them their knowledge of the literature of Greece and Rome, establishing monasteries like St. Gall and Reichenau, which won renown for their scholarship.

The monastic schools are; however, not as significant in the history of education as the schools founded by bishops, usually in connection with a cathedral. These bishops' schools are sometimes looked upon as successors of the grammar schools of the Roman empire, and they are also often regarded as the parents of the grammar school of modern times. In their efforts to provide education the bishops sometimes had the support of the new rulers. Learning had no more ardent friend than Charlemagne (*q.v.;* 742– or 743–814), who attracted scholars from many quarters to help him in his plans to bring about a cultural revival. He was distressed to find such poor standards of Latin in his correspondence, the offenders including even bishops and abbots from all parts of his empire who, he complained, were in their letters often very correct in sentiment but very incorrect in grammar. He was fortunate to secure as master of his palace school and educational adviser so great a person as Alcuin (732–804) who brought with him from York high standards of scholarship. Alfred the Great also stands out as a royal patron of learning. When he came to the throne in 871 cultural standards had fallen to a low level, partly because of the Danish invasions. He was grieved to find so few who could understand their church services in English or translate a letter from Latin into English. He himself translated into English some great books of that age, including Boethius' *De consolatione philosophiae, Cura pastoralis* by Gregory the Great and Bede's *Ecclesiastical History;* he sought in other ways, by precept and example, the spiritual and intellectual regeneration of his people. We know little of what Alfred actually accomplished for education but, like Charlemagne, he helped to ensure the survival of scholarly traditions in a bleak and uncouth age. There was, however, nothing like a general advance in education until after the moral and cultural awakening during the 11th and 12th centuries.

5. Medieval Education. — By the 11th century Europe was reaching a condition of comparative political stability and social tranquility. The barbarians had been converted to Christianity, and there was general acceptance of the authority of the church in matters of belief, conduct and education. Soon contact with the east, by trade and in the crusades, and with the highly cultivated Moors in Spain further stimulated intellectual life. Arabic renderings of some of the works of Aristotle together with commentaries were translated into Latin, exercising a profound influence on the trend of culture. Other translations of Aristotle followed, notably those by the Dominican, William of Moerbeke, archbishop of Corinth. In the Christian world scholasticism (*q.v.*) became the dominant mode of thought with Peter Abelard (1079–1142) and St. Thomas Aquinas (1225–74) its dominant figures. The widespread intellectual ferment, the zeal in disputation characteristic of scholasticism and the growth of towns all contributed to the creation and development of universities (*see* UNIVERSITY). They met a great need of the western world at that time and by 1500 as many as 79 universities had been founded in Europe. While modern universities may seem very unlike their medieval prototypes, the essence of a university has not changed since its beginning more than 700 years ago.

The founding of universities was naturally accompanied by a corresponding increase in schools of various kinds. In most parts of western Europe there were soon grammar schools of some type available for boys. Not only were there grammar schools at cathedrals and collegiate churches but many others were founded in connection with chantries and guilds and a few in connection with hospitals. It has been estimated that toward the close of the middle ages there were in England and Wales for a population of about 2,500,000 approximately 400 grammar schools, rather better provision than in Victorian days. Knowledge of the teaching provided in the grammar schools at this period is too slight to justify an attempt at a description. No doubt the curriculum varied, but religion was all-important, with Latin as a written and spoken language the other major element in the timetable. There might have been instruction in reading and writing in the vernacular, but in addition to the grammar schools there were writing and song schools and other schools of an elementary type. Elementary teaching was given in many churches and priests' houses, and children uho did not receive formal scholastic instruction were given oral teaching by parish priests in the doctrines and duties of the faith. The evidence of accounts, bills, inventories and the like suggests that there was some careful teaching of writing and of an arithmetic that covered the practical calculations required in ordinary life.

Girls mere sometimes taught in nunneries, but usually in the home, and those of the upper classes, at least, generally learned to read, write and keep accounts, to perform household duties and to obtain such elementary medical knowledge as might be helpful when called on to treat minor accidents or ailments. For young and grown-up alike there was much that was educative in medieval society, and the influence of the community life of church, guild and village was an important factor. "Every village has its painter," wrote William Morris of the middle ages in his *Gothic Architecture* (1893), "its carvers, its actors even . . . . The few pieces of household goods left of its wreckage are marvels of beauty; its woven cloths and embroideries are worthy of its loveliest building; its pictured and ornamented books would be enough in themselves to make a great period of art." Medieval education had many shortcomings, and its benefits were too often confined to a few; but on the whole the mass of the people were by no means sunk in brutish ignorance. The number of people who could read the vernacular, as evidenced by the demand for books in the vulgar tongue as soon as printing made them available, is proof that the latter part of the middle ages was certainly not a time of general illiteracy.

In fulfillment of its responsibility for education, the church from the 11th century onward made the establishment of an effec-

tive educational system a central feature of ecclesiastical policy. During the papacy of Gregory VII all bishops were asked to see that the art of grammar was taught in their churches, and a Lateran council in 1215 decreed that grammar school masters should be appointed not only in the cathedral church but also in others that could afford it. Solicitude at the centre for the advancement of education did not, however, result in centralized administration. It was the duty of bishops to carry out approved policy but it was left to them to administer it and they in turn allowed schools a large measure of autonomy. Such freedom as medieval schools enjoyed was, however, always subject to the absolute authority of the church, and the right to teach was restricted to those who held a bishop's licence. This device was used to ensure that all teachers were loyal to the doctrines of the church, and the power to issue or withhold the licence was often delegated to an officer of the cathedral, the scholasticus or chancellor.

In medieval society there was an entirely different training for boys of high rank, and this created a cultural cleavage. Instead of attending the grammar school and proceeding to a university, these boys served as pages and then as squires in the halls and castles of the nobility, there receiving prolonged instruction in chivalry. The training was designed to fit the noble youth to become a worthy knight, a just and prudent master and a sensible manager of an estate. Much of this knowledge was gained from daily experience in the household, but in addition the page received direct instruction in reading and writing, courtly pastimes such as chess and playing the lute, singing and making verses, the rules and usages of courtesy and the knightly conception of duty. As a squire he practised more assiduously the knightly exercises of war and peace and acquired useful experience in leadership by managing large and small bodies of men. But this was a type of education that could only flourish in a feudal society and, while some of its ideals survived, it was outmoded when feudalism was undermined by the growth of national feeling.

6. The Renaissance. — The Renaissance was a landmark in the history of western education. One of its principal characteristics was a revival of the learning of ancient times but no less strong was the yearning for a new world with a fuller and more interesting way of life. In schools and universities the first of these two trends predominated, and educators of the period turned eagerly to the literature inherited from Greece and Rome. It was in the cities of northern Italy that this revival of learning began and from Italy it spread gradually to countries north of the Alps. But for about two centuries Italy stood in the van of European culture.

The educational ideals of the Renaissance were first expounded by Paulus Vergerius (1349–1420), who in one of his treatises advocates a liberal education, describing it as one that calls forth, trains, and develops the highest gifts of body and mind. He wrote a commentary on Quintilian's *Institutio oratoria* that helped to secure for that work a vogue much greater than it enjoyed in its own day. Vergerius' ideals found practical expression in the teaching of Vittorino da Feltre (1378–1446), the great humanist schoolmaster who taught the family of Gianfrancesco Gonzaga, lord of Mantua. Naming his school *La Giocosa* (the house of joy), he had about 60 pupils including the sons and daughters of his patron and boys of other noble families as well as some poor boys chosen for their ability. The language and literature of Rome and Greece were the central features of the curriculum, but other subjects such as arithmetic, geometry and music were taught as well as games and physical exercises, following the Greek ideal of development of body and mind. An important omission was the teaching of the vernacular. By precept and example Vittorino strove to make his school a Christian community, and there were daily devotions. For him classical studies were not the end and sum of education but a means of implanting ideas, developing taste and acquiring knowledge, all as helps and ornaments of a Christian life.

When the Renaissance reached northern Europe, there were still no signs of antagonism between the new humanism and Catholic faith and practice. It made its first advances in the Netherlands where, in the free cities ruled by a powerful and wealthy burgher element, conditions bore some resemblance to those of the Italian cities. There the Brethren of the Common Life (*q.v.*) introduced humanistic studies into their schools side-by-side with definite religious teaching and observances. The earlier German humanists such as Nicholas de Cusa, Alexander Hegius, Johann Agricola and Jacob Wimpheling adopted the same attitude, and Erasmus (1466–1536) himself, bitterly as he attacked the practical abuses of the church, remained in communion with it and aimed at harmonizing classical culture with the Christian life. He outlined his educational aims as: to sow the seeds of piety; to create a love of liberal studies; to prepare for the duties of life; and to promote good manners. In England the same love of classical culture combined with devotion to the church was seen in the leading humanists, most of whom were Erasmus' friends such as Thomas Linacre, John Colet and Sir Thomas More, whose enthusiasm for the new learning was as undoubted as their loyalty to Catholicism. Both Oxford and Cambridge welcomed the new learning, and in France even the conservative University of Paris — the headquarters of scholastic philosophical theology — permitted the teaching of Greek as early as 1458. One of the most interesting of the humanist educators was the Spaniard, Juan Luis Vives (1492–1540). He spent a few years in England under the patronage of Catherine of Aragon, tutored her daughter Princess Mary, and wrote at Catherine's request a treatise, *The Instruction of a Christian Woman*. His most influential work, however, was a comprehensive treatise on the curriculum and methods of study, *De tradendas disciplinas (On Education)*.

It looked then. at first, as if the classical revival would result in a deepening of literary culture and the substitution of real inquiry for dialectical subtleties in the courses of schools and universities without any break with established religious teaching. It is true that when the religious revolt in Germany under the leadership of Luther (1483–1546) threw Europe into two hostile camps the majority of the schools had not been much affected by the Renaissance, and many universities had given but a half-hearted welcome to humanistic studies. Even so, the new learning had already won some notable victories and the prospect for further advance was promising, when education became enmeshed in the complex religious struggle that shattered the unity of Christendom.

7. Some Consequences of the Reformation. — The Reformation had a disruptive, disintegrating influence on education. The secularization of ecclesiastical property too often absorbed the endowments of the schools so that, both in Germany and in England, the majority of grammar schools either disappeared or continued a starved existence with depleted funds. Education was also profoundly affected by decisions in some countries to support one particular form of Christianity in pursuance of the principle that the religion of the people must be the religion of their ruler. Several of the German states adopted Lutheranism, their schools and universities being remodeled on Protestant lines. In this work Philipp Melanchthon (1497–1560), who came to be known as *Praeceptor Gernzaniae*, was pre-eminent and under his influence a number of universities were founded or reorganized and many schools set up or re-established. He also, by his own teaching and writing, did much to promote a combination of humanism and protestantism in the education of northern Europe and exercised a far-reaching influence through his many disciples and friends. One of these was John Sturm (1507–89), whose Latin *Gymnasium* at Strasbourg became a model for the grammar schools of the Protestant countries. John Calvin (1509–64) taught for a time in Sturm's *Gymnasium*, and he drew on his experience there when framing the curriculum of the college he founded in Geneva. Because of Calvin's eminence as a religious leader, the educational principles observed at his Geneva college were adopted in countries where his religious doctrines took root. The Huguenots in France, the Reformed Church in Holland, the Puritans in England and Wales and the Presbyterians in Scotland were in varying degrees influenced by Calvin's educational thought and practice.

In countries that remained Catholic the Roman Church retained control of education. The practical reform of abuses by the Council of Trent and the energy and skill of the Society of Jesus,

founded by St. Ignatius of Loyola in 1534 and recognized by the pope in 1540, brought most of south Germany back into the fold of the Catholic Church. In the Catholic universities, mainly staffed by Jesuit fathers, scholasticism, purged from the formalistic excesses that had degraded it, was fully restored. "They are so good," said Francis Bacon of the Jesuit teachers in his *Advancement of Learning* (Everyman ed., 1954), "that I wish they were on our side." By their successful teaching and comparatively mild discipline the Jesuit schools attracted thousands of pupils. The curriculum was purely classical, but importance was attached to spacious, well-adapted buildings and amenities designed to make school life interesting. In general, however, the religious conflict did great harm to education, which suffered much because contestants who gained power used the schools to propagate their cause, discarding teachers not of the approved persuasion. Moreover, apart from religion. the schools continued to ignore the new directions of men's minds, and the classical languages and literature, especially Latin, remained the only essential elements of secondary education. In the 17th century grammar-school teaching became more and more remote from the needs of life, and the absurdity of it was accentuated as Latin gradually ceased to be the language of the world of learning. In vain Bacon deplored the obsession with "words, not matter" and, foreseeing the necessity of laboratories and apparatus, urged that "other helps are required besides books" *(Advancement of Learning,* Everyman ed., 1954). The universities like the schools declined for the most part to contemplate any enlargement of the frontiers of knowledge and were too often deeply involved in the religious conflicts of the time. Toward the close of the 17th century there was a revival of mathematical studies at Cambridge, largely as a result of the work of Sir Isaac Newton. and a new academic era opened in Germany with the foundation of the universities of Halle (1694) and Gottingen (1737). But in general the main current of intellectual life tended to drift away from the orthodox centres of learning. The formation of the Berlin academy in Germany. the Royal society in England and the Académie des Sciences in France reflected this tendency.

There were, however, some interesting attempts to relate education to the needs of the time. One of the most ardent reformers was Johann Comenius (1592–1670), the great Czech educationist who. driven from his home by the severities of the Thirty Years' War, was invited to England for conversations about education when the Puritans were in power. His *Great Didactic,* in which he expounds his principles, brought a new note of realism into educational thought and, urging the claims of experimental science, was an important influence in shaping the curriculum of the Dissenters' academies established in England and Wales during this period. Another influence was John Milton's tractate *Of Education* (1644) in which he condemned the pedantic teaching of the classics in grammar schools. In France, and later in Germany, it became unusual for children of rank to attend such schools, and some of the best writing about education was concerned with teaching in aristocratic academies or at home. Two books written in the 16th century had a considerable vogue: Baldassare Castiglione's treatise on courtly manners *Il Cortegiano* ("The Courtier," 1528); and Sir Thomas Elyot's *The Boke Named the Governour* (1531) in which, recalling Plato's guardians, Elyot expounds an education designed as a preparation for public life. Such ideals found expression in the courtly academies which flourished in France in the 17th century and were soon imitated in the *Ritterakademien* of Germany.

8. The 18th Century. — There could not, however, be any general advance in education until religious animosities had died down. Happily the storms abated during the 18th century and the approach to educational problems became more tolerant. While John Locke's educational writings are important, probably his greatest services to education were his advocacy of a more liberal spirit in his *Letters concerning Toleration* (1689–92) and his widespread influence as a protagonist of civil liberty. But toleration came slowly, and meanwhile education went through a bleak period in which many universities and grammar schools stagnated at a low level. Schools providing education of an elementary kind were few and grossly inadequate, and there was mass illiteracy. The plight of poor children led to some notable philanthropic enterprises on their behalf, among which were the Christian schools that had been instituted in France by St. Jean Baptiste de la Salle toward the end of the 17th century and the charity schools provided in Britain by the Society for the Promotion of Christian Knowledge. Other ventures in the same cause were August Francke's charity school at Halle (1695) and, a later effort, the Sunday School movement initiated in England by Robert Raikes (1780).

It was, however, a period of great activity in reformulating educational principles, and there was a ferment of new ideas, some of which in time wrought a transformation in school and classroom. Of those who thought and wrote about education no one has had so great an influence as Rousseau (1712–78), whose *Émile* has often been called the charter of childhood. "The first thing," he wrote in his preface, "is to study your pupils more, for it is very certain that you do not know them." By stressing the importance of helping children to grow and develop naturally Rousseau started a revolution in educational theory which in time completely changed the relationship of teacher and pupil. His insistence that child nature is wholly good helped to destroy the harsh systems of discipline widely prevalent in his day, but it should be noted that it is a view at variance with Christian doctrine and with the findings of modern psychoanalysis. His version of education, so different from the artificial, conventional, formal teaching then usual, inspired others to continue the revolution that he initiated. He had many illustrious followers who if they did not adhere strictly to his creed were nonetheless of his fold; among them were such great educators as Johann Pestalozzi (1746–1827), Friedrich Froebel (1782–1852), John Dewey (1859–1952) and Maria Montessori (1870–1952).

9. The 19th Century. — Educational systems are strongly rooted in their nation's history and, therefore, differ in structure and scope even when, as in the western world, they share a similar cultural inheritance. But there were in the 19th century several general trends that were still influencing education in all western countries in the second half of the 20th century. Of these the most significant was the gradual acceptance of the view that education ought to be a responsibility of the state. In a sense the idea of a controlling state was a return to the Greek conception with which the history of western education opens, but its modern history began when Prussia set about its task of regeneration after its crushing defeat at Jena. Inspired by Johann Gottlieb Fichte (1762–1814) and Wilhelm von Humboldt (1767–1835) the Prussian educational system became the mainspring of recovery. In 1808 a department of public instruction was established and educational reforms soon followed. In the next year the University of Berlin was established, and then secondary education was reconstructed. First *Gymnasiums* were provided, several of the old grammar schools being reformed for this purpose. Their curriculum was mainly classical and, with an age range of 9 to 18, they were designed for boys who intended to proceed to the university or enter one of the professions. There was an officially prescribed school-leaving examination, and to maintain a good standard of teaching and raise the status of the teachers a special qualifying examination was instituted for men who proposed to teach in these schools. Gradually an alternative modern type of secondary education evolved, the *Realschule,* and succeeded so well that it became the envy of educational reformers in other countries. Although von Humboldt, Fichte and other progressive leaders also wished to see a good system of primary education established, advance in that field proved more difficult owing to reactionary obstruction: but Prussia gradually succeeded in building up a comprehensive system of education of a two-class type with the *Volkschule* providing an elementary education for the great majority of children. Attendance was compulsory, and before the end of the century it was made free. To maintain a supply of suitable teachers for the *Volkschulen* training colleges were established, and although the school curriculum was in many respects narrow, there were progressive influences at work. Among those who staffed the colleges were several disciples of Pestalozzi

and there were exponents of the educational ideas of Johann Friedrich Herbart (1776–1841), which had a considerable vogue. Froebel's doctrines were also becoming popular when in 1851 the minister of education dealt the movement a severe blow by prohibiting kindergartens. In the second half of the century continuation schools were developed and there were important advances in technical education. Victory in the Franco-German War, the unification of Germany and the creation of the German empire greatly enhanced the prestige of the system of education established by Prussia: education in Germany continued to develop until the outbreak of World War I, its statesmen recognizing the importance of education to their policy of industrial and commercial expansion and as a means of promoting national unity and an ardent patriotism.

It was in France, however, that the idea that the state would control education was first revived. Louis René de la Chalotais (1701–85) expounded the doctrine in his *Essay on National Education* (Eng. trans., 1934), criticizing at the same time the education given by the Jesuits. "I venture to claim for the nation," he urged, "an education which depends only on the state, because it is essentially a matter for the state. . . ." His *Essay* had a considerable influence, and during the 19th century France developed its highly centralized educational system. Napoleon initiated it, creating in 1808 the "Université de France," which was not so much a university as a government department under a rector responsible for the administration of education. Napoleon wished to ensure that the state was well provided with military officers and civil servants and he therefore encouraged the establishment of *lycées* and colleges. He paid relatively little attention to primary education, leaving it to the church and the communes. François Guizot, when minister of education, first organized primary schools under his law of 1833. Each commune had to maintain such a school: each town with more than 6,000 inhabitants had to provide a senior primary school, and each *département* a training college for primary teachers. There were several crises about the powers of church and state, and after France's catastrophic defeat in the Franco-German War there was much political controversy about the future of education. With the knowledge of uhat education had accomplished in Prussia it was realized that it could be an important asset in the Third Republic's efforts to revitalize the nation, but proposals for educational reform encountered much opposition. Eventually, at the instance of Jules Ferry, a strong education minister, primary education became in the 1880s secular, compulsory and free. New *lyce'es* were established, and provision was made for secondary education for girls, which had hitherto been mainly undertaken by the church. Technical education was developed and, between 1885 and 1896, 15 universities were reestablished as state universities. In the course of the century there were many attempts to modify the curriculum of the *lyce'es* but there was great reluctance to depart from the classical tradition, for much importance was attached to *culture générale* as the hallmark of an educated Frenchman. The relationship of church and state in educational affairs continues to be a source of controversy. A committee set up to find an acceptable solution produced a conciliatory report in 1959 only to provoke a renewal of bitter argument in which the question of state aid for church schools was the main issue.

England under the spell of laissez faire hesitated a long time before allowing the state to intervene in educational affairs. At the beginning of the 19th century education was regarded as entirely the concern of voluntary or private enterprise, and there was much unsystematic philanthropy. Attempts were made to canalize and concentrate it, and many hoped that the Church of England and the dissenting churches would join in a concerted effort to provide a national system of elementary education on a voluntary basis. But discordant views prevented such co-operation, and two voluntary societies were founded. one representative of the Church of England and the other of dissent. In 1829 the Catholics were emancipated by law from disabilities they had long suffered, and so they also were able to provide voluntary schools. Other religious bodies joined in the effort to meet the growing need for elementary schools but it was soon evident that voluntary finance would not be equal to this formidable task. In 1833 the government made a small building grant to these societies, and in this modest way state intervention began. Six years later a committee of the privy council was established to administer the state grants, now made annually, and to arrange for the inspection of voluntary schools aided from public funds. The work involved led to the establishment of a small central education department which was the beginning of the ministry of education.

England paid heavily for its prolonged reliance on voluntary initiative; for year after year population increased and with the growing industrialization people crowded in increasing numbers into the new towns. At last in 1870 parliament after long acrimonious debates passed an Elementary Education act, the foundation upon which the English educational system has been built. Religious teaching and worship were the crucial issues in the debates, and the essentials of the settlement agreed upon were: (1) a dual system of voluntary and local authority schools; and (2) careful safeguards about conscience to ensure as far as possible that no child would receive religious teaching at variance with his parent's wishes. It was left to the school boards—as these first local education authorities were called—to decide whether to make elementary education compulsory in their districts. In 1880, however, it was made compulsory throughout England and Wales, and in 1891 fees were abolished in all but a few elementary schools.

Secondary education, however, was still left to voluntary and private enterprise, and attention was focused on the '.public" schools (independent secondary schools, usually for boarders from upper and well-to-do middle-class homes), which under the leadership of outstanding headmasters like Thomas Arnold (1795–1842) were thoroughly reformed. Several new universities were founded during the century, and during the latter half of it a number of girls' high schools and boarding schools mere founded in which an education was given comparable to that in boys' public schools and grammar schools. Several training colleges for teachers were established by voluntary agencies, and universities and university colleges toward the end of the century undertook the training of postgraduates as teachers in departments of education created for this purpose. At the same time much thought was given to the secondary curriculum not only in England but throughout the western world. It was considered by such various bodies as the Imperial conference in Berlin (1890), the Ribot commission in France (1892), the Committee of Ten appointed by the National Education association in the United States (1892) and the Bryce commission in England (1895). In England the Education act of 1902 abolished school boards and made county and county borough councils the local education authorities; it empowered them to provide secondary and technical as well as elementary education. In the secondary schools that the local education authorities founded, the curriculum, while academic, was more broadly based than that which had been customary in the endowed grammar schools, and there were also interesting developments in postprimary education, providing an alternative education of a more practical type.

10. The 20th Century.— During the 20th century educational advance was halted by World Wars I and II and the ensuing economic dislocations. In preparation for World War II education was exploited in Germany and Italy to serve the ends of the dictators, but the general effect of both wars was to stimulate a yearning for social improvements and for educational reforms. Chiefly there was a desire for more equality in educational opportunity and for an education more appropriate to the interests and abilities of individual pupils. Such aspirations led to a more democratic attitude toward the organization of schools. The traditional British and European system of elementary schools for the masses and secondary schools for only a limited number of fee payers and scholarship holders became outmoded and the pattern emerging in the 1960s was one in which all pupils passed from the primary to the secondary stage. While this conception was largely because of the growth of a more egalitarian society, its adoption was stimulated by the spread of industrialization, which not only created a demand for better educated workers but also resulted in improved standards of living and an increase in the number of parents who

wanted their children to have a good education. The demand for secondary education led to extensions of the school-leaving age and to proposals to extend it still farther; there were important changes in the scope of secondary education and new types of schools were created to bring secondary education more in line with the needs of contemporary society. With a view to meeting the requirements of a scientific and technological age there nere substantial developments in technical education and a remarkable expansion of universities, both as regards number of students and range of studies. While educational reform has usually come gradually in response to popular demands for social justice, it has in modern times had the vigorous support of statesmen, who have recognized the importance of education as an essential of national survival in a competitive and troubled world. In a wartime talk on the radio in 1943 Winston Churchill expressed the modern statesman's view: "The future of the world is to the highly educated races, who alone can handle the scientific apparatus necessary for pre-eminence in peace or survival in war."

In England the reports of the consultative committee, especially those known as the Hadow reports and the Spens report. paved the way for the reconstruction of the educational system provided for in the Education act of 1944; and the 1959 report of the central advisory council for education in England, the Crowther report, made important recommendations. In France the Langevin-Wallon recommendations made after World War II provided a comprehensive program of reform; the times were not propitious for its implementation but it had a formative influence in the schools and some of the proposals were carried out. Child study and the influence of psychologists not only transformed the teaching of infants and juniors but also brought about a gro ing realization of the significance of the pre-school stage and the value of co-operation between schools and home. In Italy first the sisters Rosa and Carolina Agazzi and then Maria Montessori. who opened the first of her children's homes in Rome in 1907, showed how much can be accomplished by education in early childhood. In France *écoles maternelles* have a long history and in the early 1960s there were about 4,000 of these institutions in which the children grow and learn in a happy environment. In England interest in the upbringing of very young children was roused by the work of Rachel and Margaret Macmillan, who established a nursery school at Deptford, London, in 1914. (See also ELEMENTARY EDUCATION; PRE-ELEMENTARY EDUCATION.)

By the second half of the 20th century it had become increasingly recognized that progress depends on an adequate supply of suitably qualified teachers. When teachers have not been forthcoming, classes have been large, making it difficult for teachers to give the pupils individual attention. But the problem has not been just one of recruiting teachers in sufficient numbers; modern methods of teaching require teachers of ability, well-prepared for their vocation. The staffing requirements of the schools have become more and more diversified as a result of the widening scope of education and the proliferation of subjects; it is not easy, especially where there are strong traditions of freedom, to organize the recruitment and training of teachers in such a way that the various staffing needs of schools are met satisfactorily. There was, for example, in the 1950s a shortage, both in the United States and Britain, of teachers of mathematics and science. Industry was attracting potential teachers qualified in these subjects, and at the same time by its demands for more and more scientists, technologists and technicians was adding to the number of students and pupils wanting to study these subjects in technical colleges and schools. In the U.S.S.R. the demand for teachers of these subjects was even greater, for in their specialist institutes and technicums the Russians were training more engineers than any other country both in terms of actual figures and per head of the population. But by central direction they were fairly successful in producing an adequate supply of suitably qualified teachers and in maintaining a high standard of scientific and technological education.

Much attention has been given in modern times to the preparation of teachers for their vocation. For a long time it was assumed that teachers in primary or elementary schools did not require a university education, and instead a training largely on apprenticeship lines was provided for them. On the other hand, secondary-school teachers were expected to have acquired at the university a knowledge of the subject they were going to teach but, except in Germany. they did not receive training of a vocational character. During the 20th century opinion about the preparation of teachers has been gradually changing, mainly as a consequence of new conceptions of education of primary and secondary teachers that were not easy to justify, but if much remains to be done in this field. it is no less true that there has been substantial progress. No country in the 20th century has done more for teacher education than the United States and some of its institutions, like the Teachers' college of Columbia university, are among the best of their kind. One great advance there has been the evolution of the normal schools, for training teachers, into teacher colleges, offering degrees to students completing a four-year course. In England the tmo-year training college course was extended to three years in 1960. and the regular co-operation of training colleges with university education departments in what are known as area training organizations had helped to created a liaison between the non-graduates and the university systems of teacher education.

II. NATIONAL SYSTEMS

The history of national systems of education providing public schools controlled and financed by the state and with attendance required by law is traced to the rebuilding of Prussia after the defeat at Jena (see The 19th Century, above). The following descriptions of national systems illustrate various aspects of this history. The United States was the first country to provide universal education through a common (one-track) school system, with separation of church and state. The history of the development of education in England traces the long conflict between voluntary and religious groups and the state, while Scotland's system has been free and independent and the commonwealth countries represent various adaptations of British institutions to local conditions. France and Germany illustrate highly organized educational systems established by centralized states. The U.S.S.R. has, in the 20th century, reduced illiteracy from about 70% (1920) to less than 2% (1960) and established ten years of universal compulsory schooling. (For a discussion of various types of school administration, control, management and direction see SCHOOL ADMINISTRATION.)

A. UNITED STATES

1. Control of Education in Colonial America. — During the colonial period, from the founding of the colonies in the 17th century to the Revolutionary War in the later 18th century, American schools generally reflected European educational ideas but they also began to reveal some distinctive characteristics of their own. Education was one of the powers of government transferred to the ne world by delegation from the British crown to stock companies, proprietors, royal governors and colonial legislatures. From the very beginning of the colonies, therefore, power over schools was held by governmental authorities. Inasmuch as established churches were closely allied with civil governments in the 17th century, religion played a large part in most colonial schools and colleges. Although feudalism did not gain a strong hold on American life, certain definite distinctions between upper and lower classes were reflected in a dual system of schools, with elementary schools designed for the lower classes and secondary schools for the upper classes.

In the course of the 18th century colonial governments continued to maintain authority over education but began to delegate to private individuals and religious groups the right to establish and support their own schools. This shift from governmental to private control arose when a number of religious sects began to demand greater religious freedom, a fact that eventually contributed to the separation of church and state. Where religious

diversity was honoured and where religious groups had freedom of conscience and worship, the schools founded by public authorities could not continue to teach everyone the same religious doctrines. The early 18th-century solution to this problem was to permit the several religious denominations to conduct their own schools as private institutions.

The growth of towns and commerce, the rise of a strong middle class and the consequent economic development of the country led to the demand for new types of educational institutions and instruction that would meet the practical needs of the populace. These trends began to threaten the academic traditions that had produced the dual system of schools based upon distinctions of economic and social class, and served to create more flexible and democratic types of education from the middle of the 18th century onward.

Government Control of Schools.—During the 17th century the New England colonies exercised more direct public control over and support of schools than did the other colonies. Their relatively compact forms of town life, their Calvinist zeal for education and their strongly established Puritan forms of church control (except in Rhode Island) led to public initiative in this respect. In the 1630s several New England towns took steps to establish schools under the authority and supervision of the town meetings. In 1642 the general court (colonial legislature) of Massachusetts passed a law requiring all parents and masters of children to see that their charges were taught reading, the capital laws, the religious catechism and apprenticeship in a trade. Although no schools were established by this law, the colonial legislature exerted its authority to require compulsory education for the good of the commonwealth. Other New England colonies soon followed suit.

In 1647 Massachusetts again took the lead by passing a law requiring all towns of 50 or more families to appoint a teacher of reading and writing and making it possible for the teacher to be paid out of tax funds if the people so ordered. The law of 1647 also required all towns of 100 or more families to provide a teacher of Latin grammar as a means of preparing boys to enter college. Again, the other New England colonies followed Massachusetts and helped to formulate the New England conception of a public school which included the following principles: the state had authority to require parents to educate their children; the state could require the towns to establish schools; public moneys could be used to support schools; and the public authorities had the right to establish, control, supervise and directly manage and administer public schools.

In the 18th century two further developments took place. With respect to public schools the units of governmental control became smaller. As people moved into the back country, away from the populated places, the small local districts gained the right to set up their own schools apart from the jurisdiction of the larger town. This process of decentralization of control was a response to the frontier conditions of life and reflected the agrarian interests of the districts in contrast with the growing commercial interests of the central towns. The second development uas an increase in the number of nonconformist religious groups that resisted the authority of the established churches. Stimulated by the religious revivals, they wanted their own forms of religious worship free from the control of the state church, and they wanted their own schools in which they could teach their own religious doctrines. Gradually, therefore, the colonies began to authorize different religious groups and private incorporated bodies to establish and maintain their own schools.

Public interest in education was not so extensive in the southern colonies as it was in New England. There it was assumed that education was rather a function of the church and of parents who could afford to educate their children, as had been the practice in England. But even so, the colonies' public concern with education was exerted in two principal ways. The southern colonial legislatures passed many laws requiring apprenticeship and education in literacy and religion for poor children, orphans and illegitimate children. The southern colonies thus exerted their authority over children who had no parents or whose parents could not properly care for them. In addition, the parish authorities (boards of vestrymen), which were civil as well as religious in nature, sometimes made provision for education. Beyond these efforts, several sporadic attempts were made to establish colony-wide systems of public education in Maryland, South Carolina and especially in Virginia, where Thomas Jefferson in 1779 proposed a complete system of public schools; but his proposals were not accepted by the legislature.

In the middle colonies the Dutch in New Netherland and the Quakers led by William Penn in Pennsylvania made early attempts to establish public control over education. But religious diversity in both colonies prevented the culmination of these plans in the 18th century, and the typical arrangement came to be denominational control of education.

Private Control of Schools.—In the 18th century several types of private schools came to characterize education in the colonies. Some of these were endowed schools whose support came largely from gifts or bequests of land, livestock or other goods of value. Such schools had a difficult time until control was vested in corporate bodies of men who were authorized to act as continuing trustees for the lands, buildings and endouments. The incorporated school under the control of a self-perpetuating board of trustees and created by charter by the state became an important type of private school toward the end of the 18th century.

Thus was born the academy, which soon replaced the Latin grammar school as the typical. form of American secondary school. Many private elementary schools were also established by the several religious denominations. Some of these were conducted by individual congregations, others by groups of neighbouring churches and still others by large religious bodies, notably the Society for the Propagation of the Gospel in Foreign Parts. Still another type of private school was exemplified by the private-venture schools that arose in the seacoast towns in the early 18th century. These schools, set up by enterprising teachers for their own profit, were designed to make available a more practical type of education for young men and women.

2. Colonial **Types** of Instruction.— The curriculums and methods of instruction of colonial schools reflected the currents of religious thought of the Protestant Reformation, the humanist emphasis upon the classical liberal arts, the aristocratic ideal of an education for a gentlemanly class and the practical needs of vocational training for a rising middle class.

Elementary Education.—The dominant concerns in elementary schools were literacy and religion. This meant that children were taught reading and writing and often some elements of arithmetic. The materials of instruction were likely to be simple and usually religious in nature. These usually consisted simply of the alphabet, easy syllables. the Lord's Prayer, some hymns and Bible stories. The most famous of colonial schoolbooks was the **New** *England* Primer. Methods of instruction emphasized memory work, and punishment was often severe. For poor children and orphans, education was likely to consist of a form of apprenticeship whereby the child was taught a trade by his master and incidentally may have acquired some reading, writing and knowledge of the catechism. In general a child was fortunate if he had as much as two or three years of formal schooling, and the majority probably never attended any school at all.

Secondary *Education.*—Throughout most of the colonial period the dominant type of secondary instruction was carried on in Latin grammar schools in which the focus of attention, as the name indicates, was upon the study of Latin. In general the Latin grammar school was attended by the children of the more privileged families of the upper classes and was looked upon as providing the preparation necessary for college education and for positions of leadership in church and state. It thus reflected not only the aristocratic tradition of a gentleman's education but also the traditions of Renaissance humanism, according to which an educated person must be accomplished in knowledge of the classics.

In the 18th century the aristocratic and classical character of secondary education was modified and broadened somewhat by the appearance of new types of secondary schools. "English" schools were set up to provide instruction in a much wider range of studies,

including English, modern languages, mathematics, navigation, surveying, commercial arithmetic, bookkeeping, geography, history, music and the arts. These schools gave a more practical type of education to middle-class youth who were going into trade and commerce rather than to college. They also widened the opportunity for education of girls.

More permanently a part of American education were the academies which arose not only to meet such practical needs as mentioned above but also to provide a religious setting for the education of young men and women. The curriculums of the academies included languages, the social studies, the sciences, mathematics, the arts and music as well as the classics. They thus combined the religious, humanistic and practical concerns of the later 18th century.

Higher Education.—One of the most remarkable features of American colonial education was the fact that nine degree-granting colleges were established prior to the American Revolution. In general their programs were modeled after the colleges of the English universities. They were designed primarily to give education in the traditional liberal arts of Latin and Greek grammar, rhetoric, mathematics and philosophy. Even though the colonial colleges were not exclusively training schools for ministers, most of them were sponsored by the several religious denominations and thus combined religious and humanistic qualities. To a greater or lesser degree they adapted themselves to the new science and mathematics that were being developed during the 18th-century Enlightenment. Although they revealed varying elements of public control, they set the pattern for private higher education which prevailed in America until the 19th century. Harvard (1636), Yale (1701) and Dartmouth (1769) were established by the Congregationalists; William and Mary (1693) and Columbia (1754) were established by the Anglicans; Princeton (1746) by the Presbyterians; Brown (1764) by the Baptists; Rutgers (1766) by the Dutch Reformed; and the University of Pennsylvania (College at Philadelphia, 1755) was nondenominational.

3. Public Education in Early National Period.—During the years between the American Revolution (1775–81) and the Civil War (1861–65) Americans developed educational policies dedicated to the new national ideals of democracy, equality and freedom. If the new republic was to rest upon the consent of the governed, then all people would need to be educated for their responsibilities as citizens of a democracy. If the republic was to be strong and secure despite the differences of language and culture brought by immigrants from many lands, then all people must acquire the common language and values of U.S. citizenship. If talents were to be rewarded on the basis of ability and not upon class, economic privilege or place of national origin, all must have equal educational opportunity. If religious freedom and separation of church and state were to become realities in a country of divided religious loyalties, then education must be divorced from sectarian control.

To achieve these ideals the U.S. turned away from private systems of education based upon economic, class, national and religious distinctions and turned toward a system of common schools that would be free, universal and open to all. Despite vast difficulties and vigorous opposition, it was gradually decided that such values could be achieved only through the establishment of a free system of public education, publicly controlled and supported. The main outlines of such a system were achieved by the middle of the 19th century.

State Systems of *Common* Schools.—The ideal of public education was achieved under the leadership of a determined band of educational statesmen who acquired the support of increasing numbers of middle-class liberals, reformers, humanitarians and labouring and farm groups. Notable among them were James G. Carter and Horace Mann in Massachusetts, Henry Barnard in Connecticut, Calvin Wiley in North Carolina, Charles F. Mercer in Virginia, Robert Breckinridge in Kentucky, Calvin Stowe in Ohio, Caleb Mills in Indiana, Ninian Edwards in Illinois and John D. Pierce in Michigan. They worked through scores of organized groups, school societies, conventions and meetings; they utilized periodicals, journals, reports and pamphlets; and they occupied strategic posts in state governments and school systems. They had three main objectives: public support, state control and freedom from religious sectarianism.

Public Support.—If public schools were to become effectively free for all children, the schools must be supported by general taxation in order to overcome the inequalities of ability to pay for education. Traditionally, schools had been supported in a wide variety of ways: endowments, gifts, bequests, land grants, tuition, lotteries, licence fees and sometimes taxes. To these had been added rate bills whereby parents with children in the schools paid special rates depending upon the number of their children attending school.

Also, several states had set up common-school funds, the principal of which was largely derived from grants of public land bestowed by the federal government under the Land ordinances of 1785 and 1787 and a number of other federal laws. But none of these sources could provide the amounts of money necessary for a vast system of public schools.

The school reformers had to combat the prevailing notion that "free schools" were to be provided only for pauper children, and they had to convince state legislatures and the people of the states that direct and general taxation upon the whole community was the only adequate way to provide education for all the children of all the people. This was usually done in several steps. The state legislatures passed bills permitting local districts to tax themselves for schools if they elected to do so; then the states prodded the local districts by offering state aid to those districts that taxed themselves; and finally the states required the local districts to tax themselves for public schools. In this process major legislative victories were won in 1827 in Massachusetts, in 1834 in Pennsylvania, in 1867 in New York, in 1868 in Connecticut and in the 1850s in the middle western states.

State Control.—The second main objective was to widen the scope of educational control. So long as each local district could determine school policies for itself, great inequalities were bound to appear. Therefore the authority of the state had to be reasserted in order to assure adequate schooling for all the children of a state. Colonial precedents of the 17th century had established state authority, but decentralized control had gained headway in the late 18th century. The Massachusetts law of 1789, for example, recognized the local town school committees as agencies for supervising schools and appointing teachers. By 1820 the smaller districts had gained still more power. Then ensued a period of 20 to 30 years during which the power was gradually transferred from the local districts back to the towns and eventually back to the state governments themselves.

The principal means by which state authority was reasserted was the establishment of the office of state superintendent of schools and the appointment of state boards of education. New York created a state superintendent of schools in 1812, and virtually every northern state had done likewise by 1850. New York created its board of regents as early as 1784, and the movement toward state boards of education was accelerated when Massachusetts set up its board in 1837 with Horace Mann as secretary. Connecticut followed in 1839 with Henry Barnard as secretary. By 1860 several other states had used this means to raise educational standards and equalize opportunity within the states. Inasmuch as the U.S. constitution did not mention education, the states moved to reassert their colonial prerogatives and extend them, establishing a trend toward greater centralization of educational control and support despite a large degree of local and decentralized management of schools.

Freedom From Sectarianism.—The third critical problem in the struggle for free common schools was the religious issue. The U.S. had become a country of many tongues, peoples and religious sects. The tendency of new immigrants was to seek schools of familiar religious and nationality associations. The necessity for a common language and widespread agreement concerning democratic processes in political affairs pointed to the public school as a primary agency in creating unity in U.S. culture and in preventing permanent divisions in political, economic or social life. But the federal and state constitutions had agreed that there

must not be religious conformity imposed by government or by established religions.

Therefore it was soon realized that the drive for unity could not encompass religion and that the public schools could not impose religious conformity. On the other hand the religious groups wished to maintain their schools as a means of promoting their distinctive modes of worship and belief. Some Roman Catholics fought the establishment of public schools; some Protestants wanted the public schools to teach nonsectarian Protestantism; others wanted them to be sectarian. The conclusion was that public schools should be secular. Especially vitriolic were the struggles in New York, Massachusetts and Pennsylvania in the period from 1820 to 1860. The result was the general decision that sectarian religious instruction should not be given in public schools and that public funds should not be diverted from the public schools to private schools under sectarian control. New York settled the issue for the time being by legislation in 1842, Massachusetts by constitutional amendment in 1855.

4. Expansion of the Educational Program.—U.S. elementary schools in the early national period were called upon to broaden their aims and curriculums. They were expected not only to promote literacy, mental discipline and good moral character but also to help prepare children for citizenship, for jobs and for individual development and success. As a result, the elementary school curriculum not only maintained its earlier emphasis upon reading, spelling, writing and arithmetic, but added to these English grammar, geography, history and often bookkeeping and music.

Methods remained dominantly oriented to textbook memorizing, strict discipline and severe punishment; but a more sympathetic attitude toward children began to appear in the early 19th century. As the numbers of pupils expanded rapidly, individual methods of "hearing recitations" by children ranging in age from 5 to 15 began to give way to group methods. The monitorial or Lancasterian system became popular because it enabled one teacher to use older children to act as monitors in teaching specific lessons to younger children in groups. Similarly, the practice of dividing children into grades or classes according to their age began to spread as schools gre larger.

It soon became apparent that special training for elementary school teaching was needed if the common schools were to be adequately staffed, especially in view of the fact that increasing numbers of unskilled women were serving as teachers. New ground was broken in the 1820s when Samuel R. Hall established a private normal school at Concord, Vt., and James G. Carter did likewise at Lancaster, Mass. The movement for training elementary teachers in special schools outside the colleges gained further headway when the first public normal school was opened in 1839 in Lexington, Mass. By the outbreak of the Civil War, 12 such schools had been established in eight states.

Appearance *of* the Public High School.—During most of the 19th century the private academies were the dominant secondary schools in the U.S. They were typically controlled by self-perpetuating boards of trustees, often incorporated by charter from the state. They mere supported by tuition and by gifts and endowments. They were often controlled by religious institutions and often open to girls either as coeducational institutions or as girls' schools.

Despite the popularity of the academies, however, the feeling grew that there were large numbers of children who should be able to continue their education but could not afford the fees of the academies. It was also felt that the private academies might impose a highly selective system of schools on top of the common schools and thus prevent genuine equality of educational opportunity. Some states took steps to open wider the doors of the academies by giving them grants of state funds or by trying to integrate them into the state educational systems. But the more popular move was to establish free public high schools under the control of local boards of education and supported by public funds as an extension upward of the common-school system. The first such high school mas established in Boston in 1821, and although the growth was slow there were several hundred in several states by the time of the Civil War. Originally designed to offer a curriculum for boys and girls who were not going to college, the high school eventually provided a curriculum even broader than that of the academies, including college preparatory studies as well as terminal education for those who did not go to college.

State University Movement.—Higher education in the pre-Civil War period expanded rapidly. Whereas there had been nine colonial colleges at the time of the Revolutionary War, there were about 200 such institutions by 1860. Most of these were private colleges founded by the several religious denominations; the most active were Presbyterians, Methodists, Congregationalists, Baptists, Episcopalians and Roman Catholics. As might be expected from the growth of the idea of public education, the movement to make higher education free and available under public control and public support also gained headway.

Some of the states first thought that they could transform the private colleges into public universities. This was attempted in various ways in Virginia (William and Mary), New York (Columbia), Pennsylvania (University of Pennsylvania), Connecticut (Yale) and Massachusetts (Harvard). The decisive attempt was made in New Hampshire when the legislature tried to make Dartmouth college a state university. However, the U.S. supreme court in 1819 decided that the charter of Dartmouth college was a contract constituting it a private corporation which could not be impaired by the state under the U.S. constitution.

Thereafter the private colleges expanded rapidly. The states began to establish their own universities under public control and with public support. Six of the original states and 14 new states established state universities before the Civil War. In most cases religious interests sought to prevent the establishment of these universities (and were successful in doing so in seven other states) or tried to obtain public funds for their own private institutions. In 1862 the U.S. congress passed the Morrill act, which gave substantial land grants to the states for the establishment of agricultural and mechanical colleges. Many of the states used the funds from these grants for the strengthening of their state universities or for establishing separate state colleges of agriculture and engineering. With this stimulus the state university movement was accelerated in the latter part of the 19th century. *(See* also LAND-GRANT COLLEGES AND UNIVERSITIES.)

5. Modern **U.S.** Education.—In the century between the Civil War and the second half of the 20th century, U.S. education was extended, broadened and modified in several ways. Despite wide variety and differences among the several states the characteristics noted below were more or less national in scope.

Freedom of Public Education to All.—In the United States, in contrast with the historic dual systems of Europe where elementary education was designed for the lower classes and secondary education was reserved for the upper classes, the several states established their "ladder systems" beginning at the first year of schooling and extending through the graduate and professional schools of the university. Ideally every child was free to begin at the lowest level and progress as far as his abilities would take him. Indeed the welfare of society and the need for a common education in good citizenship led to compulsory attendance laws; beginning with Massachusetts in 1852, all states by 1918 had established some requirements for attendance at school. By 1960 five states required attendance to age 18 or high school graduation, another five to age 17 and forty to age 16.

The most obvious breakdowns in the ladder system have been the inequality among states in establishing good schools, the unequal ability of parents to afford higher education for their children and the establishment of segregated school systems for Kegro and white children in 17 southern states and Washington, D.C., following the Civil War. Attacks upon the segregated school systems were intensified after World War II. Two supreme court decisions required southern universities to admit Negro students, and in the historic decision of May 17, 1954, the supreme court declared that segregation in schools was inherently a denial of equality of educational opportunity and thus prohibited by the 14th amendment to the U.S. constitution.

The "border" states moved more or less rapidly to comply. The

states of the "deep south," however. not only delayed action to desegregate their schools but even when required by federal court order to do so the state governors of Arkansas and Virginia closed some of the public schools in 1958 rather than permit them to become integrated.

Centralized *Authority;* Decerztralized Administration. — Whereas there is relatively little centralized control of education by the federal government (except for court decisions), the authority for the sponsorship and control of public education is largely centralized in the hands of the several state governments as expressed in state constitutions, legislative enactments and court decisions. However, the day-to-day management and administration of schools has been largely delegated to local school districts operating within the authority of the state and the regulations of the state department of education. In general the people of the local school districts elect their own boards of education, which in turn levy school taxes and appoint local administrators and teachers for the schools. The intention is thus to establish a balance between the common values of general welfare to be achieved by centralized authority and the values of flexibility, originality and local initiative to be achieved by decentralized management.

Financial *Support From* Larger Units. — After about 1850, the proportion of funds spent on all education came increasingly from public sources and taxation and decreasingly from private sources. Furthermore, an increasing proportion of public funds came from state and federal governments and less proportionately from local districts. cities. towns and counties. In 1930, 83% of all funds for public schools came from local units and only 17% from state sources; by 1960 about 40% was coming from the states. The basic trend was to achieve greater equality of educational facilities despite financial inequalities among local units. Correspondingly, local units tended to decrease in number and to grow larger in size as small districts were consolidated into larger districts (approximately 90.000 school districts in the U.S. in the second half of the 20th century). Nevertheless there remained great inequality of wealth among the states; some states spent four times more per pupil per year than did other states.

The question of federal aid for education was a recurring issue. In the 1870s and 1880s several attempts were made by Republicans to indhce congress to pass the Hoar and Blair bills, which would have granted land or money to the states; but no bill was passed by both houses of congress at the same time. The issue was raised significantly again, this time with the Democratic party taking the lead, in the 1930s and especially in the years following World War II, becoming an issue in the 1960 presidential campaign. These attempts to provide federal funds for financial aid to the states for general support of education also were unsuccessful. Fear that federal support would mean federal control of education and that the central government would usurp the states' rights in education (especially in regard to implementing desegregation), and fear that public funds would be used to aid private and parochial schools as well as public schools were the rocks upon which the proposals for federal aid foundered.

Meanwhile, however, the federal government vastly increased its financial support for specialized types of education, notably for agricultural research (Hatch act of 1887), co-operative extension work in agriculture and home economics (Smith-Lever act in 1914), vocational education in secondary schools (Smith-Hughes act in 1917 and several others), federal relief programs in the depression years of the 1930s (National Youth administration and Civilian Conservation corps), war and defense training in World War II, educational benefits to veterans of World War II and grants for scientific research in colleges and universities. The federal school lunch program initiated in 1935 mas continued under the National School Lunch act of 1946 and subsequent amendments. Legislation passed in 1950 authorized financial assistance for school construction and operation to local educational agencies in areas affected by federal defense or other activities.

The successful launching of the first artificial earth satellite. Sputnik I, by the U.S.S.R. in 1957 so alarmed congress about the state of U S. education that it passed the National Defense Education act of 1958. This provided scholarships, loans and grants to improve teaching in science, mathematics and foreign languages, to develop television, radio, and audio-visual aids, and to promote guidance, counseling and testing services that would identify talented youth quickly and accurately.

Freedom for Private and Parochial Schools. — Despite the gradual growth of public education in the G.S. following the Civil War, private and religious groups continued freely to maintain, establish and support their own institutions. The U.S. supreme court decision in the Oregon case of 1925 reaffirmed this principle. In general the public policy was that no public funds should be used for the direct support or aid of religious institutions, in order to protect religious freedom and preserve the separation of church and state. Despite these restrictions the proportion of students enrolled in nonpublic schools increased from 9% of all school children in the 1930s to nearly 15% in the 1960s. Ninety per cent of these were in Roman Catholic schools. Controversies arose over the proposed use of public funds for the direct or indirect support of parochial schools. The U.S. supreme court decision in the Everson case in 1947 permitted public funds to be used for bus transportation of children to parochial schools as a public welfare benefit for the child.

The court reaffirmed that no tax funds could be used to aid any or all churches to promote religious activities on the grounds that the first amendment to the constitution requires separation of church and state.

Broader Tasks for Education. — In the light of the needs of a democratic, industrialized and complex society the educational needs of individuals broadened after the mid-19th century. The "three R's" (reading, writing, arithmetic) were considered to be as necessary as ever but no longer sufficient preparation for modern life. The educational program was gradually expanded to include studies appropriate to vocational and technical preparation, education for citizenship, personal adjustment and development and health and recreation as well as new studies in language, science, mathematics, social science and the arts. The sheer amount of information necessary to do advanced work in any field of knowledge required a longer period of study than ever before. Adherents of a narrow, academic and intellectualized curriculum consistently resisted the broadening of the school experience, but the demands of knowledge, scholarship, social welfare and individual competence were increasingly recognized by the public and by the educational profession.

The most controversial curriculum question had to do with religious instruction in the public schools. Bible reading was permitted in many states but prohibited in a few. Released time for religious instruction within public school buildings was declared unconstitutional by the U.S. supreme court in the McCollum decision in 1948, but later conceded to be constitutional if conducted outside school buildings and with no coercion upon children to attend (Zorach decision of 1952). In June 1962, however, the supreme court ruled that the organized recitation in public school classrooms of a nondenominational prayer composed by the New York State Board of Regents was unconstitutional.

Increased Attention to Individual Development. — Outlooks toward the child and his development also underwent revision in accordance with developments in philosophy, psychology and religious beliefs. Earlier conceptions of the child as in need of strict discipline and even brutal punishment gave way to more sympathetic views of the child as an individual. Distinctive periods of child growth and development were recognized as stages leading toward physical, mental and emotional maturity.

The modern outlook tried to take account of varying interests, capacities and needs of different children. Educational method was thus liberalized to emphasize individualized methods of instruction for the normal as well as for the talented, the abnormal and the subnormal. Special attention was given to the physically and mentally handicapped child, the slow learner, the defective, the non-English-speaking, the diseased and the exceptional. Authoritarian discipline and corporal punishment were softened, and greater attention nas given to development of habits of self-discipline. Recurrent criticisms were made of "Soft pedagogy," especially in the 20th century, but the new methods were defended

in studies showing that children learned as much as, if not more than, under traditional methods.

Improvement of the Teaching Profession. — Merely "keeping school" was no longer sufficient. The period of preparation for teaching was extended to at least four years of education beyond high school — a training that mould include the liberal arts as well as a professional body of knowledge for the teacher and administrator. University preparation was established for elementary as well as secondary school teachers. By the 1960s, 17 states required four years of college work for elementary school teachers and another 23 states required more than one year of college; 37 states required four years of college for secondary school teachers, 4 states required more than four years.

Widespread Availability of Education. — One result of the expansion of U.S. educational facilities was an enormous increase in attendance figures during the 100 years following the Civil War. While the total population was increasing from 31,000,000 in 1860 to 179,323,175 in 1960, the school and college enrollment increased much more rapidly. For example, at the end of World War I the total population was approximately 100,000,000 and attendance at all schools and colleges, public and nonpublic, was about 20,000,000. By 1960 the attendance had reached well over 45,000,000. While the total population was increasing by half in a period of 40 years, the school and college population was more than doubling. One American in four was attending an educational institution in the 1960s, not including adult and informal educational activities that touched perhaps 50,000,000 more. Tremendous shortages in school facilities and numbers of teachers marked the period following World War II.

Elementary school enrollment roughly paralleled population growth and decline, rising steadily from 16,000.000 in 1900 to 24,000,000 in 1930. Then it dropped to around 20,000,000 in the 1930s and early 1940s with the decline in birth rate during the depression years. But beginning in 1947–48 elementary school enrollment began to rise as a result of the increased birth rate following World War II until it reached a new high of more than 30,000,000 in 1960. Virtually 99% of children age 7 to 13 were in school.

During this period there was a more rapid rate of growth in secondary and higher education. Secondary school enrollment of 1,000,000 in 1910 had increased tenfold to more than 10,000,000 in 1960 (about 5% of the total school enrollment in 1910, and more than 32.6% in 1960). In 1900 only about 10% of high school-age youth were going to school; by 1930, 50% aged 14 to 17 were actually in school; and by the 1960s 90.3% of all children in this age group were actually in school. Universal secondary education was well on its way to being achieved. The wider range of abilities and the more heterogeneous character of the secondary school population were reflected in the fact that in 1900 about 75% of high school graduates went on to college, but in the early 1950s only about 25%. The proportion going on to college rapidly increased to 35% by the late 1950s.

An even greater rate of increase in enrollment characterized higher education. About 300,000 were enrolled in 1910, and nearly 4,000,000 in 1960. This represented a rise from about 2% of the total school and college enrollments to about 9% of the total number attending all educational institutions. Whereas about 5% of youth aged 18 to 21 were attending college in 1910, more than 35% of the age group were in higher institutions in the 1950s. Illiteracy among persons aged 14 or over had been reduced to about 2%, and the median number of years of schooling attained by all Americans was ten.

6. Changes in Organization and Program. — For most of the period from the Civil War to mid-20th century the typical pattern of educational organization was an eight-year elementary school, beginning at age six, followed by a four-year high school. Then came the four-year liberal arts college, followed by the graduate and professional schools. Significant rearrangements were made, especially after the turn of the 20th century, to give greater attention to children younger than six years of age in the kindergarten, to early adolescent youth in the junior high school and to older adolescents in the junior college.

Childhood Education. — The first supplement to the eight-year elementary school was the introduction from Germany of the kindergarten, which had been initiated by Friedrich Froebel to provide preschool education for children between four and six. The kindergarten made much of play activities, greater freedom and group methods and regard for the emotional and spiritual nature of the child. A private kindergarten was established in Wisconsin in 1855 and in Boston in the 1860s, and the St. Louis public school system added kindergartens under the direction of Susan Blow in 1873. By the early 1950s, 60% of all city school systems were operating kindergartens as part of the public school system, enrolling about 1,000,000 children; another 150,000 were in private kindergartens. Nursery schools for two-, three- and four-year-olds were established in about 10% of the U.S. city school systems, but did not become so popular as the kindergarten.

In the elementary grades for children 6 to 12 or 14 the three R's remained staple, but the curriculum was gradually expanded to include such studies and activities as health, creative art, drawing and music, nature study, geography and history, manual training and domestic arts. Beginnings in this direction were made as early as the 1860s when the "object method" of teaching and methods of nature study were introduced according to the pattern of the Swiss educator Johann Heinrich Pestalozzi. Edward A. Sheldon and the normal school at Oswego, N.Y., were influential in spreading Pestalozzian ideas in America.

Another influential leader in making the child and his interests the centre of the educative process was Francis W. Parker in his schools at Quincy, Mass., and at the Cook County Normal school in Chicago in the 1880s and 1890s. Further stimulus to modern educational methods came from John Dewey through his experimental school at The University of Chicago in the late 19th and early 20th centuries and through his writings on educational theory and practice. The leading spokesman for the Dewey philosophy in education was William H. Kilpatrick of Teachers college, Columbia university.

Many plans were designed to individualize the curriculum and break the academic lock step; these included project methods, unit plans, homogeneous grouping, ability grouping and integrated programs. (See also SCHOOL AND CURRICULUM.) School systems expanded their services to include audio-visual aids, libraries, guidance departments, school lunches, health departments, recreation, transportation and work experience. The development of objective tests and measurements of scholastic achievement aided the process of diagnosing individual abilities and setting standards of school achievement for the various age and grade groups. Leaders in the psychological and scientific movement in education were Edward L. Thorndike of Teachers college, Columbia university, Charles H. Judd of The University of Chicago and Lewis M. Terman of Stanford university.

Youth Education. — One of the most distinctive and historically revolutionary characteristics of modern U.S. education was the attitude toward the education of children and youths aged 12 to 18. Universal secondary education was made possible legally by a number of court decisions in the 19th century, notably the Kalamazoo case in Michigan in 1874, which affirmed the right of local boards of education to establish and maintain free high schools as an integral part of the public school system and support them with general tax funds.

The basic pattern was a comprehensive coeducational high school offering a variety of courses, in contrast to the system in many countries where children are at age 12 sent to different kinds of schools — academic, technical, vocational, domestic science, etc. The U.S. comprehensive high school typically has not only several courses designed for nonacademic as well as academic pursuits but also the range of studies acceptable for college preparation.

This change in emphasis was signalized by several important statements by national bodies. The Committee of Ten on Secondary School Subjects in 1893 and the Committee on College Entrance Requirements in 1899 were especially concerned to standardize the secondary school curriculum with a view to college preparation. In contrast the Seven *Cardinal* Principles *of*

Secondary Education formulated in 1918 stressed health, command of the fundamental processes, worthy home membership, vocational preparation. civic education. leisure-time activities and ethical character as goals of secondary education. Similar objectives appeared in the statements of the Educational Policies commission from the 1930s onward, especially in Education for *All* American Youth in 1944.

Special provisions were made to adapt secondary education to the needs of adolescents. Organizationally this was done by the development of the junior high school, designed to provide an appropriate exploratory and general education for 13-, 14- and 15-year-olds in the seventh, eighth and ninth grades. Beginning in Ohio and California as early as 1909 and 1910, the junior high school was widely adopted until the six-year elementary school, the three-year junior high school and the three-year senior high school had become the commonest pattern of school organization by mid-20th century.

Similarly. at the top of the secondary system the junior college was established to provide continuing general education, vocational and semiprofessional preparation and opportunities for personal and social development for 18- to 20-year-olds. The junior college movement grew rapidly from about 2,300 students in 74 institutions in 1915 to more than 500 institutions enrolling more than 400,000 students in 1960. Whereas 75% of junior colleges were privately controlled in 1915, more than half were publicly controlled by 1960, and these enrolled more than 85% of all junior college students. In effect the public junior colleges were becoming the 13th and 14th grades of the public school system, providing an extended terminal education for many students and providing for others the first two years of undergraduate college work.

Higher Education.—By the early 1960s there were more than 1,300 degree-granting higher educational institutions in the United States, including (1) about 130 universities consisting normally of undergraduate colleges and professional and graduate schools; (2) nearly 700 four-year liberal arts colleges; (3) about 300 separate technical and professional schools; and (4) about 200 teachers' colleges. The universities enrolled approximately half of all students attending higher institutions. The liberal arts colleges were almost entirely under private or religious control, and about four-fifths of the teachers' colleges were public institutions Of the total number of higher institutions of all kinds (including junior colleges), about two-thirds were under private control, but more than half of all students were in public institutions. Financial support for higher education was coming in increasing proportion from state and federal funds as compared with private sources of income and tuition.

The former curriculum embracing a few subjects with emphasis upon the classics, mathematics and philosophy had been expanded to include a large number of studies in modern languages and humanities, the sciences, the social sciences and the arts. The elective system whereby students had wide choice of studies outran the prescribed curriculum by the beginning of the 20th century. and then in turn the specialization permitted by the elective system was modified in the direction of requirements for a broad and general education. The ideal of a small liberal arts college persisted but was often overshadowed by the large university with its emphasis upon professional preparation and research. Many new scientific, technical and practical studies took their places alongside the traditional academic or cultural studies, adding to the tendency to specialize. The disciplinary and religious character of higher education had to compete with an emphasis upon greater freedom for students and greater concerns with social, civic and occupational goals.

B. Great Britain and the Commonwealth of Nations

1. Elementary Education in England to 1900.—The development of industry and the social unrest at the end of the 18th century, following on the French Revolution. combined to bring home to the public mind the need of a national system of day schools. Unfortunately, just at this moment the revival of Nonconformity as the result of the religious vitality of the Evangelical movement divided the nation once more into hostile camps, to which class distinctions lent additional bitterness. The controversy between Andrew Bell and Joseph Lancaster and their respective followers in the opening years of the 19th century served to define the religious difficulty substantially in the form in which it continued to exist for more than 100 years. Both these remarkable men conceived independently the idea of a national system of popular education upon a voluntary basis; both concurred in extolling the merits of the monitorial system, which each claimed to have originated. The controversy between them, begun upon personal grounds, resolved itself into a national contest of rival principles of religious teaching. Lancaster, as a young Quaker schoolmaster, confronted with pupils drawn from various religious bodies. planned his religious instruction upon the lines of doctrine common to all the orthodox Christian denominations. Thus he is the father of the undenominational religious teaching which later formed the basis of the Cowper-Temple compromise of the 1870 act (see below). But whereas the Cowper-Temple clause was purely negative in form and so seemed to point to an undogmatic religion, the Lancastrian teaching was essentially positive and dogmatic within its limits. The church as a whole refused to cooperate in religious teaching upon the basis of a common Christianity and joined issue with Lancaster and his Whig and Nonconformist following not merely upon the question of the exclusion of dogmatic formularies but also upon the question of the control of whatever religious teaching should be given. In fact, the vital question at this period was whether the clergy of the established church were to control national education. The religious issue u-as prominent in connection with the remarkable attempt at legislation made by the Whig statesman Samuel Whitbread in his Parochial Schools bill of 1807. It was rejected by the lords, mainly on the ground that it did not place education on a religious basis or sufficiently secure control to the minister of the parish.

Early *Voluntary* Schools.—The failure of the liberal proposals of Whitbread, and the strength of the opposition to any settlement on purely church lines (such as that advocated by Andrew Bell in 1808 for establishing schools under the control of the parochial clergy), rendered recourse to voluntary effort inevitable. In 1808 the Royal Lancasterian society was formed to carry on the work of Lancaster, the name being afterward changed to the British and Foreign School society. In 1811 the National Society for Promoting the Education of the Poor in the Principles of the Established Church throughout England and Wales was formed, nith Bell as its superintendent. In voluctary effort on a grand scale the church easily outdistanced its opponents, and in 1831 the National society was able to show that there were more than 13,-000 schools in connection with the church, of which about 6,500 were both day and Sunday schools, having a total attendance of 400,000.

The rapid development of the voluntary school system was no doubt greatly facilitated by the monitorial plan of teaching, upon which Bell and Lancaster equally relied. This plan never rested upon any educational theory; it was simply a rough-and-ready expedient for overcoming the practical difficulty caused by the dearth of competent teachers. Historically it is important as the precursor of the pupil-teacher system of apprentice teachers (see Teacher Training) which long formed the exclusive basis of the English elementary system.

Meantime, Lord Brougham in 1816 procured the appointment of a general commission of inquiry into endowed charities. The labours of this inquisition lasted for 20 years and led to the reformation of many cases of abuse or waste of wealthy endowments and eventually to the establishment of the Charity commission in 1853. In 1820 Brougham introduced a bill which proposed to require teachers to be members of the Church of England arid to be appointed upon a certificate from the parochial clergyman and on the other hand to prohibit religious formularies and to confine religious instruction to Bible reading without comment. The bill naturally failed, through the opposition of the Nonconformists, and served only to accentuate the religious impasse.

Establishment of State Aid.—In *1832* the Whig government placed on the estimates a sum of *£20,000* for public education, thus initiating the system of the annual grant voted by parliament. The funds thus granted were to be confined to the erection of school buildings, and to be administered only through the National and the British and Foreign School societies. In *1839* Lord Melbourne's government, by means of an order in council, established a Committee of Council on Education, and the sum voted by parliament was increased to *£39,000.* The original intention of the government mas to establish a state normal school or teachers' training college as the foundation of a national system of education. Unfortunately this design had to be abandoned in view of the religious difficulty, with the result that the training of elementary teachers was left in private hands. In view of the limited resources placed at its disposal by parliament, the committee of council was at first compelled to confine its assistance to aid in the provision of school buildings, but in the distribution of the money three important conditions were at once imposed. In the first place, the continuing right of inspection was required in all cases; secondly. promoters were obliged to conform to a fixed standard of structural efficiency; thirdly, the building must be settled upon trusts permanently securing it to the education of poor children.

By the minute of Aug. *10, 1840,* the committee of council concluded nhat came to be known as the concordat with the church. Under this minute no appointment was to be made of any persons to inspect schools in connection with the Church of England without the concurrence of the archbishop of the province, and what seems still more extraordinary to modern ideas, any such appointment could be revoked by the archbishop at any time. The altered financial relations, however. between the state and the voluntary managers brought about by the institution of maintenance grants soon rendered this concordat obsolete.

Among the first acts of the committee of council was the promulgation of a set of model trust deeds. The necessary conditions nere the permanent appropriation of the site to purposes of education and the permanent right of government inspection; a conscience clause was not obligatory and indeed was only offered in the limited form of exemption from instruction in formularies and attendance at Sunday school or public worship. Special facilities for the conveyance of land for school purposes were afforded to limited owners by the School Sites acts of *1841* and subsequent years. The landed gentry responded with great public spirit to the call thus made upon their generosity by the state, with the result that the vast majority of rural, and many urban, parishes were freely endowed with sites for elementary schools.

The Grammar Schools act of *1840,* which was passed to deal with the case of the decayed grammar (*i.e.,* classical) schools which abounded throughout the country, belongs to the history of elementary rather than secondary education. As a result of this act a considerable number of ancient endowments were reorganized so as to afford an improved elementary instead of an inefficient classical education, and the plans made under the act constituted an early, but not very successful, experiment in the direction of higher elementary schools.

In *1843* the committee of council decided to make grants-in-aid of the erection of normal schools or training colleges in connection with the National society and the British and Foreign School societies, thus marking the abandonment of the system of relying on voluntary effort for the provision of training colleges.

In *1846* an important step forward was taken in the foundation of the pupil-teacher system. The regulations of that year inaugurated annual maintenance grants in the form of stipends for apprenticed pupil-teachers receiving a prescribed course of instruction under the head teacher and a lower grade of stipendiary-monitors in schools where such instruction could not be provided. These regulations inaugurated the system of Queen's scholarships to assist pupil-teachers to proceed to a training college; they also established capitation grants for the support of such colleges and annual grants to elementary schools under government inspection of from £15 to *£30* in aid of the salary of every trained teacher employed. At the same time provision was made for retirement pensions for elementary teachers.

To facilitate the recognition of denominational schools other than Church of England. the committee of council in 1847 issued a minute dispensing schools not connected with the established church from inquiries concerning their religious condition, and in the same year state aid was extended to Wesleyan and Roman Catholic schools. Jewish schools received recognition in *1851* upon condition that the Scriptures of the Old Testament should be daily read in them.

During the middle of the century various unsuccessful attempts were made to establish a national system of elementary schools upon the basis of rate aid. The only one that calls for notice is the bill introduced by Lord John Russell (called the Borough bill, because it was restricted to municipal boroughs) in *1853,* which formed part of a comprehensive plan of legislative and administrative reform of which a portion was actually carried into effect. The bill as a measure for elementary education was supplemented by an administrative system of capitation grants for rural areas. The government plan also comprised a measure dealing with the administration of charitable trusts (which took shape as the Charitable Trusts act, 1853), the constitution of the department of science and art and university reform upon the lines recommended by the Oxford and Cambridge commissions.

The failure of the Borough bill did not affect the new system of capitation grants which was introduced by minute of the committee of council dated April *2, 1853.* These grants nere fixed at a scale varying from *3s.* to 6s. per head. payable upon certain conditions, of which the most important were that the school must be under a certificated teacher and that three-quarters of the children must pass a prescribed examination. The capitation grant was, by minute of Jan. 26, *1856.* extended to urban areas. As in the case of all the early grants, the regulations governing the distribution of the capitation grants were framed upon the principle that subventions of public money must be met by local funds derived from voluntary contributions, endonments and school fees; thus the basis of the denominational system as fostered by the state at this stage was one of financial partnership.

In *1856* a purely administrative bill nas passed, establishing the office of vice-president of the Committee of Council on Education as a minister responsible to parliament. At the same time, the science and art department was transferred from the board of trade to the committee of council.

The Newcastle Commission.—The progress of state-aided education during this period may be measured by the increase of the annual parliamentary grant. which rose from *f30.000* in 1839 to *£663,400* in *1858.* This expansion was viewed with misgiving by the friends of the denominational system and by the strong individualists of that day, who clung to the old ideal of voluntary initiative. These sections combined with the advocates of further state intervention to press for an inquiry, and a royal commission was appointed in 1858, under the chairmanship of the duke of Newcastle, to inquire into the state of popular education in England and to consider and report what measures, if any, were required for the extension of sound and cheap elementary instruction to all classes of the people Their report. issued in *1861,* contained an exhaustive account of the condition of elementary education and, with due allowance for the grave defects revealed, in particular the glaring inefficiency of the numerous little private-venture schools kept by "dames" and others, the graphic picture drawn by the commissioners constituted a striking tribute to the sterling qualities of self-help and religious earnestness which were characteristic of the time. It was found that in round numbers about *2,500,000* children were attending day schools, the proportion to population being one in seven. as compared with one in nine in France, one in eight in Holland and one in six in Prussia, where education was compulsorp. On the other hand, of this number only *1,675.000* were in public schools of all kinds, only *1,100,000* in schools liable to inspection and *917.000* in schools receiving annual grants. Thus only one child in every 20 was attending a school whose efficiency could be in any way guaranteed by the state. The commissioners as a body rejected free arid compulsory education in view of the religious difficulty and upon general

grounds of individualistic principle. In view of the solution adopted in 1902 it is of interest to note that the Newcastle commissioners deliberately rejected the parish as unfit to be taken as the unit of elementary education. upon the ground that management by parochial ratepayers must tend to be illiberal and niggardly. and recommended the constitution of county boards with power to levy a rate for the aid of existing voluntary schools.

The one definite achievement of the Newcastle commission mas the system of payment by results. Impressed by the defects of the existing teaching, the commissioners reported that the only way of securing efficiency was to institute a searching examination by competent authority of every child in every school to which grants mere to be paid. with the view of ascertaining whether the indispensable elements of knowledge were thoroughly acquired, and to make the prospects and position of the teacher dependent to a considerable extent upon the results of this examination. They recognized that to raise the character of the children, both morally and intellectually, was and must always be the highest aim of education; but they thought that the training in the rudiments of education had been lost sight of and that there was justice in the common complaint that while a quarter of the scholars were really taught, three-quarters after leaving school forgot almost everything they had learned there.

Robert Lowe (later Lord Sherbrooke), as vice-president of the committee of council (1859–64), adopted the system of payment by results in what became famous as the Revised code, issued in 1862. This provided for the payment of a grant of 4s. upon the old principle and a further grant of not more than 8s. upon the result of examination. Lowe declared of the system in the house of commons that "if it was costly it should at least be efficient; and if it was inefficient it should at least be cheap." In fact, it proved to be cheap; the grant fell from £813,400 in 1861 to £636,800 in 1865. Later, to meet objections, some modifications were introduced in the code under the Conservative government in 1867. The system of paying grants upon the result of individual examination of the scholars was not finally abolished till 1904.

The Act of 1870 and Its *Effects.*—In 1868 the Conservative government brought in, but did not proceed with, an education bill deliberately discarding the principle of rate aid on the ground that it would destroy voluntary contributions and gradually starve out the denominational schools. In 1867 and again in 1868, Liberals Henry Austin Bruce (afterward Lord Aberdare), W. E. Forster and Algernon Egerton introduced a bill which formed the basis of the measure of 1870. As redrafted in 1868 this bill proposed a universal system of municipal and parochial rating with liberty for voluntary schools to unite themselves to the rate-aided system under their existing management. subject to the acceptance of a conscience clause. The bill also proposed to empower town councils to co-opt outsiders upon their education committees. Both the principle of co-optation and the extension of rate aid to schools not under public control anticipated certain features of Balfour's Education act of 1902. In the meantime, in the country the Education league, originated at Birmingham, was carrying on propaganda in favour of free secular schools, while the opposing Education union urged a settlement upon the old lines. As a concession to the popular feeling against secularism, the league proposed to allow Bible reading without doctrinal exposition. Thus opinion was sufficiently focused to enable William Gladstone's administration in 1870 to undertake a comprehensive measure of educational reform.

The Elementary Education act of 1870 bore in every respect the marks of compromise. As Forster explained in introducing the bill, the object of the government was "to complete the voluntary system and to fill up gaps," not to supplant it. To this end the education department was charged with the duty of ascertaining whether or not there was in every parish a deficiency of school accommodation and of providing for the formation of school boards in every school district (*i.e.*, parish or municipal borough) requiring further school accommodations.

Three important changes were made in the measure during its passage through parliament: (1) In lieu of the rate aid as first suggested, the government proposed an increased grant from the treasury, that is to say, the voluntary schools were left as state-aided schools under private management, side by side with the new rate-supported schools. (2) The character of the religious instruction in the board schools was determined by a provision, which became known after the name of its author as the Cowper-Temple clause, directing that "no religious catechism or religious formulary which is distinctive of any particular denomination shall be taught in the school." This was not intended to exclude doctrinal exposition, and was in fact a compromise not merely between absolute secularism and denominationalism but between denominationalism and the view of those who would have the Bible read without note or comment. The Apostles' Creed as a symbol common to all denominations of Christians nas held by Forster (at Gladstone's suggestion) not to be excluded under the Cowper-Temple clause. The result was the establishment in the schools, upon the lines laid down by Joseph Lancaster at the beginning of the century, of what may be termed the common Protestantism of the English nation. The Cowper-Temple compromise, notwithstanding its inherent want of logic, stood the test of experience for more than a generation against the consistent denominationalists on the one hand and the party of secular education on the other. (3) The third change in the bill was the substitution of the ad *hoc* school board for the municipally appointed board originally proposed. These boards were elected by the system of cumulative voting under which each elector had as many votes as there were candidates to be elected. with liberty to give all his votes to one candidate or to distribute them among the candidates as he thought fit. This system was much criticized as being unduly favourable to minorities, whose representation it was devised to secure; it continued, however. until the act of 1902.

School boards were empowered not only to acquire sites for schools under powers of compulsory purchase but also to take transfers of existing voluntary schools from their managers. The act of 1870 did not introduce either direct compulsory attendance or free education, but it took a distinct step forward in each direction by enabling school boards to frame bylaws, rendering attendance compulsory. and also to pay the school fees in cases of poverty. Building grants were continued temporarily for the benefit of those who applied (as voluntary managers alone could apply) before Dec. 31, 1870. On the other hand, the education department was authorized to refuse parliamentary grants to schools established in school-board districts after the passing of the act if the department thought such schools were unnecessary.

The following figures show the progress made under the act of 1870. In the year 1870 there was accommodation in inspected day schools for about 2,000,000 children; the average attendance was 1,168.000, and the number on the books about 1.500 000. It was computed, however, that there were, exclusive of the well-to-do classes. at least 1,500.000 children nho attended no school at all or schools not under inspection. In 1876 accommodation had been provided for nearly 3,500.000, and of the 1,500,000 new places nearly two-thirds were provided by voluntary agencies It was reported that these agencies had received grants-in-aid for about one-third of the schools they had built, the grants defraying about one-fifth of the cost of the aided schools On the other hand, the growth of school boards was rapid and continuous, notwithstanding the permissive character of the act and the strenuous efforts of the voluntary agencies and their supporter5 to keep pace with the new demands. This development enabled Benjamin Disraeli's government to pass in 1876 a law, generally known as Lord Sandon's act, designed to improve school attendance and making it the duty of every parent to see that his child received efficient instruction in reading, writing and arithmetic.

This act had a marked effect on school attendance, which rose in four years by about 500.000. Parents were groning accustomed to sending their children to school and, with a substantial increase in school accommodation, a further advance was soon possible. This came in 1880 after the Liberals had returned to power. Gladstone's adminiitration passed a short act—Mundella's act—which required school boards and attendance committees. required in all districts in which there were no school boards, to frame bylaws, if they had not already done so, governing the attendance

of children at school. There was now a complete system of universal compulsory education. Under the acts of *1876* and *1880* the average attendance increased from *2,000,000* in *1876* to *3,500.000* in *1878* and *4,000,000* in *1881;* in terms of percentage to population, *8.06%* in *1876, 9.60%* in *1878* and *10.69%* in *1881.* In the last-mentioned year the annual grant rose to *£2,200,000,* having more than doubled in the decade.

In *1887* a royal commission under Viscount Cross was appointed to inquire into the working of the education acts. The labours of this commission produced a thorough discussion of the educational problem in all its aspects — political, administrative, scholastic and religious. For any clear recommendations with regard to the reorganization of education generally the moment was not opportune, inasmuch as the commission just preceded the establishment of the new county authorities, to which parliament was shortly to confide, under the Technical Instruction acts, powers with respect to instruction other than elementary. Nevertheless the report of the majority of the commissioners pointed unmistakably toward the solutions adopted in the act of *1902.* and their definite recommendation that voluntary schools should be accorded rate aid without the imposition of the Cowper-Temple clause served as the basis of that legislation.

Of later developments, it is convenient to mention in the first place. out of chronological sequence, the practical establishment of free education by the act of *1891,* not by the absolute prohibition of school fees but by the device of a special grant, payable by parliament in lieu of fees, called the fee grant. The result of this legislation and of subsequent administrative action was to place free education within the reach of every child, fees being retained (with few exceptions) only where some instruction of a higher elementary type was given.

2. Secondary and Technical Education to 1900.—The establishment of county councils by the Local Government act, *1888,* introduced a new factor, destined to exert a determining influence upon subsequent developments of public education. In the first place, it at once rendered possible the partial and experimental provision for higher education attempted by the Technical Instruction acts, which affected secondary education as well as technical education in the proper sense of the term.

In order to understand the state of secondary education at this period it is necessary to refer to the first attempts made at state intervention. In *1861* the first step was taken by the appointment of a royal commission, presided over by Lord Clarendon, to inquire into the condition of nine of the chief endowed schools in the country, Eton, Winchester, Westminster, Charterhouse, St. Paul's; Merchant Taylors', Harrow, Rugby and Shrewsbury. The report of this commission led to a statute, the Public Schools act of *1864,* which introduced certain reforms in the administration of seven of these schools, leaving the two great London day schools, St. Paul's and Merchant Taylors', outside its operation.

The Schools *Enquiry* Commission.—In *1864* the Schools Enquiry coinmission was appointed under the presidency of Lord Taunton to inquire into all the schools which had not been included either in the commission of *1861* or the Popular Education (Newcastle) commission of *1858.* It thoroughly explored the field of secondary education and "its luminous and exhaustive report" (to quote the words of the Bryce commission of *1891)* was an excellent introduction to the problem of public secondary education in England. The existence of numerous and frequently very wealthy endowments arising from private benefactions and bequests had at all times been a feature in education as in other departments of English social life. At the date of the Schools Enquiry commission the state of the ancient endowments was largely one of abuse. Many endowments intended for advanced education were applied for instruction of a purely elementary character, and that of an inferior kind; indeed the possession of an endowment in a rural locality not infrequently operated to prevent the establishment of an efficient state-aided school. The evidence showed that the proportion of scholars in the country grammar schools who were receiving some tincture of the classical education intended by the founders was steadily decreasing, and nothing had been done to bring the curriculum into harmony with the actual needs of the time. In addition to the general inelasticity of the curriculum, the special evils from which the grammar schools suffered were the want of effective governing bodies on the one hand and the freehold tenure of the headinasterships on the other.

The report of the commission was immediately followed in 1869 by the Endowed Schools act, which conferred upon a special commission (united in *1874* with the Charity commission) very wide and drastic powers of reorganizing ancient endowments A direction for extending the benefits of endowments to girls did much to assist the movement for secondary education for girls. (See also CHARITY COMMISSIONERS FOR ENGLAND AND WALES.)

The Schools Enquiry commission also submitted proposals for the general organization of a system of secondary education. They recommended the establishment of three authorities: (1) a central authority; *(2)* a local or provincial authority, representing the county or a group of counties; and (3) a central council of education charged with examination duties Further, it nas proposed to raise the level of proprietary and private schools by offering them inspection and examination and by establishing a system of school registration Lastly, it was proposed to confer upon towns and parishes powers of rating for the establishment of new schools. For these proposals as a whole the time was not ripe. The bill of *1869* attempted to give effect to the suggested creation of a central council, but exigencies of parliamentary time made it necessary to drop this part of the measure; the result was that the plan of the commissioners was only half carried out. Nevertheless the work accomplished under the Endowed Schools act and subsequent acts was sufficient to exert a considerable influence upon the secondary education of the country. Thus in *1895* the Bryce commission was able to report that plans under the acts had been made for *902* endowments in England, excluding Wales and Monmouth. leaving untouched only *546* out of the total of *1,448* endowments in England known to be subject to the acts. The gross income of the endowments known to be subject to the Endowed Schools acts,' and therefore available for purposes of secondary education, was in *1895* about *£735.000.*

The creation by the Local Government act in *1888* of the representative and popular county authorities rendered the municipalization of secondary instruction at last possible. In *1889* the Technical Instruction act (extended by an act of *1891)* empowered the councils of counties. boroughs and urban districts to levy a rate (not exceeding a penny on the pound) for the support of technical or manual instruction. Comparatively few councils were prepared to resort to their rating powers, but progress under these acts was greatly facilitated by the Local Taxation (Customs and Excise) act of *1890,* which mentioned technical instruction as one of the purposes to which the imperial contribution paid to local authorities in respect of the beer and spirit duties might be applied. (See TECHNICAL EDUCATION.) By virtue of the liberal interpretation given to technical instruction by these acts the financial assistance afforded under them was extended to cover the whole field of mathematical and physical science, as well as modern languages.

At the same time the department of science and art gradually utilized its grants to encourage literary studies in secondary schools as well as the scientific and mathematical subjects to the promotion of nhich it was primarily directed. Thus the combined effect of the local resources available under the Technical Instruction act and the imperial grant administered by the department was gradually to develop a national system of secondary education aith a marked bias toward physical science. But the schools giving higher education still practically consisted, apart from the big "public" (independent) schools, of endowed grammar schools or proprietary schools established by religious bodies or joint-stock companies. No public body had, as yet, the right to build a secondary school.

An undoubted stimulus was given to secondary education in the great centres of industry during the last quarter of the 19th century by the rise of the new university colleges (*q.v.*), among which must be reckoned those established expressly for women. At the same time *(1889)* a beginning was made of state aid to these colleges, through a committee appointed by the treasury in a min-

ute of July 1. Meanwhile, with the development of elementary education, the school boards found themselves obliged to provide for the further education of their best pupils in what were known as higher-grade elementary schools. These were really secondary schools of the third grade, and, as the Secondary Education commission observed, the school boards simply stepped in to fill the educational void which the Schools Enquiry commissioners had proposed to fill by schools of that name. Their creation was greatly fostered by the upper departments in such schools being recognized for grants by the science and art department. In fact they continued to multiply and prosper till 1901, when the famous judgment in the test case of Rex v. *Cockerton* pronounced them to be illegal. It was at once recognized that the legislature must, without delay. step in to secure the educational work which the undoubtedly correct principles of judicial interpretation had placed in jeopardy.

Secondary Education Commission.—Meanwhile, as far back as 1894, a royal commission had been appointed under James (later Lord) Bryce to inquire into secondary education. The principal recommendations of the commission were: (1) the unification of the existing central authorities, viz., the department of science and art, the Charity commission (so far as it dealt with educational endowments) and the education department, in one central office, and the establishment of an educational council to advise the minister of education in certain professional matters; (2) the establishment of local authorities; to consist of committees of the county councils with co-opted elements; (3) the formation of a register of teachers with a view to the encouragement of professional training. and a system of school registration upon the basis of inspection and examination. The first of these recommendations was carried out by the Board of Education act, 1899, and under the same act an attempt was made to give some effect to the third-named object, which unfortunately fell short of success. The realization of the second, and most important, of the recommendations was deferred till 1902, when it was brought about as part of a wider reorganization of the educational system.

In 1896 an endeavour was made to meet the demands of the voluntary managers of elementary schools by means of a bill introduced by Sir John Gorst. This bill with its provision for a special aid grant to be administered by county education authorities, which were to exist side by side with the school boards, represented a kind of compromise between the system of 1870 and what later developed in 1902. It encountered opposition in all quarters and was withdrawn. In 1897, however, the position of the denominational school was strengthened by the Voluntary Schools act, which provided for a special aid grant of 5s. per head of the scholars in average attendance in these schools.

Partial effect was given to the recommendations of the Secondary Education commission by the Board of Education act of 1899, which united the department of science and art with the education department in one central office under the title of the board of education, with a president and parliamentary secretary; provided for the transfer to this board of the powers of the Charity commissioners in relation to educational endowments; and provided also for a consultative committee, consisting, as to not less than two-thirds, of persons qualified to represent the views of university and other bodies interested in education, for the purpose of (1) framing a register of qualified teachers and (2) advising the board of education upon any matters referred to the committee by the board. In 1902 a tripartite division was adopted to correspond with the three branches of education with which the board of education was concerned, viz., elementary, secondary and technological. Mention may also be made here of another uncontroversial measure, the Elementary Education act of 1899, which dealt for the first time, from the point of view of the state, with mental deficiency.

3. Organization of a New Era.—Two statutes marked the beginning of a new era in the history of education in England and Wales. The Board of Education act, 1899 (see above), provided a unified central administration, while the Education act, 1902. established a comprehensive system of local government for both higher and elementary education. The latter was a bold, constructive measure sponsored by Arthur (later Lord) Balfour, who became prime minister during the act's long and stormy passage through parliament. In framing it he owed much to Sir Robert Morant, who, as the first permanent secretary of the board of education, was mainly responsible for bringing it into operation. It created new local education authorities, empowered them to provide secondary schools and develop technical education and made fundamental changes in the relations of the voluntary schools to the state.

Under the act the county and county borough councils became the local education authorities, The school boards were abolished; there were far too many of them (2,568) and they had never been a popular institution. But one concession was made to local pride: noncounty boroughs with a population of more than 10,000, and urban districts with a population of more than 20,000, were allowed under part iii of the act to exercise autonomous powers for elementary education. Except in these part iii areas, as they came to be called, the county councils were, like the county boroughs, responsible for both higher (*i.e.*, secondary and technical) and elementary education. All councils having powers under the act uere required to appoint an education committee with a proportion of co-opted members with experience of education, of whom some were to be women. As the earlier reference to the case of Rex v. Cockel-ton indicated, there was urgent need of legislation to resolve the difficulties that had arisen over the provision of secondary education. The impasse that resulted from the Cockerton judgment was terminated by a provision in the act enabling local education authorities "to supply or aid the supply of education other than elementary." Taking advantage of this, local education authorities provided many new secondary schools which were mainly of one type. For in regulations issued in 1904 Morant, disregarding the opportunities offered by the wide terms of the act, set a pattern for their development based on the academic tradition of grammar and public schools.

It was the voluntary-school issue that made the act one of the most fiercely contested measures of the 20th century, especially the decision to give voluntary schools the benefits of rate aid. Voluntary schools as well as the council (former board) schools were brought under the general control of the new local education authorities, and the maintenance of the voluntary schools became as much a rate charge as that of the council schools. The managers of voluntary schools were. however, required to provide the school building, keep it in good repair and make such alterations as might reasonably be required. They retained the power of appointing teachers, subject to the consent of the local authority, which could not be withheld except on educational grounds. The managing body was to consist of four foundation managers and two local authority representatives, and the religious teaching was to be in accordance with the trust deed of the school. As a result, the dual system agreed upon in 1870 was not only confirmed but strengthened, while at the same time unified administration under the new local education authorities of all elementary schools opened the way to a general advance in this important branch of education.

By putting the voluntary schools "on the rates," Balfour aroused the bitter antagonism of Nonconformists, many of whom refused to pay the sum levied for education and under the leadership of John Clifford joined in a campaign known as passive resistance. In Wales some local authorities, responding to the eloquence of young Lloyd George, who denounced the act as "a fresh endowment of the church." refused to carry out their new statutory duties. The government countered their opposition by passing an act which empowered the board of education, in the case of default by a local authority, to make payments direct to the managers of schools. Happily the discord gradually died down and with its passing the board of education and local education authorities began to establish a good working relationship. At the same time, the teaching profession, through its national union and other associations, was slowly acquiring solidarity and becoming a third force in shaping educational policy. In a retrospective survey of the first half of the century the ministry of education described it as "the story of a progressive partnership between

the Central Department, the local education authorities and the teachers." Summarizing the aims pursued, the ministry claimed: "To build a single. but not uniform, system out of many diverse elements; to widen educational opportunity and at the same time to raise standards; to knit the educational system more closely into the life of an increasingly democratic and industrialized community; these are among the main ideas which, despite two major wars, have moved legislators and administrators alike" *(Education* 1900–1950, Report of the Ministry of Education for the year 1950. H.M.S.O.. London, 1951).

The religious discord generated in 1902 gradually died down. With the advent of a Liberal government in 1906, bills were introduced by successive presidents of the board of education—Augustine Birrell, Reginald McKenna and Walter (later Lord) Runciman—to amend the provisions affecting religion in the 1902 act, but they all failed to reach the statute book. On the other hand, the Liberals, so active in promoting social legislation, passed measures which laid the foundation of two services which have achieved much for the well-being of children at school—school meals and medical inspection and treatment. A sense of partnership among all concerned in furthering education developed rapidly after David Lloyd George, when he became prime minister during World War I, invited H. A. L. Fisher, then vice-chancellor of Sheffield university, to become president of the board of education. The first occupant of the officeto have a predominantly academic background, Fisher imparted a new spirit into administrative affairs nith the assistance of Amherst Selby-Bigge, nho had become permanent secretary.

Fisher's Education act of 1918, re-enacted with surviving earlier legislation in consolidated form in the Education act of 1921, aimed at the establishment of "a national system of public education available for all persons capable of profiting thereby." Local authorities were called upon to prepare plans for the orderly and progressive development of education. For the first time authorities mere empowered to establish and assist nursery schools for children between two and five years of age. The school-leaving age was raised to 14, and power was given to local authorities to extend it to 15; the exemptions that made part-time attendance at school possible for older pupils—"half time" as it was called—were abolished. Provision was made for central schools and for classes for the older and more intelligent pupils in elementary schools. But perhaps the most notable clauses of this act were those designed to establish a system of compulsory continuation schools for young persons between 14 and 18 who were no longer in full-time attendance at school. The act also sought to give an added momentum to adult education. Unfortunately the financial restrictions imposed in the 1920s under the "Geddes axe" *(see* GEDDES. SIR ERIC CAMPBELL) played havoc with the Fisher act, and the principal gain derived from it was the raising of the leaving age and the abolition of half time. The project for compulsory continued education remained in abeyance until R. A. Butler revived it in the form of county colleges in the act of 1944, only to see it suffer a somewhat similar fate. The system of financing education, based on the Kempe report of 1914, which Fisher sponsored, survived the assault of the Geddes committee, which stigmatized it as a "money-spending device." Thereafter the main load of the education budget a-as shared between taxes and local rates, the contribution of the former consisting of block grants related to total expenditure and largely determined by an elaborate formula. Certain services were dealt uith exceptionally; *e.g.*, school meals were paid for almost entirely by taxation and parental contributions; but generally speaking the grant was related to the number of children in the area and the capacity of the area to pay for their education. The incidence of the burden as between exchequer and locality varied. but the general effect of the formula in the 1950s was that the exchequer bore two-thirds of the expenditure and the local education authority one-third. This grant system did much to strengthen the conception of a constructive partnership between central and local authorities. The Local Government act of 1958, however, replaced the system by a general grant to local authorities.

Fisher's principal achievement was not his ill-starred act but certain administrative reforms that proved of enduring value. An outstanding one was the establishment of the Burnham committee —so-called because Lord Burnham was its first chairman. This led to the provision of national scales of salary for teachers, established the principle of collective bargaining on a national level and encouraged the practice of consultation between local authorities and teachers. It also drew public attention to the grossly inadequate salaries that many teachers were then receiving and provided permanent negotiating machinery for the revision of salary scales. Other important reforms were the establishment of state scholarships to enable talented pupils to proceed to the university, the institution of approved examining bodies for the award of school certificates and the formation of a Secondary Schools Examination council. Fisher also set up an Adult Education committee under the dynamic chairmanship of William Temple.

Although the 1920s were a bleak period, marked by financial stringency and problems created by juvenile unemployment. 1926 brought promise of better days with the publication of the report of the board of education's consultative committee on the *Education of the Adolescent,* generally known as the Hadow report. It concentrated public attention on the reorganization of education, urging the division of education into two stages. primary and post-primary, with 11 as the age of transfer. Thus it set the key to future policy and stimulated the provision of some good senior elementary schools. prototypes of the later secondary modern schools. The financial crisis of 1931 checked development, but one of the Hadow recommendations, advocating the raising of the leaving age to 15, found expression in the abortive Education act of 1936. which provided for this but with exemption at 14 for "beneficial employment." This act also enabled local authorities to make grants of 50%–75% to voluntary senior schools. thus encouraging the managers of voluntary schools to implement the recommendations of the Hadow report regarding reorganization. Other developments in this period were a Physical Training act and the planning of an extensive modernization of technical education. But early in 1939 the prospect of educational advance was overshadowed by the gathering threat of war. Toward the end of 1938 the consultative committee published another important report, *Secondary Education With Special Reference to Grammar Schools and Teclznical High Schools* (the Spens report). With the Hadow report it later formed the basis of the reconstruction embodied in the Education act of 1944.

4. Wartime Measures.--On Sept. 1. 1939. the day on which the leaving age was to have been raised to 15 under the act of 1936, the evacuation of children began from about 40 centres under a voluntary plan Within 11 days 750.000 school children and many thousands below school age were transported to rural districts nhere arrangements had been made for their reception, billeting and schooling. No bombing then occurred, however, and by Christmas more than half the evacuees were back at home. During these first three months of war the public system of education was gravely disorganized in the populous areas to which so many evacuees had returned, for in these the schools could not be reopened until some kind of air-raid shelters had been provided. But gradually order was restored. schools were reopened and plans for further evacuation. if necessary. mere completed. When heavy bombing began in Sept. 1940 the educational services were well prepared.

Largely as a consequence of the stress of wartime conditions, a number of educational services were developed. Previously the welfare of youth had been largely the responsibility of voluntary organizations. which covered only a limited field. At the outbreak of war these organizations were in danger, through loss of leaders and the onset of new demands. of being overwhelmed. The government. therefore, in Nov. 1939 launched a plan, "the service of youth," calling into partnership the local education authorities and the voluntary youth organizations and offering grants-in-aid of their joint efforts to provide educational and social facilities for young persons. The youth service has since become an integral part of the public system of education. War also gave a new significance to the provision of school meals. Under the Provision of Meals act, 1906, meals had been provided as a public

service mainly as a means of feeding needy children, the number fed daily averaging about 160,000 in 1939. Lord Woolton, as wartime minister of food, realized the value to national health of ensuring that children everywhere had their daily ration of milk and a nutritious midday meal; the board of education with the support of the ministry of food was soon engaged in promoting a school meals service on a nationwide scale. The service developed rapidly, parents contributing to the cost according to their means; by 1950 the number of children taking school dinners had reached 2,750,000, and about 5,000.000 children were having daily milk. Annual reports of the chief medical officer afford abundant evidence of the beneficial effects of this service upon the health and physique of school children. After the war there was an increasing concern for the education and welfare of handicapped and socially maladjusted children, and this was attributable to some extent to the experience gained with such children during evacuation. Many hostels, improvised for their occupation during the war, were taken over by local authorities, and there was a considerable increase in the number of residential and also day special schools. Camp schools, much used in wartime, stimulated an interest in such schools and in camping generally. Provision for boarding-school education was made in the Education act, 1944.

The most important consequence for education of the wartime upheaval was the demand it created for educational reform. The board of education was prompt in preparing for this and early in 1941 circulated to interested bodies a comprehensive document, seeking opinion on various fundamental issues. They received in reply more than 100 detailed memoranda, many of which were published by the bodies which had prepared them. Public interest in educational reform quickened, and in July 1941 R. A. Butler became president of the board of education. With J. Chuter Ede, the parliamentary secretary, and Sir Maurice Holmes, the permanent secretary, he entered into a long series of discussions with interested parties. Two years later, after protracted negotiations, he submitted to parliament a White Paper, *Educational Reconstruction,* in which he outlined the principles which the government proposed to follow in the education bill under preparation. In Dec. 1943 he introduced his bill, and, generally welcomed, it passed into law with certain additions and amendments as the Education act, 1944.

5. The 1944 Act.—So bold and comprehensive a measure would not have had so easy a passage if it had not been the product of a coalition government. While it respected tradition and retained some of the essential features of the acts of 1870 and 1902, it was also revolutionary, involving a thorough recasting of the educational system. The board of education with a president empowered only to superintend mas replaced by a minister who was to direct and control the local education authorities. Subject to parliament, he was to have an almost absolute authority, and in support of his controlling function the act had 24 provisions enabling him to make regulations, 39 for directions by order and 38 for informal directions. He could also overrule local authorities. governors and managers if they appeared to him to be acting unreasonably. Vested with such authority a minister could do much to ensure a more even standard of educational opportunity throughout England and Wales, and he could determine priorities and take the lead in planning. The act provided two formidable planning devices; every local education authority was required to submit for the minister's approval a development plan for primary and secondary education and a plan for further education in its area. Two central advisory councils were constituted by the act, one for England and another for Wales. Unlike the former consultative committee, they had power, in addition to dealing with problems set by the minister, to tender advice on their own initiative.

The government decided to abolish those authorities, created by the act of 1902, which were responsible only for elementary education. The larger of these authorities, many of which had good records of administration, put up a strong case for survival; but their disappearance was essential to the government's policy of treating education as a continuous process and destroying the old division of education into higher and elementary. Some authorities were allowed to become excepted districts, holding special executive status within the system of county administration. As a result of the extinction of these authorities for elementary education only, the total number of education authorities in England and Wales was reduced from 315 to 146, namely the London County council, 83 county boroughs and 62 county councils. To enable the county education committees to keep in touch with local circumstances, provision was made for a considerable delegation to divisional executives, who with the various bodies of school governors and managers do much to ensure local interest and initiative.

The complexity of the educational system in England and Wales is partly because of the pioneer work done in the past by voluntary bodies and a desire to retain the voluntary element in the state system. The act of 1944 continued the religious compromise expressed in the acts of 1870 and 1902 but elaborated and modified it after much consultation with the parties concerned. The act required that in every state-aided primary and secondary school the day should "begin with collective worship on the part of all pupils" and that religious instruction should be given in every such school. As in the earlier legislation there was, ho ever, a conscience clause and another to ensure that no teacher should suffer because of his religious convictions. The old timetable clause was repealed, with the result that religious teaching had no longer to be confined to the beginning and end of a session. Religious teaching was now to be open to inspection by H.M. inspectors.

The dual system was fully retained by the act of 1944, but some of the provisions were so elaborate as to make it difficult for anyone unfamiliar with their administration to understand them. One of the principal considerations was to ensure as far as possible that voluntary schools would be not less able than county schools (the new name for council schools) to comply with the building and other regulations prescribed by the minister. Voluntary managers were given the choice of two alternatives: their school could be either aided or controlled. An aided school is officially described as "a voluntary school in which the managers appoint the teachers, have responsibility for religious instruction, and meet half the cost of structural improvement and external repairs." A controlled school is "a voluntary school in which the local education authority is responsible wholly for the cost of structural improvements and maintenance, and, subject to the reservation of certain rights to the managers or governors, for the appointment of teachers and for religious instruction." In a controlled school the authority's representatives are in a majority on the governing body. There was yet another kind of voluntary school provided for in the act, namely a "special-agreement school"; this is a school "in receipt of financial assistance in respect of its construction, structural alterations or improvements from the local education authority under the Education act, 1936."

The essential difference between these kinds of voluntary schools is that in aided and special-agreement schools the religious teaching can be denominational every day, while in controlled schools denominational teaching can be given only twice a week, the syllabus otherwise conforming to that prescribed for county schools in the area. Such syllabuses are determined by a conference in each area of theologians, teachers and administrators. Although there is no specific reference to Christianity in the act, the general effect of the expanded compromise was to strengthen the Christian foundations of education in England and Wales.

Two fundamental reforms in the act were the abolition of the elementary school and the requirement of secondary education for all. The former distinction between elementary and higher education mas replaced by a new classification of "three progressive stages to be known as primary education, secondary education, and further education." Thus the primary stage, compulsory from age 5, covers the period from 2 years old to 11–12; the secondary stage, compulsory to 15, covers the period from 11–12 to 18–19; while further education was officially described as "the post-secondary stage of education, comprising all vocational and non-vocational provision made for young people who have left

school, and for adults." Further education thus embraces not only the vast range of technical, commercial and art education and the wide field of adult education of a tutorial kind but also, in the words of the act, facilities for "leisure-time occupation, in such organized cultural and training activities as are suited to their requirements. for any persons over compulsory school age who are able and willing to profit by the facilities provided for that purpose."

6. Developments After World War 11.—It was widely assumed in 1944 that it would take at least a generation to give full effect to the act, but progress was slower than then expected because of postwar economic conditions. It was soon demonstrated, however, that the act itself stood up well to the test of day-by-day administration, and later amending legislation was of a minor character involving no fundamental change. In spite of much frustration and delay: the postwar years were not unproductive; more new schools were erected than at any earlier period, and there was much development and thought in all the three stages of education. Little was done to associate the public schools with the general educational system, the problem on which the Fleming committee reported in 1944, while the part of the act affecting private schools was not brought into operation until 1957. On the other hand. and more important. the organization outlined in the report of the McNair committee *(Report on the Supply, Recruitment and Training of Teachers and Youth Leaders,* 1944) was set up, and although it was a period of full employment the supply of teachers was fairly well maintained although there were serious shortages in some areas and in certain subjects, notably science and mathematics. Universities and training colleges then became closely associated through the new institutes of education and the area training organizations. a national advisory council supervising training and supply. The abnormally high birth rate of the war and immediate postwar years created special difficulties of accommodation and staffing, and too often classes were large and classrooms overfull. The vast amount of rehousing and the considerable movements of population greatly intensified the demand for new schools. with the result that it was necessary to give priority in school building to centres of new population. In 1953 the select committee on estimates drew attention to the large amount of inadequate and unsuitable school accommodation still existing.

During postwar years much attention was given to educational principles and practice. At the primary stage this was focused upon method and, while belief in the value of activity, interest and play did not diminish, there was greater stress on self-discipline and on the importance of the "three R's," especially reading ability. At the secondary stage the question of how best to provide alternative types of education was a major issue not only in educational circles but also in party politics. The Norwood committee (1943) urged a tripartite system of grammar, modern and technical schools but some local authorities. including London, favoured comprehensive schools and, by 1958, 50 schools of this type had been established. Much thought was given to the curriculum and to methods of determining the ability and aptitude of entrants to the secondary stage, whereas in further education attention was directed to the best way of providing for advanced study and research in the technological field. In 1945 a committee under the chairmanship of Lord Percy reported on higher technological education, and subsequently there was prolonged debate as to whether to develop the higher studies in some of the existing technical colleges, to look to the universities to supply leading technologists or to create one or more new technical institutions of university rank. Early in 1953 the government announced its decision to promote the expansion of the Imperial College of Science and Technology within the University of London, and between 1957 and 1962 it was planned to about double the number of its students, bringing the total to approximately 3,000. The ministry of education also encouraged advanced study and research in some of the leading technical colleges and in 1956 issued a White Paper on *Technical Education,* which provided the basis for a policy of expansion. Another notable postwar development was the substantial increase in the number of young workers released by industrial and commercial firms for part-time continued education, and a welcome feature was the growing interest of industry in scientific and technological education.

7. Scotland. — For centuries the Scots have been zealous for education and are justly proud of their long tradition of free public schools. In the *First Book of Discipline* (1560), largely attributed to John Knox, emphasis is laid on the necessity of ensuring "the virtuous education and godly upbringing of the youth of this realm," an ideal still dominant in Scottish thought and practice. Several attempts were made in the 17th century to provide a system of schools, and ultimately in 1696 an act for "Settling of Schools" ordained that there should be a school and schoolmaster in every parish. Subsequently parish schools were generally provided, and, although elementary in character, many of them supplied a secondary education for the abler pupils, sending them directly to the university. There has never been in Scotland such a distinct separation of elementary and secondary education as in England. Nor has Scotland been seriously affected by religious differences about the provision of schools; kirk and state were able to work together for the advancement of education, much as did the theocracies of the New England states in America in the 17th centyry. But the parish school system had its shortcomings, the most serious being its failure to meet the needs of the larger towns. They relied chiefly on burgh schools and academies, both mainly secondary, and trusted largely to voluntary effort to provide elementary education. As in England this proved inadequate, and when population increased thousands of children were without schooling. It was also found that where parishes had a very large area or a scattered population, as in the Highlands and the islands, the parish school system could prove inadequate.

Although England and Scotland have shared one parliament since 1707, Scotland has fully retained its separate educational system and traditions: and the secretary of state for Scotland is responsible for the central administration of Scottish education. In the long series of separate enactments: one of the most important was the Education act of 1872, which set up elective school boards for the administration of parish and burgh schools and made education compulsory between ages 5 and 13. (The school-leaving age was raised to 14 in 1901 and to 15 in 1947.) The school boards had the task of filling the serious gaps in school provision in the large towns; when the act of 1872 was passed 30,000 additional school places were needed in Glasgow and more than 4,000 in Edinburgh. Religious instruction was given at the discretion of each school board subject to a conscience clause. With two or three exceptions the boards made the Bible and the Shorter Catechism the basis of instruction.

The Education (Scotland) act of 1918 was another important landmark. It provided that primary education should normally end at 12, made mandatory free intermediate and secondary schooling for all children able to profit by it and replaced the 947 school boards by 33 county ad *hoc* education authorities and 5 similar authorities for Edinburgh, Glasgow, Dundee, Aberdeen and Leith. It also provided for the transference to these authorities of Roman Catholic, Episcopalian and other voluntary schools but without diminishing their denominational character. Thus Scotland, unlike England, has no dual system. Other notable provisions in that act were the establishment of an advisory council and the institution of minimum scales of salary for teachers. In 1920 a national committee for the training of teachers was constituted, charged with the supervision of training centres at St Andrews, Aberdeen, Edinburgh and Glasgow; it was also given responsibility for the former voluntary training colleges. In 1929 the ud *hoc* education authorities were abolished by the Local Government (Scotland) act, and the local government of education was entrusted to the county councils and the councils of Edinburgh, Glasgow, Dundee and Aberdeen. Since 1939 post-primary schools have been designated secondary and fall into two main categories: junior, for pupils intending to leave at 15, and senior for those staying to 17 or 18. The Education (Scotland) act of 194.5 did not involve fundamental reconstruction like its English counterpart of 1944, for Scottish education was already organized in progressive stages, nor was it ronironted with the problems of a

dual system. More important from the standpoint of reconstruction were three valuable reports of the Scottish Advisory Council on Education—*Primary* Education (1946), Technical Education (1946) and Secondary Education (1947). The last emphatically rejected "the tripartite organization" as "unsuitable for Scotland." (See also SCOTLAND.) (W. O. L. S.)

8. Commonwealth of Nations.—Religious schools were founded by missionaries soon after the first settlements had been established, but large-scale immigration caused a demand that soon exceeded the financial strength of the missions. This led to support from public funds, and interdenominational quarrels prepared the way for national systems which were to be free, compulsory and secular. Arnbitious colonists everywhere desired for their children educational facilities at least as good as those available in the home countries and were eager to support colleges and universities. which thus began very early. Social equality facilitated the establishment of single-stream, nonselective secondary schools, and the demand for geographical equality of opportunity, especially between town and country, together with the financial weakness of rural local authorities, helped the growth of strong central authorities at the provincial level. Federation of separate colonies into dominions left control to the provinces or states, though there was little difference between the separate systems of each province. The models copied in each case were those of the home countries, and adaptation to local geographical and social conditions was slow. For an account of the development of education in the colonies see COMMONWEALTH OF NATIONS. In addition to the following descriptions of public education in Canada, Australia and New Zealand, see also separate articles on commonwealth members such as CEYLON; PAKISTAN.

Canada.—French Catholic education started with a Jesuit school in Quebec (1635) and by 1760 there mere more than 30 elementary schools. 1 college and 2 seminaries, as well as more than 15 convent schools for girls, chiefly Ursuline. Probably about one-third of the French inhabitants were literate. In the English areas, inadequate facilities were provided by voluntary and missionary agencies. The Quebec act (1774) did not encourage French-speaking Catholic schools but allowed them to operate. From 1763 to about 1840 in eastern Canada and until 1800 in the west, schools for the people were run mainly by the church or the parish: they were supported by low fees and small grants from public sources. Secondary schools, either grammar schools or academies, depended upon fees. Later, strong central authorities promoted free schools largely dependent upon locnl taxation. Provincial control was enhanced in the interest of equalizing opportunity and from this system evolved the ten independent provincial systems of modern Canada. The British North America act of 1867 gave each province full authority over education, maintaining only the rights of denominational schools and leaving to the federal government the provision of education in extraprovincial territories. Universal free schooling was available in the east by 1870 and in the west by about 1910. In 1860 enrollment in day schools was 600.000: in 1960, 2,700.000. In 1860 an average of three years was spent in school; in 1960, 10 or 11 years.

Education for Indians was promoted by missionaries; but nomad life was a handicap although after 1830 the government gave a little financial help. The federal government accepted responsibility in 1868 and the code of 1894 made school attendance compulsory. For subsequent developments see CANADA: Education and *Education* sections of separate articles on the provinces.

Australia.—The chaplain of New South Wales started the first school in 1793 and by 1797 there were six Church of England schools. After 1816 Gov. Lachlan Macquarie tried to establish schools in all settlements. allocating part of the customs duties for their help, thereby accepting the principle of public support. The 1825 act gave full charge of education and 120,000 a year to the established church. In 1829 there were 36 schools and 1,265 pupils. Other denominations became active and religious rivalries hampered progress. Sir Richard Bourke (1833) called for a national secular system, similar to that proposed for Ireland. He was opposed by all religious groups and the resulting act of '848 was a compromise. establishing a national and a denominational board of education. The great 1866 act, which served as a model to similar acts in the other colonies of Australia, anticipated the English act of 1870. It abolished the dual system and established free, secular and compulsory schools in all localities where a minimum of 25 pupils could attend. England was copied as regards curriculum, teaching methods, teacher training and inspection. From Scotland came the notion of education for all and free secondary education for the children of those who could not pay the fees of private schools. The developments in other colonies followed a very similar path. The nomadic habits of the aborigines made it difficult for missionaries to establish schools. The few which exist are aided by the commonwealth, which since 1945 has also provided special schools intended to adapt the aboriginals to settled civilization.

New Zealand.—The first Anglican mission school (for Maoris) uas started in 1816. Wesleyans and Catholics soon followed, but the Church of England was never as strong as in Australia. The Grey ordinance (1847) instructed provincial authorities to pay grants to Anglicans, Catholics and Wesleyans, but some authorities refused to obey. The 1877 Education act established a secular, free, compulsory system of primary education organized under 12 (later 9) regional education boards. The secondary schools were left as independent institutions, each governed by a local board, with one-quarter of the education endowment allotted to their use. All but two were nationalized in 1920. In 1877 a central education department was set up, intended at first to distribute funds. It quickly grew in power so that it came to control education as completely as in any fully centralized system. At first, English (partly Scottish) models were copied in curriculums and methods When George Hogben took control of the education department in 1899 he offered subsidies to secondary schools that taught science, agriculture and manual work. Partial failure led to the establishment of district high schools, intended to be agricultural, later (especially after 1920) of flourishing technical high schools.

Maori education was promoted by the missions, by 1847 receiving generous grants and after 1877 strongly supported by the department.

India.—An account of the evolution of education in India is presented under Education in the Eastern World: India, below. (J. A. LA.)

C. FRANCE

In the middles ages in France, as elsewhere in Europe, the universities mere the first educational institutions to become organized into faculties teaching in Latin and subordinating all other disciplines to their final end, theology. Colleges were then founded to prepare young men for the university, and became the basis of secondary education. The Jesuit colleges which were created at the time of the Renaissance reconciled the teaching of the new humanism of the time with the established doctrines of the Roman Catholic Church, and flourished with special brilliance.

Despite the changes brought about by the Renaissance, the attention given to the sciences in the 17th and 18th centuries and the efforts of philanthropists such as St. Jean Baptiste de La Salle to develop a form of primary education, it was not until the advent of the French Revolution that the universal right to education was proclaimed.

The constitution of 1791 decreed "that public education shall be organized. common to every citizen and free in respect of those parts of education that are indispensable to all men." The Convention created the *écoles centrales* uhich brought the primacy of Latin to an abrupt end. introduced the sciences that had been looked at askance by the colleges before the Revolution, and based education on the French language.

Unfortunately the Revolution hardly had the opportunity to realize these principles, and Napoleon restored the oid system. with his only concession a provision for the study of mathematics. He did, however, reorganize the structure of secondary and higher education in a unified state system, uith secondary schools maintained by the *communes, lycées,* state establishments and universities Within this structure the rector of a university headed a teaching body, recruited by the state and supervised by an in-

spectorate. ranging through various grades up to the university council. Grades of proficiency in studies from simple certificates, to the *baccalaure'at, licence,* and doctorate were awarded on the result of examinations, and these tests were made a necessary condition of entry into such professions as medicine, law and teaching. This structure, despite many modifications, has survived until modern times.

1. Development of State Education. — French educational history in the 19th century is essentially the story of the struggle for the freedom of education. of the introduction at the secondary level of the scientific branches of learning, and, under the third republic, of the establishment of primary education, at once secular and compulsory, between the ages of 6 and 12. There was a sort of middle education between the ages of 13 and 16, and finally a professional and technical education.

Under the Restoration education fell inevitably under the control of the church, but under the Liberal monarchy François Guizot in 1833 passed a law which laid the foundations of modern primary instruction, obliging the *communes* to maintain schools and pay the teachers. The higher primary schools which he founded were unfortunately suppressed by the *loi Falloux;* their restoration constituted one of the great positive services rendered by the third republic to the cause of popular education. The *loi Falloux* of 1850, passed by the second republic under the influence of the prince president, restored the liberty of teaching, which meant in effect free scope for priestly schools *(see* FALLOUX, FRÉDÉRIC ALFRED PIERRE, COMTE DE). This law also made provision for separate communal schools for girls, for adult classes and for the technical instruction of apprentices. In 1854 France was divided for purposes of educational administration into 16 academies, each administered by a rector with an academy inspector under him for each department.

The ministry of Victor Duruy (1865–69), corresponding to the period of the Liberal empire, made primary schools for girls obligatory in *communes* of more than 500 inhabitants. Duruy also provided for the introduction of free instruction at the option of the *commune.*

The task of educational reform imposed itself upon the republic by a twofold necessity. The wars of 1866 and 1870 were victories for the Prussian schoolmaster, and aroused western Europe to the importance of popular education. For France the reform of popular education was an essential part of the work of national restoration. For the republic, too, menaced by older and hostile traditions, the creation of a national system of education inspired by its own spirit was an essential condition of the security of its government and the social ideals of which that government was the expression. Hence the energy with which the republican state addressed itself to the organization of primary instruction, "obligatory, gratuitous, secular."

By the law of June 1, 1878, there was imposed upon the *communes* the obligation of acquiring their school buildings; and as a grant in aid a sum of £2,400.000 was set aside for this purpose by the state. In 1879 a law was passed compelling every department to maintain training colleges for male and female teachers. The two higher normal schools of Fontenay and St. Cloud were founded to supply the training colleges with professors. During this period, among other certificates were established the *certificat d'aptitude pddagogique,* which qualified probationer-teachers *(stagiares)* for appointment as teachers in full standing (*titu-Eaires).* and the *certificat d'aptitude* for primary inspectors and heads of normal schools. The law of June 16, 1881, rendered obligatory for all teachers. whether public or private, the *brevet de capacité.* It was found, however, impracticable to carry this law into immediate effect.

The lams making primary education free, compulsory and secular are indissolubly associated with the name of Jules Ferry. The law of June 16, 1881, abolished fees in all primary schools and training colleges, the law of 1882 established compulsory attendance. and finally the lam of Oct. 30. 1886, enacted that none but lay persons should teach in the public schools and abolished in those schools all distinctively religious teaching. In the boys' schools, members of religious communities were to be displaced within five years, but in girls' schools the *religieuses* might remain till death or resignation. The law of Aug. 9, 1936, made education compulsory to the age of 14. The religious dissensions which broke out over the problem of the schools. and which were at one time keen, gradually died down. The government schools did, in fact, accept pupils and teachers of any philosophical or religious persuasion. and these worked together in a common humanism that respected every form of conviction.

2. Secondary Education. — In proceeding to sketch the French system of higher primary and secondary schools, it may be observed that European systems of higher education were generally framed upon the view that secondary education is a training distinct from the preparatory stage to the university, with aims and ideals of general culture which differentiate it radically and at the very outset from education of the elementary type. Down to the reform of 1902, explained below, the French system could be regarded both as a typical and extreme example of the European theory.

Higher Primary Schools. — The aim of the *e'coles primaires supérieures* was to fill the void which must otherwise exist for those needing a higher education than the primary school could give. Throughout the organization of primary education the French kept steadily in view the danger of creating an intellectual proletariat. *"Nous poursuivons la culture générale du caractère et de l'esprit, mais nous cherchons en même temps à orienter l'enfant vers la vie pratique,"* says an official report. The aim of the higher primary school was to continue education in this spirit up to the age of 16 so as to prepare the scholar to take an honourable place in the higher ranks of skilled industry or in the middle ranks of the professions. In 1942 the *e'coles primaires supérieures* were replaced by the *collèges modernes* ("modern schools'? .

Lyckes, Classical Schools and Modern Schools. — French secondary education for boys is given in the *lycées,* which are secondary schools maintained and controlled by the state. in the so-called classical schools maintained by the municipalities and in the *collèges modernes* mentioned above.

Secondary Education for Girls. — The foundation of secondary schools for girls was in its way one of the most notable achievements of the third republic. It was inaugurated by the law of Dec. 22, 1890, called after its author the *loi Camille Sée.* At first the curriculums were different from those of the boys'. and the course of study was only five years. There were no ancient languages, and mathematics was not carried to so high a level as in the boys' *lycées.* After 1932 there were three types of establishments. the same as for boys *(see* above).

Private Secondary Schools. — Secondary education in private schools. also shaken by the laws against religious orders. nevertheless continued to develop, and at one time the number of pupils in them was hardly smaller than the number of those in government secondary schools. although by the end of the 1950s the proportion of pupils in private schools was decreasing as the child population increased.

Secondary School Curriculum. — In 1902 reforms were made in the curriculum. The decree of May 31, 1902, provided for a full course of secondary studies of seven years' duration, divided into two cycles of four and three years. In the first cycle the scholar had two options. In section 1 Latin was obligatory and Greek optional from the beginning of the third year (*classe iv*). In section *2* there was no Latin. At the end of the first cycle the state granted a *certificat d'études secondaires du premier degre'.* In the second cycle one of four courses might be taken: section 1 with Latin and Greek continued the old classical education; section 2 consisted of Latin and modern languages; section 3 of Latin and science; and section 4 of modern languages and science. The *baccalauréat,* or secondary school-leaving examination *(see* also EXAMINATIONS), conducted by the university, was adapted to all the courses.

Technical Schools. — A certain number of technical schools, formerly under the ministry of commerce, were brought under jurisdiction of the ministry of public instruction. They included six national professional schools, six *e'coles nationales d'arts et métiers,* higher schools of commerce and *écoles pratiques de com-*

merce et d'industrie, as well as commercial and technical courses. There was also a network of institutions and schools run by the ministry of agriculture, from the national agricultural institute of Paris, and the national schools of agriculture at Montpellier and Rennes, down to the *fermes-écoles* and the *e'coles pratiques d'agriculture.* In 1919 the *loi Astier* unified these diverse institutions and created a special tax. the *taxe d'apprentissage,* to provide for technical training. Since World War II. the *centres d'apprentissage* received pupils from the primary schools.

3. Reforms After World War 11.—After World War II French educationists mere much occupied in rebuilding schools that had been destroyed or damaged, and in providing additional accommodation for the extra numbers resulting from the wartime increase in the birth rate. At the same time there was a strong demand for educational reform. and this led the ministry of education to ask a commission, presided over first by P. Langevin and later by H. Wallon, to make a comprehensive survey of the educational system. The commission recommended a radical reconstruction of school organization and of university education, and advised a substantial reform of teaching methods. It was estimated that the proposals if fully implemented would increase the national education budget almost 50%. An important feature of the proposals was the stress laid on the differing needs of individual pupils and on the importance of having regard to aptitude and ability. There was a new emphasis on technical aspects of education. For the secondary stage tao cycles were proposed The first (ages 11–15) was designed to provide a course common to all pupils, with special subjects suited to individual needs: it was also recommended that this stage should be designed to disclose aptitudes and abilities. The second cycle (ages 15–18) was to be of a more specialized character with provision for part-time education. Experiments were carried out along these lines so as to facilitate the formulation of legislation. There also was a marked change in teaching method, with more emphasis on group and individual initiative. The proposals of the Langevin commission were not applied except in the case of the *classes nouvelles,* where they affected 200 *établissements du second degre'* in the first four years. But these proposals were followed by other projects largely inspired by them.

On Jan. 6, 1959, the government under Charles de Gaulle passed a decree raising the school-leaving age from 14 to 16 and establishing for pupils entering an *établissement du second degré* a period of observation lasting two years (from 11 to 13), to make it easier to direct them to the branch of study for which they showed aptitude.

In addition measures were taken after 1950 obliging future teachers of the *second degre',* after passing the *licence,* to spend a year in professional training on the completion of which a *certificat d'aptitude à l'enseignement* was granted; *e'coles normales d'apprentissage* were created to train teachers for the *centres d'apprentissage,* and the *école normale supe'rieur de l'enseignement teclzniqme* was developed for teachers in technical colleges. Two new *baccalauréats* covering technical and industrial subjects and the economic and humane sciences point to the value placed upon technical education. Teachers must pass the *baccalauréat* in an *école normale* and follow a course of professional training. At last, by the law of Dec. 31, 1959, it was made possible for private establishments to receive total or partial aid from the state in return for some degree of state control.

4. French Community.— The demand for education in French overseas territories had become no less keen than in the mother country in the second half of the 20th century. By the early 1960s. the general tendency was to develop in the territories of the French Community a type of education close to the French system, at the request of the inhabitants themselves seeking similar educational opportunities for their children. Great efforts were made to meet the costs of such a provision, to adapt education to local conditions, and to organize higher education.

See also FRANCE. (Ro. G.)

D. GERMANY

1. Early Provision.— Martin Luther's famous letter to the German municipalities in 1524 urged upon them the duty of providing schools and upon parents the duty of sending their children to school. An attempt to carry this into effect was made by the electoral government of Saxony, which in 1528 issued an ordinance. drawn up by Philipp Melanchthon, providing for the establishment in every town and village of Latin schools, for the Protestant reformers were solidly in favour of classical education. The ordinance issued by the elector of Wiirttemberg in 1559 represented the first systematic attempt to provide both elementary and higher education directing the establishment of elementary schools throughout the country and of Latin schools (or *Particularschulen*) in every considerable centre of population. These promising beginnings were brought to nothing, however, in the troubled times of the Thirty Years' War. and by the desolation and national decadence that followed it. The permanent and positive value of Luther's pronouncement of 1524 lies not so much in its direct effects as in the associations which it established for Protestant Germany between the national religion and the educational duties of the individual and the state. This no doubt helped create that healthy public opinion which rendered the principle of compulsory school attendance acceptable in Prussia at a much earlier date than elsewhere, except in Scotland where a similar religious influence was supplied by John Knox. State intervention in education was almost coincident aith the rise of the Prussian state In 1717 Frederick William I ordered all children to attend school where schools existed This mas followed in 1736 by edicts for the establishment of schools in certain provinces and by a royal grant of 50 000 thalers for that purpose in the following year. In 1763 the *Landschulreglement* of Frederick the Great laid down the brosd lines upon which the Prussian state thereafter proceeded. asserting the principle of compulsory school attendance.

2. Wilhelm von **Humboldt.**—However, the schools established a tradition of curriculum that ignored the changing needs of life and fields of knowledge and no effective reorganization of the educational system was carried out until after the disaster of Jena (1806). which brought about the virtual collapse of Prussia and at the same time introduced a period of reform in the government as a whole One of the first acts of the minister Baron von Stein in 1807 was to abolish the semiecclesiastical *Oberschulkollegium* and to place education under the ministry of the interior, with Wilhelm von Humboldt (*q v.*) at the head of a special section. Humboldt's policy in secondary education mas a compromise between the narrow philological pedantry of the old Latin schools and the large demands of the new humanism of the period The measure introduced by Humboldt in 1810 for the state examination and certification of teachers checked the then common practice of permitting unqualified theological students to teach in the schools. and at once raised the teaching profession to a high level of dignity and efficiency which of itself sufficed to place Prussia in the forefront of educational progress. It was due also to the initiative of Humboldt that the methods of J. H. Pestalozzi were introduced into the teachers' seminaries, through them to vitalize the elementary schools. To this period also belong the revival, in 1812. of the *Abiturientenexamen* ("the school-leaving examination"). which had fallen into abeyance, and the institution about the same time of the local authorities called *Schulvorstände* for the country and *Schuldeputationen* for the towns

3. Developments After 1815.—Though the period that succeeded the peace of 1815 was one of political reaction, the nork of administrative organization was carried on by defining the duties of the *Provinzial-Schulkollegium* and the *Regierung.* In 1834. an important step nas taken in regard to secondary education by making it necessary for candidates for the learned professions as well as for the civil service and for university studies. to pass the leaving examination of the *Gymnasiums* Thus through the leaving examination the state held the key to the liberal careers and was thereby able to impose its own standards upon all secondary schools.

In connection with the *Kulturkampf,* or struggle between the state and the Roman Catholic Church, the *Schulaufsichtsgesetz* of 1872 reasserted the absolute right of the state alone to the supervision of the schools. Nevertheless the Prussian system remained

both for Catholics and Protestants essentially denominational. All schools, whether elementary or secondary, were Evangelical, Catholic, Jewish or mixed. In the elementary sphere, in particular, recourse was had to the mixed school only where the creeds were so intermingled that a confessional school was impracticable. In all cases the teachers were appointed with reference to religious faith; religious instruction was given in school hours and was inspected by the clergy.

The official classification or grading according to the type of curriculum of secondary schools in Prussia (and throughout Germany) was very precise. The following were the officially recognized types of the period: (A) Classical schools: (1) *Gymnasium,* with nine years' course; (2) *Progymnasium,* with six years' course. (B) Modern schools: (1) with Latin (semiclassical)—(a) *Realgymnasium* (nine years' course), (b) *Realprogymnasium* (six years' course); (2) without Latin (nonclassical)—(a) *Oberrealschule* (nine years' course), (b) *Realschule* (six years' course).

The differentiation between the types was the result of a natural educational development corresponding with the economic changes which transformed Prussia from an agricultural to an industrial state. The classical schools long retained their social prestige and a definite educational advantage in that their pupils only were admissible to the universities. From the foundation of the empire (1871) the history of secondary education was largely concerned with a struggle for a wider recognition of the work of the newer schools. The movement received a considerable impetus by the action of the emperor, who summoned a school conference in 1890 at which he set the keynote with the statement, "It is our duty to educate young men to become young Germans and not young Greeks or Romans." New schedules were framed in which the hours devoted to Latin were considerably reduced, and no pupil could obtain a leaving certificate without a satisfactory mark in the mother tongue. The results satisfied neither party, and the reform lasted only a single school generation. In 1900, after a second conference, equality of privileges was granted to three types of schools, subject to certain reservations—the theological faculties continued to admit only students from classical schools and the pupils of the *Oberrealschule* were excluded by their lack of Latin from the medical faculties. but insofar as Latin was required for other studies, such as law or history, it could be acquired at the university itself.

Although the official curriculums were binding on the schools, their rigidity was not absolute; experiments were possible, but they were carefully supervised. It was thus that the modifications of the classical school curriculum known as the Frankfurter system came into being, after a similar experiment had been tried at Altona. The chief innovation—and there the two schemes agreed—was the postponement of the beginning of Latin to *Untertertia* (lower fourth form) and the introduction of French as the first foreign language. This enabled parents to defer their decision as to the form of their son's education until he was about 12 years of age.

A further instance of the willingness of the authorities to sanction reasonable changes was seen in the permission accorded to certain schools to vary the course of study in the top classes, as a preparation for the freedom of choice of the university.

4. Girls' Schools.—In Prussia, as elsewhere, the higher education of girls lagged far behind that of boys and received little attention from the state or municipality, except insofar as the services of women teachers were needed in the elementary schools. Thus it came about that in Prussia secondary schools for girls were dealt with administratively as part of the elementary school system. After the establishment of the empire a conference of directors and teachers of these schools was held at Weimar and put forth a reasoned plea for better organization and improved status. The advocates of reform, however, were not at unity in their aims; some wished to lay stress on ethical, literary and aesthetic training, others stressed intellectual development and claimed an equal share in all the culture of the age. But even in the schools the women fought an unequal battle, for all the heads and a large part of the staff were men, usually academically trained. The women continually demanded a larger share of the work, and this was secured by the establishment of a new higher examination for women teachers. University study though not prescribed was in fact essential, and yet women had not the right of access to the university in Germany. They were allowed to take the *Abiturientenexamen,* for which private institutions prepared them, but their admission to the university rested with the professor.

Economic necessity and the growing strength of the women's movement at last brought the desired change. New schemes were issued in 1908, organizing the girls' schools in two degrees: the *Lyceum,* a ten-class institution for girls from 6 to 16; and an *Oberlyceum* of three classes of varying types, one of which might be a training department for teachers, another for home life. But apart from these normal courses, opportunity was given to girls to follow from their 12th or 13th year courses similar to those of the higher schools for boys. The form generally preferred was that of the *Realgymnasium.* At the same time a ministerial decree opened the German universities to women on the same terms as men.

5. The Weimar Republic.—In no sphere of public activity did the establishment of the German republic after World War I cause more far-reaching changes than in that of education. The ultimate aims which these innovations envisaged were clearly stated in the Weimar constitution, and led to a single system of national education. It was recognized that this goal could be reached only by gradual steps, and the responsibility for educational administration was left with the federated states. The state ministries, however, had to observe the principles enunciated in the constitution and had to conform to the federal laws.

The elementary school, which under the old regime was a class school, became a national institution, sewing all and used by all. It had no rivals, and private elementary schools were forbidden. The *Einheitsschule* ("common school"), which the popular parties had demanded before World War I, became an accomplished fact as far as the first four years of the course were concerned. As a concession, reluctantly granted, specially gifted children were allowed to complete the course in three years.

When the *Grundschule* ("basic school") had been passed the child might be transferred to a secondary school, organized to lead on to the university, or he might go to the *Mittelschule,* if he wished to enter commerce or industry about the age of 16, or he might remain at the elementary school, if he had to enter on employment at the earliest possible age.

After 1918 the interests of poor but gifted boys were well served. Two new types of schools catered to their particular needs. There was first the *deutsche Oberschule,* in which, in harmony with the sentiment of the Weimar constitution, the emphasis was laid on the training of a national spirit, and German history, literature and art were all studied from this national standpoint, though foreign languages were not excluded. These schools replaced, to a large extent, the old institutions which prepared former elementary school pupils for admission to the training colleges for teachers of primary schools.

The other new type was the *Aufbauschule* ("built-on" or supplementary school). Its place in the educational scheme resembled the high school of the United States in that it received only pupils who had completed the elementary school course.

6. The Third *Reich.*—Under Adolf Hitler the formal organization of the elementary and secondary systems was not changed radically, but the content of education underwent a vast transformation to make it conform with National Socialist ideology. Youth labour camps were established in which the educational keynote was nationalistic and utilitarian. The personnel of the schools was transformed, studies were wrested from their proper position and twisted to fit fascist theories and principles, and indoctrination permeated the whole educational system; wherever German influence extended before and during World War II, anti-Semitism followed, resulting in the expulsion of Jewish teachers. (*See* also NATIONAL SOCIALISM; FASCISM; ANTI-SEMITISM.) The traditional nine-year course was reduced to eight, and potential Nazi leaders were sent to *Adolf-Hitlerschulen,* administered by the party. During this period the number of *Gymnasiums* was

reduced. the Nazis favouring the deutsche *Oberschule*, with its emphasis on German tradition. The system introduced during the Weimar republic which placed teacher preparation on a university basis was discarded and replaced by one which was to recruit candidates at the age of 14 from a new type of higher primary school (*Hauptschule*) and train them in small institutions for five years. This represented a return to a system against which German teachers had been protesting for a century.

(A. E. Tw.; Jn. E. W.)

7. Changes After World War 11.—For several years after World War II education was conducted in each zone under the supervision of the British, Americans, French and Soviets, respectively, and under the Allied control council. In 1948 the council suggested the general principles for the reorganization of the educational systems, In May 1949 the Federal Republic of Germany (West Germany), consisting of seven Lander and three city-states. was established. and in Oct. 1949, the German Democratic Republic (East Germany) was created. The basic law of the Federal Republic (May 23. 1949) granted autonomy in educational matters, and the Lander and city-states passed their own laws. In 1949 a standing conference of ministers of education was established to discuss problems common to all; it is advised by a federal educational council. created in 1953.

Since each member of the Federal Republic administers its own system, education in Germany is marked by uniformity and diversity. The uniformity is due to provisions in the basic law regarding the status of private schools and making religious instruction a part of the regular curriculum but not compulsory. Compulsory attendance is required full-time from age 6 to 14 or 15 and part-time to 18. Tuition fees and supplies are free in all the systems except that of Württemberg-Baden. Full-time attendance to 15 is compulsory in Bremen, Hamburg. west Berlin and Schleswig-Holstein. Pre-schools and kindergartens are private. The length of the basic school (*Grundschule*) is four years in the Lander and six years in the city-states, and is followed by four years in the upper division of the elementary school, or by three, four, or five years in an intermediate form of secondary education, or by six, eight. or nine years in an academic, technical, or general secondary school leading to the university. Generally the system in the city-states approximates the *Einheitsschule* idea. although the traditional forms of secondary education are still selective As elsewhere there are considerable criticisms of the overemphasis on the intellectual and too little attention to other educative factors. (I. L. K.)

E. The U.S.S.R.

1. The Tsarist Period. — Except in the western Ukraine and Belorussia. the system of education in Russia at the beginning of the 18th century was directed from St. Petersburg by the tsarist government and was imparted in Russian. Whereas in western Europe education was initiated by the church and was subordinated to church ideals and purposes, the Russian school system was started by Peter the Great (1672–1725) as a state organization for purposes of administration in peace and war and for the development of mining and industry. Peter the Great did not intend to promote the Orthodox faith or formal classical learning. whether Greek. Latin or Slavonic. He created mathematical, navigation, artillery and engineering schools for utilitarian purposes. Thus the schools were secular and scientific and were controlled and maintained by the state. The Moscow School of Navigation and Mathematics mas founded in 1701 on the model of the Royal Mathematical school at Christ's hospital in London The Moscow school served as a centre for a whole system of loner-vocational schools and trained sailors, teachers, engineers and craftsmen These utilitarian, secular and scientific characteristics of Peter's schools became the dominant features of the Russian system, but, as a result of the many changes of policy of his successors, they did not develop into a national system of education. Only the Naval academy (developed from the Moscow School of Navigation) and the Academy of Sciences survived all the vicissitudes of Russian history and were in the 1960s. among the leading institutions of the C.S.S.R. The Academic University of St. Petersburg was soon closed and gave way to the University of Moscow, founded in 1755.

A second attempt at building up a national system of schools was made by Catherine II. After many abortive schemes Catherine issued in 1786 a statute for schools, which can be considered the first Russian education act for the 17-hole country. According to this act a two-year course in minor schools was to be started in every district town and a five-year course in major schools in every provincial town. Religion was taught only in the three lower classes and Latin only for those pupils who intended to enter gimnazii ("secondary school") and Moscow university. Other subjects included Russian (26 hours a week per school). arithmetic (18), foreign languages (21), morals (5), geography (11). history (16), sciences (10), mathematics and physics (14), and drawing (30). As this curriculum shows, Catherinian schools were also utilitarian, scientific and secular. At the end of the 18th century 254 towns had the new schools but 250 smaller towns and rural districts had no schools whatever. The Catherinian system was state-controlled, coeducational and free to all subjects of the empress, including serfs.

The third attempt was made by Alexander I, and was influenced by the French Revolutionary leaders, the marquis de Condorcet, Gilbert Romme and Pierre Daunou and the English utilitarians, J Bentham and J. Lancaster. The new statutes (Vilna, 1803 and Russian provinces. 1804) maintained the principles of utility and secular scientific instruction. The parochial schools in the rural areas were to instruct the peasantry in reading, writing and arithmetic and elements of agriculture. the district schools of urban areas and the provincial schools (gimnazii) were to give instruction in subjects necessary for civil servants (law, political economy, technology and commerce). The whole system was state-controlled, free for all subjects of the tsar and formed a continuous ladder leading to the universities. During Alexander's reign the old Catherinian schools were remodeled and many new schools founded. In 1825 there were six universities (Moscow. St. Petershurg. Dorpat. Vilna [Vilnius], Kharkov and Kazan). four lyceums (Odessa, Kremenets, Nezhin and Yaroslavl), three veterinary institutes, two forestry institutes, 60 gimnazii, 370 district schools and 600 parochial schools. In addition there were 18 girls' secondary schools and about 360 private schools for privileged classes. The students of higher institutions received maintenance grants so that out of a total of 3,000 students 1,300 were state scholars.

The successor of Alexander I. Nicholas I, considered this democratic trend harmful and decreed that "It is necessary that in every school the subjects of instruction and the very methods of teaching should be in accordance with the future destination of pupils, that nobody should aim to rise above that position in which it is his lot to remain." In consequence in 1827 serfs were forbidden to enter gimnazii and universities. The new statute decreed that parochial schools were intended for the peasants, the district schools for merchants and other townspeople. and *gimnazii* for children of the gentry and civil servants. Instruction in the *gimnazii* in Latin and Greek was increased (69 hours out of 270). Although the legislation of Nicholas I established a class system. one way for the gentry and another for the rest. the utilitarian character of the whole system remained. In 1849 even the *gimnazii* were divided into two departments. one with Latin (only 20 hours) and another without Latin, which accepted all subjects. except serfs.

The Russian radical intelligentsia was fiercely opposed to the privileged schools for the gentry and demanded the re-establishment of a democratic system with a more modern curriculum in secondary schools. This was coupled with the demand for the emancipation of the serfs and the equality of women in education. The new ttar. Alexander II. inaugurated a period of liberal reforms. The serfs were emancipated in 1861 and thus all social restrictions were removed. A new system of local government in rural areas (zemstvo) was enacted with a right to found schools for the peasantry, non free. Although the reign of Alexander II was marred by some reactionary measures the net result was an unprecedented growth of schools in the rural areas, which the com-

bined efforts of the government, *zemstvos* and peasant communities produced. The utilitarian trend was evident in the establishment of technical schools with vocational differentiation. The education of women was promoted and the first higher courses for women were founded in main cities.

The assassination of Alexander II by revolutionaries led to a second period of reaction under Alexander III. All reforms were suspended and the growth of educational institutions interrupted. The chief procurator of the Holy Synod, K. P. Pobêdonostsev, attempted to build up a rival system of parochial schools under the control of the orthodox clergy and the minister of public instruction, T. D. Delyanov, tried to return to the class system of Nicholas I. These reactionary measures only temporarily set back the growth of education.

The reign of the last tsar saw a constant hesitation between concessions to liberal demands of the intelligentsia and attempts to stop the growing revolutionary movement. The establishment of the state *duma* (*q.v.*), the first Russian house of representatives, resulted in a rapid growth of industry and edncstion. However, all the comprehensive schemes of the state *duma* for a radical reform of education were obstructed by the tsarist government. The deepening gulf between the tsar and the people resulted in the Revolution of 1917 and the abdication of Nicholas II.

2. The Soviet Period. — The history of education during Soviet rule may be divided into four periods: 1917–22; 1923–33; 1934–41; and the period since World War II.

The period of 1917–1922 was the time of civil war, and of general disorganization of social and economic life. The Soviet authorities had not yet elaborated a Marxist theory of education and relied on the radical tradition of the Russian intelligentsia and a few remarks of Marx on polytechnical education. The anarchist-communist ideas were reflected in the Education act of 1918. The demand for social equality resulted in the transformation of the old class system into a comprehensive school consisting of primary school of four grades (8–12) and secondary school of five grades (12–17). Pupils' self-government and control by Communist youth organizations supplanted the old discipline and teacher's authority. All private schools were nationalized and religious instruction was eliminated from the curriculum. All examinations were abolished and the entrance to higher institutions was open to all citizens of more than 16 years of age.

During the second period the Communist party developed a Marxist policy in education that was more realistic and more utilitarian. The Education act, 1923, reflected these views. As the government had to train new cadres of the Communist party and new technicians, school discipline was tightened and the authority of teachers restored. Subject instruction was reintroduced to fit the rapid industrialization of the country. In 1928 technical education was given priority over general culture and the two upper grades of secondary schools were transformed into technical schools. The universities were dissolved into special institutes and faculties of philosophy and history were closed. The number of higher institutions increased to 900 and the number of students to 400,000.

The quantitative success of the new policy unavoidably lowered the standard of general education. The third period, 1933–41, therefore was devoted to the reintroduction of general culture as the basis of technical education. The subjects of history and geography were separated from the general "complex" of social studies and the time devoted to political indoctrination was considerably cut. General secondary schools and the old universities were restored with old faculties. Examinations and old academic degrees were reintroduced and the number of technical institutes reduced to 345. To raise the general culture of technical students all technical institutes introduced in 1934 the so-called "universities of cultures" which were made compulsory. The administration was made more centralized by creating in 1933 a federal (union) organ for higher education. In 1940 a federal ministry of labour reserves was founded to administer all vocational education throughout the U.S.S.R. School reform was started during World War II. In 1943 special military schools (Suvorov schools for the army and Nakhimov schools for the navy) were founded as boarding institutions. In the same year the Academy of Pedagogical Sciences was established in Moscow. In July 1943 a decree was issued introducing separate schools for boys and girls in larger towns. Compulsory coeducation was reintroduced in 1954 *(see* COEDUCATION).

3. Developments After World War 11.—After the war and reconstruction period the growth of schools of every level was very rapid. The fees in the upper grades of secondary schools were abolished in 1956 and the number of pupils in the three upper grades (8, 9 and 10) rose to 5,200,000. It was evident that the majority of graduates of secondary schools could not continue their education in higher institutions and had to enter directly into industrial and agricultural manual occupations. This led to a most important reform, enacted in 1958. In November of that year N. S. Khrushchev presented his memorandum on the connection of school and life to the central committee of the Communist party. In December the U.S.S.R. government enacted Khrushchev's theses as law and in April 1959 the Russian Soviet Federated Socialist Republic, or Russia proper government followed suit Both laws dealt with "the strengthening of connection between school and life." The whole system of education was reorganized in accordance with these laws. The main features of the new organization were as follows:

1. Compulsory school attendance was extended to eight years (7 to 15) and the seven-year school transformed into an eight-year school.

2. Secondary education was extended by a year (9, 10 and 11 grades) to run from 15 to 18 years of age. This period could be spent in three different ways: (a) at the evening (part-time) secondary school for young peasants and workers who were employed in industry and agriculture; (b) at a full-time secondary school combining general education with practical production, based on the ideas of polytechnical education; and (c) at technical and special secondary schools that combined general and technical (or artistic) education.

3. The boarding-school system was extended to an eleven-year course, combining the eight-year school with three years of polytechnical secondary school.

4. Higher institutions were opened to graduates of secondary schools who qualified after a severe competitive examination, preference being given to candidates with practical experience in factories, state farms and collective farms.

The reorganization was started in 1959.

III. THE EASTERN WORLD

Writers on oriental education have usually chosen either India or China as a type. These represent the two great civilizations of the orient and both have exerted great influence on neighbouring countries. In this article, Indian education and Chinese education will be discussed as the two major types, with Japanese education as a variant. (See also CLASSICAL EDUCATION: *In the Orient.)* Indian civilization was metaphysical, religious and otherworldly, while Chinese civilization was humanistic and more concerned with worldly interests such as the problems of human relations and the organization of society and the state. Japan, on the other hand, was distinguished by its nationalism and military tradition; though it borrowed much from China in culture and education, subsequent development made it quite different from China or India. Since India was for more than a century a British colony, Indian education in that period is examined as an example of colonial education in the orient.

The most important difference between eastern and western culture lies in the fact that at the time the west was emerging from the conservatism and stagnation of medievalism, India and China were both under foreign rule. In one case, colonial education prevented a recapture of ancient creative spirit; in the other, an insecure alien dynasty adopting Chinese culture as superior to its own was so anxious to preserve the traditional forms and institutions and so afraid of innovations and new ideas that a once thriving civilization was left behind while the rest of the world moved on. In Japan, however, social and political conditions were

more favourable for a quick transition from medievalism to modernism, and Japanese education reflected the new spirit of national resurgence. In most countries in the eastern world, a new and vibrant national life is in the making, and education has become an important instrument of change and progress.

A. India

The formative period of Indian literature, culture and education extended over a number of centuries prior to the Christian era. Vedic literature, consisting of sacred hymns and historical poems and ballads, was composed before 1000 B.C. From 1000 to 200 B.C. was a most creative period and metaphysics as well as mathematics and early science made noteworthy progress. It was the age of the Upanishads and the Sutras, when new branches of learning enriched the content of education.

By about 500 A.D., a decline in creativity was observable. The caste system was becoming more and more rigid; education became more narrow in content and restricted to certain classes of the population; child marriages struck a blow to feminine education; intellectual creativity had vanished. The deterioration of Indian culture and education coincided with a series of foreign invasions after the 4th century which culminated in the establishment of Muslim rule. Buddhism died out and Buddhist art and education were given a severe blow. Only Hinduism survived as the religion of the majority of people in India. After the Muslims came the Portuguese traders, the first Europeans in India, followed by the Dutch and the French. In time Great Britain became the leading power there.

1. Vedic Education. — The literature of ancient India was religious in nature. The Vedas, collections of sacred hymns. constituted the basic books; to them were later added the Upanishads (philosophical treatises). the Sutras (instructions in the form of aphorisms), and the Brahmanas (theological and ritual treatises) *(see* Sanskrit Language and Literature). Since they did not appear in writing till about 300 B.C., oral instruction was the only means of transmitting the cultural heritage.

In early times the warriors and commoners shared the opportunity of teaching and learning, but, later on, education became a monopoly of the priestly class, the Brahmans. It was maintained that the sacred literature was the spoken word of God, and, in the absence of written books, only the select few were competent to pass it on without distortion. As the caste system became more rigid, the Brahmans became the only teachers not only of Vedic literature but also of non-Vedic subjects preparing for military and commercial careers. In time the Shudras (non-Aryan stock) and the outcastes were completely debarred from education, and in medieval India education became an exclusive privilege of the Brahmans.

Priestly domination of education enhanced its religious character and rituals were prescribed for various stages of a student's life. Before taking up the Vedic studies, he went through the elaborate Upanayana ritual, which included a shave, a bath, the offering of a sacrifice to the sacred fire and other symbolic acts. He also promised to submit to a strict discipline, to observe decorum of behaviour, and to practice abstinence and celibacy until the completion of his course of study.

Another religious duty of the student was to beg for his food, and it was a practice for families to offer food to him. Even rich students well able to take care of their own needs had to do some begging. This was believed to be of value in teaching students to be humble and in encouraging society to support young persons struggling for an education.

Excepting vocational training in the form of an apprenticeship system the chief aims of education were to develop piety and religious discipline and to transmit the heritage of the past. The caste system called for differentiated programs for different classes. Such programs were narrow and specific and did not require the mastery of a broad range of subjects.

Study was conceived of as discipleship, and the student owed the utmost reverence and obedience to his mentor (guru) who, in the ideal case, instructed him without fee in the Vedas and certain ancillary subjects, such as phonetics, etymology and grammar. Memorization was a major aim, with an emphasis upon the recall of unquestioned knowledge which has continued to mark the Indian student.

Elementary schools were commonly held in a temple or a private home. Some Gurukulas, or schools of Vedic studies. developed into centres of learning. in large towns or in forests near them, to which outstanding teachers and pupils were drawn. The earliest of these "ancient universities" now known is Taksashila, in the far northwestern part of India, which existed from the 7th to the 3rd century B.C. More than 60 distinct arts and sciences were taught there by master teachers, assisted by their abler pupils. Other leading "ancient universities" were Benares, which came into prominence as a centre of Brahmanical and Sanskritic learning after Taksashila disappeared, and the greatest of all, Nalanda, in Bihar. Founded in the 6th century A.D. as a Buddhist monastery, Nalanda grew in the course of 800 years into a great complex of libraries, hostels and lecture halls, to which students flocked from all parts of Asia.

2. Decline of Creative Spirit. — Originally Indian education was progressive and liberal. Secular studies such as mathematics, astronomy, history, economics and chemistry received as much attention as theology and ritualism. The caste system had not become so rigid, and all members of the early Aryan community (not merely the Brahmans) were given the right of education, women as well as men. (Later child marriages came into vogue and Vedic education was prohibited to women.) Before deterioration set in, literacy in the population was as high as 60%. How far Indian education degenerated may be seen from the fact that on the eve of World War II less than 10% of the population was literate.

Buddhist education was a reaction against caste education and the monopoly of the Brahmans. Its content was Buddhist, not Vedic, literature, and it was available to all people regardless of caste. The Buddhist school was the monastery, and the boy of exceptional ability but of humble origin could be taught there, although religious and humanistic learning was not available to the majority of Indian youth. An elaborate system of apprenticeship, under the control of highly organized guilds, provided vocational training to the sons of artisans and maintained a high order of technical skill. The nunneries provided a stimulus to women's education. During the period when Buddhism was active and growing. Buddhist universities, such as Nalanda, were among the most celebrated centres of learning in India.

During the period of Muslim rule, Koranic schools and centres of higher learning (Madrasahs) were established in such places as Agra Lahore and Delhi. Although some Hindu and Buddhist universities nere destroyed, private patronage maintained the Hindu system of education to the end of the Mogul period, and the first Europeans found a large complex of Hindu and Muslim educational institutions throughout the country.

Unfortunately, foreign conquests and the entrenchment of an inflexible caste system gradually put an end to the progressive and creative trends. Perhaps even the earlier period, with the reliance on oral instruction, recapitulation, and memory work, was already producing adverse effects on the creative spirit. At any rate, medieval India was engrossed in narrow otherwordly interests to the neglect of secular studies. Even in religious studies, conformity to the sacred books discouraged critical thinking or any deviation from orthodoxy. Concentration on Sanskrit and the neglect of the vernacular tongue further restricted education to the limited few.

3. British Education in India. — In the beginning the British in India had little interest in education. Some feared that education would merely work to the disadvantage of the conquerors. Others felt that education was the concern of religious groups and therefore the government should stay out of it in order to maintain its policy of religious neutrality. Moreover, England itself had traditionally adopted a laissez-faire policy in education, and the British were used to considering education as a luxury to be enjoyed by the privileged class.

The British East India company did nothing about education until it was directed by the British parliament in 1813 to set

aside a sum each year for the education of the natives. This provision was not immediately implemented. It took 10 years to organize a Committee of Public Instruction for Bengal and one for Madras. Then a controversy arose as to whether the money should be used to promote oriental learning or western learning. The debate between the Orientalists and the Anglicists was settled in favour of the latter when Thomas Babington Macaulay's "Minute on Indian Education" of 1835 recommended that higher education in India should be devoted to western learning, and that English should be the medium of instruction. This ruling determined the character of Indian education for the ensuing century. Primary education did not enter the discussion; Orientalists and Anglicists alike were concerned only with using funds for higher education.

In 1859 the administration of India passed into the hands of the British crown and the control of education was subsequently transferred to the provincial governments. Private schools multiplied but government responsibility for education was neglected. Without government initiative and support, a comprehensive plan of national education was impossible.

The characteristics of British education in India may be briefly summarized as follows: The central purpose was to impart western learning. English was the sole medium of instruction. The educational program was top-heavy; the education of a few in the universities was considered more important than the education of the masses. Through the decades a number of commissions and reports criticized this preoccupation with higher education and urged more attention to Indian languages and Indian culture, but inertia as well as the lack of funds prevented any fundamental change in the pattern of colonial education. Universities were organized according to the English model. They were concerned nith culture as the English understood it; their main task was to produce the kind of Indians who could serve in various capacities in the British colonial administration in India. Since the narrow literary curriculum did not fit the students for anything other than government service, there grew up in time an oversupply of university graduates who could not find employment and who constituted a discontented group feeling ill at home in Indian society. Their education had neglected India's own heritage and kept them removed frorn the masses. Secondary education was geared to higher education, its purpose being to prepare students for the university. There was consequently the same exclusive concern with western knowledge and the neglect of Indian languages and Indian culture. Primary education received scant attention. There were missionary schools and private schools established by Indrans, but the government did little to promote the education of the masses.

4. Critique of British Education. — Rising Indian nationalism in the latter part of the 19th century became more and more critical of the domination of western learning. It demanded more attention to Indian languages and Indian culture and a state system of education with provisions for compulsory universal education for the masses. The Indian National congress, the All-India Muslim league and other groups raised their voices against the British system of education. Nor were British authorities altogether blind to the needs of the country. An official survey in 1904 reported that four out of five villages were without a school and recommended that the state should accept greater responsibility for primary education. The promise, however, remained unfulfilled.

Nevertheless, British education made important contributions to Indian life. It opened the doors to modern western learning and broke down the provincialism of medieval India. Western learning also gave birth to liberal ideas and stimulated the very movement of nationalisin that opposed British colonialism. Moreover, the British stressed secular education as contrasted with India's traditional religious education, and they also introduced an educational program ignoring caste distinctions.

If an effort had been made to integrate the new western learning with India's own heritage, the introduction of it would have been a great blessing Unfortunately British education in India did not e cape the evils of colonial education. Its main concern was to produce candidates of the bureaucracy and public servants reared in the English tradition. It saw no value in India's cultural heritage and native languages. It rejected indigenous education and imposed on a conquered people what was essentially a foreign product. As Macaulay said in his "Minute on Indian Education," the aim of British education in India was to produce "a class of persons, Indian in blood and colour, but English in taste, opinions, in morals, and intellect."

Too much of the student's time and energy was absorbed in the effort to master a foreign language; *i.e.,* English. Most reprehensible was the neglect of primary education. Only lip service was paid to popular education, and after a century of British rule India remained a predominantly illiterate country.

5. Independent India. — Under Mahatma Gandhi's leadership, an All-India National Educational conference was convened at M'ardha in Oct. 1937. The conference proposed what became known as the Wardha Scheme, providing for free compulsory education in the mother tongue, with the curriculum organized around manual and productive work in the form of a basic craft. The period of universal compulsory education was to be divided into a junior level (age 6–11) and a senior level (age 11–14). Those desiring secondary education would, at the age of 11, enter the secondary schools for a six-year course. Two types of secondary schools were to be provided: the academic high school, preparing for the university, and the technical or vocational school complete in itself.

After India became independent, its leaders saw clearly the need of a comprehensive plan for a national system of education. Two proposals have guided the thinking of Indian planners: the Wardha Scheme and the Sargent report. The latter, entitled *Post-War Educational Development in India,* was prepared by Sir John Sargent, educational adviser to the government of India, in 1944. It recommended free compulsory education of eight years, subdivided into the junior basic (age 6–11) and the senior basic (11–14). About 20% of selected pupils from the junior basic schools were to be admitted for secondary education. which was bifurcated into the academic high school and the technical high school. The university would take 10% or less of the gifted pupils completing the high school.

The influence of the Wardha Scheme on the Sargent report is obvious. Needless to say, such a plan could not be carried out in a short time, and in the early 1960s compulsory universal education in India remained a hope to be realized in the future. There were not enough schools and not enough teachers for a nationwide program of universal popular education, and financial limitations prescribed slow progress toward the goals.

The British practice of leaving education to the provinces still prevailed, and there was no direct control or supervision of education by the government of India. The local schools were ill-equipped, the teachers inadequately trained. Many pupils who started primary education dropped out prematurely; only a third reached the fourth class.

Theoretically, the academic high school and the technical high school were two alternatives of equal importance, but the academic high school still enjoyed a much higher prestige and most young people chose it in preference to the vernacular vocational school. A rigid curriculum in the English language still characterized the academic high school; it was the gateway to the university and government service and was dominated by the matriculation examination.

Nevertheless, noteworthy progress was made. The constitution of the Indian republic iaid down the principle of compulsory education till the age of 14, and it stipulated equality of status and opportunity for all citizens. Scholarships, though limited in number, were provided for needy students. Teachers' salaries were raised and the number of trained teachers increased. Attention was given to adult education and to the gradual elimination of illiteracy. Hindi was declared the state language of independent India, and Indian thought and culture became appropriate subjects for study and research. As the tempo of economic development is stepped up in India, educational progress will doubtless also be accelerated there. *See* also INDIA: *Education.*

B. China

In its long history China has been invaded and conquered many times. Its territories have expanded and shrunk, and more than once China was divided, with different rulers controlling independent areas. Yet China has a continuous history of several thousand years. This continuity is in essence a cultural continuity. made possible by a well-organized system of education which produced a cultural unity transcending local differences and separatist tendencies.

It has been said that China often absorbed and conquered her conquerors. This was true when conquerors of inferior culture but greater military might adopted Chinese culture and perpetuaied Chinese ideas and Chinese institutions. The influence of Chinese culture of neighbouring countries has been extensive and lasting. Chinese thought. Chinese religions. Chinese art, and the Chinese language were imported into Korea and Japan. In both these countries the study of classics was in large part the study of Chinese classics. and the Chinese written language remains as the basis of advanced Korean and Japanese writing. There are also clear indications of Chinese influence on the language and culture of countries in southeast Asia, such as Vietnam and Burma.

Written literature and educational institutions appeared in China more than 2.000 years before Christ. Even in those early times, records were kept of the names of rulers and major events in government and social life. A great increase in the volume of literature and interest in education took place in the Chou dynasty (*c.* 1122–256 B.C.). which saw the rise of the classical schools of philosophy later identified as Confucianism, Taoism, Moism. Legalism and their subsidiary offshoots *(see* CHINESE PHILOSOPHY).

These schools of thought are so well known that some people consider the Chou dynasty as the only creative period of Chinese civilization. Actually, Chinese culture flourished in different ways in different periods. The Han dynasty (202 B.C.–A.D. 221) was known for its military prowess as well as scholariy historical works. the T'ang dynasty (A.D. 618–906) for its matchless poetry. its artistic achievements and its contributions to Buddhist thought, while in the Sung dynasty (A.D. 960–1279) Chinese creativity found expression in exquisite paintings and in a new school of thought known as neo-Confucianism. Instead of one creative period followed by steady decline and stagnation, China's civilization grew slowly and gradually. Now and then development was interrupted by periods of relative sterility and stagnation. The 19th century was such a period; unfortunately it was at this time the west first came to know China.

Even in the realm of philosophy, the dominance of Confucianism came about gradually and its content was subject to change and reinterpretation through the centuries. Historians speak of the age of classical schools of philosophy in China as the period of the "hundred schools." There were diverse schools competing for ascendancy. each offering solutions to the problems of the day. Unlike Indian philosophy, these schools mere less concerned with metaphysical and strictly religious questions than with practical social, economic and political problems. The presence of diverse schools indicated not only a wide range of intellectual activity but also the freedom to differ and to propose vastly different ways of solving the problems of life. Confucianism was only one of the rival schools; Confucius actually retired in frustration because his principles were not generally accepted, and his illustrious disciple Mencius complained that too many people were flocking to rival schools.

At the close of the Chou dynasty Confucianism mas no more influential than the other schools, Moreover, it was the first school of thought to meet official ban and persecution. when the emperor of Ch'in ordered Confucian books to be burned (213 B.C.). In reaction to this persecution the ensuing dynasty of Han made an earnest effort to revive Confucian learning and thus took the first steps toward making Confucianism a state cult (136 B.C.).

There was another reason why Confucianism became the dominant school of thought in China. Its ideas were more directly applicable to government and more in line with the traditional social order. Confucius frankly stated that his teachings were essentially conservative. He did not challenge the feudal society of his day; he merely wished to stabilize it. His teachings supported and strengthened the old family system. Besides, Confucianism had a larger body of literature which could be made the basis of education.

1. Ancient Education. — A unique characteristic of ancient Chinese education was the identification of education with government service. A major aim of education was to prepare for positions in the civil bureaucracy, which dominated Chinese government much more than the military chieftains. For this reason. the provision of education was early recognized as a function of the government. Its concern. however. was not to extend elementary education to the many, but to enable the few to prove themselves worthy of public office.

A national university was established in 125 B.C.; in the 2nd century A.D. some 30.000 students were enrolled. In subsequent periods, Chinese universities attracted students from Korea and Japan, who took Chinese ideas and Chinese institutions back to their homeland. Much attention was given to libraries. When the capital was moved from one city to another. one of the important tasks was to make sure that the new capital would have a good imperial library. The invention of papermaking in the 1st century A.D. and of printing in the 9th century were important milestones in the production of books in large quantities and in making learning available to more people.

In time, the state became more interested in the selection of scholars than in the making of scholars, more concerned with the conducting of examinations than in the establishment of schools. The civil examination system itself was also the result of centuries of evolution. The practice of selecting government personnel by examinations began in the 2nd century B.C., but even then the content of the examinations was subject to change.

The resulting system became a most useful instrument for establishing an "aristocracy of scholars" whereby China could be sure of a cultural unity by entrusting the government to scholars reared in a common tradition, nurtured in a common intellectual heritage and dedicated to common principles of political and social life. Selection was rigorous. After preliminary examinations, the first stage of screening, there were three ascending levels of examinations; successful candidates mere awarded academic degrees corresponding. interestingly enough. to the modern bachelor's. master's. and doctor's degrees. The three degrees were known as *hsiu-ts'ai* ("flowering talent"), *chü-jen* ("promoted man"). and *chin-shih* ("advanced scholar"). The examination for the first degree was given in the county seat, that for the second in the provincial capital; the highest examination was given once in three years in the national capital only. The most distinguished of those who passed the "advanced scholar" examination mere granted membership in the Hanlin academy. the highest honour a scholar could attain.

The examinations were strict and, on the whole, administered with fairness. The names of the candidates did not appear on the examination papers, to avoid favouritisrn on the part of examiners. The examinations lasted for several days and the candidate was closeted in his cubicle and shut off from all contacts. In general, only 1% of those sitting for an examination could expect to pass. Success, however, meant not only a gateway to high position but immense glory and pride to the family and even to the home community. One who attained the highest degree achieved national fame and his home became a shrine to which his neighbours looked with pride; long after his day it remained a point of interest in his city or village. a centre of attraction to travelers and tourists.

Much could be said for the Chinese examination system at its best. It mas the root of the Chinese tradition of government by civilians. It made the scholars the most highly esteemed people of the land. It offered an open and equal opportunity to all men of ability. Ability, not birth, determined one's position in the social hierarchy. Chinese society was not without classes but there was a high degree of mobility, and education was the chief channel by which one could raise his own position and that of his family.

The examinations were open to all. There was no age limit, and

failure in an examination did not prevent further attempts in the future. Cases were known of father and son, even grandfather and grandson, sitting in the same examination.

Equal opportunity, of course, was limited by the many years needed for study before the examinations. No doubt many an able youth never had the opportunity of advancement because his family could not afford to support him in a prolonged period of study. On the other hand, it was not uncommon for a family. a clan or even a whole village to contribute to the support of a promising lad to enable him to study for the examinations, and the absence of rigid classes is evidenced by the fact that parents of even the poorest families could always cherish the hope that one of their sons might some day become a scholar and thus rise to the top of the social and economic scale.

At the same time, the system had serious drawbacks. The evils arising from the domination of education by examinations were as damaging in China as in British education in India. The sole aim of the student was to pass the examinations. The nature of the examinations determined the content of education; nothing not covered by the examinations was of importance to scholars.

The evils were accentuated as the content of the examinations became more and more limited in scope. Chinese education in early times was broad and liberal. The educated person was expected to possess virtuous character arid to have acquired harmony and equilibrium in thought and action. He was supposed to be versed in the "six arts," namely rituals, music, archery, charioteering, writing and mathematics. In time: however. this broad concept of education was forgotten and the examinations concentrated on the testing of literary ability and knowledge of the classics. Art, music and science were left out; even arithmetic was not given a place alongside reading and writing.

The classics formerly encompassed more than the Confucian books. In the T'ang dynasty, scholars studied Taoism and Buddhism as well as Confucian classics. In later periods, however, the examinations were concerned exclusively with Confucian learning (*see* CHINESE CLASSICS).

Higher criticism was once an important phase of scholarship. As early as the Han dynasty, scholars critically examined the classical texts to determine their authenticity. Other scholars in later dynasties concerned theinselves with critical interpretation of the classics. After the Mongol conquest. however, the Ming rulers were so concerned with the restoration of Chinese institutions that they bent backwards to be conservative; under Manchu rule this conservatism was enhanced and led to sterility and stagnation.

Chinese education went through a process of degeneration somewhat like the loss of creativity in India and not unlike the formalization of classical learning in the west. Education devolved into the uncritical and verbatim reproduction of the ideas and writings of past scholars. Essay writing. which constituted the major part of the examinations, became the mechanical imitation of a style of writing; form was more important than content. With its narrow content and formalistic methods of learning, the educational program was quite out of tune with the traditional spirit oi Chinese education. to say nothing of its utter inadequacy to meet the new needs of the modern age.

2. The Chinese Renaissance. — The impact of the west and the spectacular rise of Japan caused a great shock to the Chinese nation and created a demand for a radical change in education. A modern school system was adopted in 1903 and the old examination system was abolished in 1905. Christian missionary schools played an important role;' they ranked among the outstanding pioneering schools of modern China. With the founding of the republic in 1912, modernization and westernization gained momentum, and a system of schools comparable in external features to the American system was evolved.

Elementary education consisted of six years. There were two stages of secondary education: the three-year junior rniddle school or junior vocational school, followed by the three-year senior middle school or senior vocational school or normal school. The senior middle school led to the four-year college or university or to technical or professional schools. This system, with minor variations introduced from time to time, remained until the Comrnunist conquest of the Chinese mainland.

With the new schools came a flood of new ideas. The years during and after World War I were such a period of intellectual ferment that they have been called the Chinese Renaissance. Wilsonian democracy, Marxism, John Dewey's educational ideas. the philosophies of Bertrand Russell and his contemporaries all had their eager disciple; and exponents in China. New books and new periodicals sprang up like mushrooms.

One of the most important phases of the Renaissance was the literary revolution which aimed to revitalize the Chinese language and make it more accessible to the common people. There was such a vast difference between the written language (classical Chinesej and the spoken tongue that a learner could recognize every word of a hook without comprehending any of the subject matter. It was the common practice for beginning readers to learn the words by rote memory and then to learn the meanings later by translating the written words into everyday speech. All books were written in the classical style. The leaders of the literary revolution boldly attacked this problem and proposed to change the written language from the classical to the vernacular style, called pai-hua (plain talk!. Books and periodicals began to appear in pai-hua. and textbooks were rewritten so that the learner could comprehend the meaning as soon as he learned the words.

The literary revolution gave an impetus to extending educational opportunity to the many, and compulsory universal education and the gradual elimination of illiteracy became matters of urgent concern.

Two names deserve mention in connection with these movements. One leader was Hu Shih (*q.v.*), a philosopher and historian educated in U.S. universities. He was not only in favour of writing letters and elementary textbooks in the pai-hua, but he boldly asserted that even China's great classics could be rewritten in the vernacular style so that they could he understood and appreciated by the common man. His volume *History of Chinese* Philosophy, written in the style of everyday speech, opened up new possibilities of applying modern methods of research and critical thinking to the study of China's heritage.

Another pioneer was James Yang-ch'u Yen, whose interest in mass education began when he was a Y.M.C.A. worker with the Chinese Labour corps in France during World War I. Finding that one of the great desires of the illiterate labourers was to communicate with their families at home, he organized classes to teach them to write simple letters. Soon the workers, thrilled by their ability to read and write, wanted to be informed of current events and war developments. Simple news sheets were prepared to satisfy this urge and the labourers read them with absorbing interest. After the war, Ten and his associates brought the idea to China and started other experiments in mass education. In time, a nationwide movement was launched with the support of the government as well as public-spirited citizens.

Despite the new interest in education. progress was slow and irregular in the early years of the republic on account of political instability. When the country was embroiled in civil strife, no government was in power long enough to make constructive long-range plans. In view of inadequate government support, private effort in education became especially important. Outstanding among the private schools were the Christian missionary schools. Christian education offered a complete range of schools from the kindergarten and the primary school through the university. These institutions were pioneers in women's education, in coeducation: in music education and in physical education. They were distinguished for their stability, their freedom from shifting politics and their good instruction in English arid in western learning. Despite subsequent criticisms of thrir "denationalization" their contributions to modern Chinese education were of inestimable value.

3. Education Under the Nationalist Government. — After 1930, the Nationalist government gained in prestige and stability. For the first time in the modern period. China had a government able to make long-range plans for national reconstruction, and a well-organized national system of education came into being. The

government demanded centralized control of all phases of national life, and private education was put under strict government control. to the extent that little variation from the public-supported schools was permitted. The public schools, however, were for the first time assured of financial support. National universities won recognition at home and abroad as outstanding centres of learning and research.

Further progress was made in mass education. Adult education programs showed more imagination and creative ideas than the rigidly controlled program of the schools. Promising beginnings were made in social education, which encompassed a wide range of activities including public libraries, museums, recreation centres. and the use of the radio and of films for educational purposes.

Schools and school enrollment increased steadily from 1930 to 1937. when progress was interrupted by war. A realistic plan was formulated to achieve universal compulsory education by stages. By 1937, 43% of school age children were enrolled in some form of primary school. Though many of the schools were incomplete primary schools or part-time schools, there is no doubt that great strides were being made toward the goal of universal education.

The same trend was continued on the island of Taiwan (Formosa). The Nationalists built on the foundation laid by the Japanese and maintained a steady increase in school enrollment. More than 90% of school age children attended elementary schools and about 1.775.000 persons out of a total population of nearly 10.000.000 were enrolled in schools and colleges of the island.

4. Communist Education. — Education was a very important phase of the Communist program of total revolution. Its task was to change the thinking, attitudes. habits, and behaviour patterns of the people to conform with the ideology and policies of the regime. It was indistinguishable from indoctrination and propaganda. Formal and informal education were merged into one integrated process, governed by the same objectives. Students and teachers were expected to be active in politics, not only to learn the ideology but to take part in political tasks and propaganda activities (see also SCHOOL ADMINISTRATION : *Polificnl Party Control).*

The curriculum was purged of "feudal and bourgeois ideology." The study of Marxism-Leninism and "thought reform" by means of inquisitional sessions of "criticism and self-criticism" in small. closely supervised groups was accorded first importance. 'The study of the Russian language was energetically promoted. Soviet textbooks. Soviet theories. and Soviet methods were considered the last word in education.

The Communists were not bound by tradition and they boldly adopted new forms and new methods to achieve their objectives. There were "universities" with courses to be completed within a few months and "colleges" which were actually part-time adult education agencies. There were "spare-time schools" and "spare-time universities" which peasants and workers attended when they were not working.

Illiteracy was being eliminated rapidly. Official statistics claim that in the early 1960s, 94% of school age children mere enrolled in schools. When the Communists came to power in 1949 there were 350.000 schools with 25.000.000 pupils: by 1960 there were nearly 1.000.000 schools with more than 100.000.000 pupils. The percentage of "worker-peasant youth" in the school population increased year by year. Language reform was pushed ahead by the use of a simplified form of writing and by the experimental use of an alphabet. Both on the mainland and in Taiwan. China was fast becoming a literate nation.

C. JAPAN

1. Chinese Influence and **Tokugawa** Rule. — Japan's earliest educational system followed the adoption of Chinese political institutions in the 7th century AD. and was designed to educate the aristocracy in Chinese learning as a prerequisite to social standing and political eminence. The 8th century code of *Yōrō* provided for a national university. whose students came to number about 400, and a supporting network of provincial schools. The principal emphasis in these schools was on Confucian learning, and high officials were for a time expected to qualify for office by passing examinations. From the year 704 to 937 only 65 students qualified for the highest degree of "exceptional talent," however, and since selection of students mas restricted to sons of families of high court rank the education and examination system never operated to favour social mobility as in China. Private and family schools supplemented the official colleges while continuing the same emphasis, and Buddhist schools trained young men in the sacred law. Literary training was highly developed at the Heian court and its courtiers and ladies produced a great literature, but learning did not penetrate beyond the aristocracy.

As the Chinese governmental models became inadequate to deal with the growing provincial interests and opportunities for official positions at court became fewer, the system of official education declined. The court aristocracy became less prosperous and the feudal warrior groups did not immediately gain the opportunity to acquire learning. As a result the Buddhist clergy were for several centuries the chief bearers of the scholarly tradition. During the 15th and 16th centuries new literary and philosophical developments benefited from the patronage of feudal lords whose realms grew in extent and wealth, and with the years of peace that followed the establishment of Tokugawa rule in 1600 education and learning flourished.

The Tokugawa shoguns encouraged their retainers to take up Confucian learning and their vassals followed the example of the shogun in this as in other things. Shogunal and fief schools for ranking samurai emphasized a curriculum of Chinese Confucian learning as well as military arts. Private schools and academies transmitted much of the same teaching to groups of commoners able to afford prolonged study, with the result that prominent rural leaders and urban merchants were frequently well-educated. Everywhere *terakoya* ("temple schools") were established to train commoners in the rudiments of literacy. Outstanding teachers and scholars trained disciples of varied social origins from many areas, and a number of theorists wrote widely on educational philosophy; one of the most notable of the theorists was Kaibara Ekiken (1630–1714). (This and following personal names are given in the Japanese manner, with the family name first.) Thus the Tokugawa years of peace equipped Japan for the 19th century process of nation building with widespread literacy and the basis for a modern educational system.

2. Western Influence and Compulsory Education. — In late Tokugawa days schools of western learning multiplied and produced many leading educators of modern times. among them Fukuzawa Yukichi (1834–1901), founder of Keiō university in 1868. Out of the shogunate's school for western learning came Tokyo Imperial university, formed in 1877 as the pinnacle of the modern educational system and designed to train government servants. In 1872 an educational law decreed that all people, regardless of class or sex, should receive education. The country was initially divided into eight university districts which weie further subdivided into middle, secondary and elementary school district.. In the years that followed the government pursued its educational goals vigorously, experimenting with a number of foreign institutional models. Private institutions grew in number, and Waseda university, founded in 1882 by Ōkuma Shigenobu, ranked with Keiō as a leading university.

Progress in public education in 19th-century Japan profited from the alacrity with which most groups seized upon the new learning as providing the means for personal and national advancement. In an age in which Samuel Smiles' Self *Help* was a best seller: education in the practical learning seemed to offer the key to modernization. Gradually, however, government leaders came to fear that in the rush for progress much of the stability provided by old values might be lost. As a result they strengthened central controls, reintroduced Confucian and Shinto values, and oriented the system that resulted toward service for a family-state and divine father-emperor. Japan enforced universal compulsory education with the same efficiency exhibited in building industries and modernizing the military forces. Just as I'russia set the pace for universal education in the West, so Japan became the most

literate nation in the orient. Indeed, its record in the first half of the 20th century of enrolling 99.5% of school age children in primary schools excelled that of most western nations.

After 1885 the system of public education received its definitive form. Minister of Education Mori Arinori incorporated German organizational and pedagogical patterns to ensure a strongly nationalist emphasis. Even these measures drew resistance from nationalists who deprecated German influence. In 1890 an imperial rescript on education provided the ideological basis for the system! making it clear that traditional Confucian and Shintō values were to serve as the basis of moral education. This emphasis was implemented by courses on "ethics" (*shūshin*) which served as the core of the curriculum. In 1903 a system of national textbooks was added, giving the educational ministry the capacity to alter, add or delete indoctrination in accordance with political currents. Thus the textbooks reflected the moderate and democratic trends of the 1920s as well as the extremist militarism of the 1930s.

3. Changes After World War 11.—After Japan's surrender in 1945 the educational system came in for sweeping revision in line with the suggestions of U.S. ohservers and Japanese educators. Compulsory education was increased from six to nine years. The imperial rescript of 1890 was rescinded by diet action and the Fundamental Law of Education of March 1937 set the tone for an education dedicated to the goals of democracy, peace and individual dignity. "Ethics" disappeared from the curriculum, and traditional units of study were replaced by social studies designed to prepare children for life in a democratic society. Administratively the powers of the educational ministry were curbed; textbooks were privately produced and schools were controlled locally by elective boards of education. The complex prewar system of specialty schools for boys and girts gave way to the U.S. sequence of grammar, junior high and senior high schools, while prefectural universities (often based upon earlier specialty schools) broadened educational opportunities.

After the recovery of Japanese independence in 1952, modifications were made in the postwar pattern to increase central direction and hinder political indoctrination by the radical and powerful Teachers' union. Controls on textbook certification were strengthened, boards of education were made appointive, plans for a "morals" (*dōtoku*) course were announced and efficiency ratings for teachers were instituted. The principal postwar changes of general education and broader opportunity, however, enjoyed widespread support and seemed well adapted to postwar Japanese society. By 1960 Japan had over 21,000,000 pupils in lower schools, nearly 80,000 students in about 250 junior colleges, and over 500,000 students in more than 200 universities.

EDUCATION, INTERNATIONAL. International education may mean education on international relations, education for internationalism or education for foreign or international service. but it usually refers to the exchange of persons for educational purposes between nations. and in this sense is as old as the academic community. From the wandering scholar who journeyed from Rome to Athens to the 20th-century Fulhright fellow in Delhi or Paris, men have traveled abroad in search of knowledge and training. The earliest formal universities in France and Italy attracted students from all Europe. And the 19th-century gentleman was not considered truly cultured until he had made the "grand tour" of the continental schools.

What had been a leisurely, informal movement became a big business in the 20th century, and the Mecca of the exchangee shifted from Europe to the United States. The largest number of foreign students in the G.S. in the late 1950s came from the far east. Latin America sending the next largest number and Europe the third largest. Engineering, the humanities and the social sciences were the most popular fields of study. On the other hand, almost two-thirds of U.S. students studying abroad were in Europe. The fields of study attracting the most U.S. students abroad were medicine, the humanities, theology and the natural and physical sciences.

Students, however, were not the only members of the exchange population. Foreign physicians training in U.S. hospitals and foreign faculty members teaching and doing research in U.S. colleges and universities swelled the numbers. At the same time, a number of U.S. faculty members were overseas on teaching or research assignments.

Governments, colleges and universities. foundations, corporations, organizations and individuals, all became sponsors of exchangees, providing the necessary funds for international study. However, a number of exchange scholars were self-supporting financially.

The basic purpose of educational exchange is, of course, to educate. In the 20th century, however, other new and important considerations motivated the sponsors and practitioners of international education. Among the most important were the attainment of world peace through international understanding and the sharing of technical knowledge with underdeveloped countries. These nen goals brought many changes to the exchange of persons. Governments nhich tended to view exchange of persons as an arm of foreign policy naturally emphasized exchanges with those countries or areas considered politically critical. Programs with underdeveloped countries stressed opportunities in the practical application of science and technology.

See Institute of International Education, *Open Doors 1959: a Report on International Exchange;* Quincy Wright, *The Study of International Relations,* with extensive bibliography (1955). (G. K. H.)

EDUCATION, PHILOSOPHY OF, is the attempt to formulate the over-all objectives, content and strategy of education in terms of a consistent, integrated organization. The literature of. nearly every age is laden with advice on rearing the younger generation. The abundance of this advice would indicate that perplexities in child training are perennial. For their solution there have been various resources on which to draw. To seek help from the direction of educational philosophy, however, may strike the average layman as rather formidable. As a matter of fact, however, educational philosophy is nothing more than an extension and refinement of common sense.

Scope and **Function.**—When confronted with the complexities of child rearing, the usual tendency is to approach them in common-sense fashion. This common sense is drawn from a long accumulation of firsthand experiences with children which is handed down from generation to generation. Yet, sound as common sense may be when winnowed by succeeding generations, it suffers from a kind of shortsightedness born of its closeness to firsthand experience. This shortsightedness immediately becomes evident when one extends the range of common sense to other times and places. The writer of Ecclesiasticus in the Old Testament, for example, warned parents not to play or laugh with their children if they wished to save themselves from later grief and sorrow. While this may have seemed sound common sense in the Holy Land of biblical times. it would generally make nonsense in 20th-century Europe or America.

In other words, common sense cannot stand by itself; it needs correction and refinement. It needs a wider or longer view of its object. This is provided by "theory" which, etymologically, has the same Greek root as "theatre" and emphasizes the idea of getting a panoramic view or understanding of the whole area of concern. Common sense can be refined and made more dependable theoretically in two directions. In one direction the educator tries to become more exact. He breaks an educational problem down into its component parts. Then he studies only as many parts, or variables, as he can control experimentally. By allowing one of these to vary while he holds the rest constant, he notes the consequences. Thus be is able to achieve a high degree of reliability and objectivity about the precise role of this particular variable. To refine common sense in this manner is to refine it scientifically.

A second direction the educator might take to improve on common sense would again start with an awareness of the variables involved. But this time, instead of working with only a limited number of them, he would insist on taking as many as possible into account, whether or not he can control them. In doing so he excludes any hope of gaining reliability or objectivity in his thinking. But he gains a certain wholeness of viewpoint. To seek, to think and to act in the light of all the relevant factors is to take a philosophical point of view of the situation.

Although science and philosophy seem to refine common sense by proceeding in opposite directions, it would be a mistake to consider them incompatible with each other. On the contrary, they really complement each other. The parent or teacher will want to refine his common-sense reaction to educational perplexities not just in one or the other direction but rather in both. Impressive as is the usual consensus on scientific results, this consensus is purchased at the price of limited results. On the other hand, disturbing as may be the perennial disagreement among educational philosophers, this is the price of attempting to train a child in the light of all the diverse circumstances bearing on him.

To illustrate, take the case of a child not doing well in school. Time was when common sense might have crowned him with a dunce's cap. Mistrusting so simple a solution, the modern teacher would undoubtedly try to extend the range of his understanding of this case by calling to his aid a variety of experts with scientific training. He might first consult the school psychologist regarding the child's I.Q. and his results on standardized achievement tests. High in the former, the pupil might be low in the latter. In accounting for this discrepancy the help of a psychiatrist might be needed. The family doctor might find the child to be the victim of some debilitating disease, or a visiting teacher might find the child's home to be in a poor environment or to suffer from unemployment of the father or to be rent by religious differences between the parents. Each diagnosis would have its own limited therapy. But what to do in the light of all the circumstances, how to balance all the relevant values: this is much more than a simple task for common sense.

On the way to striking a balance it may be necessary to inquire just how to conceive the nature of the child, how to state the proper ends of education—and of life itself, for that matter—how to decide the proper roles of church and state in promoting the child's welfare, how to be assured of the logic by which this analysis has proceeded and how to deal with a number of other equally weighty questions.

As the questions just raised suggest, philosophy is not a simple discipline. To answer the kind of educational problems posed it is necessary to recognize three main subdivisions of philosophical effort. One has to do with values or ethics. It examines the nature of the good. Without a criterion of value the parent or teacher will be on uncertain ground in determining the aims of education or which parts of the social heritage should be included in the curriculum. A second major subdivision concerns itself with knowledge, or technically. epistemology. It inquires how the learner comes to know and whether what he knows is true. Keeping an eye on the canons of knowledge provides a yardstick by which both teacher and learner can constantly measure the curriculum and methods of instruction employed. A third and final category of philosophy considers the nature of reality or. again more technically, metaphysics. There will be continual differences of opinion about the good and the true in education, which can only be adjudicated by appeal to what is the real nature of man and the world he inhabits. To determine the generic traits of reality may seem to be just a matter of common sense, but it is far from being so easy a matter.

If the educator must appeal controversial questions about the good and the true to the generic traits of reality, it would appear that a sound philosophy of education rests ultimately on a metaphysical base. As a matter of fact, this is what a number of notable educational philosophers have held. But just what is reality? For instance, are its dimensions—and consequently those of education as well—measured by the here and now or do they include the hereafter as well? If they include the latter too, how can the parent or teacher know with certainty what these dimensions require as to the ends, content and method of instruction? The answer is highly speculative at best. One can argue logically enough to a number of different conclusions but which conclusion, which set of premises from which these conclusions take their origin, is the true one? This analysis would make it appear that questions of epistemology take precedence over questions of metaphysics. But a moment ago it seemed that what was true depended on what was real. Now it appears that what is real depends on what can be taken to be true.

This impasse directs attention to the fact that the truth about reality perhaps can never be completely known. On the one hand, this may be due to human limitations in the capacity to know anything. On the other, it may point to the need for redefining the role of philosophy. Some think philosophy should help educators by clarifying the statements in which they clothe their educational theories, policies and practices. Men use language in three different ways, they point out. One is cognitive; it represents or describes what is the fact. Another is emotive; it expresses feeling. And a third is persuasive or imperative; it seeks to influence the conduct of others. When educators misuse or confuse these uses they will need philosophy; in the sense of linguistic analysis, to untangle themselves.

Take Horace Mann's statement that everyone born into this world has a natural right to an education. Supposedly Mann was using language in the first sense as he seems to be making a descriptive statement of fact. On closer analysis, ho ever, he may well have been trying to convince others of this principle, the third

sense. Indeed, not only may he have been trying to convince others but to sweep them into his camp by the implied justification that the principle u-as anchored in fact. But is it a fact? Or just an expression of Mann's own feelings, the second category? And, if he was speaking descriptively, uhat does he mean by "natural?" Is there any factual — observational, empirical — evidence that would lay this query to rest? And if not, is the statement as a fact meaningless? However Mann's statement is taken, philosophy should help the educator to be aware of the possible different meanings.

History. — Whatever the scope and function of educational philosophy, it has been important only intermittently throughout the long span of educational history. Prior to the 20th century, teachers and nriters on education for the most part have been content to follow the lead of common sense. This nas the case with the great Roman educator, Quintilian (c. AD. 35–c. 95) when he wrote his *Institutio oratoria.* The later *Ratio studiorum* of the Jesuits (1599) was also largely a distillate of the firsthand experience of the members of that great teaching order. John Locke (1632–1704), when he wrote *Some Thoughts Concerning Education,* confined himself to his earlier experiences as a tutor instead of giving his "thoughts" the larger theoretical setting of his An Essay *Concerning Humane Understanding.* And even Jean Jacques Rousseau (1712–1778) included many purely empirical exhortations in his *Émile,* which must be considered a leading work in educational philosophy.

A few great philosophers like Aristotle and Aquinas gave theoretical attention to education, but only in a limited rather than a systematic way. Thus Aristotle (384–322 B.C.) treated education as an aspect of his Politics, holding that the theory of education should conform to the pattern of the state. Hence, since the Greek state admitted of freemen and slaves, he conceived and handed down to posterity the division between liberal and vocational education. But the clue to his larger political setting of education lay in the idea of happiness, the clue to which, in turn, lay in the practice of virtue. Aquinas (1225–1274) turned his attention briefly to education in his De *magistro* nhere he described the function of the teacher as analogous to that of the physician. Since the physician cannot heal his patient but can only assist the processes of nature to heal itself, so it is not only bad grammar but bad theory to expect the teacher to "learn" his pupil. The pupil must be self-active in learning. Teaching can only assist this process; it cannot be a substitute for it.

Among the few who have given major attention to refining common-sense educational notions by philosophical theory the first, and perhaps the greatest was Plato (427–347 B.C.). His famous work, the *Republic,* written as a dialogue between Socrates and various others, still stands as one of the greatest educational essays of all time. Going far beyond specific rule-of-thumb directives for the immediate teaching of the young. Plato placed education in the larger setting of social improvement. Imperfections in the existing state of affairs impressed him as all too evident. But these imperfections were only apparent. Behind the world of appearances lay the true norld of perfect reality. The main business of education was to aid the human intellect by a dialectical or logical process to pierce through the shifting shadons of the immediate world to the ideal world of reality beyond. After acquiring a firm grasp on ultimate truth through the dialectic process it would be possible to rule the state justly.

But precisely what is the dialectic of learning ultimate truth? Plato early concluded that there nas no hope of the mind acquiring this kind of knowledge from outside itself. Knowledge must, therefore, emanate from ideas which were innate at birth. This natal knowledge was so latent. however, that the individual seemed to have forgotten it. The educative process, consequently, became one of reminiscence. Using the Socratic method of asking questions. the teacher literally tried to draw the truth out of his pupils. (It is no accident that the English word education stems from the Latin *educere,* meaning "to lead forth.")

Plato nas well aware of the fact that not everyone responded with equal competence to the dialectical process of drawing forth ideal forms of knowledge. As a matter of fact, he recognized three levels of ability. To the topmost level he entrusted the government. The best-educated men. those most able to lay hold the ideal form of truth, were to rule. Indeed justice required it for, Plato said, a just education obtains where each one is educated according to his ability, but in such a way as to benefit the whole social group.

After Plato there was a long pause in systematic theoretical thinking about education. Only one attempt, a failure, was made to implement his onn theory in practice. No doubt the *Republic* was too utopian even for the advanced times in which Plato lived. In spite of such intervening educational classics as those already mentioned, the next educational work of philosophical stature was Rousseau's *Émile.* Envisaging many specific directives for rearing Émile, Rousseau, like Plato, conceived the larger task of education to be one of social regeneration. Rousseau saw 18th-century society as honeycombed with injustices and iniquities. Consequently a conventional education in the customs of the day would be similarly corrupted. From what source, then, was education to draw its purifying influence? From nature, said Rousseau. As he put it in the opening sentences of *Émile,* everything is good as it comes from the hands of the Creator; it is only in the hands of man that it degenerates.

A principal implication of this statement was that child nature is fundamentally good. This ran counter to the widely held Christian conviction that original nature is tainted with sin. Nevertheless. if Rousseau was right, the hope for social regeneration was to be realized by an education patterned closely after nature rather than social custom. The educational directive to parents and teachers, therefore, was to give the child freedom to express his native goodness. If free rein for his native tendencies produced untoward results, then let the child learn from the consequences of his acts. Rural rather than urban life seemed to Rousseau the better place in which his educational philosophy could work itself out. But to claim that this point of view was antisocial on this account or on account of his emphasis on freedom is overstating the case.

In the century following Rousseau, Johann Friedrich Herbart (1776–1841) was undoubtedly the leading philosopher to give systematic attention to educational problems. The main bearing of his thinking on the problems of parents and teachers was moral and psychological (psychology at the time being still a philosophical rather than a scientific discipline). Herbart took the concept of association of ideas. a notion at least as old as Aristotle. and developed it into the educational theory of apperception. According to this theory the pupil does not just perceive the new thing to be learned but he *apperceives* it or, in more familiar language, he learns the new in terms of the old. To take better advantage of this principle Herbart arranged the curriculum according to his "culture epoch" theory. This theory, also of long standing before Herbart adapted it to his own ends, called for the child to repeat in the course of his education the various epochs — savagery, nomadism, agrarianism, etc.—through which the race had passed in its long history.

Next in line of great educational philosophers was John Dewey (1859–1952). Like Rousseau and Plato before him. he too conceived of education as an instrument of social reform. Unlike Rousseau. however, he did not accept nature uncritically as his standard; nor did he. like Plato, seek his standard in some ideal realm behind and beyond nature. Following the lead of modern science. Dewey saw reform as basically experimental. Consequently problem solving, first expounded in his *How We* Think, became the basic method in the classroom. This method started with some problem, preferably the child's own. drawn from the community in which he lived. After clearly defining the difficulty, the child was taught to gather data for its solution. With these resources and the guidance of the teacher, he learned to formulate a hypothesis for overcoming the obstacles standing in his way. The final step was to test the hypothesis by acting on it to see whether the consequences of action bore out the anticipations of the hypothesis. Thus learning necessarily involved student activity for Dewey as it did for Xquinas. But to St. Thomas' psychological justification for activity Dewey added an epistemological

one as well. In other words, it not only is a fact that learning is self-active, but one must also be active to learn what is true.

The social corollary of Dewey's method naturally called for the fullest possible sharing of ideas and resources for the solving of problems. Only in this way could there be continual and effective reconstruction of individual and social experience. Indeed, maximizing communication (increasing the sharing of ideas) within any social group on the one hand and between social groups on the other is the measure of the good or democratic society which Dewey laid down in the most famous of all his educational works, Democracy and Education. There can be little doubt that Dewey subscribed to the necessary compatibility of the scheme of education with the social frame demanded by Aristotle. Yet, while in Aristotle's time the separation of liberal and vocational education was compatible. with a social frame admitting of freemen and slaves, Dewey insisted on the interpenetration of liberal and vocational education in a social frame where everyone was free and everyone worked.

20th-Century Philosophies. — While systematic writers on philosophy of education were rare before the 20th century, there was a veritable flood of them after 1900. In fact, it is probably not overstating the case to say that more books appeared in this field in the first half of the 20th century than in all the preceding centuries put together. It would appear that the tremendous advances of science and the enormous growth in complexity of political and economic organization created a situation in which the common-sense approach to education became progressively less and less adequate. The variable forces which drive education this way and that were so numerous and diverse that parents and teachers would have been overwhelmed without the advantage of a comprehensive theory or philosophy of education.

Progressive *Education.*—First to sense the need for bringing educational philosophy abreast of the times was a group who gathered under the banner and title of "progressive education" or, as it was called in Europe. "the new education." At first they were loud in protest against the rigidity and aridity of the traditional education inherited from preceding centuries. To point education in a new direction they founded numerous experitnental schools. It soon became clear, however, that the founders of these schools mere by no means of one mind in their educational theory. Roughly two theories were evident.

One wing of the progressive movement seemed to take its inspiration from Rousseau. It made a fetish of freedom for the child. It was as anxious to get away from the conventional molds of the 19th and 20th centuries as Rousseau had been to break those of the 18th. Along the way it received encouragement from some of the kindergartners who followed Friedrich Wilhelm Froebel (1782–1852) too closely, from G. Stanley Hall (1844–1924) whose theory of catharsis took Herbart's culture epochs too literally, and from some followers of Sigmund Freud (1856–1939) who sought freer self-expression as a way of avoiding neuroses caused by social repression.

Another wing of the progressive movement took Dewey for its leader. Less romantic than the former group. it was sobered by the hard facts met in the experimental method. Nevertheless it was definitely liberal in outlook. Its theory of progress was Darwinian and therefore "open-ended" in character, as William James would have said. Consequently neither the values embodied in the aims of education nor the truths included in the curriculum could take any final or fixed form. Leaning heavily on Dewey's essay, *The Influence* of *Darwin* on *Philosophy,* the progressives held to the theory that the end of education was growth and the only end of growth, more growth. (*See* also PROGRESSIVE EDUCATION.)

Traditionalism.—The progressive philosophy of education, starting at the end of the 19th century, had some difficulty gaining momentum. At first the sheer inertia of tradition impeded its pace. After World War I, however, it commenced to make such headway that alarmed traditionalists began to oppose it actively. Yet it was a decade or so before the philosophy underlying traditional education was made explicit. That one had long been implicit no one seemed to doubt. The surprising fact was that no one in recent centuries had taken occasion to state it systematically. Perhaps there was such general agreement on it that there was no occasion to define or explain it until its dominance was challenged.

On the whole, this unstated philosophy of education was conservatively religious in character. Consequently, as already hinted, it not only took a dim view of the romantic wing of progressive education but tended to be very skeptical of the Darwinian implications of the second or pragmatic wing as well. Fearful of the flux and relativity implied in the latter position. it bore down heavily on enduring values and the unchanging nature of truth undergirding education. To assure themselves of such stability, some traditionalists based their educational theories on Plato, and particularly on his notion that the real world was not this temporal one of change but an unchanging ideal one supporting it.

Others pieced together various elements of Aristotle's general philosophy to produce much the same educational result. Unlike Plato, Aristotle did not relegate change to a realm of unreality. On the contrary, he saw change as the process by which an organism is able to realize its potentialities. In fact, every species has a cycle of development from birth to maturity through which it fulfills itself. While change, growth and development unmistakably occur within this cycle, the cycle itself does not change. In this uay Aristotle managed to strike a brilliant synthesis of the static and dynamic which has appealed to his followers right doun to the 20th century. But to claim that the cycle does not change is to claim that species do not change, and to claim this is to fly in the face of Darwin's On *the* Origin of Species. The neo-Aristotelian educators were too shrewd to do exactly that. Rather they met the issue obliquely. It will be time enough, they asserted, to turn progressive when a new species of man actually emerges. In the meantime, lacking evidence that the nature of man had changed within the period of recorded history, they found a stable base for their educational theories in the apparently unchanging nature of man. Therefore they held that the aim of education, instead of varying with time and place, ought to be the same for everyone everywhere and always. The most notable advocates of this philosophy of education have been Robert M. Hutchins (1899–) and Mortimer J. Adler (1902–).

Religious Absolutes. — Still others have grounded the aims of education and the truths of the curriculum in religious absolutes. They have, consequently, a theology as well as a philosophy of education. In addition to scientific and metaphysical truth, they depend on supernaturally revealed truth as well. This last, which in no sense contradicts the other two, makes them absolutely sure of the rightness of their philosophy of education. As a consequence they feel they can teach with greater authority than can the adherents of other philosophies. This supreme confidence poses a problem for the public schools patronized by parents and staffed by teachers of contrary viewpoints. The private or parochial school has been a necessary corollary of theological philosophies of education. This position is particularly characteristic of Roman Catholic writers as nitness J. D. Redden and F. A. Ryan's *A* Catholic Philosophy of Education (1956).

Democratic and *Non-Democratic* Philosophies. — All the foregoing philosophies of education claim to be democratic. All therefore are libertarian and equalitarian in the best tradition of the French and American revolutions. Loyalty to the tradition of freedom nould cause them to lay considerable store by the worth of the individual as a rational being capable of making decisions and would therefore educate him for moral and political autonomy. Their belief in individuality, reinforced by psychology's scientific study of individual differences in the 20th century, would cause them to insist on a large measure of freedom to express this individuality. This would extend all the way from a flexible curriculum to an assurance of academic freedom in the discussion of controversial issues The connection of freedom with individual differences has necessitated some reconstruction of the time-honoured conception of equalitarianism. Instead of meaning identical education for each child, equalitarianism has come to refer to an equality of educational opportunity. But even this has not seemed altogether just. Some have held, with Platonic justice in mind, that those with superior abilities should have superior educational opportunities. Thus freedom and equality have been

seen to be incompatible dimensions of democratic education.

Not all 20th-century philosophies of education, it needs mention, have been set in a democratic frame of reference. The Fascists. for example, took exception to the individualism of democratic education. Because of an individualistic education, democracies were subject to the whims of changing majorities, Fascists thought, and therefore lacking in stable ideals. Against this ideology fascism posed the view of a state as organically something more than the sum of the individuals who compose it, as an entity that has ends of its own which, if in conflict with the individual's, are nonetheless quite superior to his personal educational hopes and ambitions. Though the individual was subordinated to the state, fascists hoped that he would actually achieve a greater fulfillment of his personality by being taught to identify it with the longer-range and less selfish interests of the body politic.

The Communists, too, took exception to the individualism of democratic education, especially in its western or capitalistic form. The motivation of individual success in the latter's schools they found quite bourgeois and inferior to social service in a proletarian society. In the C.S.S.R. talented individuals were advanced in school. not for their own interest. but because of the use their talents would be to the state as a whole. The best interests of the state were determined by the Communist party line. In this line all students were indoctrinated throughout their educational careers. Students together with their parents and teachers could have an abiding confidence in their indoctrination because it was rooted in Marxist philosophy. Drawing on a theory of culture epochs not unlike those of Herbart, Marx was convinced of the scientific inevitability of communism as the final historical epoch. With anxiety over ultimate ends dispelled, there should be no surprise in the Communist confidence that the Communist student was freer than the democratic one. Whether this contention was right or wrong, it led to some confusion when Communists described their educational philosophy in the same terms of democracy and freedom that western nations did.

The "cold war" of the mid-20th century tended to make the differences between various educational philosophies sharper and more rigid rather than more flexible and therefore more negotiable. While this outcome was unfortunate, the resounding clash of opinion focused attention on the importance of educational philosophy as never before.

For further discussion of philosophical concepts referred to in this article see separate articles on EPISTEMOLOGY; METAPHYSICS; KNOWLEDGE. THEORY OF; VALUE, THEORY OF, etc. See also PHILOSOPHY, HISTORY OF and articles on various philosophers and educators.

EDUCATION, SOCIETIES OF. Voluntary associations concerned with various aspects of education have become numerous since the early 19th century. The first were philanthropic and charitable associations to provide schools for children of the working class, such as the National Society for Promoting the Education of the Poor in the Principles of the Established Church (1811) and the undenominational British and Foreign School society (1808), in England; and such organizations as the Free School Society of New York (1805), in the United States. Subsequently, associations were formed to advocate the establishment of free tax-supported schools (*e.g.,* National Public Schools Association in England, and the Pennsylvania Society for the Promotion of Public Schools).

The following discussion is concerned principally with professional societies of teachers, school administrators and other educators.

For nonprofessional organizations see ADULT EDUCATION; PARENT EDUCATION; PARENTS AND TEACHERS, NATIONAL CONGRESS OF.

PROFESSIONAL ASSOCIATIONS

With the spread of education and the establishment of statewide or national educational systems, teaching became recognized as a profession. Professional associations of educators, formed at first on a local basis. had been founded in 23 of the 31 states then comprising the United States, when in 1857 the National Teachers association (later, National Education association) was founded. Similarly, in England, delegates from 26 local teachers' associations established the National Union of Teachers (1870).

In many countries the objectives of defending teachers' interests has led to the formation of separate organizations for teachers at different school levels. In some cases. the organizations have formed close ties with labour unions or with political parties, while in other cases such ties have been carefully avoided.

National or regional associations exist in such fields as administration, audio-visual education, business and commercial education, counseling and guidance, higher education, home economics and other areas of special interest.

The efforts of independent and professional educational associations to raise the economic and social status of the teaching profession are paralleled by their contribution toward raising the quality of teaching. They promote educational research and the application of research findings; help to establish standards for the certification of teachers; promote continued in-service training and exchange of professional knowledge through publications and conferences; establish codes of ethics for the teaching profession; inform the public on educational issues; advocate educational reform; and defend impartial and objective teaching against political and other pressures.

UNITED STATES

More than 7.500 professional associations of educators are listed in official directories. The range of their activities is very nide. They hold periodic meetings, issue publications, maintain committees and study-groups, and carry on research. The organizations are local, state and national in scope. There is scarcely a county that does not have an organization, and every city has one or more. State-wide organizations are particularly important for the defense of teachers' interests, because educational authority is vested in the several states.

The most influential educational organization in the United States, the National Education Association (N.E.A.), mas organized at Philadelphia, Pa., in 1857, under the name of the National Teachers' association. Its general purposes may be considered the objectives of many educational associations in the U.S.: "The purpose and object of the incorporation shall be to elevate the character, to advance the interests of the profession of teaching, and to promote the cause of education in the United States." Departments of the N.E.A. include, for example, those on adult education, art education, audio-visual instruction, business education, classroom teachers, deans of women, educational research, educational secretaries, elementary school principals, exceptional children. health, physical education and recreation, higher education, home economics, industrial arts, journalism directors, kindergarten-primary education, mathematics teachers, music educators, retired teachers, rural education, school administrators, school public relations, science teachers. secondary school principals. social studies. speech teachers, supervision and curriculum development, teachers' colleges and vocational education. New departments may be created and old ones discontinued or reorganized.

The N.E.A representative assembly was created in 1921. In it state and local educational associations may be represented according to the number of their members who belong to the national body. The representatives take part in business sessions and in establishing the general policy. Under this reorganization, the association undertook to carry its influence and support to every teacher in the United States. The membership was extended from 8.557 in 1918 to more than 632,000 by the second half of the 20th century.

The N.E.A. is concerned with promoting teacher welfare through the establishment of retirement systems and the assurance of tenure of position, increasing the numbers of teachers and ob-

taining reasonable teacher loads, and the defense of teachers and schools.

Many national organizations represent special interests. The American Council on Education is a federation of associations, schools and universities with special committees on education of women, education in international affairs, co-operation in teacher education and other phases of educational interest.

The American Federation of Teachers, an affiliate of the American Federation of Labor-Congress of Industrial Organizations, seeks to promote the economic welfare of teachers and to protect academic freedom. The National Council of Teachers of English is one of the largest of the many groups concerned with specific subjects and which conduct studies, hold conventions and publish influential periodicals. The National Catholic Educational association, made up of educators in Catholic institutions, serves as a clearinghouse for the exchange of ideas and as a means of promoting co-operation among the members. It seeks to safeguard and promote Roman Catholic educational interests. The American Association of University Professors is concerned with the problems of professors, particularly tenure and academic freedom.

GREAT BRITAIN

The largest educational association in England is the National Union of Teachers. From an organization of some 400 elementary teachers in 1870, it has become in the second half of the 20th century a comprehensive professional organization with more than 220,000 members, serving in all types of schools and establishments for further education. The union retains its original character as a union of local associations. The controlling body is an annual conference of about 2,000 delegates, held at Easter, representing the local associations which, for the most part, are grouped together in 60 county associations. The executive board consists of 40 members, directing a large professional and clerical staff. The union's principal objects are to associate and unite the teachers of England and Wales; to provide means for co-operation and expression of collective opinion upon matters affecting education and the teaching profession; and to secure the establishment of an efficient national system of education. It is concerned to promote an integrated system of education and a unified profession of teachers. It seeks to raise the general level of salaries through negotiations. and has the majority representation on the Teachers Panel of the Burnham (Main) committee which deals with the salaries of teachers in primary and secondary schools. The union provides legal assistance to its members and works for better conditions of tenure and service, adequate pensions, safeguards against unjust dismissal and greater freedom for the teacher. It works for educational development through membership in ministry committees and national educational bodies such as the National Committee for Visual Aids in Education and the National Foundation for Educational Research, by maintaining an information service and by organizing refresher courses for teachers.

There are four major associations of teachers in secondary schools: the Association of Head Mistresses incorporated (founded 1874), the Incorporated Association of Head Masters (founded 1890), the Association of Assistant Mistresses in Secondary Schools incorporated (founded 1884) and the Association of Assistant Masters in Secondary Schools incorporated (founded 1891). They have branches or divisions throughout England, Wales and Northern Ireland. The majority of their 35,000 members are in the schools which were termed secondary before the 1944 Education act, after which they became known as the secondary grammar schools; but teachers in secondary modern and secondary technical schools are also included in their membership, The aims of the four associations are to promote the cause of education generally, and of secondary education in particular and to protect the interests and improve the professional status of their members. The Headmasters' conference (1896) is limited to 200 members and is confined to the headmasters of independent and direct grant schools and such other headmasters as may be invited to apply for election.

Teachers in Scotland are associated in the Educational Institute of Scotland.

Other associations serve a wide variety of interests: university teachers of Great Britain are represented by the Association of University Teachers (founded 1919). In technical education, there are three main associations. The Association of Teachers in Technical Institutions was founded in 1904 for the advancement of technical education and the safeguarding of professional interests. It issues the *Technical* Journal monthly. The Association of Technical Institutions includes representatives from technical institutions in Great Britain. There is also an Association of Principals of Technical Institutions. On the administrative side, there are the Association of Education Committees, representative of the education committees of local education authorities, and the Association of Education Officers. There are numerous subject associations. The New Education fellowship. founded to promote progressive educational practice, became an internal association.

INTERNATIONAL ASPECTS

Education associations have developed considerably in the Commonwealth of Nations and in western European countries, and they are emerging also in other parts of the world. The Canadian Education association, originally the Dominion Education association, held its first annual meeting in 1892 and the Canadian Teachers federation was organized in 1920, the Canadian School Trustees association in 1923 and the Canadian Federation of Home and School in 1928. In European countries, the structure and goals of the education associations tend to reflect prevailing policies in education and the nay in which the school system is organized; thus the important Ligue française de I'enseignement with 2,000,000 members (founded 1866), aims to protect secular public education in France. Distinctions occur between primary, secondary, technical and higher education groups in France, Germany, the Netherlands and most other European states. Divisions along confessional and political lines are also common. In Asia there has been a remarkable growth of education associations in Japan, where almost all aspects of professional, political and trade union interests are reflected in the groups.

Many efforts have been made during the 20th century to create international federations of education associations. The movement has become accentuated since World War II; in most cases these federations are concerned with some single specializations. Attention should be drawn, however, to the more broadly based federations of recent origin, *e.g.*, the World Confederation of Organizations of the Teaching Profession. This was established in 1951 with strong backing from British and American teachers' associations, following negotiations between three organizations International Federation of Teachers' associations International Federation of Secondary Teachers, and World Organization of the Teaching Profession. By 1957. its membership included national associations in 52 countries. The confederation excludes from its debates all questions involving political, political party or religious controversy and makes no racial discrimination. Its purposes are to foster a conception of education directed toward the promotion of international understanding and good will; to improve teaching methods, educational organization, and the academic and professional training of teachers; to defend the rights and interests of the teaching profession; and to promote closer relationships between teachers. The confederation holds regional and world conferences, advises national groups on techniques of building professional organizations, studies particular problems, and maintains a research and information centre at its headquarters in Washington, D.C.

Among other international organizations of teachers may be mentioned the World Federation of Teachers' Unions (founded 1945), which is the Teachers Trade department of the Communist World Federation of Trade Unions, and the World Union of Catholic Teachers (founded 1910), of which the headquarters is in Rome. (H. J. AB)

EDUCATIONAL ARCHITECTURE includes a wide range of buildings in type. size and standard of accommodation They vary from a one-room rural school to a university campus; from the simplest of structures to significant examples of modern architecture.

ELEMENTARY (PRIMARY) AND SECONDARY SCHOOL ARCHITECTURE

The characteristics of educational architecture depend on the characteristics of the education for which it is designed. A rigid, unimaginative system of education will be reflected in rigid, institutional buildings; an educational system that is free to grow and experiment will require freedom in its buildings.

In the past school buildings were generally recognizable by a particular character, an identifiable architecture with a sombre dignity, real or assumed. In the 1930s, however, a change began to take place, arising in part from changes in educational theory, in part from a new attitude of architects, in which there was a growing awareness that the character of a school environment must be determined by the activities and life within the school.

The environment needed for school children in the second half of the 20th century is radically different from that at the beginning of the century. Learning has come to be concerned not only with the static processes of the mind but also with the activities of the whole body, for which are necessary not only more space and equipment but also more imaginative arrangements and treatments of space, based on a more scientific, less formalistic approach. All countries are striving to provide more educational opportunities for greater numbers of children, and large educational building programs are widespread, demanding co-operative effort of teachers, architects and administrators. (M. CR.)

UNITED STATES

Historic Development. — Since the success of representative government depends upon an enlightened citizenry, education has long been mandatory in the United States *(see* EDUCATION, HISTORY OF: *United States)*. Puritan emphasis on Bible reading and individual salvation led to the erection of schoolhouses for all classes. The middle states adopted a parochial school system supported by churches that were often able to build large schools, richer architecturally than those of New England, with separate rooms for each grade. Wealthy planters in the south generally relied upon apprenticeship and private tutoring until after the Revolution.

As neighbourhoods grew, and more pupils had to be housed than could be handled by one teacher, larger square or rectangular buildings were erected with two to four rooms off a central hallway, sometimes on each of two or three stories. The most advanced buildings had internal plumbing and tall windows; heat was provided by stoves in classrooms, later from a furnace in the cellar; most buildings were of wood, and fire was a common hazard. Some 18th-century buildings were noteworthy for architectural reasons; for example, the Academy at Schenectady, N.Y., designed by Philip Hooker. Most, however, were utilitarian, and improvised rooms were used throughout the 19th century. Henry Barnard's *School Architecture*, published in 1849, set a high standard. virtually unrealized by contemporary school buildings, and he enlisted the aid of the architect James Renwick, who incorporated Barnard's suggestions in such buildings as the Tryon Park school in New York city, which provided good light, ventilation, sanitation and safety within commodious spaces, treated in Gothic Revival style.

Such buildings, however, were not common. In 1901 E. M. Wheelwright, school architect in Boston, deplored the sad condition of school buildings. Wheelwright wanted to reduce classrooms to accommodate no more than 40 to 48 pupils and to lessen the standard room width of 28 ft., and he insisted upon better sites with play areas. The architect-engineer William Atkinson attempted to incorporate educational ideas in his design for a low building in which large window areas filled one classroom wall while the remaining walls were solid, but his farsighted scheme was shunted aside in deference to standard, multiple-story-plan types, either closed (in the form of a solid rectangle, a hollow rectangle uith interior courts or a rectangle with interior auditorium and courts) or open (in the form of the letters I. T, U, E or H).

In 1925 the National Education association issued a report, *Schoolhouse Planning,* which reinforced state and local codes to establish concise standards for school buildings. Classrooms generally became 12 ft. high, 22 to 24 ft. deep and long enough to accommodate 30 to 40 pupils at fixed seat and desk units. Daylight came from windows in one wall with a surface equal to 20% of the floor area, and artificial illumination from pendant incandescent fixtures supplemented natural light. These standards perpetuated themselves past all justification, and they distracted attention from imaginative attacks upon spaces for instruction.

Role of the School in the 20th Century. — The earliest architectural recognition of progressive education did not appear till 1908. John Dewey and his sister had incorporated into their thinking the Froebelian and Pestalozzian methods of object-centred instruction. They thought that the theatre, art and music were important instruments of education and that school architecture should reflect domestic architecture. The suburban Chicago school built by Frank Lloyd Wright for Mrs. Avery Coonley, to whom the Deweys were educational advisors, was child-scaled and set among gardens and a pool, the classroom wing containing activity spaces and specially designed furniture: teacher-student relations were informal and close. Published in the Deweys' *Schools of To-morrow,* it heralded the advent of modern schools in the middle west, among them D. H. Perkins' Carl Schurz high school in Chicago, built in 1910.

As schools came to include more students seeking training in science and technology rather than the classics, new kinds of classrooms, museums and laboratories for scientific instruction became necessary. Athletics and physical health, requiring gymnasiums and clinics for dental care, eye and ear testing and general examination, became the responsibility of the schools. The space needed by expanding curriculums was most easily provided on rural sites where buildings could be spread out. About 1915 California offered some noteworthy examples of well-planned educational facilities, such as Elmer Grey's one-story open-air school at Pasadena and Myron Hunt's patio schools with one-story shops and classrooms surrounding a cloistral walk.

The belief that the school should be the cultural centre for the community led often to the planning of schools on a community and regional basis. Motor transport made it possible to plan large consolidated schools on undeveloped land where buildings could be disposed with a low density and large playgrounds, athletic fields. parking areas and landscaping. Kindergartens became accepted portions of elementary schools, and classrooms in elementary schools generally contained movable furniture, sinks, work counters and abundant storage space. A floor area of 30 to 35 sq.ft. per child was common, and the resulting deep rooms required multiple sources of daylight. Hence, single-story structures prevailed. Often there were playrooms, auditoriums and gymnasiums, though in small schools a multi-purpose room served several functions, including that of a place for public gatherings. Probably the most significant building was the Hempstead high school on Long Island, N.Y., built in 1920 by Ernest Sibley. After a careful environmental study, which showed the need for an adult centre, the school was designed in two sections, with a classroom wing and a community block containing the auditorium, gymnasium, shops and administrative offices.

Led chiefly by European *émigré* architects, U.S. school designers after about 1935 experimented with the distinctive forms of modern architecture; particularly notable were those designed by R. Neutra, Eliel Saarinen and W. Lecaze. Their work culminated in one remarkable classic of modern design, the Acalanes high school at Lafayette, Calif. (Franklin and Kump's design, 1941). Built on a finger plan, the school had pavilion-type classrooms spread outward from a core containing the administrative offices. space for athletics, an auditorium, cafeteria and shops. Growth of new communities during World War II offered architects opportunities to design modern schools like Saarinen's at Center Line, Mich., and Franklin and Kump's at Ducor. Calif. Intensive investigation of school needs by architects and educators around mid-century, such as that conducted by the Texas Agricultural and Mechanical college, led to results like William Caudill's core scheme for classrooms, where one compact unit contained all mechanical equipment.

Types of Plan. — Seven basic school plan types may be dis-

cerned: (1) the wing plan, with classrooms on one or both sides of central corridors; (2) the finger plan, with several pavilions of classrooms projecting from a central core; (3) the cluster-type plan, with two or four classrooms grouped about a play space; (4) the loft plan, with large building blocks divided into classrooms and corridors; (5) the multi-use-corridor plan, in which the circulation space serves also as activity space for classrooms; (6) the core-type plan, which eliminates corridors and places the classrooms back to back against a utility core; (7) a campus plan, used for a few large high schools. in which separate buildings are erected for classrooms, shops, gymnasiums and auditoriums. Each of these has advantages and inherent disadvantages.

Particular study should be made of several schools. The Blythe Park school at Riverside, Ill., by Perkins & Will, and numerous other schools by these architects, showed a human quality in design that had wide appeal. The climatic conditions of the south presented special problems which were met, for example, in the shaded courtyards of the elementary school at West Columbia, Tex. (1952; Donald Barthelme & Associates), and in the umbrella-type roof protecting clusters of classrooms in the elementary school at Port Arthur, Tex. (1952; Caudill, Rowlett, Scott, Neff & Associates). Cluster-type plans for more temperate climates were developed for the Heathcote elementary school at Scarsdale, N.Y. (1953; Perkins & Will), and the elementary school at Darien, Conn. (1953; Ketchum, Giná & Sharp). An example of the loft plan appeared in the high school at Killsdale, Calif. (1953; John Lyon Reid). The Sunset Community centre, San Francisco, Calif. (1952; Wurster, Bernardi & Emmons, co-ordinating architects), was but one of many examples in which large school complexes were used as centres for community educational, recreational and social life. Although these and other schools were outstanding, they did not pass uncriticized, particularly by those who questioned the expense or luxury of schools like the Heathcote at Scarsdale. (See also CITY PLANNING.)

Private Schools.—Private-school architecture contains a few unique problems, notably those of providing residence and dining facilities for the school community. In general, private schools utilize the campus type of planning. Except for a few notable schools like Cranbrook, at Bloomfield Hills, Mich. (Eliel Saarinen), their architecture has been conservative. Lawrenceville school (Lawrenceville, N.J.), Phillips Exeter academy (Exeter, N.H.) and St. Paul's school (Concord. N.H.), for example, followed the fashions prevailing at Ivy league colleges, and not until after mid-century did a few schools like Phillips academy (Andover, Mass.) begin to exemplify modern design. (A. B.-B.)

GREAT BRITAIN

Historical Background.—From their medieval beginnings as part of monastic establishments, schools in Britain have been closely associated with the church, and the buildings, often situated in the shadow of the churches, were markedly ecclesiastical in character. It was not until nearly the end of the 19th century, with the advent of school boards empowered to provide and maintain school accommodation for all children from 5 to 13 years of age. that the beginning of an organized system of education, and consequently of school building, began to emerge. The board schools, many of them still to be seen, reflected in their planning and character the type of education for which they were built. Their design was dominated by the requirements of supervision and control, and the materials of which they were constructed were characterized by strength and endurance. Such schools were—and still are—almost indestructible. Classrooms were tightly planned around a central hall or marching corridor, with consequent problems of noise, poor ventilation and inadequate lighting.

With the establishment of the board of education at the turn of the century, and the beginning of local education authority administration, new standards began to influence school design. The Schools medical service, for example, drew attention to the health of children, and the first building regulations appeared in 1905. laying down requirements for such things as lighting, ventilation and hygiene. Classrooms became standardized in area and height, and more open planning with cross ventilation was introduced. Accommodation was increased to include such spaces as practical rooms, gymnasiums and assembly halls. A pattern of school layout became established: on restricted urban sites, a symmetrical quadrangular plan arrangement; in areas where space was less restricted, long wings of classrooms strung along single loaded corridors. Few schools were more than two stories in height; many mere on one floor. Roofs were pitched, and up to the 1930s elevations were broadly neo-Georgian in style. During that decade the modern architectural movement began to influence school design. and a new style based on a more imaginative approach was beginning to emerge when World War II put a stop to school building,

After 1945.—The schools of the public educational system in England and Wales were designed and built by the local education authorities and by the churches, and in Scotland entirely by the local authorities. These largely autonomous bodies were free to adopt whatever kind of school architecture they wished, provided their buildings neither exceeded the maximum cost nor fell below the minimum standards laid down by the central government. Most schools were designed in the architects' departments of local authorities, the remainder by architects in private practice.

It was necessary to build large numbers of schools after 1945, partly because of bomb damage, movement of population and the raising of the school-leaving age, but mainly because of the rise in the birth rate Between 1945 and 1960 the school population in England and Wales increased by 40%. By Dec 1960, accommodation for 2,800,000 new places had been provided. and many improvements carried out to existing accommodation. at a total cost of £620,000,000, excluding architects' fees and furniture and equipment. Although building costs doubled during this period, the cost of new schools was actually reduced without educational loss. In 1960 the average area of the new schools was approximately 42 sq.ft per pupil under 11 years of age and approximately 72 sq ft. per pupil over 11 years. Of this area, roughly 60% was teaching space, the proportion of nonteaching space having been considerably reduced. An even larger school building program was planned for the 1970s, in order to raise the standards of old schools. to relieve overcrowding and to implement the policy of expanding secondary education envisaged in the Education act, 1944.

In 1945 each authority set out to survey its long-term educational and building requirements, and subsequently worked to an agreed annual building program in order to ensure the best distribution of available resources. In 1949 the ministry of education set up a development group within its architects and building branch, in which educators, administrators and architects together undertook investigation and actual school design and building, in collaboration with individual local authorities. In this way solutions to selected educational and technical problems were put forward, and the experience thus gained was shared; there was a working relationship between local and central authorities, between educators, administrators and technicians. After the war, developments in school architecture were in part encouraged by the stringent conditions under which schools had to be designed and built; large numbers nere needed at a time of limited financial resources, competing programs of national reconstruction, rising costs and shortages of materials and of manpower.

Prefabricated systems of construction were widely associated with Britain's new schools, though many schools were of course built by traditional methods. Prefabrication did not develop from architectural dogma, nor as a temporary expedient in an emergency. Although it was indeed an answer to acute shortages of building materials and of site labour, it was vested with permanent architectural and educational qualities. Prefabricated schools proved not only to be sufficiently competitive in terms of cost hut also to result in higher productivity on the building site. They combined standardization. for large-scale economical production, with flexibility in plan and section; the method, not the result, was standardized. Such schools brought with them an informality which was in sympathy with modern trends in education. Prefabricating methods were applied to steel. concrete, timber and aluminum, and as a result an important section of the building

industry grew to serve the school building program.

Experience has shown, however, that the success of such architecture depends on the close and continuous association of architect, educator and administrator. Its development has been made possible because the majority of schools were the responsibility of local authorities who employed both educators and architects, and because of the stimulus the ministry's development group was able to give. The collaboration of several local authorities, in order to increase the benefits of the prefabricated systems, was a logical outcome, and proved that further advances in terms of costs and quality could be achieved, provided that higher educational and architectural quality was the motive rather than mass production for its own sake.

School architecture is not only a question of building techniques; at the beginning of the 1960s the best schools were the result of continuous and joint development of both architecture and education, and their designers were sensitive to changing needs of education. These schools had not only formal architectural significance but also a quality of environment which was dependent on the sensitive and imaginative treatment of such things as acoustics, heating, lighting, colour and furniture. In all these aspects the school building programs promoted research and development, to the advantage of the building industry as a whole, and of school architecture in particular. School architecture in Britain does not have the stamp of personality because it has not been influenced by dominant individuals; it has been a concerted and largely anonymous effort of many specialists. (M. CR.)

Public Schools.—The architecture of English public schools was created piecemeal, according to the date and type of the educational foundation concerned, and in this its history follows that of the Oxford and Cambridge colleges. Isolated examples of late medieval or early Tudor buildings, such as Eton and Winchester, were followed by sporadic development culminating in a spate of Victorian building in the second half of the 19th century. The superficial styles of these buildings varied, but in general some form of Gothic revival was most popular, and the collaboration of public school governors with their architects has resulted in very little work of outstanding architectural merit. A considerable degree of austerity is common to many of the interiors, although this does not apply in cases such as Stowe where a fine 18th-century mansion mas converted to school use. (E. C. D.)

EUROPE

Continental European schools in the 20th century, like those of Great Britain and the United States, were in need of rebuilding, though little was done before the middle of the century when Britain began to play a leading part. New schools clearly reflected the educational ideas of such 19th-century reformers as Froebel and Pestalozzi. Glass-walled pavilions were set in gardens in close touch with nature and in imitation of the ideal domestic architecture. Classrooms were often set at an angle to each other to avoid the massed effect of a block and to provide a feeling of intimacy. Health facilities, such as showers and rest rooms, were provided increasingly, and classrooms and corridors were used as recreational spaces and for handicrafts and practical activities. The emphasis was on artistic design and colour that was likely to appeal to children.

Advanced building before World War II was mainly in response to the needs of handicapped and ba'ckward children. In Holland J. Duiker built an open-air school at Amsterdam, remarkable for its toner of glass-sided balconies. Near Paris E. E. Beaudouin and M. Lods designed the Suresnes school (1935–36) set in gardens and provided with extensive medical services and collapsible canvas beds for afternoon resting. Hermann Baur's primary school in Basle, with copper roofing and glass walls, was built on a child scale.

After 1945, occupied or devastated countries faced the need for reconstruction at a time when their national economics were too strained to admit much school building. The most notable schools were constructed, therefore, in countries which escaped the worst effects of the war. P. Hedqvist followed up his prewar Bromma high school with a communal school at Stockholm (1944) and the brick Ahrahamsberg school (1946). Nils Ahrbom and H. Zimdahl built the Eriksdal school, with its tunnel-like sports hall, and Xke Lindqvist Björkhagen elementary school. In Switzerland the Bachtobelstrasse school at Zürich (A. H. Steiner, city architect; 1946) continued the theme of building for the particular needs of children by constructirig timber pavilions surrounded by trees, while the Lucerne school of Felsberg (E. Jauch and E. Burgi; 1948) followed a similar idea with two-storied buildings stepped up a slope. The Parc Geisendorf at Geneva (G. Brera and P. Waltenspuhl) with its mosaic floor was similarly adapted to child living. In Finland the Tapiola kindergarten (Viljo Rewell; 1956) and the Kulosaari school (J. Jarvi; 1954–55) were both built near Helsinki; the latter is remarkable for the contrasting diagonal lines of its brick hall.

In the Netherlands W. M. Dudok's school at Hilversum was a superb example of modern planning; the Spinoza school at Utrècht (D. J. Schenk) used exterior colour and emphatic vertical lines to counter the length of its pavilions. Brederode school, Bergen (J. C. de Vries and T. Wijnalda) provided yet another original ground plan.

After the Suresnes school and that which André Lurçat erected at Villejuif in 1932, French architecture developed little that was new, though provincial construction—for example, the Poitiers scheme of 19 projects for village schools—continued. In such schools as the Paris Lycées at Boulevard Bassières (1953) attempts were made to vary the classroom blocks.

In Italy, Mussolini's building enthusiasm unfortunately did not extend to the schools, and though in other fields Italian architecture after World War II was both interesting and enterprising, provision for schools was inadequate.

Recovery from war devastation in Germany was slow but by the 1950s, and often with financial assistance from the United States, schools like the Gansberg school (G. Wilhelm) and the Gymnasium (H. Briillmann) at Stuttgart, the Mainz-Gustavshurg school (F. Novotny) with pavilions and covered ways, and the Hanover Gymnasium (city architects department with W. Dierschke and A. Bätjer-Kiene) were built. The ability to plan from the beginning (a result of war devastation) rather than to carry out extensions of old schools favoured the architect, and though the new schools were not often outstanding for their architectural originality, they were built in large numbers.

Later interesting new buildings were Danish: the Sond school at Copenhagen (K. Gottlob; 1947) is notable for its dramatic hall with oval galleries and its glass-sided ramp; Arne Jacobsen introduced a variant on the garden theme with the Søborg school, Copenhagen (1952), and the Munkegaard school at Gentofte (1952–56), designed as a series of one-storied classrooms regularly checkered with courtyards.

UNIVERSITY AND COLLEGE ARCHITECTURE

HISTORICAL DEVELOPMENTS

From the 12th to the 19th centuries university functional requirements remained simple—instruction was mainly oral and required little equipment—and until the end of the period architectural changes mere due either to changed building technique or to the upheaval of taste marked by the Renaissance. Most universities other than Oxford and Cambridge from the 16th century onward followed the general type of Renaissance palace, a large square block in an urban street, with a courtyard surrounded by one or two galleried floors containing classrooms and, in some cases, rudimentary living accommodation. Examples are Cracow (1194). Padua (1542) and Bologna (1562–67).

The popular conception of university architecture, however, owes nothing to any of these centralized continental institutions. It is based on the Oxford and Cambridge colleges, which from the 13th century to the present have been societies of teachers and students living as self-contained and sovereign communities which in loose federal association form the two universities, select their entrants and regulate their academic affairs. Nearly all the colleges consist of one or more quadrangles approached by a tower

gated against riots of townsfolk or unruly students. Within this arrangement the outstanding elements are a chapel, dining hall and kitchens, a library and living quarters. The latter consist of separate sets of rooms, each with a living room, bedroom and pantry, built in pairs up staircases. The domestic scale of the colleges is due to this arrangement: the quadrangles are seldom more than 100 ft. square, their sides punctuated every 30 ft. by the small staircase entrances, and, apart from towers and spires, none of their buildings higher than 40 ft. or so to the ridge. The college buildings, apart from exceptional chapels like King's, Cambridge, and Christchurch, Oxford (which also doubles as a cathedral), were and are severely simple and unpretentious, typical of the humbler domestic architecture of their periods. By mid-20th century standards they are mostly cold and damp, with few bathrooms and uncertain hot water. But the calm isolation of their quadrangles is still valued in a noisy age; their cool la ns, generous gardens. mellow brick and crumbling stone, and above all their intimate scale, have endeared them to generations of undergraduates and made them imitated, often inappropriately, throughout the world.

Such noncollegiate buildings as Oxford and Cambridge possess remain relatively few, but they include some of the outstanding masterpieces of the English Renaissance style: Sir Christopher Wren's Sheldonian theatre (1664–69) used for ceremonial conclaves, the Clarendon building (1711–24) and James Gibbs' Radcliffe Camera (1739–47) at Oxford; and the Senate house at Cambridge (James Gibbs, 1722–30).

A new phase of development began in mid-18th-century France ivith the establishment of the technical colleges of the Écoles des Mines, des Ponts et Chaussées, et du Génie. Growing industrialization demanded institutions for training scientists and technologists instead of the lawyers or adininistrators of the older universities. Germany, importing French scientific talent under Frederick the Great, was the first to see clearly the role of the scientist in the modern industrialized state and to equip rich and large laboratories like those at the Vienna Technische Hochschule in 1815, Karlsruhe (1825), Dresden and Stuttgart (both 1829) and Darmstadt (1836).

These new laboratories, however, were housed in makeshift adaptations or in temporary buildings. By an ironic paradox, just when building requirements had reached these unprecedented levels of complexity, architecture had been demoted to a merely decorative art. By the time other countries, spurred perhaps by German success in the Franco-German War, awoke to the importance of science as a university subject and to the need for new universities in industrial centres like Manchester (1880), Birmingham (1900) or Liverpool (1903), architecture had ceased entirely to be a function of the activities it housed. It was regarded mainly as a symbol of prestige. The new universities, even those of the United States and the newly developed countries of the Commonwealth of Nations, imitated the colleges of Oxford and Cambridge with their ruling-class associations, irrespective of the institutional pattern they adopted. Examples of chemistry and physics laboratories modeled on medieval monastic refectories can still be found in Leeds and Manchester.

Modern Universities

Institutions on the continental noncollegiate pattern and the 19th-century industrial foundations, catering as they did mainly to local students, ceased to sponsor halls of residence. After the 1920s, homever, interest in them revived, not only because of the shortage of other lodgings but also as a partial corrective of overspecialization. It was hoped that communal life with teachers, researchers and students studying different subjects would lead to understanding of the spirit and interrelation of the different branches of learning, and act as a civilizing influence. Unfortunately: many halls of residence built with such aims in view have imitated the Oxford and Cambridge precedents (especially in England, much less so in the United States) without considering factors such as the shortage and high cost of domestic labour, the modern reaction against most forms of paternalism and the fact that universities are now coeducational. Interesting experiments in nhich residence aims at making the student mature in an environment more akin to the extramural world have been made; groups of accommodation are much smaller and each has its own eating and recreational space in which students can live together without supervision. A good example is the University College of Sorth Staffordshire, Keele, Eng. An even more progressive experiment has been made — nearly a century after the admission of women to the universities — at the Golden Gate Theological seminary, Marin County, Calif., where students ranging from young men and girls to families with children all prepare for missionary work. The group living experience, it is thought, can contribute to the educational preparation, and thus the seminary plan includes units domestic in character and scale, with patios, play yards and carefully detailed landscape.

Many modern universities encourage, with a fairly generous capital outlay, activities such as debating and amateur drama. Student unions form a centre for such activity, often including a central dining room for the large body of students who still remain nonresidential and sometimes a concert hall and a health centre.

The modern university still requires a large proportion of building with fairly unspecialized functions suitable for teaching "by talk and chalk." Old buildings can often be adapted and new ones need differ from them only in that they are more comfortable, although a groning number of universities reach large audiences by means of closed-circuit television. The major share of university capital. homever, is invested in specialized laboratories and demonstration theatres for science and medicine, engineering and technology. This poses problems in housing of complicated equipment. movement of personnel, fire resistance, protection against radioactivity and disposal of radioactive waste. Finally. the pace of scientific and technological development demands that such buildings be capable of ready modification and enlargement.

Thus, there is no real validity in attempts to impose on buildings of this kind a recognizable academic stamp. Economic conditions and the pressure of demand insist that the fullest use be made of modern building techniques and consequently modern forms. At the beginning of the 1960s, however, even the most adventurous universities had only drawn abreast of the position reached by the vanguard of modern architecture in the 1930s. There was nothing in the university field to match the English prefabricated schools (see above) nor was there any obvious trend toward basing the concept of buildings on the fully considered needs, educational, humanistic and technical, of the people who live and work in them. In the national universities of South America the most extravagantly baroque tendencies of the modern movement have been allowed full play, while similar grandiose pretensions characterize the vast buildings for Moscow university on the Lenin hills, although there the style represents that curious bastard revivalism called "people's architecture" which marked the Stalinist era. Incomparably the best exceptions to this generally dismal scene are found in the United States (Brandeis university, Waltham, Mass.; Drake university. Des Moines, Ia.; Santa Barbara college, University of California); in Sweden (Chalmers university, Göteborg); in Denmark (Aarhus); and in Finland (Turku). In these places real attempts have been made to match the environment to the quietist and reflective aspects of the university ideal.

Layout and grouping are as important as the individual buildings. The modern university consists of numerous specialized teaching departments, which. apart from general matters of administrative policy, are largely self-contained. Nevertheless, there are strong practical reasons why different departments should not be too widely dispersed. First is that they use many services in common; second. economy dictates that they share central libraries, lecture theatres: eating places and social facilities; and third, even though a student may specialize in one department, he usually requires supplementary teaching from another.

Before 1939 the slow growth of universities frequently prevented coherent grouping or comprehensive planning. But after World War II their rate of building increased rapidly, either to keep pace with the developments of resurgent nationalism, as in Africa and Asia, or, as in the case of Great Britain where building

for six new universities was to be started in the 1960s, to meet the threat of competition from abroad. In these instances, aided by powerful state finance, new universities usually enjoy the benefit of one large site sufficient to contain the whole complex undivided. In this respect they are able to follow the American tradition rather than the European — the campus tradition first epitomized in the University of Virginia at Charlottesville, designed between 1817 and 1825 by its first rector, Thomas Jefferson, aided by Benjamin Latrobe. On either side of broad lawns, rows of pavilions for lectures and teachers' residences alternate with dormitories for students. Outside these, two ranges of dormitories and dining halls mark the ends of fine gardens. A rotunda, modeled upon the Pantheon, is the library, presiding over the whole "academical village." The plan assures variety within a closely knit community, and it affords good circulation, quiet, privacy, ventilation and safety from fire.

The demand for playing fields and other sports facilities further inflates the size of the new university campus. For the first time since the idea of universities originated, they have become forced growths on virgin sites of 150 ac. or more, situated either in open country or on a suburban fringe, withdrawn within themselves, remote from transport and services, shops, entertainments, housing and any cultural activity not of their own making.

Joseph Hudnut, dean of the Harvard Graduate School of Design, has pertinently written:

Theories of esthetics, stylistic uniformities and sentimental associations are less trustworthy guides in our search for form than are those adaptations to service and techniques which anchor our buildings in a reality which, however harsh, is ever present and known. . . . Form is the medium through which those meanings we have discovered in buildings can be apprehended . . . active and persuasive in their consciousness . . . People who build universities usually believe in them, their need for form will not be satisfied by convenience in operation merely, . . . but by the way in which the university idea is given definition and eloquence. *(Architectural Record,* p. 161, Aug. 1957.)

The difficulty facing the universities in the second half of the 20th century is that many of them are being forced into emergency improvisations to counter the world shortage of scientists and technologists; as a result the university ideal has become blurred and indistinct.

EDUCATIONAL PSYCHOLOGY is concerned with the psychological factors underlying the education of children and adults. It tries to show how the schools or other educational agencies can foster the full development of an individual's potentialities. It recognizes that the schools have a role in physical. social and moral development as well as in intellectual training. Psychology is fundamental to teaching in the way that physiology is to medicine. The teacher who tries to understand the thoughts and behaviour of children, to control them and to guide their learning is *ipso facto* applying educational psychology. Even if he has not studied the subject as a scientific discipline he will evolve his own amateur psychology largely on a basis of recoilections of his own upbringing and by generalizing from practical experience.

That psychology can provide the "why" of teaching methods is more fully recognized in the United States than in any other country, and throughout the 20th century curricula and techniques have been notably influenced by psychologists' views. As a result educational psychology has been partly. though not wholly, responsible for many fashions in education, in particular the "child-centred" and other progressive movements, and it has been unduly blamed for the low standards of achievement that are popularly attributed to these movements. In Great Britain educational psychology has received less general acceptance. The course in principles of education at most training colleges for teachers is as much philosophical and historical as psychological, and few teachers are trained by lecturers who are competent exponents of modern psychological knowledge. Moreover, among teachers, administrators and parents there is a traditional distrust of the theoretician; hence a rejection of the idea that research can solve any of the practical problems of the classroom. Nevertheless. changes have occurred, though slowly. Especially in the infant school, for children aged five (or under) to seven, more attention is being paid to the psychological needs and capacities of children. In the junior school it is becoming recognized that psychologists can help in the remedial treatment of seriously backward or maladjusted pupils, and that psychological techniques provide the most reliable means of allocating pupils to suitable forms of secondary education. Both these trends, however, remain subject to constant attack in Britain,

It must be pointed out that the term "educational psychologist" is frequently used in Britain to refer specifically to a teacher who has been trained to carry out work with backward and other "problem" children and to advise individual schools or local education authorities on guidance and allocation of children — a teacher who is, in other words, a member of the Schools Psychological service. But it would be more accurate to label these people school psychologists (or perhaps, as in the United States, counselors), and to call educational psychologists persons who have been trained in general psychology and have then specialized in educational matters. School teaching experience is useful to them, but other expeiience with children or work with adult students may be equally relevant.

Educational psychology is not so much a distinct subject as a collection of relevant portions of child psychology and development, learning and motivation, social psychology, mental hygiene and counseling. the psychology of individual differences and mental measurement. *(See* also CHILD PSYCHOLOGY AND DEVELOPMENT; LEARNING; MOTIVATION; DIFFERENTIAL PSYCHOLOGY; PSYCHOLOGICAL TESTS AND MEASUREMENTS.) There is a plethora of textbooks on educational psychology in which these diverse topics are presented in simplified form. The more advanced student usually has to turn to separate treatises in each of the above-mentioned fields. On the other hand, some writers aver that psychology in the classroom is not merely an application of academic psychology. In any case it includes the study of a number of factors which are unlikely to be dealt with elsewhere, such as the processes involved in teaching reading, arithmatic and other school subjects; the measurement of educational aptitudes and attainments and their prediction; psychological factors in the teacher's own adjustment to his duties; and the characteristics of social groups in the school environment.

A history of educational psychology would likewise be mainly a history of psychologists who have made their major contributions in other fields, the only outstanding exception being E. L. Thorndike, whose three-volume treatise, *Educational Psychology,* was published in 1913. His chief precursors in the United States were William James, whose *Talks to Teachers* appeared in 1899, and Stanley Hall, who wrote on *Adolescence* in 1904. In England James Sully was one of the first to study children psychologically (*Studies of Childhood,* 1895), and James Ward began to lecture to student teachers in 1880. *(See* also PROGRESSIVE EDUCATION; ELEMENTARY EDUCATION; EDUCATION. HISTORY OF.)

Learning Theories.—A major difficulty in presenting educational psychology as a consistent discipline arises from its varied origins. As a result of its reflection at different times of the many

different schools of psychology, it has not infrequently given contradictory advice to teachers. Classical associationist theory, together with Hermann Ebbinghaus' work on memorizing nonsense syllables and Thorndike's experiments on animal learning and transfer of training, culminated in the connectionist view of learning. Education mas conceived as the building up of connections in the mind between specific ideas or skills through repeated practice and the reward or reinforcement of correct associations. It was even stated that: "You learn what you learn. Nothing in the mind ever spreads." Thorndike aimed to break up the school curriculum into small steps which could be acquired cumulatively and to concentrate on items of knowledge which would be useful in adult life—the "social utility" approach. In part this was a reaction against the fallacies of 19th-century faculty psychology and theories of formal discipline, which had regarded education as the development of such faculties as reasoning, memory and imagination by the exercise of the mind, preferably with classical studies.

The connectionist approach certainly had some value; it was further elaborated in the light of Pavlovian conditioning and of C. L. Hull's, E. R. Guthrie's and B. F. Skinner's behaviouristic learning theories. It has led to the production of teaching machines, which appear to be remarkably efficient for courses ranging from engineering to foreign languages. The virtue of these machines lies in the skilful breakdown and organization of the course into a series of steps, the acquisition of each step being immediately reinforced by knowledge of progress, and the devolving of responsibility upon the individual student. They are sometimes criticized, however, for eliminating the social aspects of classroom learning.

More appealing, perhaps, to the teacher are the opposing group of field or Gestalt theories of learning (*e.g.*, those of Kurt Koffka, Max Wertheimer, E. C. Tolman), which stress the grasping of relationships and insight into meanings (*see* PSYCHOLOGY, HISTORY OF: *Gestalt* Psychology). Even the learning of multiplication tables! it is claimed, depends more on the understanding of number relations than on rote memorizing; and the education of the dull as well as of the bright child should be envisaged as a process of discovery or problem-solving, with the teacher helping to guide his interpretations. It should aim, also, at maximum transfer; *i.e.*, at the development of concepts, skills and attitudes which can be applied to novel problems in the future. The early experiments, which influenced Thorndike's views, suggested that transfer is possible only insofar as specific elements of the previous training enter directly into the new task. But most investigations since then have shown appreciable transfer to occur, particularly among brighter children or when the teacher succeeds in bringing out the wider implications of the instruction.

Motivation.— From James and Thorndike onward, psychologists have stressed the importance of motivation to learn, pointing out that no amount of training will produce improvement without it. But it was, perhaps, mainly under Dewey's influence that education, in the United States at least, became conceived in terms of the child's own activity rather than of dictation by society. In England, William McDougall's theory of instincts as the fundamental sources of human motivation was widely accepted by educationists, and his views on sentiment formation provided an intelligible account of character development. In both countries there was early recognition of the value of psychoanalytic concepts in explaining the irrationalities in young children's behaviour and their dependence on the teacher as a parent substitute. With the realization that play is not just a relaxation from work but is the child's natural method of learning and sorting out his concepts of the world and of adults. a remarkable revolution occurred in the approach to young children. However, both Freudian theory and behaviourism undermined the notion of universal instincts, and behaviour is now explained more in terms of drives or needs and of culturally determined goals. There are, of course, the primary organic drives, which must be reasonably satisfied if the child is to be motivated to learn anything, but the secondary needs for psychological security and freedom from anxiety, for exploration and adventure, for exercise of and progress in bodily and mental skills and for acceptance by and contribution to the social group operate in most forms of society without having to be regarded as innate, causal agencies. It was the tradition for schools to ignore or repress such needs, whereas now they aim rather to enlist them in support of learning.

Maturation.— Not only is the child a dynamic being, not a mere stimulus-response mechanism, but also his learning depends on the stage of development or maturity of his perception, intelligence and temperament. Genetic factors rather than training determine when he can walk, and they play an important part in his capacity to make useful progress in reading or handwriting, in formal grammar or algebra and in appreciating art, literature and philosophic concepts, as well as in his sexual development. Therefore, too early an introduction to some skill such as reading may engender a dislike inhibiting progress at a later age. A. L. Gesell and many other workers have traced a fairly orderly sequence in the appearance of bodily and linguistic skills despite variations in rate from child to child and marked variability in the day-to-day performance of the same child. However, this does not mean that optimum ages can be laid down for tackling successive stages in the school curriculum. although attempts at this have been made, as in C. Washburne's investigations of arithmetic learning. Apart from individual differences, too much depends on the method of presentation to make such schemes practicable, and it is probably expedient to introduce the tool subjects well before the age of maximum absorption. Tests of readiness to begin reading have been based on perceptual discrimination, vocabulary and intelligence, but they do not seem to be notably more predictive than teachers' observations of children's pre-reading activities and interests.

In the 1950s and 1960s the work of Jean Piaget at Geneva attracted great attention among European educational psychologists. His findings on the development of children's spatial and numerical concepts and their understanding of the world and of morals are as highly relevant to the work of the primary teacher as is his account of the emergence of more abstract or formal reasoning to the secondary teacher. His notion that distinct levels are reached at particular ages is not, however, accepted everywhere. Longitudinal studies in the Cnited States lay more stress on individual patterns than on uniformities in grouth curves. Moreover, the theoretical antithesis between maturation and learning is breaking down. a child's readiness for any school subject or any social learning is the cumulative product of genetic influences and experience.

Thorndike's finding that cognitive learning ability increases up to the age of 25 or 30 is important in adult education, even though it is probably untrue of many motor skills, including language pronunciation. It suggests that adults' difficulties in study are due more to their having to provide their own motivations than to any decline in their abilities, which does not become considerable until after the 40s.

Individual Differences in Abilities.— The development of methods for measuring intelligence and attainments was of major importance in breaking down the notion that all children of the same age can be taught at the same rate. Alfred Binet's device for expressing intellectual development in mental age units, and the analogous formulation of reading. arithmetical and other "ages", showed that the brighter children in a given age group may well be two or more years advanced beyond the average of the group, and the duller ones (even eliminating the mentally defective) two years below; it was shown also that this range widens with increasing age. The production of well standardized tests of intelligence or of such component factors as verbal comprehension, reasoning, spatial ability, etc., as also of tests of scholastic attainment, has become a major industry among educational psychologists in view of the demonstrable value of such tests for surveys, grading. diagnosis of difficulties, selection and guidance. The earlier notion that intelligence tests could measure a child's basic educability regardless of any effects of his upbringing is discredited, although, within a homogeneous cultural environment, these tests can be shown largely to reflect genetic differences between children. But, even when regarded as measures of general thinking capacity developed up to a given age, they are quite efficient for the prediction of future educational attainment and even of vocational level,

as illustrated by L. M. Terman's follow-up of high-scoring children over a period of 35 years.

There is still much controversy as to the bearing of mental measurement on school organization; *i.e.,* as to whether it is advisable to grade children by ability, so that those in any one class shall not differ too widely. This is common practice in England. Classes within each age group are usually graded, and approximately the brightest 20% are selected at 11 years of age for more advanced secondary education in grammar schools. But this system is widely criticized, both because children vary in their different abilities and change as they grow older and because of what are held by many to be the undesirable social effects of such grouping by ability. In the United States, on the other hand, where more attention has been paid to social than to intellectual "readiness," opinion is veering toward greater differentiation, either by accelerating bright children or by enriching their curricula.

There has been much testing of sex differences, rural-urban and racial differences, differences between socio-economic classes and of the effectiveness of particular teaching methods (*e.g.,* instructional films). Educational psychologists have also made notable contributions to the technique of examining (see EXAMINATIONS), having demonstrated the serious unreliability of conventional essay-type examinations, due to variations in standards and subjectivity in marking. The "objective" examination was developed in the United States; in it the student chooses one from a number of presented answers and scoring is wholly objective—often, indeed, being done by an electrical device. Well constructed tests are by no means confined to assessing knowledge of detailed facts; they are used for evaluating the achievement of broader educational objectives—understanding and application of principles, critical judgment, etc. However, like the conventional essay examinations, they have their dangers; for example. they often stimulate undesirable methods of study and coaching.

School Psychological Services.—Among the most notable applications of psychology in education are the attention given to deviant children (e g., the physically handicapped, the backward and feeble-minded and the emotionally maladjusted) and the help made available to normal pupils nith vocational or other problems. There are child guidance clinics, staffed by psychologists, psychiatrist. and social workers, for treatment of the maladjusted, besides specialized agencies such as schools for the deaf or for the low-grade mental defective. Most British local education authorities also provide diagnostic and remedial services for the backward in educational clinics, special classes or special schools. School-leavers are assisted in their choice of jobs by the Youth Employment service. by (relatively untrained) careers teachers or by psychologists of the National Institute of Industrial Psychology. In the United States it is more common to have trained counselors in each school. responsible for educational and vocational guidance conceived as a continuous process.

Methods of Learning.—It is difficult to select the moat significant implications of the vast number of investigations, stemming from diverse theoretical standpoints, which have been made into various aspects of learning. Early experimenters concentrated particularly on the study of rote memorization, showing the effects of good distribution of learning periods upon acquisition and retention and of retroactive inhibition or interference by subsequent learning of similar material. They showed, too, the value of active reproduction or self-testing as contrasted with passive repetition; the effect of overlearning and of the pupil's awareness of his own progress; and some advantages of studying a lengthy task as a whole rather than in parts. Studies of manual skills drew attention to the irregularities of learning, to the existence of stale periods or "plateaus," to the effects of environmental conditions and to the importance of incentives. Later writers, however, were more interested in finding common features in the much nider range of learning that goes on in schools, pointing out that children are continually acquiring concepts and insights, techniques of thinking and sets and attitudes over and above the information or habits that are the immediate objects of instruction. They can learn, for example, habits of inattention; they can learn to co-operate with others, to compete with them or to cheat.

The general pattern of learning, as L. J. Cronbach points out, is as follows: faced with a new task or situation, the learner perceives or interprets certain features of it, depending on his motivation and on his "readiness" (*i.e.,* his aptitude as developed by relevant past experience). He makes a trial response to it, and if this is successful in the attainment of his goal it is followed by satisfaction and reinforcement. If it is unsuccessful he may reinterpret and make a new trial, or else behave nonadaptively. developing feelings of frustration and inferiority or giving up. The teacher's first function, therefore, is to set significant goals or purposes to the children, if possible arising out of their needs—in other words, to get them "ego-involved." Next, by good organization or structuring of the presented material they can he helped to perceive its essential features and to achieve insights. Mere exposure and practice, even when accompanied by approval or other rewards for success. are not enough. It is to be noted also that "attention" is not invoked as a power of the mind. To some extent attentiveness is part of readiness (*i.e.,* it depends upon intelligence and training); for the rest it follows on motivation to concentrate upon the significant elements in the situation.

Such principles have many applications in the planning of courses, from infant to university level, and there exist books on how to study, how to read effectively, how to take notes, etc. Comparisons of over-all teaching techniques (*e.g.,* the lecture with the discussion seminar) tend to give inconsistent findings from one teacher and learner to another. However, numerous studies have shown that instructional films or television can valuably supplement, sometimes replace, face-to-face instruction; and the extensive Pennsylvania State college researches have brought out many of the desirable characteristics of educational films. (See also AUDIO-VISUAL EDUCATION.)

Reading.—Photographic recordings show that the eyes of a mature reader do not move along the letters of a reading passage consecutively, but jump from one group of words to another, taking in a third of a line or more at a time. Less skilled readers need more fixations per line! often jump back or regress to earlier parts of a line or word and may articulate each word in turn. The reading process varies also with the complexity of the passage and with the reader's purpose. These findings, together with Gestalt views on perception, have been adduced in support of "look and say" or "word and sentence" methods of teaching reading as against phonic methods. However, follow-up evidence fails to show any clear superiority for whole word teaching methods; if anything, the opposite. The reason presumably is that words cannot be adequately distinguished by shape alone. Such methods have the advantage of enabling the child to know at the earliest stages that he is progressing, but they need to be supplemented by analytical training.

There has been much study of the psychological factors of backwardness in reading. Widespread inefficiency at this skill is to be found among older students and adults, largely because they have had no systematic training in reading for meaning, in skimming and in thinking about the subject matter. Courses for improving adult reading speed without loss of comprehension are now available. but their success probably depends more on the instilling of appropriate habits and motivation than on the training of the actual eye movements. There have also been investigations into the variations of typography to suit readers of different ages and into the assessment of the vocabulary and structural difficulties of different reading materials; *e.g.,* textbooks. (See also READING.)

Spelling and Writing.—Graded lists of commonly used regular or irregular words are available, and it is realized that the memorization of long and unusual words has no "disciplinary" value. Elaborate spelling rules also serve little purpose, although structural regularities should be established where possible. The main essentials at which to aim are an analytical interest in words rather than a phobia against them, and the provision of variety in the type of practice given; *e.g.,* in reading, in composition and in preparing dictionaries and wall charts, rather than mere memorizing in isolation.

The early handwriting movements are gross and ill co-ordinated; hence it is an advantage to begin by teaching the formation of large script letters. Later these movements become more fluid, integrated and automatic. Short, frequent practices are desirable. The teacher should aim at standards appropriate to the children's ages, rather than at perfection, and should realize that speed and ease are as important as accuracy. There is in general a more humane attitude nowadays toward the left-handed child, despite a lack of understanding among teachers of his special requirements. The origins of left-handedness and its relations to speech development are problems of considerable interest.

Fluent and expressive writing can hardly be expected until these skills of spelling and handwriting are sufficiently automatic to become a vehicle for thought. Extensive previous experience of oral composition is desirable, whereas training in formal grammar is hardly worthwhile until Piaget's propositional stage is reached.

Arithmetic.—Early research concentrated on analyses of curricula, *e.g.*, measuring the difficulty of successive operations: and on comparisons of techniques for teaching, for example, subtraction. 'The results of such work on the value of systematic practice still hold good, but there is now more awareness of the need to gear arithmetic to children's developing concepts of space. time, distance, classifying and ordering and to their emotional maturity. In order to avoid teaching arithmetic too early by purely rote methods without enlisting the children's understanding, concrete apparatus has become fashionable; *e.g.*, the blocks of L. W. Stern or G. Cuisenaire. How far these succeed in establishing number concepts has yet to be proved, but it is clearly important to tie numbers to situations arising out of the children's experience. The teacher's own confidence and interest in arithmetic also has an important influence.

Mechanical arithmetic is known to depend on mental abilities or factors somewhat distinct from eeneral intellieence: hut the ability to do problem arithmetic and mathematics goes much more closely with all-around intellectual development; hence the avoidance of these subjects by weaker students. The abstractions involved in algebra, for example. are difficult to grasp until a mental age of nhout 12 has been reached.

Social Studies and Natural Sciences.—These could profitably be introduced early in the primary school. in view of children's natural curiosity concerning the world around them arid its peoples and their joy in discovery. Hut they should be taught inductively rather than in terms of information or ready-made concepts; *i.e.*, observation, experiment. discussion, generalization and application should be provided for. One of the main handicaps to the promotion of scientific ahility and interest in children is the inadequacy of early number teaching; but despite this, and despite their primitive understanding of spatial and chronological relations until the age of 10 or 12. children can learn much about biology and the world of work and things, and they can he trained in attitudes of inquiry and open-mindedness rather than in stereotyped and irrational thinking. The availability of good educational films and television programs should help to make up for the inadequate foundation in experience of so many of the concepts taught verbally in schools.

Foreign *Languages.*—Fallacious notions of transfer of skills have probably done more harm in the field of foreign language teaching than in any other. The formal translation and grammar approach still holds sway in spite of the difficulty of supplying motivation by this method and despite its inefficiency in producing either fluent speech or appreciation of foreign cultures. There is also the problem of deciding at what age a child is best started on a foreign language, since on the one hand his optimum plasticity of speech seems to occur before the age of ten, while on the other hi: seems unlikely to make good progress in a new language until he has shown facility in his mother tongue. Useful work has been done in preparing minimum vocabularies and lists of grammatical structures in several languages. as also in the production of tests of aural comprehension and written attainment.

The Teacher. — Many teachers admit to choosing their career for inadequate reasons and some express great dissatisfaction with conditions of work, pay and status. There is evidence that the teacher of overdominant or unstable personality can have a bad, even if temporary, effect on the children he teaches. Careful selection of recruits to the profession, then, is desirable but is difficult to impose, both because of the shortage of candidates and because of the lack of reliable techniques. Innumerable researches have shown moderate correlations between intelligence tests or educational level and marks in courses on the theory of teaching. but they have shown scarcely any agreement with assessments of teaching practice, except possibly in the lower ranges of ahility. Other studies often yield positive correlations with tests of emotional stability and extraversion, but so small that there would be no justification for accepting only candidates of one "type." The interview, in spite of its subjectivity, is therefore generally used in conjunction with previous school records; probably a trial period of teaching would be most predictive. It is also difficult to decide what constitutes good teaching, for though much is known of the qualities appreciated by tutors and heads of schools and by pupils themselves, there is poor agreement among those who do the rating. Nor have attempts to grade teachers according to what their pupils have learned yielded much. Less stress has therefore come to be laid on picking personalities "suitable" at the start and more on helping those candidates who present themselves to mature as people and to adjust to their double role both as parent substitutes and leaders of young children and as servants of their employers and of the community.

Teacher-Pupil **Relationships.**—Although the origins in a child of maladjustment or delinquency on the one hand or of harmonious internal controls or values on the other lie mainly in his home hackground and his own temperament, the school has a part to play as a socializing agency. Teachers often fail to realize how their criticism may afiect 3 child's concept of himself; that oral or written tests and examinations may arouse considerable anxieties and inhibit clear thinking; or that when they alone control all class activities they are preventing the development of co-operation and responsibility and stimulating the formation of rebellious cliques. They should he aware, too, of the characteristic social interactions and attitudes to authority of children of different ares, social classes and sexes. K. Lewin's work on authoritarian, democratic and Iaissez-iaire social climates and J. L. Moreno's sociometry have been widely, and perhaps uncritically, accepted. especially in the United States. However, several follow-up experiments such as the eight-year study of New York secondary schools and D. E. M. Gardner's comparisons of formal and progressive schools for English children up to the age of seven have demonstrated that social co-operation and intellectual resourcefulness can he iostered without any loss in standards of attainment.
